Loss of miR-378 in prostate cancer, a common regulator of KLK2 and KLK4, correlates with aggressive disease phenotype and predicts the short-term relapse of the patients

Abstract: A large number of prostate cancer (PCa) patients receive treatment without significant benefits, strengthening the need for accurate prognosis, which can be supported by the study of miRNAs. In silico specificity analysis was performed for the identification of miRNAs able to regulate KLK2 and KLK4 expression. Total RNA was extracted from prostate tissues obtained from PCa and benign prostate hyperplasia patients. Thereafter, RNA was polyadenylated and reverse transcribed to cDNA, which was used for qPCR analysis. miR-378 was predicted to target both KLK2 and KLK4 and down-regulated levels detected in PCa patients ($p=0.050$). The reduction of miR-378 was correlated with higher Gleason score ($p=0.018$), larger diameter tumors ($p=0.034$), and elevated serum PSA ($p=0.006$). Regarding prognosis, miR-378 was able to improve risk stratification according to Gleason score or tumor stage, while higher risk to recur highlighted for the patients expressing lower miR-378 levels. Finally, the loss of miR-378 was able to predict the short-term relapse of ‘high’- and ‘very high’-recurrence-risk patients, independent of Gleason score, tumor stage, PSA, and age as indicated by Kaplan-Meier survival curves ($p=0.030$) and multivariate Cox regression analysis ($p=0.018$). In conclusion, loss of miR-378 expression increases the risk for PCa progression and relapse, despite active treatment.

Keywords: kallikrein-related peptidase; KLK; miR-378a; miR-422a; molecular tumor markers; prostate tumors.

Introduction

Despite the ongoing debate about the reduction of prostate cancer (PCa) mortality, the introduction of prostate-specific antigen (PSA) screening of the male population is primarily responsible for the high rate of PCa diagnosis in Western populations. However, this beneficial use of PSA, as kallikrein-related peptidase 3 (KLK3) is largely known, suffers from a high rate of overdiagnosis and overtreatment (Andriole et al., 2009; Schroder et al., 2009).

PCa is characterized by great heterogeneity in terms of disease progression rate and life-threatening potential. Prostate tumors range from clinically insignificant and not life threatening to rapidly progressive and lethal ones, despite active treatment. Consequently, a large number of patients receive radical therapy without important clinical benefits, which further worsens health-related quality of life. Risk stratification and treatment decisions are mainly determined by Gleason score, pathological stage, serum PSA levels, and patient’s life expectancy (Freedland, 2011). However, the diverse outcomes of the same risk group of patients clearly highlight the need for a more accurate risk stratification and prognosis of the diagnosed patients, as well as more personalized patient’s management.

KLK2 and KLK4 are two highly expressed members of the kallikrein-related peptidases (KLK) gene family in the prostate gland, encoding for KLK2- and KLK4-secreted serine proteases, both responsible for semen liquefaction (Borgono et al., 2004). KLK2 and KLK4 are significantly overexpressed in PCa compared to benign or normal epithelium (Darson et al., 1997; Herrala et al., 2001; Klokkel et al., 2007; Avgeris et al., 2011), facilitating prostate tumorigenesis and cancer cells spread. KLK2 and KLK4 were able to deliver tumorigenic stimuli in prostate cells by the overactivation of the insulin-like growth factor (IGF) axis,
through IGF-binding protein (IGFBP) degradation, the proteolytic cleavage of cell surface proteinase-activated receptors 1 and 2 (PAR1 and 2) and the stimulation of AR and mTOR signaling in PCa cells. Moreover, the KLK2- and KLK4-mediated cleavage of extracellular matrix (ECM) components facilitates cancer cell invasiveness and bone metastasis (Avgeris et al., 2010, 2012; Mavridis and Scorilas, 2010). Therefore, the regulation of KLK2 and KLK4 expression is critical for prostate homeostasis and the progression of prostate malignancy.

Although the direct AR-mediated regulation of KLK transcription in prostate gland is well documented, and several androgen response elements (AREs) have been identified in the promoter regions of KLK2 and KLK4 (Lawrence et al., 2010), recent findings have drawn attention to miRNAs as a novel posttranscriptional regulators of KLK expression (Chow et al., 2008; Pasic et al., 2012). Taking into account the deregulated levels of several miRNAs in PCa (Porkka et al., 2007; Schaefer et al., 2010a; Wach et al., 2012), the identification of miRNAs targeting KLK2 and KLK4 and the evaluation of their clinical significance for the patients would further support the need for improvement of disease prognosis.

In the present study, in an effort to improve the risk stratification of the PCa patients and the prediction accuracy of their survival outcome following treatment, we have identified, in silico, hsa-miRNA-378-3p (miR-378) as a common regulator of KLK2 and KLK4 expression, and thereafter, we analyzed its expression levels in PCa.

### Results

miR-378-3p predicted to target KLK2 and KLK4 expression

Several miRNAs were predicted to bind on the 3’-UTR of KLK2 and KLK4 mRNAs and, thus, to regulate their levels. In order to achieve a good balance between sensitivity and specificity, we focused on those miRNAs predicted to target KLK2 and KLK4 by multiple programs. The miRNAs predicted to regulate both KLK2 and KLK4 by three or more programs are presented in Table 1. As shown in Table 1, hsa-miR-378-3p and hsa-miR-422a, a paralog of hsa-miR-378-3p, are the most probable candidates to target both KLK2 and KLK4. The several variants of hsa-miR-378-3p (miR378a-j and miR-422a), although they are encoded by different stem-loop precursors, share the same seed sequence and, therefore, mRNA targets. Among them, hsa-miR-378a-3p, previously annotated as hsa-miR-422b, is the predominantly expressed variant of the miR378/422a family. Taking into consideration the increased transcriptional levels of KLK2 and KLK4 and the reduced miR378 levels in prostate malignancy (Martens-Uzunova et al., 2012), we decided to investigate miR378 clinical significance for PCa patients.

Expression analysis of miR-378 in prostate tumors

Decreased miR378 levels (p=0.050; Supplemental Figure 1) were detected in PCa (range: 0.10–62.63 RQ units; median: 2.80 RQ units) compared to BPH patients (range: 0.32–113.97 RQ units; median: 3.87 RQ units). ROC analysis highlighted the clinical value of miR378 in prostate malignancy to discriminate the PCa patients from the BPH ones (AUC: 0.597; 95% CI: 0.503–0.692; p=0.050; Supplemental Figure 1), which was further confirmed by univariate logistic regression analysis (OR: 0.487; 95% CI: 0.243–0.977; p=0.043).

Downregulation of miR-378 correlates with tumors of higher Gleason score and larger diameter as well as elevated serum PSA levels

In order to evaluate the prognostic significance of miR378 for PCa, the miR378 expression levels were analyzed relatively to the classical and clinically used prognostic markers. A statistically significant (p=0.018) downregulation of miR378 was observed as the disease progressed to poorly differentiated tumors (Figure 1A). More precisely, significantly lower miR378 levels were found in Gleason score ≥8 (median: 1.20 RQ units) and Gleason score 7 (median: 2.11 RQ units) tumors compared to those of Gleason score ≤6 (median: 4.37 RQ units). Additionally, the reduction of miR378 in PCa was found to correlate with higher PSA serum levels as significantly lower (p=0.006) miR378 expression was detected in PSA ≥10 μg/l cohort (median: 1.34 RQ units) compared to 4–10 μg/l (median: 4.08 RQ units) and <4 μg/l (median: 11.06 RQ units) cohorts (Figure 1B). This negative correlation between miR378 and PSA levels was also supported by Spearman’s correlation coefficient (rS: -0.273; p=0.021; Figure 1C). Finally, miR378 expression was also found to correlate with larger tumor diameter in PCa patients, as illustrated by Spearman’s correlation (rS: -0.402; p=0.034; Figure 1D). However, no statistically significant correlation was observed between miR378 levels and tumor stage (Supplemental Figure 2).

Downregulation of miR-378 highlights the poor disease-free survival of the patients and improves risk stratification

The prognostic significance of miR-378 for patients’ outcome following radical prostatectomy was assessed by Kaplan-Meier survival curves (Figure 2A) and Cox regression analysis (Table 2). Although not statistically significant, Kaplan-Meier curves (p=0.070) and univariate Cox analysis (HR: 1.911; 95% CI: 0.932–3.921; p=0.077) showed the unfavorable disease-free survival (DFS) and the higher risk for biochemical relapse of the miR-378(-) PCa patients compared to the miR-378(+) ones.

In order to improve patients’ risk stratification, the prognostic significance of miR-378 was further analyzed in combination with patients’ Gleason score and tumor stage. As indicated by Kaplan-Meier DFS curves, a more accurate prediction of the DFS expectancy following radical prostatectomy was achieved for the patients of the same Gleason score or tumor stage cohorts. More precisely, grouping patients according to Gleason score, miR-378 loss was able to distinguish the patients with worse DFS outcome for both ≤3+4 and ≥4+3 groups (Figure 2B). Similarly, miR-378 loss was demonstrated to predict the poor DFS for both ≤pT2c and ≥pT3a groups compared to patients with miR-378 overexpression of the same cohorts (Figure 2C).

These findings clearly underscore the unfavorable outcome of the patients with reduced miR-378 levels at the time of treatment and the beneficial impact of miR-378 on the improvement of patients’ risk stratification. Additionally, the ability of miR-378 loss to distinguish the patients with worse DFS outcome in the same Gleason score or tumor stage cohorts prompted us to study miR-378 prognostic significance in each individual recurrence risk groups.
Loss of miR-378 predicts the short-term relapse of the high-recurrence risk patients

NCCN guidelines for PCa were used for the classification of the patients according to their recurrence risk (Mohler et al., 2010). Kaplan-Meier analysis, as well as Cox regression analysis (Table 3), was conducted in order to study miR-378a prognostic value for each cohort.

Regarding ‘high’- and ‘very high’-recurrence risk patients (≥pT3a or Gleason score 8–10 or PSA >20 μg/l; Supplemental Table 1), a significantly (p=0.030) higher risk for short-term relapse was observed in the patients with reduced miR-378 levels (Figure 3A). In particular, a significantly shorter DFS expectancy was demonstrated for the miR-378(-) high- and very high-risk patients compared to the miR-378(+) ones. For the same group of patients, risk-group stratification was not efficient enough to predict the DFS of the treated patients (p=0.275; Figure 3B), strengthening, in this way, the prognostic potential of miR-378. Studying miR-378 levels in low- and intermediate-recurrence risk patients (Supplemental Table 1), similar DFS intervals were demonstrated for miR-378(-) and miR-378(+) patients.

The significance of the miR-378 expression in the prognosis of ‘high’- and ‘very high’-recurrence risk patients was also supported by Cox regression survival analysis. A significantly higher risk to relapse (HR: 2.824; 95% CI: 1.051–7.585; p=0.040) was observed in the miR-378(-) patients compared to miR-378(+) patients by univariate models. For the same patients’ group, only Gleason score was proved to have a statistically significant prognostic value for the prediction of biochemical relapse. Finally, multivariate Cox regression models revealed prognostic value of miR-378 levels for the prediction of patients’ DFS following treatment (HR: 4.792; 95% CI: 1.130–17.522; p=0.018) independent from Gleason score, tumor stage, PSA, DRE, and age. Summarizing, miR-378 loss in PCa represents an independent prognostic marker for the prediction of high- and very high-recurrence risk patients’ short-term relapse.

Discussion

Since their discovery, miRNAs have emerged as powerful posttranscriptional gene expression regulatory mediators (Bartel, 2004), and deregulated miRNA levels have been documented in the majority of human malignancies (Calin and Croce, 2006; Bartels and Tsongalis, 2009). Therefore, the study of miRNAs’ role in several
cancer-related molecular cascades would aid to the elucidation of the clinical significance for PCa patients' management (Schaefer et al., 2010b; Fendler et al., 2011; Larne et al., 2013; Lichner et al., 2013).

Using miRNA-target prediction programs, miR-378-3p was found to be the most frequently predicted miRNA candidate able to regulate both KLK2 and KLK4 expression. This is in agreement with miRNA microarray-based results showing downregulated miR-378 levels in PCa (Martens-Uzunova et al., 2012), opposite to the elevated expression of its KLK2 and KLK4 targets (Avgeris et al., 2012). Among the different variants of miR-378-3p (miR-378a-j and miR-422a), miR-378a-3p (previously annotated as miR-378 or miR-422b) is the predominantly expressed variant of the miR-378/422a family, encoded by MIR378A, an intronic miRNA encoded gene embedded within the first intron of PPARGC1B gene in the 5q32 chromosomal locus.

Although MIR378A has been studied in various human malignancies, its function and expression profile has not been fully elucidated yet. MIR378A overexpression in U87 glioblastoma and MT-1 breast carcinoma cells was essential for cell survival, tumor growth, and angiogenesis, through the downregulation of SuFu and Fus-1 tumor suppressors by miR-378a-5p (Lee et al., 2007), while miR-378a-3p was found to be crucial for Myc-mediated cell transformation, following the silencing of the TOB2 antiproliferative factor (Feng et al., 2011). Regarding non-small cell lung cancer, mir-378a overexpression in NCI-H292 cells resulted to downregulation of HMOX1 and increased cell proliferation and migration (Skrzypek et al., 2013), while higher miR-378 levels were associated with patients' brain metastasis, tumor growth, and angiogenesis of A549 xenografts (Chen et al., 2012).

However, studies of miR-378 in the pathophysiology of the heart question its oncogenic properties. In particular,
reduced miR-378 levels have been found in hypertrophic heart growth and cardiac failure (Ganesan et al., 2013; Nagalingam et al., 2013). These antihypertrophic activities of miR-378 are mainly exerted through the suppression of the MAPK/ERK and PI3K/AKT signaling pathways. More precisely, miR-378 overexpression blocks cardiac hypertrophy by preventing Ras activation and thus MAPK/ERK and PI3K/AKT downstream cascades, by targeting the GRB2 upstream mediator (Nagalingam et al., 2013), as well as MAPK1 (ERK2), IGF1R, and KSR1 members of the MAPK pathway (Ganesan et al., 2013). The miR-378a-mediated regulation of IGF1R signaling is even more critical in PCa pathogenesis. Overexpression of miR-378 resulted to the translational inhibition of IGF1R and to apoptotic cell death, while miR-378 knockdown launches IGF1R-related Akt cascade (Knezevic et al., 2012).

In order to evaluate miR-378 clinical significance for PCa, we measured miR-378 levels in cancerous and benign prostate tissues. Decreased miR-378 levels were found in PCa patients compared to BPH control ones. In PCa patients, miR-378 loss was further correlated with high Gleason score, tumors with larger diameter, and elevated serum PSA levels. Motivated by the correlation of miR-378 loss with unfavorable prognostic markers, we analyzed the significance of miR-378 in the survival outcome of the patients. As expected, Cox regression analysis revealed a significantly higher risk for relapse of the patients with reduced miR-378 levels, and Kaplan-Meier DFS curves indicated the correlation of miR-378 loss with the shorter DFS intervals following radical prostatectomy. Interestingly, miR-378 quantification was shown to be able to improve significantly the Gleason score- or tumor stage-based risk stratification of the patients.

The prognostic significance of miR-378 was further evaluated in ‘low’- and ‘intermediate’-recurrence risk as well as in ‘high’- and ‘very high’-recurrence risk patients. Interestingly, the loss of miR-378 in high- and very high-risk groups of patients (≥pT3a or Gleason score: 8–10 or PSA>20 μg/l) predicts their short-term relapse, highlighting the utility of miR-378 for a more accurate prognosis of high- and very high-risk group. Kaplan-Meier curves suggested significantly worse DFS of the patients displaying miR-378 loss, while univariate Cox regression analysis pointed out an approximately threefold higher risk for relapse. Multivariate models highlighted that the prediction of the short-term relapse of the PCa patients with miR-378a loss and their poor DFS is independent of Gleason score, tumor stage, serum PSA levels, age, and DRE. These results not only support a possible central role of miR-378 in disease progression but also underscore miR-378 as a novel independent prognostic marker for ‘high’- and ‘very high’-recurrence risk cohort.

Although prostate carcinogenesis is not the result of a single molecular event, ligand-independent pathways (outlaw pathways) of AR overactivation, especially in the late disease stages, are essential for disease progression and aggressiveness. Regarding ‘outlaw’ activation of AR, receptor-tyrosine-kinases (RTK) signaling, mediated mainly by IGF1R, and IL6- and IL8-related signaling, triggers AR overactivation through PI3K/AKT, MAPK, and JAK/STAT3 pathways, while KLK2 and KLK4 have been found to enhance AR activity in an androgen-independent
manner (Mavridis et al., 2014). Consequently, the ability of miR-378 to target KLK2 and KLK4, along with IGF1R signaling and key components of MAPK and AKT pathways, highlights a possible regulatory role of miR-378 upon AR signaling in prostate cells. This is in agreement with the observed, in our analysis, correlation of miR-378 down-regulation with higher Gleason score and larger-diameter prostate tumors, as well as with the poor survival expectancy of the patients.

In conclusion, in the present study, we have identified *in silico* miR-378 as a common regulator of KLK2 and KLK4 PCA-related members of the KLK family and analyzed miR-378 clinical significance for the prognosis of PCA patients. Reduction of miR-378 levels was observed in PCA tissues compared to benign gland lesions. The downregulation of miR-378 expression was correlated with disease progression, as patients with higher Gleason score tumors and elevated serum PSA concentrations were found to have significantly lower miR-378 levels. This was further verified by the higher risk for relapse and the worse DFS of the patients with lower miR-378 expression. Finally, in high- and very high-recurrence risk patients, miR-378 loss was shown to predict the short-term relapse following treatment of PCA patients independent from Gleason score, tumor stage, PSA levels, and age. Overall, these findings highlight the reduced expression of miR-378 in PCA, the correlation of miR-378 downregulation with high Gleason score tumors and elevated serum PSA levels, and finally the ability of miR-378 to predict the survival outcome of the treated patients, supporting, in this way, miR-378 potential use to improve PCA prognosis.

**Materials and methods**

**miRNA targeting prediction analysis**

MiRanda, TargetScan, DIANA micro-T v3.0, miRTarget2, MicroCosm, PITA, RNA22, and miRWalk online available programs (see Table 1 for links to the above-mentioned algorithms) were used for the prediction of KLK2- and KLK4-targeting miRNAs via miRecords (http://www.mirecords.umn.edu/miRecords/), miRNA body map (http://www.mirnabodymap.org/), and miRWalk (http://www.umm.uni-heidelberg.de/apps/zmf/mirwalk/), databases. The analyses were performed using the databases’ default parameters.

**Study population**

Prostate tissue specimens were obtained from 73 PCA patients who underwent radical retropubic prostatectomy (Supplemental Tables 2 and 3) and 64 transurethral or open prostatectomy treated benign prostate hyperplasia (BPH) patients. Focusing on PCA patients, a tissue sample of approximately 200 mg was sectioned from the peripheral zone of prostate gland based on the preoperative features of the biopsy and on macroscopic findings. The sample was thereafter divided into two mirror-image specimens, one of which was tested by a pathologist, while the other one was immediately frozen in liquid nitrogen and stored at -80°C until analysis. None of the patients included received hormonal therapy or radiotherapy prior to surgery. The last measurement of serum PSA prior to prostate biopsy and diagnosis, approximately 1-2 months prior to radical prostatectomy, was used in our analysis. Our study was approved by the ethics committee of ‘Laiko General Hospital’ and performed with respect to the ethical standards of the Declaration of Helsinki, as revised in 2008.

The follow-up data from 62 PCa patients were used for the assessment of miR-378 prognostic significance for prostate cancer, while 11 PCA patients were excluded from the monitoring plan due to either unclear follow-up data or the administration of adjuvant therapy before biochemical recurrence. PCA patients’ were followed-up according to European Association of Urology (EAU) guidelines, and biochemical relapse was defined by two consecutive measurements of serum PSA ≥0.2 μg/l. The National Comprehensive Cancer Network (NCCN) guidelines for PCa (Supplemental Table 1) were followed for the evaluation of patients’ recurrence risk (Mohler et al., 2010).

**Extraction and polyadenylation of total RNA**

Total RNA was isolated using TRI-Reagent (Molecular Research Center, Inc., Cincinnati, OH, USA) according to manufacturer’s instructions, following the pulverization of 60-120 mg of tissue specimen. Total RNA concentration and purity were determined spectrophotometrically at 260 and 280 nm, while RNA integrity was evaluated by agarose gel electrophoresis. Therefore, 1 μg of total RNA was polyadenylated at the 3'-end in a 15-μl reaction at 37°C for 60 min using 800 μM ATP and 1 U of *Escherichia coli* Poly(A) Polymerase (New England Biolabs Inc., Ipswich, MA, USA). Enzyme heat inactivation was performed at 65°C for 15 min.

**First-strand cDNA synthesis**

The polyadenylated total RNA was reversed transcribed in a 20-μl reaction containing 50 U MMLV reverse transcriptase (Invitrogen, Carlsbad, CA, USA), 40 U recombinant ribonuclease inhibitor (Invitrogen), and 0.25 μM poly(T) adapter 5'-GCGACACAGAATTAATAGGAATCTAATAGTTTTTTTTTTTN-3' (V=G, A, C and N=G, A, T, C) at 37°C for 60 min (Avgeris et al., 2013; Mavridis et al., 2013). The reverse transcriptase was inactivated by heating at 70°C for 15 min.

**Quantitative real-time PCR (qPCR)**

Specific forward primers for the miR-378a and the small nucleolar RNA, C/D box 48 (SNORD48), also known as RNU48, were designed based on their published sequences (NCBI RefSeq accession number: NR_029870.1 and NR_002765.1, respectively) and *in silico* specificity evaluation. Moreover, a universal reverse primer, able to hybridize to
the above-mentioned poly(T) adapter, was also synthesized. The combination of the 5′-GGACTGGACTGGAGTCAGAA3′ forward primer for miR-378 or the 5′-TGATGTAGCCCGAGTAACCTC3′ forward primer for SNORD48 with the universal reverse primer 5′-GGAGACACAGATAATACGAC3′, amplified a 67-bp miR-378- and a 105-bp SNORD48-specific amplicon, respectively (Avgeris et al., 2013; Movridis et al., 2013).

The qPCR assay was performed in the 7500 Real-Time PCR System (Applied Biosystems, Carlsbad, CA, USA) and the 10-µl reaction consists of Kapa SYBR® Fast Universal 2x qPCR Master Mix (Kapa Biosystems, Inc., Woburn, MA, USA), 200 nm of each PCR primer, and 0.2 ng of cDNA. The thermal protocol comprised of a 3-min polymerase activation step at 95°C, 40 cycles of denaturation at 95°C for 15 s, and a primer annealing and extension step at 60°C for 1 min. Following the amplification, melting curve analysis and agarose gel electrophoresis were used for the determination of specific reaction products compared to nonspecific ones or primer dimmers. Using serial dilutions of a control cDNA as template, calibration curves for miR-378 and SNORD48 amplification were generated covering six orders of magnitude (Supplemental Figure 3). The linear increases of miR-378 (y = 3.47x + 43.49; r² = 0.991) and SNORD48 (y = 3.32x + 38.02; r² = 0.999) amplification highlighted the 94.3% and 99.9% reaction efficiencies, respectively, as well as the absence of PCR inhibition by the template. Relative quantification (RQ) of miR-378 was performed using the 2-ΔΔCt method, where the LNCaP prostate cancer cell line was used as our assay calibrator and SNORD48 as an endogenous reference control (Larne et al., 2009). Duplicate reactions were performed for each tested sample, and the average Ct was calculated for the quantification analysis. No template controls, reverse transcriptase-negative controls, Poly(A) polymerase-negative controls, and DNA template controls generated undetectable Ct, or >36.

Statistical analysis

The analysis of miR-378 levels between PCa and BPH patients was performed using the Mann-Whitney U-test. Univariate logistic regression analysis, calculating log(mir-378 odds ratio (OR) and ROC curve analysis were used for the evaluation of miR-378 ability to discriminate PCAs from BPH patients.

Differences in miR-378 expression levels among patients of different Gleason score, tumor stages, PSA group, or digital rectal examination (DRE) were analyzed using Mann-Whitney U and Kruskal-Wallis tests. The correlation of miR-378 expression with PCa patients’ PSA levels and tumor diameter was assessed by Spearman’s correlation coefficient (r). Using the X-tile algorithm, the 312 RQ units of miR-378 (equal to the 52nd percentile of the PCAs’ cohort) were adopted as an optimal cutoff to classify PCa patients into miR-378(+) and miR-378(-) cohorts, expressing higher and lower miR-378 levels, respectively.

The prognostic significance of miR-378 was evaluated by Kaplan-Meier survival analysis, using log rank test, and Cox proportional hazards regression models. Univariate and multivariate Cox regression models were employed for the calculation of the hazard ratio (HR) of miR-378, Gleason score, tumor stage, serum PSA, patient’s age, and DRE.
