Methods: A survey was carried out in September 2012, with quota samples on gender, education, and locality of residence. A total of 1000 respondents participated. Obtained data included socio-demographic characteristics, measure of the food-related lifestyle scale and self-reported frequency of physical activity. Individuals were classified as physically active if the frequency of physical activity was one-twice a week or more frequently. The Cronbach's alpha test was carried out to assess the internal reliability of the FRL scale dimensions. FRL scores are presented as means and standard deviation. Comparisons of means within both groups have been performed with one-way ANOVA tests.

Results: Non-active respondents scored lower on all dimensions of quality, particularly on freshness (4.89 vs 5.21), price/quality relation (4.80 vs 5.03) and health (4.09 vs 4.26). They attached lower levels of importance of shopping list (4.47 vs 4.60), women's task (4.46 vs. 4.64); security (4.53 vs. 4.71), social relationships (4.37 vs. 4.69), and social event (3.73 vs. 3.99). Physically active respondents scored lower only on one dimension of consumption situations, ie. snacks vs. meals (3.59 vs. 3.74). Thus, physically non-active respondents are generally less involved with food than physically active, especially regarding the FRL quality and purchasing motives dimensions. They preferred snacks vs. meals.

Conclusions: Exploring FRL as determinants of food intake and its association with consumers' physical activity might be of great interest for public health, particularly for implementation of more efficient interventions focused on nutrition and physical activity.

Key words: Food-Related Lifestyle; physical activity; eating behaviour; eating attitudes.

PO1211**META-ANALYSIS OF DIETARY PATTERNS AND ESOPHAGEAL CANCER RISK***X D. Liu¹, S H. Lin¹, X R. Wang¹*

¹School of Public Health and Primary Care, the Chinese University of Hong Kong, Hong Kong, China

Background and objectives: Dietary patterns, which represent a complex integration between food and nutrients, have been reported to be related to the risk of esophageal cancer. However, there is no synthetically quantitative analysis from available. To clarify the associations between dietary patterns and esophageal squamous cell carcinoma (ESCC) and esophageal adenocarcinoma (EAC), respectively, by pooling the results of available studies.

Methods: Pertinent articles published up to January 2013 were searched through Pubmed, EMBase, CNKI and VIP and related citations (web of science). The most common dietary patterns were selected. Studies defining dietary patterns through principle component/factor analysis were included. Random effects model was used to estimate adjusted odds ratios (ORs) by comparing the highest with lowest categories of a selected dietary pattern. Heterogeneity was tested using chi-square test and I² statistic. Publication bias was assessed by funnel plot and Egger's and Begg's tests.

Results: 6 case-control studies were included into this study and 3 common patterns were selected: western/meat/fat pattern, vegetable-fruits/healthy/antioxidant pattern, alcohol drinking pattern. Smoking and other covariates or confounding factors were considered in all of papers. In comparison between the highest and the lowest scores of specific dietary patterns, western/meat/fat pattern significantly increased the risk for EAC (OR=2.56, 95%CI: 1.13-5.80), but not for ESCC (OR=0.64; 95%CI: 0.81-3.32). Alcohol drinking pattern was associated with an increased risk for ESCC (OR=2.50, 95%CI: 1.46-4.30). Vegetable-fruits/healthy/antioxidant pattern was related to a decreased risk for ESCC (OR=0.44, 95%CI: 0.35-0.57) and EAC (OR=0.89, 95%CI: 0.44-1.77), though no statistical significance in the latter.

Conclusions: The results from the limited number of studies suggested that dietary patterns may be a determining factor for EAC, though variation existed in ESCC and EAC. More research focusing on the dietary patterns in esophageal cancer patients is needed to provide more convincing evidence.

Key words: esophageal cancer, dietary patterns, meta-analysis.

PO1212**ORDERING FOOD ONLINE: THE HABITS OF KUWAIT'S RESIDENTS***S D. Garduno-Diaz¹*

¹General Education, American University of The Middle East, Egaila, Kuwait, Kuwait

Background and objectives: Fast-food consumption has been linked to a plethora of chronic conditions and to poor dietary indicators. Residents in countries undergoing economic development are exposed to obesogenic environments that include ample access to high-fat/high-sugar foods. Kuwait, one of the richest countries in the world, is rapidly becoming one of the fattest; home-delivered food ordered from on-line systems is widely popular in this country. Frequently consumed home-delivered foods and their nutrient contribution to the diet of Kuwaiti residents is presented for the first time in this study.

Methods: Data from a popular on-line food delivery system was accessed and the ten most frequently ordered foods in Kuwait were identified. Nutrient composition for these foods was calculated using data from the USDA and is presented per portion. Portion sizes were obtained by direct weighing of the portions delivered by the on-line delivery system. The most frequently ordered foods from the same on-line system in neighboring countries were also identified and compared.

Results: Out of the 100 most popular food items ordered for home-delivery in Kuwait only three were not high-fat/high-sugar foods. On average, the top ten most frequently ordered foods contributed 783 calories, 14.4g of saturated fat, 1271 mg of sodium and 10.2g of sugar per portion to the diet. The most popular food items ordered included burgers, cookies and fries. Compared to neighboring countries, Kuwait has a higher number of high-fat/high-sugar foods among its most frequently home-delivered orders.

Conclusions: Rapid lifestyle changes leave little room for adjustment in levels of physical activity, energy intake and diet quality. Availability and accessibility to an almost unlimited amount of food, energy, trans fats and sugars are likely to be significant contributors to obesity and diet-related diseases by creating obesogenic environments in Kuwait.

Key words: Kuwait, obesity, fast food, obesogenic environment, food composition.

PO1213**SCHOOL-BASED INTERVENTION PRACTICES TO REDUCE BODY MASS INDEX: META-ANALYSIS OF 57 RANDOMIZED TRIALS**

P.H. Guerra¹, M.R.C. Nobre², J.A.A. Taddei³, J.A.C. Silveira⁴

¹Programa de pós-graduação em ciências do Instituto Coração da Faculdade de Medicina da Universidade de São Paulo (InCorHCFMUSP) - Cardiologia, São Paulo, Brazil

²Diretor da Unidade de Epidemiologia Clínica do Instituto do Coração da Faculdade de Medicina da Universidade de São Paulo (InCorHCFMUSP), Brazil

³Professor Associado da Disciplina de Nutrologia do Departamento de Pediatria, Universidade Federal de São Paulo (UNIFESP), Brazil

⁴Programa de pós-graduação em Pediatria e Ciências Aplicadas à Pediatria, Universidade Federal de São Paulo (UNIFESP), Brazil

Objective: To evaluate the effectiveness of interventions that promoted physical activity and/or nutrition education in the school environment for the reduction of overweight and obesity in children and adolescents by body mass index.

Study Design: Systematic Review and Meta-analysis

Methods: We searched 14 databases and analyzed papers published up to September 2012. The standardized mean difference was calculated using Hedges' *g*, and random-effects model was used to obtain the summarized effect. We stratified the primary analysis by studies with specific samples of overweight/obese children.

Results: Of 5,906 papers initially retrieved, in the primary synthesis 57 community randomized trials provided data on 41,634 children and adolescents, resulting in an effect of -0.03 (95% CI: -0.09 to 0.03, *p*=0.3, *I*²=87%). The results of the overweight/obese children subgroup showed the following effect: -0.21 (95% CI: -0.54 to 0.13, *p*=0.2, *I*²=74%, *n*=644, 7 trials). After excluding those seven studies of primary analysis, the summarized effect was not changed in the statistical perspective: -0.02 (95% CI: -0.08 to 0.04; *p*=0.6; *I*²=88%).

Conclusions: Although the findings of this meta-analysis were inconclusive, we reinforce the beneficial role of physical activity and nutrition education interventions in the school environment. The high percentages of heterogeneity obtained derive from the different characteristics of the randomized trials and jeopardize the external validity of the results. This suggests caution in generalizing these findings to other populations.

Key Words: (PubMed MeSH): schools, nutritional sciences, physical education and training, overweight, review

PO1214**BOLIVIA AND MALNUTRITION ZERO: EXAMINING ORGANIZATIONAL CAPACITY FOR MULTISECTORAL NUTRITION AGENDAS**

K. Cunningham^{1,2}, R. Uauy^{1,2}, L. Rico Aranibar³

¹London School of Hygiene and Tropical Medicine, London, UK

²Institute of Food Nutrition and Food Technology (INTA), Santiago, Chile

³Technical Committee of the National Council of Food and Nutrition, La Paz, Bolivia

Background and objectives: Undernutrition, remains a significant burden in developing countries, as an important contributor to child death and disability. Multi-sectoral nutrition programming and implementation is claimed to effectively address this pressing issue for millions. This requires not only designing evidence-based interventions but also ensuring successful delivery, often through complex partnership structures. Little attention has been paid to the organisational capacity requirements for these endeavors.

Methods: We applied an organisational capacity framework to analyse the partners involved in Bolivia's Malnutrition Zero initiative; in addition we sought to assess particular organisational capacity constraints related to strategic leadership, structure, human resources, financial management, infrastructure, programme management, process management, and inter-organisational linkages, all of which may hinder effective implementation. Data collection included key informant interviews, document review, and structured observations.

Results: In Bolivia, findings reveal the particular importance of: 1) strategic leadership including empowerment of all partners, 2) clear governing structures and division of roles and responsibilities, 3) substantial investments in operationalizing communications strategies, 4) joint meetings involving representatives from different levels of the governing structure, and 5) flexibility in approach.

Conclusions: These organisational capacity weaknesses of the Bolivian program are context-specific, but provide examples of the type of capacity constraints which, if ignored, may prevent substantial investment of time, energy, and funds in programming from having their intended pay off in reducing undernutrition. There is new ground for discussion regarding how to best to strengthen organisational capacities of institutions involved in complex programming to address undernutrition or other development challenges.

Key Words: Undernutrition, organisational capacity, multi-sectoral, implementation.

PO1215**SUCCESS FACTORS IN INTERVENTIONS AND ACTIVITIES IN THE NEIGHBORHOOD VINKHUIZEN IN GRONINGEN (THE NETHERLANDS) TO PREVENT OVERWEIGHT.**

J. van der Kruk^{1, 2}, H. Jager-Wittenaar¹, I. Stoker-Koekoek²

¹Professorship in Health Care and Nursing, Groningen, Hanze University of Applied Sciences, The Netherlands

²Division of Care & Youth, Groningen, Common Health Service, The Netherlands

Background and objectives: The aim of this study is identifying success factors in group interventions to prevent overweight in the neighborhood Vinkhuizen in Groningen (the Netherlands). The study is part of the project (2010- 2014) “what is an effective approach to prevent overweight among low SES-groups in the neighborhood, by a community based, integrated approach in collaboration with stakeholders?”

Methods: We screened already collected information on group interventions (2011-2012) in Vinkhuizen regarding effectiveness. To assess whether an intervention has sufficient potential to be successful, the quickscan developed by Coöperatieve Effectieve Youth Care Nederland (SJEN) was used.

Results: In total 102 group interventions to prevent overweight were organized in Vinkhuizen. 16 interventions were carried out by professionals. Two of them were reviewed as “well described”, two as “well founded” and two as “program with potential”. No detailed information was available about the effectiveness of these interventions. 86 interventions were carried out by volunteers. These interventions were summarily described and had no methodical approach. Health perspectives and effectiveness were indirect targets, pleasure was more important. We suggest to define the group interventions by volunteers as “activities”. Due the lack of information none of the “activities” could be labeled as “programs with potential” and data of effectiveness were missing. We developed a modified version of the quickscan specific for “activities”, consisting the SJEN items and added with successful Dutch BBOFT elements. BBOFT is a Dutch acronym for encouraging Breastfeeding, Exercise and Outdoor Playing, Breakfast and limiting Soft Drinks and TV/PC watching.

Conclusions: Most of the group interventions in the neighborhood were carried out by volunteers. Additional information is needed about content, methodology, results and experiences to screen success factors and monitor effectiveness.

Key words: overweight, neighborhood, interventions, activities.

PO1216**ASSESSING IMPLEMENTATION OF INTEGRATED MANAGEMENT OF ACUTE MALNUTRITION PROTOCOL FOR MANAGEMENT OF ACUTE MALNUTRITION IN PILOTING SITES OF WAKISO DISTRICT**

T. Rwegyema¹, E. Nabankema¹

¹Institute of health policy and management, International Health Sciences University, Kampala, Uganda

Background and objectives: In Uganda, the malnutrition levels are unacceptably high and recently the Ministry of Health developed guidelines on management of acute malnutrition. Integrated Management of Acute Malnutrition (IMAM) protocol should be part of the routine activities within health facilities. IMAM to be successfully implemented, a favorable environment of adequate technical human resource like the nutritionists, doctors, and nurses is paramount. The protocol has been piloted with support from UNICEF in Kampala and Wakiso districts. The study assessed capacity of piloting facilities, level of integration and exploring other basic requirements for implementation in Wakiso to integrated IMAM into routine services.

Methods: It was a descriptive cross sectional study design. The study population was all health workers in pilot sites in Wakiso district and total 7 pilot health facilities were purposely selected.

Results: Only 25% of the health workers within the facilities have been trained to implement IMAM as a new approach in the district. Despite low training coverage, majority of the health workers (68.6%) know that weight is a nutrition assessment criterion and is also conducted regularly in most health facilities. However, more than 10% of health workers do not know how to interpret the nutrition assessment results using indices like BMI, and Z-scores. As such, the capacity of health workers is still lacking within most facilities to implement IMAM. Only 27.5% of the health workers are directly involved in management of acute malnutrition out of which majority are only nurses involved.

Conclusions: The integration of IMAM protocol within the health facilities has not been realized. The low involvement of health workers and lack of key supplies and equipment at key points indicates they are implementing but not as a routine activity.

Key words: Malnutrition, Health workers, Health facilities.

PO1217

CORRELATING DIET AND LIFESTYLE TO OBESITY IN BULGARIAN SAMPLE

D. Ivanova^{1,2}, D. Vankova¹, D. Gerova², V. Madjova², Y. Kiselova¹

¹Department of Biochemistry, Molecular Medicine and Nutrigenomics, Medical University Varna, Bulgaria

²Department of General Medicine and Clinical Laboratory, Medical University Varna, Bulgaria

Background and objectives: Obesity as a multifactorial origin disease results from the interplay of social, behavioral, psychological, genetic, cellular, molecular and metabolic factors. Nowadays obesity is related to increased prevalence of metabolic diseases, cardiovascular diseases, colon cancer and even mortality. The present study aims to investigate the contribution of nutritional habits, physical activity and certain socio-demographic factors to the manifestation of obesity in Bulgarian sample.

Methods: The study involved 182 adults of Bulgarian origin. Anthropometric characterisation included height, weight, waist and hip circumferences, body mass index (BMI) and waist/hip ratio. Obesity-associated clinical indices were determined: levels of plasma glucose, triglycerides, total cholesterol, high-density lipoprotein cholesterol (HDL-C), and blood pressure (systolic/diastolic). Respondents filled in questionnaires including their diet habits, physical activity, educational and social status.

Results: Statistically significant difference in all clinical parameters between the two groups - normal weight and obese subjects was established. Regular consumption of fresh fruits and vegetables was related to lower BMI, while juices rich in sugar had a negative impact. Interestingly, the consumption of salty foods was not prevalent in overweight people but rather in those with normal weight. The level of physical activity had significantly positive impact on BMI. A positive correlation between BMI and age, hypertension, and marital status, and a negative correlation between BMI and employment was found.

Conclusions: Some features specific to the Balkan area were established for the Bulgarian sample. Data obtained in this study may serve in creating adequate recommendations for a healthy lifestyle to optimize national strategies for obesity prevention.

Key words: obesity, Bulgarian population, diet, lifestyle.

PO1218

25-HYDROXYVITAMIN D AND COGNITIVE PERFORMANCE IN MID-LIFE

J. Maddock¹, M C. Geoffroy¹, C. Power¹, E. Hyppönen¹

¹Centre for Paediatric Epidemiology and Biostatistics, Institute of Child Health, University College London, London, UK

Background and objectives: Hypovitaminosis D has been linked with poor cognitive function, particularly in elderly populations, but the effect of reverse causality remains unknown. We aimed to assess the relationship between 25(OH)D and subsequent performance in cognitive tests in mid-adulthood and the influence of earlier life factors including childhood cognitive ability, on this association.

Methods: Information came from members of the 1958 British birth cohort (n=6, 496). Serum 25(OH)D, indicating vitamin D status, was measured at 45y. Verbal memory (immediate and delayed word recall), verbal fluency (animal naming) and speed of processing were tested at 50y. Information on childhood cognitive ability, educational attainment, vitamin D-related behaviours and other covariates was collected prospectively from participants throughout their life.

Results: Childhood cognitive ability and educational attainment by 42y were strongly correlated with cognitive performance at 50y, and with several vitamin D-related behaviours in mid-adulthood, but not with 25(OH)D concentrations at 45y. Participants with both low (<25nmol/l) and high (>75nmol/l) 25(OH)D concentrations at 45y performed significantly worse on immediate word recall. Associations attenuated after adjustment for childhood cognitive ability, education, and socioeconomic position, however, for immediate word recall test, there was a non-linear association with 25(OH)D even after further adjustment for obesity, menopausal status, smoking, alcohol, physical activity and depressive symptoms at 45 years (p_{curvature}=0.01).

Conclusions: 25(OH)D concentrations were found to be non-linearly associated with immediate word recall in mid-life. Clarification of the level of 25(OH)D that is most beneficial for predicting better cognitive performance in mid-life is required.

Key words: Vitamin D; Cognitive function; 1958 British Birth Cohort.

PO1219**VITAMIN D AND COMMON MENTAL DISORDERS IN MID-LIFE: CROSS-SECTIONAL AND PROSPECTIVE FINDINGS**

J. Maddock¹, D. Berry¹, M. C. Geoffroy¹, C. Power¹, E. Hyppönen¹

¹Centre for Paediatric Epidemiology and Biostatistics, Institute of Child Health, University College London, London, UK

Background and objectives: While there is a biologically plausible link between vitamin D and common mental disorders (CMDs), epidemiological evidence to date remains unclear. We aimed to determine if behaviours affecting vitamin D concentrations differ between individuals with or without CMDs and evaluate, cross-sectionally and prospectively, the extent to which the association between 25(OH)D and CMDs are explained by these behaviours.

Methods: Data are from the 1958 British birth cohort (n=7,401). Behaviours were ascertained by questionnaire at age 45 years. CMDs (depression, anxiety, panic, phobia) were assessed using the Clinical Interview Schedule-Revised at 45 years and depression using Mental Health Inventory-5 at 50 years.

Results: Participants with CMDs at 45 years differed from others on some but not all vitamin D related behaviours. There were inverse, cross-sectional associations at 45 years of 25(OH)D with depression and panic, which persisted after adjustment for vitamin D related behaviours (OR=0.57, 95%CI: 0.40, 0.81 and OR=0.33, 95%CI: 0.40, 0.81, respectively). Association between 25(OH)D and subsequent (50 years) risk of depression was non-linear (p=0.01), with lower risk for participants with 25(OH)D between 50 and 85 nmol/l compared with those with lower or higher concentrations.

Conclusions: This study provides support for an association of low 25(OH)D concentrations with current and subsequent risk of depression in mid-adulthood.

Key words: Vitamin D; Common mental Disorders; 1958 British Birth Cohort.

PO1220**SERUM FOLATE AND VITAMIN B12 IN ELDERLY CHILEANS. RESULTS FROM THE NATIONAL HEALTH SURVEY 2009-10**

C. Castillo-Lancellotti¹, P. Margozzini², G. Valdivia², O. Padilla², R. Uauy^{3,4}, J. Tur¹, J. Rozowsky⁵

¹Research Group on Community Nutrition and Oxidative Stress, Department of Fundamental Biology and Health Sciences, University of the Balearic Islands, Balearic Islands, Spain

²Department of Public Health, Faculty of Medicine, Pontifical Catholic University of Chile, Santiago, Chile

³Public Health and Nutrition Unit, Laboratory of Molecular Epidemiology, Institute of Nutrition and Food Technology, University of Chile, Santiago, Chile

⁴Department of Pediatrics, Faculty of Medicine, Pontifical Catholic University of Chile, Santiago, Chile

⁵Department of Nutrition, Diabetes and Metabolism, Faculty of Medicine, Pontifical Catholic University of Chile, Santiago, Chile

Background and objectives: Supraphysiological levels (SFL) of serum folate (SF) derived from the flour fortification with folic acid (FA) could determine major health risks especially in older adults with low levels of vitamin B12 (B12). The objective of this study is to describe and analyze SF and B12 levels in elderly Chileans and to identify risk groups.

Methods: Participants were 1043 seniors from the National Health Chilean Health Survey 2009-2010 (NChHS 2009-10), a multistage stratified random sample, representative of the national population. SF (µg/L) and B12 (pg/ml) were determined in fasting samples (Competitive Chemiluminescence Immunoassay). Average, deciles and percentiles (5th and 95th) were calculated. We define four SF categories: <4, 4 (deficit); 4, 41-20 (normal) and SFL: 20, 01-25, 6; 25, 601-29 and > 29 µg/L (80th percentile of the distribution) and three vitamin B12 categories: < 200 (deficit); 200, 01-299, 5 (marginal deficit) and >299, 5 (normal). Prevalences by sex and age were calculated. Multiple and logistic regression models were used and adjusted considering educational level and urban/rural area.

Results: FS and B12 average and 95th percentil: 21, 2(± 0.56)/38, 6 µg/L and 348, 4(±7, 6)/637(pg/ml). 0, 3% and 8, 1% present folate and B12 deficiency. Men versus women have significantly lower SF level >29µg/L (OR adjusted 0, 47 95%CI: 0, 26-0, 84). B12 shows no significant variation by age and sex. No statistically significant association was observed between levels of folate and B12.

Conclusions: For the first time, NChHS 2009-10 enabled the evaluation of effects of folic acid fortification in older adults. SF deficit is low, but a significant percentage of elderly sample have SFL. Only 4, 1% of the total sample has SFL associated with B12 deficiency.

Key words: folic acid, vitamin B12, seniors, fortification

PO1221

BREASTFEEDING PRACTICE, PARENTAL EDUCATIONAL LEVEL AND STUNTING IN CHILDHOOD

*I. Purnakarya*¹

¹Faculty of Public Health, Andalas University, Indonesia

Background and objectives: Malnutrition among childhood is a major public health problem in developing countries, including Indonesia. The objective was to study association between exclusive breastfeeding, duration of breastfeeding, mother's education, father's education and stunting in childhood.

Methods: A cross-sectional survey was conducted on 81 mother-child pairs of 3 – 8 years old children in West Sumatra between October and November 2012. A bivariate analysis was performed using a chi square test. This study examined exclusively breastfeeding, duration of breastfeeding, mother educational level, and father educational level in relation to childhood stunting.

Results: The analysis revealed that 37.0% of children 3 – 8 years old were suffering from stunting. The result of this study showed that analysis significantly association between non exclusive breastfeeding (OR=3.00, 95% CI=1.18-7.64) but not duration of breastfeeding and childhood stunting. There was also significantly relationship between mother with low level of education (OR=3.07, 95% CI= 1.18-8.01), father with low level of education (OR=3.09, 95% CI=1.16-8.22) and stunting in childhood.

Conclusions: Development and implementation on exclusively breastfeeding program aimed at addressing childhood malnutrition should also consider improving parental educational level.

Key words: childhood stunting, breastfeeding, parental education.

PO1222

DECLINING INEQUALITY IN OBESITY AMONG URBANISED ADULT MEXICAN WOMEN, BUT IT IS NOT GOOD NEWS

*C. Perez Ferrer*¹, *A. McMunn*¹, *EJ. Brunner*¹

¹Department of Epidemiology and Public Health, University College London, London, UK

Background and objectives: The objective of this study was to assess the trend in socioeconomic inequalities in obesity from 1988-2012 for adult Mexican women. We hypothesised that education would be inversely associated with obesity in richer urban areas of Mexico but not in rural areas, and that the gradient in urban areas would become steeper as the nutrition transition progressed.

Methods: Data came from four nationally representative surveys carried out in 1988, 1999, 2006 and 2012. Response rate ranged from 80% to 97% and sample size of non-pregnant women age 20 to 49 from 10, 318 to 14, 531. Weight and height were measured by a nurse and education level (higher education, high school, secondary, primary or less) was self-reported. Analyses were adjusted for survey design. The relative index of inequality (RII) was computed and its trend from 1988-2012 tested.

Results: Nationally, age-standardised obesity prevalence increased from 9.3% to 33.7% over the 25 year period. An inverse association between education and obesity was observed in urban areas. In rural areas, obesity prevalence increased markedly but there was no association with education level. Obesity increased 5.92 fold (95% CI 4.03, 8.70) among urban women with higher education in the period 1988-2012 compared to 3.23 fold (95%CI 2.88, 3.63) for urban women with primary or no education. The RII in urban areas declined over the period (2.87 (95% CI: 1.94, 4.25) in 1988, 1.55 (95% CI: 1.33, 1.80) in 2012, trend $p < 0.05$).

Conclusions: As expected, an inverse association between education and obesity was observed in urban areas of Mexico. However, the stepwise decline in obesity inequalities was because obesity prevalence increased faster among higher educated groups. In rural areas there was no association between education level and obesity across the four surveys.

Key words: obesity, socioeconomic status, middle income countries, health trends, Mexico.

PO1223**BODY SHAPE CONCERNS IN FEMALE COLLEGE STUDENTS: VALIDATION STUDY***W. Silva¹, J. Maroco², F. Pimenta², J. Campos³*

¹Department Food and Nutrition, area of Nutritional Sciences, Faculty of Pharmaceutical Sciences of Araraquara - State University Júlio de Mesquita Filho, Brazil

²Psychology Research Unit and Health - UIPE Superior Institute of applied psychology, SPA/IU, Lisboa, Portugal

³Department of Social Dentistry, Faculty of Dentistry Araraquara - State University Júlio de Mesquita Filho, Brazil

Background and objectives: The body shape concerns may have an important role in the daily life of an individual. Usually, clinical and epidemiological studies use scales to assess the information. Therefore, knowing the validity and reliability of these instruments is important so that the decision making regarding their use is well informed. The Body Shape Questionnaire (BSQ) evaluates the level of body shape concerns. Thus, the present study was developed to assess the BSQ's psychometric properties, in a sample of female college students.

Methods: Overall 753 students participated in the study. The Portuguese full version of the instrument (entailing 34 items) was used. It was considered the original factorial model, with a single factor. A characterization of the sample was done through sociodemographic and anthropometric data collection. Construct validity was estimated through factorial and convergent validity. A Confirmatory Factor Analysis (CFA) was done. The Composite Reliability (CR) and the Average Variance Extracted (AVE) were estimated. The internal consistency was given by the Cronbach's Alpha.

Results: The student's mean age was 20.9 (SD=4.0) years old. Most students (70.1%) presented an adequate weight, were studying in the Humanities field (70.6%), do not work (69.6%) and have a monthly income of USD 1307.09 – 2339.57 (52.3%). The factorial model presented an inadequate quality of fit ($\chi^2/df=7.280$; CFI=.826; GFI=.699 and RMSEA=.091). To achieve an adequate fit between the model and the sample used, items 26 and 32 were removed ($\chi^2/df=6.321$; CFI=.868; GFI=.751 e RMSEA=.084). Adequate values of convergent validity (AVE single-factor=.51; CR single-factor=.97) and internal consistency (single-factor=.97) were shown.

Conclusions: To assess the body shape concerns in female college students, the BSQ should be used without two items, in order to collect data with quality.

Key words: body shape; validity; college students. Grant number FAPESP: 2012/13475-4.

PO1224**EFFECT OF FEEDING PRACTICES ON ANTHROPOMETRIC STATUS OF CHILDREN 0-5 YEARS IN ORPHANAGES OF ABUJA, NIGERIA.***C. Steve-Edemba¹, N. Nnam*

¹Department of Primary Health Care, FCT Primary health care Board, Federal Capital Territory Abuja, Nigeria

²Department of Home Science, Nutrition and Diets, University of Nigeria Nsukka, Nigeria

Background and objectives: The Prevalence of malnutrition increases rapidly in under-five children because of their rapid growth and development. The objectives was to assess the feeding practices, Anaemia and anthropometry status of orphans and provide evidence based data for appropriate nutrition interventions for orphans in Nigeria.

Methods: Cross sectional descriptive study was used among 20 orphans, 96 males and 104 females between 0-5 years living in ten orphanages. Hemocue was used for anaemia assessment. The children were screened for malaria parasites and worm infection. Height, weight and MUAC were used for anthropometric assessment. Feeding practices and socioeconomic were assessed using questionnaires. Dietary intake was determined using food frequency questionnaire and weighed food intake. The values obtained from nutrient intakes were compared with FAO/WHO recommended nutrients intake. Abuja Health Research Ethics Committee approved the study. Informed verbal consent was obtained from the management of the orphanages.

Results: The study recorded high prevalence of malnutrition among the children. 45.5% of the orphans were underweight, 63.5% were stunted while 47.5% were wasted. Anaemia prevalence was 42.5%. The children met the mean daily energy, protein, calcium, iron, thiamin and riboflavin intake. Zinc, vitamin A, niacin and ascorbate were below the recommended allowance. There was low prevalence of malaria parasite (12.5%) and worm infestations (10.0%). Anaemia was significantly ($P<0.05$) associated with helminthes infestation as well as malaria parasite. The children were feed infrequently as against recommended standard. These deficiencies were associated with poor feeding practices, low caregiver to child ratio (1:5) and low socio-economic status. There was significant ($P<0.05$) difference between income level and the prevalence of malnutrition and also significant ($P<0.05$) relationship between the children that were moderately stunted and zinc deficiency.

Conclusions: The study shows that protein energy malnutrition is still of public health important in Nigeria.

Key words: Anemia, Anthropometric, Feeding practices, Orphanages.

PO1225**EARLY DETERMINANTS OF CHILDHOOD OBESITY: WHAT FACTORS CONTRIBUTE TO ITS DEVELOPMENT SIMULTANEOUSLY IN URUGUAYAN CHILDREN 6-23 MONTHS?***F. Peregalli¹, I. Bove¹*¹Master of Nutrition, Catholic University of Uruguay, Montevideo, Uruguay

Background and objectives: The roots of the obesity pandemic require an early focus on the life cycle to prevent accelerated growth and childhood obesity so as to prevent its impact on health throughout life. This paper aims to study the factors that contribute to the childhood obesity simultaneously in Uruguayan children aged 6-23 months.

Methods: Analytical-cross. 1619 children were studied in a nationwide survey. Multivariate analysis was performed using multiple logistic regression. Test: Chi2. Processing: Anthro-Plusv1.0.2. Statistical analysis: SPSSv15.

Results: Children were distributed evenly by gender (50.7% male) and age. The 11, 9% were obese (> BMIZ 2DS) and 1.9% severely obese (> 3 BMIZ DS). Risk factors (RF) were included in the equation: rapid weight gain (Z score P/E variation > 0.67) OR: 8.12 (4.74 to 13.91); obese mother OR: 3.69 (2.06 to 6.63), macrosomia OR: 3.40 (1.29 to 8.99), cesarean OR: 1.76 (1.10 to 2.82), no consumption of fruit OR 1, 78 (1.03 to 3.05) and growth retardation in height (stunting) OR: 2.90 (1.28 to 6.57). The low birth weight (LBW), stunting and low ponderal index (PI <10 p) at birth, like not being breastfed were RF for rapid weight gain. Gestational Diabetes (GDM) and excess weight gain during pregnancy increased the risk of macrosomia. These latter, obesity and maternal age > 35 years increased the risk of cesarean delivery. Failure fruit consumption was associated with low income. LBW infants whose mothers had low height and pre-pregnancy underweight showed more chances of stunting and it increased almost three times the likelihood of obesity.

Conclusions: The high prevalence of childhood obesity emphasizes the need to focus prevention efforts as early as possible in the lives of children. This work contributes on identifying RF in which would correspond to act.

Key words: childhood obesity, rapid weight gain, stunting, breastfeeding.

PO1226**EFFECT OF A NUTRITION EDUCATION INTERVENTION ON CONSUMPTION OF FRUITS, VEGETABLES AND FISH IN FAMILIES***G. Fretes¹, J. Salinas¹, F. Vio¹*¹Instituto de Nutrición y Tecnología de los Alimentos (INTA), Universidad de Chile, Santiago, Chile

Background and objectives: In Chile there have been different initiatives to address the problem of childhood obesity, especially from nutrition education in schools. For this purpose, different types of educational materials have been used, but only a few cover preschool and school children including their families. The objective of this study was to assess the impact of a nutrition education intervention on fruits, vegetables and fish consumption in pre-school and school age children families.

Methods: A three months education intervention was developed, with a pre-post evaluation in 22 intervened families and 29 controls from public schools in Santiago, Chile. A food-frequency questionnaire on fruits, vegetables and fish, and a survey on food and nutrition knowledge, attitudes and practices were applied. The intervention consisted in six 90 minutes cooking workshops, including the utilization of videos and photovoice for those who cooked in the families.

Results: showed a significant more consumption of fruits, vegetables and fish in the intervened than in the control group (test de Kolmogorov-Smirnov, test de Wilcoxon, p<0, 05). Comparing pre-post consumption by group, significance differences were for the intervened group in all cases (test de Wilcoxon for paired samples, p<0, 05). In parents, fruit consumption increased 135.8 g, vegetables 19.5 g, and fish 10, 2 g per day. In children, the increase in fruits was 92.1 g, vegetables 65.9, and fish 5.2 g per day. All the intervened families (n=22) introduced a significant healthy food improvement at home.

Conclusions: Results showed that it is possible to change food habits in families with the implementation of a nutrition education intervention including cooking workshops, videos and photovoice.

Key words: nutrition education; fruits, vegetables and fish consumption; cooking workshops.

PO1228**IRON AND CANCER RISK - A REVIEW OF THE EPI-DEMOLOGICAL EVIDENCE**

A. Agudo¹, P. Jakszyn¹, A. Fonseca-Nunes¹

¹Unit of Nutrition, Environment and Cancer, Cancer Epidemiology Research Programme, Catalan Institute of Oncology, IDIBELL, Barcelona, Spain

Background and objectives: Iron has been suggested as a risk factor for different types of cancer due to its prooxidant activity which can lead to more oxidative stress and DNA damage. Our purpose was to systematically review and analyze the link between iron intake and body iron status and the risk of developing cancer.

Methods: In this article, using the PUBMED database, we gathered information on dietary iron, heme iron, iron biomarkers, and cancer risk from 54 studies (38 prospective and 16 case-control) published between 1995-2012.

Results: From the six studies studying colorectal cancer and heme iron intake, two found a positive association with cancer risk and one was statistically significant while the other four studies reported no association. Within the same cancer type, three out of the four studies investigating the association between serum ferritin and colorectal cancer found a statistically significant negative association. This same effect was found in a gastric and an esophageal cancer study. Three out of four studies researching the association between esophageal cancer and heme iron intake reported a positive association (two were statistically significant). For gastric and lung cancer, two out of three studies for each cancer type found a positive association between heme iron intake and cancer risk (one each was found to be statistically significant).

Conclusions: Despite the heterogeneity of the results found in this review, there is some tendency towards the positive association between heme iron intake and cancer risk. Moreover, data on iron biomarkers was insufficient. Nevertheless, serum ferritin clearly showed a negative association with gastro-intestinal cancer risk. For this reason, more studies combining research on iron biomarkers, dietary iron intake and also genetic output need to be conducted for better understanding the role of iron on cancer development.

Key words: cancer, iron, dietary, heme, biomarkers.

PO1229**EFFECTIVE GOVERNANCE AND POLICIES TO IMPROVE NUTRITION OUTCOMES: A CROSS COMPARISON OF NINE COUNTRY CASES**

A. Meija Acosta¹, J. Fanzo²

¹Governance Team, Institute For Development Studies, Brighton England

²Institute of Human Nutrition, Columbia University, New York, USA

Background and objectives: Undernutrition chronically afflicts 171 million children worldwide which has lifelong negative consequences. One of the underlying reasons why undernutrition persists is because of the lack of credible and sustained government commitment to tackle the issue. Yet, understanding the motivations, institutions, and dynamics of nutrition government and non-government actors remains an underexplored area in advancing the nutrition agenda.

Methods: This study used a political economy approach to compare the formulation and implementation of government nutrition strategies in nine countries. In order to identify the drivers of nutrition governance, a framework was developed focusing on three key factors: Intersectoral cooperation between government sectors and nongovernment agencies, vertical coordination across different levels of government, and sustainable funding to encourage policy coordination, implementation and ownership. The available data includes original stakeholder interviews and nutrition statistics available in each of the case studies.

Results: The study looks at the formation and maintenance of relevant policy coalitions behind effective nutrition policies. There is a set of institutional factors that facilitate improved government commitment. Depending on the context, effective coalitions around nutrition may be facilitated with the presence of decisive political leadership, cooperation across different government sectors, and effective coordination of interventions from the national to the local sphere. Finally, the comparative study argues that abundant nutrition funding is a necessary but not sufficient condition for success; a critical factor is the actual coordination and allocation of funding sources, including greater government participation, to ensure effective delivery of nutrition interventions and increased accountability.

Conclusions: In the context of global efforts, e.g. the Scaling Up Nutrition movement, this is a critical time to understand how governance works best to improve nutrition outcomes, and how various stakeholders can support government officials in sustaining political commitments over the long term.

Key words: governance, commitment, accountability, financing, undernutrition.

PO1230**THE ALADINO STUDY: A NATIONAL STUDY OF PREVALENCE OF OVERWEIGHT AND OBESITY IN SPANISH CHILDREN IN 2011**

T. Robledo de Dios¹, M A. Dal Re-Saavedra¹, N. Perez-Farinos¹, C. Villar-Villalba¹, E. Labrado-Mendo¹, C. Biansan¹

¹Spanish Agency For Food Safety and Nutrition

Background and objectives: The monitoring of the child obesity epidemic requires the use of accurate, up-to-date information. The aim of the present work was to analyse the prevalence of overweight and obesity in Spanish children using different sets of cut-off criteria.

Methods: This cross-sectional study involved 7569 boys and girls aged 6-9 years. All were weighed, measured, and asked questions about their socio-economic background, food habits and physical activity. The BMI of each was calculated and the prevalence of overweight and obesity determined by age and sex using Spanish reference tables, IOTF reference values, and WHO growth standards. The McNemar test for independent samples was used (comparing two sets of data each time) to determine the significance of the differences in the prevalence values of overweight and obesity returned using these different sets of cut-off criteria.

Results: The prevalence of overweight in boys ranged from 13.9% to 26.5%, and in girls from 13.8% to 25.6%, depending on the cut-off criteria. Similarly, the prevalence of obesity in boys ranged from 11.5% to 21.8%, and in girls from 11.9% to 16.2%. Independent of the criteria used, the prevalence of overweight was found to be greatest among 9 year-olds in both sexes. The prevalence of obesity was highest among these same children when using the Spanish reference tables or WHO criteria, but among 7 year-olds (both sexes) when using the IOTF reference values.

Conclusions: The results show that overweight and obesity remain widespread among Spanish children, underscore the need for periodic studies on their prevalence, and the necessity of coming to consensus on the definition of overweight and obesity cut-off criteria.

Key words: Childhood Obesity, Prevalence, Body Mass Index, Reference values.

PO1231**ABDOMINAL OBESITY AS PREDICTOR OF OTHER CARDIOMETABOLIC RISK FACTORS. STUDY IN TWO URBAN POPULATION GROUPS: COTONOU (BENIN) AND PORT-AU-PRINCE (HAÏTI)**

A. El Mabchour¹, H. Delisle¹, P. Larco², C. Vilgrain²

¹TRANSNUT, Department of Nutrition University of Montreal, Canada

²FHADIMAC, Port-Au-Prince, Haïti

Background and objectives: The nutrition transition increases cardiometabolic risk factors (CMRFs) like abdominal obesity, dyslipidemia, dysglycemia, hypertension and insulin resistance. We aimed to compare the prevalence of CMRFs and to assess the relationship of abdominal obesity with other CMRFs in two urban black population groups with a common African heritage but living in two different countries, Benin and Haiti.

Methods: Our cross sectional study included 452 apparently healthy men and women, 200 from Cotonou and 252 from Port au Prince (PAP), aged 25y to 60y. Criteria for abdominal obesity (Waist circumference > 94cm in men and >80cm in women), hypertension, dyslipidemia and hyperglycemia were those of the International Diabetes Federation. Insulin resistance was defined as the 75th centile of HOMA for the study population. Biochemical analyzes were performed in the same laboratory (Nancy, France).

Results: Mean age of subjects was 36.9±10.3y in Haitians and 38.9±9.8y in Beninese. Abdominal obesity was observed in 83% of Beninese women versus 67% of Haitians and in 22% of Beninese men versus 9.6% of Haitians. The prevalence of high blood pressure was 26.5% in Beninese and 20% in Haitians (p=.088). Low HDL-cholesterol was highly prevalent in both cities but significantly higher in PAP, 89% versus 79% in Cotonou (p=.003). Controlling for age and gender, in subjects with abdominal obesity, the odds ratio for high blood pressure was 5.3 in Beninese and 4.8 in Haitians, the odds for insulin resistance was 6.0 in Beninese and 5.2 in Haitians, and the odds for low HDL-cholesterol was 3.5 in Beninese and not significant in Haitians.

Conclusions: CMRFs were widespread and abdominal obesity was predictive of high blood pressure and insulin resistance in both population groups and it was associated with atherogenic blood lipid profile only in Benin.

Key words: Abdominal obesity, cardiometabolic risk factors, Benin, Haiti.

PO1232**EATING BEHAVIOUR PATTERNS AND BMI IN PORTUGUESE HIGHER EDUCATION STUDENTS**

R. Poínhos¹, B M P M. Oliveira^{1,2}, F. Correia^{1,3,4}

¹Faculdade de Ciências da Nutrição e Alimentação, Universidade do Porto, Porto, Portugal

²Laboratório de Inteligência Artificial e Apoio à Decisão, Instituto de Engenharia de Sistemas e Computadores, Tecnologia e Ciência, Portugal

³Centro Hospitalar de São João, E.P.E., Porto, Portugal

⁴Unidade de Investigação e Desenvolvimento de Nefrologia, Faculdade de Medicina, Universidade do Porto, Porto, Portugal

Background and objectives: Our aim was to determine prototypical patterns of eating behaviour among Portuguese higher education students, and to relate these patterns with BMI.

Methods: Data from 280 higher education students (63.2% females) aged between 18 and 27 years were analysed. Several eating behaviour dimensions (emotional and external eating, flexible and rigid restraint, binge eating, and eating self-efficacy) were assessed, and eating styles were derived through cluster analysis. BMI for current, desired and maximum self-reported weights and the differences between current and desired BMI and between maximum and current BMI were calculated.

Results: Women scored higher in emotional eating and restraint, whereas men showed higher eating self-efficacy. Men had higher current, desired and maximum BMI. Cluster analysis showed three eating styles in both male and female subsamples: "Overeating", "High self-efficacy" and "High restraint". Unlike the other pairs, the two high restraint clusters show relevant differences. Relationships between eating styles and BMI are presented and discussed.

Conclusions: Restrictive women and men differ on important eating behaviour features, which may be the cause of differences in the relationships with BMI. Eating self-efficacy seems to be a central variable moderating the relationships between other eating behaviour dimensions and BMI.

Key words: Eating behaviour; Eating styles; Body Mass Index.

PO1234**EXPERIENCES FROM A COMPREHENSIVE COMMUNITY NUTRITION PROGRAM IN TWO DISTRICTS IN KENYA. LESSONS FOR NATIONWIDE MNP SUPPLEMENTATION ROLL OUT**

J. Suryantan¹, F. Wambua², S. Mutua³, D. Tyler³, M A. Bloem¹

¹CWS Inc, New York, USA

²Nutrition Division, Ministry of Public Health and Sanitation, Government of Kenya

³CWS Africa Regional Office, Nairobi, Kenya

Background and Objectives: Kenya has high stunting rates (35%) and is experiencing rise in diet-related non-communicable diseases. Kenya joined SUN in 2012. Third strategic objective of NNAP 2012-2017 includes scaling up and strengthening of existing strategies of MNP supplementation at all levels. MNP supplementation in Kinango and Mwingi District was part of a comprehensive community nutrition program. A survey was also conducted in Kinango district to assess health and nutritional status of under-five children.

Methods: Cross-sectional survey used two-stage cluster sampling method (SMART) in 3 divisions of Kinango District. Total of 430 households (43 clusters) were visited and 583 children from 6 to 59 months were part of anthropometric survey.

Results: Survey revealed that GAM and stunting prevalence amongst children under-five years old are 10.9% and 50%, respectively. Early initiation of breastfeeding within 1 hour of birth for children born in past 24 months was 43.5%. 13% of children less than 6 months of age were exclusively breastfed in past 24 hours. Only 18% of children aged 6 – 23 months met minimum dietary diversity in past 24 hours. MNPs supplements are well accepted by mothers which covers more than 2800 under-five children. Mothers observed positive changes like improved appetite and less prone to illness. After initial positive impacts, program coverage expanded from 8 to 23 health facilities. Outreach activities brought health services nearer to mothers and their children.

Conclusions: Prevalence of malnutrition is higher than national figure. IYCF practices are far from optimal and might exacerbate nutritional status even further. MNPs are required to improve quality of food fed to children. Strengthened outreach activities increased MNP coverage. As such, nationwide MNPs supplementation in Kenya seems feasible. Strengthening outreach activities can also be used as entry point in addressing underlying causes.

Key words: Stunting, IYCF, Kenya, MNPs, SUN

PO1235

METHODS OF INFLUENCE: A CONTENT ANALYSIS OF THE CANADIAN FEDERAL MENU LABELLING POLICY COMMUNITY

M. Smith¹, R. Yada¹, J. Sheeshka², T. MacLaurin³, Q. Liu⁴

¹Department of Food Science, University of Guelph, Guelph, Ontario, Canada

²School of Biomedical and Health Sciences, Victoria University, Melbourne, Victoria, Australia

³Department of Hospitality and Tourism Management, University of Guelph, Guelph, Ontario, Canada

⁴Structure and Function Team, Agriculture and Agri-Food Canada, Guelph, Ontario, Canada

Background and objectives: Policy-makers may lack the access, time, and skills required to critically appraise nutrition research related to addressing population health problems. As such, the stakeholders engaged in any nutrition issue (i.e. the policy community) have an important role in bringing potential food policy solutions to the attention of public policy-makers. However, this is a poorly understood process. This research aims to clearly describe the methods a policy community uses to create political will for healthy public policy.

Methods: Documents pertaining to Bill C-398, a Canadian federal menu labelling bill, were identified from the academic and unpublished/grey literature using a defined search strategy. Messages pertaining to the bill were extracted and coded to record the sender, the target audience, the major themes, and how the message was sent. Content analysis protocol, including a second coder, was used to analyze the results.

Results: A total of 246 unique messages were identified from 103 documents. The menu labelling policy community was made up of 31 stakeholders, the most active of whom were consumer public interest groups (26% of messages). The majority of messages were targeted to federal politicians (24%), but members of the media (23%) and general public (15%) were also frequent recipients. Major themes identified were: defining and describing the problem and potential solutions, explaining the bill, its intended outcomes, and the technical feasibility of enacting it, and identifying support. Messages were sent through 35 channels, but participating in interviews (14%), creating online documents (12%), and writing letters (11%) were the top three.

Conclusions: Individual policy communities are complex and employ diverse methods to influence political will. Results from this project may help nutrition advocates identify gaps in their current approaches to knowledge translation for policy-makers.

Key Words: content analysis; healthy public policy; menu labelling; policy community.

PO1236

TRACE ELEMENTS OF COLON CANCER – A CASE CONTROL STUDY

N. Alfaris¹, D. Ahmad², N. Alqohaiz¹

¹Department of Nutrition and Food Science, Princess Nora University, Riyadh, Saudi Arabia

Background and objectives: The pathogenesis of a number of diseases like cardiovascular diseases, diabetes and cancer has been associated with changes in the balance of certain trace elements.

Methods: In the present study we aimed to investigate the levels of trace elements like calcium, copper, iron and zinc in colon cancer patients in comparison with healthy controls. Serum samples were collected from 256 colon cancer patients and 180 healthy age and sex matched controls. Trace element levels were detected using commercially available kits and an Auto-Analyzer (ChemWell 2910, Awareness Technology, and USA).

Results: The concentrations of calcium, copper and iron were not significantly different in patients in comparison with healthy controls. The concentration of zinc was significantly lower in colon cancer patients ($p = 0.001$) as compared to normal subjects. Conclusions: Deficiency of zinc may play a role in the development of colon cancer or may contribute to damage already underway. Zn may represent an independent risk factor for colon cancer and therefore a possible target for prevention.

Key words: Colon cancer; Trace elements; Calcium; Copper.

PO1237

BOLSA FAMILIA PROGRAM: NUTRITIONAL STATUS AND DIET QUALITY OF WOMEN IN A RURAL AREA OF THE NORTHEAST BRAZIL

F. Lima¹, C. Barreto², C. Dantas², O. Raposo², E. Ribeiro²

¹Department of Nutrition, Universidade Federal da Paraíba, Brazil

²Universidade Federal de Sergipe, Brazil

³Departament of Statistics, Universidade Federal de Sergipe, Brazil

Background and objectives: The Bolsa Família Program is the largest program of conditional cash transfer in Brazil, and its major goal is to reverse the current food insecurity. In spite of that, there are few studies that shows nutritional status and food habits for this population in rural area. This study aimed to describe the nutritional status and diet quality of women enrolled in the Bolsa Família program in Campo do Brito, rural area of Sergipe State, Northeast Brazil.

Methods: Cross-sectional study with women enrolled in Bolsa Familia Program in the municipality of Campo do Brito, rural area of Sergipe State, Northeast Brazil. A total of 301 beneficiaries, aged 19 years or more, were interviewed. A 24 hour-recall was applied to assess diet quality and the Healthy Eating Index (HEI) was used as a parameter to categorize the group into consumption levels. To assess the nutritional status of this population, we measured weight (kg), height (cm), and calculated the body mass index (BMI).

Results: According HEI, 79, 1% of the population has a diet that requiring adjustments. The median score of each component of the HEI shows a low intake of pulses, milk and dairy products, and high intake of cereals, beans and meat. Overweight prevalence was 30, 6% and 18, 9% from obese.

Conclusions: Bolsa-familia program help to promote nutritional food security. Studies that evaluate diet quality and nutritional status are essential to support the implementation of nutrition education programs aimed at the core of the problem present in the populations studied.

Key words: Nutritional status, diet quality, overweight.

PO1238

HIGH PREVALENCE OF HOUSEHOLD LEVEL FOOD INSECURITY AND ITS DETERMINANTS IN AN URBAN SLUM POPULATION IN NORTH INDIA

K. Yadav¹, P. Chinnakali², R K. Upadhyay³, D. Shokeen⁴, K. Singh⁴, M. Kaur⁴, A K. Singh¹, A. Goswami¹, C S. Pandav¹

¹All India Institute of Medical Sciences, New Delhi, India

²Indira Gandhi Medical College and Research Institute, Puducherry, India

³Vardhman Mahavir Medical College and Safdarjung Hospital, New Delhi, India

⁴Institute of Home Economics, University of Delhi, New Delhi, India

Background and objectives: India has the world's largest population living in slums and these have largely been an under-served population. Various studies have been conducted to assess food insecurity at global level; however, the literature is limited as far as India is concerned. The present study was conducted with the objective of estimating the prevalence of food insecurity at household level and its determinants in an urban slum population of northern India.

Methods: This cross-sectional study was conducted in an urban resettlement colony of South Delhi, India. A pre-designed, pre-tested, semi-structured questionnaire was used. Food insecurity was assessed using Household Food Insecurity Ac-

cess Scale (HFIAS). Logistic regression analysis was performed to determine the factors associated with food insecurity.

Results: A total of 250 women were interviewed through house to house survey. Majority of the households were having a nuclear family (61.6%) with mean family size being 5.5 (SD ± 2.5) and the mean monthly household income being INR 9784 (SD ± 631). Nearly half (53.3%) of mean monthly household income was spent on food. The study found that a total of 77.2% households were food insecure (49.2% households mildly food insecure, 18.8% households moderately food insecure and 9.2% of the households severely food insecure). Education of the women handling food [0.37, 95% CI 0.15 – 0.92; 0.03] and number of earning members in the household [0.68, 95% CI 0.48 – 0.98; 0.04] were associated with lesser chance/odds of being food insecure.

Conclusions: The study demonstrated a high prevalence of food insecurity in the marginalized section of the urban society in India. The government of India needs to adopt urgent measures to combat this problem.

Key words: Food insecurity; Urban slum; Prevalence; Determinants; North India.

PO1239

DEVELOPMENT AND VALIDATION OF A FOOD SELF-EFFICACY SCALE

R. Poínhos¹, H. Canelas², B M P M. Oliveira^{1,3}, F. Correia^{1,4,5}

¹Faculdade de Ciências da Nutrição e Alimentação, Universidade do Porto, Rua Dr. Roberto Frias, Porto, Portugal

²Nutritionist, Independent Researcher, Porto, Portugal

³Laboratório de Inteligência Artificial e Apoio à Decisão, Instituto de Engenharia de Sistemas e Computadores – Tecnologia e Ciência, Porto, Portugal

⁴Centro Hospitalar de São João, E.P.E., Porto, Portugal

⁵Unidade de Investigação e Desenvolvimento de Nefrologia, Faculdade de Medicina, Universidade do Porto, Alameda Prof. Hernâni Monteiro, Porto, Portugal

Background and objectives: Self-efficacy refers to the beliefs in the ability to organise and implement the action plans needed to achieve a certain result and the feeling of control over the behaviours and environment. It determines the initiation, maintenance and cessation of strategies or behaviours, being a good predictor of eating behaviour. Despite its potential in terms of research, prognosis and evaluation of interventions, we are unaware of instruments to assess global features

of food self-efficacy validated for the Portuguese population. The aim of this work is to develop and validate a scale to assess general features of food self-efficacy ("Escala de Auto-Eficácia Alimentar Global").

Methods: We evaluated a sample of 275 higher education students, and the analysis was performed separately for the subsamples of females and males. The items were created through the adaptation of the six items of the self-efficacy subscale of the "Inventário Clínico de Auto-Conceito" (Serra, 1986).

Results: The analysis led to the maintenance of five of the six items initially considered. The scale shows a unifactorial structure, and the proportion of total variance explained by the principal components extracted is higher than 64%. It also shows good internal consistency, with values of Cronbach's alpha above 0.85. The study of relations with other measures showed evidence of its construct, convergent, and discriminant validities.

Conclusions: The "Escala de Auto-Eficácia Alimentar Global" showed good psychometric properties, and may prove to be an useful tool for the prognosis and the evaluation of interventions related to the change in eating habits.

Key words: Eating self-efficacy; Scale; Development; Validation; Psychometric properties.

PO1240

MALNUTRITION AND ITS CORRELATES AMONG PRIMARY SCHOOL CHILDREN IN FOGERA DISTRICT, RURAL ETHIOPIA

H. Zeleke¹, T. Adafrie², T. Kisi³

¹Health and nutrition Promotion and Disease prevention Directorate, Federal Ministry of Health, Addis Ababa, Ethiopia

²Institute of Public Health, University of Gondar, Gondar, Ethiopia

Background and objectives: Malnutrition is a major public health concern affecting a significant number of school children influencing their health, growth and development, and school academic performance. The objective of the study was to determine the nutritional status of school children in terms of stunting, underweight and thinness at Fogera woreda, Northwest Ethiopia, 2012.

Methods: Institutional and community based cross sectional study was conducted from June to December, 2012. The study included 790 primary school children who were selected from the source population by multi stage random sampling technique. Data were collected through interview with parents with a standardized and pretested questionnaire, microscope, physical examination and anthropometric measuring and data were entered and analyzed using SPSS version 16.0 and

AnthroPlus softwares. Binary and Multivariate logistic regression analyses were used to identify factors associated with malnutrition among school children.

Results: Prevalence of malnutrition was high among school children aged six to fourteen years old (mean age 11.4 ± 2.1 years); Study contents include questionnaire surveys, anthropometric measurement, observation and laboratory methods. Finally 790 school-age students took part in study. The results showed that the overall prevalence of stunting was stunting, underweight and thinness were 243 (30.7%), 96(59.7%) and 294 (37.2%). Rice consumption, family size, Family radio, infection, vaccination and latrine availability were significantly associated with malnutrition.

Conclusions: The study found high prevalence of malnutrition and parasitic infection among primary school children. De-worming, vaccination, family planning, latrine construction and utilization, rice production and prevention and early treatment of infection are essential to reduce the risk of malnutrition.

Key words: malnutrition, school children, Fogera, Ethiopia.

PO1241

MODIFYING EFFECTS OF MATERNAL NUTRITION STATUS ON THE RESPONSE TO MULTIPLE MICRONUTRIENTS SUPPLEMENTATION ON PRETERM AND NEONATAL MORTALITY IN CHINA

L. Zeng¹, H. Yan¹, Y. Cheng¹, M. Dibley²

¹School of Public Health, Xi'an Jiaotong University College of Medicine, Xi'an City, Shaanxi Province, China

²The Sydney School of Public Health, Faculty of Medicine, The University of Sydney, Sydney, NSW, Australia

Background and objectives: Nutritional status of peripregnancy affect the health and survival rate of the new born. Maternal mid-upper arm circumference (MUAC) is currently the best tool for screening pregnancy women eligible for supplementation programmers. We assessed the modifying effects of baseline maternal MUAC on responses to micronutrient supplements in pregnancy on gestational age and neonatal mortality.

Methods: A cluster randomized double-blind controlled trial conducted in two rural counties in north-western China. All pregnant women in villages were randomly allocated from enrolment until delivery to daily supplementation with folic acid (control), iron/folic acid, or multiple micronutrients (MMN) with a recommended allowance of 15 vitamins and minerals. MUAC was categorized as indicator of maternal nutritional status for the lower (<23.5 cm) and normal (≥23.5

cm). Analysis was by intention to treat with GEE models to adjust for the cluster randomized design.

Results: In the pregnant women with MUAC <23.5 cm, MMN supplement significantly increased the duration of gestation by 0.29 weeks (95% CI: 0.12 - 0.45), reduced preterm birth by 35% (RR 0.55, 95% CI: 0.32 - 0.93), and reduced neonatal mortality by 58% (RR 0.42, 95% CI: 0.19 - 0.90) compared to folic acid. Iron/folic acid significantly increased the duration of gestation by 0.27 weeks (95% CI: 0.09 - 0.45), reduced early preterm birth by 59% (RR 0.41, 95% CI: 0.17 - 0.98), and reduced neonatal mortality by 54% (RR 0.46, 95% CI: 0.22 - 0.96) compared to folic acid. Iron/folic acid and MMN supplements had no significant effects on women with MUAC \geq 23.5 cm.

Conclusions: Women with poor nutritional status had higher responses of perinatal outcomes to antenatal micronutrient supplementations in rural China. In these women standard iron/folic acid provided similar protection for neonatal survival than MMN supplements.

Key words: micronutrients, randomized controlled trials, mid-upper arm circumference, neonatal death.

PO1242

LIFESTYLE PATTERNS ARE CORRELATED WITH SIGNS OF THE METABOLIC SYNDROME IN KILIMANJARO REGION, TANZANIA

K M. Demmler¹, C. Ludwig¹, J. Msuya², M B. Krawinkel¹

¹Institute of International Nutrition, Justus-Liebig-University, Giessen, Hessen, Germany

²Department of Food Science and Technology, Sokoine University of Agriculture, Morogoro, Tanzania

Background and objectives: A shift in lifestyle patterns towards energy-dense foods and low activity levels leads to an increase in signs of the metabolic syndrome in East Africa. In the Kilimanjaro Region, Tanzania, nearly 35% of women are already overweight or obese, accompanied by increased blood glucose and lipid levels. The current study assessed food intake, physical activity, and health indicators to identify signs of the metabolic syndrome in Tanzania.

Methods: A cross-sectional study with a standardized survey was conducted in several urban and rural areas around Moshi, Kilimanjaro Region, 2012. Women and men between 18 and 65 years with no diagnosed diseases were randomly selected. Dietary intake and physical activity were assessed by a food frequency and physical activity questionnaire, respectively, and two 24 hour recalls each. As health indicators for the metabolic syndrome, body mass index (BMI), waist-to-hip-ratio (WHR), blood pressure, fasting blood glucose (FPG), and -cholesterol were measured.

Results: Out of four derived dietary patterns, the roots and tuber diet showed significantly positive correlations with FPG. Intake of carbohydrates, polyunsaturated fats, dietary fiber, and physical activity level were negatively correlated with BMI. Alcohol consumption was significantly positively correlated with blood pressure. Of the total 105 participants in the data analysis, 59% had high blood pressure, 17% were classified as pre-diabetic, 8% as diabetic, and 23% were obese (BMI >30 kg/m²). Almost 10% had at least three of these metabolic syndrome signs simultaneously.

Conclusions: Lifestyle patterns are correlated with an alarming high number of obesity and secondary outcomes. Nutrition- and social settings need to be studied and addressed with preventative action plans to stem the merging signs of the metabolic syndrome.

Key words: lifestyle patterns, metabolic syndrome, Tanzania.

PO1243

INTERDISCIPLINARY COLLABORATION BETWEEN SOCIAL WORKERS AND DIETICIANS TO IMPROVE NUTRITIONAL STATUS AND LIFE QUALITY OF CHILDREN IN RISK

Á. García González¹, P. Muro Sans²

¹Facultad Farmacia, Universidad CEU-San Pablo, Madrid, Spain

²Fundació Pere Tarrés, Universidad Ramon Llull, Barcelona, Spain

Background and objectives: Physical well-being will not be understood without social welfare and vice versa. Interdisciplinary work between Social Workers and Social Educators (SW) and Dieticians (D) is an obvious necessity, especially when it comes to social vulnerable populations, but it does not occur in real life. Nutrition is not just a biological aspect it is related to poverty and social psycho aspects. Furthermore, equity in health is involved in the field of social justice in different ways, and must be understood as a multidimensional issue. To establish the bases for an interdisciplinary work between SW and D an innovative, multidisciplinary and multicultural educational program, that faces students to real situations that require social and dietary action for success, was held.

Methods: TS and D Students from 5 European universities, participating in the Erasmus Intensive Program: Quality of Food Intake and Social Exclusion were challenged, by some Institutions that work with children at risk of social exclusion, to develop an educational program aimed to improve the nutritional status of the children. They should empower the stakeholders into healthy eating habits, taking into account the socio-economic and cultural environment, as well as use food

as a tool to improve independence, self-esteem, socialization and social integration.

Results: The collaboration between students of both disciplines resulted in programs adapted to the real situation, taking into account the sociocultural environment, and that exceeded to simple nutritional recommendation. The proposed activities (games, workshops, theatre) tried to improve the nutrition status of children while facilitating the integration of families and their involvement in the care of children (multicultural fairs, games with families, parent's council)

Conclusions: Interdisciplinary collaboration facilitated mutual understanding between both professionals and increased their competences in health education intended for vulnerable groups. Collaboration is viable and productive.

Key words: Nutrition education, Social exclusion, children at risk.

PO1244

ADULTS' KNOWLEDGE OF FAT AND CHOLESTEROL

L S. Akan¹, M V. Yilmaz¹, E. Energin¹, E D. Ciracioglu¹, N. Yabanci¹, H. Yardimci¹, A. Ucar¹, A O. Ozcelik¹, M S. Surucuoglu¹, F P. Cakiroglu¹

¹Nutrition and Dietetics, Ankara University, Ankara, Turkey

Background and objectives: Having insufficient and/or incorrect information about fat and cholesterol is known to increase the prevalence of some chronic diseases. This study is planned and conducted in order to identify the adults' knowledge of fat and cholesterol and the factors affecting it.

Methods: The study sample consists of 1710 subjects (M:531, F:1179) who agreed to participate among the ones who apply to Family Health Centers in different regions of Ankara. Data collection were made using a questionnaire which contains questions about demographical data and fat and cholesterol knowledge (30 questions of fat and 25 questions of cholesterol). The confidence bounds of fat and cholesterol questions are calculated and Chronbach's Alpha values are 0.634 and 0.749 respectively. Total fat and cholesterol scores were calculated giving "1" point for each correct answer and "0" point for each incorrect answer. Data evaluation was made using SPSS program.

Results: 33.0% of the participants were high school graduates and 69.2% of them were married. According to BMI classification, 36.9% of the participants were in normal range and 60.2% of them were pre-obese and obese. The mean score of fat knowledge has found 18.20±3.96 and cholesterol knowledge has found 13.99±4.29. Female participants' mean fat (p<0.05) and cholesterol (p<0.001) scores were higher than

the males'. There has found a statistically significant difference between both mean scores and BMI caused by obese subjects (p<0.05) whose mean fat score was lower and mean cholesterol score was higher than normal range subjects. A positive correlation identified between education level and mean fat score (p<0.001).

Conclusions: Having information about fat and cholesterol is closely related to BMI, gender and education. It's concluded that it's essential to provide subjects with nutrition education continuously.

Key Words: Turkey, Fat, Cholesterol, Knowledge.

PO1245

SITUATIONAL ANALYSIS AND EXPERT EVALUATION OF THE NUTRITION AND HEALTH STATUS OF INFANTS AND YOUNG CHILDREN IN SUB-SAHARAN AFRICA

M. Alles¹, S. Eussen¹, O. A-T², S. Diouf³, A. Tanya⁴, A. Lakati⁵, A. Oduwole⁶, C. Mauras⁷

¹Danone Research – Centre For Specialised Nutrition, Wageningen, The Netherlands

²Institut National de Santé Publique, Abidjan, Ivory Coast

³Institut de Pédiatrie Sociale UCAD, Dakar, Senegal

⁴Department of Public Health, University of Yaounde, Yaounde, Cameroon

⁵African Medical and Research Foundation, Nairobi, Kenya

⁶College of Medicine, University of Lagos, Lagos, Nigeria

⁷Danone Baby Nutrition Africa & Overseas, Villefranche sur Saone, France

Background and objectives: The poor feeding practices of pregnant women, infants and young children contribute to the burden of malnutrition, and subsequently to childhood morbidity and mortality in sub-Saharan Africa. Gaining insight into the nutritional and health status of infants and children will help to focus future nutrition programs and actions. This review aims to provide an overview of the nutrition and health status of infants and young children in five sub-Saharan African countries (Ivory Coast, Senegal, Cameroon, Kenya and Nigeria)

Methods: Published and gray literature was critically reviewed and enriched with the views of local experts from academia, hospitals and institutions in order to assess infants' and children's diet and health in the African countries. Subsequently, the Africa Nutriday Conference was held in Senegal

(November 2011) to discuss key challenges, action plans and recommendations for future research.

Results: In sub-Saharan Africa, the under 5-year mortality rate is high, mainly because of deaths from diarrhea, malaria and pneumonia. Malnutrition is the main contributor of this high burden of disease, with vitamin A and iron continuing to be the most important nutritional deficiencies in the region. Paradoxically, there is at the same time a rising prevalence of overweight and obesity. Education for parents and health care professionals is urgently needed in order to increase their knowledge on breastfeeding, vaccination programs and over- and undernutrition. Moreover, an integrated health and nutrition surveillance program is required both to identify micronutrient deficiencies and to recognize early signs of overweight. These data will inform nutrition education and food fortification programs in the target population.

Conclusions: Different countries in sub-Saharan Africa face similar nutrition and health issues and are currently not sharing best practices, nutrition programs and scientific studies optimally. There is a need for a close collaboration between scientists and policy makers within and between countries.

Key words: Nutrition, children, adolescents, hospitals.

All-type cognitive impairment was defined as the combined incidence of all-type dementia and cognitive decline, measured with Mini Mental Test. Cox proportional hazard regression and logistic regression with multivariable adjustments was used.

Results: Altogether 84, 143 and 198 developed AD, all type dementia or all-type cognitive impairment, respectively. A LCHP-resembling pattern was weakly related to all-type dementia and all type cognitive impairment, whereas adherence to MDS appeared as protective for all type cognitive impairment. When only adequate reporters of energy intake according to Goldbergs cut-off ($n=564$) were considered, a high adherence to MDS was highly protective even after adjustment for energy intake, education level, ApoE4 carriage, marital status, smoking and physical activity (OR 0.32, 95% CI 0.11, 0.89).

Conclusions: A high adherence to a Mediterranean like dietary pattern among older Swedish men was associated with a more than halved risk for all-type cognitive impairment during a 12-year period. A combined intake low in carbohydrates and high in proteins may associate with a risk of developing cognitive dysfunctions.

Key words: Dietary pattern, dementia, alzheimers disease, Epidemiology.

PO1246

DIETARY PATTERNS AND COGNITIVE DYSFUNCTION IN A PROSPECTIVE STUDY OF 70-YEAR-OLD SWEDISH MEN

E. Olsson¹, B. Karlstrom¹, L. Kilander², L. Byberg³, T. Cederholm¹, P. Sjogren¹

¹Unit of Clinical Nutrition and Metabolism, Department of Public Health and Caring Sciences, Uppsala University, Sweden

²Unit of Geriatrics, Department of Public Health and Caring Sciences, Uppsala University

³Uppsala Clinical Research Center, Uppsala University, Sweden

Background and objectives: With the global increase in life span dementia disorders are increasing in prevalence and nutritional intake is one modifiable life style factor that may play a role in this context. We therefore studied the association of dietary patterns with the 12-year incidence of Alzheimer's disease (AD), all-type dementia, and all-type cognitive impairment in elderly Swedish men.

Methods: Dietary habits in 1138 men from the Uppsala Longitudinal Study of Adult Men (ULSAM study) were determined by a 7-day food record. Adherence to the following dietary patterns were assessed: i) recommendations according to WHO guidelines, ii) a Mediterranean-like diet score (MDS) and iii) a low carbohydrate high protein diet score (LCHP).

PO1247

A SCHOOL MEAL STUDY: COMPARING PLATE WASTE AND LIKINGS OF PACKED LUNCH AND LUNCH BASED ON THE NEW NORDIC DIET

A V. Thorsen¹, A D. Lassen¹, E W. Andersen², L M. Christensen¹, A. Biloft-Jensen¹, R. Andersen¹, C T. Damsgaard³, R A. Petersen³, I. Tetens¹

¹Division of Nutrition, National Food Institute, Technical University of Denmark, Denmark

²Department of Applied Mathematics and Computer Science, Technical University of Denmark, Denmark

³Department of Nutrition, Exercise and Sports, Faculty of Science, University of Copenhagen, Denmark

Background and objectives: The majority of Danish children do not eat in accordance with the national dietary guidelines. The OPUS School Meal Study is a school-based intervention study testing the health effects of the New Nordic Diet (NND). The aim of this sub-study was to compare edible plate waste and self-reported likings between packed lunch from home and the served NND meal.

Methods: The OPUS School Meal study is a cluster-randomized controlled 2-period cross-over study consisting of two three-month periods: an intervention period (NND) and a control period. 187 children (8-11y) at two schools were as-

signed to the sub-study. Edible plate waste was measured by weighing individually meals for 5 consecutive days before and after lunch at the end of each dietary period. Self-reported smiley ratings from a web-based dietary assessment software for children were compared to edible plate waste. The data were modelled in two steps, a generalised linear mixed model was fitted for the probability of waste/no waste, and secondly a linear mixed model for positive waste data was fitted.

Results: 74% of all meals (N=1558) had edible plate waste (>5g). Looking at all lunches the odds for leaving edible plate waste was 11 times higher for NND than for packed lunch (P < 0.001). Looking at the meals with edible plate waste (N=1060) the amount was not significantly different between meal types; the median (IQR) for NND was 85.0 (36.5; 150.0) and for packed lunch 70.0 (40.0; 119.0). Lunches rated as 'really bad' or 'bad' in the self-reported likings had more waste than lunches rated 'really good' (P < 0.001).

Conclusions: The odds of having edible plate waste were significantly higher for NND meals compared to packed lunch. Liking of school meals are an essential determinant in order to reduce edible plate waste.

Key words: School-intervention, New-Nordic-Diet, packed-lunch.

PO1248

CONSUMPTION OF MEDITERRANEAN DIET COMPONENTS IS ASSOCIATED WITH LOWER CARDIOVASCULAR RISK. DATA FROM ALIMENTATE SANO, A CROSS-SECTIONAL INTERNET SURVEY

G. Echeverria¹, P. Jimenez¹, S. D'Acuña¹, I. Urquiaga¹, A. Rigotti¹, F. Leighton¹

¹Centro de Nutricion Molecular y Enfermedades Crónicas, Pontificia Universidad Católica, Santiago de Chile, Chile

Background and objectives: Self-administered online food intake surveys offer new opportunities to assess dietary intake at population levels. Aliméntate Sano (AS, www.alimentatesano.cl) is a website in Spanish that promotes and educates on healthy lifestyles, including Mediterranean diet intake, to prevent chronic diseases. It has a personal and private record of self-reported lifestyle habits and health status. Our goal was to evaluate the ability of this website tool to detect a relationship between Mediterranean diet (MD) intake and risk of cardiovascular disease (CVR).

Methods: Diet quality was measured through a validated MD score (MDS). CV risk was assessed by presence of metabolic syndrome (MS) components: waist circumference (WC), blood pressure (BP), HDL cholesterol, triglycerides (TG) and glycemia (G). Data of 3,219 users over 20 years old, who answered

red MDS and reported valid MS components, were analyzed to correlate MD food groups and MS components using one-way ANOVA adjusted for sex and age.

Results: People who consumed ≥ 3 vegetable or ≥ 2 whole cereals servings/day had significant lower BP, WC, TG and G. In contrast, people with high sugar consumption had significant increased levels of BP, WC, TG and G than people with moderate and low sugar consumption. In addition, there was an inverse correlation between legume consumption and WC. Fatty red meat and/or processed meat consumption was associated with higher levels of BP, WC, TG and G; while lean red meat and poultry showed no association with MS. Among dairy foods, low fat and fermented dairy product intake was inversely associated with BP, WC, TG and G, whereas consumption of whole dairy was positively associated with MS.

Conclusions: This cross sectional internet survey shows that high consumption of foods recommended by Mediterranean diets is associated with lower CVR measured by the presence of MS components. Supported by Fundación Banmédica.

Key words: Mediterranean-diet, cardiovascular-risk, metabolic-syndrome.

PO1249

EAT, SLEEP, WORK, PLAY: RELATIONSHIPS AMONG HEALTH-RELATED BEHAVIORS OF YOUNG ADULTS BY WEIGHT STATUS

C. Byrd-Bredbenner¹, V. Quick², A. White³, O. Brown⁴, S. Colby⁵, S. Shoff⁶, B. Lohse⁷, G. Greene⁸, T. Horacek⁹, T. Kidd¹⁰

¹Rutgers University, Department of Nutritional Sciences, New Brunswick, USA

²Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Division of Epidemiology, Statistics and Prevention Research, Bethesda, USA

³Food Science and Human Nutrition, University of Maine, Orono, Maine, USA

⁴Department of Nutrition, Dietetics, and Hospitality Management, Auburn University,

⁵Department of Nutrition, University of Tennessee, Knoxville, USA

⁶Department of Nutritional Sciences, University of Wisconsin-Madison, Madison, USA

⁷Nutritional Sciences, The Pennsylvania State University, University Park, USA

⁸Department of Nutrition and Food Sciences, University of Rhode Island Kingston, USA

⁹Department of Public Health, Food Studies and Nutrition, Syracuse University, Syracuse, USA

Background and objectives: Few studies have examined how health behaviors relate to weight status in college students, a population at risk for weight gain. This study examined relationships among health-related behaviors (i.e., sleep duration, fruit/vegetable intake, exercise level, and work time [based on credit load and hours of paid employment]) and socio-demographic characteristics by weight status (non-overweight [BMI <25] vs. overweight [BMI ≥25]) of college students (N=1252; 18-24 years) from 9 U.S. universities.

Methods: Valid, reliable measures administered online were: Pittsburgh Sleep Quality Index (PSQI), Three-Factor Eating Questionnaire (TFEQ), Satter Eating Competence Inventory (ecSI), National Cancer Institute Fruit/Vegetable Screener, International Physical Activity Questionnaire. Participants also reported height, weight, race, course credit load, and hours worked weekly.

Results: Bivariate logistic regression analyses revealed that gender (female), race (non-white), older age, lower ecSI Contextual Skills scale score, higher TFEQ Emotional Eating scale score, and higher PSQI Sleep Quality scale score were significantly ($p < 0.05$) associated with overweight status. These variables were subsequently entered into a multivariate logistic regression model with overweight status as the outcome variable of interest. Regression results indicated that gender (female; OR=1.84, CI: 1.39-2.43), older age (OR=1.35, CI=1.21-1.50), and lower SECI Contextual Skills score (OR=0.96, CI:0.92-0.99), and higher PSQI Sleep Quality scale score (OR=1.08, CI:1.02-1.14) are significantly ($p < 0.05$) associated with overweight status.

Conclusions: Findings suggest that obesity prevention interventions for college students should include an education component to enhance contextual skills associated with eating competence (e.g., planning regular meals, considering nutritious selections) and emphasize the importance of overall sleep quality.

Key words: young adults, health, behaviors, sleep.

PO1250

A SYSTEMATIC REVIEW AND META-ANALYSIS EXAMINING 'A POSTERIORI' DIETARY PATTERNS AND RISK OF TYPE 2 DIABETES.

C. McEvoy¹, C. Cardwell¹, J. Woodside¹, I. Young¹, S. Hunter², M. McKinley¹

¹Centre for Public Health, Queen's University Belfast, Belfast, United Kingdom

²Regional Centre for Endocrinology and Diabetes, Belfast Health and Social Care Trust, Belfast, United Kingdom

Background and objectives: Dietary pattern (DP) analysis may help to elucidate diet-disease relationships, such as the relationship between eating behavior and risk of type 2 diabetes mellitus (T2DM). This review and meta-analysis was performed to examine the association between a posteriori-derived DP and risk of T2DM.

Methods: MEDLINE and EMBASE were searched for articles published up to July 2012 and data was extracted by two independent reviewers. Prospective studies examining DP, derived by principle component analysis, and T2DM risk were eligible for meta-analysis. Multivariate-adjusted odds ratios were combined, using a random-effects meta-analysis.

Results: Nine prospective studies involving 309, 430 participants and 16, 644 incident cases of T2DM were included for meta-analysis. Two broad DPs ('Healthy/Prudent' and 'Unhealthy/Western') were identified based on food factor loadings published in original studies. Pooled results indicated a 15% lower T2DM risk for those in the highest category of 'Healthy/Prudent' pattern compared with those in the lowest category (95% CI:0.80, 0.91; $P < 0.0001$). Compared with the lowest category of 'Unhealthy/Western' pattern, those in the highest category had a 41% increased risk of T2DM (95% CI: 1.32, 1.52, $P < 0.0001$).

Conclusions: Food intake is an important determinant for T2DM risk independent of other lifestyle factors, including body weight. A DP characterized by increased intake of fruit, vegetables and complex carbohydrate and reduced intake of refined carbohydrate, meat, processed meat and fried foods is likely to reduce the public health burden of T2DM. However, an optimal DP for T2DM prevention is not fully elucidated at this time.

Key words: Dietary pattern, diabetes, meta-analysis.

PO1251**PHYSICAL ACTIVITY IN PRESCHOOL CHILDREN MEASURED WITH ACTIHEART MONITORS**

C. Viera-Casiñol¹, V. Ruiz-Álvarez¹, G. Morea², D. Bustamante², M. Hernández-Triana¹

¹Department of Biochemistry and Physiology, Institute of Nutrition, La Habana, Cuba

²Faculty of Medicine, University La Plata, Argentina

Background and objectives: There are scarce records of physical activity in children of developing countries.

Methods: With this objective, 77 preschoolers (5.9 y of age, 37 girls, 40 boys) were evaluated according to WHO growth standards; total daily energy expenditure (TEE) was measured by Actiheart monitors, each 15 seconds during two week-days and 1 week-end-day, values were weighed for a week, and cleaned with the software of the University La Plata, Argentina.

Results: Boys with similar age and BMI, showed higher TEE values than girls (1489 vs. 1372 kcal/d; $p=0.03$), and also per kg body weight (68, 5 vs. 59; $p=0.04$). As a consequence of the boys' higher BMR (1013 vs. 944 kcal/d, $p=0.014$), the PAL values of boys and girls were low (1, 44 and 1, 45) and not different ($p=0.87$). Normal vs. overweight boys showed higher TEE (72 vs. 57 kcal/kg, $p=0.000005$) in spite of the higher BMR of the overweight ones (1195 vs 957, $p=0.00000$). Overweight boys expended less time than the normal ones in moderate+heavy physical activity (35 vs. 101 min/d, $p=0.011$) and showed lower values of energy expended in physical activity (AEE, 16 vs. 23 kcal/kg/d, $p=0.03$), and similar Physical Activity Level (PAL, 1.40 vs. 1, 47, $p=0.42$); but not girls (58 vs. 94 min/d, $p=0.19$) (AEE, 17.2 vs. 17.9 kcal/kg/d, $p=0.75$) (PAL, 1.49 vs. 1, 38, $p=0.23$).

Conclusions: Cuban preschool children showed all a low physical activity level; half of them did not accomplish the daily physical activity recommendation.

Key words: physical activity, preschool children, accelerometry, heart rate, Actihearts

PO1252**INTERNATIONAL NETWORK FOR FOOD AND OBESITY/NCD RESEARCH, MONITORING AND ACTION SUPPORT: BENCHMARKING FOOD ENVIRONMENTS TOWARDS HEALTHIER DIETS**

S. Vandevijvere¹, G. Sacks², B. Swinburn¹

¹School of Population Health, Department of Epidemiology and Biostatistics, University of Auckland, New Zealand

²World Health Organization Collaborating Centre for Obesity Prevention, Deakin University Melbourne, Australia

Background and objectives: The World Health Organization (WHO)'s monitoring of risk factors for non-communicable diseases (NCDs) does not include 'upstream' monitoring of many aspects of food environments that influence population diets. INFORMAS (International Network for Food and Obesity/NCDs Research, Monitoring and Action Support) is a global network of public-interest organisations and researchers that aims to monitor, benchmark and support public and private sector actions to create healthy food environments and reduce obesity and NCDs. This monitoring of public and private sector policies, and their impacts on the healthiness of food environments, seeks to complement existing WHO monitoring efforts.

Methods: Monitoring areas are divided into process, impact and outcome modules. The two process modules focus on monitoring and benchmarking the policies and actions of the public and private sector. The seven impact modules focus on monitoring and benchmarking the impact of those policies and actions on key aspects of food environments, such as food composition, labelling, promotion, provision, access, availability, affordability, and trade and investment. The three outcome modules focus on monitoring and evaluating changes in behavioural, dietary, physiological and metabolic risk factors, as well as health outcomes. Some aspects of these outcome components are being developed by WHO as part of their global NCD monitoring framework.

Results: The development of protocols and pilot testing is planned for 2013-2015. The monitoring framework will be trialled in large and small, and high- and low-income countries globally. Within five years, it is expected that all countries will be invited to collect their own data and contribute those data to a global database for benchmarking food environments.

Conclusions: Benchmarking data and good practice exemplars will be communicated to policymakers, civil society and the food industry with the aim of stimulating improvements in the healthiness of food environments.

Key words: Food environments, non-communicable diseases, benchmarking.

PO1253**THE INFORMAS FRAMEWORK FOR MONITORING AND BENCHMARKING HEALTHY AND UNHEALTHY FOOD AVAILABILITY IN RETAIL FOOD ENVIRONMENTS**

S. Vandevijvere¹, C. Ni Mhurchu², L. Thornton³, W. Waterlander², B. Kelly⁴, A. Cameron³, B. Swinburn¹

¹School of Population Health, Department of Epidemiology and Biostatistics, University of Auckland, New Zealand

²National Institute for Health and Innovation, University of Auckland, New Zealand

³Deakin University Melbourne, Australia

⁴University of Sydney, Australia

Background and objectives: The International Network for Food and Obesity/NCD Research, Monitoring and Action Support (INFORMAS) is setting benchmarks for creating healthy food environments and reducing obesity and NCDs. One of the INFORMAS modules concentrates on monitoring and benchmarking the availability of healthy and unhealthy foods and non-alcoholic beverages in retail food environments. Certain dimensions of both the community and the consumer food environment are associated with food purchasing behaviour and dietary quality.

Methods: A step-based framework was developed to monitor and benchmark the availability of healthy and unhealthy foods and non-alcoholic beverages in communities and within food outlets. Each country can select an approach based on local resources and capacity available.

Results: Within the 'minimal' approach, density of food outlets in a defined geographic area, and linear shelf space of fresh fruits and vegetables (FV) and energy-dense, nutrient-poor foods (EDNPF) within outlets will be measured. In the 'expanded' approach, density of food outlets within a specified buffer around residents' homes and schools, and both shelf-space and placement (end-of-aisle and check-outs) of all FV and EDNPF within outlets will be measured. In the 'optimal' approach, relative density of healthy and unhealthy food outlets within a specified buffer around residents' homes and schools, presence or absence of food outlets within predefined distances to homes and schools, placement and cumulative shelf space of healthy and unhealthy foods within outlets will be measured. The framework is designed to support monitoring of retail food environments over time and comparison between countries.

Conclusions: Systematic monitoring of healthy and unhealthy food availability in retail food environments and their potential positive and harmful impacts on nutrition is essential for the development of effective policy approaches aimed at reducing the burden of obesity and NCDs.

Key words: Retail food environment, benchmarking, food access, food availability, food placement.

PO1254**EFFECTIVENESS OF COOKING DEMONSTRATION, SMALL ANIMALS AND KITCHEN GARDENS PROMOTION BY COMMUNITY COOPERATIVES ON CHILD NUTRITION, A CASE OF RWANDA**

S. Boltena¹, E. Uwanyiligira², M. Loha³, J. Mugenzi⁴

¹Health and Nutrition Department, World Vision International East Africa Region, Ethiopia

²Health and Nutrition, World Vision Rwanda, Rwanda

³Health and Nutrition Department, World Vision International East Africa Region, Kenya

⁴Health and Nutrition Department, World Vision International East Africa Region, Uganda

Background and objectives: Malnutrition is one of the leading social and developmental problems in Rwanda. The level of malnutrition in the country remained very high stunting level of 44% and underweight prevalence of 11.4%. The government of Rwanda and its partners are committed to reduce the burden of malnutrition in the country and establishment and capacity building of community cooperatives one of the successful approaches. The purpose of this study was to share the WV program impact in reducing the burden of malnutrition in rural communities in Rwanda.

Methods: the assessment was conducted using program and health facilities report review. In addition the key informant interview and focus group discussion were held with key partners working with World Vision and the beneficiaries. The cooperatives deliver key health and nutrition messages and conduct cooking demonstrations and establishment of kitchen garden and small animal production. Primary and secondary data were analyzed manually.

Results: between 2009–2012 the program trained 14, 339 community health workers in 29 World Vision operational areas. These cooperatives weighed 47, 740 children during the growth monitoring and promotion sessions, identified and referred under weight to enroll in to the nutrition program. Among the referred children 27828 were successfully rehabilitated, a graduation rate of as high as 86.5% in some areas, children. Ruhuha health center data showed drop of acutely malnourished children by 70% (1936 – 638) and malnourished pregnant mothers by 75% (553 – 130). In some communities the underweight prevalence has reduced from 46% to 7% in 2011 and as low as 0.3% in 2012. Cooperatives avail vegetables and eggs to the nutrition education sessions.

Conclusions: use of local community health workers organization successfully rehabilitation of malnourished children through availing nutritious foods. Other countries in the region need to learn from this experience.

Key words: community cooperatives, cooking demonstration, rehabilitation.

PO1255**EATING DISORDER CHARACTERISTICS AMONG GERMAN MALE AND FEMALE TRIATHLETES***S. Niessen¹, K. Kohlenberg-Mueller¹, W. Hofmann¹*

¹Department of Nutritional, Food and Consumer Sciences, Hochschule Fulda, University of Applied Sciences, Fulda, Germany

Background and objectives: Triathlon is a popular sport in Germany and the number of memberships in Triathlon Clubs, which belong to the German Triathlon Union, is rising. This sport is known to be associated with lean body mass, but the occurrence of eating disorders in triathlon is unknown. The aim of the present study was to characterize active triathletes and to investigate the occurrence of eating disorders in comparison to the general population.

Methods: All Participants of four selected leisure triathlon events in north-western Germany received an standardized online questionnaire prior to the competition. Inclusion criteria were defined as not more than 20 training hours per week. Data collection included first three scales of the Eating-Disorder-Inventory 2 (EDI-2) as well as the extent of training, anthropometric data and motivation for triathlon.

Results: 284 triathletes (82 women, 202 men) average age 38.5 years (women 36.8 ± 10.4 years; men 39.2 ± 11.1 years) participated in the study. Mean BMI was calculated with 21.6 ± 2.7 kg/m² in women and 24.0 ± 2.3 kg/m² in men. 26.7% of males were overweight, 1.5% obese. Triathletes scored higher on EDI-2-scales than the control group of Thiel et al. (1997). Women scored higher than men, younger than 30 year old participants scored higher than over 30 year old participants.

Conclusions: The present study shows a higher rate of eating disorder characteristics among triathletes. Due to methodical limitations the question, if eating disorders are the motivation for triathlon or if eating disorders are a consequence of triathlon, could not be answered. It is recommended to develop low-threshold intervention programs to promote healthy nutrition in triathlon for primary prevention of eating disorders.

Key words: triathlon, eating disorder, Eating-Disorder-Inventory 2 (EDI-2), BMI, primary prevention.

PO1256**FACTORS AFFECTING THE REHABILITATION OUTCOME OF SEVERELY MALNOURISHED CHILDREN AMONG SEMI-NOMADIC COMMUNITIES IN SOUTHERN ETHIOPIA***Y. Gedefa¹, S. Sinamo²*

¹World Vision Ethiopia, Ethiopia

²World Vision International East Africa Region

Background and objectives: Malnutrition is one of the priority health and developmental challenge in the country. Understanding the underlying causes is important in the design and implementation of both emergency and non-emergency programs. World Vision Ethiopia conducts nutrition survey in its program areas to assess the nutrition situation and understand the need and measure impact of its interventions. The purpose of this study is to assess the factors that affect the rehabilitation outcome of under nutrition children among the semi-nomadic communities in rural Ethiopia.

Methods: a two stage cluster sampling method was employed to conduct the nutrition assessment. 591 children of 6-59 months old from 50 villages were included for anthropometric measurement. Household interviews were also conducted in 250 households and community interviews were also conducted in 50 villages (clusters). The program provided therapeutic interventions. Data was analyzed using the ena /SMART/ and SPSS software.

Results: by the end of its eight months intervention the prevalence of global acute malnutrition (GAM) among the surveyed population reduced from 10.7% (7.8 - 14.6 95% C.I) to 7.1 % (4.8 - 10.4 95% C.I.). The prevalence of severe acute malnutrition (SAM) reduced from 1.0% (0.5 - 2.1 C.I.) 0.3 % (0.1 - 1.4 95% C.I.). According to the key informants the main contributor for this change was relatively improved crop production and livestock performance. The morbidity rate for common childhood infectious diseases (Diarrhea, malaria and ARI), though low and the low coverage vitamin A supplementation remained unchanged during the course of the program.

Conclusions: nutritional interventions contribute to reduce the nutrition status. Future program to consider interventions that addresses common childhood illnesses and improve services such as Vitamin A supplementation and immunization to maximize the impact.

Key words: under nutrition, childhood illnesses, vitamin A supplementation and acute malnutrition.

PO1257

ANTHROPOMETRIC PROFILE AND PREVALENCE OF OVERWEIGHT AND OBESITY IN A POPULATION OF UNIVERSITY STUDENTS

R. Ramírez y Ayala², O. Vera-López¹, P. Aguilar-Alonso², A. Navarro-Cruz¹, R. Avila-Sosa¹, M. Lazcano-Hernández¹, R. Ramírez-Valverde¹, P. Munguía-Villeda¹, R. Dávila-Márquez¹

¹Departamento de Bioquímica-Alimentos, Facultad de Ciencias Químicas, Benemérita Universidad Autónoma de Puebla, México

²Posgrado en Ciencias Químicas, Facultad de Ciencias Químicas, BUAP, México

Background and objectives: Obesity is a major modifiable risk factor for the development of chronic non communicable diseases, such as diabetes mellitus and cardiovascular disease (the two leading causes of death in Mexico). According to the National Survey of Health and Nutrition (ENSANUT 2012), overweight and obesity affect 7 in 10 Mexican adults. The aim of this study was to evaluate the prevalence of overweight and obesity in a population of university students at the Autonomous University of Puebla.

Methods: A study was conducted on 974 students of which 517 (51.7%) were men and 457 (45.7%) women aged between 18 and 25 years old. They were weighed and their height measured. They were given a questionnaire on food frequency, dietary habits and physical activity. The statistical treatment of the data was performed using the computer program R-sigma Babel 2000. The Student t test was used to compare the distribution between sexes for quantitative parameters such as weight, height and body mass index (BMI).

Results: We found an average weight of 67.97 ± 12.42 Kg, an average BMI of 24.29 ± 2.95 kg/m² significantly lower ($p < 0.001$) in women. The percentage of underweight students was 1.54%, the normal weight of 60.37%, the 34.91% of overweight and obese 3.18%, with no difference by gender. The frequency of fast food consumption increased with increasing BMI, from a daily intake of 6.67% to 9.68%. 84% of students usually have breakfast while the rest do not

Conclusions: Only five out of ten adult undergraduate students at the Autonomous University of Puebla had adequate nutritional status, this is a smaller proportion than reported in ENSANUT 2012; however, the data provided by the national survey covered an older group.

Key words: Nutritional status, BMI, obesity.

PO1258

STUDENT WELLNESS AND ADVOCACY PROJECT: ENGAGING YOUNG MINDS

S. McWhinney¹, A. McDonald², C. Outley², E. McKyer²

¹Prairie View A&M University, Texas, USA

²Texas A&M University, Texas, USA

Background and objectives: Obesity has been identified as one of the ten leading health indicators resulting in the call for action to reduce the number of children in this category. Childhood obesity continues to be a growing concern in all segments of the population regardless of ethnicity, income, and location. Recent report has indicated that the overall population increase in obesity has slowed, however, monitoring and intervention is still warranted. To aid in the continued fight against childhood obesity, a culturally tailored school based nutrition and physical activity intervention project was implemented in six rural low income middle schools in a southeast Texas County.

Methods: The design and development of the curriculum administered was guided by the contextual data analyses from pre-administered focus groups and structured interviews that were completed within the selected population. The school based intervention was conducted among 4th grade students over a period of 9 months, and included 298 children between the ages of 9 and 10 years old. At the culmination of the intervention period, children were selected from each school to participate in focus group sessions to evaluate the program effectiveness. Forty three percent of the children who participated in the intervention represented minority groups and over 60% were from homes with less than \$30,000 annual income. Qualitative data were analyzed using Atlas ti.

Results: indicated that a majority of the participants retained the knowledge imparted during the intervention. Children were able to convey relevant nutrition information to their parents at home and even while food shopping.

Conclusions: Overall the children demonstrated improved nutrition knowledge, skills, and understanding. They were more physically active but indications suggested no change in afterschool television viewing and video game activities. Funding was made possible by Grant # 1P20MD0002295 from the National Center on Minority Health and Health Disparities obesity nutrition children physical activity.

Key words: Young, wellness, nutrition.

PO1259**ACUTE RESPIRATORY INFECTIONS IN CHILDREN LIVING IN HIV-AFFECTED COMMUNITIES IN GHANA**

³Department of Nutrition and Food Science, University of Ghana, Legon, Ghana

⁴Nutrition Department, Noguchi Memorial Institute for Medical Research, Legon, Ghana

⁵School of Public Health, Yale University, New Haven, Connecticut, USA

Background and objectives: Acute respiratory infections (ARI) remain one of the leading causes of morbidity. They account for 17% of deaths in children under the age of five years. We examined the incidence and days ill with ARI among infants of women of different HIV status: HIV positive (HIV-P), HIV negative (HIV-N) and unknown HIV status (HIV-U).

Methods: Pregnant women (n=492) were recruited from three antenatal clinics in Ghana and their infants were followed from birth to 1 year of age. Data on ARI (presence of cough or difficulty in breathing, with or without fever) was collected weekly.

Results: Incidence of ARI was 0.81 ± 0.03 episodes/100-d at risk. Overall total days ill with ARI was 7.52 ± 0.37 days ill/100-d observed. There was no difference in both incidence (HIV-P 0.86 ± 0.07 episodes/100-d at risk, HIV-N 0.77 ± 0.05 episodes/100-d at risk, HIV-U 0.83 ± 0.06 episodes/100-d at risk, $P=0.807$) and total days ill with ARI (HIV-P 7.06 ± 0.67 days ill/100-d observed, HIV-N 7.29 ± 0.60 days ill/100-d observed, HIV-U 8.20 ± 0.66 days ill/100-d observed, $P=0.189$) by maternal HIV status.

Conclusions: Interventions to reduce morbidities from acute respiratory infections in HIV-affected communities should focus on all children, irrespective of their mother's HIV-status.

Key words: Acute Respiratory Infections, HIV, Ghana.

PO1261**MALNUTRITION AND ITS RISK FACTORS AMONG PERSONS WITH DISABILITIES IN MALAYSIA**

S T. Chen¹, K L. Soo², A R. Azriani³, H. Van Rostenberghe⁴, H. Sakinah¹

¹Dietetics Program, School of Health Sciences, Universiti Sains Malaysia, Kelantan, Malaysia

²Nutrition Program, School of Health Sciences, Universiti Sains Malaysia, Kelantan, Malaysia

³Department of Community Medicine, School of Medical Sciences, Universiti Sains Malaysia, Kelantan, Malaysia

⁴Department of Pediatrics, School of Medical Sciences, University Sains Malaysia, Kelantan, Malaysia

Background and objectives: Population with disabilities are susceptible to malnutrition and limited data has been documented especially for those with low socio-economic background. A cross-sectional study was conducted to assess the nutritional status of persons with disabilities (PWD) in Kelantan, Malaysia; and to identify the malnutrition risk factors.

Methods: There were 462 PWD (276 children and adolescents; 186 adults) recruited from rehabilitation centres in 2010. Socio-demographic and food intake information was obtained from their primary caregivers. Body weight and height of PWD were measured.

Results: The prevalence of malnutrition, as indicated by BMI-for-age for children and adolescents and BMI categories for adults, demonstrated 20.3% were underweight while 22.7% were overweight and obese. Nutrition screening checklist documented 7.5% of respondents required others assistance for feeding; 14.7% needed food texture modification; 8.8% had difficulty in chewing; 9.3% suffered from choking; 15.3% had drooling; 66.6% had dental problems; 13.5% had food allergy; 16.0% had constipation; and 22.7% with food choosy problems. Among the socio-demographic parameters, multiple linear regression analyses demonstrated that birth weight ($R=1.14$), ability to ambulate by own self ($R=3.51$) and primary caregivers' years of education ($R=0.30$) were significantly associated with BMI of the children and adolescents; while birth weight ($R=2.27$), household size ($R=0.70$) and monthly household income ($R=0.01$) were the significant socio-demographic determinants for the adults. For the food intake characteristics, analyses showed that ability of self feeding ($R=3.57$), eating duration ($R=0.07$), having drooling ($R=2.83$) and dental problems ($R=2.22$) were significantly associated with BMI of the children and adolescents; while difficulty in chewing ($R=12.29$) and the need for food texture modification ($R=7.43$) were the significant risk factors among the adults.

Conclusions: The dual burden of malnutrition was noticeable. Identification of its risk factors may help in public health nutrition effort in overcoming this problem.

Key words: body mass index, disabilities, malnutrition.

PO1262**DISORDERED EATING, PHYSICAL ACTIVITY, BODY WEIGHT STATUS AND SELF-ESTEEM AMONG FEMALE COLLEGE STUDENTS IN MALAYSIA***K.L. Soo¹, A.S. Mohamad¹*¹Nutrition Program, School of Health Sciences, Universiti Sains Malaysia, Kelantan, Malaysia

Background and objectives: Studies regarding disordered eating indicate that the prevalence of disordered eating is increasing from time to time across the world and female college students are regarded as one of the high risk group exposed to this problem. Hence, this cross-sectional study aimed to determine the prevalence of disordered eating and its relationship with physical activity, body weight status and self-esteem.

Methods: The Eating Attitudes Test-26 (EAT-26), the Rosenberg Self-Esteem Scale (RSES) and the International Physical Activity Questionnaire (IPAQ) were administered on 262 female college students aged 18 to 24 years to assess disordered eating, self-esteem and physical activity, respectively. The respondents were recruited from one nursing college and one public university in the Eastern region of Peninsular Malaysia.

Results: Most of the respondents were Malay (76.8%), followed by Chinese (16.6%), Indian (5.4%) and other ethnicity (1.2%). Based on the Asian cut-off point for Body Mass Index (BMI) classification, the prevalence of overweight (27.9%) and underweight (22.5%) respondents was quite close. There was 14.9% respondents at-risk of eating disorders. Mann-Whitney U Test showed no significant different between disordered eating group and normal eating group in terms of their physical activity, self-esteem and body weight status. However, Spearman correlation showed there was significant relationship between disordered eating and physical activity ($r_s = 0.233$, $p < 0.01$), as well as BMI ($r_s = 0.238$, $p < 0.01$).

Conclusions: higher BMI or physical activity level is linked to disordered eating. Colleges and universities can become great setting for promoting healthy eating habit. Future studies are needed to create health-promotion strategies that best suit the needs of college students as well as those young adults who not enrolled in tertiary institutions.

Key words: EAT-26, disordered eating, physical activity, college students

PO1263**ASSESSMENT OF FOOD SECURITY STATUS AMONG RURAL AND URBAN HOUSEHOLDS IN KUCHING DISTRICT, SARAWAK, MALAYSIA***M.A.B. Wan Azdie¹, M.R. Ainnalina¹*¹Department of Nutrition Sciences, Kulliyyah of Allied Health Sciences, International Islamic University Malaysia, Kuantan, Pahang, Malaysia

Background and objectives: Food security can be defined as the availability of and accessibility to food, acquired in an acceptable means at any given time and place in a way that could maintain health and wellbeing. Research on food security in Malaysia is still in its infancy stage, and the extent of food security situation in Sarawak, a part of Borneo Island, remains unexplored.

Methods: This cross-sectional study aimed to measure the prevalence of food insecurity and to examine the associations between food security status with demography, socioeconomic factors and coping strategies. A total of 127 mothers from low income households in Padawan and Petra Jaya areas in Kuching District, Sarawak were interviewed. Structured questionnaire was used to collect the data and information. The Radimer/Cornell Hunger and Food Insecurity measures were used to assess food security status.

Results: The information gathered from this study indicated that majority of households in this study were food insecure. The results show that 75% of the respondents interviewed were experiencing household food insecurity, whereas 58.3% having individual food insecurity and 48.8% with child hunger. Higher prevalence of household food insecurity was observed in the urban area. Meanwhile, individual food insecurity and child hunger were more prominent in the rural area. From the variables available in this study, household income, income per capita and coping strategies showed a significant associations with food security status ($p < 0.05$). **Conclusions:** The findings suggest that food insecurity among household in this study were primarily a direct result of inadequate income to buy sufficient foods for the household members. This further suggests why more households were found to rely on non-food related coping strategies in order to acquire enough foods to feed their family.

Key words: food security, hunger, Malaysia.

PO1264**ETHNIC DIFFERENCES IN ASSOCIATION BETWEEN SERUM VITAMIN D AND PARATHYROID HORMONE CONCENTRATIONS: THE 2008/09 NEW ZEALAND ADULT NUTRITION SURVEY**

C. Skeaff¹, R. Brown¹, S. Williams¹, W. Parnell¹

¹University of Otago, Dunedin, New Zealand

Background and objectives: Suppression of serum parathyroid hormone (PTH) concentration is a potential indicator of vitamin D requirement. Evidence shows that the decline in serum PTH in Black Americans is sharper and occurs at lower concentrations of serum 25-hydroxyvitamin D than in White Americans. Our purpose was to examine and compare the relation between serum PTH and 25OHD in three different New Zealand ethnic groups, Maori, Pacific People, and New Zealand European and Others (NZE0). Skin colour tends to be darkest in Pacific and lightest in NZEO.

Methods: Serum 25OHD and PTH were measured in 2960 individuals, 15 y or over, participating in the 2008/09 New Zealand Adult Nutrition Survey; 548 Maori, 342 Pacific, and 2070 NZEO. Survey regression analysis adjusting for age, sex, BMI, latitude, ethnicity, and date of blood sampling was used to determine the change in serum PTH concentration per 10 nmol/L increase in serum 25OHD.

Results: In participants with serum 25OHD less than 50 nmol/L, the decrease in serum PTH per 10 nmol/L increase in serum 25OHD was significantly greater in Pacific than in NZEO – ratio of decreases between Pacific and NZEO was 1.16 (95%CI, 1.03 to 1.29; P=0.012). In participants with serum 25OHD 50 nmol/L or higher, the decrease in serum PTH per 10 nmol/L increase in serum 25OHD was not significantly different between Pacific and NZEO – ratio of decreases was 0.98 (95%CI, 0.92 to 1.04; P=0.515). Thus, the decrease in serum PTH per incremental increase in serum 25OHD was significantly greater in Pacific than in NZEO only when serum 25OHD was below 50 nmol/L (P=0.011 for interaction).

Conclusions: These results suggest that maximal suppression of serum PTH occurs at lower serum 25OHD concentrations in Pacific than in NZEO.

Key words: parathyroid hormone, vitamin D requirement, national survey, ethnicity.

PO1265**ASSOCIATIONS OF MATERNAL FOLATE STATUS WITH BIRTH OUTCOMES IN AN ASIAN POPULATION: GROWING UP IN SINGAPORE TOWARDS HEALTHY OUTCOMES (GUSTO)**

L W. Chen¹, M F F. Chong², A. Tan³, Y S. Chong⁰, P. Gluckman³, K. Godfrey⁶, K. Kwek⁷, S M. Saw¹, F. Yap⁷, Y S. Lee^{5,8}, R. van Dam^{1,9}

⁵National University Health System, Singapore

⁶Medical Research Council Lifecourse Epidemiology Unit and NIHR Southampton Biomedical Research Centre, University of Southampton and University Hospital Southampton NHS Foundation Trust, Southampton, UK

⁷KK Women's and Children's Hospital, Singapore

⁸Department of Paediatrics, Yong Loo Lin School of Medicine, National University of Singapore, Singapore

⁹Department of Medicine, Yong Loo Lin School of Medicine, National University of Singapore, Singapore

Background and objectives: Insufficient maternal folate intakes have been associated with adverse birth outcomes, but the evidence is inconclusive. We aimed to further elucidate these associations in an Asian population.

Methods: The GUSTO birth cohort study comprises participants (n=1152) with a mean age of 30.4 years (SD 5.2) and ethnic composition of 54.3% Chinese, 27.3% Malay, and 18.3% Indian women. Maternal blood samples (n=999) collected during 26th-28th week gestation were assayed for plasma folate concentrations. Relationships between folate concentrations with preterm birth and neonatal anthropometry were assessed using logistic and linear regression respectively, with adjustment for important confounders.

Results: Deficient or marginal folate status (<6ng/mL) was observed in 6.1% of Chinese, 19.9% of Malay, and 13.4% of Indian women in this cohort. Higher plasma folate concentrations were associated with lower risk of preterm birth [OR=0.74 per SD increase of folate; 95% confidence interval (CI) = 0.58, 0.93] and longer gestational duration (β =0.13 week, 95% CI= 0.02,

0.24). Similar trends were observed in analyses stratified by ethnicity (P-values for interaction >0.05). In univariate analysis, higher folate concentrations were associated with greater birth weight ($\beta=28.3$ g, 95% CI= 0.58, 56.0) and birth length ($\beta=0.21$ cm, 95% CI= 0.08, 0.34), but these associations were no longer apparent after adjustment for gestational duration (birth weight), infant gender, maternal age and ethnicity (birth length). Folate concentrations were not associated with neonatal head, mid-upper arm and abdominal circumferences or with neonatal triceps and subscapular skinfold thickness. Similar findings were observed when folate was modeled based on clinical cut-offs.

Conclusions: Higher maternal folate concentrations were associated with a lower risk of preterm birth, but were not independently associated with birth weight and length. The current results suggest that adequate folate intake during pregnancy remains a concern even in this high-income Asian population.

Key words: Maternal, Folate, Birth outcomes.

PO1266

KNOWLEDGE, ATTITUDES AND PRACTICES ON FOLIC ACID SUPPLEMENTATION AMONG PREGNANT MOTHERS IN A SRI LANKAN SETTING

A. Wickramasinghe¹, U. Senarath²

¹Office of The Medical Officer of Health - Mahara, Kadawatha, Sri Lanka

²Department of Community Medicine, Faculty of Medicine, University of Colombo, Colombo, Sri Lanka

Background and objectives: Folic acid supplementation programme is in existence in Sri Lanka to prevent neural tube defects of fetuses and anaemia of women in childbearing age. The programme is implemented through Public Health Midwives (PHMM). After several years of implementing the programme the country is still lacking reliable data on its progress and outcome. Objective of this study was to describe knowledge, attitudes and practices on folic acid supplementation and associated factors among pregnant mothers.

Methods: A descriptive cross-sectional study was carried out in a health unit in Sri Lanka in 2011. Data were collected from a systematic random sample of 524 pregnant mothers through an interviewer administered questionnaire representing all the antenatal clinics of the health unit.

Results: Awareness of folic acid was 96.4% (n=505). Though the majority (81.9%, n=429) have received knowledge on folic acid from PHMM, overall knowledge on folic acid was 'poor' in 84.9% (n=445). Ninety-six percent (n=503) have used folic acid at any stage of pregnancy, but only 46% (n=241) have used it before conception. Among the mothers who used folic acid

before conception, majority (88%, n=212) have bought it from a private pharmacy. Poor knowledge was associated with lower age, belonging to an ethnicity other than Sinhalese, living in urban or estates and low education. A lower rate of utilization of folic acid before and during pregnancy was associated with low education, unplanned pregnancies and not receiving advice from healthcare workers. Parity 2nd or higher, belonging to an ethnicity other than Sinhalese and living in estates were also predictors of poor preconceptional folic acid use.

Conclusions: Planned health promotion campaigns, preventing unplanned and teenage pregnancies, distributing folic acid through government clinics during preconceptional period and developing monitoring systems for folic acid supplementation programme are recommended.

Key words: Folic acid, pregnancy, preconception, Sri Lanka.

PO1267

IMPROVEMENT OF PHYSICAL FUNCTIONS AND NUTRITIONAL STATUS IN ELDERLY PERSONS BY LONG-TERM TRAINING FOR PREVENTIVE CARE

N. Hirano¹, N. Nishioka², N. Tanaka³, A. Kaizaki³, M. Nakamura⁴

¹Department of Food and Nutritional Science, Kobe Women's Junior College, Kobe, Hyogo, Japan

²Kobe International Cooking and Pastry College, Kobe, Hyogo, Japan

³Graduate School of Life Sciences, Kobe Women's University, Kobe, Hyogo, Japan

⁴Kansai College of Health Sciences, Ashiya, Hyogo, Japan

Background and objectives: We have examined changes in physical function and also the correlation between physical function or mastication ability, or comprehensive QOL and nutritional status, in elderly who received long-term training for preventive care.

Methods: Forty elderly aged 65 years or older who have been trained at our fitness club (RTG). Sixteen elderly in RTG who were able to participate in a 3-year exercise evaluation have been examined the efficacy of our training program on physical ability. The items of physical fitness tests were divided into ten items including the knee extension strength and one-leg standing time with eyes open. The average nutrient intake of energy was calculated by using a meal questionnaire for diet content of 3 days prepared to participants. The masticatory performance was evaluated by using color-chewing gum. The assessment of QOL was performed by using SF-8TM questionnaire.

Results: The knee extension strength and one-leg standing time with eyes open were significantly increased following the

training. We recognized a significant positive correlation between the masticatory performance and knee extension strength, and between the masticatory performance and average nutrient intake of energy for 3 days. Furthermore, there were significant negative correlations between their initial values and changes resulting from training. In addition, there was a significant positive correlation mental component summary score in the SF-8TM questionnaire and BMI in the elderly received the long-term training.

Conclusions: These results of this study demonstrate that our long-term training was effective for improving physical ability and maintaining the masticatory performance and good nutrient status in the elderly. It is suggested that long-term training would be useful for preventive care in elderly persons, especially those with lower physical function. Furthermore, it was clear that good mastication led to better physical function and comprehensive QOL.

Key words: elderly, long-term training, physical function, nutrition, mastication.

PO1268

PREVALENCE AND FACTORS ASSOCIATED WITH ANEMIA IN THAI ELDERLY

⁵Epidemiology Unit, Faculty of Medicine, Prince of Songkla University, Songkhla, Thailand

⁶National Health Examination Survey Office, Health System Research Institute, Nonthaburi, Thailand

⁷College of Public Health Sciences, Chulalongkorn University, Bangkok, Thailand

Background and objectives: Anemia is an important health problem in elderly people but it is mostly overlooked. This study aimed to study the prevalence and factors associated with anemia in Thai elderly.

Methods: Data from the multistage cross-sectional National Health Examination Survey (NHES) IV of Thai older adults aged 60 years and higher conducted in 2009 were used. There were 22,847 which had blood test results and other selected factors assessed by interviewed using standard tools. Anemia was defined due to the World Health Organization criteria as hemoglobin levels below 12g/dL in women and below 13 g/dL in men.

Results: The prevalence of anemia in Thai elderly was 40.3% in overall, 34.5%, 48.4%, and 60.7% in the group of 60-69, 70-79, and >80 years old, respectively. Multiple logistic regression analysis showed that people with older age, female, depression, having care giver, poverty, chronic kidney disease are more likely to have anemia than those without these conditions, significantly. Herbal used elderly are less likely to have anemia.

Conclusions: Due to high prevalence of anemia in Thai elderly, it is a significant severe public health problem. Health team should keep in mind and properly manage in old and very old persons and all who had the risk factors.

Key words: Elderly, anaemia, nutrition, NHED.

PO1270

GENDER DIFFERENCES IN FOLATE STATUS OF AN ADULT POPULATION IN GHANA

M. Asante¹, M. Pufulete², J. Thomas², E. Wiredu³.

¹Department of Dietetics, School of Allied Health Sciences, University of Ghana, Accra, Ghana

²Nutritional Science Division, Kings College London, UK

³Department of Pathology, University of Ghana Medical School, Accra, Ghana

Background and objectives: Folate deficiency has been associated with neural tube defects, certain cancers and vascular disease. Low concentrations of folate have been associated with elevations in plasma homocysteine. We conducted a cross-sectional study to compare blood folate and homocysteine concentrations in men and women living in a coastal area in Ghana.

Methods: A total of 140 healthy individuals (men - 86; women -74) participated in this study. Subjects in this study were part of a larger study to compare folate status of a first generation migrant Ghanaian population in the UK with an urban population in Accra. Anthropometric measurements were taken and dietary intakes were determined using three 24 hour recalls. Blood samples were collected for determination of serum and erythrocyte folate concentrations and the methylenetetrahydrofolate reductase (MTHFR) 677C ? T polymorphism.

Results: Results showed that serum and erythrocyte folate were significantly lower in men compared to women ($p < 0.05$).

This was accompanied by significantly higher homocysteine concentrations in males ($p < 0.001$). There was no significant difference in folate intakes between gender ($p > 0.05$) however, folic acid supplement use was significantly higher in females than males (18.9% vs. 5.8%, $p < 0.001$). A significant association was found between dietary folate and erythrocyte folate ($p < 0.01$). Male sex was the main predictor of plasma homocysteine concentrations in this population ($p < 0.001$).

Conclusions: Findings of this study suggest that women living in a coastal area in Ghana have improved biomarkers of folate, although there were no differences in dietary folate intakes between gender. Intervention programmes to improve folate status of men in this population are needed.

Key words: folate status, homocysteine, Ghana.

PO1271

EFFICACY OF A SHORT INTERVENTION PROGRAM TO IMPROVE FRUIT AND VEGETABLE ACCEPTANCE AMONG CHILDREN

V.M. Rodríguez¹, A. Elbusto¹, J.R. Mauleón², I. Etaio³, O. Martínez⁴, A. Perales¹, G. Aizpuru¹, L. Cassetti¹, F.J. Pérez-Elortondo³, F. Gómez⁵, M.P. Portillo¹

¹Nutrition & Obesity Group, University of the Basque Country UPV/EHU, CIBEROBn Physiopathology of Obesity and Nutrition, Vitoria-Gasteiz, Spain

²Sociology II, University of the Basque Country UPV/EHU, Vitoria-Gasteiz, Spain

³Sensory Analysis Laboratory (LASEHU), University of the Basque Country UPV/EHU, Vitoria-Gasteiz, Spain

⁴Food Sciences, University of the Basque Country UPV/EHU, Vitoria-Gasteiz, Spain

⁵Department of Environment and Public Area, Vitoria-Gasteiz City Council, Vitoria-Gasteiz, Spain

Background and objectives: Eating habits, which are determinant for health, are established during childhood. 80% of children from Vitoria-Gasteiz do not eat enough vegetables and 60% don't eat enough fruit. Effective intervention programs are needed to improve these foodstuffs eating. The objective of the present work was to improve fruit and vegetable (FV) acceptance among children aged 6-12 years from Vitoria-Gasteiz City.

Methods: A short intervention program, was carried out in the municipal market. The program which consisted in three workshops (nutritional, dietetic, sensorial and culinary aspects of FV), allows us to work on food choice determinants: motivation (nutritional and dietetic knowledge), abilities (dietetic, culinary, sensorial), opportunity (environment), reward (salad,

fruit) and models (teachers, parents). After the workshops, children visited the greengrocer's and were given a piece of fruit for the next day breakfast. Instructions were given to parents and teachers for the positive reinforcement. Questionnaires were used to evaluate the process, the program impact on FV choice determinants and intention to consume FV.

Results: 914 children participated in the program. 51% and 54% acquired nutritional and dietetic knowledge respectively. 22%, 23% and 40% acquired culinary, sensorial and dietetic abilities. After the program, 77% showed intention to eat more fruit (18% even new and unknown fruits) and 60% to eat more vegetables. 43% ate the fruit in the next day breakfast (38% ate it before). 74% of parents found that their children were more interested in eating more FV.

Conclusions: The program has positive effects on acceptance of fruit and vegetables. Motivation or knowledge is easier to change than abilities. Promoting the consumption of vegetables is more difficult than promoting the consumption of fruit.

Key words: children, eating habits, food choice determinants, fruit and vegetable intake Research funded by University of the Basque Country UPV/EHU and Vitoria-Gasteiz City Council.

PO1272

PHYSICAL ACTIVITY LEVEL OF HEALTHY ADULT WOMEN IN VALLADOLID (SPAIN)

M.J. Cao^{1, 2}, M.J. Castro^{1, 2}, E. Quinto¹, J.M. Jimenez², V. Niño², A. Mayo³

¹Instituto Endocrinología Y Nutrición (IENVA) Universidad de Valladolid, Spain

²Departamento Enfermería, Universidad Valladolid, Spain

³Departamento Estadística, Universidad de Valladolid, Spain

Background and objectives: Both a balanced diet and a regular physical activity are important to promote and maintain health (European Public Health Commission, 2007). That is important for women because there are biological factors related to health explained from a gender (masculine) point of view (Rohlf's 2000). Adult women should be considered as a vulnerable group, and must be analyzed specifically to be reoriented towards healthier habits.

Key words: Physical activity, women, health. To study the physical activity during both working hours and leisure time of women between 40 and 60 years old in the city of Valladolid (Spain).

Methods: A sample of 500 women was selected through random sampling. They were asked to fill the Global Physical

Activity Questionnaire (WHO 2008) which includes activity in work and leisure.

Results: Activity at work: Light: 32.4%. Moderate: 56.5%. Heavy: 6.4%. Not listed: 4.0%. Activity during leisure time: Light: 63.2%. Moderate: 28.0%. Heavy: 5.8%. Not listed: 4.0%. Classification of Physical Activity: SEDENTARY: 0.8%. LIGHT: 64.2%. MODERATE: 29.0%. HIGH: 1.6%.

Conclusions: Women physical activity can be classified as "light" in most cases. It would be necessary to implement actions to promote its increase, especially during leisure time with moderate activities such as walking or swimming. Those activities will help in improving the health of women.

Key words: physical activity, adults, women, health.

PO1273

EXCESSIVE RED AND PROCESSED MEAT CONSUMPTION IN SÃO PAULO, BRAZIL: DIET QUALITY AND ENVIRONMENTAL IMPACT

A. Carvalho¹, S. Selem¹, A. Mendes¹, J. Pereira¹, R. Fisberg¹, D. Marchioni¹

¹Department of Nutrition, Faculdade de Saúde Pública, Universidade de São Paulo, São Paulo, São Paulo, Brazil

Background and objectives: Red and processed meat consumption has been negatively associated with diet quality in some countries. Furthermore, livestock production has been linked to negative environmental impacts, like greenhouse gases emission. The aim of the present study was to evaluate red and processed meat consumption and also to assess the impact of this consumption on the diet quality and on the environment in São Paulo, Brazil.

Methods: A cross-sectional population-based survey among a representative sample (n=1677) of adults and elderly people living in São Paulo, Brazil, was conducted in 2003. Diet was assessed by Multiple Source Method, using two 24-hour dietary recalls. The recommendation of 500g/week of red and processed meat consumption was considered excessive consumption. To investigate the relationship between meat consumption and diet quality we used the Brazilian Healthy Eating Index Revised. The environmental impact was analyzed according to estimates of CO₂ equivalents emission from meat production (production of 1kg of Brazilian beef generates about 44 kg of CO₂ equivalents).

Results: The mean of red and processed meat intake was 110g/day (138g/day for men and 81g/day for women) and about 70% of population consumed more red and processed meat than what is recommended. Diet quality was inversely associated with excessive red and processed meat consumption in men. The greenhouse gases emission from meat consumption

in São Paulo, in 2003, were estimated at approximately 18,071,988 tons of CO₂ equivalents, representing about 5% of total CO₂ emitted by agriculture in Brazil in 2003.

Conclusions: The excessive red and processed meat consumption, associated with poorer diet quality and important environmental impact observed, support initiatives and policies to advise to reduce red and processed meat consumption within the recommended amounts, as part of a healthy and environmentally sustainable diet.

Key-words: red and processed meat; food intake; diet quality; environmental impact.

PO1274

NUTRITION OF CHILDREN WITH NEUROLOGICAL DISORDERS AND MENTAL RETARDATION FROM SOCIAL ESTABLISHMENTS IN BULGARIA

V. Duleva¹, L. Rangelova¹, S. Petrova¹, E. Chikova-Ischerner¹

¹Department Food and Nutrition, National Centre of Public Health and Analyses, Sofia, Bulgaria

Background and objectives: Children with neurological disorders and mental retardation are at risk for nutrition and nutritional status. The most common deficits in these children are reduced average daily intake of energy and nutrients: protein, vitamins (vitamin D, vitamin B12, folate) and minerals (calcium, copper, phosphorus, magnesium, zinc). The aim of the study is to assess the food offered in social establishments in Bulgaria.

Methods: In November 2010, the survey on nutrition of children aged of 3 to 19 years old with neurological disorders and mental retardation from 12 social establishments in Bulgaria was carried out. The weekly menu and corresponding food balance sheet from 4 seasons were analyzed. The results were compared with Reference Values for Energy and Nutrients Intake for healthy children with moderate physical activity.

Results: The main results reveal that the average daily Intake from offered food for - Energy, Vitamin B1, Folate, Vitamin D, Iron, Magnesium, Zinc and Calcium are under the recommendation for the children from two studied groups (3-7 and 7-19 years old) and Sodium is over the recommended levels. In the weekly menu the wholegrain products, milk and milk products, fruit and vegetables, meat and fish are insufficient and unbalanced presented. There are increased risk for deficiency of main nutrients and impaired nutritional status of children.

Conclusions: The results are basis for methodical guideline material and recommendations for improving nutrition of children with neurological disabilities and mental retardation from social establishments in Bulgaria.

Key words: children with neurological disorders, children with mental retardation, nutrition, requirements.

PO1275

“SALT REDUCTION IS HEALTHY, BUT MY INTAKE IS FINE” INTERNATIONAL RESEARCH REVEALS BARRIERS FOR PROGRESS IN SALT REDUCTION.

R. Newson¹, I. Elmadfa², G. Biro³, Y. Cheng⁴, V. Prakash⁵, P. Rust⁶, M. Barna³, R. Lion¹, G. Meijer¹, N. Neufingerl¹, I. Szabolcs³, R. van Zweden¹, Y. Yang⁷, G. Feunekes¹

¹Department of Research & Development, Unilever, The Netherlands

²Institute of Nutritional Sciences, University of Vienna, Vienna, Austria

³Faculty of Health Sciences, Semmelweis University, Hungary

⁴Nutrition Sciences Group, Chinese Nutrition Society, China

⁵Council of Scientific & Industrial Research (CSIR), JSS Institution, India

⁶Department of Nutrition Sciences, University of Vienna, Vienna, Austria

⁷National Institute of Nutrition and Food Safety, Chinese Center for Disease Control and Prevention, China

Background and objectives: Salt reduction is important for reducing hypertension and risk of cardiovascular events, nevertheless worldwide salt intakes are consistently higher than recommendations. Consequently strategies to reduce intake are required, however effective strategies require an understanding of salt intake behaviours, and limited information is available on this. As such, a multinational study was conducted to derive knowledge on salt intake and salt reduction characteristics and behaviours in the general population.

Methods: Participants, aged 18–65 years, were recruited from Germany, Austria, Hungary, India, China, South Africa, and Brazil (n=5, 987: stratified by age-group and gender). Information was collected on: salt intake and openness to change, perceptions of intake and key sources of salt, knowledge of intake recommendations, beliefs and attitudes towards salt reduction, responsibility and communication preferences.

Results: While salt reduction was seen as important and healthy, over one third of participants were not interested in salt reduction and the majority were unaware of recommendations. Salt intake was largely underestimated, and there was a lack of awareness of the sources of dietary salt. Across all countries participants saw themselves as the main person responsible for their salt intake, but also acknowledged the role

of a variety of key players. In order to improve salt reduction participants wanted to learn more about why salt was bad for health, and what the main sources in the diet were.

Conclusions: Strategies to reduce salt intake need to raise interest in engaging in salt reduction – through improving awareness, and increasing understanding of levels of intake and sources of salt in the diet. Similarities and differences were noted between the countries, indicating that while some aspects of salt reduction can be globally implemented, local tailoring is required to match the stage of salt reduction that the population is in.

Key words: salt reduction, cardiovascular disease, behaviour.

PO1276

DELPHI METHOD TO IDENTIFY EDUCATIONAL MATERIALS ON HEALTHY FOOD FOR TEACHERS, SCHOOL-AGE CHILDREN AND THEIR PARENTS.

F. Vio¹, L. Lera¹, J. Salinas¹, A. Fuentes-García²

¹Institute of Nutrition and Food Technology (INTA), University of Chile, Chile

²School of Public Health, University of Chile, Chile

Background and objectives: Delphi method applied to get expert consensus about healthy food topics to include in educational materials for preschool and school-age children, their parents and teachers is described.

Methods: The questionnaire was developed with the results of surveys and focus groups in children, parents and teachers made previously in a research project. The questionnaire was mailed to 54 experts in nutrition, education and communication in a first round. The results were analyzed and forwarded in a second round with the subjects without consensus with 38 responses.

Results: The cycle was completed by a validation conducted through a questionnaire with two groups of teachers and two groups of parents (total 20 parents and 23 teachers). Results prioritized audiovisual educational materials on the writings, favoring participatory activities such as cooking workshops, games, activities over the passive, such as information at parent meetings, delivery of educational materials and conferences of experts. There was consensus on education in health behaviors such as not giving them money to carry to school for buying non healthy snacks, make healthy food choices on family outings and recreational activities associated with healthy eating during weekends; prefer healthy food prepared at home instead of the processed food; restrict eating out candy and prefer family meals without watching TV and food instead of taking a snack in the evening.

Conclusions: These results are critical to design educational materials on healthy eating plans to change current eating

habits that are contributing significantly to increase childhood obesity. Acknowledgements: This study was funded by FONDECYT project N° 1110044.

Key words: Delphi method, healthy eating, nutrition education, eating habits.

PO1277

CONSUMPTION OF MACRO AND MICRONUTRIENTS IN CHILDREN BETWEEN 6 AND 23 MONTHS OF AGE IN THE HIGHLANDS OF PERU

A. Vargas¹, H. Torres¹, N. Zavaleta², G. Respicio²

¹Technical Department, Action Against Hunger Spain, Lima, Perú

²Instituto de Investigación Nutricional, Lima, Peru

Background and objectives: The period of infant growth between 6 and 23 months is critical in developing countries, with high prevalence of chronic malnutrition and iron deficiency anaemia. Investigations on food consumption in the Andean region are not common despite their importance for food and nutrition policy formation. This study examines the extent to which macro and micronutrient consumption levels compare with standard requirements in the province of Vilcasuaman, Ayacucho, in Peru.

Methods: The study is descriptive, using a random subsample of 50 conglomerates (one child per conglomerate), which belong to a multistage stratified probabilistic sample, by conglomerate, with a level of confidence of 95% and 5.08% maximum error. A food consumption survey was applied, combining the 24 hour recall method and direct weighing of food portions, from January to March, with mothers as informants.

Results: 3 age groups are presented, from 6 to 8, from 9 to 11 and from 12 to 23 months of age, and intake from complementary foods is considered. Average calorie consumption was 186 Kcal/day; 310 Kcal/day, and 517 Kcal/day respectively, and that of protein was 5.54 g/day; 9.2 g/day and 15.1g/day respectively. Average iron consumption was 1.8 g/day, 2.6 g/day and 4.4 g/day respectively, and that of vitamin A was 525.6 RE/day; 252.8 RE/day and 320.8 RE/day respectively. Considering that food consumption of these age groups also includes a portion of breast milk, 38% of children manage to cover their caloric requirements, 82% cover recommended protein levels, 12% those of iron, and 66% those of vitamin A.

Conclusions: A high percentage of children from 6 to 23 months of age in rural areas show deficient consumption of calories and iron, as well as protein and vitamin A deficiencies, which impede proper child growth and development.

Key words: calories, protein, iron, vitamin A, rural.

PO1278

IRON DEFICIENCY ANAEMIA IN CHILDREN IN RURAL DISTRICTS OF PERU

A. Vargas¹, L. Espejo¹, J. Diaz¹, H. Torres¹, R. Ruiz²

¹Technical Department, Action Against Hunger Spain, Lima, Perú

²Technical Department, INTERSOCIAL, Lima, Perú

Background and objectives: Iron deficiency anaemia is a severe public health problem in Peru. Few studies have investigated the situation in rural areas. This study examines anaemia and associated factors in 4 rural districts in the region of Ayacucho.

Methods: The study is descriptive and analytic, with a two stage probabilistic sample with a level of confidence of 95% and 5% accuracy. Hemoglobin levels in 297 children from 6 to 35 months were measured with a HemoCue[®] photometer hemoglobin detection system, with adjustments for altitude. A survey and qualitative recall for child food consumption for the previous day were implemented.

Results: 74% of children from 6 to 35 months suffer from iron deficiency anaemia (<11 g/dl Hb). The prevalence is higher in those from 6 to 12 months (90%). In relation to mothers' knowledge, 83% do not know the causes and consequences of anaemia and 92% do not know preventative measures. Regarding food consumption, 45% of children ingested food rich in iron, 8% consumed an iron-absorption enhancer and 53.2% consumed iron-absorption inhibitors, mainly herbal teas. The study identified less anaemia in children whose mothers work for income compared to those whose mothers do not (67% vs 77%; p=0.001). Within the group of anaemic children rates of moderate and severe anaemia were higher for those whose mothers do not know preventative measures (65% vs 46%; p=0.02), those who do not consume enhancers (67% vs 36%; p=0.000) and those who do consume inhibitors (72% vs 55%; p=0.000).

Conclusions: Iron deficiency anaemia in children under three is high in rural areas. Factors associated with the prevalence of anaemia are the child's age and the mother's participation in salaried work. Factors associated with the severity of anaemia are knowledge regarding preventative measures, and consumption of enhancers and inhibitors.

Key words: anaemia, rural, enhancers, inhibitors.

PO1279

REVIEW OF FOOD-BASED DIETARY GUIDELINES IN LATIN AMERICA AND THE CARIBBEAN AND EMERGING RECOMMENDATIONS

V. Molina¹, E. Muehlhoff¹, C. Alvarez¹, C. Dárdano¹

¹FAO, Guatemala

Background and objectives: Food-Based Dietary Guidelines (FBDG) are important in the promotion of healthy diets and lifestyles and can play a critical role in countries' efforts to improve dietary patterns and public health. FAO carried out a study to assess progress made by Latin America and Caribbean (LAC) countries in the development, implementation and evaluation of FBDG.

Methods: National responsible officers for FBDG in 33 countries were requested to complete a questionnaire and provide their published FBDG. This was supplemented by a literature review to evaluate information relating to the implementation and evaluation of FBDG in LAC.

Results: Twenty-four countries in the LAC region have developed FBDG; to date 11 have revised them, messages show a shift in orientation from addressing undernutrition and micronutrient malnutrition to obesity and NCDs, with frequent focus of messages on: 'maintain a healthy weight', 'reduce salt or fat consumption', reflecting the nutrition transition that the region is experiencing. Often guidelines use ambiguous terms (i.e. increase/decrease consumption) and do not specify quantities and portion sizes, making it difficult for people to put them into practice. While most countries (15) have implementation plans, these are not comprehensive enough and lack the necessary political and financial support to reach the public at large. FBDG are rarely evaluated thus their impact remains unknown; also the published literature on implementation in the LAC region is very limited. Some LAC countries are initiating novel approaches through integrating FBDG into a broader health promotion strategies (e.g. Chile "Elige Vivir Sano" program) involving diverse sectors backed up by high level political support.

Conclusions: To halt the rising tide of obesity and NCDs, improvements are needed in the implementation and evaluation of FBDG. Emerging recommendations are discussed for consideration by countries when updating their FBDG.

Key words: Food-Based-Dietary-Guidelines, healthy diets and lifestyles, NCDs prevention.

PO1280

THE SCHOOL FRUIT SCHEME IMPACT ON FRUITS AND VEGETABLES CONSUMPTION BY CHILDREN IN POLAND.

K. Wolnicka¹, M. Jarosz¹, J. Jaczewska-Schuetz¹, A. Taraszewska¹

¹Department of Dietetic and Nutrition in Hospitals with Clinic of Metabolic Diseases and Gastroenterology, National Food and Nutrition Institute, Warsaw, Poland

Background and objectives: The main objective of evaluating the UE School Fruit Scheme was to determine its impact on the eating habits of children, especially on fruits and vegetables consumption.

Methods: The evaluation of the School Fruit Scheme was performed among third-grade pupils (9 years old) from 58 randomly selected primary schools before launching the distribution of fruit and vegetables (October 2010) and at the end of the fruits and vegetables distribution period (May-June 2011). The study was conducted in schools participating in the School Fruit Scheme (intervention group) and in schools not participating in the Scheme (control group). Evaluation of fruits and vegetables consumption was based on the 3-day food record method.

Results: At the end of the School Fruit Scheme, fruits consumption, vegetables consumption and total fruits and vegetables consumption on school days and weekends days was significantly higher in the intervention group than in the control group but was still under recommendations. At the end of the Scheme the total consumption of fruit and vegetables on school days in the intervention group was 21% higher in comparison to the control group.

Conclusions: The evaluation results show that the Scheme has a very strong potential and is an appropriate tool to improve the eating habits of children towards consuming more fruit and vegetables for the future.

Key words: intervention, school, fruits vegetables consumption, children, public health.

PO1281**THE SCHOOL FRUIT SCHEME IMPACT ON SELECTED NUTRITION BEHAVIOURS OF PARENTS IN POLAND.**

M. Jarosz¹, K. Wolnicka¹, A. Taraszewska¹, J. Jaczewska-Schuetz¹

¹Department of Dietetic and Nutrition in Hospitals with Clinic of Metabolic Diseases and Gastroenterology, National Food and Nutrition Institute, Warsaw, Poland

Background and objectives: The main objective was to determine the UE School Fruit Scheme impact on the nutrition behaviours of parents especially their attitudes towards child nutrition.

Methods: The analysis was performed among third-grade pupils (9 years old) from 58 randomly selected primary schools before launching the distribution of fruits and vegetables (October 2010) and at the end of the fruits and vegetables distribution period (May-June 2011). The study was conducted in schools participating in the Scheme (intervention group) and in schools not participating in the Scheme (control group). The analysis of parents habits was undertaken by means of a children's questionnaire.

Results: After the intervention, children from the group participating in the Scheme significantly statistically more often responded that their parents encouraged them to eat vegetables ($p < 0, 0001$) and to eat fruit ($p < 0, 0001$) daily or almost every day. A child's participation in the School Fruit Scheme may have had a positive effect on its parents' behaviour and on encouraging parents to more frequently remind their children about eating vegetables/fruits. Positive changes related to children bringing vegetables to school were observed only in the group participating in the School Fruit Scheme (11.7% before the Scheme vs 18.6% towards the end of the Scheme; $p < 0, 0001$). The mean calculated on the basis of answers reflecting the frequency of providing children with prepared, ready-to-eat sliced fruit between meals was significantly greater in the intervention group than in the control group after the Scheme's completion ($p = 0, 03$).

Conclusions: The Scheme influenced some of the parents' dietary habits, especially their attitudes towards child nutrition e.g. encouraging children more frequently to eat fruits and vegetables, serving children sliced fruit between meals more frequently or packing vegetables into children's lunchboxes more frequently.

Key words: intervention, fruits and vegetables, schools, nutrition behaviours, parents.

PO1282**FOOD KNOWLEDGE AND FOOD CONSUMPTION IN SCHOOL-AGE CHILDREN, PARENTS AND TEACHERS: A COMPARATIVE ANALYSIS**

F. Vio¹, J. Salinas¹, L. Lera¹, C. Gloria. González¹, C. Huenchupán¹

¹Institute of Nutrition and Food Technology (INTA) University of Chile, Chile

Background and objectives: The objective was to conduct a comparative analysis about food knowledge and food consumption in pre-school and school-age children, their parents and teachers, to establish a baseline for a nutrition education intervention model in schools.

Methods: Surveys were conducted to pre-school and school-age children, their parents and teachers about healthy and non healthy food knowledge and food consumption.

Results: showed an excellent healthy food knowledge and food consumption in children (100% recognized fish, fruits and vegetables as healthy food). In parents, despite a good knowledge about healthy food, consumption was unhealthy: 30.8% of pre-school parents drank more than 2 soft drinks per day, compared to 64.7% of basic school parents ($p < 0.001$). Teacher's food consumption was also unhealthy: 64% ate more than two portions of bread per day, 36% salty snacks and 64% sweet snacks during the week, and 55% consumed hamburger or pizzas at least twice per week. Distribution of food during the day showed that 98% of parents had breakfast; 96% had lunch, and 77% had an afternoon snack with a lot of bread and soft drinks, and just 55% had dinner. 69% of pre-school age parents ate dinner compared to 44% of school-age parents ($p < 0.01$). Pre-school age parents did not give money to their children to buy snacks at the school; however, a third of the school-age parents gave money to their children ($p < 0.05$). This fact demonstrates a major care for healthy food in pre-school age children that is not maintained during the first school grades.

Conclusions: This study shows how to design nutrition education programs, considering the present food knowledge and food consumption of pre-school and school age children, their parents and teachers. Acknowledgements: This study was funded by FONDECYT project N° 1110044.

Key words: food knowledge, food consumption, nutrition education, school food programs.

PO1283**HOSPITAL SUPPORT FOR MALNOURISHED CHILDREN***O. Ousmane*¹¹Université de Ouagadougou/UFR-SVT/CRSBAN, Burkina Faso²Université de Kara/FAST, Togo

Background and objectives: Malnutrition which is a consequence of disease and inadequate food intake is one of the main problems of health and well-being affecting children 6 to 59 months in Burkina Faso. The objective of this study is: determining provenance geographic and social of ill children, identify health structures which refer the malnourished children at the Saint Camille CREN.

Methods: it is a longitudinal study which focused on data of 60 children in nutritional rehabilitation at the medical center CREN Saint Camille. For the collection of data, two methods have been used: individual maintenance where individual informed consent has been asked to all the mothers of the children and observation.

Results: During the study period, the annual average of the admission is 600 children. The classic excess morbidity of women has been found (52% of girls compared with 48% of boys). The socio-economic level of the mothers it appears that 80% do not have a job or access to a regular income. The low income of the parents and their lack of knowledge of the nutritional needs of the children explain the maximum recruitment of the malnourished in these groups. Dietary therapy cured rate is 86.7% for an average length of stay of 28 ± 6 days. They have on average 6, 8 g / kg/day during the stay at the CREN. Ignorance, poverty and family difficulties prevent the parents to provide the child malnutrition, care and adequate food.

Conclusions: It is very important that persons dealing with children have appropriate recommendations for infant and young child, and both illness feeding, they know the path to follow for the management of malnourished.

Key words: Support, malnutrition, Burkina Faso.

PO1284**DO WE NEED TO CORRECT SERUM FERRITIN FOR INFLAMMATION TO ASSESS IRON DEFICIENCY IN OBESITY-RIDDEN SETTINGS? EXAMPLE IN URBAN MOROCCO***A. Gartner*¹, *J. Berger*¹, *A. Bour*², *J. El Ati*³, *P. Traissac*¹, *E. Landais*¹, *S. El Kabbaj*⁴, *F. Delpeuch*¹¹UMR Nutripass IRD-UM2-UM1, Institut de Recherche pour le Développement (IRD), Montpellier, France²Equipe de Transition Alimentaire et Nutritionnelle (ETAN), Faculté des Sciences, Université Ibn Tofail, Kénitra, Morocco³Service Etudes et Planification, Institut National de Nutrition et de Technologie Alimentaire (INNTA), Tunis, Tunisia⁴Laboratoire de Recherche et d'Analyses Médicales (LRAM), Fraternelle de la Gendarmerie Royale, Rabat, Morocco

Background and objectives: Many developing countries are already facing high levels of overweight/obesity, along with still high levels of iron deficiency (ID). Although causes of inflammation as infectious/malaria/parasitic diseases are no longer widespread, new reasons to correct serum ferritin (SF) concentrations, such as adiposity-induced inflammation, should be taken into consideration. Objective was to assess the extent of underreporting of ID when using uncorrected SF vs. corrected SF according to adiposity.

Methods: A cross-sectional survey in the area of Rabat used a random sample of 811 women aged 20-49y. Corrected SF was $SF \times 0.65$ when inflammation (C-reactive protein > 5mg/L). ID was $SF < 15 \mu\text{g/L}$. Adiposity was assessed by BMI (normal BMI < 25, pre-obese $25 < \text{BMI} < 30$, obese BMI > 30 kg/m²), waist circumference and body fat. Differential effect of SF correction on ID status based on adiposity was assessed by models including adiposity x correction interactions and accounting for repeated measurements.

Results: Prevalence of pre-obesity was 33.0%, of obesity 34.0% and of inflammation 26.7%. Adjusted for socio-demographics or not, inflammation was strongly linked with adiposity (9.6%, 23.7% and 46.1% in normal, pre-obese and obese subjects, respectively, $P < 0.0001$). Not correcting SF underestimated prevalence of ID (37.2% vs. 42.1%; difference = -4.9%, $P < 0.0001$). The difference increased with adiposity (-1.3%, -4.3% and -9.1% in normal, pre-obese and obese subjects, interaction $P = 0.0002$). False negative ID cases (SF not corrected vs. corrected) reached 22.4% in obese women vs. 3.0% in normal-BMI. Analogous results were observed for other adiposity measures.

Conclusions: Using corrected SF avoided failure to detect ID in about one woman out of five because she was obese. In

middle-income countries concerned by ID and obesity, assessment of ID with a single indicator still needs to use corrected SF even if infectious diseases are no longer widespread but because overweight/obesity has become the main cause of inflammation.

Key words: Adiposity-induced inflammation; Women; North Africa; Health/nutrition transition.

PO1285

NUTRITIONAL STATUS IN THE CUBAN POPULATION MORE THAN 15 YEARS OLD OF THE III NATIONAL SURVEY OF RISK FACTORS

M E. Díaz-Sánchez¹, S. Jimenez-Acosta¹, R. García-Roche², M. Bonet², M. Hernández-Triana¹

¹Instituto de Nutrición e Higiene de los Alimentos, La Habana, Cuba

²Instituto Nacional de Higiene, Epidemiología y Microbiología, La Habana, Cuba

Background and objectives: The world-wide tendency of the body weight and adiposity increase promotes the population studies in different countries.

Methods: Data of the Body Mass Index and the Waist/Hip ratio obtained from a complex sample design by multi-stage conglomerates, in men and women of III the National Survey of Factors of Risk carried out in Cuba, older than 15 years. The nutritional status in the urban and rural zone of the country was evaluated. Objectives: Analyze the changes of the nutritional status in Cuban population by ages, sex, zone of residence and other socio demographic characteristics.

Results: Lower body weight is present in the 7, 6% [IC: 6, 9-8, 3] of the total population, normal weight is 47, 6% [IC: 46, 2-48, 9]. The 44, 8% [IC: 43, 4-46, 3] of global overweight and the 15, 0% [IC: 14, 0-16, 1] of the obesity, indicate that the excess of body weight has been increased in Cuba in the last decade. The global overweight in men (41.16% [IC: 39.2-43.1]) is less than in women (48.3% [IC: 46.6-50.0]), to expenses mainly of a higher prevalence of the obesity in these last ones. Approximately a quarter of the population has a greater proportion of body fat deposited around the waist, more elevated in feminine sex; the risk for a waist increased by central adiposity excess exists even with normal weight. The higher percentage of overweight appears in people with university instruction and married, of different labor activities. Higher prevalence of overweight and obesity in the urban zone stand out.

Conclusions: The Cuban population has reduced its prevalence of low weight, but it was increased the obesity in the last years significantly.

Key words: Nutritional status, Obesity, Risk Factors.

PO1286

EVIDENCE FOR A NEED TO REVIEW CURRENT RECOMMENDATIONS: SEDENTARY BEHAVIOUR AND PHYSICAL ACTIVITY IN URBAN SOUTH ASIAN WOMEN

I. Waidyatilaka¹, P. Lanerolle¹, R. Wickremasinghe², S. Atukorala¹, N. Somasundaram³, A. de Silva⁴

¹Department of Biochemistry and Molecular Biology, Faculty of Medicine, University of Colombo, Colombo, Sri Lanka

²Department of Public Health, Faculty of Medicine, University of Kelaniya, Ragama, Sri Lanka

³Endocrine Unit, National Hospital of Colombo, Colombo, Sri Lanka

⁴Department of Physiology, Faculty of Medicine, University of Colombo, Colombo, Sri Lanka

Background and objectives: Despite Asians being at a higher risk of type 2 diabetes mellitus than non Asians, the relative effects of physical activity and sedentary behaviours on glycaemic status among South Asians are unclear. Our aims were to describe physical activity and sedentary behaviours in urban Sri Lankan women of South Asian ancestry, and examine their relative contribution to glycaemic status.

Methods: 2800 women (30-45 years) from urban Colombo were selected by random cluster sampling and screened for dysglycaemia. All newly diagnosed drug naive dysglycaemics (n=272) were recruited, and a further 345 normoglycaemic women were randomly selected from each cluster. Glycaemic status was confirmed by HbA1c. Physical activity and sedentary behaviours were assessed by International Physical Activity Questionnaire (IPAQ). TV viewing time, demographic data, diet and anthropometry were recorded. Contribution of variables to dysglycaemia was assessed through logistic regression analysis.

Results: Mean energy expenditure on walking (2648.5 ± 1023.7 MET-min/week) and on moderate and vigorous physical activity (4342.3 ± 1768.1 MET-min/week) for normoglycaemic and dysglycaemic women (walking; 1046.4 ± 728.4, moderate and vigorous physical activity; 1086.7 ± 1184.4 MET-min/week) exceeded WHO recommendations. 94.3% spent > 1000 MET-minutes/week on physical activity. Mean sitting and TV time for normoglycaemic and dysglycaemic women were 154.3 ± 62.8, 38.4 ± 31.9, 312.6 ± 116.7 and 140.2 ± 56.5 minutes/day respectively. Both, physical activity and sedentary behaviour contributed to dysglycaemia, after adjusting for family history, diet, systolic blood pressure and BMI.

Conclusions: Although compared to recommendations, physical activity was high and sedentary behaviours were low, both were associated with glycaemic status. Urban South Asian women are at risk of dysglycaemia at lower levels of sedentary behaviour and greater physical activity than western popula-

tions, indicating the need to re-visit current classifications in physical activity guidelines for South Asians.

Key words: Physical activity, sedentary behaviour, Asia.

PO1287

EFFECTS OF ECONOMIC TRANSITION ON DIETARY FAT INTAKE AMONG CHINESE ADULTS

B. Zhang¹, H. Wang¹, W. Du¹, C. Su¹, S. Du², Z. Wang¹, J. Zhang¹, J. Zhang¹, F. Zhai¹, B. Popkin²

¹National Institute of Nutrition and Food Safety, Chinese Center For Disease Control and Prevention, China

²Department of Nutrition, University of North Carolina at Chapel Hill, USA

Background and objectives: To explore effects of economic changes on dietary fat intake among Chinese adults.

Methods: Data of the China Health and Nutrition Survey from 1991 to 2009 were used. Dietary data were collected by using 3 consecutive 24-hour recalls in combination with weighing methods. Tertiles of urbanization scales and per capita annual household income were used to measure economic changes over time.

Results: Average fat intake among Chinese adults increased from 62.7 grams/day (g/d) in 1991 to 77.2 g/d in 2009. Fat intake increased faster in low urbanization group (from 54.0 g/d to 72.1 g/d) than in high urbanization group (from 72.1 g/d to 80.8 g/d). It was increasing constantly in low urbanization group while it increased before 2000 and declined thereafter in high urbanization group. More than half of Chinese adults consumed 30% or more energy from fat, including 39.8% population in low urbanization group and 47.6% in low income group in 2009. The patterns and trends were similar among income and urbanization tertiles.

Conclusions: This study presents extra evidence that increased income is pushing Chinese adults away from traditional low-fat diet to high-fat diet, particularly in low income and urbanization populations.

Key words: fat intake, urbanization, income.

PO1288

CONSUMER ACCEPTABILITY AND EFFECTIVENESS OF SIX MENU CALORIE LABELING FORMATS ON FOOD CHOICES USING MOBILE TABLET TECHNOLOGY

M. Fotouhinia Yepes^{1,2}, M. Siegrist¹, J. Yen²

¹Department of Consumer Behavior, ETH Zurich, Zurich, Switzerland

²Department of Nutrition, EHL Lausanne, Lausanne, Switzerland

Background and objectives: In an effort to reduce national obesity epidemic, placement of calorie information on restaurant menus has been approved as national law in certain countries. With increasing proportions of foods consumed away from home, such legislation serve to provide simplified and visible nutrition information at points of purchase. This study aimed to determine the most acceptable and effective nutrition labeling format for use in restaurant settings.

Methods: Using mobile tablet technology, five different nutrition labeling formats were tested including combinations of numeric calorie labels, Traffic Light (TL) system and % Daily Intake system (%DI), plus a control group without calorie information. Using a local restaurant menu, 126 participants made their food selection and completed a post selection questionnaire on perceived attractiveness and influence of each labeling formats on their food decision process. Each participant was exposed to a single labeling format and calorie content of each participant's selection was calculated to determine actual impact of calorie labeling on food choices.

Results: Overall participants indicated a strong support for inclusion of nutrition information on restaurant menus using tablet technology. Comparisons of different labeling format using One way ANOVA indicated a significant overall difference between labeling groups in terms of attractiveness $F(4, 100) = 4.353, p = .003$. The response for attractiveness was highest amongst TL color coding groups. The attractiveness was significantly increased if color coding was combined with %DI information. The results revealed a positive correlation between attractiveness and perceived influence on food choice for the TL groups. ($r = 0.712, p < 0.001$). The findings indicated no significant effect of calorie labeling on total calories selected.

Conclusions: Tablet technology can be used to provide valuable nutrition transparency to consumers, in a format that's easy to understand and use while making food decisions in restaurant settings.

Key words: Menu calorie labeling, food choice, technology

PO1289**SEASONAL CHANGES IN IRON AND VITAMIN A STATUS AMONG WOMEN IN RURAL SOUTH-EAST PERU**

U. Chavez Zander¹, J. Erhardt², A. Mujica Sanchez³, M. Krawinkel¹

¹Justus Liebig University of Giessen, Giessen, Germany

²VitA-Iron Lab, Willstaett, Germany

³Universidad Nacional del Altiplano UNA, Puno, Peru

Background and objectives: Dietary diversity (DD) is a long term strategy to tackle micronutrient deficiencies in resource-poor populations but may be influenced by seasonal food availability. In isolated regions, qualitative food scores are a proxy indicator of diet quality. In this context, micronutrient status based on biochemical data also needs to be assessed using field-friendly methods. Objective: A) To assess iron and vitamin A status, and DD and their seasonal changes among women of childbearing age in the post-harvest (post-S) and farming season (farm-S). B) To examine whether the micronutrient status is associated with DD.

Methods: A repeated cross sectional study was carried out with 167 women aged 15 – 49 in post-S and 157 in farm-S during 2007. DD was assessed with a qualitative 24h recall in each season. Haemoglobin (Hb) and soluble transferrin receptor (sTfR) for iron status, retinol binding protein (RBP) for VA status, and inflammation indicators were measured using dried blood spot assays.

Results: Prevalence of anemia was 51.4% and 43.6% in each season, but only 12.6% and 4.0% of the women had a low iron status, respectively. Vitamin A status was marginal in 11.5% and 28.2% of the women. A significant seasonal decrease in sTfR (amelioration of the iron status) and RBP (impaired VA status) concentrations could be identified. Two women had VAD (2.8%) in farm S. Lower DD was associated with lower Hb concentrations, while animal source foods (ASF) were correlated with higher Hb and RBP levels ($p < 0.05$), and gathering of herbs with better VA status ($p < 0.01$) in post-S only.

Conclusions: Anemia in this population is still highly prevalent and might not be related to iron deficiency only. Seasonality alters iron and VA status. Even qualitative dietary assessments detected an association between consumption patterns and nutritional status.

Key words: anemia, dietary diversity, vitamin A.

PO1290**LOGIC MODEL OF THE INITIATIVE LINKING THE BRAZILIAN NATIONAL SCHOOL FEEDING PROGRAMME AND FAMILY FARMING**

F. Schwartzman¹, C. Mora¹, B. Januario¹, C. Bogus², B. Slater¹

¹Department of Nutrition, School of Public Health, University of São Paulo, Brazil

²Department of Public Health Practice, School of Public Health, University of São Paulo, Brazil

Background and objectives: The application of logic models in the evaluation of process and outcomes of public policies is highly recommended. The Brazilian National School Feeding Program (PNAE) has more than 50 years of existence and to date, there is no knowledge of the development of logic models to support it. The program has undergone important changes, one them being the strong connection with family farming. Since 2009, with the implementation of the Law 11.947, at least 30% of the resources transferred to the states and municipalities for PNAE should be used in the procurement of foods directly from family farmers. The implementation of this initiative is underway and it is important to evaluate how the process is taking place and its possible effects in schools and for local producers. The objective was to build a logic model focusing on the initiative linking PNAE with family farming.

Methods: Key informants who participated in the drafting of the Law were interviewed. Information on the origin, objectives, target audience, actions implemented and expected results of the initiative were collected, analyzed and systematized.

Results: The information obtained subsidized the development of a graphical representation of the logic model (which will be presented in the event) which allowed the identification of the main components of the initiative linking PNAE and family farmers, in an articulated way. It also allowed the systematization of the expected results, supporting the identification of intermediate and final results, and direct and indirect effects, both for schools and students, as for local farmers.

Conclusions: The development of the logic model has been important to identify the main elements of this initiative and has helped in the identification of the best performance indicators to use in its process and outcome evaluation.

Key words: Evaluation, logic model, PNAE, school feeding, family farming.

PO1291**PREVALENCE OF INADEQUATE INTAKE OF FOLATE IN BRAZIL AFTER MANDATORY FORTIFICATION: RESULTS FROM THE FIRST NATIONAL DIETARY SURVEY**

D M. Marchioni¹, E. Verly Jr², J. Steluti¹, R M. Fisberg¹, R. Pereira³, R. Sichieri²

¹Universidade de São Paulo, São Paulo, Brazil

²Universidade Estadual do Rio de Janeiro, Rio de Janeiro, Brazil

³Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil

Background and objectives: evidence that folic acid decreases the incidence of neural tube defects led to mandatory food fortification in more than 50 countries, including Brazil. Our aims were to estimate the prevalence of folate inadequacy (POFI) according to life-stage and socio educational status.

Methods: data from two non-consecutive food records from the National Dietary Survey/Household Budget Survey (HBS) 2008-2009 (33, 004 individuals over 10 years old) were used to estimate the usual dietary intake amounts of folate in mcg DFE - dietary folate equivalents, using the National Cancer Institute method to account for within person variance and the EAR (Estimated Average Requirement) cut-point method was used to calculate the POFI.

Results: Overall POFI was 29.3%. In women of childbearing age, the POFI was 36.7%, and in women over 50 y was higher than 40%. In men, POFI ranged from 14% in the youngest to 36% in the eldest group. The median intake of folate was < 400 mcg for women in all age groups. The 95th percentile of folate intake was 740 mcg.

Conclusions: In Brazil, public policy aiming to prevent POFI

has been achieving positive results. Fortification with folate enhanced folate intake in all sex age groups, while maintaining the intake in a safe range. However, our data suggest that further actions need to be taken to assure that women in childbearing age accomplish the recommended intake of 400 mcg/d.

Key words: folate, folic acid, food fortification, survey.

PO1292**FOLATE AND OTHER ONE CARBON METABOLISM RELATED NUTRIENTS AND RISK OF BREAST CANCER**

D M. Marchioni¹, D. Chan², M R. Vieira², T. Norat²

¹Universidade de São Paulo, São Paulo, Brazil

²Imperial College London, London, UK

Background and objectives: Adequate intake of folate appears to protect against cancer, however, it might act as a cancer promoting agent under circumstances of excessive intake. We conduct a systematic review and meta-analysis of the relationship between folate and metabolically related vitamins B12 and B6 and breast cancer.

Methods: Seventeen cohort studies, identified from a Pubmed search up to December 2012, presented results on folate, B12 and B6 and breast cancer risk. Summary relative risks estimates (RR) and 95% Confidence Intervals (CI) for the highest versus the lowest level (HxL) and for linear dose-response analysis were estimated using a random effects model.

Results: Total folate intake ranged from 45 to 1082 mcg/d. Intake of dietary folate and folic acid supplements were not related to breast cancer risk. The summary relative risks per 100 mcg/d intake increase were 1.00 (95% CI: 0.99, 1.02; I2: 56%) for dietary and supplemental folate and 0.98 (95% CI: 0.95, 1.02; I2:56%) for dietary folate. The RR for 2ng/ml/d increase in blood levels was 1.00 (95% CI: 0.93, 1.09; I2: 64%). No association was observed in HxL meta-analysis. The analysis for B12 (dietary, supplemental and blood levels) and B6 intake yielded null results. Stratified analysis for total folate by folate intake level, age at first birth, parity, familial cancer, alcohol intake, smoking, BMI and energy intake displayed no significant associations.

Conclusions: The reviewed evidence does not support the hypothesis of an effect of folate, B12 and B6 vitamins on breast cancer incidence. Acknowledgement: TN, DC, AV have been funded by the World Cancer Research Fund International (Grant number: 2007/SPO1). They may not represent the views of the funders.

Key words: breast cancer, folate, meta-analysis, B vitamins.

PO1293**IT'S UTILIZATION, NOT SPATIAL ACCESS TO FOOD STORES THAT MATTERS, ESPECIALLY IN RURAL AREAS**

J. Sharkey¹, W. Dean¹, C. Nalty¹, C. Johnson²

¹Program For Research In Nutrition and Health Disparities, School of Rural Public Health, TAMHSC, College Station, TX, USA

²UNC Department of Nutrition, UNC-CH, Chapel Hill, NC, USA

Background and objectives: With a few notable exceptions, the majority of food environment research is urban-centric and has not ventured into unincorporated and rural areas. Furthermore, much of the research on the environmental determinants of food choice and dietary intake focuses on spatial access to the retail food environment, especially larger supermarkets. However, distance to a food store alone may not reveal the way in which individuals interact with the food environment. Thus, the question becomes not one of estimating spatial access defined as distance, but what patterns of utilization exist? And, how does utilization vary within an area?.

Methods: Two 2006 datasets were linked: 1) a community health assessment of 1, 169 adults in six rural Central Texas counties (demographics, perceived community food environment, food security, location of store where most groceries were purchased, and travel for medical/dental services) and 2) ground-truthed identification and geocoding of all supermarkets and convenience stores in the 11, 567 km² region. Analyses included descriptive statistics, correlations, and hierarchical regression analyses for grocery purchases outside the 6-county region compared with shopping within the region.

Results: 34% of survey participants shopped outside the 6-county region. The odds for shopping outside the region were greater for adults who could not afford to eat balanced meals, traveled a greater distance for multiple services, and lived greater than 14.4 miles to the nearest large supermarket.

Conclusions: Although the nearest food store that marketed fresh and canned fruits and vegetables was located within the 6-county region, more than one-third of participants shopped outside the region and many combined shopping trips with traveling outside the region for medical and dental services. Understanding environmental influences on dietary health must go beyond potential spatial access and take into consideration patterns and determinants of utilization.

Key words: food environment, food store utilization, rural.

PO1294**NIGERIAN WOMEN PARTICIPATING IN AN INTEGRATED MICROCREDIT AND mHEALTH BREASTFEEDING PROMOTION INTERVENTION WERE MORE LIKELY TO ADOPT INTERNATIONAL BREASTFEEDING RECOMMENDATIONS**

V. Flax¹, M. Negerie², A. Usman², S. Leatherman³, E. Daza¹, M. Bentley¹

¹Carolina Population Center, University of North Carolina, Chapel Hill, NC, USA

²Partners for Development, Abuja, Nigeria

³Department of Health Policy and Management, University of North Carolina, Chapel Hill, NC, USA

Background and objectives: International breastfeeding recommendations are intended to reduce morbidity and mortality in infants living in resource-limited settings. Only a small proportion of mothers in northern Nigeria follow the guidelines. This study tested if providing group breastfeeding counseling during routine microcredit meetings and sending cell phone breastfeeding messages would promote recommended breastfeeding practices in Bauchi state, Nigeria.

Methods: We conducted a cluster-randomized controlled trial within the context of women's microcredit. Several small groups of microcredit clients (with 5-6 women) met together monthly with their credit officer, who conducted seven monthly breastfeeding learning sessions with them. Randomization occurred at the level of the monthly meeting groups. Text and voice messages were sent out weekly to a cell phone provided to each small group. Pregnant clients were recruited at baseline and interviewed again when their infants were >6 months. Logistic regression models adjusted for clustering were used to estimate the odds of performing behaviors in the intervention versus control group.

Results: Among the women who completed the final survey (n=390), there were no significant differences in breastfeeding intentions at baseline. Post-intervention, reported practices were: exclusive breastfeeding to six months (51% intervention, 34% control); initiation of breastfeeding within one hour of delivery (70% intervention, 47% control); and giving fluids other than milk during the first three days of life (14% intervention, 30% control). The odds of exclusive breastfeeding (OR 2.4, 95% CI 1.4, 4.0) and timely breastfeeding initiation (OR 2.6, 95% CI 1.6, 4.1) were increased while the odds of giving non-breastmilk fluids in the first days of life (OR 0.4, 95% CI 0.2, 0.7) were decreased in the intervention versus control group.

Conclusions: A face-to-face and mhealth breastfeeding promotion intervention provided in the context of microcredit increased the likelihood that women adopted recommended breastfeeding practices.

Key words: breastfeeding, microcredit, mhealth.

PO1295**VITAMIN D INTAKES OF CHILDREN DIFFER BY INCOME AND RACE/ETHNICITY IN THE UNITED STATES, 2007 TO 2010***C. Moore¹, J. Radcliffe¹, Y. Liu²*¹Texas Woman's University, USA²United States Department of Agriculture/Agricultural Research Service, Children's Nutrition Research Center, Department of Pediatrics, Baylor College of Medicine, USA

Background and objectives: Vitamin D status is a public health concern in the United States (U.S.), and differences in vitamin D intake may contribute to health disparities of children from different race/ethnic groups. Methods: Total, dietary and supplemental vitamin D intakes of 6226 children age 1 to 18 years in the U.S. were estimated and compared by income (low, medium, high) and race/ethnicity. Vitamin D intake was estimated utilizing 24-h dietary intake recalls and dietary supplement use questionnaires from the 2007-2010 National Health and Nutrition Examination Survey. Statistical analyses of weighted data were performed using SAS (V 9.2) to estimate vitamin D intake (means \pm SE).

Results: The race/ethnic distribution of children was 62% Non-Hispanic (NH) White, 23% Hispanic, and 15% NH Blacks. One-third of the children (33% \pm 1.6) were in the low income category. Race and ethnic intake differences controlling for income, gender and age were assessed by ANCOVA. Total (dietary and supplement) vitamin D intake was greater in the high (7.9 \pm 0.3 ug/d) income versus the low (7.2 \pm 0.2 ug/d) income category. Total vitamin D intake of Non-Hispanic (NH) White children (8.1 \pm 0.2 ug/d) was greater than Hispanic children (7.5 \pm 0.1 ug/d) and NH Black children (5.9 \pm 0.2 ug/d) ($P < 0.05$). Although supplements were consumed by 80% of the children, the majority (73 % \pm 0.9) were not meeting the Estimated Average Requirement for vitamin D from diet and supplements.

Conclusions: Public health efforts should target health messages especially to Black and Hispanic parents to increase vitamin D intake of children. Sponsored by a Texas Woman's University Chancellor's Research Fellowship grant.

Key words: vitamin D, children, income, ethnicity.

PO1296**METABOLIC SYNDROME IN HEALTHCARE PERSONNEL FROM THE UNIVERSITY OF ANTIOQUIA-COLOMBIA: LATINMETS STUDY***L. I. González-Zapata¹, G. Deossa¹, J. Monsalve-Álvarez¹, J. Díaz-García¹, N. Babio², J. Salas-Salvadó²*¹School of Nutrition and Dietetics, University of Antioquia, Medellín, Colombia²Human Nutrition Unit, Universitat Rovira i Virgili, Reus, Spain

Background and objectives: Hypertension (HTN), atherogenic dyslipidemia, an increased glycemia in a fasting state, and abdominal obesity (AO), constitute a cluster of risk factors for cardiovascular disease named metabolic syndrome (MS). The objective of this research was to analyze the prevalence and distribution of MS and its components in healthcare personnel from the University of Antioquia.

Methods: Cross-sectional study conducted between 2010 and 2011. The collected data included anthropometrical, biochemical, socio-demographic, and lifestyle variables. The MS was diagnosed using the harmonized IDF/AHA definition. Descriptive and analytical statistical analyses were performed, including Chi2 tests, and $\alpha = 0.05$.

Results: 285 volunteers (29.1% men) with ages between 20-61 years were included. 31.6% of participants were overweight (Body Mass Index BMI higher than 25 kg/m²). AO (29.8%) and HTN (29.8%) were the most frequent components of MS. Global prevalence of MS was 17.5% (95%CI:13.1;22). There was no significant difference between men and women in terms of the prevalence of AO (women 30.7%, men 27.7%; $p > 0.05$), and low HDL (women 28.7%, men 24.1%; $p > 0.05$), but the other diagnostic components were more prevalent in men. Except for the HDL, all the diagnostic components of MS were associated with being overweight by BMI. There was a lower presence of MS among women (OR 0.328; 95%CI:0.175;0.614; $p < 0.05$), and a positive gradient with age and income. Likewise, the prevalence of MS was higher among smokers and those who are overweight ($p < 0.05$). After adjusting for age, MS was associated with sex (OR 0.348; 95%CI: 0.178;0.680) and being overweight (OR 14.592; 95%CI: 6.343;33.570).

Conclusions: The most frequently observed components of MS in the studied sample were AO and HTN. BMI, sex, and socio-economic status are important independent risk factors associated with MS.

Key words: Metabolic syndrome, cardiovascular disease, socio-demographic risk factors, Body Mass Index, healthcare personnel.

PO1297**THE INFORMAS FRAMEWORK FOR MONITORING FOOD MARKETING TO CHILDREN**

B. Kelly¹, L. King², L. Baur², M. Rayner³, T. Lobstein⁴, C. Monteiro⁵, J. Macmullan⁶, S. Mohan⁷,

¹School of Molecular Bioscience, The University of Sydney, Sydney, Australia

²Prevention Research Collaboration, The University of Sydney, Sydney, Australia

³British Heart Foundation Health Promotion Research Group, University of Oxford, Oxford, UK

⁴International Association for the Study of Obesity, London, UK

⁵School of Public Health, University of Sao Paulo, Sao Paulo, Brazil

⁶Consumers International, London, UK

⁷Public Health Foundation of India, New Delhi, India

Background and objectives: The International Network for Food and Obesity/NCD Research, Monitoring and Action Support (INFORMAS) is setting benchmarks for creating healthy food environments. This paper describes the framework for assessing the extent of children's exposure to food marketing and the nature of these promotions. A standardised framework is needed to allow comparisons between countries, between companies and between different time periods.

Methods: A review of studies measuring the nature and extent of food marketing was undertaken to identify approaches to monitoring across media platforms. This was supplemented with detailed methods used by the authors in national and international monitoring studies since 2007 to describe food marketing across multiple media, including television, print, internet and outdoor advertising.

Results: Food marketing studies indicate children in both high and low/middle income countries are exposed to large volumes of unhealthy food promotions on different media. Active monitoring using a standard assessment tools is currently underway in a range of countries, including China, Mongolia, Malaysia, Philippines and these 2012/3 data will be released. A step-wise approach to monitoring food marketing is proposed, suitable for differing levels of engagement and resources. This framework includes monitoring activities that assess the frequency of food promotions across different media and time points, and measures of persuasive appeal of promotions.

Conclusions: Globally, children are exposed to high volumes of unhealthy food promotions. The monitoring framework proposed here will assist in the implementation of the World Health Organization's set of recommendations on the marketing of foods and non-alcoholic beverages to children, which recognise the need for reducing the impact of unhealthy food marketing to children.

Key words: food; non-alcoholic beverage; marketing; monitoring; public health.

PO1298**MODELLING HEALTH BENEFITS OF FOLIC ACID FORTIFICATION IN NEW ZEALAND**

M. Gibbs¹, T. Ryan², C. Thornley¹

¹Science and Risk Assessment, Ministry for Primary Industries, Wellington, New Zealand

²Ryan Analysis Ltd, Raglan, New Zealand

Background and objectives: Higher intakes of folic acid in women are associated with a decreased risk of neural tube defect affected pregnancies (NTD). Accordingly, many Governments internationally have introduced mandatory folic acid fortification of cereal products. In 2012 the New Zealand government reviewed its folic acid fortification standard. The objective of this study was to estimate the effects of folic acid fortification of bread, in line with two proposed policy options, on the prevalence of NTDs in New Zealand to inform the review.

Methods: Two policy options were compared: mandatory fortification of bread at 140 ug per 100 g of bread; and lower proportions of bread fortified at 200 ug/100 g. A stochastic model was developed to estimate the effect of increased intake of folic acid through fortification of bread on the prevalence of NTDs. Available survey data on bread consumption and serum folate status were used to calculate the change in folate status post-fortification in a simulated population of women. Changes in folate status were applied to published equations to estimate reductions in NTDs from baseline prevalence rates.

Results: Mandatory folic acid fortification of bread, at 140 ug/100g, was estimated to result in a mean reduction of 17 (95%CI 14, 20) NTDs per year. Fortification of 70% of bread at 200 ug/100g resulted in a larger reduction than the equivalent proportion at a lower concentration (140 ug/100g), preventing 15 (95% CI: 13, 17) compared to 9 (95%CI 7, 11) NTDs per year, respectively.

Conclusions: Mandatory fortification had the greatest impact on reducing NTDs. However, fortifying a lower proportion of bread at a higher concentration had a similar impact. The effectiveness of folic acid fortification of bread can be improved either through increasing the proportion of bread fortified or level of fortification.

Key words: folic acid, fortification, neural tube defects.

PO1299**EVALUATION OF A COMMUNICATION STRATEGY ON CENTRAL ADIPOSITY***F. Fontes*¹

¹Ministerio de Salud, Departamento de Salud Nutricional, Panamá, Republic of Panama

Background and objectives: Obesity is increasing in the Republic of Panama, having a fourfold increase in prevalence among adults in the last 26 years. Recent studies revealed that six out of every ten adult Panamanians are overweight and were able to determine the relationship with cardiovascular diseases. A mass media campaign was carried out to increase awareness in the population about the consequences of excess body fat, focusing the communication strategy on central adiposity due to its cardiovascular risk. The objectives of this work were to assess the understanding of the campaign's message, to know the perception and awareness of the population regarding the consequences of central adiposity and to identify the most watched communication media.

Methods: a survey was conducted among 1,378 persons, with a non-probabilistic sample, by quotas, in all the 9 provinces and the 3 indigenous region of the country.

Results: 75.8% responded having seen or heard the Campaign; among these, 86.5% remembered the message correctly and 99.0% believed that fat around the waist was a health problem. Among those who saw the campaign, 82.5% responded having seen it on television, 23.4% on the radio and 9.6% in billboards.

Conclusions: Mass media campaigns, with well-defined objectives, are able to have an impact on the knowledge about a health problem and its consequences. Television has a high penetration in Panamanian households. Respondents reported having interest in the subject and requested follow-up to the mass media campaign, with topics aimed at decreasing central adiposity.

Key words: 'central adiposity', 'educational campaign in nutrition', 'mass media'.

PO1300**LOW BIRTH WEIGHT: COMPARISON OF TWO BIRTH COHORTS IN SÃO LUIS, NORTHEASTERN BRAZIL, 1997/98 AND 2010***H. Veloso*¹, *A. Silva*¹, *M. Barbieri*², *H. Bettiol*², *R. Batista*¹, *V. Simões*¹, *F. Lamy Filho*¹

¹UFMA, Sao Luis, Brazil

²USP Ribeirão Preto, Sao Luis, Brazil

Background and objectives: To analyze factors associated with LBW in São Luis comparing two birth cohorts with an interval of 12 years.

Methods: 2,426 births were analyzed in 1997/98 and 5,040 in 2010. The dependent variable was LBW considered birth weight (<2,500 g) and without LBW (>2,500 g). To verify the association of independent variables and LBW, multiple logistic regression was performed. Data were also obtained from SINASC to analyze stillbirths rate and LBW historical series from 1996 to 2010.

Results: LBW, intra-uterine restriction growth (IURG), preterm birth, maternal smoking and parity rates remained stable. Despite stabilization of LBW rate in the two cohorts, data derived from SINASC showed increasing rates of LBW until 2001 then a decline after that. Significant reduction was observed in rates of small for gestational age, teenage mothers, mothers with up to 4 years of education, family income up to the minimum wage and mothers who did not have prenatal care. There was an increase in mothers over 35 years with 12 or more years of schooling and who underwent prenatal properly. It was also observed a decrease in the rate of stillbirths coinciding with the period of highest elevation in the rate of LBW.

Conclusions: The stability of LBW rate in São Luis can be explained because IUGR and preterm birth rates remained stable in spite of improvement in maternal education, assistance to prenatal and delivery care. However, this apparent stability hides amid increased the period to 2001 and change in the pattern of the components of LBW, because in 2010 increased the proportion of births without LBW, preterm and not without IUGR. The rise and fall in the rate of LBW were parallel to the reduction of the stillbirth rate period, suggesting improvement in medical care.

Key words: Low birth weight. Prematurity. Cohort studies.

PO1301**DIETARY HABITS AMONG PRESCHOOL CHILDREN IN SEVERAL AREAS IN JAPAN***Y. Sato*¹, *R. Suzuki*², *Y. Sato*³¹National Institute for Environmental Studies, Japan²Tokyo Healthcare University, Japan³Yokohama National University, Japan

Background and objectives: Dietary habits during childhood have been widely studied, but epidemiologic data of recent dietary habits are insufficient in Japan, especially that for preschool children. We have planned a detailed dietary survey to examine the recent dietary pattern and other diet-related factors among preschool children living in Japan.

Methods: The survey began in March–June 2012. Subjects were enrolled by the network of society of dietitians and public health center. Their mothers and/or guardians (i.e., the person who prepared the child's diet) completed a questionnaire and dietary records. The questionnaire included questions about the child's physique, meal frequency, eating-out habits, use of supplements, and precooked/instant foods. It also included questions about the children's family, such as household income, number of family members, number of siblings, and characteristics of the mother and/or guardian (age, occupation, and education).

Results: A total of 467 children, aged 2–6 years and living in 13 prefectures in Japan (Hokkaido, Iwate, Miyagi, Gunma, Niigata, Ishikawa, Chiba, Tokyo, Kanagawa, Hyogo, Hiroshima, Kochi, and Kagoshima) participated in this study. Briefly, the characteristics of the mother and/or guardian as follows: median age was 36 years (range, 22–60 years), 53% were full-time housewives, 71% graduated from a university or college, 46% had an annual household income of 4–8 million yen. Additionally, almost 98% children had breakfast every day, 50% ate out less than once per week, 62% ate precooked foods almost once a month, and 7.2% used supplements.

Conclusions: We conducted a survey to reveal the recent dietary habits among preschool children. Basic data collected from several areas are apparently insufficient in Japan. This study provides useful epidemiologic data. Acknowledgements: This study was supported by research grants from Advanced Research Programs in National Institute for Environmental Studies, Japan.

Key words: Dietary habit, preschool children, Japan.

PO1302**ELEMENTS OF SOCIAL FRANCHISING IMPROVE THE QUALITY OF INFANT AND YOUNG CHILD FEEDING COUNSELING SERVICES IN GOVERNMENT CLINICS IN VIETNAM***P. H. Nguyen*¹, *P. Menon*², *S. C. Keithly*³, *S. Kim*⁴, *N. Hajeebhoy*⁵, *L. M. Tran*¹, *M. T. Ruel*⁴, *R. Rawat*⁴¹International Food Policy Research Institute (IFPRI), Hanoi, Vietnam²IFPRI, New Delhi, India³Institute of Social and Medical Studies, Hanoi, Vietnam⁴IFPRI, Washington DC, USA⁵FHI 360, Hanoi, Vietnam

Background and objectives: Evidence indicates that social franchising improves the quality of health services in developing countries but this approach has not been tested for nutrition services. Under the Alive & Thrive (A&T) initiative, elements of social franchising, particularly, standardized and branded services for infant and young child feeding (IYCF) counseling were introduced in 800 government-owned health centers as the first step towards establishing a social franchise service. This study assessed the role of the A&T interventions in shaping the quality of the counseling facilities and services.

Methods: Using a cluster-randomized design, process-related data were collected 12 months after implementation, to compare A&T-supported facilities (A&T-F, n=20) to standard facilities (SF, n=12) across 3 dimensions of service quality: structure, process and outcome that capture the quality of facilities, service delivery and client perceptions and use. Data collection included facility inventories (n=32), provider surveys (n=96), counseling observations (n=137), client exit interviews (n=137), and in-depth interviews with mothers (n=48).

Results: Structure: A&T-F facilities were more likely to have a well equipped room (65.0% vs. 10.0%) for nutrition counseling than SF. Process: A&T-F providers had slightly better knowledge of optimal IYCF practices, substantially better interpersonal counseling skills and offered longer and more focused counseling sessions. Outcome: While overall utilization was low given the early stage of implementation, utilization by pregnant women was satisfactory at 48.9%, compared with utilization by mothers with older infants (1.4%). Client satisfaction was not different between A&T-F and SF, but users valued the A&T-F facilities for problem solving on feeding issues.

Conclusions: Incorporating elements of social franchising significantly enhances the quality of nutrition counseling services within government primary health facilities. This model has the potential to improve IYCF practices provided utilization of services increases substantially.

Key words: social franchise, counseling, infant and young child feeding practices, quality of care, Vietnam.

PO1303**FATTY ACID INTAKES, PLASMA FATTY ACIDS AND MORTALITY: AN AUSTRALIAN PROSPECTIVE STUDY**

K. Miura¹, M.C. Hughes¹, T. Ibiebele¹, A.C. Green^{1,2}

¹Cancer and Population Studies Group, Queensland Institute of Medical Research, Brisbane, Queensland, Australia

²Manchester Academic Health Sciences Centre, University of Manchester, Manchester, UK

Background and objectives: High intakes of total fat and saturated fat are associated with increased mortality from cardiovascular disease (CVD) and cancer, whereas high intakes of omega-3 may reduce risk of CVD mortality. We aimed to examine the association between intake of major types of fatty acids, plasma polyunsaturated fatty acids and mortality from all causes, CVD, or cancer.

Methods: A 16-year prospective study was conducted in a community-based sample of Australian adults (25–79 years). Mean fatty acid intakes were estimated from food frequency questionnaires collected in 1992, 1994 and 1996. Plasma phospholipid fatty acid levels were measured in 1996. Death data from 1997–2012 were determined from the National Death Index. Hazard ratios (HR) and 95% confidence intervals (95% CI) were calculated according to tertiles of intake and plasma level.

Results: Of 1185 participants, 167 (14%) died during the follow-up period. Causes of death included cancer 60 (5%), CVD 67 (6%) and other causes 60 (5%). After adjusting for confounders, participants with the highest intakes of total fat (HR 2.14; 95% CI 1.08–4.23, *p*-trend=0.03) and saturated fat (HR 2.38; 95% CI 1.17–4.87, *p*-trend=0.02) had the highest risks of cancer mortality compared with the lowest tertiles. Intakes of total omega-3, omega-6, eicosapentaenoic (EPA) or docosahexaenoic acid (DHA) were not associated with mortality from any cause. Higher plasma EPA tended to reduce the risk of mortality (HR 0.69; 95% CI 0.46–1.04, *p*-trend=0.09). No other significant associations were observed.

Conclusions: Increasing intake of total fat and saturated fatty acids increased the risk of cancer mortality whereas high intakes or high plasma concentrations of omega-3 fatty acids did not show any effect. Food sources of fatty acids, omega-3 to omega-6 ratio, sex-specific effects and interaction with history of medical conditions will be explored.

Key words: Fatty acids, mortality, omega-3, omega-6.

PO1304**STOCKPILES AND FOOD SUPPLY AFTER GREAT EAST JAPAN EARTHQUAKE IN FEEDING FACILITIES**

M. Nozue¹, K. Ishikawa-Takata², N. Sarukura², N. Tsuboyama-Kasaoka^{3,4}

¹Center for International Collaboration and Partnership, National Institute of Health and Nutrition, Japan

²Department of Nutritional Education, National Institute of Health and Nutrition, Japan

³Department of Nutritional Epidemiology, National Institute of Health and Nutrition, Japan

⁴The Japan Dietetic Association, Japan

Background and objectives: Public concerns on stockpiles have increased after recent disaster worldwide. The purpose of this study was to clarify the stockpiles of food and drinking water before the Great East Japan Earthquake. In addition, food supply in feeding facilities after the Great East Japan Earthquake was also investigated.

Methods: Questionnaire survey was conducted to dietitians who belong to the Japan Dietetic Association in Iwate, Miyagi and Fukushima prefecture between August and October 2012. The questionnaire included items on types of feeding facilities, stockpiles of food, drinking water and food for special dietary uses (FOSDU) before the Great East Japan Earthquake. Situations of supply of food were also asked by period (within 3 days and 4 days to 1 month after the Great East Japan Earthquake).

Results: The surveys were completed by 435 dietitians (response rate: 21.8%). Dietitians who worked at feeding facilities and answered types of facilities where they belonged were included for analysis. 39.9% of subjects belonged to hospital, 32.5% belonged to facilities for elderly, 12.5% belonged to school and 15.1% belonged to other facilities. More than 70% of subjects in hospital and facilities for elderly answered that they had stockpiles of food and water. In school, 6.3% answered they had stockpiles of food and 23.5% answered they had stockpiles of drinking water. About situations of supply of food, supply of water, rice and vegetables were raised to 70%, but supply of dairy products was 40% within a month after the Great East Japan Earthquake.

Conclusions: Stockpiles of food and drinking water were varied by feeding facilities. Situations of food supply were different depending on food groups. These findings are helpful to consider future stockpiles of feeding facilities.

Key words: stockpiles, food supply, feeding facilities, Great East Japan Earthquake.

PO1305**CHARACTERISTICS OF SOLO-EATING AMONG YOUNG JAPANESE: DIFFERENCES IN MEAL OCCASIONS AND CONTEXTS**

M. Tsubota-Utsugi¹, W. Takeda², Y. Ohmori³, O. Yujin⁴, L. Youngmee⁵, N. Aiba³

¹Department of Nutritional Epidemiology, National Institute of Health and Nutrition, Tokyo, Japan

²National Centre for Epidemiology and Population Health, the Australian National University, Canberra, Australia

³Department of Nutrition and Life Science, Kanagawa Institute of Technology, Kanagawa, Japan

⁴Nutrition and Health Service Team, Korea Health Promotion Foundation, Seoul, Korea

⁵Department of Food and Nutrition, Gachon University, Seoul, Korea

Background and objectives: Recent studies show that solo-eating practice (eating alone) leads people's unhealthy eating behaviors and health outcome, e.g., overeating and depression. However, contexts of solo-eating practices in various meals (i.e., breakfast, lunch, dinner and snacking) have not yet reported. The aim of study is to identify characteristics of solo-eating practice in various meals.

Methods: A total of 753 university students (men 40.2%) who completed questionnaires were analyzed. Solo-eaters were defined by eating alone more than 2 times/day. The relationships with social (e.g., living arrangement, income), lifestyle (e.g., duration of sleep, wake-up/bed time, in/out campus activity, part-time job), psychological (e.g., self-rated health, fear of awareness), and contexts of each solo-eating practices (e.g., occasions, place, duration, and frequency) were examined.

Results: Among participants, 307 solo-eaters (men 41.0%) were identified. In multiple logistic regression analysis, several factors were associated with a high frequency of solo-eating [Odds Ratio (95% Confidence Interval); living alone 4.04 (2.74-5.97), early wake-up (before 6 a.m.) 0.50(0.32-0.80), scholarship recipients 1.73(1.17-2.54), and higher income (> 40,000 yen per month) 1.50 (1.01-2.21), respectively]. For contexts of solo-eating practices, less vegetable eater for breakfast[2.82 (1.31-6.06)], those who always think of meal balance for lunch[2.27 (1.01-5.10)], those who keep eating as long as food is available for dinner [1.93 (1.07-3.48)], and those who snack in less than 5 minutes [1.48 (1.02-2.15)] were significantly associated with solo-eating.

Conclusions: The present study revealed different characteristics for solo eating in meals. This finding provides in-depth understanding of solo-eating practice among young people, and contributes to more effective development of nutrition education guideline.

Key words: Solo-eating (eating alone), Japanese, University student, Food intake

PO1306**ABDOMINAL OBESITY ASSOCIATED TO FOOD INSECURITY IN YOUNG ADULTS FROM TABASCO, MEXICO**

A E. Sierra-Ovando¹, F. Lopez-Mendoza², L. A. Barragan-Lizama¹, J. Milla-Aguilar¹, L. J. Quiñones-Diaz¹, E. Pichardo-Ontiveros³, X. Formiguera-Sala⁴

¹Centro de Investigación División Académica de Ciencias de la Salud, Universidad Juárez Autónoma de Tabasco, Villahermosa, Tabasco, México

²Consultora Independiente, Ciudad de México, México

³Instituto Nacional de Ciencias Medicas y Nutrición Salvador Zubirán, Ciudad de México, México

⁴Institut Català pel Tractament i Recerca de l'Obesitat. Barcelona, España

Background and objectives: Food security, FS is a high priority issue for all nations, its main objective is to promote physical and economic access to safe and nutritious food in order to cover specific needs for an active and healthy lifestyle. A menace to food security is the failure of a sufficient supply and availability of adequate food which can generate a food gap between supply and demand. Globalization has helped to close such gap, especially in urban areas; however, access to certain foods may not be suitable for healthy eating, for example food offered at coffee shops of universities. The globalizing phenomenon increase diseases such as metabolic syndrome and abdominal obesity AO, which has proven to be an indicator of metabolic risk. The aim of this study is to determine the correlation between the degree of food insecurity and abdominal obesity in young adults from a university of Tabasco.

Methods: Evaluation of anthropometric parameters and dietary intake by 24 hours reminders. The study describes the food offered at the university's coffee shops analyzing breakfast, snack and lunch content.

Results: 197 people 75.5% female and 24.5% male with a mean age between 30.47 ± 10.92 years old. Findings: 80.9% of AO; food consumption: 69.2% sugary drinks, 35.8% carbonated beverages, 27% pastries, 66.7% red meat, 37.1% fish, 65.4% chicken, 70.4% milk, 51% fries, 86.2% vegetables, 69.8% fruits, 30.2% nuts and 85.5% cereal. People without AO consumed less sugary drinks and have a higher fruits, vegetables, milk, and cereal intake.

Conclusions: As a result of a positive correlation between AO and consumption of foods with low nutritional level, limited availability of food with adequate nutritional quality produce food insecurity. Nutrition intervention programs are needed to promote FS and close the food gap between supply and demand of nutritious food abdominal-obesity, food-insecurity.

Key words: Obesitiy, youth, Tabasco.

PO1307**CONTRIBUTION OF A SCHOOL MEAL TO ENERGY AND NUTRIENT INTAKES OF SELECT FILIPINO SECONDARY SCHOOL STUDENTS**

I. Angeles-Agdeppa¹, A. Eilander², C. Magsadia¹, K. van Elk², M. Principe³, J. Buenviaje³, C. Patalen¹

¹Department of Science and Technology, Food and Nutrition Research Institute, Philippines

²Unilever R&D Vlaardingen, The Netherlands, Netherlands

³Unilever Philippines, Manila, Philippines

Background and objectives: Currently, Filipino school canteens serve meals consisting mostly rice, meat or fish, and minimal fruits and vegetables. Nutri-meals, representing major food groups, were developed to increase energy intake and nutrient balance, while maintaining the liking of the meal. The study aims to assess the energy and nutrient intake and liking of nutri-meals compared to regular school meals.

Methods: About 112 Filipino students aged 13-16 years participated in the study. The first two weeks of the study, students consumed the regular school meal for 5 d/wk (baseline), followed by 7 weeks of nutri-meal consumption. Actual consumption of meals was calculated by weighing plate waste per dish which was subtracted from the portion size served. Consumption was converted into nutrient intake using USDA and local food composition tables. Differences in nutrient intake between regular and nutri-meals were calculated with mixed model ANOVA. Liking was measured directly after every meal using a self-administered questionnaire to a random subsample of 22 students.

Results: Preliminary results showed that students consumed significantly more vegetables (+ 80±1 g), fruits (+ 77±1 g), fish (+ 19±0.3 g) and less meat (-17 ±0.5 g), all $P < 0.001$) from nutri-meals compared to regular meals. Consequently, intakes of energy (+ 125±3 kcal), protein (+ 2.8±0.1 g), and micronutrients from the nutri-meals were significantly greater, all $P < 0.001$, except for zinc (- 0.37±0.02, $P < 0.001$). Data of the liking questionnaire is currently being analysed.

Conclusions: The school meals were effective in increasing energy and nutrient intake. However, it remains difficult to meet energy and nutrient requirements, due to factors such as budget restrictions for school meals and food preferences of the students. Further optimization of the school meal composition is needed, and micronutrient fortification and nutrition education are essential strategies to address the nutrient gap.

Key words: school meal, dietary intake, adolescents.

PO1308**THE INFORMAS FRAMEWORK FOR ASSESSING THE IMPACT OF TRADE AGREEMENTS ON FOOD ENVIRONMENTS AND OBESITY RISK**

S. Friel¹, C. Hawkes², D. Sanders³, L. Hattersley¹, W. Snowdon⁴, T. Lobstein⁵, A M. Thow⁶

¹National Centre for Epidemiology and Population Health, The Australian National University, Canberra, ACT, Australia

²Policy and Public Affairs, World Cancer Research Fund, London, UK

³School of Public Health, University of the Western Cape, Cape Town, Western Cape, South Africa

⁴C-POND, Fiji National University and Deakin University, Suva, Fiji

⁵International Association for the Study of Obesity, London, UK

⁶Menzies Centre for Health Policy, School of Public Health, The University of Sydney, Sydney, NSW, Australia

Background and objectives: The International Network for Food and Obesity/NCD Research, Monitoring and Action Support (INFORMAS) was established to monitor and support upstream actions for creating healthy food environments to reduce the burden of obesity and NCDs. The INFORMAS Trade and Investment module is concerned with monitoring the risks and benefits to food environments and diets from trade agreements. Trade underlies many of the upstream drivers of contemporary food environments, because it shapes the availability, price, nutritional quality, and promotion of foods for human consumption.

Methods: Based on a systematic review of the published literature on the relationship between trade agreements, food environments and diets, a framework was developed to monitor the actual and potential impacts of trade agreements on national food environments.

Results: The proposed monitoring system encompasses a set of guiding principles, recommended procedures for data collection and analysis, and quantifiable minimal, expanded, and desirable indicators relating to the form and scope of trade agreements, trade in goods, trade in services, foreign direct investment, and policy space and governance. The framework is intended to be used by countries during both the negotiation and implementation phase of a trade agreement to assess how the provisions may facilitate or inhibit healthy food environments, and to identify potential measures to mitigate the adverse impacts, and enhance the positive impacts, of that agreement. The framework is designed to support monitoring of impacts over time and, where possible and relevant, comparison between jurisdictions.

Conclusions: When conducted in the context of a multi-level obesity monitoring system, as proposed by INFORMAS, systematic monitoring of trade agreements and their potential positive and harmful impacts on food environments is essential for the development of effective policy approaches aimed at reducing the burden of obesity and NCDs.

Key words: Obesity, Trade agreements, Food environments, Monitoring.

PO1309

EFFECTS OF EXERCISE TRAINING AND DETRAINING ON FATTY LIVER IN ZUCKER FATTY RATS.

Y. Shiroya¹, Y. Kurosaka¹, H. Kitamura¹, K. Minato¹, H. Yamauchi²

¹School of Human Ecology, Wayo Women's University, Ichikawa, Chiba, Japan

²Jikei University School of Medicine, Tokyo, Japan

Background and objectives: Exercise training is commonly recommended for prevention and amelioration of obesity and lifestyle-related diseases. We have recently shown that exercise training with diet-restriction may improve fatty liver in obese rats. The aim of this study was to investigate whether the exercise training-induced improvements in fatty liver of Zucker Fatty rats are influenced by detraining.

Methods: Male Zucker Lean rats were used as control (LC). Male Zucker Fatty rats were divided into 3 groups; Obese (OB), Trained (TR) and Detrained (DTR) groups. The LC and OB rats had free access to food, the TR and DTR rats had food intake restricted to 78 % of the OB group level. The TR and DTR rats were exercised voluntarily on the wheel ergometer with a load of 30 % on their body weight every day. Following 4 weeks of exercise training, DTR rats were kept inactive (i.e., detrained) for 2 weeks with free access to food. After 6 weeks, all rats were prepared for experiment. The liver was excised and weighed. Hepatic tissue was prepared for transmission electron microscopy.

Results: OB rats became overweight, exhibited elevated levels of hepatic triglycerides, and electron micrographs revealed numerous lipid droplets in the hepatocytes. Voluntary wheel running attenuated weight gain and reduced serum glucose and triglycerides in TR rats compared with OB rats. Hepatocytes from TR rats also showed reduction of lipid droplets. However, detraining increased body weight, elevated serum triglycerides, and further accumulated lipid droplets in the hepatocytes.

Conclusions: Exercise-induced improvements observed in fatty liver were not long lasting, since they were reversed toward the obese rat levels after 2 weeks of detraining.

Key words: exercise training, detraining, fatty liver, electron microscopy, obesity.

PO1310

EFFECTS OF EXERCISE AND DIET RESTRICTION ON THE EXPRESSION OF HEPATIC FAT/CD36 IN ZUCKER FATTY RATS

Y. Kurosaka¹, H. Kitamura¹, H. Yamauchi², Y. Shiroya¹, K. Minato¹

¹Wayo Women's University, Chiba, Japan

²Jikei University School of Medicine, Tokyo, Japan

Background and objectives: We recently reported that diet restriction may facilitate fatty liver while voluntary exercise may suppress fat accumulation in the liver of fasted fatty rats. Fatty acid translocase (FAT/CD36) is a key protein involved in regulating the uptake of fatty acid (FA) in the liver. The purpose of the present study was to investigate the effects of exercise and diet restriction on FAT/CD36 protein expression in the liver of Zucker fatty rats.

Methods: Male Zucker lean rats were used as the control group (L, n = 8). Male Zucker fatty rats were divided into obese (Ob, n = 8), diet restriction (DR, n = 8), and diet restriction+exercise (DR+Ex, n = 8) groups. The rats in the L and Ob groups had free access to food. Food intake in the DR and DR+Ex groups was restricted to 67% and 70% of the Ob group level, respectively. The rats in the DR+Ex group voluntarily exercised on a wheel ergometer with a load of 30% of their body weight. After 6 weeks, all rats were prepared for the experiment. Blood was collected to measure serum leptin and free fatty acid (FFA) levels. Liver tissue samples were excised to measure the hepatic triglyceride (TG) content and the FAT/CD36 expression level.

Results: Hepatic TG content, serum FFA, and serum leptin levels were significantly higher in the DR group than in the Ob group whereas significantly lower in the DR+Ex group than in the Ob group. Hepatic FAT/CD36 expression was significantly higher in the DR group than in the Ob and DR+Ex groups.

Conclusions: These results suggest that hepatic FAT/CD36 expression may contribute to the effect of exercise and diet restriction on fatty liver.

Key words: Fatty liver, obesity, lifestyle diseases.

PO1313**ASSOCIATION OF PHYSICAL ACTIVITY WITH EATING HABITS AND KAUP INDEX IN PRESCHOOL-AGED JAPANESE CHILDREN.***K. Minato¹, H. Kitamura¹*¹Exercise Physiology, Wayo Women's University, Ichikawa, Chiba, Japan

Background and objectives: The results of recent lifestyle surveys in Japan have indicated that Japanese children take nutritionally inadequate meals, and are physical inactive. We have developed a physical activity (PA) questionnaire for the evaluation of PA status of adults. The purpose of this study was to determine whether habitual physical activity was associated with food habits and Kaup Index in preschool-aged Japanese children using our PA questionnaire for children and food-frequency questionnaire.

Methods: We surveyed 980 nursery-school children (1-5 years old), all residents of Funabashi city (a suburb of Tokyo). We assessed their PA and food intake (FI) with original questionnaires answered by their mothers. Furthermore, we assessed their mothers PA with the questionnaires for adults. Based on the results of the questionnaires, we estimated a PA score and a FI score. A one-way ANOVA was used to compare the differences among the three classes of PA scores.

Results: Mean PA score of children was 15.8 (range: 4-23, max: 26). Mean PA of their mothers was 13.8 (range: 2-25, max: 28). Mean FI score of children was 26.7 (range: 6-55, max: 60). Mean Kaup Index (KI) of children was 15.7 (range: 9.8-32.7). There was a significant difference in PA score of children among the three classes of PA score of their mothers. There were significant differences in both FI score and KI among the three classes of PA score of children.

Conclusions: Physical activity levels of preschool-aged children were affected by their mothers' active lifestyle. High PA score associated with high FI score, and low KI in preschool-aged Japanese children. A more active lifestyle may improve eating habits and anthropometric characteristics of children.

Key words: preschool-aged children, physical activity, food intake, Kaup Index.

PO1314**PROMOTION AND ASSESSMENT OF NUTRITION AND HEALTHY LIFESTYLE IN THE WORKPLACE: PHILIPPINES' DOST EXPERIENCE***C. Javier¹, M. Capanzana¹, R C. Tan¹, N L. Santos¹*¹Food and Nutrition Research Institute, Department of Science and Technology, Philippines

Background and objectives: The Department of Science and Technology (DOST) in the Philippines conducted a wellness activity which aimed to promote healthy lifestyle among employees. The event promoted the tagline, "Science in Wellness. Wellness in Science", to emphasize the scientific way to wellness, and that people in the science community should achieve good nutritional well-being and practice healthy lifestyle both in the workplace and outside.

Methods: The event was open to all DOST employees. A fun run and aerobic dancing sessions were organized. All participants were given fitness passes. A total of five fitness stations were set up, including BMI and blood pressure assessment booths and nutrition counselling. Participants received rewards if they received services from the five fitness stations as indicated by the five stamps in the fitness pass. To further promote healthy eating, nutritious breakfast was distributed among the participants.

Results: The event was participated in by 645 employees and executive officials of the Department. Participants were asked about their fitness goals and the top three responses were to live longer (13.5%), increase stamina (13.2%) and look great (12.9%). Some said they want to lose weight (11%) and increase strength (10.4%). In terms of BMI, 61.2 percent were normal, 28.7 percent were overweight, 4.8 obese, and 5.3 percent were underweight. In terms of blood pressure measurement, 77.1 percent were normal, 12.0 percent were pre-hypertensive, while the rest were hypertensive. Those who were found overweight, obese and hypertensive were given health and nutrition counselling by doctors and nutritionists, respectively.

Conclusions: The active participation of employees showed commitment to live a more fit and healthy lifestyle. Other activities to complement the event and support sustainability of the employees' pledge to practice healthy lifestyle must be implemented.

Key words: nutrition promotion, wellness, employee fitness.

PO1315**DIETARY FAT AND BREAST CANCER SURVIVAL: A SYSTEMATIC REVIEW AND META-ANALYSIS.**

S. Brennan¹, J. Woodside¹, M. Lunny¹, C. Cardwell¹, M. Cantwell¹

¹Centre for Public Health, Institute of Clinical Sciences B, Queen's University Belfast, Northern Ireland, UK

Background and objectives: A positive association between dietary fat and breast cancer risk has been previously reported but its influence upon survival is unclear. As the number of breast cancer survivors increases worldwide, the aim of this review and meta-analysis is to critically appraise the published literature and conduct meta-analyses to clarify the association between dietary fat and breast cancer survival.

Methods: Articles published up to March 2011 that examined dietary fat and breast cancer recurrence/survival were identified from searches in MEDLINE and EMBASE. Meta-analyses were conducted in which we evaluated the risk of all-cause or breast cancer specific death in women in the highest compared with the lowest categories of intake and per 20 gram increase in total and saturated fat intake (g/day). Multivariable adjusted hazard ratios (HR) and 95% CIs from individual studies were weighted and combined using a random-effects model to produce a pooled estimate.

Results: Fifteen prospective cohort studies investigating total fat and/or saturated fat intake (g/day) and breast cancer mortality were included. There was no difference in risk of breast cancer specific death (n=6; HR=1.14; 95% CI: 0.86, 1.52; P=0.34) or all cause death (n=4; HR=1.73; 95% CI: 0.82, 3.6; P=0.15) for women in the highest versus lowest category of total fat intake. Breast cancer specific death (n=5; HR=1.63; 95% CI: 1.19, 2.24; P<0.01) was however higher for women in the highest versus lowest category of saturated fat intake. No trends were observed per linear (20 gram) increase in intake of total or saturated fat.

Conclusions: The results of this systematic review and meta-analysis suggest that a lower saturated fat intake is associated with a lower risk of breast cancer death. Modification of dietary intake, to reduce saturated fat intake may therefore be warranted.

Key words: Breast cancer survival; dietary fat.

PO1316**AUTUMN VITAMIN D STATUS IN 782 EIGHT-ELEVEN YEAR OLD DANISH CHILDREN - PRELIMINARY RESULTS FROM THE OPUS SCHOOL MEAL STUDY.**

R A. Petersen¹, C T. Damsgaard¹, S. Dalskov¹, L B. Sørensen¹, R P. Laursen¹, L. Kjølbaek¹, R. Andersen², I. Tetens², H. Krarup³, A. Astrup¹, K F. Michaelsen¹, C. Mølgaard¹

¹Department of Nutrition, Exercise and Sports, Faculty of Science, University of Copenhagen, Denmark

²Division of Nutrition, The National Food Institute, Technical University of Denmark, Denmark

³Department of Clinical Biochemistry, Section of Molecular Diagnostics, Aalborg University Hospital, Aalborg, Denmark

Background and objectives: Low vitamin D concentrations are frequently reported among groups of children and adolescents at northern latitudes, particularly during winter. Negligible solar UVB radiation from October-March at latitudes above ~52°N is acknowledged as a major determinant. Few studies have focused on status and determinants of vitamin D in Nordic school children during autumn where UVB has recently peaked. Objective: To evaluate and identify determinants of vitamin D status in 782 healthy 8-11 year old Danish children (55°N) during September-November.

Methods: Cross-sectional baseline study from the OPUS (Optimal well-being, development and health for Danish children through a healthy New Nordic Diet) School Meal Study, including 3rd and 4th graders from nine schools. In autumn 2011, a fasting blood sample was drawn and serum 25-hydroxyvitamin D (25(OH)D) analysed (CLIA). Background interviews were conducted and anthropometry, puberty stage, dietary intake and intake of dietary supplements registered. Data analyses by linear mixed model.

Results: Serum 25(OH)D ranged from 15.2 to 132 nmol/l, with mean of 60.8 nmol/l±18.7. Twenty-six per cent of the children had concentrations between 25-50 nmol/l, while 2.4% had concentrations <25 nmol/l. 25(OH)D was inversely associated with age, was higher in boys, Caucasians, children who had ancestral roots in Denmark, who took dietary supplements >3 days a week (n=305), or whose parents had educational levels >16 years, (All p<0.05). Also, 25(OH)D was lower in November compared to September and October (p<0.05). BMI, waist circumference, dietary vitamin D intake and puberty stage were not associated with 25(OH)D.

Conclusions: A substantial number of children did not reach the recommended 50 nmol/l of serum 25(OH)D despite the recent seasonal peak in solar UVB radiation. Body composition and dietary intake of vitamin D was not found to be determinants in autumn.

Key words: Vitamin D, Children. OPUS is supported by a grant from the Nordea Foundation.

PO1317**RELATIONSHIP BETWEEN BONE MINERAL DENSITY AND ALCOHOL CONSUMPTION IN KOREAN MEN**

H. Kwon¹, B. Cho², C-M. Lee¹, K.Y. Son², H.C. Cho²

¹Seoul National University Hospital Healthcare System Gangnam Center, Korea

²Seoul National University Hospital, Korea

Background and objectives: In recent days, interest in osteoporosis in men is increasing. One of the risk factors, drinking, is a common problem in Korean men. However, there are controversies about the relationship between alcohol consumption and bone mineral density (BMD). No study using large-scale data has been reported in Korea.

Methods: A cross-sectional study was performed on 2,421 men aged over 40-93y from the fourth Korea National Health and Nutrition Examination Survey in 2008-2009. Alcohol intake was calculated by self-administered questionnaire and BMD was measured by dual energy x-ray absorptiometry. ANOVA was used to find the relationship between alcohol intake and BMD, and ANCOVA was done after adjustment for age, body mass index (BMI), education, house income, smoking status, calcium intake, physical activity and serum 25-hydroxyvitamin D level.

Results: With increasing alcohol intake, BMD increased significantly in the lumbar spine, femur total and femoral neck (p for trend=0.028, p for trend <0.001, p for trend <0.001, respectively). But, after adjustment for age, statistical significance disappeared in all three bone sites (Lumbar; p for trend=0.606, Femur total; p for trend=0.342, Femoral neck; p for trend=0.549). In addition, after adjustment for age, BMI, education, house income, smoking status, calcium intake, physical activity and serum 25-hydroxyvitamin D level, no significant relationship was reported in all three bone sites (Lumbar; p for trend=0.451, Femur total; p for trend=0.150, Femoral neck; p for trend=0.343).

Conclusions: In Korean men, after adjustment for age and other confounders, no significant relationship was reported between alcohol intake and BMD

Key words: Osteoporosis, Alcohol, Bone density.

PO1318**THE ATTITUDES, INTENTIONS, PERCEPTIONS AND BEHAVIOUR OF OBESE PEOPLE IN RELATION TO THEIR WEIGHT, WESTERN AUSTRALIA 2009**

C. Pollard^{1,2}, A. Daly¹

¹School of Public Health and Curtin Health Innovation Research Institute, Faculty of Health Sciences, Curtin University, Perth, Western Australia, Australia

²Department of Health in Western Australia, Royal Street Eat Perth, Western Australia, Australia

Background and objectives: Obesity is rising annually in Western Australia. Knowledge of intentions, influences, steps and difficulties around losing weight is critical to developing effective interventions. This study aims to identify how obese people perceive themselves in relation to their weight.

Methods: The 2009 Nutrition Monitoring Survey conducted telephone interviews with a random sample of 1284 adults aged 18 to 64. Self-reported height and weight, perceptions and intentions regarding weight loss and knowledge of the health effects of being overweight were measured. BMI was calculated using the WHO methods adjusted for over-reporting of height and under-reporting of weight. Data were weighted for probability of selection and adjusted to the 2009 age, sex and area of residence distribution of the population.

Results: Chi Square and WALD tests were used to determine significant differences. Ten percent of obese adults (BMI > 30) thought their weight was 'about right'. Compared with people who are not obese, obese people reported no willpower to exercise (3.8 vs 9.6 p<.001) and no willpower to eat better (4.3 vs 11.3 p<.001). A fifth of obese adults weighed more now than 12 months ago, and 19% of these were currently doing nothing about their weight. Only 12.7% of obese adults reported being influenced by a doctor to lose weight. Obese people were more likely to report difficulties losing weight compared with those who were not obese (0.9 vs 1.3; F=30.9 p<.001). Knowledge of health effects of excess weight was low.

Conclusions: Knowing what obese adults find difficult about losing weight is important for development of interventions. Over optimistic perception of current weight and poor knowledge of the health effects of excess weight may be barriers to change. Acknowledgements: Healthway funded Curtin University to assist the translation of research into practice.

Key words: obesity, perceptions, attitudes, behaviour.

PO1319**NNR 2012: NORDIC NUTRITION RECOMMENDATIONS – INTEGRATING NUTRITION AND PHYSICAL ACTIVITY**

W. Becker¹, S A. Anderssen², M. Fogelholm³, I. Gunnarsdottir⁴, U K. Koivisto Hursti¹, H M. Meltzer⁵, A N. Pedersen⁶, U. Schwab⁷, I. Tetens⁶, E. Wirfält⁸

²Department of Sports Medicine, Norwegian School of Sport Sciences, Oslo, Norway

³Department of Food and Environmental Sciences, University of Helsinki, Helsinki, Finland

⁴Unit for Nutrition Research, Faculty of Food Science and Nutrition, School of Health Sciences, University of Iceland & Landspítali-University Hospital, Reykjavik, Iceland

⁵Department of Food Safety and Nutrition, The Norwegian Institute of Public Health, Oslo, Norway

⁶Department of Nutrition, National Food Institute, Technical University of Denmark, Copenhagen, Denmark

⁷Institute of Public Health and Clinical Nutrition, Department of Clinical Nutrition, University of Eastern Finland, Kuopio Campus, and Kuopio University Hospital, Kuopio, Finland

⁸Department of Clinical Sciences in Malmö, Nutrition Epidemiology, Lund University, Malmö, Sweden

Background and objectives: The Nordic countries have collaborated in setting guidelines for dietary composition and recommended intakes of nutrients for several decades. The Nordic Nutrition Recommendations (NNR) are based on current scientific knowledge taking into consideration the current nutritional situation in the Nordic countries. The NNR constitute the scientific basis for planning and assessing diets for population groups, and form the basis for the development of national guidelines for food-based dietary guidelines and physical activity in the Nordic countries. The NNR give reference values for the intake of and balance between individual nutrients which, based on current scientific knowledge, are adequate for development and optimal function and reduce the risk of development of certain diet-related diseases. The NNR are currently being updated using an evidence-based approach. Systematic reviews (SR), covering years 2000–2012, have been applied, including a quality assessment of all pertinent studies and grading of the overall evidence for selected nutrients/topics. Previous editions mainly focused on setting dietary reference values (DRVs) for the intake of, and balance between, individual nutrients. The current 5th edition puts the whole diet in focus and more emphasis is given to the role of die-

tary patterns and food groups contributing to the prevention of diet-related chronic diseases. Also, the NNR emphasize the importance of adequate physical activity that in combination with a food pattern supports maintenance of a healthy body weight in the long-term. Most of the recommendations from the 4th edition (2004) are proposed to remain unchanged. Proposed changes include increased recommended intakes (RI) for vitamin D and selenium. Also, more emphasis is put on quality of fats and carbohydrates and their dietary sources. NNR 2012 will be launched in June 2013, after being subject to an open public consultation. All information about the project is available at www.nnr5.org.

PO1320**INCREASING THE NUTRITIONAL IMPACT OF THE INDONESIAN CONDITIONAL CASH TRANSFER PROGRAM: EVIDENCE FOR SOCIAL PROTECTION POLICY**

A. Usfar¹, S. Nazara¹, F. Howell¹, P. Agnew¹

¹Secretariat of The National Team For The Acceleration of Poverty Reduction, Indonesia

Background and objectives: The government of Indonesia implements a Conditional Cash Transfer (CCT) program targeted at very poor households, with pregnant or lactating women, and children conditioned on the use of basic health and education services. Initial reviews of the program showed higher protein intake by beneficiaries. This presentation aims to highlight the nutritional requirements and gaps of the target families of the CCT program and proposes interventions to increase the nutritional impact of the program.

Methods: A calculation of the macro-and-micronutrient requirements of an average beneficiary family of four was conducted and broken down by family members based on age, sex, and activity. The results were then compared with national & international standards to estimate gaps and develop recommendations.

Results: The main identified gaps are low intake of energy, protein and iron leading to anemia of women of reproductive age and children under the age of five. To address these, a series of focused interventions are proposed: provision of 15 kg of fortified rice/family/month; 6 kg of eggs/month; multiple micronutrients for the mother and child under-five; deworming for children 12-59 months; zinc for diarrhea for children 6-59 months; and an additional cash transfer of USD 10/month. The rice and the egg contribute to nearly two-thirds of the energy and protein adequacy of the mother respectively, and fulfilling the adequacy of both nutrients for the children under-five. With the provision of the above, the household would only need to complement USD 25 monthly to cover nutrients for other family members.

Conclusions: Development of a series of interventions to address identified nutritional gaps within a piloted study.

Key words: Conditional Cash Transfer, Indonesia, Nutrition.

PO1321

THE EFFECT OF AN INDIVIDUALLY TAILORED NUTRITION INTERVENTION FOR DUTCH PARENTS ON DIETARY INTAKE AND PHYSICAL ACTIVITY OF THEIR CHILDREN

E. Hooft Van Huysduynen¹, L. van Lee¹, A. Geelen¹, E. Feskens¹, P. van 't Veer¹, C. van Woerkum², J. de Vries¹

¹Division of Human Nutrition, Wageningen University, The Netherlands

²Division of Communication Sciences, Wageningen University, The Netherlands

Background and objectives: Parents are an important role model of a healthy diet for their primary schoolchildren. To improve the diet of parents, an intervention strategy was evaluated. The objective of our study was to determine the effect of an individually tailored nutrition intervention for parents on dietary intake and physical activity of their children.

Methods: In total, 165 Dutch participants with children aged 4-12 were randomized to intervention or control group. During five visits distributed over a six-month intervention period, the dietician provided dietary counselling based on motivational interviewing and the Dutch guidelines for a healthy diet. During the six-months the dietician also sent the participants three personalised e-mail messages based on the participant's goals and dietary intake. The dietary counselling and the e-mails were focused on the parent taking the family setting into account. The control group did not receive any treatment. Before and after the intervention period, participants filled in a questionnaire on dietary intake and physical activity of their child.

Results: The fish intake of the children in the intervention group increased by 1.1 portions per month and the fruit and vegetable intake by 1.4 and 1.6 portions per week, respectively. These increases were significantly larger than in the control group. In addition, the intake of soda decreased by 2 glasses and the intake of snacks by 1.8 portions per week, and physical activity increased by 30 min per week. However, these changes were not significantly different from the control group.

Conclusions: The present study is one of few studies studying the effect of an intervention tailored to the diet of the parent on the dietary intake of their children. We conclude that focussing on the parents' diet is beneficial on fish, fruit and vegetable intake of children.

Key words: intervention, dietary intake, parents, children.

PO1322

THE IMPORTANCE OF HAVING INTEREST IN COOKING AND VEGETABLES AND FRUIT INTAKE FOR CHEWING CONSCIOUSNESS IN PRIMARY SCHOOLCHILDREN

N. Tanaka¹, T. Okuda², H. Shinohara³, I. Hamaguchi⁴, Y. Asano⁵, Y. Higashine⁶, J. Kang⁷, K. Wakimoto⁸, N. Hirano⁹

¹Faculty of Home Economics, Kobe Women's University, Kobe, Japan

⁷Department of Nutrition, Hyogo NCC College, Nishinomiya, Japan

⁸Nishitani Primary School, Takarazuka, Japan

⁹Department of Food and Nutrition Science, Kobe Women's Junior College, Kobe, Japan

Background and objectives: The chewing ability is one of important factors for good health and thus for developing and educating dietary good habits. Recently, the decrease in chewing abilities of children is discussed. We examined their chewing consciousness and its relation to daily and dietary habits through questionnaire survey.

Methods: Questionnaire survey about daily and dietary habits was done in 592 children (294 males and 298 females, 11-12 years old) from four primary schools at the Kansai area in Japan. When high score was allotted in their better habits, there were significantly positive correlations between gCC: chewing consciousness and gHIC: having interest in cooking h or gFVFI: frequency of vegetables and fruit intake h. According to each category score, they were divided into high and low score groups. Statistical analysis in contingency tables was done by chi-square test. And then the multiple regression analysis, as CC or gLMLA: learning motivation and learning attitude h with a dependent variable, was done.

Results: In the higher score group of HIC, scores of FVFI, CC, and LMLA were significantly higher than those in the lower score group of HIC. In the higher score of FVFI, scores of HIC, g playing sports and studying well h, and also CC were significantly higher than those in its lower score group of FVFI. The multiple regression analysis, as CC with a dependent va-

riable, indicated that CC was affected by HIC and FVFI with 27 % coefficient of determination. Also, LMLA was affected by FVFI, g self-efficacy h, g refrain from between meals and eating outside h, and CC with 23% coefficient of determination.

Conclusions: The present analytical results indicated that the chewing consciousness was affected by having interest in cooking and frequency of vegetables and fruit intake, and the learning motivation and learning attitude was affected by FVFI and CC.

Key words: chewing consciousness, cooking, vegetables.

PO1323

HOW MEALS INTAKE BEHAVIOURS ARE RELATED TO FRUIT AND VEGETABLES CONSUMPTION IN SPANISH ADULTS?

K. Keller¹, S. Rodríguez López¹, M. Carmenate Moreno¹, P. Acevedo Cantero¹

¹Department of Biology, Universidad Autónoma de Madrid, Madrid, Comunidad de Madrid, Spain

Background and objectives: Despite the strong evidence that fruit and vegetables are health promoters against chronic diseases, their intake is reduced in many countries. Therefore, we aimed to identify meals intake behaviours, which might lead to a recommended consumption of fruit (RCF) and vegetables (RCV).

Methods: During the events “Jornadas de Prevención en Salud” in four Spanish cities in 2008, we collected data from 958 women and 543 men (aged 20-89) about their daily intake of fruit and vegetables, the number and kind of meals, and snacking patterns between meals. A recommended intake was assumed when more than one ration of fruits (RCF) and vegetables (RCV) was consumed. We used χ^2 -tests to determine differences within RCF and RCV in the categories of the meals intake behaviours variables.

Results: A greater number of persons showed a RCF when compared with the RCV (75, 9% vs. 38, 0% in women; 71, 3% vs. 28, 5% in men). Consuming four/five meals daily vs. three meals, breakfast, forenoon and afternoon meals, and abstaining from snacking, leads to a higher frequency of women with a RCF, whereas the number of women having a RCV is greater when five meals daily and forenoon meal ($p < 0, 05$) are consumed. A higher number of men achieve RCF when having four/five meals daily, breakfast and afternoon meal. The same applies for the RCV, but with the forenoon meal instead of the breakfast ($p < 0, 05$).

Conclusions: The investigated meals intake behaviours are related with the number of persons consuming the recommended servings of fruit and vegetables, but which of them leads to a higher RCF and RCV depends on sex.

Key words: meals intake behaviours, fruit and vegetables consumption, Spanish adults
Acknowledgements: The “Universidad Autónoma de Madrid” supported this work by providing a studentship to one of the authors.

NON-EXERCISE ALGORITHMS TO ESTIMATE CARDIORESPIRATORY FITNESS: ASSOCIATIONS WITH MORTALITY AND NON-FATAL CARDIOVASCULAR DISEASE

E G. Artero^{1,2}, X. Sui², A S. Jackson³, S N. Blair^{2,4}

¹Area of Physical Education and Sport, Department of Education, University of Almería, Spain

²Department of Exercise Science, Arnold School of Public Health, University of South Carolina, USA

³Department of Health and Human Performance, University of Houston, Texas, USA

⁴Department of Epidemiology and Biostatistics, Arnold School of Public Health, University of South Carolina, USA

Background and objectives: Unlike other risk factors, cardiorespiratory fitness (CRF) is not routinely measured as it requires trained personnel and specialized equipment. The purpose of this study is to predict risk for non-fatal cardiovascular disease (CVD) and disease-specific mortality using CRF algorithms that do not involve exercise testing (non-exercise CRF).

Methods: Participants were 43 356 adults (21% women) from the Aerobics Center Longitudinal Study followed between 1974 and 2003. Non-exercise CRF was estimated based on sex, age, body mass index, waist circumference, resting heart rate, physical activity level and smoking status. Exercise CRF was measured by a maximal treadmill test.

Results: The mean intra-individual differences between non-exercise CRF and exercise CRF were 0.4 ± 1.7 and 0.3 ± 1.6 METs in men and women, respectively ($p < 0.001$ in both). Bland-Altman analyses showed a tendency to underestimate at high values of CRF. During an average follow-up of 13.3 years, 1934 deaths occurred: 627 (32.4%) due to CVD and 737 (38.1%) due to cancer. In a sub-sample of 18 095 participants, 1049 cases of non-fatal CVD events were ascertained. After adjusting for potential confounders, a higher non-exercise CRF was associated with a lower risk of mortality from all-causes (hazard ratio per 1 MET increase = 0.85, 95% confidence interval = 0.82–0.88 in men; 0.87, 0.75–0.99 in women), from CVD (0.81, 0.77–0.86 in men; 0.84, 0.64–1.12 in women), from cancer (0.86, 0.82–0.91 in men; 0.99, 0.79–1.23 in women) and a lower risk of non-fatal CVD (0.89, 0.85–0.93 in men; 0.76, 0.58–0.99 in women).

Conclusions: Although non-exercise CRF method is not ideal, it predicts risk for non-fatal CVD, and all-cause and disease-specific mortality. It could be useful for identifying persons at risk and for exercise prescription for primary prevention.

Key words: fitness, mortality, cardiovascular disease, cancer, non-exercise algorithms.

PO1325

PERCEPTIONS OF FIRST YEAR STUDENTS ON FRUIT INTAKE AND EXERCISE HABITS

J. Setorglo¹, M. Steiner-Asiedu², S.A. Morenike²

¹University of Cape Coast, School of Medical Science, Ghana

²University of Ghana, Department of Nutrition and Food Science, Legon, Ghana

Background and objectives: Consuming fruits regularly and performing exercise is a good health promoting behaviour. This study seeks to determine the perception of University students on fruit intake and exercise habits.

Methods: This was a cross sectional study involving 400 (197 males and 203 females) randomly sampled first year students resident in 4 halls/hostels on University of Ghana campus. Semi structured questionnaires on exercise habits and perception on fruit intake were administered for self completion. Anthropometric information were collected according to standard procedures and categorized according to WHO body mass index cut-offs. Statistical Package for Social Scientist (SPSS, version 16) was used to analyse data.

Results: About 84.3% consumed fruit because of perceived health benefits, 98.8% protection against development of chronic diseases while 14.5% has no reason for consuming a fruit ($p = 0.015$), 76% consume fruit when they feel like ($p = 0.004$). Majority (60.0%) buys one serving of fruit to last for a day and factors that discourage fruit consumption includes unattractiveness (72.8%) and short life span (68.8%), unavailability of fruits (60.8%). A significant positive association was observed between BMI and attitude towards frequency of fruit consumption ($r = 0.119$, $P = 0.047$) although there was no difference in the perception between the sexes. More males (85.8%) than females (75.9%) perceived that they need exercise regularly to build muscle and lose weight respectively ($P = 0.034$). Duration and frequency of exercise were both significant ($p < 0.001$).

Conclusions: Perception of students on the health benefits of fruit intake was high but consume fruits when they choose. Both sexes' exercise habits are different and the outcomes of exercise sought are also different.

Key words: Fruits, perception, exercise habits, anthropometry

PO1326

ACCEPTABILITY OF YELLOW CASSAVA FOR CONSUMPTION BY SCHOOLCHILDREN IN DIDJA, BENIN

I D. Brouwer¹, V. Uwirigiyimana¹, E F. Talsma¹, R A M. Dossa², A. Melse-Boonstra¹

¹Division of Human Nutrition, Wageningen University, Wageningen, The Netherlands

²Department of Nutrition and Food Sciences, University of Abomey-Calavi, Cotonou, Benin

Background and objectives: Consumption of yellow varieties of cassava with an elevated beta-carotene content may contribute to reducing the high prevalence of vitamin A deficiencies (VAD). The success of this strategy is for a large part depending on the acceptability of yellow cassava. We studied the factors determining the intention to consume yellow cassava by schoolchildren in Didja, a rural cassava consuming community in Central Benin.

Methods: A cross-sectional survey, based on an integrated model of the theory of Planned Behaviour and the Health Belief Model was conducted among 147 randomly selected caretakers of schoolchildren (6-12 years old). Multivariate analyses and correlations were used to determine associations between summed scores for model constructs.

Results: More than 90% of the caretakers had the intention to prepare yellow cassava for their children 2 or more times a week. Knowledge on yellow cassava and VAD ($\hat{\alpha} = 0.20$, $p = 0.01$) and perceived susceptibility of the child to develop VAD ($\hat{\alpha} = 0.13$, $p = 0.05$) predicted health behaviour identity with 55% of the variance explained. Cues to action (sight problems of children, recommendations of health workers, high productivity and educational campaigns about benefits of yellow cassava) determined intention to consume yellow cassava ($\hat{\alpha} = 0.48$, $p = 0.00$) with 11% of variance explained. Barriers and attitudes towards yellow cassava did not determine intention to consume cassava.

Conclusions: In a cassava consuming area intake of yellow cassava by schoolchildren can be promoted by (1) increasing knowledge of caretakers on ability of yellow cassava to reduce VAD, (2) raising awareness on risk their children run on VAD and (3) positive triggers to yellow cassava consumption such as recommendations from influential people and educational campaigns. Acknowledgments The project was realized in the framework of INSTAPA Project, funded by the European Union's Seventh Framework Programme [FP7/2007-2013] under grant agreement nr 211484

Key words: Biofortification, cassava, acceptability, schoolchildren, Benin

PO1327**IDENTIFICATION OF FACTORS DETERMINING CONSUMPTION OF YELLOW MAIZE BY SCHOOL-CHILDREN IN KANDI, NORTHERN BENIN**

I D. Brouwer¹, B. Ates¹, E F. TAlisma¹, R A M. Dossa², A. Melse-Boonstra¹

¹Division of Human Nutrition, Wageningen University, Wageningen, the Netherlands

²Department of Nutrition and Food Sciences, University of Abomey-Calavi, Cotonou, Benin

Background and objectives: Through biofortification varieties of yellow maize with an elevated beta-carotene concentration have been developed. However, adding beta carotene may alter perception and taste of maize, determining success of biofortification to reducing vitamin A deficiencies (VAD). We studied the factors determining the intention to consume yellow maize by schoolchildren in Kandi, in northern Benin.

Methods: A descriptive cross-sectional survey, based on an integrated model of the Theory of Planned Behaviour and the Health Belief Model was conducted among 149 randomly selected caretakers of schoolchildren (6-12 years old). Multivariate analyses and correlations were used to determine associations between summed scores for model constructs.

Results: More than 60% of the caretakers had the intention to prepare yellow maize for their children daily. Perceived susceptibility of the child to attract VAD ($\hat{\alpha}=-0.17$, $p=0.05$), perceived severity of VAD ($\hat{\alpha}=-0.21$, $p=0.03$), and the value given to good health of the child ($\hat{\alpha}=0.25$, $p=0.00$) predicted health behaviour identity. Intention to consume yellow maize was associated with positive health behaviour ($\hat{\alpha}=-0.22$, $p=0.05$) and subjective norms ($\hat{\alpha}=-0.21$, $p=0.03$). A significant correlation was shown between health behaviour identity and barriers to consumption ($r_s=-0.29$, $p=0.00$), but barriers had no significant influence on intention.

Conclusions: Consumption of biofortified yellow maize by schoolchildren in Kandi could be promoted by increasing the awareness about the risks their children run to develop VAD and the severity of the consequences, involving mothers, family members and local authorities. Acknowledgements The project was realized in the framework of INSTAPA Project, funded by the European Union's Seventh Framework Programme [FP7/2007-2013] under grant agreement nr 211484 Key words Biofortification, yellow maize, acceptability, Benin, VAD.

Key words: Schoolchildren, nutrition, beta-carotene.

PO1328**THE ROLE OF WOMEN AND THE DETERMINANTS OF CHILD NUTRITION IN THE 2009 EXTREME WEATHER EVENTS IN THE PHILIPPINES**

E. Clark¹, C. Banwell¹, S. Friel¹, K. Lokuge¹, D. Zoleta-Nantes², T. Neeman³

¹National Centre of Epidemiology and Population Health, Australian National University, Acton, ACT, Australia

²Crawford School Resource Management of the Asia Pacific, Australian National University, Acton, ACT, Australia

³Statistical Consulting Unit, Australian National University, Australian National University, Acton, ACT, Australia

Background and objectives: Increasing extreme weather events (EWEs) attributed to climate change has direct and indirect effects on health and food and nutrition security. Vulnerable communities in developing countries such as the Philippines will be increasingly challenged. EWEs trigger a cascade of events that can lead to child malnutrition. The 2009 EWEs Tropical Storm Ketsana and Typhoon Parma were used as a case study to determine the factors affecting child undernutrition and to understand the role of women in the process of child nutrition preservation in natural disaster situations.

Methods: A cross-sectional study was carried out in 13 flood-affected villages of District IV Laguna Province, 18-24 months after the flooding disaster. Combined methods using structured questionnaires and in-depth interviews were administered to mothers to examine socio-demographic characteristics and explore women's disaster experiences. Clinical history and physical examination with anthropometry were conducted on 946 children to evaluate health and nutritional status using weight for age and height for age. Statistical analysis using logistic regression and thematic analyses were done.

Results: The prevalence of underweight in children was 27.3% while stunting was 36.7%. The child's age, number of siblings, birth order and their village of residence were important determinants of child nutritional status. During and after the floods, maternal care ensured preservation of child health and nutrition.

Conclusions: Child undernutrition can be an indirect consequence of flood exposure. With the future threat of climate change, policies and multidisciplinary malnutrition prevention programs in flood-prone areas should focus not only on the determinants but also consider ways to support women's contribution in the prevention of poor child nutritional outcomes.

Key words: climate change, women, malnutrition, Philippines.

PO1329**SALT CONTENT CONTROL IN PUBLIC MASS CATERING MEALS DEDICATED TO CHILDREN, ADOLESCENTS AND STUDENTS IN THE CITY OF NOVI SAD**

L J. Trajkovic Pavlovic¹, M. Popovic, R. Velicki, L J. Torovic, S. Bijelovic

¹Institute of Public Health of Vojvodina, University of Novi Sad, School of Medicine, Novi Sad, Serbia

Background and objectives: Investigations brought evidences that salt intake was in a positive relationship with blood pressure and that children and adolescents with higher blood pressure were more susceptible to develop hypertension in adulthood. The aim of this paper was to analyze data on four-year (2008/2011) salt reduction program in meals provided by the public catering service for children, adolescentst and students in Novi Sad.

Methods: Relating to the established program, each year during the four-year period, 50, 22, 26 and 25 daily meals were taken from kindergarten, school canteens, boarding schools, student'srestaurants, respectively. In the meal time unannounced samplers took meals from public kindergartens, schools (breakfast, dinner, snack), boarding schools and student'srestaurants (breakfast, dinner, supper). Laboratory examination of energy value and salt content in daily meals was performed using standardized and validated methods. student'st-test was applied to determine statistical differences in energy and salt content of the average daily meals at the beginning and at the end of the observed period.

Results: The average annual energy values of the controlled daily meals in kindergartens, school canteens, boarding schools and student'srestaurants for the 2008/2011 were 1025.7Å±167.19kcal/1059.83Å±152.96kcal; 1617.39Å±249.16kcal/1602.04Å±288.04kcal; 3127.07Å±403.32kcal/3005.68Å±311.59kcal and 2745.80Å±1072.19kcal/3033.39Å±248.42kcal respectively, statistically significant difference were not recorded ($p>0.05$). The average annual salt content values in daily meals in kindergartens, school canteens, boarding schools and student's restaurants fallen from: 5.02Å±2.09g to 3.27Å±1.03g; 5.79Å±2.14g to 7.45Å±3.07g; 18.10Å±4.00g to 8.62Å± 5.08g, respectively. The decline was statistically significant ($p<0.0001$).

Conclusions: Within the observed period, the program on salt reducing in meals of controlled public facilities has been implemented successfully, salt content dropped significantly, but the established goals have not been achieved. Acknowledgment: The program was supported by the Secretariat for Health and Social Policy of the City of Novi Sad.

Key words: Salt, meals, schools, children, adolescents.

PO1330**ADOLESCENTS' VIEWS ABOUT A PROPOSED REWARD INTERVENTION TO PROMOTE HEALTHY EATING IN THE SCHOOL SETTING**

C T. McEvoy¹, J. Lawton², F. Kee¹, I S. Young¹, J V. Woodside¹, J. McBratney³, M C. McKinley¹

¹Centre for Public Health, Queen's University Belfast, UK

²Centre for Population Health Sciences, University of Edinburgh, UK

³Health and Social Wellbeing Improvement Directorate, Public Health Agency, Belfast, UK

Background and objectives: A reward or incentive scheme may be an effective method to influence young people's eating behaviour but evidence regarding this approach is limited. The aim of this qualitative study was to explore the views of 11-12 year olds about a proposed reward intervention associated with their food choices in the school canteen.

Methods: Focus groups were held in ten extended schools (i.e. the most disadvantaged schools according to the areas in which their pupils live) in Northern Ireland. Focus group sessions were audio-recorded and transcribed verbatim. An analytical data coding framework was applied to transcript data.

Results: Five schools were located in urban-cities, three in urban-towns and two in rural areas. Ninety pupils took part in the focus groups (54 girls, 36 boys). There was a high degree of acceptability for the concept of a reward scheme. There was diversity in the type of rewards valued by pupils, largely defined by geographical area and socio-cultural differences; for example, pupils from rural and small urban-towns tended to emphasise more group-based and longer-term rewards, whereas pupils from urban-city schools tended to suggest more individualistic and immediate rewards. In terms of factors influencing food choice within the school canteen, the major factors were food price, value for money, taste and visual appearance. Pupils felt that factors outside of their control, such as being assigned to the second lunch sitting, availability of seating and length of queues, placed considerable constraints on their food choice.

Conclusions: This research indicates a high degree of acceptability for a proposed rewards-based intervention but has also highlighted a number of socio-cultural and micro-environmental factors that need to be considered and addressed when developing such an intervention. Acknowledgements: This research was funded by the Northern Ireland HSC R&D Office.

Key words: Focus groups, school, healthy eating, rewards.

PO1331

QUANTITY AND QUALITY OF FATS IN GLUTEN CONTAINING FOODS COMPARED TO SPECIFICALLY GLUTEN-FREE PRODUCTS

J. Calvo Lerma¹, P. Crespo Escobar¹, A. Durán¹, C. Ribes-Koninckx¹

¹Pediatric Gastroenterology unit, La Fe University Hospital, Valencia, Spain

Background and objectives: To compare the quantity and quality of fats in common gluten-containing foods (GCF) and special gluten-free products (GFP).

Methods: We conducted a prospective pilot study to determine the most frequently GCF and brands consumed by children in the general population as well as, similar GFP consumed by celiac children. Quantity and quality of fat content was obtained from different sources of information.

Results: Ten of the most frequently consumed products were analyzed: The amount of fat in the products with low lipid content such as pasta, flour or cereal was very similar in both type of product (with and without gluten) and the difference was not statistically significant ($p > 0.05$ for all compared items). However, if we compare complex manufactured products, GCF have a lower fat content than GFP and this difference is statistically significant for all analyzed foods ($p < 0.01$). Regarding to the quality of fats of GFP, it is noteworthy that in many of them saturated fat percentage is higher than in equivalent conventional foods, reaching values above 50% of the total lipid contents.

Conclusions: It can be asserted that celiac children consuming special gluten-free products, are at risk of a higher fat intake as compared with children consuming conventional products, and a higher percentage of saturated fats. Thus food labels should clearly specify both the fat amount and the quality; however this information is often missing and not easily accessible. These preliminary results reflect the need to control the diet of celiac children in order to avoid a fat intake exceeding the recommendations, and to ensure these children carry a balanced diet. A prospective study in a pediatric coeliac population is currently on going.

Key words: Fats, specific products, children.

PO1332

DIETARY HABITS AND GROWTH: AN URBAN/RURAL COMPARISON IN THE ANDEAN REGION OF APURIMAC, PERU

L. Andrissi¹, G. Mottini¹, V. Sebastiani², L. Boldrini², A. Giuliani³

¹Institute of Scientific and Technological Acting, University Campus Bio Medico, Rome, Italy

²MSci in Food Science and Human Nutrition, University Campus Bio Medico, Rome, Italy

³Environment and Health Dept. Istituto Superiore di Sanit, Roma, Italy

Background and objectives: In this work we investigated the relations between dietary pattern and growth comparing children from a rural and urban area in Andean Peru, in terms of food habits and anthropometric variables to develop a model usable in context interventions against malnutrition.

Methods: A sample of 159 children (80 from urban, 79 from rural area), aged from 4 to 120 months ($72, 7 \pm 37, 5$ SD) was collected. The data were investigated by a multidimensional (Principal Component Analysis followed by inferential approach) analysis to correlate anthropometric and dietary variables.

Results: Under 20 months children are more fatty than the reference population in general, and rural more than urban (Student's t-test $p < 0, 0005$). In children > 20 months is showed an higher caloric intake in the city with a marked gender dependence (Pearson $r = 0.33, p < 0.0001$). About malnutrition there is a statistically significant difference (Chi-square = 5.03 $p < 0.02$) in the two sets (42% in rural vs. 25% in urban). Malnutrition cannot be considered as pure quantitative extreme of dietary intake given the complex relation it has with dietary and anthropometric patterns.

Conclusions: This is a direct proof of the need to calibrate interventions on food and socio-cultural field for understand malnutrition effects on growth. The main way to do that is to start from the analysis of malnutrition not as an effect but as a "source of variation" of the studied variables. A periodic evaluations of the growth of children are a prerequisite for any Public Health intervention against malnutrition.

Key words: Multidimensional Analysis, Malnutrition, Public health intervention, Dietary habits.

PO1333**BMI AND PERCEPTIONS, ATTITUDE AND PRACTICES OF UNDERGRADUATE STUDENTS OF THE UNIVERSITY OF THE FREE STATE, SOUTH AFRICA, REGARDING EXERCISE**

V.L. Van Den Berg¹, E. Du Toit¹, J. Raubenheimer²

¹Department of Nutrition and Dietetics, Faculty of Health Sciences, University of The Free State, South Africa

²Department of Biostatistics, Faculty of Health Sciences, University of The Free State, South Africa

Background and objectives: A sustainable pattern of participation in physical activity is important to maintain health and prevent chronic diseases of lifestyle. Studies find that adolescents typically transition from an active youth to more sedentary adult behavior patterns. This study aimed to determine perceptions, attitude and practices of undergraduate students at the University of the Free State, South Africa, regarding exercise.

Methods: A cross sectional descriptive study was conducted via a self-reported electronic questionnaire made available to all students. The questionnaire included assessment of physical activity levels with the International Physical Activity Questionnaire (IPAQ, short version), self-reported body weight and height, and knowledge, attitudes and practices regarding physical activity.

Results: The respondents (N=1311; 21±3yrs), were mostly female (54%); black (61%) or white (31%), and 69% resided off-campus (with 47% of these walking or cycling to campus). Eighty percent strongly agreed that exercise is important; around 80% knew the exercise recommendations; and over 90% had correct perceptions on the role of exercise in health. Most (72%) participated in sport at school. When asked whether they exercise, most (72%) indicated that they do, and around 60% claimed that they adhere to the recommendations, listing their main motivations as physical fitness, health improvement and enjoyment. In contrast, the IPAQ revealed that 46% have low activity levels; and 39% were overweight /obese. Those admitting to not exercising, listed lack of motivation to exercise alone, time constraints and expenses as main reasons. Low social support for exercising, low use of campus exercise facilities, and various misperceptions regarding exercise were identified.

Conclusions: Although the students knew the benefits of exercise and revealed positive perceptions of and attitudes towards exercise, almost half had low actual activity levels. Misperceptions and barriers regarding exercise, which interventions should focus on, were identified.

Key words: students, exercise, knowledge, attitudes, practices.

PO1334**GUADIX, PROMOTING HEALTHY EATING HABITS FROM LOCAL GOVERNMENT**

F. Rivas-García¹, J. Lorente Fernández¹, J. A. González Alcalá¹, L. Serrano Cruz¹, M. C. Alcalá¹, M. Sánchez¹, J. Perona², A. Martos-López³

¹Ayuntamiento de Guadix, Granada, Spain

²Instituto de la Grasa (CSIC), Sevilla, Spain

³Colegio Oficial de Veterinarios, Murcia, Spain

Background and objectives: As part of the legislative powers of local government, the city of Guadix (Granada) initiated a municipal strategy designed to prevent obesity, which has subsequently been subsumed under the Health Plan I (2010-2014). Currently Guadix has acquired a leading role in the implementation and development of public policies about obesity. Objective: To prevent childhood obesity through optimization and unification of all available local resources and put the politics of health promotion in Guadix.

Methods: It has managed to develop an intersectorial common and continuing between all municipal departments that may be involved directly and indirectly in preventing obesity.

Results: Among the most highlights the participation of students, estimated at 2180, ages 6 and 17, from different educational levels, 62 percent of the activities have focused on the school while the rest about 32 per cent were distributed in the community and familiar. 6 percent of the proceedings had as objectives the health sector including the incorporation of the city in a research study on childhood obesity and restoration. Information campaigns were developed and 32, 965 people participated in outdoor activities.

Conclusions: Current date have built a healthy lifestyle based on promoting physical activity and healthy eating also have generated new lines of work under the municipal health plan.

Key words: Guadix; Healthy habits; Childhood obesity.

PO1335**TASTE SENSITIVITY AND DIETARY HABIT AMONG SCHOOLCHILDREN IN MIYAZAKI**

H. Shinohara¹, T. Okuda², N. Tanaka³, I. Hamaguchi⁴, Y. Asano⁵, Y. Higashine⁶, J. Kang⁷

¹Faculty of Education and Culture, University of Miyazaki, Miyazaki, Miyazaki, Japan

²Faculty of Human Sciences, Tezukayamagakuin University, Sakai, Osaka, Japan

³Faculty of Home Economics, Kobe Women's University, Kobe, Hyogo, Japan

⁴Faculty of Human Sciences, Konan Women's University, Kobe, Hyogo, Japan

⁵Faculty of Health Science, Kio University, Koryou, Nara, Japan

⁶Department of Health Sciences, Osaka Aoyama University, Minoo, Osaka, Japan

⁷Department of Nutrition, Hyogo NCC College, Nishinomiya, Hyogo, Japan

Background and objectives: The common problems of eating habits in children are inadequate chewing, taking no breakfast, and dislikes of certain tastes. The purpose of this study is to clarify the sense of taste and dietary habit of primary schoolchildren.

Methods: The survey was conducted from February to December 2011 on 222 schoolchildren (112 boys, 110 girls, aged 11-13 years old) in Miyazaki, Japan. Taste examination was performed using five basic tastes (sweet, salty, sour, bitter, and umami) and five g dashi h soup (Japanese soup stock: brown kelp, dried bonito, mixed brown kelp and dried bonito, dried sardines and monosodium glutamate). The questionnaire survey (55 items) consisted of four scales; namely, dietary habit and life-style. We performed statistical analysis by Chi-square test, factor analysis by the least-square method, and path analysis.

Results: The rate of all correct answer tasting was 12.6% for the five basic tastes, and 30.6% for the five g dashi h soup. The taste sensitivity was higher for salty taste than for umami and bitter taste, and higher for brown kelp taste than for dried bonito and mixed taste. The high-score group of five basic tastes showed significantly higher scores in interested in good taste, learn how to cook by books and chewing food thoroughly than the low-score group. Factor analysis was conducted and five factors were extracted; namely, interest in cooking, intake frequency of vegetables and fruits, refrainment from eating between meals, refrainment from eating out, and enjoyment of sports. The path analysis revealed that the number of correct answers for the five basic tastes had significant direct effect on the interest in cooking.

Conclusions: These results suggest that the teachers and parents should work together to develop interest in cooking and sense of taste in the schoolchildren.

Key words: sense of taste, dashi, dietary habit, schoolchildren, interest in cooking.

PO1336**USING NEW METHODS TO ASSESS COVERAGE OF DECENTRALIZED NUTRITION PROGRAMMES IN COMPLEX EMERGENCIES IN EAST AND THE HORN OF AFRICA**

C. Ouma¹

¹Health and Nutrition Learning Centre, World Vision, Kenya

Background and objectives: For a long time acute malnutrition programmes have been implemented in complex emergencies but without scientific methodologies to evaluate population access and coverage. Currently low-resource methods capable of evaluating program coverage, identifying barriers to service access have been developed. Semi quantitative evaluation of access and coverage method was used to evaluate access and coverage and investigate any barriers to uptake.

Methods: In stage 1, prior, the expression of beliefs about coverage based on qualitative and quantitative data provided by the Mind Mapping exercise. The distribution of prior coverage estimate was determined through a beta distribution of the belief of or perceived possible coverage estimates. The prior estimate of programme coverage was then further refined by determining the likelihood through conducting a wide area survey. Using an active and adaptive case-finding methodology informed and defined by the information gathered during prior building, cases of severe acute malnutrition children were identified and categorized as either being in or out of the programme.

Results: Programme Coverage was 83.2% in galckayo, Somalia, 76% in Rwanguba and 68.9% in Masisi territory of Democratic republic of Congo, 63% in Turkana county of Kenya, 67% in Durame in Ethiopia and 67.1% in Tonj South County of south Sudan. Major barriers to access included distance, insecurity, mothers' workload, cultural issues and long waiting times at feeding centres.

Conclusions: Even in protracted and complex emergencies, nutrition programmes can produce good quality and high coverage. They can still meet international SPHERE standards for coverage of more than 50% with enhanced access and decentralization.

Key words: coverage, complex emergencies, nutrition.

PO1337**2012 "DON'T GET DEHYDRATED" HEALTH CAMPAIGN**

A. García¹, M.R. Pastor¹, J.A. Tur¹, J.M. Miquel¹, A. Hardisson¹, M.P. Zaragoza¹, E. Franco¹, A. Bach¹, A. Sierra¹, M. Motero¹, I. Espada¹

¹National Committee of Nutrition, General Council of Spanish Pharmacists, Madrid, Spain

Background and objectives: From July to September 2012 the 'Don't Get Dehydrated' health campaign was conducted in order to educate the populace about the importance of preventing dehydration to enjoy an enhanced quality of life and better health.

Methods: During the carrying-out of this campaign pharmacists throughout Spain offered pharmacy patrons personalized guidance with regards to hydration. To this end they employed a technical consensus document and a brochure for customers featuring '10 Dehydration Prevention Tips' to get their message across. These materials were distributed to pharmacies through the General Council of Spanish Pharmacists. Member pharmacists were also able to consult and download materials at www.portalfarma.com.

Results: The health campaign 'Don't Get Dehydrated 2012' featured participation by a total of 47 Spanish provinces, from whose pharmacies a total of 961, 850 brochures were distributed amongst the general population, offering them '10 Dehydration Prevention Tips.'

Conclusions: - Pharmacists play an essential role by informing and counseling the public about healthy lifestyle habits. - The widespread participation in this educational campaign led to preventive and awareness-raising efforts keys to an essential educational drive carried out by Spanish pharmacists. - There is a need for educational Health Campaigns making it possible to establish preventive and informative programs at all levels. These programs should encourage the adoption of healthier habits, based on our traditional diet, regular and moderate exercise, and shifts to healthier habits by the population.

Key words: Hydration, mineral salts, water.

PO1338**POST SUPPLEMENTARY AND THERAPEUTIC FOOD DISTRIBUTION AND UTILIZATION MONITORING SURVEY IN WUROR COUNTY, SOUTH SUDAN**

C. Ouma¹

¹World Vision, Nairobi, Kenya

Background and objectives: The post distribution follow-up was conducted to investigate the utilization of emergency relief commodities provided with the aim of establishing how much of the rations were actually consumed by the malnourished child. The data collection was conducted by the nutrition staff as part of the routine home visits among beneficiaries. The target was families of children still registered in the humanitarian programme.

Methods: Primary caregivers of malnourished children under five year's children admitted in the supplementary or therapeutic programme. 90 randomly selected from 3 centres. Home visits done three to seven days after the distribution. Structured questions administered to families of beneficiaries. Physical examination of rations done to assess use and storage.

Results: Of the 90 families which had received the rations, only 20 (22%) had some of the 14 day-ration. 65 (72%) of the mothers were able to produce the expected number of sachets 71 (78%) of the caregivers visited could not account for the entire Plumpy nut ration on the visit day. 13(14%) had more RUTF than was required. 69 carers (76%) of the mothers correctly described how to prepare porridge and only 43(47%) followed the method. Hygiene during preparation and serving was observed to be minimal. In distant villages, the mothers obtained water from the open pools, filtered it before using it for cooking.

Conclusions: Household practices on the utilization of emergency nutrition rations for treatment are poor. Intensification of post distribution home visits and follow-ups to ensure that the child under rehabilitation is crucial.

Key words: supplementary, Therapeutic, food distribution.

PO1339**RESPONSE EXECUTION/INHIBITION TRAINING WITH FOOD IMAGES ALTERS ON SUBSEQUENT EATING BEHAVIOUR***K. Kazami^{1,2}, S. Shiga², K. Yamanaka²*¹Department of Health and Nutrition, University of Human Arts and Sciences, Saitama, Japan²Graduate School of Human Life Sciences, Showa Women's University, Saitama, Japan

Background and objectives: Some previous studies suggested that training to inhibit food-related responses may be effective to decrease food intake. In the present study, therefore, we examined whether response execution/inhibition training with images of three confectionaries (chocolate, manju (Japanese steamed bun stuffed with red bean paste), and sio-senbei (rice cracker flavored with salt)) affected subsequent their intakes.

Methods: For the training, we used a go/no-go task that involved repeatedly respond to a go signal or not to respond to a no-go signal, both of which simultaneously presented with one of the images of three confectionaries or empty plate. A total of 80 Japanese university students, 40 male and 40 female, were divided into two conditions: go signal consistently presented with chocolate image (chocolate-go condition) or no-go signal consistently presented with chocolate image (chocolate-no-go condition). In both conditions, manju and senbei images were presented evenly with go and no-go signal. We measured amount of consumption of each confectionery in a sham taste test following the go/no-go training.

Results: Female participants ate $13.3 \pm 9.4\text{g}$ (go condition) and $21.0 \pm 12.1\text{g}$ (no-go condition) of chocolate while male participants ate $26.8 \pm 12.7\text{g}$ (go condition) and $17.5 \pm 12.7\text{g}$ (no-go condition) of chocolate. Two-way ANOVAs on chocolate consumption did not reveal significant main effects of condition and gender, but revealed significant interaction of them ($F[1,76] = 10.378$, $p = 0.02$). On the other hand, two-way ANOVAs on manju and senbei consumptions reveal no significant main effect or interaction.

Conclusions: These findings demonstrate that, after the response execution/inhibition training with food images, eating behaviour only in the food whose image is used in the training might be altered differently between male and female. We suggest that such training might be effective for the control of eating behaviour.

Key words: eating behaviour, go/no-go training, food image

PO1340**DIFFERENCES IN BEVERAGE CONSUMPTION STRUCTURE FOR ADULTS IN RELATION TO AGE***A. Jarosz¹, M. Jarosz¹*¹Food and Nutrition Institute, Warsaw, Poland

Beverage consumption may have a significant influence on a variety of health related elements, such as excess weight and obesity, diabetes therapy or the development of certain types of cancer. They are an important part of everyday diet. Aim: Comparison of beverage consumption between adults aged 18 – 24 and adults aged 55 – 64.

Method and material: 209 persons aged 18 – 24 and 199 persons aged 56 – 64 took part in the study. The average age was 21 and 60 years correspondingly. The consumption was assessed using a 7 day consumption log.

Results: The average beverage consumption in the younger group was at a level of 1,85l/day and 1,55l/day for the older. Water consumption was similar for both groups and was measured at 560 ml which made up for 33% of all liquids consumed. The senior group consumed a higher amount of warm liquids (782ml vs 648ml, 46 vs 38%) while the younger group drank more coloured soft drinks (140ml vs 40ml, 8 vs 2%). Additionally persons aged 18 – 24 drink more milk and fruit beverages. Alcohol consumption is identical and was measured to be 85ml on average making up for 5% of all the liquids consumed. Energy drinks are drunk by younger persons but on average it's only 55ml – 3% of all liquids consumed.

Conclusions: Younger persons consume more liquids. Furthermore they drink more coloured soft drinks and fruit drinks. Older persons prefer warm beverages like tea and coffee. The results show the need for further education.

Key words: beverages, consumption, relation to age

PO1341**EPILEPSY: ANALYSIS OF NUTRITIONAL STATUS AND SERUM VITAMIN D LEVEL (VIT D).**

P. Jesus^{1, 3, 4}, B. Godet^{2, 3, 4}, L. Pouchard¹, F. Abdallah-Lebeau², O. Villeneuve², C. Marcon², L. Gimenez², P. Faye-mendy¹, P. M. Preux^{3, 4}, P. Couratier^{2, 3, 4}, J. C. Desport^{1, 3, 4}

¹Nutrition Unit, University Hospital, Limoges, France

²Department of Neurology, University Hospital, Limoges, France

³INSERM UMR1094, Tropical Neuroepidemiology, Limoges, France

⁴Univ Limoges, School of Medecine, institute of Neuroepidemiology and Tropical Neurology, CNRS FR 3503 GEIST, Limoges, France

Background and objectives: In France, the number of people with epilepsy (PWE) is estimated to 500000. Their nutritional status is poorly studied. Impaired nutritional status might play a role in the response to treatment. Vit D might be involved in some forms of epilepsy. The main purpose of this study was to describe the nutritional status of patients with epilepsy and analyze their serum vit D level.

Methods: After consent, a nutritional assessment was performed in 46 PWE with or without drug resistance. Weight, height, body mass index (BMI), waist circumference, triceps skinfold (TS), biceps, supra-iliac, subscapular skinfolds, arm circumference, fat mass (FM) and fat-free mass (FFM) by bioimpedance were measured. The serum vit D dosage was realized before supplementation (deficiency <30 ng/mL). Statistical analysis used Student's t test, chi2 and ANOVA.

Results: The mean age was 44.5 ± 14.3 years, with a sex ratio M/F at 1.3. 60.9% were drug-resistant. BMI was 28.7 ± 7.0 kg/m², with 2.2% of malnourished and 30.4% obese. Vit D concentration was 15.3 ± 9.9 ng/mL with 87% of deficient patients, and 40% with severe deficiency (<10 ng/mL). The TS was higher in the drug-resistant group (p=0.03). Drug resistance was not linked with nutritional status, other skin fold measures, FM, FFM and vit D level.

Conclusions: The number of PWE was low, but the study shows that they are rarely malnourished. However, studies focused primarily on clinical cases or African populations. Obesity is common in PWE, possibly iatrogenic and should be deeply studied. Vit D deficiency is very common, often severe, but as nutritional status, seems not playing on the drug-sensitivity of patients studied.

Key words: Epilepsy, drug resistance, nutritional status, vitamin D.

PO1342**NUTRITIONAL VULNERABILITY OF UNDER-5 CHILDREN IN URBAN POOR SETTLEMENTS OF DELHI, INDIA: NEED FOR ALIGNING POLICY TO FOOD CONSUMPTION PATTERN**

S. Ghosh-Jerath¹, N. Devasenapathy¹, A. Singh², S. Zodpey¹

¹Indian Institute of Public Health-Delhi, Public Health Foundation of India, New Delhi, India

²Department of Biochemistry, All India Institute of Medical Sciences, New Delhi, India

Background and objectives: One in every three malnourished children in the world lives in India. Millions of children living in urban poverty confront daily violations of rights and fare poorer than rural counterparts in terms of undernutrition and under-5 mortality. Objective: To assess nutritional status of children residing in urban poor settlements of Delhi and identify factors that may affect their dietary consumption pattern.

Methods: A cross sectional study on random sample of 202 under-5 children from population of 30, 000 in 3 urban poor settlements of North-East district of Delhi. Nutritional status was assessed using standard anthropometric techniques, 2 days dietary recall along with food frequency questionnaire. Key socio-demographic characteristics, IYCF practices and dietary intake pattern were assessed.

Results: High prevalence of undernutrition with underweight (WAZ<-2SD) as 34.9 %, stunting (HAZ<-2SD) as 61.3% and wasting (WHZ<-2SD) as 10.2% was observed. Mean calorie and protein intake was higher than RDA for age. Mean intake for iron, zinc, thiamine, riboflavin, niacin, vitamin C was poor when compared to age specific RDAs. Mean consumption of vegetables (4 gm/day), fruits (32gm/day) and pulses(16gm/day) was sub-optimal. About 90% reported a daily consumption of packaged snack foods like chips, chocolates, local crisps, sweets, aerated beverages(known sources of saturated fat, trans fat, energy, refined carbohydrates and salt).

Conclusions: In spite of an adequate consumption of calories, habitual diet had poor nutritional quality. Targeted marketing, food policy especially pricing policy and easy access to unhealthy foods may have bearing on food behaviour of a vulnerable community. While addressing nutrition gap, it is essential to have a multidimensional approach and apart from creating awareness and access to community based nutrition services, there is need to create an enabling environment with nutrition sensitive policies that make healthier options more accessible and affordable to community.

Key words: Urban poor children nutritional status.

PO1343**BIOAVAILABILITY OF VITAMIN D2 AND D3 IN HEALTHY VOLUNTEERS – A RANDOMIZED TRIAL**

U. Lehmann¹, F. Hirche¹, G. I. Stangl¹, K. Hinz², S. Westphal², J. Dierkes³

¹Institute of Agriculture and Nutritional Science, Martin-Luther University, Germany

²Institute of Clinical Chemistry and Biochemistry, Otto-von-Guericke University Magdeburg, Germany

³Dept. of Clinical Medicine, University of Bergen, Norway

Background and objectives: Vitamin D exists as ergocalciferol (vitamin D2) and cholecalciferol (vitamin D3). It was the aim of the study to investigate whether both forms are bioequivalent.

Methods: We tested the effect of supplementation of either 50 µg/d vitamin D2, D3 or a placebo for a period of 8 weeks on 25(OH)D2, 25(OH)D3, total 25(OH)D serum levels, and parathyroid hormone in healthy volunteers. Blood samples were collected at baseline, after 4 and 8 weeks of supplementation.

Results: 25(OH)D3 decreased in the placebo group from 39.4 ± 14.2 nmol/L to 31.1 ± 12.4 nmol/L after 8 weeks ($p < 0.01$). In the vitamin D3 group, concentrations of 25(OH)D3 increased from 41.5 ± 22.8 nmol/L at baseline to 88.0 ± 22.1 nmol/L after 8 weeks ($p < 0.01$). In the group receiving vitamin D2, 25(OH)D2 concentrations increased from 1.3 ± 1.9 nmol/L at baseline to 51.2 ± 18.5 nmol/L after 8 weeks. The 25(OH)D3 concentration decreased from 36.4 ± 13.3 nmol/L at baseline to 16.6 ± 6.3 nmol/L after 8 weeks ($p < 0.01$). Total 25(OH)D was not different among the groups at baseline, but was significantly different among the 3 groups after 4 and 8 weeks (by ANOVA, $p < 0.001$).

Conclusions: Vitamin D3 is more effective than vitamin D2 which was demonstrated by the increase of the total 25(OH)D concentration. Vitamin D2 supplementation was associated with a decrease in 25(OH)D3 which can explain the different effect on total 25(OH)D.

Key Words: ergocalciferol, cholecalciferol, bioavailability.

PO1344**WHICH NUTRIENTS LIMIT CHANGES TO MORE SUSTAINABLE DIETS?**

G. Horgan¹, J. Macdiarmid², J. Kyle², A. Perrin¹, G. McNeill²

¹Biomathematics & Statistics Scotland, Aberdeen, UK

²Rowett Institute, University of Aberdeen, Aberdeen, UK

Background and objectives: Improving the environmental sustainability of human diets is clearly desirable but changes to achieve this need to take into account nutritional requirements and recommendations. Recommendations of some nutrients are harder to meet than others if animal foods are reduced, and it is important to be able to identify these.

Methods: Reducing greenhouse gas emissions (GHGE) was used as an indicator of improving sustainability. Linear programming was used to create diets that minimised GHGE while still meeting dietary requirements for health. These include requirements which are lower limits (energy, protein, vitamins and many minerals and micronutrients) and upper limits (fat, sodium). In the diets generated, some nutrient requirements tend to be at their limit and prevent further reduction of GHGE.

Results: In the diets generated, it became apparent that requirements for sodium (maximum) and calcium (minimum) were often at their limit. This meant that satisfying them prevented greater selection of lower GHGE food items. In the case of sodium, it was then possible to investigate the effect of reducing the amount in e.g. bread and breakfast cereals, as it tends to be added in processing rather than naturally present. In the case of calcium, fortification of wheat based foods allowed more of these to be selected instead of higher GHGE items which contained natural calcium. Reducing fat in foods also led to GHGE reduction, though this was less effective because fat reduction also reduces energy content, the primary requirement.

Conclusions: Some dietary requirements limit the ability to construct more sustainable diets. Policies such as reducing added sodium or considering further fortification of certain foods may have a role to play in improving diet sustainability.

Key words: sustainable diets, healthy, greenhouse gas emissions, food, nutrients.

PO1345**DIFFERENT HEALTH RELATED BEHAVIORS CONDUCTED BEFORE SCHOOL HOURS IN SEVEN EUROPEAN COUNTRIES – THE ENERGY PROJECT**

M. Roed¹, F.N. Vik¹, J. Brug², Y. Manios³, E. Bere¹

¹Department of Public Health, Sport and Nutrition, University of Agder, Kristiansand, Norway

²EMGO Institute for Health and Care Research and the department of Epidemiology and Biostatistics, VU University Medical Center, Amsterdam, The Netherlands

³Department of Nutrition and Dietetics, Harokopio University, Athens, Greece

Background and objectives: Children in Europe have different habits before they start their schooldays. The purpose of this study was to create a score on “a good start of the school day” assessing different health related behaviors conducted before school hours in seven European countries, as well as assessing potential inequalities regarding gender, ethnicity and parental education in the score.

Methods: The study sample included 5595 children and one of their parents/caretakers from the ENERGY cross sectional study with data on health related behaviors. A score was created by four frequency items from the child questionnaire concerning breakfast and active commuting to school. Further, one item from the parent questionnaire about children's sleep hours, was added in the score. Each unit got one point per healthy behavior. Descriptive frequency analyzes, analyzes of variance (ANOVA) and Post Hoc test were used to assess the differences in socioeconomic status, ethnicity and gender.

Results: The children in Norway, The Netherlands, Belgium and Spain had a higher score than Greece Slovenia and Hungary. Children with highly educated parents had significantly more healthy morning habits ($p < 0.001$) than children with low educated parents. Non-native children had a lower score, than natives ($p < 0.001$). No such disparities were observed for gender differences.

Conclusions: In families with at least one highly educated parent, the children made more favorable choices before they began the school day. Being non-native was associated with a lower score. Gender was not associated with differences in how children start their school day.

Key words: Morning habits, socioeconomic status, children.

PO1346**ASSESSMENT OF THE POTENTIAL IMPACT OF THE NUTRITIONAL COMMITMENTS OF FOOD OPERATORS ON FRENCH NUTRIENT INTAKES**

C. Battisti¹, C. Perrin¹, J. Gauvreau-Beziat¹, J.L. Volatier¹, C. Menard¹

¹French Agency For Food, Environmental and Occupational Health & Safety (Anses), Maisons-Alfort, France

Background and objectives: In accordance with French health authorities, food operators have signed voluntary commitment charters to improve the nutritional quality of their foodstuffs. The purpose of this study is to assess the potential cumulative impact of these reformulations on French consumers' nutrient intakes.

Methods: Initial nutrient intakes were computed by combining the data from the French individual consumption survey (INCA 2) and the CIQUAL food composition database. Potential new nutrient intakes were simulated by integrating improved nutrient contents to foodstuffs concerned by reformulations. These new contents were matched with the corresponding consumption data, according to the real market shares of these improved foodstuffs. New nutrient intakes were simulated for 1918 adults and 1544 children and compared to the initial intakes.

Results: Potential improved nutrient intakes differed significantly from the initial ones for all the nutrients studied (sugars, dietary fibers, lipids, saturated fatty acids, trans fatty acids, sodium, calcium, vitamin D). For instance for men, sodium and lipids intakes decreased (-1.1% and -0.4%) mainly due to reductions in delicatessen meats and sugar intakes decreased (-0.4%) mainly due to reformulations of dairy products and soft drinks. All socio-economic groups were significantly impacted by the reformulation agreements proposed and for all the nutrients studied (except for calcium).

Conclusions: This study represents an interesting tool to assess French nutritional policies. This impact assessment of reformulations proposed by food operators doesn't take into account all reformulations but only those defined in the agreements. This study highlights the limited potential impact of these reformulations on French nutrient intakes. Now, the magnitude of the impact depends on the number of food operators involved and on their market shares. That's why new commitments are needed to enhance the impact.

Key words: nutrition policies assessment, food composition, nutritional improvements, nutrient intakes, socio-economic groups.

PO1347**ADHERENCE TO THE DUTCH DIETARY GUIDELINES AND 20-YEAR MORTALITY: THE ROTTERDAM STUDY**

L. van Lee¹, N. Vonk¹, N. Jankovic¹, J. Kieft - de Jong², A. Hofman², J. Witteman², E. Hooft van Huysduynen¹, J. de Vries¹, A. Geelen¹, P. van 't Veer¹, O. Franco², E. Feskens¹

¹Division of Human Nutrition, Wageningen, The Netherlands

²Department Epidemiology, Erasmus Medical Centre Rotterdam, Rotterdam, The Netherlands

Background and objectives: The Dutch Healthy Diet index (DHD-index) assesses adherence to the Dutch dietary guidelines for a healthy diet of 2006. These dietary guidelines were mainly developed for preventing chronic diseases. Consequently, adherence to these guidelines as assessed by the DHD-index, should hypothetically lower the risk of chronic diseases as coronary heart diseases (CHD). However, this has not been examined yet. Therefore, we aimed to examine the association of the DHD-index with all-cause mortality and CHD mortality in the Netherlands.

Methods: We studied 4, 829 men and women aged 55 years and older from baseline (1990-1993) measurements of the Rotterdam Study. Maximum follow-up was 20 years. Coronary heart diseases and mortality cases were determined from general practitioners databases, hospital databases, and follow-up examinations. Diet was assessed at baseline with a 170-item food frequency questionnaire. Based on these dietary data the DHD-index score was calculated excluding the component on consumption occasions of acidic drinks and foods. This results in a range of scores between 0-90, where higher scores indicate better adherence to the dietary guidelines. Cox proportional hazards models were used to estimate hazard ratios (HR) and 95% confidence intervals (95% CI) adjusted for age, sex, total energy intake, smoking and educational level.

Results: Out of 4, 829 participants, 2, 394 (49.6%) participants died. In 3, 770 participants free of CHD, in 554 participants occurred fatal CHD event. A ten-unit increment in DHD-index score was inversely associated with all-cause mortality (HR: 0.92; 95% CI: 0.88-0.96), and CHD mortality (HR: 0.88, 95% CI: 0.81-0.96).

Conclusions: Better adherence to the Dutch dietary guidelines for a healthy diet was associated with a significant lower risk of all-cause mortality and CHD mortality

Key words: DHD-index, dietary guidelines, mortality, cohort.

PO1348**NEW MEANINGS OF EATING OUT FOR A GROUP OF ELDERLY IN BRASIL**

M C. Carvalho¹, C. Monsores², S. Prado², F. Ferreira²

¹Universidade Federal do Rio de Janeiro, Universidade do Estado do Rio de Janeiro, Brazil

²Instituto de Nutrição, Universidade do Estado do Rio de Janeiro, Brazil

Background and objectives: To make meals out of home in major centers in Brazil is a habit that has become part of the daily life of a good portion of the population in recent decades, this is due to the accelerated pace of life, convenience, low cost, wide range of restaurants and industrial products and greater sociability. The home kitchen has no longer a central role in the preparation of meals and eating out has become a common practice in the lives of seniors. To understand this habit is a way to improve Public Health Programs. The objective of this study is to analyze the meanings of food habits of eating out in a group of elderly population.

Methods: Our study followed an Extension Program Promoting health and quality of life of elderly, developed at the Federal University of the State of Rio de Janeiro for 17 years, and, based on ethnography analyze the transition social phenomena of eating out considering the meaning that social actors attribute to their actions (Geertz, 1989).

Results: We realize that biological, psychological and social factors as retirement, widowhood and children leaving home are related to changes in food habits of elderly men living alone, beyond disinterest in preparing meals and a search for new environments more propitious to social relations. Eating outside became a way of socialization, besides being a form of inclusion in the globalized world.

Conclusions: frequenting food plazas eventually, especially when someone is alone, proved most interesting for the elderly than spending time in the kitchen to prepare a meal that will not always be shared. We observed that eating out as well as buy food outside and bring it back home promotes new kinds of relationships in this age range of the population

Key words: eating out, elderly, life style.

⁸La Mina Primary Care Center, University of Barcelona, Barcelona, Spain; IDIAP JordiGol, Barcelona, Spain

⁹Department of Preventive Medicine, University of Malaga, Malaga, Spain

¹⁰Department of Cardiology, University Hospital of Alava, Vitoria, Spain

Background and objectives: The traditional Mediterranean dietary pattern (MedDiet) has shown a beneficial relationship with longevity and several chronic conditions such as with cardiovascular disease (CVD), obesity, and cancer. However, scarce information on who is more likely to follow this food pattern is available. We aimed to evaluate which factors are associated with lower MedDiet adherence in elderly Spanish subjects.

Methods: We included 7305 participants (men aged 55-80 y, women 60-80 y) at high CVD risk from the PREDIMED trial (ISRCTN35739639). Lifestyle, anthropometric and socioeconomic characteristics and CVD risk factors were collected. MedDiet adherence at baseline was evaluated with a validated 14-item questionnaire. Multivariate logistic regression models were used to estimate odds ratios (OR) and their 95% confidence intervals for lower adherence to the MedDiet (<9 points out of 14) and ascertain which factors were independently associated with adherence to the MedDiet.

Results: Former smoking (OR=0.87; 95% CI, 0.78-0.98), physical activity (OR for the 3rd vs. the 1st tertile: 0.69; 0.62-0.78), and higher educational level (OR for university vs. less than primary school: 0.54; 0.38-0.77) were associated with higher MedDiet adherence. Conversely, having a larger waist-to-height ratio (OR for 0.1 units, 1.35; 1.22-1.49), being diabetic (OR=1.13; 1.03-1.24), being single (OR=1.27; 1.01-1.61) or divorced or separated (OR=1.44; 1.09-1.89), and current smoking (OR=1.28; 1.11-1.47) were associated with lower adherence.

Conclusions: Participants with little education, a larger waist-to-height ratio, or diabetes and those who were less physically active, single, divorced, or separated, or smokers were less likely to adhere to the MedDiet, an ideal model for food choices. Stronger efforts of health promotion are needed in these groups to foster adoption of the MedDiet.

Key words: Mediterranean diet, lifestyle factors, PREDIMED trial.

PO1350**INCREASE IN BODY MASS INDEX IS ASSOCIATED WITH A WORST LUNG FUNCTION IN SPANISH MEDITERRANEAN SMOKERS WITHOUT RESPIRATORY DISEASE**

M. Sorlí¹, C. Jardí¹, E. Aparicio¹, F. Martín¹, J.L. Piñol¹, G. Flores¹

¹GEPAR Research Group, Unitat de Suport a la Recerca Reus-Tarragona, Institut Universitari D'Investigació en Atenció Primària Jordi Gol (IDIAP Jordi Gol), Reus, Catalunya, Spain

Background and objectives: Trends of overweight and obesity have increased dramatically in Spain. The aim of this study was to determine the association between body mass index (BMI) and the lung volumes in a smoking population without history of respiratory disease.

Methods: Cross-sectional study. Setting: 12 Spanish primary care centers. The period of study was between June 2008 and June 2010. Subjects: smokers of 10 or more packs/year, 35 to 70 years, of both sexes and no history of lung disease who consented to undergo spirometry with bronchodilator test. Study variables: demographic data, smoking habit, medical history, anthropometric measures and spirometric values. We performed multivariate analysis unconditional logistic regression, using SPSS for Windows v15.

Results: Sample comprised of 738 patients (53% male) with a mean age of 53.7 years old (SD: 8.3), BMI of 27.2 kg/m² (SD 4.8). With regard to smoking, consumption was 34.6 packs /year (SD: 21.8). Spirometric values were: FVC 93.3% (SD 16.5) and FEV1 94.7% (SD 18.1). In multivariate analy-

sis, after adjusting for all variables studied, were independent determinants for altering FEV1, age (OR:1, 05 ; IC95%:1, 03-1, 07), male gender (OR:2, 70 ; IC95%:1, 72-4, 25), smoking (packs/year) (OR:1, 01 ; IC95%:1, 00-1, 02) and BMI (OR:1, 05 ; IC95%:1, 02-1, 11), and FVC were age (OR:1, 05 ; IC95%:1, 03-1, 08), male gender (OR:3, 27 ; IC95%:2, 03-5, 26), smoking (packs/year) (OR:1, 02 ; IC95%:1, 01-1, 03) and BMI (OR:1, 11 ; IC95%:1, 06-1, 15).

Conclusions: BMI, as well as age, gender and accumulated consumption of tobacco is an independent determinant of lung function in Spanish Mediterranean smokers without a known respiratory disease.

Key words: Body Mass Index, Lung function, Smoking

IRON STORES AND ANAEMIA PREVALENCE AMONG SCHOOL CHILDREN FED COWPEA-BASED FOOD PLUS FISHMEAL WITH VITAMIN C-RICH DRINK

G. Egbi¹, M. Steiner-Asiedu², F. Saalia², I. Ayi¹, W. Ofosu³, J. Setorglo⁴

¹Nutrition Department, Noguchi Memorial Institute for Medical Research, College of Health Sciences, University of Ghana, Legon, Ghana

²Department of Nutrition and Food Science, University of Ghana, Legon, Ghana

³Department of Nutrition and Food Science, University of Ghana, Legon, Ghana

⁴Parasitology Department, Noguchi Memorial Institute for Medical Research, College of Health Sciences, University of Ghana, Legon, Ghana

Background and objectives: Iron deficiency anaemia affects growth, development and academic performance of school children. This study investigated the effect of cowpea-based food fortified with fishmeal consumed with vitamin C-rich drink on the iron status and anaemia prevalence among school children.

Methods: The study consisted of a cross-sectional baseline and a six month's nutrition intervention phase. The participants were 143 school children (78 males and 65 females), aged 6 to 12 years, randomly assigned into 3 groups: group I (cowpea + fishmeal + vitamin C), Group II (cowpea + vitamin C) and a control group (cowpea only). Socio-demographic data were collected using questionnaires at baseline. The following data were collected at baseline and end-line: height and weight by standard procedures, dietary data by 24-hour recall and food frequency questionnaires, haemoglobin concentrations by Haemocue Haemoglobinometer and serum ferritin by Enzyme

Linked Immunosorbent Assay (ELISA). Malaria parasites and soil-helminthes were examined throughout the study.

Results: Mean ferritin concentrations at baseline were 23.21±12.64ng/ml, 24.96±18.67ng/ml, 23.53±13.81ng/ml; at end-line 32.71±21.45ng/ml, 27.62±16.29ng/ml and 26.83±17.06ng/ml for intervention group I, II and control group respectively. The mean haemoglobin concentration increased significantly in intervention I, intervention II and control group from 120.08 ± 9.8 g/L, 119.09 ± 12.4 g/L and 119.16 ± 10.4 g/L at baseline to 128.41 ± 7.2, 126.37 ± 8.9 g/L and 123.12 ± 6.6 g/L respectively at end-line. Prevalence of anaemia reduced largely in group I (23.5% to 3.9%), followed by group II (34.9% -9.3%) and control group (30.6% -18.4%).

Conclusions: Cowpea-based food plus fishmeal and vitamin C-rich drink consumption improved ferritin and haemoglobin concentrations significantly and reduced anaemia prevalence in school children. The meal promises to be an important dietary strategy for improving ferritin, haemoglobin concentration and controlling anaemia among school children.

Key words: Fishmeal, cowpea, anaemia, children, vitamin C.

PO1352

STABILITY IN WEIGHT STATUS DESPITE INCREASED SEDENTARY BEHAVIOR AFTER TWO YEAR FOLLOW-UP IN SWEDISH SCHOOLCHILDREN

L. Moraeus¹, L. Lissner¹, A. Sjöberg²

¹Department of Public Health and Community Medicine, University of Gothenburg, Gothenburg, Sweden

²Department of Food and Nutrition, and Sport Science, University of Gothenburg, Gothenburg, Sweden

Background and objectives: Sedentary behavior and physical activity are factors influencing children's weight status. We aim to observe longitudinal changes in weight status and some lifestyle factors in schoolchildren in Western Sweden.

Methods: Anthropometric data from 1182 schoolchildren (7-9 y) in the county of Västra Götaland, Sweden were collected in 2008, following a standardized methodological protocol. A follow-up was conducted in 2010 including 1055 children (9-11 y). Included in this study were 810 children (69%) that were measured both years. Prevalence of pre-obesity and obesity were classified using International Obesity Task Force cut-offs. Parents filled in lifestyle questionnaires containing questions about physical activity and sedentary behavior. 555 children (69%) returned the questionnaire.

Results: Prevalence of pre-obesity was 13.0% in 2008 and 13.6% in 2010 (p=0.53), corresponding numbers for obesity

was 2.8% and 2.5% ($p=0.44$). Most children, 92%, remained in the same weight category both years, 4% increased one category, 4% decreased one category. One child moved two categories from normal weight to obese. 30% of children spent more time on sedentary activities in 2010, while 60% spent the same amount and 10% spent less time. At the same time, 33% of children increased the number of days they participated in sports over the 2 year follow-up, while 56% reported the same level.

Conclusions: Most children did not change weight category after two years of follow up. We observed an increase in sports participation as the children grew older but sedentary behavior also increased. It may be possible to identify positive and negative lifestyle changes in children after a relatively short period of time, which can be of importance when planning public health interventions.

Key words: child, obesity, lifestyle, longitudinal Acknowledgements Funded by the Swedish Research Council, The Swedish Council for Working Life and Social Research and Västra Götaland region.

PO1353

PERCEPTIONS, ATTITUDES AND PRACTICES OF UNDERGRADUATE STUDENTS AT THE UNIVERSITY OF THE FREE STATE REGARDING DIETARY SUPPLEMENTS AND ALTERNATIVE DRINKS

W. du Toit¹, L. van den Berg,¹ J. Raubenheimer.²

¹Department of Nutrition and Dietetics, University of The Free State, Bloemfontein, South Africa

²Department of Biostatistics, University of the Free State, Bloemfontein, South Africa

Background and objectives: The sales of dietary supplements and alternative drinks (including so-called energy drinks) run into billion figures worldwide, yet evidence to support the benefits of these products are often lacking. This study aimed to determine the perceptions, attitudes and practices regarding dietary supplements and alternative drinks of young South African adults.

Methods: A cross sectional descriptive study was conducted via a self-reported electronic questionnaire made available to all students. The questionnaire included assessment of perceptions and attitude of students regarding the use of dietary supplements and alternative drinks; and practices related to dietary supplement use, alternative drinks and food intake.

Results: The respondents (N=1311; 21±3yrs), were mostly female (54%); black (61%) or white (31%) ethnicity. The 63% who reported consuming supplements, indicated that they use vitamin (56%), mineral (31%), herbal (11%), sport (11%) and homeopathic (2%) supplements. In contrast less than 30% reported daily intakes of fruit and vegetables. Most users ob-

tained information regarding supplements from the internet (35%) and magazines (34%), and supplements were mostly recommended to users by their families (45%), and friends (42%), with parents paying for supplements in 40% of cases. Eighteen percent of users reported having experienced side-effects. "Energy drinks" like Bioplus® (30%) and Red Bull® (28%) were popular mainly for the taste and to provide energy. Various misperceptions regarding supplements were also identified.

Conclusions: The use of dietary supplements and alternative drinks and misperceptions regarding these products were common among these students. Most relied on information and recommendations from unreliable sources and unqualified people. Interventions to educate students on the safe and efficient use of the products, and adequate fruits and vegetables consumption are required.

Key words: students, dietary supplements, perceptions, attitudes, practices.

PO1354

DOUBLE BURDEN OF MALNUTRITION IN AFRICA

A. Melse-Boonstra¹, A. van der Honing¹, S J M. Osendarp^{1,2}, I D. Brouwer¹

¹Division of Human Nutrition, Wageningen University, Wageningen, The Netherlands

²OsendarpNutrition, Vlaarding, The Netherlands

Background and objectives: Various studies have reported that despite increases in income in low-to-middle income countries, the problem of undernutrition is persisting, whereas it does generate new disease burdens related to overnutrition, with overweight and obesity as early signs. In the present study, we have analyzed associations between income and various indicators of over- and undernutrition for low-to-middle income countries in Africa.

Methods: Country statistics were obtained from the World Bank and from the WHO Nutrition Landscape Information System, and countries were classified into low, low-to-middle and upper middle income categories. Double burden of malnutrition was defined as a prevalence of stunting >30% and a prevalence of overweight >15% in children (aged < 5y), or a prevalence of BMI>25 >50% in adults within a country.

Results: Prevalence of stunting correlated negatively with income indicators ($r=-0.63$ to -0.70 , $P<0.001$), whereas the prevalence of overweight in both men and women was positively correlated with income indicators ($r=0.50$ to 0.70 , $P<0.001$). Large heterogeneity in the prevalence of both forms of malnutrition existed among African countries with a gross national income (GNI) per capita < 2,000 US\$. Seven out of 43 countries could be classified as experiencing the double burden of

malnutrition, namely Botswana, Comoros, Guinea-Bissau, Lesotho, South Africa, Swaziland, and Zimbabwe. Strikingly, three of these countries are low income countries and two are low-to-middle income countries.

Conclusions: The double burden of malnutrition is not confined to upper middle income countries, but is also present in low and low-to-middle income countries in Africa. Identification of the etiology of the double burden of malnutrition in low and low-to-middle income countries is urgently required in order to define integrative approaches to reduce stunting and to prevent overweight simultaneously.

Key words: Stunting; Overweight; Income; Double burden of malnutrition; Africa.

PO1355

DIETARY PATTERNS AND ASSOCIATED HEALTH-RELATED LIFESTYLE FACTORS IN DENMARK

V K. Knudsen¹, A. Biloft-Jensen¹, J. Matthiessen¹, M R. Sørensen¹, M. Groth¹, U H. Gondolf¹, E. Trolle¹, T. Christensen¹, S. Fagt¹

¹DTU Food, Søborg, Denmark

Background and objectives: Poor diet has been associated with increased risk of lifestyle-related diseases. Despite having had food-based dietary guidelines in Denmark since 1970'ties, the compliance is still low. Identification of major dietary patterns in the population may facilitate Health authorities in more targeted nutrition education towards potentially vulnerable groups in the population. The objective was to identify dietary patterns in the Danish population, and to describe associations with lifestyle factors.

Methods: Data derive from the Danish National Survey of Diet and Physical Activity, an ongoing, nation-wide cross-sectional survey. Food intake was assessed by means of a 7-days food diary in a sample of the adult Danish population (n=3354), recruited 2003-2008. Foods and drinks were combined into 53 overall food groups, and Principal Component Analysis (PCA) was applied to identify underlying dietary patterns. Multiple regression analysis was applied to determine associations between dietary patterns and gender, age and health-related lifestyle factors (smoking, physical activity and BMI).

Results: Three dietary patterns were detected: A Traditional pattern characterized by high correlation with rye bread, topping on bread, meat, potatoes and gravy; a Health Conscious pattern, highly correlated with fruit and vegetables, nuts, coarse bread, water and tea, and a Fast food pattern, correlated with pizza, hamburger, soft drinks, sweets and crisps. The traditional pattern was positively associated with being male and physically active, while the health conscious pattern was associated with age, and being female, non-smoker, physical

ly active, and negatively associated with body mass index. The fast food pattern was negatively associated with age and being physically active.

Conclusions: Three dietary patterns were identified, and associations with health-related lifestyle factors were assessed. Identification of dietary patterns can be useful in future nutrition education to increase the proportion in the population complying with dietary guidelines.

Key words: Dietary patterns, PCA, lifestyle factors, Denmark.

PO1356

MODELLING OF USUAL NUTRIENT INTAKES: POTENTIAL IMPACT OF THE CHOICES PROGRAMME ON NUTRIENT INTAKES IN YOUNG DUTCH ADULTS

A. Roodenburg¹, A. Van Ballegooijen², M. Dötsch-Klerk³, H. Van der Voet⁴, J. Seidell²

¹HAS University of Applied Sciences, Den Bosch, The Netherlands

²Institute of Health Sciences, VU University Amsterdam, Amsterdam, The Netherlands

³Unilever Research & Development Vlaardingen, Vlaardingen, The Netherlands

⁴Wageningen UR – Biometris, Wageningen, The Netherlands

Background and objectives: The Choices Programme is an internationally applicable nutrient profiling system with criteria for trans fatty acids (TFA), saturated fatty acids (SAFA), sodium, added sugar and for some product groups energy and fibre. These criteria determine whether foods are eligible to carry a "healthier option" stamp. The objective of this study was to evaluate these criteria by investigating the potential effect on nutrient intakes using an nutrient intake modelling method.

Methods: Data were combined from the 2003 Dutch food consumption survey in young adults (aged 19-30) and the Dutch food composition table into the Monte Carlo Risk Assessment (MCRA) model. Three scenarios were calculated: the "actual intakes" (scenario 1) were compared to scenario 2, where all foods that did not comply were replaced by similar foods that did comply with the Choices criteria. Scenario 3 was the same as scenario 2 adjusted for the difference in energy density between the original and replacement food. Additional scenarios were calculated when snacks were not or partially replaced.

Results: Calculated intake distributions showed that median energy intake was reduced by 16% by replacing normally consumed foods with Choices compliant foods. Intakes of nutrients with a maximal intake limit were also reduced (ranging

from -23% for sodium and -62% for TFA). Effects on intakes of beneficial nutrients varied from an unintentional reduction in fat soluble vitamin intakes (-15 to -28%) to an increase of 28% for fibre and 17% calcium.

Conclusions: This intake modelling method showed that with the consumption of Choices compliant foods, nutrient intakes shift towards population intake goals for the nutrients for which nutrition criteria were defined, while effects on beneficial nutrients were diverse.

Key words: nutrient intake modelling, nutrient profiling, reformulation.

PO1357

THE EPIC-GRANADA-GIPUZKOA PROJECT ON DIETARY PATTERNS, ANTIOXIDANTS AND BIOMARKERS OF OXIDANT-ANTIOXIDANT STATUS (EUROPEAN PROSPECTIVE INVESTIGATION INTO CANCER AND NUTRITION)

E. Molina-Montes^{1,2}, P. Amiano^{3,2}, M D. Ruiz-López⁴, R. Artacho⁴, E. Guerra⁴, B. García-Villanova⁴, C. Samaniego⁴, E. Molina-Portillo¹, E. Sánchez-Cantalejo^{1,2}, M. Azpiri³, A J. Pérez-Cruz⁵, M J. Sánchez^{1,2}

¹Andalusian School of Public Health, Granada, Spain

²CIBER Epidemiología y Salud Pública, CIBERESP, Spain

³Public Health Division of Gipuzkoa, BioDonostia Research Institute, San Sebastián, Spain

⁴Department of Nutrition and Bromatology, University of Granada, Granada, Spain

⁵Hospital Virgen de las Nieves, Granada, Spain

Background and objectives: The role of antioxidant nutrients on the relationship between intake of antioxidant-rich foods and the prevention of chronic diseases remains unknown. Total Antioxidant Capacity (TAC) and dietary patterns are both a measure of overall exposure to antioxidants and to the diet, respectively. The project's aims are to identify dietary patterns associated with TAC, and to examine whether biomarkers of oxidative stress are associated with TAC.

Methods: Cross-sectional study including 7, 879 and 8, 417 participants from Southern (EPIC-Granada) and Northern Spain (EPIC-Gipuzkoa), respectively, recruited during 1992-1996. TAC of the diet will be assessed through published TAC data (ORAC, TRAP, FRAP, DPPH, ABTS) in food. TAC in plasma will be analyzed in a subsample. Dietary patterns will be derived through a priori and a posteriori approaches, also considering different definitions of the Mediterranean Diet (MD), geographic variations (South-North Spain), Quality Diet In-

dexes and Dietary Guidelines. Statistical analysis: Regression analysis between TAC and the adherence to dietary patterns, and between TAC and antioxidant-oxidant and inflammation biomarkers, considering potential confounding variables and effect modifiers (smoking habits, and other lifestyle factors), will be performed.

Results: A dietary pattern characterized by a combination of food groups of high antioxidants content, such as the MD, is expected to be associated with a higher TAC. Variants of the MD might be more antioxidants rich, leading to higher concentrations of TAC and antioxidant status (carotene, vitamin C, vitamin E), and to lower levels of biomarkers (IL-6, IL-8, ...). This effect might be more prominent in subjects with healthier lifestyle habits.

Conclusions: This project will contribute to expand the knowledge on dietary patterns associated with a higher TAC and antioxidant status. The ultimate goal is to understand the role of dietary antioxidants in the aetiology of cancer and chronic diseases related to oxidative stress.

Key words: dietary patterns, antioxidants, biomarkers.

PO1358

PREVALENC OF UNDERNUTRITION IN HOSPITALIZED INFANTS IN TABRIZ, IRAN COMPARED TO GLASGOW UK

S. Milani A^{1,3}, K. Gerasimidis², M. Rafeey³, A. Tester², C. Woodley², O. Purcell², M. Tsiountsioura², C M. Wright¹

¹EACH Unit, School of Medicine, MVLS College, University of Glasgow, UK

²Department of Human Nutrition, School of Medicine, MVLS College, University of Glasgow, Glasgow, UK

³Child Health Research Center, Tabriz University of Medical Sciences, Tabriz, Iran

Background and objectives: Hospitalized children are thought to be at high risk of undernutrition in developed, as well as developing countries, but little is known about undernutrition risk in children under one year. The apparent prevalence is likely to depend on the background prevalence of undernutrition, but also varies with the thresholds and measures used. We thus surveyed hospitalized infants in two countries to compare the prevalence of •Risk of undernutrition using the Paediatric Subjective Global Nutritional Assessment (SGNA) tool •Malnutrition using Triceps and subscapular skinfolds z score Subjects and

Methods: Infants were studied at admission to two tertiary children's hospitals, 210 in Glasgow UK and 187 infants in Tabriz, Iran, between September 2011 and 2012.

Results: Participants were aged mean (SD) 5.42 (2.97) months in Iran and 4.65 (3.43) months in UK. Their mean

lengths z-scores were similar (Iran -0.58 (1.53) UK -0.06(1.33)) but the Iranian children had much lower BMI (Iran -1.65(1.39) UK -0.45(1.23)). More Iranian than UK infants had high SGNA risk (Iran 59, 31.6%; UK 14, 6.7%; $p=0.0001$) and acute malnutrition, defined as skinfolds z score <-2 (Iran 54, 42.9%; UK 6, 5.4%; $p=0.0001$) but there were similar rates of medium risk (Iran 47, 25.1%; UK 63, 30.3%). Within each SGNA category UK children had markedly higher skinfolds than Iranian children. While in Iran 80%(33) of high risk and 45%(18) of medium SGNA risk children had SF z score $<-2SD$, in the UK only 17%(1) and 10%(3) respectively had SF z score $<-2SD$.

Conclusions: Higher rates of both undernutrition risk and acute undernutrition were seen in Iran than in the UK. Few of the UK children with raised undernutrition risk actually had objective evidence of undernutrition, but these were closely related in Iran.

Key words: undernutrition, skinfold, SGNA.

PO1359

ASSOCIATIONS BETWEEN DIETARY FATTY ACIDS AND BLOOD LIPIDS IN HEALTHY SOUTH AFRICAN ADULTS: THE PURE STUDY

M. Richter¹, J. Baumgartner¹, E. Wentzel-Viljoen¹, C M. Smuts¹

¹Centre of Excellence For Nutrition, North-West University, Potchefstroom, South Africa

Background and objectives: Results from baseline Prospective Urban and Rural Epidemiology (PURE) study in South Africa, found higher prevalence of unfavorable blood lipid levels than previously documented in South African populations. We investigated associations between dietary fat and individual fatty acid (FA) intake and blood lipids of subjects from the PURE study.

Methods: Cross-sectional data analysis within the PURE baseline study of healthy subjects ($n=2000$, 35–70years) from rural and urban areas. Dietary data was collected and blood lipid analysis performed. Hierarchical multiple linear regression models were used to determine associations between blood lipids and dietary fat and FA intake, gender and urbanization.

Results: Dietary fat intake was significantly higher in urban (males=27%E, females=25%E) than rural areas (males=18%E, females=20%E), the same was true for specific FAs. However, essential FAs and long chain PUFA intake was below recommendations in all groups. Total cholesterol (TC) and LDL were higher in females than males, with no differences between rural and urban areas. Intake of ALA (C18:3n-3) was significantly associated with higher LDL ($r=0.152$, $p=0.016$) and triglycerides ($r=0.241$, $p<0.001$) in males, adjusting for age, urbanization, energy intake, BMI and physical activity. In females ARA

(C20:4n-6) and EPA (C20:5n-3) were associated with higher TC (ARA: $r=0.107$, $p=0.020$ and EPA: $r=0.283$, $p=0.014$) and LDL (ARA: $r=0.091$, $p=0.045$ and EPA: $r=0.252$, $p=0.027$), while DHA (C22:6n-3) predicted lower levels of TC ($r=-0.2$, $p=0.022$) and LDL ($r=-0.255$, $p=0.028$).

Conclusions: Blood lipid profiles were more unfavorable in females than males. Though higher in urban areas, mean dietary fat intake was within recommendations. The low essential and long-chain PUFA intake in all groups is concerning, considering the inverse association of DHA with TC and LDL found in females. However, the positive association between ALA and TC, LDL and triglycerides in males was unexpected at such low levels.

Key words: blood lipids, dietary fatty acids, urbanization.

PO1360

EFFECTS OF VITAMIN D3 AND BETA-CAROTENE ON RISK OF ESOPHAGEAL SQUAMOUS CELL CARCINOMA-A CASE-CONTROL STUDY IN CHINA

G. Huang¹, L. Yang¹, M. Su², S. Wang¹, H. Yin¹, J. Wang³, G. Sun¹

¹Key Laboratory of Environmental Medicine and Engineering of Ministry of Education, and Department of Nutrition and Food Hygiene, School of Public Health, Southeast University, Nanjing, China

²Huaian District Center for Disease Control and Prevention, Huaian City, China

³Department of Environmental Health Science, College of Public Health, University of Georgia, USA

Background and objectives: Beta-carotene (BC) and vitamin D3 (VD3) may be protect factors for cancer risk, while the results are inconsistent, and few reports are about the effects of BC and VD3 on esophageal cancer in human epidemiologic studies. Our aim is to evaluate the etiological roles of BC and VD3 in the development of esophageal squamous cell carcinoma (ESCC) based on a case-control study in Huaian, China. Methods A population based case-control study was conducted in 100 new ESCC diagnosed cases from 2007 to 2008 and 200 residency- age-, and sex-matched healthy controls were recruited from Huaian, a high esophageal cancer incidence region of China. Food frequency questionnaire (FFQ) and reversed phase high-performance liquid chromatography (RP-HPLC) were used to measure the beta-carotene intake and concentrations of beta-carotene and vitamin D3 in serum. We calculated the odds ratios (OR) and 95% confidence intervals (CI) by using the conditional logistic regression models. Results The dietary intake of beta-carotene was 3322.92 μg in case group and 3626.83 μg in control group per capita per day and

their quartile ranges (QR) were 3701.84 µg and 3866.05 µg. There was no significant difference on BC intakes between case and control groups by Wilcoxon test $p > 0.05$. The OR values of highest quartile and the lowest quartile of vitamin D3 and beta-carotene are both 0.127.

Conclusion: The circulating vitamin D3 and beta-carotene in serum were associated with a reduced risk of ESCC in this China population. But no evidence was found between dietary beta-carotene intake and ESCC risk.

PO1361

IMPROVED BEHAVIOR IN CHILDREN AGED 3 TO 5 AFTER ONE YEAR OF A SCHOOL-BASED INTERVENTION FOR HEALTHY LIVING

J.L. Peñalvo¹, M. Sotos-Prieto¹, G. Santos-Beneit¹, J. Redondo¹, S. Pocock^{1,2}, V. Fuster^{1,3}

¹Department of Epidemiology, Atherothrombosis and Cardiovascular Imaging, Centro Nacional de Investigaciones Cardiovasculares (CNIC), Madrid, Spain

²Department of Medical Statistics, London School of Hygiene and Tropical Medicine, London, UK

³Department of Cardiology, Mount Sinai School of Medicine, New York, USA

Background and objectives: The onset of inadequate lifestyle-related behaviors is known to occur early in life. An effective program for health promotion should focus on children, and include strategies capable of establishing life-long habits. We aimed to evaluate the efficacy of a behavioral intervention to introduce healthy lifestyle habits into children, their parents and teachers, through the school environment.

Methods: We carried out a cluster-randomized controlled intervention in schools from Madrid targeting 3-5 year old children. A total of 24 schools were assigned to the usual scholar curriculum or to engage in an additional multi-domain (Program SI!) intervention organized for a total duration of three years. Primary outcome are 1-year, and 3-year changes from baseline in knowledge, attitudes, and habits (KAH scores) of children, parents and teachers in regards to health-related (diet, physical activity, human body, and emotion's management) behaviors.

Results: There were 12 intervention schools and 12 control schools including a total of 2062 children, 1949 parents, and 150 teachers. Children in the intervention group showed a significantly larger increase (4.3%) in all overall KAH score. By class level, 3 year old-children benefited the most, with an increment 5.8% higher than the controls. By domain, the largest difference was found in the KAH-physical activity score (6.4% more on intervention). No effect for the emotion domain was found. There was a significant interaction with children's age

($p=0.046$), as well as children's baseline score ($p=0.051$), and parental socioeconomic characteristics ($p=0.008$), and higher economic status ($p=0.011$).

Conclusions: Interim results after 1-year intervention with the Program SI! can be considered as a proof of an effective, and feasible preventive strategy at improving knowledge, attitudes and habits related to a healthy lifestyle in very young children.

Key words: Comprehensive health; Behavior; Lifestyle; Cluster-randomized controlled intervention

PO1362

OPEN (OBESITY PREVENTION THROUGH EUROPEAN NETWORK), STRENGTHENING AND UP SCALING THE IMPLEMENTATION OF COMMUNITY-BASED PROGRAMMES AT EUROPEAN LEVEL

H. du Plessis¹, J.N.M. Borys¹, L. Walter¹, H. Flinch¹, P. Richard¹, P. Harper¹

¹Proteines SAS, Paris, France

Background and objectives: Building on the EPODE European Network (EEN) project (2008-2011) and according to the needs of the Community-based Programmes (CBPs) OPEN is a project supported by the European Commission (DG SANCO), aims to scale-up a minimum of 12 European Community-Based Programmes/Initiatives (CBPs/Is) that involve communities, in terms of quality and amount of actions developed and in term of increased diversity of the target groups reached. This, in order to reduce overweight and obesity among children and adolescents, including socially deprived groups.

Methods: During 3 years, OPEN will base its childhood obesity prevention approach on the EEN recommendations and recent EU-funded researches (ENERGY, SPOTLIGHT, TEMPEST, IDEFICS). The CBPs progress will be measured according to the WHO Good Practice Appraisal tool. An OPEN Coordination team will assess the needs of 12 CBPs from 17 European countries willing to strengthen their methodology and improve their interventions. A scientific committee will gather, disseminate and facilitate practical application on the field of evidence and practice-based findings.

Results: A network of 7 universities and scientific partners interested in the issue of 9 Community/School-Based Programmes and 2 European health promotion boards to develop coordinated research plans in health-related diet and physical activity behaviours in the future was created with the support of DG Sanco.

Conclusions: OPEN will focus on increasing amount and efficiency of local actions developed among various target groups and facilitate implementation of innovative actions and dissemination through a best practice database to support the development and the efficiency of CBPs.

Key words: Community-Based Programmes, Prevention, obesity, healthy lifestyle.

PO1363**STRENGTHS AND WEAKNESSES OF COMMUNITY-BASED PROGRAMMES FOR OBESITY PREVENTION**

H. Du Plessis^{1,2}, L. Walter^{1,2}, J-M. Borys^{1,2}, P. Harper^{1,2}, H. Finch^{1,2}, P. Richard^{1,2}

¹EPODE International Network, 109-111 rue Royale, Brussels, Belgium

²Proteines SAS, 11 rue Galvani, 75017 Paris, France

Background and objectives:The EPODE International Network (EIN) is a non-governmental organisation which has been created to support Community-Based Programmes (CBPs) aimed at preventing obesity. Today, 25 CBPs are member of this network (9 in Europe, 11 in America and 5 in Asia-Pacific region). The objective of this study was to identify the strengths and weaknesses and the needs of these programmes in terms of scientific and strategic expertise, evaluation processes, political and institutional commitment, Public-Private Partnerships (PPP), programme visibility and communication strategy.

Methods: The programme managers were interviewed around three topics: Network Functioning, Strengths and weaknesses, experience sharing. The aim of the first part was to identify the four main expectations of the CBPs towards the three network supporting platforms (Scientific, PPP and Political). The second part was dedicated to explore the strengths and weaknesses of the CBPs (self-reported) and the last one to identify their global needs.

Results: In total, 19 out of 25 CBPs members of the EIN answered the questionnaire (76% response). The main expectations reported by the CBPs are the need of a methodological support within their monitoring and evaluation process, a sustainable funding and a guidance for building and managing PPP. The strengths and weaknesses will be presented during ECO. One of the aspects that emerge is the need of a greater link between the field and the scientific community. **Conclusions:** Based on this study the EIN will suggest a pragmatic methodology to improve the functioning and sustainability of the CBPs aimed at preventing obesity.

Key words: Community-Based Programmes, prevention, obesity, evaluation, coordination.

PO1364**CHILDHOOD OBESITY PREVENTION : A SIGNIFICANT DECREASE OF OVERWEIGHT PREVALENCE IN TWO PILOT TOWNS OF THE VIASANO PROGRAMME AFTER 2 YEARS OF INTERVENTION.**

J.M. Borys¹, M. Roillet², J. Beysens², N. Jacobs², J. Nève³

¹EPODE International Coordination, Brussels, Belgium

²VIASANO Coordination, Brussels, Belgium

³Université libre de bruxelles, Brussels, Belgium

Background and objectives:VIASANO is a Community Based Programme in Belgium adapted from the EPODE methodology. It is a coordinated, capacity-building approach for communities to implement effective and sustainable strategies to prevent childhood obesity. This methodology enables the entire community to be empowered and contribute to create a healthier environment facilitating social norm changes and healthier behaviours.

Methods: The interventions involved the whole population of these pilot towns (families and children) in whole-of-community actions targeting physical activity and nutrition. The national coordination team using social marketing and organizational techniques trained and coached a local project manager nominated by the local authorities. The project manager was provided tools to mobilize local stakeholders through a steering committee and local network. The BMI of the children was assessed in 2008 and then 2 years later (in 2010) in the two pilot towns and in the French Community as comparator.

Results: Over 1300 Children aged 3-6 were assessed in VIASANO towns in 2008 and 2010. There was a significant 22% reduction in the prevalence of overweight in these pilot towns between 2008 and 2010 ($p < 0,04$) and between these pilot towns and comparison towns of the French Community.

Conclusions: The results of this whole community programme are supporting the encouraging results of EPODE methodology which show that the involvement of the whole community is necessary to reduce the prevalence of childhood obesity.

Key Words: Prevention, obesity, decrease, evaluation.

PO1365**EPHE (EPODE FOR THE PROMOTION OF HEALTH EQUITY), A 3 YEARS EUROPEAN PROJECT TO PROMOTE HEALTHIER LIFESTYLES AND REDUCE OBESITY-RELATED HEALTH INEQUALITIES**

H. Du Plessis¹, J-M.Borys¹, P. Harper¹, P. Richard¹, L. Walter¹

¹Proteines SAS, Paris, France

Background and objectives: Background and objectives: "Overweight and obesity most affect people in lower socioeconomic groups, and this in turn contributes to a widening of health and other inequalities." EPHE is a European project designed to evaluate how Community-Based Programmes (CBPs) can reduce health inequalities linked to diet and physical activity.

Methods: This 3 year project will conduct a pilot-life testing in 7 communities around Europe implementing the EPODE methodology with CBPs (Belgium, Bulgaria, France, Greece, Portugal, Romania, The Netherlands). They will implement 2 years whole of population interventions enhancing the deprived population around 4 themes: improve fruits and vegetables consumption, sleep duration and water consumption and decrease sedentary lifestyle. The evaluation will be conducted on each of these 4 themes and a quartile analysis of income will be done to compare results from the highest and lowest quartiles within and in-between communities. Each CBPs will evaluate 150 families through questionnaire. The questionnaire will be anonymous and will be made up of three parts, so as to appropriately analyse the aforementioned measurements: • Assessment of SES, in terms of education, profession and social status • Assessment of the behaviour of the four themes and their determinants • Parents' perception of a healthy body

Results: 7 Communities-Based Programmes together with 8 European Universities are involved in this project and the results of the first survey will be presented during the IUNS.

Conclusions: This project will lead to produce concrete guidelines and best-practices for policy makers, health promotion services to implement sustainable and focused strategies among communities to reduce health inequalities linked to diet and physical activity.

Key words: health inequalities, prevention, reduction, community.

PO1366**DIETARY INTAKE OF PHYLLOQUINONE IS RELATED TO A REDUCED RISK OF ALL-CAUSE MORTALITY: THE PREDIMED STUDY.**

⁹Department of Preventive Medicine, University of Malaga, Malaga, Spain

¹⁰Institute of Health Sciences, University of Balearic Islands and Hospital Son Espases, Palma de Mallorca, Spain

Background and objectives: Vitamin K has been associated with a reduced risk of CHD and fatal cancer. Dietary menaquinones intake has been associated with cancer mortality. However, the association between the dietary intake of vitamin K and all-cause mortality has not been evaluated in a Mediterranean population at high cardiovascular risk.

Methods: A prospective analysis was conducted in 7216 participants in the framework of the PREDIMED cohort (median follow-up: 4.8y). Energy and nutrient intakes were evaluated using a previously validated 137-item food frequency questionnaire. Dietary phylloquinone and menaquinone intake was calculated using the USDA database and previous published

data, respectively. All-cause mortality was verified by medical records and consultation of National Death Index. Cox proportional hazard models were fitted to assess the relative risk of all-cause mortality.

Results: At baseline, energy-adjusted dietary phyloquinone intake was associated with a significantly reduced risk of all-cause mortality after controlling for potential confounders (HR: 0.64; 95% CI: 0.43, 0.96). No significant associations were found between quartiles of energy adjusted dietary menaquinones intake and risk of all-cause mortality. In a longitudinal manner, subjects who increase their consumption of vitamin K, phyloquinone or menaquinone, had a lower risk of all-cause mortality (HR: 0.58; 95% CI: 0.45, 0.74 and HR: 0.59; 95% CI: 0.45, 0.78, respectively) compared with subjects who decrease their consumption.

Conclusions: The results showed that an increase of dietary intake of vitamin K is related with a reduced risk of all-cause mortality in a Mediterranean population at high cardiovascular risk.

Key words: Vitamin K, Mortality, Phyloquinone, Menaquinone.

PO1367

ANTHROPOMETRY AND BLOOD PRESSURE IN 3-5 YEAR OLD CHILDREN OF MADRID: PROGRAM SI! STUDY

G. Santos-Beneit¹, M. Sotos-Prieto¹, J.L. Peñalvo¹, S. Pocock^{1,2}, J. Redondo¹, V. Fuster^{1,3}

¹Department of Epidemiology, Atherothrombosis and Cardiovascular Imaging, Centro Nacional de Investigaciones Cardiovasculares (CNIC), Madrid, Spain

²Department of Medical Statistics, London School of Hygiene and Tropical Medicine, London, UK

³Department of Cardiology, Mount Sinai School of Medicine, New York, USA

Background and objectives: The Program SI! for comprehensive health is a multi-level school-based intervention working on four key domains (diet, physical activity, human body and management of emotions) for the promotion of a healthy lifestyle. The intervention has been initiated at preschool (3-5 years) level, and its efficacy to modify children's behavior is currently evaluated. As part of this evaluation, anthropometry and blood pressure measurements have been collected at baseline to assess the long-term impact of the intervention.

Methods: The design of the study was a cluster-randomized controlled intervention trial including 24 public schools of Madrid (Spain). Weight, height, skinfolds thickness (triceps and

subscapular), waist circumference and blood pressure were assessed in 2011 children (1009 boys and 1002 girls). Body fat was calculated according to Slaughter. Obesity and overweight were defined in relation to BMI international references proposed by the IOTF.

Results: Percentage of body fat in boys and girls was 14.5±3.6 and 15.8±3.5 respectively, waist circumference was 52.2±4.0 for boys and 51.6±4.1 for girls, and systolic / diastolic blood pressure was 99.6±8.2 / 60.0±7.2 for boys, and 98.5±8.4 / 61.2±7.4 for girls (p<0.01, for all). The prevalence of overweight children was 10% for boys (n= 101), and 14.9% for girls (n= 149) (p<0.01), and for obese children was 4% for boys (n=40), and 4.6% for girls (n= 46) (p<0.01) using BMI categories.

Conclusions: Obesity is less prevalent in these children in comparison to other studies in Spain with the same age range. Significant changes in anthropometric and clinical parameters of children in the intervention group will determine the long-term efficacy of the intervention.

Key words: Obesity, body composition, blood pressure, health promotion, children.

PO1368

MEDITERRANEAN DIETARY PATTERNS IN 3-5 YEAR OLD CHILDREN AND THEIR PARENTS: THE PROGRAM SI! STUDY

M. Sotos-Prieto¹, G. Santos-Beneit¹, J.L. Peñalvo¹, S. Pocock^{1,2}, J. Redondo¹, V. Fuster^{1,3}

¹Department of Epidemiology, Atherothrombosis and Cardiovascular Imaging, Centro Nacional de Investigaciones Cardiovasculares (CNIC), Madrid, Spain

²Department of Medical Statistics, London School of Hygiene and Tropical Medicine, London, UK

³Department of Cardiology, Mount Sinai School of Medicine, New York, USA

Background and objectives: Dietary habits are developed early in life. It is therefore important to understand the determinants of this development in order to design effective strategies for health promotion. Parental dietary patterns may be one of the most important determinants of children's dietary choices. Our aim is to evaluate the parental adherence to a MD and its impact to the MD quality of their children.

Methods: 24 schools from Madrid, including 2, 062 children aged 3-5, were recruited to carry out a cluster-randomized controlled trial: The Program SI! for Comprehensive Health. A total of 1, 949 parents completed a questionnaire about their children's MD quality by means of a validated questionnaire (KIDMED score). In addition, we evaluated the parents MD with the PREDIMED score (0-14 points). Information on fruit,

vegetables, fish, olive oil, and nuts consumption is provided by both questionnaires.

Results: The KIDMED score was 7.5 ± 1.9 . The MD quality distribution was classified as Poor in 2.4%, Average in 47.1%, and Good in 50.5% of the children. As for their parents, the average PREDIMED score was 6.3 ± 2.4 . Parents' adherence to MD was significantly associated with that of children ($r=0.326$; $p<0.001$). Furthermore, both parents and children follow a similar pattern for fruits, vegetables, fish and olive oil consumption ($p<0.001$), but differed in the consumption of nuts ($p=0.424$). In addition, a higher percentage of Good MD quality was observed in children from parents with upper educational level (67.9%) compared with middle (19.2%) and lower education (12.8%) ($p<0.001$).

Conclusions: In this particular Spanish population from Madrid, the parents' adherence to MD positively affects their children's dietary habits. The parents' educational status seems to play a mediating role in the beneficial effect of children's MD quality.

Key words: Mediterranean diet, preschoolers, parental education.

PO1369

ASSESSING THE CONTINUUM OF THE DELIVERY PROCESS OF AN INFANT AND YOUNG CHILD FEEDING PROGRAM IN ETHIOPIA

S. Kim¹, D. Ali¹, Y. Mekonnen², R. Rawat¹, P. Menon¹

¹International Food Policy Research Institute, Washington D.C., USA

²Mela Research, Inc., Addis Ababa, Ethiopia

Background and objectives: Process evaluation that is guided by program impact pathways (PIP) can shed light on critical challenges to delivery of interventions. Our study analyzed the PIP of a behavior change communications intervention implemented as part of Alive & Thrive, an initiative to improve infant and young child feeding (IYCF). The intervention is integrated into the Health Extension Program in Ethiopia through a cascade of training. The study aim was to determine linkages and gaps across levels of the delivery process.

Methods: Semi-structured interviews were conducted with supervisors ($n=8$), health extension workers (HEW) ($n=16$), community volunteers ($n=48$), mothers ($n=80$) and fathers ($n=32$) in two regions. Data were coded using NVivo and analyzed based on a mapping of the PIP developed with stakeholders. We triangulated responses on four topics: (1) training received, (2) use of program tools, (3) work performance context, and (4) exposure to program messages, across four levels: woreda (district), kebele (ward), gote (village/town) to households.

Results: Program-specific IYCF training reached all supervisors and HEWs in one region, but appeared variable in the other. The cascade of training was least effective at reaching volunteers, who are in most frequent contact with communities. There were competing sources of training from other programs at various levels. Patterns on the use of program tools were similar to those of training. Factors influencing work performance differed between health workers and volunteers. Volunteers had flexibility in dealing with workload, unlike the more constrained health workers. Overall, exposure and knowledge of program messages among beneficiaries were still weak.

Conclusions: Using the PIP analysis enabled us to identify patterns of linkages, gaps and the drivers along the continuum of the delivery process, leading to a cohesive understanding of the overall program process.

Key words: process evaluation, program impact pathway, infant and young child feeding, Ethiopia.

PO1370

TRANS FATTY ACIDS IN EUROPEAN DIETS

T. Mouratidou¹, J. Wollgast¹, S. Eisenwagen¹, S. Caldeira¹

¹Public Health Policy Support Unit, Institute For Health and Consumer Protection (IHCP), Joint Research Centre, European Commission, Ispra, Italy

Background and objectives: Consumption of trans fatty acids (TFAs) has been linked to adverse health effects. Efforts to reduce exposure to TFAs are on-going in different countries and regions. We aimed to collect the most recent data on the presence of TFAs in foods and their intake by the European population

Methods: A structured search of scientific articles in the English language, conducted in Europe from 2004 to 2012, was undertaken. In addition, the EuroFIR AISBL was used to extract data from national food composition datasets on TFA levels in foods.

Results: We will present the data obtained. A preliminary analysis shows that there is limited information on the consumption of TFAs in Europe over the last decade. Nevertheless, we identified eight studies on TFA intakes, four of which report separately the intake of industrial, ruminant and total TFA. We also identified twenty-eight articles evaluating the presence of TFAs in foods in Europe; eight of these, also distinguished between industrial and ruminant TFA present in foods. Twenty-six national food composition databases provide information on TFA.

Conclusions: The limited information on TFA intake in Europe is of concern. Specific population groups may be at risk of

consuming more than the recommended 1% of energy from TFAs and therefore various stakeholders from food industry to public health authorities should address this gap.

Key words: public health, trans fatty acids, European region, policy.

PO1371

THE MEDITERRANEAN LIFESTYLE INDEX: A MEASUREMENT INSTRUMENT

M. Sotos-Prieto¹, B. Moreno-Franco², J.M. Ordovás^{1,3}, M. León⁴, J.A. Casasnovas⁴, J.L. Peñalvo¹

¹Department of Epidemiology, Atherothrombosis and Cardiovascular Imaging, Centro Nacional de Investigaciones Cardiovasculares (CNIC), Madrid, Spain

²Department of Medicine, Psychiatry and Dermatology, University of Zaragoza, Spain

³Nutrition and Genomics Laboratory, Jean Mayer USDA Human Nutrition Research Center on Aging, Tufts University, Boston, MA, USA

⁴Cardiovascular Research Unit, Instituto Aragonés de Ciencias de la Salud (I + CS), Zaragoza, Spain

Background and objectives: Scientific evidence indicates that adherence to the Mediterranean diet (MD) is associated with decreased cardiovascular risk. However, it is well accepted that this association may be also influenced by other characteristics of the Mediterranean lifestyle. Our aim was to create an overall lifestyle index (MEDLIFE) that includes traditional Mediterranean-related patterns besides food consumption, and to assess its concordance with previously reported diet-quality scores.

Methods: MEDLIFE was created based on the current Spanish Mediterranean Food Guide pyramid. MEDLIFE, as well as other known diet-quality scores (alternative Healthy Eating Index (aHEI), alternative Mediterranean Diet Index (aMED), Mediterranean Diet Adherence Screener (MEDAS)) were calculated by using a FFQ that was administered to 988 participants of the Aragon workers' health study (AWHS). The MEDLIFE is a 28 item- derived index consisting of questions about frequency of food consumption (15), Mediterranean food habits (7), physical activity, as well as social habits (6).

Results: Participants presented an average MEDLIFE score of 11.3±2.6. Only a 6.1% met 1-point criteria for processed meat < serving/week) and white meat (2 servings/week). Less than a 50% achieved 1-point for fruit (18%, 3-6 servings/day), nuts (19.7%, 1-2 servings/day), olive oil (28.1%, >3 servings/day) and legumes (31.1%, >2servings/ week) consumption. However, 90.2% and 80% consumed fish/seafood and vegeta-

bles > servings/ week respectively. Only a 15.7 % consumed 1-2 servings/ day of wine, and 69.1% reported no nibbling habits. Concerning social habits, 40.9% take a nap, 81.2% sleep between 6-8 hour/day, and 54.5% socialize with friends>2hour/weekend. Finally, the MEDLIFE score was significantly associated with various diet quality-scores (aHEI, aMED, MEDAS) (p<0.001) (CI range: 0.44-0.62).

Conclusions: MEDLIFE is the first quality index including overall lifestyle habits. It is expected to be a valid instrument to measure adherence to Mediterranean lifestyle in epidemiological studies.

Key words: diet quality, Mediterranean diet, diet score.

PO1372

CONSTRUCT VALIDITY ASSESSMENT OF AN ADAPTED VERSION OF THE SAIN, LIM NUTRIENT PROFILING SYSTEM

A. Lluch¹, E. Clerfeuille², L. Demaretz¹, A. Drewnowski³, N. Darmon⁴

¹Danone Research, Palaiseau, France

²Conut.eu, Bures sur Yvette, France

³Center for Public Health Nutrition, University of Washington, USA

⁴UMR NORT INRA 1260 /Inserm/ Université Aix-Marseille, France

Background and objectives: Nutrient profiling allows ranking or classifying foods according to their nutrient composition. Existing systems are usually based on public health issues from developed countries. As part of a project aimed to develop an operational tool to be used both in developed and lower-income countries, the objective of this study was to assess the construct validity of an adapted version of the SAIN, LIM nutrient profiling system in a French adult population.

Methods: The adaptation of the SAIN, LIM system consisted in using international references for nutrients to limit (i.e. free sugars, SFA and sodium) and local recommendations for nutrients of concern (i.e. protein, fiber, vitamin C, iron, calcium and as optional vitamin D). The algorithm and classification of foods were also adapted, using 3 classes: rebalancing foods (Class A), neutral foods (Class B) and unbalancing foods (Class C). Construct validity was assessed, using linear programming, with dietary data and food database derived from the INCA French dietary survey (n=598 foods). Different hypotheses were tested to assess how the three food classes can contribute to a 2000kcal balanced diet (e.g. is it possible to have a balanced diet without class A foods?).

Results: Foods from class A were mandatory to design balanced diets, while unable alone to design unbalanced diets. It

was unfeasible to achieve balanced or unbalanced diets with class B foods only. Class C foods allowed designing unbalanced diets but not balanced diets, even combined with class B foods. The combination of foods from classes A, B and C could result in both balanced and unbalanced diets.

Conclusions: This adapted version of the SAIN, LIM is considered as valid in this French adult population. Other local contexts (India, Indonesia, USA) are currently under investigation.

Key words: Nutrient profiling system, construct validity, linear programming, diet modeling.

with a high adherence ($b = -0.51$, 95 %CI= -0.98 to -0.03 and $b = -0.68$, 95 %CI= -1.13 to -0.24 , respectively) C

conclusions: A high MD adherence might be associated with a better cognitive function. However, further studies are needed to confirm this finding.

Key words: Cognitive function, Mediterranean diet, SUN study
Acknowledgements: The SUN Study received funding from the Spanish Government (Grants PI01/0619, PI030678, PI040233, PI042241, PI050976, PI070240, PI070312, PI081943, PI080819, PI1002658, PI1002293, RD06/0045, G03/140, 87/2010), and the Navarra Regional Government (36/2001, 43/2002, 41/2005, 36/2008, 45/2011).

²Department of Nutrition, Food Sciences and Physiology, Schools of Pharmacy and Sciences, University of Navarra, Pamplona, Spain

³CIBER Fisiopatología de la Obesidad y Nutrición (CIBERObn), Instituto de Salud Carlos III, Spain

Background and objectives: The Mediterranean diet (MD) has been hypothesised to have a neuroprotective effect on cognitive function. The aim of this study was to evaluate the association between MD and cognitive function in a subsample of 823 participants (62 ± 6 years at baseline) of the SUN Project.

Methods: A validated 136-item food frequency questionnaire was used to assess the adherence to the MD at baseline, according to a nine-point score, presented in three categories (low, medium and high). The cognitive function was evaluated with the Telephone Interview of Cognitive Status-modified (TICS-m) for first time at 2008-2009 and for second time two years later. The association between MD adherence and cognitive function was assessed with linear regression models after adjusting for potential confounding variables.

Results: In the first evaluation of the cognitive function no significant association was detected between MD adherence and TICS-m score. In the second evaluation, participants with a medium adherence to MD presented a significantly lower TICS-m score compared with those with high adherence ($b = -0.63$, 95 %CI= -1.07 to -0.18). Also, a higher loss of cognitive function (score at second evaluation minus score at first evaluation) was observed among participants with low and medium adherence to MD in comparison to those participants

⁵Department of Nutrition and Food Sciences, University of Abomey-Calavi, Cotonou, Benin

⁶Applied Nutrition Programme, Department of Food Technology and Nutrition, University of Nairobi, Nairobi, Kenya

⁷International Crops Research Institute for the Semi-Arid Tropics, Bamako, Mali

⁸Centre National de la Recherche Scientifique et Technologie, Institut de Recherche en Sciences Appliquées et Technologies, Département de Technologie Alimentaire, Ouagadougou, Burkina Faso

⁹International Institute for Tropical Agriculture (IITA), Ibadan, Nigeria

¹⁰HarvestPlus, Washington DC, USA

Background and objectives: Micronutrient deficiencies are a leading cause of mortality and morbidity in young children and women. Food-based approaches involving commonly consumed staple foods such as sorghum, millet, cassava and maize, can sustainably increase micronutrient intake. INSTAPA aims at identifying innovative staple food based strategies to alleviate iron, zinc and vitamin A (VA) deficiencies in Africa.

Methods: Research was organized in 5 workpackages: (1) biofortification of sorghum (Fe) and cassava (VA); (2) optimization and (3) fortification of traditional sorghum and millet based diets; (4) safety of Fe fortification combined with supplementation in pregnant women in malarious areas; (5) long-term effect of micronutrient powders (MNP) on child development. Study approaches included acceptability studies, dietary intake assessment, randomized controlled trials and iron absorption studies conducted in Kenya, Mali, Benin and Burkina Faso. **Results:** Yellow cassava (7-12 ppm beta-carotene) was acceptable for consumption and doubled VA intake by children. Conventional breeding did not increase Fe and Zn levels in sorghum sufficiently. However, accompanying sauces based on Roselle and amaranth leaves were formulated with sufficient bioavailable Fe, Zn and VA. NaFeEDTA and Zn sulphate are the preferred fortificants for sorghum and millet based foods. However, asymptomatic malaria may blunt effect of iron fortification in malaria endemic areas. Flour fortification at posho mills increased percentage of children and women meeting their iron requirements. After 6 months, MNP supplemented children improved eye-hand coordination compared to un-supplemented children. Findings were incorporated in a training module for stakeholders.

Conclusions: Food-based approaches are promising in improving micronutrient intake. Opportunities for adding nutrient value in the supply chain differ per staple food and per micronutrient. Interaction between infections and micronutrients in food-based approaches should be further studied. Acknowledgements The project was realized in the EU-FP7 framework [FP7/2007-2013, 211484].

Key words: Staple foods, food based approaches, malaria, micronutrients, cognitive development.

IDENTIFYING BARRIERS PREVENTING LATINA WOMEN FROM ACCESSING WIC ONLINE NUTRITION INFORMATION

J. West¹, B. Crookston¹, R. Richards¹, C. Hall¹, B. Neiger¹

¹Brigham Young University, USA

Background and objectives: The Special Supplemental Nutrition Program for Women, Infants and Children (WIC) is a program for low-income women and children under age five.

The purpose of this study was to identify barriers to accessing online WIC resources among Latina WIC clients.

Methods: Five focus groups were conducted with Spanish-speaking participants recruited from a single WIC clinic.

Results: Two key themes emerged relating to barriers in accessing WIC's online resources. The first theme, access issues, included three subthemes: lack of computer/Internet resources; family barriers to computer use; and computer literacy. The second theme, perceived value of the website, included three subthemes: limited time savings; preference for on-site education; and knowledge about the website.

Conclusions: This is the first study to evaluate barriers to accessing online resources among Latina women in the WIC program. WIC sites attempting to increase utilization of online resources may be more successful if they serve clients with easy access to a computer with Internet access. They may also consider strategies to increase the value of the online resources, as compared to their current services offered to clients in a face-to-face setting.

Key words: WIC, Latinos, focus groups, computers, Internet.

PO1376

PHYSICAL ACTIVITY, OBESITY, AND ALL-CAUSE MORTALITY IN THE EPIC STUDY

H.A. Ward¹, U. Ekelund², T. Norat¹, J. Luan², A.M. May³, E. Weiderpass⁴, N.J. Wareham², E. Riboli¹

¹Department of Epidemiology and Biostatistics, Imperial College London, UK

²Medical Research Council (MRC) Epidemiology Unit, Addenbrooke's Hospital, Cambridge, UK

³University Medical Centre Utrecht, Julius Centre for Health Sciences and Primary Care, The Netherlands

⁴Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Sweden

Background and objectives: The risk of premature death due to excess adiposity may be attenuated by physical activity. **Methods:** Physical activity (PA), assessed by the 4-category Cambridge index, was examined in relation to mortality risk among 338, 215 participants with measured height, weight, and waist circumference (WC) in the multicentre EPIC cohort study. The association of PA on mortality risk was estimated by meta-analysis of centre-specific hazard ratios (HR), adjusted for sex, education, smoking, alcohol intake, BMI, and WC. Cross-classified groups of PA by BMI [<18.5 kg/m² (underweight), 18.5-24.9 kg/m² (normal weight), 25-29 kg/m² (overweight), 30-34.9 kg/m² (obese I), >35 kg/m² (obese II)] and WC quintiles were examined in relation to mortality risk

with Cox proportional hazard models, adjusted for education, smoking, and alcohol intake, and stratified by centre, sex, and age of recruitment.

Results: During a mean follow-up time of 12.4 years, there were 21, 738 deaths (11, 183 men and 10, 555 women). The risk of mortality was 10% lower per one category increase in PA (HR 0.90, 95% CI 0.89-0.92). In the combined association analysis, the risk of mortality was significantly lower across increasing levels of PA within all strata of BMI and WC. Relative to the active/normal weight group, mortality risk was higher among the active/obese I group (HR 1.34, 95% CI 1.21 - 1.49) and among the inactive/normal weight group (HR 1.53, 95% CI 1.42 - 1.66), whereas no association was detected in the active/overweight group. Similar results were obtained in the combined WC quintiles/PA analysis.

Conclusions: The greatest reduction in premature mortality risk is likely to be achieved by a combination of lower general and abdominal obesity and increased physical activity, however, higher levels of PA are associated with lower risk of mortality at all levels of adiposity.

Key words: Physical activity, BMI, waist circumference, mortality.

PO1377

DOES NUTRITION LABELING HELPS CONSUMERS MAKE HEALTHIER FOOD CHOICES?

A. Zaragoza^{1,3}, A. Norte^{1,2}, J M Martínez³, J A Hurtado^{1,3}, R Ortiz^{1,2}

¹Gabinete de Alimentación y Nutrición (ALINUA), Facultad de Ciencias de la Salud. Universidad de Alicante, San Vicente de Raspeig, Spain

²Departamento de Salud Pública, Medicina Preventiva e Historia de la Ciencia, Universidad de Alicante, San Vicente del Raspeig, Spain

³Departamento de Enfermería, Universidad de Alicante, San Vicente del Raspeig, Spain

Background and objectives: Nutrition labeling is a means of informing consumers about the nutrient content and messages about food and health that appear on the labels of commercial foods. Such labeling would help consumers choose healthier foods. Several studies conclude that at European consumers show interest the nutritional information on the packaging, but it is unknown understood that information. To assess whether nutrition labelling influences consumers when choosing a product.

Methods: Literature review of studies evaluating the influence of nutrition labeling when buying a product. We did a search in Medline (PubMed) and the Cochrane Library. Key

words established as descriptors (Mesch): food labeling, nutrition labeling, consumer behavior. Were established as inclusion criteria to evaluate all those studies consumer behavior when choosing a product, taking into account the information of nutrition labeling.

Results: There were a total of 39 articles, 9 of which met the inclusion criteria. The results show that consumers are able to use the nutrition information, but the choice is not based on the product is healthier, not on qualities such as taste and price. The choice is determined by consumer motivation and product design.

Conclusions: To ensure that consumers better understand the nutritional labeling and use them to choose healthier foods, you should design programs and education policies to ensure food labeling compression, besides establishing a standardized format: simple, clear and legible.

Key Words: food labeling, nutrition labeling, consumer behavior.

PO1378

TECHNOLOGY FOR HEALTH: A QUALITATIVE STUDY ON BARRIERS TO USING THE IPAD FOR DIET CHANGE

J. West¹, B. Crookston¹, C. Lister¹, C. Hall¹, R. Richards¹

¹Brigham Young University, Utah, USA

Background and objectives: Emergence of tablet computers has led to interest in their use to impact health-related behaviors of users. However, little is known regarding which devices are most effective for changing these behaviors, and whether or not these devices or accompanying applications (apps) are feasible or desirable vehicles for behavior change.

Methods: Four focus groups were conducted with students from a Midwestern university who were given iPads to download diet-related apps. Participants were asked questions about preferences regarding iPad functionality, app functionality, and the likelihood of using apps and iPads for facilitating diet-related behavior change in the future.

Results: Two key themes emerged from focus group discussions on diet-related apps for iPads and their usefulness to facilitate behavior change. The first theme, lack of iPad practicality, contained three subthemes: inconvenient mid-way technology, internet access barriers, and smartphone preference. The second theme that emerged was attitudes towards apps in general. Three subthemes were identified under the second theme: too intensive; positive functions not specific to iPads; and lack of reliable/trustworthy information.

Conclusions: This study is the first to report the use of qualitative methods to study the practicality of using apps and iPads in changing diet-related behaviors. Early generations

of iPads may not be effective devices for facilitating behavior change among college students; and diet-related apps seem to have poor functionality that lead to cessation of use.

Key words: iPads; diet-related behavior change; qualitative methods; technology and health; behavior change.

PO1379

SODIUM REDUCTION POLICIES IN ARGENTINA: AN ANALYSIS OF THE “LESS SALT MORE LIFE” INITIATIVE

L. Castronuovo¹, L. Allemandi¹, V. Tiscornia¹, V. Schoj¹

¹Fundación Interamericana del Corazón, Argentina

Background and objectives: In 2011, the Ministry of Health and the Ministry of Agriculture of Argentina launched a voluntary agreement (Less Salt More Life) with the food industry to reduce sodium content in processed foods. The expected reduction is between 5% and 18% on the maximum sodium levels over a period of two years. Our objectives are to describe the context in which the current policy has been created, to analyze similarities and differences with other countries, and to explore the strategies of the different stakeholders to comply with the reformulation of food composition policy in Argentina.

Methods: We performed a stakeholder analysis to map all actors involved in the voluntary agreement both from the private and public sectors and then conducted in-depths interviews with the most relevant actors. We used a purposive sample. Data obtained at the in-depth interviews was coded using qualitative data analysis. We also conducted a literature review to learn about similar experiences in other countries.

Results: The Argentinean voluntary agreement to reduce sodium content in processed foods shows relevant differences as compared with other countries. The main differences include the selected targets and the lack of other comprehensive measures such as food labeling and education campaigns. The stakeholder analysis showed that the food industry and the food associations played a crucial role in the design of the voluntary agreement and in the selection of the reduction targets. The main obstacles identified by the participants relate to the monitoring of the agreement.

Conclusions: Although the Argentinean initiative is a significant progress regarding sodium reduction in the region, further analysis of the content of the agreement should be considered, including reduction target selection and the inclusion of other comprehensive measures.

Key words: public health – processed foods – non-communicable chronic diseases – sodium.

PO1380

THE INFORMAS FRAMEWORK FOR MONITORING FOODS IN PUBLIC SECTOR SETTINGS

M. L'Abbé¹, A. Schermerl¹, B. Kelly², A. Lee³, L. Minaker⁴, P. Twohig⁵, D. Sanders⁶, M. Rayner⁷

¹Department of Nutritional Sciences, University of Toronto, Canada

²School of Molecular Bioscience, University of Sydney, Australia

³School of Exercise and Nutrition Sciences, Queensland University of Technology, Australia

⁴School of Public Health and Health Systems, University of Waterloo, Canada

⁵Faculty of Medicine, University of Calgary, Canada

⁶School of Public Health, University of the Western Cape, South Africa

⁷Department of Public Health, University of Oxford, UK

Background and objectives: The International Network for Food and Obesity/NCD Research, Monitoring and Action Support (INFORMAS) is setting benchmarks for creating healthy food environments. This study provides a step-based framework for monitoring the foods provided or sold in publically funded institutions (the focus is on school foods, but the framework can easily be applied to foods provided in other publically funded institutions).

Methods: The framework was designed by conducting a review of previous monitoring activities of school food and considering the key lessons learned. We also consulted experts in the field.

Results: The monitoring framework includes protocols for data collection and evaluation that can be applied in two phases: Phase I: which describes steps and data to compile information on existing nutrition policies and standards across jurisdictions and the principles that have been applied in developing such standards. Currently, standards vary widely globally and a comprehensive review of such standards will facilitate institutional learnings for those jurisdictions that have not yet established such policies or standards, or are undergoing review of existing ones. Phase II: consists of steps to follow in order to evaluate the quality of foods relative to the nutrition policy/guideline/program; or if no standards exists this may be an assessment of the nutritional quality of foods relative to the standards of a similar jurisdiction or other authoritative body or other appropriate standards used for defining 'healthy'. We also propose examples of measurement indicators (based on minimal, expanded and optimal measurement indicators for both food-based and nutrient based standards) that can be used to assess success or progress over time in meeting the policy objectives.

Conclusions: The monitoring framework has been developed to be pilot tested in a number of countries with varying resource capacities.

Key words: monitoring framework, public sector, nutritional quality, nutrition standards, school foods.

PO1381

STUDY OF THE EFFECTIVENESS OF AN EDUCATIONAL MODEL TO PREVENT AND CONTROL CHILDHOOD OBESITY

A P. Della Santa¹, M. Britz¹, M. Defféminis¹, T. Dornell¹, J. Martinez¹, F. Cavalleri²

¹Departamento de Nutrición Poblacional, Escuela de Nutrición, Universidad de la República, Montevideo, Uruguay

²Departamento de Métodos Cuantitativos, Facultad de Medicina, Universidad de la República, Montevideo, Uruguay

Background and objectives: As a health policy response to the high prevalence of childhood obesity in Uruguay there is a need to emphasize activities promoting healthy lifestyles, specifically eating habits and physical activity during formal education. The objective of this study was to evaluate the impact of an educational intervention in nutrition and physical activity on nutritional status, eating habits and fitness of children attending kindergarten.

Methods: Community intervention with longitudinal monitoring, applying an educational model for 5 months, in 160 children (intervention group-IG). The results were compared with those of 103 children who continued usual curricular activities (control group-CG). Measurements before and after the intervention were: BMI/age, % Fat Mass- FM (validated equation for uruguayan preschool children), fitness (distance walked in 6 minutes) and food consumption (self-administered survey to parents).

Results: Mean z BMI/age declined significantly in IG for both genders ($p < 0.02$) while increased in CG. Obesity prevalence declined significantly only in IG from 14, 1 to 10.3% ($p = 0.04$). Mean % FM had a slight not significant decline in IG while increased in CG ($p = 0.00$, both genders). Fitness post-intervention significantly increased for both sexes in IG ($p = 0.00$) while in CG did not change. The increase in daily fruit intake was higher in IG compared to the CG ($p = 0.00$). The proportion of children who did not consume vegetables daily declined more in IG (14, 4% to 6.3%) than in CG (11.7% to 9.7%). In school collation, the intake of healthy foods increased only in IG while in CG there was a slight increase in intake of non-recommended foods.

Conclusions: The strategy was effective at achieving beneficial changes in the prevalence of obese children, fitness, intake of fruits and vegetables, and type of school collation.

Key words: educational intervention, childhood obesity, eating habits, physical activity.

PO1382

FACILITATING DECENTRALIZED PROCUREMENT MECHANISM OF GOVERNMENT ENSURING UNINTERRUPTED SUPPLY FOR FULL COVERAGE OF VITAMIN A IN UTTAR PRADESH, INDIA

A. Jain¹, M. Varghese, S. Agarwal, S. Dutta, P. Khobergade, C S. Pandey

¹Micronutrient Initiative, Lucknow UP, India

²Department of Medical Health and Family Welfare, GOUP

³Micronutrient Initiative, Delhi, India

Background and objectives: Since 2006, Uttar Pradesh adopted fixed months (June and December) biannual Vitamin A supplementation strategy. These months were denoted as Bal Swastha Poshan Mah (BSPM). Micronutrient Initiative (MI) is supporting biannual VAS rounds since 2010 in 38 districts of UP with other partners UNICEF and Woman and Child Development department. A major barrier identified was untimely procurement and interrupted supply of Vitamin A marked as missed BSPM rounds or low coverage. 2010-11 was counted as zero year for full coverage due to missed round in December. In 2011-12 coverage decreased from 50% to 36%. Focus was therefore on to systematically work with government systems to establish decentralized procurement mechanism (DPM) in the state. Objective: Incorporating Vitamin A into State Drug List and establish DPM for Vitamin A

Methods: MI provided specification of vitamin A syrup for procurement to government to facilitate incorporation of vitamin A in the state drug list. Systematic plans for procurement based on targets and distribution of vitamin A were prepared for all 75 districts and shared at all levels.

Results: For the first time state published the rate contract of vitamin A syrup bottles and finalized agencies for providing Vitamin A on fixed rates to all 75 districts. This facilitated district level procurement for the first time in all districts and improved availability of Vitamin A Syrup for BSPM rounds in December 2012-13. Results were measured with improved availability of supply from 0 to 54% and expecting to benefit 11, 731, 937 children in absolute numbers.

Conclusions: Timely procurement achieved by establishing decentralized procurement mechanism within the government system for uninterrupted supply and increase coverage. Accu-

rate demand generation based on targets and distribution plan ensured distribution at all levels with proper monitoring and reporting.

Key words: BSPM, Decentralize Planning Mechanism, Full coverage of Vitamin A.

PO1383

FOLLOW-UP OF A GROUP OF POPULATION WHO IS PRESENT AT THE GYMNASIUM. EFFECT OF THE PHYSICAL EXERCISE AND THE DIET

*J. Almansa Perales*¹

¹Department of Nutrition and Food Science, Faculty of Pharmacy, University of Granada, Granada, Spain

Background and objectives: The developed work tries to determine the results obtained in a group of practicing subjects of a physical activity controlled during a period of time and submitted to control and nutritional supervision. An individualized plan of diet and exercise produced a significant loss of weight and improves the imc. the general aim is to determine the effect that an individualized plan of diet and exercise has on the loss of weight and improvement in the imc.

Methods: A study was done observacional, descriptively and comparatively of a series of cases realized in a gymnasium and with a sample of 34 sujetos, of which 16 were men and 18 women. For the accomplishment of the analysis I use the version 20.0 of the program SPSS.

Results: There takes place is produced a decrease of the weight ($p < 0.001$) and the IMC ($p < 0.001$) in three measurements of linear form, increase of the lean mass, increase of the basal metabolism, increase of the corporal water and of the muscular skeletal mass.

Conclusions: The dietetic plan and of physical exercise (fiscal year) he has proved to be an effective being since: variable weight has diminished in three measurements with approximate values of between (among) 3-4 kg, the variable IMC has diminished also in three measurements and there are improved the percentages of fat and muscular mass. The decrease of the weight is more accentuated in men that in women and IMC's decrease more accentuated in women that in men. The Weight and IMC diminish more in major subjects of 33 years.

Key words: Physical exercise, diet, nutrition, weight, imc.

PO1384

ALCOHOLIC BEVERAGE CONSUMPTION, NUTRIENT INTAKE, BODY WEIGHT AND PHYSICAL ACTIVITY AMONG GHANAIAAN ADULT ALCOHOLICS

*S. Klobodu*¹, *M. Steiner-Asiedu*¹, *E. Colecraft*¹, *K. Anderson*²

¹Department of Nutrition and Food Science, University of Ghana, Legon

²Department of Foods and Nutrition, University of Georgia, Athens, USA

Background and objectives: The effect of alcohol on nutritional status is not well understood. Although many studies have examined nutritional aspects of excessive alcohol consumption there is scarcity of data in Ghana. The present study analyzed for differences in nutrient intakes based on the amounts of alcohol consumed, and relationships among alcohol consumption, energy intake, body weight and physical activity.

Methods: This was a cross-sectional study involving 107 adult men and women screened as alcoholics using a modified Concern/Cut-down, Anger, Guilt, and Eye-opener (CAGE) and Alcohol Use Disorders Identification Test (AUDIT) questionnaire. Study participants were interviewed on their socio-demographic and lifestyle characteristics using a pretested questionnaire. The 24-hour recall method was used to obtain information on dietary intakes and consumption of alcoholic beverages. Additionally, weight and height measurements were taken. Participants were categorized by tertiles of daily alcohol consumption; < 34.5 g/day, 34.6 to 65.6 g/day and > 65.7 g/day. ANOVA and correlation analyses were used to test for differences and association among variables.

Results: There was a positive correlation between total alcohol consumed and total energy intake of participants ($r = 0.234$; $P = 0.015$). The participants with higher ethanol intake had higher weight although not significant ($r = 0.114$; $P = 0.243$). There was no significant relationship between ethanol consumption and levels of physical activity among participants. Energy and macronutrient intake did not differ by tertiles of alcohol consumption.

Conclusions: The mechanism for the positive correlation between alcohol consumption and body weight in this population needs further exploration.

Key words: Alcohol, weight, nutrient, physical activity

PO1385**THE EFFECT OF TTM MODEL ON BREAKFAST EATING PLAN OF NURSES IN THE CENTRAL HOSPITAL OF IRANIAN OIL INDUSTRY**

F. Berahmandpour¹, K. Bagheri¹, S. Shahrokhi¹, M J. Kian¹, F. Eftekhar¹

¹Health Research Institute of Petroleum Industry Health Organization, Tehran, Iran

Background and objectives: Some evidence claim that 10 to 30% people do not eat enough breakfast in developed and developing countries. Missing breakfast has long term negative effects such as stress, depressive symptoms, obesity and chronic diseases. Some studies emphasize that breakfast eating habit can be associated with physical and mental achievement in children and adults. Therefore, the purpose of study is to improve breakfast eating habits among of nurses in the central hospital of Iranian oil industry by preparing the suitable educational plans for encouraging nurses to consume suitable breakfast meal.

Methods: The participants of study were the nurses who worked in the central hospital of Iranian oil industry in autumn 2012. The sampling method was purpose sampling and the collection data was completing questionnaires by the participants. The Trans Theoretical Model of change as an effective model was selected to improve breakfast eating habit among participants.

Results: The findings of study show that the majority of participants paid attention to prepare and consume breakfast. Furthermore, there was a normal distribution between TTM stages and breakfast consumption in this study. Some reasons such as no appetite in morning, sleepy feelings and no time for eating breakfast before going to work were the common reasons for no breakfast consumption in this study.

Conclusions: Despite the findings of study show that the most of participants consumed breakfast and liked to eat breakfast, but they did not eat suitable breakfast meal. In fact, according to similar studies, the best breakfast meal should include at least three or four food groups; moreover, this breakfast must have high dietary fiber and low glycemic index until it can reduce obesity prevalence. Moreover, it should be considered some sensitive factors such as taste, color and shape.

Key words: Breakfast eating plan, TTM Model, Nurses.

PO1386**QUALITY OF DISPENSING FOLIC ACID SUPPLEMENTS TO PREGNANT MOTHERS AT FIELD ANTE-NATAL CLINICS IN A SRI LANKAN SETTING**

A. Wickramasinghe¹, U. Senarath²

¹Office of The Medical Officer of Health - Mahara, Kadawatha, Sri Lanka

²Department of Community Medicine, Faculty of Medicine, University of Colombo, Colombo, Sri Lanka

Background and objectives: Folic acid supplementation programme to pregnant mothers is implemented through Public Health Midwives (PHMM) in Sri Lanka, to prevent neural tube defects of foetuses and anaemia of pregnant mothers. Folic acid tablets are distributed to pregnant mothers free of charge at the field antenatal clinics held by the government. Objective of this study was to describe the quality of dispensing folic acid tablets to pregnant mothers in field antenatal clinics.

Methods: A descriptive cross-sectional study was carried out in a health unit in Sri Lanka in 2011. All the twelve field antenatal clinics of the health unit were directly observed on random two sessions for dispensing folic acid, using Lot Quality Assurance Sampling technique, using an observational check list. Equal or less than 50% of 'good practices' was considered as 'Highest Risk' and equal or more than 80% of 'good practices' was considered as 'Lowest Risk'; and Decision Rule of 24:8 was applied considering a Provider risk of 3.6% and Consumer risk of 7.6% where the lowest total classification error (0.112) would occur.

Results: General cleanliness and tidiness of the dispensing counter was 'acceptable' (Defective Observations (DO) =7). Both the quality (DO=1) and storage (DO=0) of folic acid were 'acceptable'. In providing knowledge on folic acid; introducing the tablet by name (DO=18), educating the usefulness (DO=24), instructing the dose to be taken (DO=20), and instructions on storage (DO=17), all the components were 'substandard'. Inquire about the compliance (DO=20) and wrapping folic acid tablets at the counter (DO=23) were also 'substandard'.

Conclusions: Though the cleanliness, tidiness, quality and storage of folic acid tablets in the clinics were satisfactory, aspects such as providing knowledge on folic acid, inquiring about compliance and wrapping the tablets need to be improved.

Key words: Folic acid, Lot Quality Assurance Sampling (LQAS), Sri Lanka.

PO1387**EFFECT OF INFORMATION ABOUT THE CALORIC CONTENT ON FOOD CHOICE IN TWO RESTAURANTS IN JALISCO, MEXICO**

M. Guzmán¹, E.Valdés¹, K. Franco¹, H. Sánchez², F. Santoyo¹

¹Behavioral Feeding and Nutrition Research Center, Cusur, University of Guadalajara, México

²Regional Development Department, Cusur, University of Guadalajara, México

Background and objectives: The overweight and obesity have been linked to excessive consumption of high-caloric foods and the growing trend of eating out. Thus, humans make decisions about food many times per day, affected by several factors, such as the information about the content of food. The purpose of this study was to analyze the effect of caloric information on food choices in two restaurants in Jalisco, Mexico.

Methods: We conducted a quasi-experimental study involving 200 adults between 18 and 65 years old in each restaurant, who were randomly divided into two groups (control and experimental). The experimental group received information about the caloric content in the dishes offered by the restaurant. Two questionnaires were used in order to identify the information considered for food choices.

Results and conclusions: The results showed that caloric information affects the decision; however it was not the only important factor that contribute for food choices.

Key words: caloric information about food, making decision, food choices.

PO1390**OVERWEIGHT, GENERAL AND CENTRAL OBESITY AND THEIR ASSOCIATION WITH ETHNICITY, DEMOGRAPHICS AND SOCIOECONOMIC STATUS IN IRANIAN WOMEN**

A. Rezazadeh^{1,2}, N. Omidvar¹, B. Rashidkhani¹

¹Community Nutrition Department, Faculty of Nutrition and Food Technology, Shahid Beheshti University of Medical Sciences and Health Services, Tehran, Iran

²Students Research Committee, Shahid Beheshti University of Medical Sciences and Health Services, Tehran, Iran

Background and objectives: Iran, as a country experiencing an accelerated nutrition transition, encounters an increasing prevalence of overweight and obesity. This study aimed

to determine the association between overweight and obesity ethnicity, demographic and socioeconomic status (SES) among women living in Tehran.

Methods: In this cross-sectional study, 460 women aged 20-50 years were selected by stratified random sampling in Tehran metropolitan. Demographics, ethnicity and SES were asked by a questionnaire through face to face interview. Weight, height and waist circumference (WC) were measured and BMI was calculated. Multivariate logistic regression was used for analysis.

Results: Distribution of main ethnic groups among the study population were as follows: Fars 66.7%, Turks 14.3%, Northern (Tabari & Gilaki) 9.3%, Kurds 5.2% and others 4.5%. The highest prevalence of overweight was observed among Turks (65.1%) and Northerners (56.1%); while general and central obesity were more prevalent in Northerners (28.7% and 48%, respectively). However, the differences were not significant. Higher risk of overweight and obesity was associated with age (OR: 1.32, 95% CI:0.34.-0.69) and duration of residence in Tehran (OR: 1.23, 95% CI:1.15.-1.49), whereas being employed (OR: 0.79, 95% CI:0.45-0.96), having university degree (OR:0.41, 95% CI:0.20-0.85), owning a house (OR: 0.62, 95% CI:0.34.-0.69), number of rooms(OR: 0.62, 95% CI:0.34.-0.69) were associated with lower chance of being overweight and obese. With regards to central obesity, being married (OR: 2.60, 95% CI:1.23-5.40) and total household income (OR:1.02, 95% CI:1.0-1.05) were related to higher risk and having university degree (OR:0.39, 95% CI:0.23-0.68) with lower risk. No significant relationship was found between obesity and central obesity with ethnicity after adjusting for age, energy intake, physical activity and SES.

Conclusions: Considering SES in overweight and obesity programs and further investigation on its role in different ethnic groups in the country is warranted.

Key words: Overweight, obesity, socioeconomic status, ethnicity, Iran.

PO1391**HOUSEHOLD FOOD SECURITY, DIETARY DIVERSITY, ANEMIA, AND ANTHROPOMETRIC STATUS OF POOR WOMEN FARMERS IN PREY VENG, CAMBODIA: A CROSS-SECTIONAL STUDY**

Z. Talukder¹, J. McLean², L. Lynd³, H. Kroeun¹, T.J. Green²

¹Helen Keller International, Phnom Penh, Cambodia

²Department of Food Nutrition and Health, Faculty of Land and Food Systems, University of British Columbia, Vancouver, British Columbia, Canada

³Department of Pharmaceutical Sciences, University of British Columbia, Vancouver, British Columbia, Canada

Background and objectives: Cambodia has been food secure for nearly a decade based on having sufficient rice for its population. However, national surveys indicate that nutritional status remains poor among women and children, particularly in rural farming households. Little is known about household level food security and how it relates to indicators of nutritional status such as dietary diversity, anthropometrics, and hemoglobin in these households. Our objectives were to determine levels of food security and explore the association between food security and indicators of nutritional status in rural farming households in Prey Veng province.

Methods: A cross-sectional study of food security, dietary diversity, and anthropometric status, and anemia was conducted among 900 poor rural women farmers in Prey Veng Province. Validated instruments were used, including the Household Food Insecurity Access Scale (HFIAS) and the Household Dietary Diversity Scale (HDDS). Hemoglobin was measured by Hemocue and weight and height measured by standardized techniques.

Results: Only 18% of households were classified as food secure and almost 12% were severely food insecure according to the HFIAS. Mean BMI (SD) was 21 (2.7) kg/m² with over 13% of women classified as underweight (<18.5 kg/m²). Mean hemoglobin was 122 (12) g/L, and 33% were anemic (<120 g/L). There was a weak association between HFIAS score and HDDS scores ($r=-0.23$; $P<0.001$) and hemoglobin ($r=-0.12$; $P=0.01$) but no association with women's BMI ($r = -0.02$; $P=0.48$).

Conclusions: There were high levels of food insecurity among poor farming households. Poorer HFIAS scores were associated with lower dietary diversity and hemoglobin but not BMI. Strategies to improve household food security may increase dietary diversity and improve hemoglobin concentration however because the associations were weak and there was no association with BMI, other strategies will be needed to improve nutritional status of rural Cambodian women.

Key Words: Undernutrition, food security, women.

PO1392**NUTRITION KNOWLEDGE, ATTITUDES AND CULTURAL PRACTICES OF RURAL WOMEN FARMERS IN PREY VENG PROVINCE, CAMBODIA.**

J. McLean¹, L. Lynd², Z. Talukder³, H. Kroeun³, P. Lakzadeh¹, S. Ly³, T. Green¹

¹Department of Food, Nutrition and Health, Faculty of Land and Food Systems, The University of British Columbia, Vancouver, British Columbia, Canada

²Department of Pharmaceutical Science, The University of British Columbia, Vancouver, British Columbia, Canada

³Helen Keller International, Phnom Penh, Cambodia

Background and objectives: Cambodia is food secure at the national level; however, the nutritional status of women and children has not improved since 2005. Food availability data indicate an adequate supply of energy yet over 20% of women have a low BMI and 40% of children are chronically undernourished. Where the food supply is sufficient, knowledge and cultural practices may limit progress towards improved nutrition status. The objectives of this study were to: 1. Understand women's knowledge of nutrition and feeding recommendations. 2. Identify cultural practices and attitudes that may be risk factors for malnutrition.

Methods: A mixed methods approach was used to evaluate nutrition knowledge and practices. Initially, 900 randomly selected women completed a household survey. Findings from the survey guided key informant interviews and focus groups, which provided additional information on practices and attitudes that could impact nutritional status.

Results: Nutrition practices and knowledge were poor. For example, almost half the women reported they did not consume 3 meals the previous day and most were unable to identify the correct number of meals pregnant women should consume. Sixty-two percent had heard of anemia and 67% said they could identify foods high in iron, yet almost all identified green leafy vegetables. The results were similar for vitamin A. The majority did not have access to a latrine and only 73% reported using soap for hand-washing and less than half after defecation.

Conclusions: Women lack relevant nutrition knowledge. Poor sanitation and hygiene practices likely contribute to undernutrition as few households have access to adequate sanitary facilities and hand-washing with soap was irregular. Improving nutritional status will require more than food-based interventions. Our results point to a lack of knowledge regarding nutrition and care practices that if improved, could positively impact nutrition and health.

Key words: Undernutrition, nutrition knowledge and practices.

PO1393**IT TAKES A VILLAGE: DEVELOPING KEY COMMUNITY-LEVEL MESSAGES TO ADDRESS THE RISE IN STUNTING IN RURAL EGYPT**

J. Kavle¹, R. Galloway¹, G. Saleh^{2,3}, S. Mehanna⁴

¹Maternal and Child Health Integrated Program (MCHIP)/Program For Appropriate Technology In Health (PATH), Washington DC, USA

²National Nutrition Institute of Egypt, Cairo, Egypt

³Smart project, MCHIP, Cairo, Egypt

⁴American University, Cairo, Egypt

Background and objectives: The United States Agency for International Development (USAID)-funded Maternal and Child Health Integrated Program (MCHIP) is implementing a project (Smart) in Upper and Lower Egypt that focuses on improving newborn health and the nutritional status of children less than two years of age. A doubling in stunting prevalence in Lower Egypt between the 2005 and 2008 Egypt Demographic and Health Surveys served as the impetus for a focus on prevention of stunting in the Smart project and the conduction of a research study examining factors associated with stunting in Smart project areas.

Methods: In-depth interviews (IDIs) were conducted with pregnant (N=40), lactating (N=40), and non-lactating women (N=40), as well as with key influencers in decision-making for infant and young child feeding including husbands (N=40), health workers (N=40) and grandmothers (N=40). IDIs were conducted in two Smart project areas: Qaliobia, Lower Egypt, where the rise in stunting occurred and Sohag, Upper Egypt, where stunting decreased slightly. Qualitative IDI were recorded, transcribed, and coded by theme and provided an in-depth examination of attitudes, behaviors, and perceptions of child growth of key family and community members in the context of poor infant and young child feeding practices and an avian flu outbreak in Lower Egypt.

Results: A counselling guide was developed, based on messages from formative research, on motivations well as economic and cultural barriers. Targeted messages were aimed at reducing junk food consumption, increasing quality and quantity of food intake, using local foods and recipes, and addressing misperceptions of mothers, family members, and health workers regarding healthy food for the child and family.

Conclusions: Counselling guides will be further tested in Smart project areas to improve infant and young child feeding in the prevention of stunting.

Key words: stunting, counselling messages, Egypt, family.

PO1394**ADEQUATE IODINE INTAKE IN PREGNANT WOMEN COINCIDES WITH MORE-THAN ADEQUATE IODINE INTAKE IN THEIR SCHOOL-AGED CHILDREN IN SOUTHERN INDIA**

N. Jaiswal¹, A. Melse-Boonstra², K.S. Sharma³, K. Srinivasan¹, M.B. Zimmermann^{2,4,5}

¹St. John's Research Institute, Bangalore, India

²Division of Human Nutrition, Wageningen University, Wageningen, the Netherlands

³Department of Obstetrics and Gynaecology, St. Martha's Hospital, Bangalore, India

⁴Institute of Food Nutrition and Health, ETH Zurich, Switzerland

⁵International Council for the Control of Iodine Deficiency Disorders, Zurich, Switzerland

Background and objectives: Universal salt iodization (USI) is a mass fortification approach to cover the iodine requirements of the population, including the sharply higher iodine requirement of pregnant women. However, WHO/UNICEF/ICCIDD recommended cut-offs leave only a narrow range for median urinary iodine concentrations (UIC) that will both meet the needs of pregnant women and not lead to excessive intake for other groups, such as children.

Methods: In a cross-sectional study, we recruited healthy pairs (n=194) of pregnant women and their 6-15 years old children in Bangalore, India. We measured UIC, household salt iodine concentration, anthropometrics and maternal thyroid volume (ultrasound), and administered a questionnaire on demographic characteristics and salt usage patterns.

Results: The iodized salt program was providing adequate iodine during pregnancy: a) the overall median (range) UIC in women was 172 (5-1024) µg/L, b) the median UIC was >150 µg/L in all trimesters and c) thyroid size did not significantly change across trimesters. At the same time, the median (range) UIC in their children was 220 µg/L (10-782), significantly higher than in mothers (p=0.008) and indicating more than adequate iodine intake at this age.

Conclusions: Our data indicate that in this region of southern India salt iodization ensures adequate iodine intake in pregnant women but at the expense of 'more-than-adequate' iodine intake in their school age children. Because recent studies data suggest iodine intake in the range of 'more-than-adequate' for children have no adverse effects on thyroid function. These findings, if confirmed in other countries, suggest the current WHO/UNICEF/ICCIDD cut-off for median UIC in children indicating 'more-than-average' intake should be re-considered.

Key words: Iodized salt; Urinary iodine concentration; Pregnant women; School children; India.

PO1395**OPERATIONS RESEARCH: TRIANGULATION OF DATA COLLECTION METHODS AND ANALYSES TO EXAMINE THE RISE IN STUNTING IN LOWER VERSUS UPPER EGYPT**

J. Kavle¹, R. Galloway¹, G. Saleh^{2,3}, S. Mehanna⁴

¹Maternal and Child Health Integrated Program (MCHIP)/Program for Appropriate Technology in Health (PATH), Washington DC, USA

²National Nutrition Institute of Egypt, Cairo, Egypt

³Smart project, MCHIP, Cairo, Egypt

⁴American University, Cairo, Egypt

Background and objectives: The United States Agency for International Development (USAID)-funded Maternal and Child Health Integrated Program (MCHIP) is implementing a project (Smart) that focuses on improving newborn health and the nutritional status of children less than two years of age. A doubling in stunting prevalence in Lower Egypt between the 2005 and 2008 Egypt Demographic and Health Surveys in comparison to Upper Egypt, served as the impetus for a focus on prevention of stunting in the Smart project and the conduction of a research study examining factors associated with stunting in Smart project areas in Lower and Upper Egypt.

Methods: Qualitative data collection consisted of in-depth interviews with pregnant, lactating, and non-lactating woman, as well as key influencers in infant and young child feeding including husbands, health workers, and grandmothers. Quantitative 24-hour recall and food frequency provided dietary data (N=120), which were analysed using Egyptian food consumption tables. Qualitative direct observations and in-depth interviews with mothers on infant and young child feeding (IYCF) practices through Trials for Improved Practices (N=150), were collected, along with anthropometric measurements of weight and length for children less than 2 years of age. Data was triangulated and interpreted.

Results: In Lower Egypt, where the rise in stunting occurred, poor IYCF practices consisted of high consumption of nutrient-poor foods (chips; high fat and high sugar cakes and cookies), low frequency and quality of dietary intake (deficient in iron, zinc), and misperceptions regarding optimal feeding practices from mothers, family members and health workers. In Upper Egypt, the consumption of better quality foods was reflected in the lower level of stunting.

Conclusions: Both quantitative and qualitative data are required to provide an in-depth examination of factors associated with stunting.

Key words: stunting, mixed methods, quantitative, qualitative.

PO1396**IMPACT OF PHYSICAL ACTIVITY ON ADIPOSITY, ADIPOCYTOKINES AND METABOLIC PARAMETERS IN MEXICAN ADULTS**

N. Ramos-Ibanez¹, L. Ortiz-Hernandez¹, L. Ferreyra-Corona¹, CA. Nunez-Alvarez², G. Morales-Xolalpa¹

¹Departament of Health Care, Autonoma Metropolitana University, Campus Xochimilco, Mexico City, Mexico

²Departament of Immunology, National Institute of Medical Science and Nutrition, Mexico City, Mexico

Background and objectives: Sedentary style life is a risk factor for developing obesity and its comorbidities. The objective of study was to determine the relationship between activity and inactivity with adiposity, adipocytokines and metabolic parameters in Mexican adults.

Methods: Participants were 221 adults. Activity was assessed with International Physical Activity Questionnaire (IPAQ) long last 7 days format. Inactivity was determined with the time spend sitting on weekdays and weekend included in the IPAQ. Adiposity was evaluated with body mass index (BMI), waist circumference (WC), percentage of total body fat (%BF) and intra-abdominal adipose tissue (IAAT). %BF and IAAT were estimated by Inbody 720 analyzer. Adiponectin and TNF- α were measured by luminometry method. Metabolic parameters were plasma concentrations of glucose, insulin, lipids, HOMA index, and systolic and diastolic blood pressures (SBP and DBP, respectively).

Results: Score of physical activity (PA) was 4662.9 MET-minutes per week. Men were more active than women (5577.3 vs 3706.2 MET-minutes per week, $p < 0.02$). There were significant negative correlations between IAAT and moderate-vigorous intensity PA, between %BP and vigorous intensity PA and between HDL and walking. Adiponectin also had a negative correlation with walking and moderate-vigorous intensity PA. Inactivity on weekday positively related with IAAT, %BF, BMI, concentration of cholesterol total, HDL, LDL, TNF- α and adiponectin. Inactivity on weekend only had positive correlation with IAAT and WC.

Conclusions: The results show that inactivity mainly on weekday could have an effect on the adiposity and alters the concentration of lipids and adipocytokines. Moderate and vigorous intensity PA are associated with less amount of abdominal and total adiposity. However, in this sample of Mexican adults there were associations that are inconsistent with those reported in the literature: a negative relationship of PA with adiponectin; and positive relationship between HDL and inactivity.

Key words: Physical activity level, metabolic parameters, adiposity, adipocytokines.

PO1397**PLASMA LEVELS OF IRON, COPPER, ZINC AND THE ANTHROPOMETRIC NUTRITIONAL STATUS IN AÑU ETHNIC CHILDREN FROM THE SINAMAICA LAGOON, VENEZUELA**

A. Bravo¹, A. Colmenares¹, E. Romano¹, D. Villalobos¹, D. Garcia¹, S. Linares², D. Fernandez³, V. Granadillo³

¹Laboratory of Research and Development in Nutrition (LIDN), University of Zulia, Venezuela

²Institute of Endocrine-Metabolic Research "Dr. Felix Gomez", University of Zulia, Venezuela

³Laboratory of Analytical Instrumentation (LIA), University of Zulia, Venezuela

Background and objectives: Malnutrition in childhood increases the risk of death in the adult people, affecting their healthy status. Minerals such as iron (Fe), copper (Cu) and zinc (Zn) are essential trace elements for adequate nutrition, participating in the growth and anthropometric development of the children. The aim of the study was to correlate the plasma levels of iron, copper and zinc and the anthropometrical study in preschool children of ethnic Añu from Sinamaica Lagoon, Venezuela.

Methods: Peripheral blood was collected in a sample of 43 preschool children. The anthropometric nutritional assessment was performed by combining the indicators weight/age, weight/height and height/age. The concentrations of Fe, Cu and Zn were determined by flame atomic absorption spectrometry (FAAS).

Results: Plasma levels of minerals (mg/ml) in preschool Añu were: Fe 0.45 ± 0.29 , Cu 0.94 ± 0.33 , Zn 0.35 ± 0.15 without differences between genders or nutritional groups. The 60.47% of children had values indicating iron deficiency, the 32.55% of children had values indicating deficiency of Cu and 97.67% of children had values indicating severe Zn deficiency. The 74.4% of children showed a normal nutritional status, followed by excess in 20.9%. There was a significant inverse correlation between serum levels of Cu and Zn with size, as well as an inverse correlation between Cu and weight ($p < 0.05$).

Conclusions: We conclude that Añu children evaluated in the present study are deficient in some of the essential trace elements analyzed, which might reveal a high prevalence of hidden hunger in this population.

Key words: Añu ethnic, children, minerals, trace elements, nutritional status.

PO1398**EVALUATION OF LIFESTYLE OF PEOPLE SELF-PERCEIVED OVERWEIGHT**

O. Vera-López¹, A. Navarro-Cruz¹, P. Aguilar-Alonso², R. Dávila-Márquez¹, N. Melgoza-Palma¹, R. Ávila-Sosa¹, R. Ramírez y Ayala², M. Lazcano-Hernandez²

¹Departamento de Bioquímica y Alimentos, Facultad de Ciencias Químicas, BUAP, Puebla, Mexico

²Posgrado en Ciencias Químicas, Facultad de Ciencias Químicas, BUAP

Background and objectives: Numerous studies have suggested the importance of the alteration of the perception of body image as an early symptom to detect eating disorders. Usually we proceed to the comparison of objective parameters, e.g. weight and height measured by the researcher, with self-reported values for the study subjects, there may be errors in weight and self-reported height; frequently, it is observed underestimation of weight and overvaluation of height, causing increased risk of obesity, so the aim of this study was to evaluate the lifestyle of people who self-perceive with overweight to determine whether this influences their feeding habits.

Methods: A survey of self-perception of body weight was applied and selected those who self-perceived with overweight, later were measured height, weight and body fat percentage and were applied surveys for lifestyle and eating habits. The statistical analysis of the data were performed using the R-sigma-Babel software.

Results: Sample consisted of 74 people, with a mean age of 41.34 ± 10.67 years, and although they were self-identified with a 'little extra weight', the average BMI was 32.84 ± 4.88 , and body fat $38.82 \pm 5.7\%$. The waist circumference of 78% of the population was of cardiovascular risk. With regard to diet, 15% had made at least three different diets over the past year and 36.5% has ever dieted in his life, despite this, 33.78% considered to have healthy eating habits and 27% have two meals a day (breakfast and dinner). 17% are smokers and 63.51% had a family history of diabetes.

Conclusions: Although a person is self-perceive with a little extra weight, they feel healthy, this is crucial in their lifestyle which impacts the acceptance of health problems such as hypertension, obesity and disorders in lipid profile. People who are mistakenly perceived have a potential hazard to their health.

Key words: Self-perception, overweight, lifestyle.

PO1399**WHAT DO WE KNOW ABOUT THE FEED-THE-FUTURE INITIATIVE'S PROGRESS TOWARD NUTRITION GOALS? RESULTS OF A GLOBAL LANDSCAPE ANALYSIS**

L. Du¹, A. Buchsbaum¹, A. Klein¹, A. Narayan¹

¹JSI, Rosslyn, VA, USA

Background and objectives: The U.S. Government's Feed the Future (FTF) initiative is a \$3.5 billion pledge for agricultural development and food security. The Bureau for Food Security of USAID has requested the Strengthening Partnerships, Results and Innovations in Nutrition Globally (SPRING) project to conduct a landscape analysis to review current programming that links agriculture and nutrition in all 19 FTF focus countries in Africa, Asia and Latin America and Caribbean.

Methods: IFPRI and FAO agriculture-nutrition pathways and principles were used to analyze country FTF multi-year strategies and key project documents provided by the USAID Missions. Supplementary key informant interviews were conducted with FTF points of contact in each country.

Results: Most countries selected child stunting and minimal acceptable diet and maternal anemia as key nutrition indicators, but predominantly rely on general nutrition education as the intervention. The design of most FTF projects adopted a "value chain" approach, and assumed that increases in agricultural production and income would lead to either greater consumption or purchase of nutrient-dense foods and improved nutritional outcomes. Staple foods were the most commonly selected value chain items, while animal-sourced foods, legume/nuts, and horticulture were selected by half of the focus countries. Women's time, labor burden, and control of income were infrequently addressed.

Conclusions: FTF projects invest in improving production and strengthening markets for value chain crops; more diverse, nutrient-dense food items need to be incorporated in these efforts, in order to impact selected nutrition indicators. Furthermore, FTF projects need to better assess the contextual factors that affect the target beneficiaries' production, purchase, and consumption decisions and practices. Projects should develop a comprehensive behavior change communication strategy to address the agriculture-nutrition continuum with a special focus on improving women's influences in household decisions that affect maternal and child nutrition.

Key words: Feed the Future, agriculture, nutrition.

PO1400**A RAPID, INITIAL ASSESSMENT OF THE DISTRIBUTION AND CONSUMPTION OF IRON-FOLIC ACID TABLETS THROUGH ANTENATAL CARE: A COMPARATIVE ANALYSIS**

A. D'Agostino¹, H. Nekatebeb¹, J. Fiedler¹

¹Strengthening Partnerships, Results and Innovations in Nutrition Globally (SPRING), John Snow International Research & Training, Rosslyn, Virginia, United States

Background and objectives: Supplementation of iron-folic acid (IFA) during antenatal care (ANC) visits has existed for decades but often has low national coverage and few women consume the World Health Organization (WHO) recommended 180 tablets. USAID's SPRING Project has developed a Rapid Assessment method that, through analysis of Demographic and Health Survey (DHS) data, illustrates pregnant women's access to and consumption of IFA tablets through ANC visits.

Methods: This tool assesses performance at four falter points (ANC attendance, IFA received, any IFA taken, and compliance with WHO standards), illustrated as flowchart, to understand how well ANC functions as an IFA supplementation platform. This assessment allows policy-makers to identify and rank bottlenecks to scaling-up IFA supplementation through ANC. SPRING performed this analysis on 23 countries, highlighting performance patterns for improved program planning.

Results: When indicators are averaged across all 23 countries, 85% of women attended at least one ANC, 80% of these women received IFA, of which 93% consumed at least one tablet, but only 13% of these women take all 180 tablets. Further analysis reveals patterns, with some countries having high ANC coverage but low IFA provision during ANC (DRC and Haiti), others having high ANC coverage and IFA provision but few women taking any tablets (Nigeria and Liberia), and countries that perform well in ANC, supplies, and initial consumption, but very few women consume the recommended 180 tablets (Liberia, Malawi, Cambodia).

Conclusions: Each performance pattern requires a different approach to improving IFA supplementation through ANC. Usually improvements will depend on identifying and addressing shortcomings in access to ANC, IFA supply management, health workers' practices, and compliance of pregnant women. This assessment tool allows for identifying and prioritizing problem areas, a practical first step in improving IFA coverage and reducing anemia.

Key words: supplementation, iron folic-acid, antenatal care, policy.

PO1401**MANAGING THE ZAMBIAN FORTIFICATION PROGRAM PORTFOLIO**

K. Lividini¹, J. Fiedler^{1,2,3}, R. Zulu⁴, G. Kabaghe⁵, J. Tehinse⁷, O. Bermudez⁶

¹HarvestPlus, International Food Policy Research Institute, Washington, DC, USA

³Strengthening Partnerships, Results and Innovations in Nutrition Globally (SPRING) Project, JSI Research & Training Institute, Inc., Arlington, VA, USA

⁴International Center for Tropical Agriculture (CIAT), Lilongwe, Malawi

⁵National Food and Nutrition Commission (NFNC), Lusaka, Zambia

⁶Department of Public Health and Community Medicine, Tufts School of Medicine, Boston, MA, USA

⁷Independent food and nutrition consultant, Abuja, Nigeria

Background and Objectives: Zambia was a world pioneer when it began vitamin A-fortification of sugar 15 years ago. However micronutrient deficiencies continue to plague it. Are there other fortification options for Zambians? We analyzed Zambia's fortification program portfolio and discuss the optimal mix based on costs, coverage, impact and cost-effectiveness.

Methods: We used household consumption and acquisition data from the 2006 Living Conditions Monitoring Survey with a Zambian food composition table to estimate usual intakes of calories, vitamin A, iron, and zinc, and estimated the prevalence of inadequate intake. Using purchases of fortified sugar and three other fortifiable staples, we modeled the additional intake of nutrients due to each vehicle (all combinations), and estimated the change in the prevalence of inadequate intake. Using estimates from the global comparative risk assessments on the incidence of each micronutrient's deficiency-related health outcomes, we calculated the disability-adjusted life years (DALYs) at baseline and total DALYs saved. We then juxtaposed the costs, coverage, impact and cost-effectiveness using Zambia's official fortification regulations with results based on World Health Organization's 2009 recommendations for wheat flour and maize meal.

Results: The greatest coverage is provided by sugar and oil (60% and 59%), followed by wheat flour (45%) and maize meal (23%). Oil fortification produced the greatest reduction in the prevalence of inadequate vitamin A intake (16%). Maize flour produced modest reductions in the prevalence of inadequate intake for iron (2.8%) and zinc (4.4%) as did wheat flour for

iron (2.7%). Greater reductions were observed by applying WHO guidelines and impacts based on DALYs saved paralleled these results.

Conclusions: In order to produce the greatest impacts, a combination of Zambia's regulations and WHO guidelines should be adopted. While combining interventions produced greater impacts, all vehicles were not necessary for producing the most cost-effective package.

Key words: Zambia, Fortification, DALYs, cost-effectiveness.

PO1402**ASSESSMENT OF THE EFFECTIVENESS OF NUTRIBUTTER® DISTRIBUTION ON ANAEMIA AND STUNTING IN REFUGEE POPULATIONS IN DJIBOUTI AND KENYA**

J. Style¹, J. Pringle¹, C. Wilkinson², I. Kassim², M. Tondeur², A. Oman², C. Dolan³, A. Seal¹

¹UCL Institute For Global Health, Institute of Child Health, London, UK

²Office of the United Nations High Commissioner for Refugees, Geneva, Switzerland

³Emergency Nutrition Network, Oxford, UK

Background and objectives: Stunting and micronutrient malnutrition are persistent public health problems in refugee populations. One of the approaches adopted by UNHCR and partners, is blanket supplementary feeding programmes (BSFP) using Nutributter®, a low-quantity lipid-based nutrient supplement. However, the evidence base for the efficacy and effectiveness of Nutributter® is limited. This secondary analysis aimed to assess the effectiveness of blanket Nutributter distribution on anaemia and stunting in children 6-23 months and to assess trends in children 6-59 months, in Dadaab, Kakuma, and Ali Addeh refugee camps.

Methods: A plausibility design using routine pre and post-intervention cross-sectional nutrition survey data was conducted. Trends in total anaemia (Hb<11g/dl), anaemia categories (mild, moderate and severe), and stunting (HAZ<2) from 2008-2011 were explored and interpreted using available contextual, and Nutributter® programme monitoring data. Data was cleaned and analysed using Emergency Nutrition Assessment for SMART software (July 2012), and Epi Info (v3.5.4).

Results: In all camps anaemia prevalence was reduced by at least 20% in children 6-59 (UNHCR short-term target) (p<0.05), however there was variation between camps in how quickly this was achieved, and total anaemia remained of high public health significance (>40%). A reducing trend in the prevalence of anaemia in children 6-23 months was seen. Improvements in anaemia were largely due to reductions in moderate

and severe anaemia; mild anaemia (10<Hb<11g/dl) remained relatively unchanged in all years, for all camps. Trends in stunting varied by camp.

Conclusions: The replicability of findings suggest that Nutributter® distribution is associated with a reduction in anaemia, especially in its most severe forms, in the Horn of Africa. These results need to be interpreted in consideration of the other anaemia reduction activities implemented in the camps alongside the Nutributter® intervention between 2008-2011. Further investigation is required in children 6-23.

Key words: Nutributter®, micronutrient deficiencies, malnutrition, anaemia, stunting.

PO1403

MANAGING THE MICRONUTRIENT PORTFOLIO: A CASE STUDY OF ZAMBIA

J. Fiedler^{1,2,3}, K. Lividini², R. Zulu⁴, G. Kabaghe⁵, J. Tehinse⁷, F. Mubanga⁵, W. Siamusantu⁵, M. Musonda⁵, K. Kabwe⁵, M. Mwanza⁵, C. Zulu⁸, O. Bermudez⁶

¹Poverty, Health, and Nutrition Division, International Food Policy Research Institute, Washington, DC, USA

²HarvestPlus, International Food Policy Research Institute, Washington, DC, USA

³Strengthening Partnerships, Results and Innovations in Nutrition Globally (SPRING) Project, JSI Research & Training Institute, Inc., Arlington, VA, USA

⁴International Center for Tropical Agriculture (CIAT), Lilongwe, Malawi

⁵National Food and Nutrition Commission (NFNC), Lusaka, Zambia

⁶Department of Public Health and Community Medicine, Tufts School of Medicine, Boston, MA, USA

⁷Independent food and nutrition consultant, Abuja, Nigeria

⁸Child Health Unit, Ministry of Health, Lusaka, Zambia

Background and objectives: There has been increasing discourse about the optimal mix of nutrition programs. However, few empirical studies examine this important issue. The objective was to examine Zambia's micronutrient program portfolio and discuss the optimal mix based on costs, coverage, impact and cost-effectiveness.

Methods: We used household consumption and acquisition data from the 2006 Living Conditions Monitoring Survey with a Zambian food composition table to estimate usual intakes of calories and key micronutrients and estimated the prevalen-

ce of inadequate intake. Using purchases of fortified sugar and three other potentially fortifiable staples, we modeled the additional intake of nutrients due to each vehicle. We also modeled biofortification of a high pro-vitamin A maize and empirically identified the key characteristics of the maize market. Finally we analyzed vitamin A supplementation through Child Health Week. For each intervention independently and all combinations, we analyzed the cost, coverage and impact including the change in the prevalence of inadequate intake and the total number of disability-adjust life years (DALYs) saved. We used IFPRI's IMPACT Model to predict changes in food production and consumption patterns through 2042 and used alternative objective criteria to optimize the micronutrient program portfolio mix over 30 years.

Results: Oil and sugar offer the greatest coverage (67%-69%) while biofortification can reach greater than 50%. Supplementation and sugar and oil fortification produce the greatest impacts. The most cost-effective 1, 2, and 3-package interventions were oil fortification alone; oil plus biofortification; and oil plus biofortification and supplementation. The sequencing of combinations affected these results.

Conclusions: Each intervention plays a significant role in combating micronutrient deficiency in Zambia. However, the choice of vehicles and the order of implementation sequencing of the interventions is crucial to optimizing overall impact and cost-effectiveness.

Key words: Biofortification, fortification, supplementation, impact, cost-effectiveness.

PO1404

NEIGHBORHOOD SOCIOECONOMIC DISPARITIES IN THE AVAILABILITY OF HEALTHY FOODS IN SAO PAULO, BRAZIL

AC. Duran¹, A. Diez-Roux², MR. Latorre³, P. Jaime^{1,4}

¹Public Health Nutrition Graduate Program, School of Public Health. University of Sao Paulo, Brasil

²Department of Epidemiology, School of Public Health. University of Michigan, USA

³Department of Epidemiology, School of Public Health. University of Sao Paulo, Brasil

⁴Department of Nutrition, School of Public Health. University of Sao Paulo, Brazil

Background and objectives: Differential access to healthy foods has been hypothesized to contribute to health disparities. Evidence from high-income countries shows that healthy foods are less likely to be found at poor neighborhoods, however, findings from low- and middle-income countries are scarce. This study examines whether the access of healthy foods varies across different types of stores and neighborhoods of different socioeconomic statuses in Sao Paulo city, Brazil.

Methods: Cross-sectional study conducted in 2010-2011 across 52 census tracts selected according to socioeconomic characteristics. Healthy food access was measured by two comprehensive micro-level food environment tools. They assessed in-store measures in (1) retail food stores and fruit and vegetable (FV) specialized stores/markets; and (2) different types of restaurants. Healthy food access was measured as the availability, variety, and promotion of healthy and unhealthy foods and was summarized into two indexes developed for retail food stores and restaurants. Multilevel models were used to examine associations of store type and neighborhood characteristics with food access indexes.

Results: Tools were tested for test-retest and inter-rater reliability. They were reliable and able to discriminate across store types. Fast-food restaurants, bars and corners stores were more likely to be located in low income neighborhoods, though supermarkets and FV specialized markets/stores were more likely to be located in neighborhoods in the 2nd tertile of income. Multilevel analyses showed that supermarkets and full-service restaurants carried more healthy items independent of local and surrounding income levels. Stores with better food access, regardless of the type, were more likely to be found at high income neighborhoods.

Conclusions: We found differences in the access of healthy foods in Sao Paulo favoring middle and high income neighborhoods. Policies and interventions aimed at reducing disparities in food access should focus low income settings.

Key words: food environment, disparities, food stores, socioeconomic factors, neighborhoods.

Survey (POF/IBGE) conducted in 2008/2009 on a probabilistic sample of 55, 970 households, with the household as the unit of study. Data analyzed were the nutritional status of individuals over 20 years and out-of-pocket healthcare expenditure. The body mass index (BMI) of the household was calculated based on the average BMI of adults and classified according to WHO (1995) categories. The out-of-pocket healthcare expenditure was calculated based on the annual per capita expenditure and included medicines, healthcare services and private insurers. We conducted a descriptive analysis and multiple linear regression models were used to evaluate the influence of BMI categories of household on the out-of-pocket healthcare expenditure (outcome), controlling for potential confounders (socio-demographic variables, such as income, proportion of children, adolescents and elderly in household, area and region).

Results: The households with BMI classified as normal (until 24.99 kg/m²) and pre-obese (25 to 29.99 kg/m²) spent R\$186.09 and R\$216.37 respectively, while households with BMI between 30.00 kg/m² and 34.99 kg/m² and over 35.00 kg/m² had per capita out-of-pocket expenditure of R\$271.72 and R\$319.48 respectively. The difference was statistically significant ($p < 0.000$). In the linear regression, adjusted to confounders, households with obesity class I or more (II or III), increased the out-of-pocket expenditure in 52% and 65%, respectively, in relation to a normal BMI household.

Conclusions: Obesity impacts on household budgets, increasing the out-of-pocket expenditure healthcare.

Key words: Obesity; Out-of-pocket; Household Budget Survey. Acknowledgements: FAPESP (São Paulo Research Foundation).

PO1405

OUT-OF-POCKET HEALTHCARE EXPENDITURE ASSOCIATED TO OBESITY IN BRAZIL: AN EVALUATION BASED ON HOUSEHOLD BUDGET SURVEY 2008-2009

DS. Canella^{1,2}, HMD. Novaes³, RB. Levy^{2,3}

¹Graduate Program in Public Health Nutrition, School of Public Health. University of Sao Paulo, Brazil

²Center for Epidemiological Studies in Health and Nutrition, University of São Paulo

³Department of Preventive Medicine, Faculty of Medicine, University of São Paulo. Brazil

Background and objectives: The prevalence of obesity is increasing in Brazil and is an important risk factor for chronic diseases and may result in higher health costs. The objective of this study was to analyze the association between obesity and out-of-pocket healthcare expenditure of Brazilian families.

Methods: Data are from the Brazilian Household Budget

PO1406

EXPLORING WHERE PEOPLE LOOK FOR INFORMATION ABOUT NUTRITION, WESTERN AUSTRALIA 2009 AND 2012

A. Daly¹, C. Pollard^{1,2}

¹Curtin University

²Health Department of Western Australia

Background and objectives: In Western Australia (WA) guidelines around healthy eating are regularly promoted. As surveys regularly report relatively low adherence to these it is important to know what do people know about the guidelines and where do they get their information. The aim of the study is to identify what WA people perceive as problems related to nutrition and where they usually get their information.

Methods: The 2009 and 2012 Nutrition Monitoring Surveys conducted a total of 2832 randomly sampled adults aged 18 to 64 in WA. The surveys, which had ethics approval, asked about perceptions of the major problems with the average Australian

diet as well as sources of nutrition information. All data were self-reported.

Results: Data were weighted for probability of selection and adjusted to the 2009 age, sex and area of residence distribution of the population. Pearson Chi Square, Adjusted WALD tests, logistic and poisson regressions were used to determine statistically significant associations. Females mentioned significantly more problems with the Australian diet (2.0) compared with males (1.6). Information sources and major problems mentioned differed by sex and year of survey. Different problems were associated with different sources of information about nutrition for example: Sugar, salt or fat as the major problems were associated with newspapers (OR 1.78); books (OR 1.44); credible health sources (OR 1.38) or the internet (OR 1.29) as nutrition information sources.

Conclusions: Sex and year of survey are associated with both perceived problems with the Australian diet and nutrition information sources. Further investigation of the sources of information could be helpful in decisions about how to promote nutrition guidelines.

Acknowledgements: The Department of Health funded the survey which is part of a Healthway funded project based in Curtin University to assist the translation of research into practice.

PO1407

NUTRITION EDUCATION OF PRE-SCHOOL AND SCHOOL-AGE CHILDREN, FAMILIES AND TEACHERS UTILISING SOCIAL PARTICIPATION WITH INFORMATION AND COMMUNICATION TECHNOLOGIES SALINAS J, CORREA F, GONZALEZ CG, HUENCHUPAN C, MONTENEGRO E, VIO F INSTITUTE OF NUTRITION AN

J. Salinas¹, F. Correa¹, C. Gonzalez¹, C. Huenchupan¹, E. Montenegro¹, F. Vio¹

¹Institute of Nutrition and Food Technology (INTA), University of Chile, Santiago, Chile

Background and objectives: A three year nutrition education applied research project is presented. The objective is to design, apply and evaluate the impact of educational materials on food and nutrition, aimed to change eating habits in children from nursery and primary school, parents and teachers to prevent infant obesity in Chile.

Methods: The methodology is the articulation of the conceptual and regulatory framework and public policy with the school, family and individual context. The methodologies and materials for schools and families are specifically based on social participation and the use of information technology and

communication including photovoice, healthy cook workshops, videos and utilization of web 2.0.

Results: A nutrition education methodology was designed and an intervention model was implemented for 50 teachers through 8 workshops to transfer healthy food knowledge and practices to pre-school and school-age children. In addition, a participative training program for families was designed based on the previous two years (2011-2012) findings of the research project. The complete model is been applied in a quasi-experimental intervention to 300 pre-school and school-age children and 300 controls during 2013.

Conclusions: The nutrition education model and the baseline results of the intervention are presented. Results of this project are crucial to determine public nutrition education policies in Chile. Acknowledgements: This study was funded by FONDECYT project N° 1110044.

Key words: nutrition education, information technology and communication (ICT), participatory methodologies.

PO1408

PROCESSED AND ULTRA-PROCESSED FOOD PRODUCTS AND OBESITY IN BRAZILIAN HOUSEHOLDS (2008-2009)

R.B. Levy^{1,2}, D.S. Canella^{2,3}, A.P.B. Martins^{2,3}, R.M. Claro², L.G. Baraldi^{2,3}, J.C. Moubarac², G. Cannon², C.A. Monteiro^{2,4}

¹Department of Preventive Medicine, Faculty of Medicine, University of São Paulo, Brazil

²Center for Epidemiological Studies in Health and Nutrition, University of São Paulo, Brazil

³Graduate Program in Public Health Nutrition, School of Public Health, University of Sao Paulo, Brazil

⁴Department of Nutrition, School of Public Health, University of Sao Paolo, Brazil

Background and objectives: The consumption of industrially processed foods and drink products has risen in parallel with the global epidemic of obesity and related chronic non-communicable diseases. The objective of this study was to analyze the relationship between household availability of processed and ultra-processed products and obesity in Brazil.

Methods: The study was based on data from the 2008-2009 Household Budget Survey involving a probabilistic sample of 55, 970 Brazilian households. The units of study were household aggregates (strata), geographically and socioeconomically homogeneous. Multiple linear regression models were used to assess the relationship between the availability of processed and ultra-processed products, and the average body mass index (BMI) and percentage of obese people in the strata. The

study controlled for potential confounders (socio-demographic characteristics; percentage of expenditure on eating out of home; dietary energy other than that from processed and ultra-processed products). Predictive values for prevalence of obesity were estimated according to quartiles of the household availability of dietary energy from processed and ultra-processed products.

Results: The mean contribution of processed and ultra-processed products to total dietary energy availability ranged from 15.4% (lower quartile) to 39.4% (upper quartile). Adjusted linear regression coefficients indicated that greater household availability of these products was correlated with higher prevalence of obesity. For example, people in the quartile who consumed most processed and ultra-processed products were 36% more likely to be obese, compared with people in the quartile who consumed least of these products.

Conclusions: Greater household availability of processed and ultra-processed food products in Brazil was positively and independently associated with higher risk of obesity in all age groups.

Key words: Obesity; Food Processing; Household Budget Survey. Acknowledgement: CNPq (National Council for Scientific and Technological Development).

and 204, irrespectively. The questionnaire was designed by the researchers.

Results: The women in earthquake region were more vulnerable to generated negative feelings including hallucinations, anxiety and worries than that in the other regions. Furthermore, the women in earthquake region became pay more attention to nutrition value and acceptability of the food than those who lived in other places. There is no significance difference among people in different region on the amount of the food consumed. The women in earthquake region have increased the consumption and reserve of basic food and snack food compared to the other females.

Conclusions: The earthquake drove the influence to women in earthquake region on diet psychology, eating attitude and dietary behavior. However there was a positive factor ingredient, which is the opportunity to carry out nutrition health education in the earthquake region to improve their diet psychology to diminish the hazard of the earthquake and benefit the post-disaster reconstruction.

Key words: Wenchuan earthquake, dietary psychological, dietary attitudes, dietary behavior. Acknowledgements: This project was funded by the Higher Education Reform Project in Chongqing, China [NO.1203131].

DIETARY PSYCHOLOGICAL, DIETARY ATTITUDES AND DIETARY BEHAVIOR AMONG ADULT FEMALE IN DIFFERENT REGIONS EXPOSED TO WENCHUAN EARTHQUAKE, CHINA

Y. Zhao¹, L. Han¹, H. Xue¹, B. Tang¹, M. Yan¹, W. Kong¹, T. Gong¹, Y. Zhang¹, M. Sharma²

¹School of Public Health and Management, Chongqing Medical University, Chongqing, China

²Health Promotion and Education, University of Cincinnati, Cincinnati, USA

Background and objectives: It is known that Wenchuan earthquake in 2008 and strong aftershocks have caused terrible casualties and damage in China. Although many investigations have been conducted on the influence of the disaster to health, few researches have examined nutritional behavior affected. The objective is to evaluate the influence of the disaster to dietary psychological, dietary attitudes and dietary behavior of the adult women in different regions of China and to provide the essential data for nutritional interventions to disaster victims.

Methods: The investigation was conducted just after the May 12th, 2008 (from July to September), and a total of 736 adult women (18-55 years) were selected randomly in earthquake region (Sichuan, China), shaking region (Chongqing, Ningxia and Shanxi China) and non-seismic region (Liaoning, China), where the amount of the participants were 206, 326

PO1410**DIETARY AND LIFE-STYLE FACTORS THAT INFLUENCE THE CHEWING CONSCIOUSNESS IN PRIMARY SCHOOLCHILDREN IN JAPAN**

⁸Nishitani Primary School, Takarazuka, Hyogo, Japan

⁹Department of Food and Nutrition Science, Kobe Women's Junior College, Kobe, Hyogo, Japan

Background and objectives: The decline of ability of chewing in the child is a major problem. The objective of this study is to clarify dietary and life-style factors that improve chewing consciousness.

Methods: A questionnaire (55 items, 1-4 points) on diet and life-style was administered to primary schoolchildren aged 11-12 years old (n=592, 50% boys) from four schools in Kansai area in Japan. Factor analysis by the least-square method was conducted and six factors were extracted. We analyzed dietary and life-style factors that affected chewing consciousness by using covariance structure analysis.

Results: "Interest in cooking" had the strongest effects (path coefficient=0.43) directly and indirectly on improvement of "chewing consciousness". "Interest in cooking" also had significant effects on "intake frequency of vegetables and fruit" and on "enjoying eating". "Intake frequency of vegetables and fruit", "enjoying eating" and "no irritation" directly influenced improvement of "chewing consciousness". "Chewing consciousness" was influenced indirectly from "enjoying sports", "refrainment from eating between meals and eating out" and "frequency of eating together at dinner". "Chewing consciousness", "intake frequency of vegetables and fruit", "refrainment from eating between meals and eating out" and "no irritation" had significant effects directly on improvement of "learning motivation

and learning attitude". The overall fit of this model was judged to be statistically satisfactory (GFI=0.986, AGFI=0.976, CFI=0.986, RMSEA=0.023).

Conclusions: Covariance structure analysis suggested that the chewing consciousness was significantly associated with multiple dietary and life-style habits in primary schoolchildren. Interest in cooking and intake frequency of vegetables and fruit were important for improved chewing consciousness. It was also shown that improved chewing consciousness was positively associated with learning motivation and learning attitude.

Key words: chewing consciousness, learning motivation and learning attitude, interest in cooking, primary schoolchildren.

PO1411**RELATIONSHIP BETWEEN MASTICATORY ABILITY AND DIETARY BEHAVIORS IN UNIVERSITY STUDENTS IN JAPAN**

J. Kang¹, T. Okuda², N. Tanaka³, Y. Higashine⁴, Y. Asano⁵, I. Hamaguchi⁶, H. Shinohara⁷

¹Department of Nutrition, Hyogo NCC College, Nishinomiya, Japan

²Faculty of Human Science, Tezukayamagakuin University, Sakai, Japan

³Faculty of Home Economics, Kobe Women's University, Kobe, Japan

⁴Faculty of Health Science, Osaka Aoyama University, Minoo, Japan

⁵Faculty of Health Science, Kio University, Koryou, Japan

⁶Faculty of Human Sciences, Konan Women's University, Kobe, Japan

⁷Faculty of Education and Culture, University of Miyazaki, Miyazaki, Japan

Background and objectives: The aim of this study was to investigate the relationship between the masticatory ability and dietary behaviors in university students.

Methods: This is a cross-sectional study with 323 university students (54 males and 269 females) in Japan. To investigate the masticatory ability, we used color-changeable chewing gum (Masticatory Performance Evaluating Gum: XYLITOL with the LOTTE Co., LTD., Tokyo, Japan). The participants chewed gum for two minutes. The numbers of chews were counted and the color changes of the gum were checked. The L*a*b* values of a color were generated by measuring the color with a spectrophotometer SE-2000 (Nippon Densyoku). Dietary behaviors and consciousness of mastication were measured using

self-administered questionnaires. Data were collected from May to July 2010.

Results: The average numbers of chews for two minutes were 161 and 145 times in male and female students, respectively. The a^* value of chewing-gum was significantly higher in male students than that of female students. Among female students, a^* value which reflects the redness of chewed gum was significantly higher in a group who does not dislike eating hard-food than a group who dislikes eating hard-food. And dietary behaviors were significantly correlated with the masticatory ability. Students with healthy dietary style had higher frequency of vegetable and bean intake, chewed food better, preferred Japanese food, savored a meal, had higher level of consciousness of mastication, and ate a low sodium diet.

Conclusions: These findings suggest that promoting healthy dietary behaviors will help to enhance the masticatory ability in female university students. Especially, education to increase masticatory ability should target students who dislike eating hard-food. Addressing a conscious effort to exercise the masticatory muscles is important.

Key words: Masticatory ability, Masticatory consciousness, Dietary behavior.

PO1412

INFLUENCE OF EATING HABITS ON THE NUTRITIONAL STATUS OF HEALTHCARE PERSONNEL AT THE UNIVERSITY OF ANTIOQUIA- COLOMBIA: LATINMETS STUDY.

J. Díaz-García¹, J M. Monsalve-Álvarez¹, L I. González-Zapata¹, A. Estrada-Restrepo¹, G. Deossa¹, J. Bressan²

¹School of Nutrition and Dietetics, University of Antioquia, Colombia

²Departamento de Nutrição e Saúde, Universidade Federal de Viçosa, Brasil

Background and objectives: Social, cultural and economic factors influence food preferences; knowledge of healthy eating does not necessarily translate into actual healthy eating. This study aims to establish the relationship between eating habits and nutritional status in students and professors from the health area's faculties at the University of Antioquia, Colombia.

Methods: Cross-sectional study, carried out from 2010 to 2011. Sociodemographic, anthropometric, dietary intake and eating behavioral data were collected. A descriptive and analytical study was performed by using chi-square tests and logistic regression models in order to classify the variables associated with overweight measured by BMI and abdominal obesity (AO) $P = 0.05$. SPSS v.19.

Results: A total of 285 volunteers (42.8% professors, 57.2% students), aged between 20 and 61 participated in the study.

In professors, the consumption of energy-dense foods such as sweet cakes and sugar, was directly related to overweight and AO respectively ($p < 0.05$). As for the students, overweight and AO were related to Colombian stuffed potatoes consumption, and overweight to chocolate drinks consumption ($p < 0.05$). Logistic regression showed a positive gradient with age as well as association with overeating perception ($p < 0.05$) in professors, in both overweight and AO. In students, an association between overweight and AO with overeating perception more than three times per week ($p < 0.05$) was found. The same association was found for overweight with the menu components: soup/salad, main course, beverage (OR = 0.310, 95% CI 0.097; 0.993).

Conclusions: The nutritional status is influenced by eating habits like the consumption of energy-dense foods. The perception of overeating in professors and students, and the menu components in students, represent relevant variables when relating them to nutritional status both by BMI and waist circumference.

Key words: Eating habits, nutritional status, healthcare professionals, overeating, obesogenic environment.

PO1413

TRENDS IN NUTRITIONAL STATUS OF CHILDREN UNDER 5 YEARS OLD FROM 2000-2010 IN HO CHI MINH CITY, VIETNAM

T T. Minh Hanh¹, V. Quynh Hoa¹, D T. Ngoc Diep¹

¹Nutrition Center of Ho Chi Minh City, HCMC, Vietnam

Background and objectives: This study aims to examine the trends of under- and over-nutrition as well growth acceleration of children under-5-years of age over a 10 year period from 2000-2010 in HCMC.

Methods: Data from 10 epidemiological cross-sectional surveys in children under-5-years old from 2000-2010 were collected. The sample size ranged from 1497 subjects in 2008 to 3105 in 2000. The proportion of boys and girls were similar in each survey. Weight-for-age $< -2SD$ and height-for-age $< -2SD$ were classified as underweight and stunting, respectively. Weight-for-height $> +2SD$ was determined as overweight. Mean of height and weight of subjects in each year was analyzed separately by sex and for each 6 months of age.

Results: The prevalence of underweight and stunting of children under 5 years old between 2000-2010 declined from 9.0% (95% CI, 8.1-10.1) to 6.7% (95% CI, 5.5-8.0), $p < 0.01$ and from 14.3% (95% CI, 13.1-15.6) to 7.8% (95% CI, 6.5-9.2), $p < 0.001$, respectively; while overweight increased three-fold from 3.7% (95% CI, 3.1-4.4) to 10.7% (95% CI, 9.2-12.3). Boys were significantly more overweight than girls. Mean height of boys and

girls under 18 months did not change. From 18-months of age children demonstrated increased height rates of 1.5cm-3.2cm for boys and 1.3cm-3.8cm for girls. Mean weight gain for children over 18 months was 1.1-3.2kg for boys and 0.9-2.5kg for girls.

Conclusions: The prevalence of underweight and stunting in children under the age of 5 has gradually decreased and has been accompanied by a rapid increase in the prevalence of overweight. Overweight children are now more prevalent than underweight children due largely to rapid economic change. We conclude that there is a secular trend in growth (both in height and weight) in children under-5-years of age with children in 2010 are taller and heavier than those in 2000.

Key words: malnutrition, children under-5-years, HCMC.

PO1414

CHANGES IN PHYSICAL STATUS OF CHILDREN IN JAPAN AND STRATEGIES TO ADDRESS CHILDHOOD OBESITY AND UNDERWEIGHT

R. Sugiura¹, M. Murata²

¹Faculty of Human Ecology, Wayo Women's University, Ichikawa, Chiba, Japan

²Wayo Women's University, Ichikawa, Chiba, Japan

Background and objectives: In Japanese school-aged children aged 6-17 years, average height according to age has plateaued since 2000, whereas average weight has gradually declined. We therefore reviewed changes in physical status of Japanese children from 1980 to 2011.

Methods: A cohort study was undertaken to assess the percentage of overweight* as an indicator of physical status in children aged 6-17 years based on data from the Annual Report of School Health Statistics (hereinafter, the 'Report') from 1980 to 2011. We reviewed these data and used them to evaluate the prevalence of obesity and underweight. *Sugiura R and Murata M: Problems with body mass index as an index to evaluate physical status of children in puberty, *Pediatrics International* (2011) 53, 634-642.

Results: Although the prevalence of obesity increased from 1980 to 2000 in boys and girls aged 6-17 years, the prevalence of obesity tended to decrease in boys and girls aged 6-10 years after 2000. In addition, after 2002-2006, the prevalence decreased in boys and girls aged 11-17 years. The prevalence of mild and moderate obesity decreased after 2002-2004 and that of severe obesity began to decline after 2006-2008.

Conclusions: These data indicate that the physical status of Japanese children has changed in recent years such that the prevalence of obesity decreased in both boys and girls, and has been replaced by an increased prevalence of underweight. Reasons for the change in physical status among Japanese children

from 1980 to 2011 and necessities for future strategies to solve the problems of childhood obesity and underweight are discussed.

Key words: obesity, underweight, children.

PO1415

THE FEASIBILITY OF MULTISECTORAL POLICIES AIMED AT REDUCING TRANS FAT IN INDIA

S M. Downs¹, A M. Thow¹, S. Ghosh-Jerath², S R. Leeder¹

¹Menzies Centre for Health Policy, University of Sydney, Sydney, NSW, Australia

²Indian Institute of Public Health (Delhi), Public Health Foundation of India, Delhi, India

Background and objectives: Non-communicable diseases (NCDs) are the leading cause of death in India. There are several dietary risk factors for NCDs, including trans fat consumption. The World Health Organization recommends replacing trans fat with polyunsaturated oils to improve diets and reduce the risk of NCDs. The objective of this study was to examine the feasibility of multisectoral policy options to support trans fat reduction in India.

Methods: Semi-structured interviews were conducted with 18 stakeholders from multiple sectors including trade, agriculture, industry, health and finance. Interviewees were asked about the feasibility of nine core policy options derived from food supply chain analysis aimed at supporting trans fat reduction and its replacement with polyunsaturated oils, in addition to sector specific policies based on their area of expertise. Interviews were coded and analysed according to key themes.

Results: Overall, interviewees were most supportive of downstream policies such as mass media campaigns aimed at increasing awareness and improved labelling. Although there was support for policies aimed at improving inputs into agriculture and streamlining the supply chain, interviewees noted several difficulties related to the implementation and enforcement of those policies. Trade policies aimed at increasing the availability of healthier polyunsaturated oils were not deemed feasible given that the country relies heavily on imports of palm oil to meet consumer demand. Many interviewees noted the need to increase the role of the private sector, given the lack of capacity for implementation of government policies.

Conclusions: There was little support for upstream policies aimed at increasing the availability of healthier oils. Nevertheless, agriculture policies that improve the availability and decrease the price of polyunsaturated oils have the potential to strengthen supply chains and lead to greater uptake of their use by industry, thereby decreasing the risk of NCDs.

Key Words: non-communicable disease, trans fat, multi-sectoral policy.

PO1416**REFORMULATING PARTIALLY HYDROGENATED VEGETABLE OILS TO MAXIMISE HEALTH GAINS IN INDIA: AN INDUSTRY PERSPECTIVE**

S M. Downs¹, V. Gupta², S. Ghosh-Jerath², K. Lock³, A M. Thow¹, A. Singh⁴

¹Menzies Centre For Health Policy, University of Sydney, Sydney, NSW, Australia

²Indian Institute of Public Health (Delhi), Public Health Foundation of India, Delhi, India

³Department of Health Services Research & Policy, LLondon School of Hygiene & Tropical Medicine, London, UK

⁴Indian Institute of Public Health (Delhi) and All India Institute of Medical Sciences, Delhi, India

Background and objectives: The consumption of partially hydrogenated vegetable oils (PHVOs) high in trans fat is associated with an increased risk of cardiovascular disease. In response to high intakes of PHVOs, the Indian government has proposed regulation to set limits on the amount of trans fat permissible in PHVOs. Global recommendations are to replace PHVOs with polyunsaturated fatty acids (PUFAs) in order to optimise health benefits. The purpose of this study was to examine the technical and economic feasibility of reducing trans fat in PHVOs and to assess the feasibility of their replacement with PUFAs in India.

Methods: Fourteen semi-structured interviews were conducted with manufacturers of PHVOs in India. Data were coded and organised according to key themes.

Results: Interviewees indicated that reformulating PHVOs was both economically and technically feasible provided that trans fat regulation takes account of the food technology challenges associated with product reformulation. The main challenge was deemed to be maintaining the physical properties that consumers prefer while reducing the trans fat in PHVOs. The availability of input oils was not seen to be a problem because of the low cost and high availability of imported palm oil. Most interviewees were not concerned about the potential increase in saturated fat associated with use of palm oil and were not planning to use PUFAs in product reformulation. Interviewees indicated that many smaller manufacturers would not have sufficient capacity to reformulate products to reduce trans fat.

Conclusions: Reformulating PHVOs to reduce trans fat in India is feasible; however, ensuring that product reformulation is done in a way that maximises health benefits will require shifts in knowledge and subsequent demand of products, decreased reliance on palm oil, investment in research and development and increased capacity for smaller manufacturers.

Key words: trans fat, product reformulation, regulation.

PO1417**STABILITY AND RETENTION OF MICRONUTRIENTS IN SIX DIFFERENT TYPES OF FORTIFIED RICE PREPARED USING FIVE DIFFERENT COOKING TECHNIQUES.**

K. Khov¹, A. Laillou², C. Guyonnet², V. Jallier², R. Moench-Pfanner², J. Berger³, F T. Wieringa³

¹Dept of Fisheries Post-harvest Technologies and Quality Control (DFPTQ), Fisheries Administration, Ministry of Agriculture Forestry and Fisheries, Phnom Penh, Cambodia

²Global Alliance for Improved Nutrition (GAIN), Geneva, Switzerland

³Institut de Recherche Pour Le Développement (IRD), IRD-UM2-UM1, Montpellier, France

Background and objectives: Fortifying staple foods such as rice hold great potential to bring essential micronutrients to a large part of the world population at risk for micronutrient deficiency. However, it is unknown what the retention is of micronutrients in fortified rice, prepared using different in cooking methods. Nor whether different methods for the production of rice premix affect the final amount of micronutrient consumed. The objective of the current study was to quantify the effect of different rice cooking techniques used throughout the world on the retention of micronutrients.

Methods: Retention of vitamin A, iron, zinc, vitamin B12 and folic acid was assessed in 6 different rice premixes, used to prepared fortified rice (by mixing normal rice with rice premix 1:100), cooked in 5 different way. Producers of rice premixes were provided with the same micronutrient premix.

Results: Retention of iron, zinc, vitamin B12 and folic acid was between 80% and 120%, and unaffected by cooking method. The retention of vitamin A was significantly affected by cooking method ($P < 0.05$), with retention ranging from 80% - 0%, depending on cooking method and producer of rice premix. No systematic differences between the different production methods of making rice premix were observed

Conclusions: This study shows that preparation methods of rice used in different regions in the world do not lead to a loss of most micronutrients with the exception of vitamin A. Factors involved in protecting vitamin A against losses during cooking of the rice need to be identified

Key words: Fortified rice, retention, vitamins, minerals, cooking method.

PO1418

INFORMATION AND COMMUNICATION TECHNOLOGIES IN HEALTH PROMOTION EDUCATION FOR PRIMARY HEALTH CARE SALINAS J, MUÑOZ C, ALBAGLI A, VIO F. INSTITUTE OF NUTRITION AND FOOD TECHNOLOGY INTA UNIVERSITY OF CHILE, SANTIAGO, CHILE

J. Salinas¹, C. Muñoz¹, A. Albagli¹, F. Vio¹

Institute of Nutrition and Food Technology INTA
University of Chile, Santiago, Chile

Background and objectives: INTA has a long experience in Health Promotion and Nutrition training programs, and in on-line education programs. The objective of this study is to evaluate an on-line Health Promotion training model for Primary Health Care professionals, based on a Diploma offering new teaching models utilizing Information and Communication Technologies for nutritionists, nurses, health education professionals, dentists, social workers and other health professionals.

Methods: A mixed quality and quantitative assessment is presented about the 8 months (248 hours) Diploma including 7 teachers, 12 monitors and 264 students from all the Regions of the country. The Diploma had 5 thematic terms, with individual and group exercises, participation in interactive blogs, tests and a final integral work.

Results: Evaluation showed that 90.15% of the students completed the Diploma successfully, which is a high rate of approval, with more than 90% satisfaction caused by the excellent interaction with teachers and monitors, the possibility of participation in blogs and exercises, the quality of the teaching process and the possibility to continue working in networks. The main barriers were the lack of time, overwork, problems with the access to internet, and inequality in the participation in work groups. The final works were done according to the real local situation of the students, with an excellent evaluation. After 8 months, a follow-up evaluation demonstrate very positive **results:** 48% of the students had implemented the final work as a project and 30% had applied part of the final work at the local level; Health Promotion interventions increased in 92% and 22% improved local work conditions.

Conclusions: With these results, it is possible to formulate an on-line model to apply in Health Promotion for Primary Health Care, utilizing Information and Communication Technologies.

Key words: Health Promotion, Primary Health Care, Communication and education.

PO1419

A MALAYSIAN RURAL STORY OF WHOLE GRAIN CONSUMPTION AND ITS EFFECTS ON WEIGHT AND BLOOD PRESSURE

N. Karim¹, TY. Pang¹

¹Nutritional Sciences Programme, School of Health-care Sciences, Universiti Kebangsaan Malaysia, Jalan Raja Muda Abdul Aziz, 50300 Kuala Lumpur, Malaysia.

Background and objectives: The prevalence of obesity and hypertension have shown an increase in Malaysia, even in the rural community. However data on whole grain consumption of Malaysians are still scarce, even it is well recognized that whole grain intake can reduce risk of hypertension and obesity. This study was carried out to evaluate the whole grain consumption and determine its association with body weight and blood pressure.

Methods: 117 subjects of Malay and Chinese ethnicity, consisting of equal number of men and women between 20 to 59 years old participated in this study. Anthropometric measurements such as body mass index, body fat percent and waist circumference were evaluated. Blood pressure was also measured. Whole grain consumption was determined using food frequency questionnaire and 2-days 24 hour recall.

Results: Mean whole grain intake of the subjects was 12.3g per day, and only 5% of the subjects achieved the Malaysian Dietary Recommendation for whole grain intake. Whole grains consumed by this community included wholegrain bread (27%), brown rice (23%) and oats (18%). Whole grain intake was significantly higher among women and the high income subjects. Majority of the subjects irrespective of sex and ethnicity were overweight or obese, had central obesity and high percent body fat as well as high blood pressure.

Conclusions: Although no significant correlation was found between whole grain consumption and body weight and blood pressure in this rural community, the intake of whole grains should be encouraged and promoted. A variety of interventions and efforts are necessary to educate Malaysians on whole grains and its benefits to health.

Key words: whole grain consumption, rural community, obesity, blood pressure, Malaysia.

PO1420**NUTRITION EDUCATION IN GERMAN AND AUSTRIAN KINDERGARTENS – QUALITATIVE SURVEY OF KINDERGARTEN TEACHERS**

P. Rust¹, E. Höld¹, B. Freytag-Leyer², V. Bauer²

¹Department of Nutritional Sciences, University of Vienna, Vienna, Austria

²Department of Nutritional, Food and Consumer Sciences, University of Applied Sciences Fulda, Fulda, Germany

Background and objectives: Early childhood nutrition is a major determinant of later health, especially for non-communicable diseases. Additionally, it influences nutrition habits and nutrition competences in adulthood. This underlines the importance of early childhood nutrition education in the kindergarten as the first institutional education place. To ensure good nutrition education skills kindergarten teachers must be trained appropriately or nutrition professionals assume responsible for nutrition education in kindergarten.

Methods: Within the framework of the Lifelong-Learning-project NUTGECS (A Nutrition Guide for Early Childhood Active Stakeholders) 27 qualitative interviews with kindergarten teachers concerning nutrition education were conducted in Vienna (Austria) and Fulda (Germany). These interviews were analysed by MAXQDA according to Mayring [2010].

Results: In both countries kindergarten teachers are aware about the importance of healthy nutrition as well as of early nutrition education and parents' participation in this process. Nutrition education is part of daily routine e.g. teachers communicate children nutrition information during consuming their meals. All participating kindergartens are lacking of money and time as well as scientific support and trained staff for good and sustainable nutrition education. Even though, in both countries a variety of good materials exists, these materials are mostly unknown to the pedagogues. These results are reflected in the kindergarten teachers' wishes concerning nutrition education: they want more nutrition training and information for themselves as well as they wish more expert-guests in kindergarten.

Conclusions: Austria and Germany faces similar challenges according to nutrition education in kindergarten. Especially limited resources seem to be a problem. Therefore, interested kindergarten teachers should be encouraged and supported in nutrition education through experts and scientific developed materials like the Nutrition Guide for Early Childhood Active Stakeholders (free download www.nutgecs.eu) in practical and theoretical aspects.

Key words: kindergarten teachers, nutrition education, qualitative interviews.

PO1421**COMMUNITY SOCIO-ECONOMIC STATUS INFLUENCES ON DIETARY INTAKE IN SOUTH AFRICAN ADOLESCENTS LIVING IN AN URBAN AREA**

R. Pradeilles¹, P. Griffiths^{1,2}, E. Rousham¹, S. Norris², A. Feeley²

¹Centre for Global Health and Human Development, SSEHS, Loughborough University, Loughborough, United Kingdom

²MRC/Wits Developmental Pathways for Health Research Unit, Department of Paediatrics, School of Clinical Medicine, The University of the Witwatersrand, Johannesburg, South Africa

Background and objectives: The influence of the community environment on adolescent dietary energy intakes has not yet been investigated in low- and middle-income countries (LMICs). This work investigates associations between community socio economic status (SES), gender, ethnicity and diet.

Methods: Analysis of data at 17-19 years from the 1990 born Johannesburg-Soweto Birth to Twenty (Bt20) cohort (n=489) were conducted. Descriptive statistics were performed on community indicators and dietary data (assessed using a locally developed Food Frequency Questionnaire). Associations between gender, ethnicity, community SES indices and dietary intake/food environment were examined using linear regression (diet) and logistic regression (food environment) whilst controlling for age, gender, ethnicity, and economic status. Ethnicity was self-identified as white, black, coloured, or South Asian. Community SES indices were created using principal components analysis applied to proxy indicators of the community environment.

Results: The mean energy intake was 4894 kcal/day for boys and 4212 kcal/day for girls (p=0.002). There was a significant relationship between gender and protein intake (142.4 g for boys vs. 122.5 g for girls, p=0.015), carbohydrates intake (611.9 g vs. 509.4g, p=0.004) and sugar intake (125.9g vs 103g, p=0.041). The association between ethnicity and protein intake was also significant (+57.2g/day for blacks vs. South Asians; p=0.048). Significant associations were shown between ethnicity and distance to fast food (p<0.01) and distance to restaurants (p<0.01). Black and coloured adolescents were less likely to be in proximity to fast food outlets compared to whites (OR=0.3 [0.1-0.5] and OR=0.4 [0.2-0.7] respectively). The same tendency was found for the distance to restaurants.

Conclusions: Factors such as gender and ethnicity seem to have a greater influence on dietary intake than environmental and SES factors at the community level. The conference presentation will also link these associations with risk for obesity.

Key words: Diet, economic status, neighbourhood, adolescents, obesity.

PO1422

THE GEOGRAPHIC CLUSTERING OF DISTRICTS ACCORDING TO PREVALENCE OF UNDERWEIGHT AMONG UNDER FIVE YEAR CHILDREN IN MADHYA PRADESH, INDIA

K. Venkaiah¹, G. Manohar Reddy¹, Il. Meshram², K. Mallikharjuna Rao², C. Galreddy², S. Kumar², M. Ravindranath², A. Axmaiah²

¹Division of Biostatistics, National Institute of Nutrition, ICMR, India

²Division of Community Studies, National Institute of Nutrition, ICMR, Hyderabad, India

Background and objectives: The type and magnitude of undernutrition may vary from district to district depending on the geographical and agro-climatic conditions and therefore, warrant region specific interventions. The objective of the present communication is to identify the geographical areas with a special reference to level of underweight and factors contributing to the same. For the purpose, cluster analysis was carried out to identify the clustering of districts with varying degree of underweight.

Methods: Information collected on children regarding age, gender, weight and corresponding WHO reference weights were utilized. Exploratory cluster analysis was carried out to identify cluster of districts with the same extent of underweight. Background characteristics of the households and the prevalence of underweight were compared between the clusters.

Results: A total of 22, 907 under 5year children (Boys: 12, 387) covered from 1000 villages in 50 districts of Madhya Pradesh. The prevalence of underweight was 52% (35%-67%). The prevalence of stunting was 49% (15.2%-66.7%), while wasting was 26% (15%-40.2%). The prevalence of underweight, stunting and wasting was significantly ($p < 0.01$) higher among districts of Cluster 1 (60.8%, 57.5% and 29.9% respectively) as compared to the districts belong to cluster 3 (40.9%, 40.6% and 22%). Where the group of districts categorized as low prevalent, the mother and child care and infant and young child feeding practices were also low.

Conclusions: The cluster analysis identified the districts into 3 groups based on the extent of prevalence of underweight, which were, low, medium and high prevalent. This analysis would be useful for the administrators to utilize their limited resources in the priority cluster districts.

Key words: underweight, stunting, districts, Madhya Pradesh, Geographic-clustering.

THE NUTRITION TRANSITION IN NEW GUNIEA HIGHLANDERS

K. Matsumoto¹, P. Watofa², G. Daimboa², K. Suastika³, E. Garcia del Saz⁴, A. Yoneda¹, H. Seguchi¹, H. Taniguchi¹, N. Kajiwara¹.

¹Department of Health, Sports and Nutrition, Kobe Women's University,

²School of Medicine, Cenderawasih University, Papua, Indonesia

³School of Medicine, Udayana University, Bali, Indonesia

⁴International and Inter-regional Association Center, Kochi University

Background and objectives: The highland inhabitants of New Guinea island are known to be healthy and active, although they have traditionally subsisted mainly on potatoes. In a previous nutritional survey conducted during 1978–1980 in the Eastern Highlands of Papua New Guinea, the dietary proportions of protein (P), fat (F) and carbohydrate (C) were 4.0%, 4.0% and 92.0% respectively (Kajiwara et al, 1982). A cross-sectional survey of the nutritional and health status of the highland population in Papua, Indonesia was conducted among villagers who migrated from rural to urban areas (rural—urban migrants).

Methods: Studies were conducted in rural and urban villages in Papua province, Indonesia, during 2007–2010. The study comprised 454 males and 382 females who were aged 18–60 years. The anthropometric measurements, including weight, height, and waist circumference, were collected according to a standard protocol. A 24-h recall test was performed to estimate the total energy intake and the energy ratio of nutrients.

Results: The estimated nutrient intake determined by the 24-h recall test showed that the non-migrant (rural) group showed similar tendency to a previous study in 1981, i.e., P = 5%, F = 6% and C = 89%. The rural—urban migrant group had a better dietary composition than the rural group, i.e., P = 12%, F = 11% and C = 77%. However, the anthropometry measurement results showed that 34.7% of males and 50.0% of females in the rural—urban migrant group were categorized as 'overweight' based on WHO criteria, whereas among their rural counterparts only 3.1% of males and 11.0% of females were overweight.

Conclusions: The results showed that a drastic change in diet affected their obesity rate among rural—urban migrants. A detailed analysis may be required to prevent future health risks among the highlanders.

Key words: New Guinea highlanders, nutrition survey, rural urban migrant

PO1424

UNDERSTANDING AND USE OF THE GUIDELINE DAILY AMOUNTS (GDA) LABEL AMONG ETHNIC GERMAN RESETTLERS

*N. Betke*¹

¹Department of Food Economics and Consumption Studies, University of Kiel, Germany

Background and objectives: The GDA label is a voluntarily nutritional labelling with the aim of empowering consumer to compose a balanced diet. Ethnic German resettlers, one of the largest migration groups in Germany with some nutritional problems, were so far neglected in research concerning GDA label. Consequently this study examines whether ethnic German resettlers understand and use the GDA label. The aim is to show which circumstances have influence on understanding and use and how they are linked.

Methods: Case studies with 10 ethnic German resettlers (age: 30-44 years; duration of stay in Germany: 8-17 years) were carried out by problem centered interviews according to Witzel. Understanding and use were tested in an experiment. Evaluation was carried out by using the qualitative summarizing content analysis according to Mayring and the software MAXQDA.

Results: Incomplete understanding and inadequate use of the GDA label is observed due to different reasons: On the one hand, it is the excessive demand with the sudden multifaceted range of food products in Germany and the complicated design of the GDA label and otherwise the resettlers' attitude which prevent them from understanding and use. The issue nutrition and health do not rate high in their life and lack of knowledge about nutrition and prevention because of little motivation and interest to acquire the knowledge about the inter-relationships between nutrition and health is observed. Limited need to change one's own behaviour is a result of allowing them to keep their habits.

Conclusions: Under consideration of the ethnic German resettlers' migration background, target group specific strategies have to be developed to enhance understanding and use. This involves both a substantial revision of the GDA label and a targeted nutrition communication where decision-making skills can be conveyed for understanding and use.

Key words: Ethnic German resettlers, GDA, case studies.

PO1426

ADDRESSING ACUTE AND CHRONIC MALNUTRITION IN ETHIOPIA: CHALLENGES TO FINDING THE POLICY BALANCE

*D. Ali*¹, *Y. Amare*², *P. Menon*¹

¹International Food Policy Research Institute, Washington DC, USA

²Consultancy for Social Development, Addis Ababa, Ethiopia

Background and objectives: The persistently high prevalence of wasting and stunting in Ethiopia is a major public health concern. Baseline interviews with stakeholders in 2010 showed that, donors, policy makers and implementers have been inclined to address wasting through recuperative approaches often ignoring stunting. Alive & Thrive focuses on infant and young child feeding (IYCF) to reduce stunting and engages in advocacy with various stakeholders. This study aims to understand whether the advocacy activities had led to any shifts in perceptions of stakeholders about wasting and stunting and the actions that were being taken to address these problems.

Methods: In-depth interviews using semi-structured guides were conducted with key policy stakeholders, including donors, implementing agencies, and the government. Transcribed interviews were analyzed using NVivo software.

Results: In 2012, interviewees emphasized on tackling both wasting and stunting and reported a shift in current strategy with an increased focus on stunting in recent years. However, greater resources for fighting wasting led to more programs focused on wasting. Implementers noted that treating wasting has an immediate visible effect, yet were frustrated by high rates of relapse. Majority stakeholders had a broad understanding about the need to reduce stunting given its long term implications. Food insecurity, lack of food-based interventions, poor promotion of complementary feeding, and lack of women's access to cash remained as challenges. Concerned sectors such as agricultural, women's affairs, and education were not involved in addressing nutrition.

Conclusions: Interviewees perceived a shift in policy to include both stunting and wasting. The relative simplicity of addressing wasting tilts the program activities towards wasting. Continued advocacy needed to ensure that stunting is kept high on agenda in a food insecure context like Ethiopia. Funded by the Bill & Melinda Gates Foundation, through Alive & Thrive, managed by FHI 360.

Key words: Ethiopia, stunting, policy.

PO1427**HOUSEHOLD FOOD INSECURITY IS ASSOCIATED WITH CHILD UNDERNUTRITION IN BANGLADESH, ETHIOPIA AND VIETNAM**

D. Ali¹, K. Saha¹, P. Nguyen¹, M. Diressie¹, M. Ruel¹, P. Menon¹, R. Rawat¹

¹International Food Policy Research Institute, Washington DC, USA

Background and objectives: Household food insecurity (HFI) is a potential determinant of child undernutrition in developing countries, but findings to date have been inconsistent. The association between HFI and child undernutrition was investigated in children 6-59 months of age in Bangladesh (BD), Ethiopia (ET) and Vietnam (VN) using baseline survey data collected as part of impact evaluation of the Alive & Thrive initiative (N= 2, 356, 3, 422, 3, 075 in BD, ET and VN, respectively).

Methods: Logistic regression models, adjusting for potential confounding factors, were used to determine the magnitude and significance of the association between HFI and child stunting, underweight and wasting.

Results: The prevalence of HFI was 66%, 40% and 32% in ET, VN and BD, respectively. The prevalence of stunting, underweight and wasting was higher in BD (47.1%, 43.7% and 19.1%, respectively) and ET (50.7%, 27.5% and 5.9 %, respectively) than in VN (20.7%, 15.8% and 5%). The odds of being stunted or underweight were significantly higher for children in severely food-insecure households in BD (stunting OR=1.88, 95% CI=1.47, 2.40; underweight OR=1.55, 95% CI=1.21, 1.97) and ET (stunting OR=1.39, 95% CI=1.01, 1.93; underweight OR=1.59, 95% CI=1.13, 2.24) and for children in moderately food-insecure households in VN (stunting OR=1.46, 95% CI=1.22, 1.75; underweight OR=1.66, 95% CI=1.22, 2.26) compared to children in food secure households. HFI was significantly associated with wasting only in BD where the prevalence was significantly higher than in ET and VN.

Conclusions: These results show that HFI is strongly associated with stunting and underweight in these geographically varied countries. Programs to improve HFI with other nutrition interventions may enable greater synergy and sustainable impacts in addressing childhood undernutrition than just nutrition interventions.

Key words: Food insecurity, undernutrition, Bangladesh, Ethiopia, Vietnam Funded by the Bill & Melinda Gates Foundation, through Alive & Thrive, managed by FHI 360.

PO1428**IMPROVEMENT IN STUNTING IN A COHORT OF CHILDREN 2 YEARS OLD ENROLLED IN A HEALTH PROGRAM WITH LNS IN MALI**

S. Shepherd¹, M. Schaumfer², M. Goyheneix², Ch. Okonta¹, T. Roederer³

¹Operations Department, Medecins Sans Frontieres, Paris, France

²Medical Department, Medecins Sans Frontieres, Paris, France

³Epicentre, Medecins Sans Frontieres, Paris, France

Background and objectives: Mali exhibits high rates of child mortality and malnutrition. In 2010 Médecins Sans Frontières, with the local health authorities, started offering comprehensive care to all children under the age of 2 years living in the sub-district of Kons'gu'la (pop.33.000), Koutiala district in southern Mali. Stunting prevalence (height-for-age Z score <-2) in the district and sub-district were 55.8% and 54.1%, respectively, among children 2 to 5 years of age in March 2010 when the project was initiated. The health package includes routine vaccination, distribution of mosquito nets, nutritional supplementation (250 Kcal/day lipid-based nutrient supplement from 6 to 24 months of age), early diagnosis and treatment of malaria, basic medical care and nutritional rehabilitation when needed. We report on HAZ and vaccine coverage for a cohort of 2 year old children who were enrolled in the program for at least 18 months.

Methods: Prospective descriptive cohort study

Results: As of July 31 2012, 1060 children aged 20-24 m had completed the program. The prevalence of HAZ <-2 for this group was 33, 9 % (mean \bar{C} 1, 59 Z). Comparatively, pooled data from 3 transversal surveys done for the rest of the district from 2010 to 2012 for the same age category show a prevalence of 52, 2 % (mean \bar{C} 2, 09) (p <0.0001). Since 2010, vaccine coverage for Pentavalent 3 among children <2 y in Kons'gu'la has increased to 84.1% from 47.8% and has remained at 50% for the rest of the district (P <0.001).

Conclusions: Provision of a comprehensive paediatric health services has resulted in an improvement of 0, 5 in HAZ and a 75 % increase in vaccine coverage over two years. Feasibility of scaling up similar interventions needs to be pursued.

Key words: stunting, chronic malnutrition, LNS.

PO1429**INCREASED HEIGHT AND COGNITION AFTER CONSUMPTION OF FORTIFIED MILK***I. Angeles-Agdeppa¹, C. Magsadia¹*¹Department of Science and Technology, Food and Nutrition Research Institute, Philippines

Background and objectives: The 2011 National Nutrition Survey data revealed that the prevalence of underweight among school-aged children is 32 % while under-height is 33.6 %. Supplementary feeding is a short-term intervention that involves the provision of food to vulnerable and at-risk groups. Milk drinking is unpopular in the Philippines. Mean one-day milk consumption of 6-12 years old children consisted of 15 grams of whole milk. Objective: This study determined the effects of consuming fortified milk on the nutritional status and cognition of schoolchildren.

Methods: 141 anemic 6-year old were randomly allocated into: Group 1: one glass of milk; Group 2: two glasses of milk; Group 3; Water. The milk was fortified with iron, zinc, Vit. A & Vit. C. Feeding was for 120 days: Monday to Friday under supervised regimen in the school and Saturday to Sunday as take home allocation. Anthropometric; food intake and cognitive measurements were collected at different time periods.

Results: There was a significant increase ($P < 0.05$) in height in all groups, with 2 Glasses milk group having the highest increment (3.3 cm). Food intake and father's education were positively correlated to endline height and weight. The steady upward trends of slopes for all cognition domains (responsiveness, memory, comprehension, and tenacity) were associated with time with the milk groups consistent in having the higher slopes than the Water group. Macronutrients and mother's education were positively associated with responsiveness and focus.

Conclusions: Drinking 2 glasses of fortified milk might have increased height of schoolchildren. Increments in all cognition domains were observed in all groups but the milk groups have consistently showed higher slopes. The increases in weight, height and cognition in the Water group could be attributed to positive deviance or the ability of certain individuals to improve even on worse conditions.

Key words: height, cognition, fortified milk.

PO1430**CHRONOTYPE AND DIETARY HABITS IN JAPANESE UNIVERSITY STUDENTS***N. Komenami¹, E. Matsuoka¹, S. Watanabe¹, E. Masutani², T. Wakamura³*¹Department of Food and Nutrition, Kyoto Women's University, Kyoto, Japan²Cancer Education and Research Center, Graduate School of Medicine, Osaka University, Osaka, Japan³Human Health Sciences, Graduate School of medicine, Kyoto University, Kyoto, Japan

Background and objectives: A disruption of circadian rhythm in nocturnal has been linked lifestyle-related diseases such as diabetes and obesity. However, few studies have reported the relationship between chronotype (Morningness-Eveningness) and dietary habits. The purpose of this study was to investigate the relationship between Morningness-Eveningness and dietary habits in Japanese university students.

Methods: This cross-sectional study evaluated 563 university students (192 males, 371 females). Chronotype was evaluated using the Horne and Östberg Morningness-Eveningness Questionnaire (MEQ) and categorized into three types: morning-types (M-types), neither-types (N-types), and evening-types (E-types). Dietary intake was assessed by a food frequency questionnaire. Health and lifestyle were similarly investigated by questionnaire.

Results: Dietary habits, health, and lifestyle differed according to sex. A significant association was noted between MEQ score and intake of certain nutrients. E-type males had a significantly lower intake of protein, minerals (potassium, calcium, magnesium, iron, and zinc), vitamins (A, C, D, K, riboflavin, B6, B12, and folic acid), dietary fiber, cereals (rice and noodles), vegetables, seaweed, beans, fruit, and sugar than M-type males. E-type females had a significantly lower intake of vitamins (alpha-carotene, beta-carotene, K, and folic acid), vegetables, seaweed, beans, fruit, and sugar and with a high intake of sweet beverages and snacks than M-type females. E-type skipped breakfast more frequently than other types.

Conclusions: These results suggest that evening-type students do not maintain a healthy lifestyle and have poor dietary habits such as low intake of protein, vitamins, and minerals. Taken together, it might be beneficial to assess and consider chronotype in educational settings to improve the unhealthy living attitudes and poor dietary habits of students.

Key words: Morningness-Eveningness questionnaire, food frequency questionnaire, skipping breakfast, circadian rhythm, nutrient intake.

PO1431**COMPARISON OF PREVALENCE OF OBESITY, DIABETES AND SMOKING IN CHILEAN WOMEN OF CHILDBEARING AGE BETWEEN 2003 AND 2009***M. Araya Bannout*¹¹Instituto de Nutrición y Tecnología de los Alimentos, Santiago de Chile, Chile

Background and objectives: health status of women of childbearing age (WCBA) before pregnancy is critical for newborn health in the long term. Objective: Analyzing whether there are changes in the prevalence of obesity, diabetes and smoking in WCBA in Chile during 2003 and 2009.

Methods: Cross-sectional study using information sources national health surveys databases (ENS2003- ENS2009). The study population included WCBA -17 through 45- in the country during 2003 and 2009. Sample: The samples were 827 in 2003 and 1507 in 2009. The following variables were compared: obesity (BMI>30), excess weight (BMI>25) overweight (BMI 25-29, 9), abdominal obesity (waist>88), morbid obesity (BMI>40), smoking (actual or occasional) and diabetes (glucose>126mg/dl or self-reported diagnosis). Statistics: Complex samples modul statistical programs SPSS were used. The prevalences of diseases were expressed as numbers of cases and percentage with confidence intervals (95%) and compared through OR; continuous variables (weight, BMI, blood glucose, waist circumference) compared through Wald F and the result was expressed as mean and standard deviation.

Results: Between 2003 and 2009 WCBA obesity increased from 21% in the year 2003 to 23, 6 % in the year 2009 (p>0, 05), excess weight raised from 51.3% to 55.6% (p>0, 05), overweight from 30, 8% to 32, 1% (p>0, 05), and abdominal obesity increased 33, 3 to 35, 7 (p>0, 05). Diabetes increased from 2, 2 to 3, 6% (P>0, 05). Morbid obesity remained in 2% and tobacco in approximately 45%. Between 2003 and 2009 increased averages weight, waist circumference and BMI, but not significantly. Prevalences and means were adjusted for education and socioeconomic status; only found a significant increase in waist circumference in 2009 compared to 2003.

Conclusions: The prevalence of obesity exceeds 20% and excess weight 50% in WCBA in both years. It's important to invest in projects to reduce excess weight in WCBA.

Key Words: obesity, diabetes, women, childbearing Acknowledgements: Chilean health ministry by providing databases ENS2003-ENS2009

PO1432**PARASITE INFESTATION AND ANTHROPOMETRIC STATUS IN CAMBODIAN SCHOOL CHILDREN.***M. Fiorentino*¹, *M. Perignon*¹, *K. Kuong*², *C. Chamnan*², *M. Parker*³, *K. Burja*⁴, *J. Berger*¹, *F T. Wieringa*¹¹Institut de Recherche pour le Developpement, Montpellier, France²Dept of Fisheries Post-harvest Technologies and Quality control (DFPTQ), Phnom Penh, Cambodia³Program for Appropriate Technology in Health, Seattle, United State⁴World Food Program, Phnom Penh, Cambodia

Background and objectives: Although nutritional status in South-East Asia has improved over the last decade, the situation in Cambodia is still worrisome with >50% of preschool children being anemic. National data reported a consistent 40% of stunting among children <5yrs in 2005 and 2010. Data on nutritional status in schoolchildren in Cambodia is scarce. Through the Fortified Rice for Cambodian SchoolChildren (FORISCA) project, nutritional status and intestinal parasite infection in children attending primary schools was assessed.

Methods: Data on school children, aged 5-15 yrs (n=2229), from 20 schools on anthropometric and micronutrient status were collected. Parasite eggs in feces were counted using Kato-Katz method.

Results: Overall prevalence of stunting and thinness was 43% and 27% respectively. No overweight was found. Stunting prevalence in children >10 yrs was higher than in younger children (57% and 43% respectively, p<0.001). Parasite infestation was found in 18% of the children (mainly hookworm infection of light intensity). Anemia prevalence was 15% with only 3 children having severe anemia. Parasite infestation and anemia was significantly higher among children attending schools taking part in the WFP SchoolMeal program (SMP) than among children from control schools (p<0.01 for both). Hemoglobin concentrations were significantly lower, and prevalence of anemia was higher, in children with intestinal parasites (p<0.01 and p=0.05 respectively). HAZ tended to be lower in anemic children (p<0.10), with stunted children being more at risk for anemia.

Conclusions: Parasite infestation is an important risk factor for anemia in Cambodian schoolchildren. Persistent poor nutritional status within schools selected for WFP SMP warrants improvement in the nutritional quality of school meals. Progressive higher prevalence of stunting with age without evidence from national data for improvements in anthropometric status in children <5yrs suggests that growth faltering continues after 5 yrs of age in schoolchildren.

Key words: children, anthropometry, parasite infection.

PO1433**MEDITERRANEAN ALCOHOL-DRINKING PATTERN AND THE RISK OF CARDIOVASCULAR MORTALITY: THE SUN PROJECT**

A. Gea^{1,2}, J.J. Beunza³, E. Toledo^{1,2}, M. Bes-Rastrollo^{1,2}, R. Estruch^{2,4}, M. García-López^{1,5}, M.A. Martínez-González^{1,2}

¹Department of Preventive Medicine & Public Health, University of Navarra, Spain

³Preventive Medicine, Universidad Europea de Madrid

⁴Department of Internal Medicine, Institut d'Investigacions Biomediques August Pi Sunyer (IDIBAPS), Hospital Clinic, University of Barcelona, Spain

⁵Department of Cardiology, Clínica University of Navarra

Background and objectives: Moderate alcohol intake has been associated with lower rates of cardiovascular mortality. However, alcohol drinking involves more than only the quantity consumed. A specific pattern of alcohol consumption is the pattern observed in Mediterranean countries. We aimed to develop a score to assess the adherence to this Mediterranean Alcohol-Drinking Pattern (MADP) and test its relationship with cardiovascular mortality.

Methods: We included 18, 223 participants (mean age: 38 years; 39.5% men) from the SUN cohort. A baseline 136-item validated food frequency questionnaire was used to assess alcohol intake. Other aspects about alcohol drinking habits were also inquired at baseline. We developed an 8-point score accounting for moderate consumption (2-points), preference for wine (1-point), wine consumed with meals (1-point), avoidance of binge-drinking (1-point), non-concentrated consumption (2-points), and low consumption of spirits (1-point). Cox regression models were performed over 136, 361 person-years to ascertain the risk of cardiovascular mortality among categories of adherence to the MADP, and for a 2-point increment in the MADP. Causes of death were adjudicated, blinded to other participant's information, according to the International Classification of Diseases, 10th Revision.

Results: Participants with low adherence to the MADP (0-4 points) were at higher risk of cardiovascular mortality compared with participants with high adherence (5-8 points) [HR (95% CI): 2.41 (1.08-5.37)]. Abstainers seemed to also be at higher risk, however the association was not statistically significant [HR (95% CI): 2.39 (0.84-6.83)]. The 2-point increment in the MADP was associated with lower risk of cardiovascular mortality [HR (95% CI): 0.49 (0.31-0.79)].

Conclusions: Adherence to the Mediterranean Alcohol-Drinking Pattern was associated with lower rates of cardiovascular mortality compared with alcohol abstinence or departure from this drinking pattern.

Key words: Alcohol; Cardiovascular mortality; Mediterranean Alcohol Drinking Pattern. Funding sources: Spanish Government (PI1002658, PI1002293, RD06/0045, G03/140 and 87/2010), and the Navarra Regional Government (45/2011).

PO1434**LINKING NUTRITION, HUMAN RIGHTS AND GOVERNANCE FOR NUTRITION POLICY: COLLABORATIVE CAPACITY DEVELOPMENT IN UGANDA, SOUTH AFRICA AND NORWAY**

P M. Rukundo¹, J. Kikafunda², B. Rukooko³, A. Kaaya², M. Marais⁴, R. Blaauw⁴, W B. Eide⁵, B A. Andreassen⁶, P O. Iversen⁵, A. Oshaug⁷

¹Department of Human Nutrition and Home Economics, Kyambogo University, Kampala, Uganda

²School of Food Technology, Nutrition and Bio-Engineering, Makerere University, Kampala, Uganda

³School of Liberal and Performing Arts, Makerere University, Kampala, Uganda

⁴Division of Human Nutrition, Stellenbosch University, Cape Town, South Africa

⁵Department of Nutrition, Institute of Basic Medical Sciences, Faculty of Medicine, University of Oslo, Norway

⁶Norwegian Centre for Human Rights, Faculty of Law, University of Oslo

⁷Faculty of Health Sciences, Oslo and Akershus University College of Applied Sciences, Oslo, Norway

Background and objectives: Lack of democratic governance and respect for human rights contributes to persistent food insecurity and malnutrition in Africa, with limited attention to such aspects in forming tomorrow's leaders, educators and practitioners in food and nutrition policy. Capacity development in nutrition and related fields should include learning about norms, principles and practice of international, regional and national human rights' systems applied to programming towards freedom from hunger and enjoyment of the human right to adequate food for all.

Methods: An innovative model combining nutrition, human rights and governance was developed by academic institutions in Uganda, South Africa and Norway for two cohorts of nutrition master students registered at the respective institutions in 2011 and 2012. Financed by the Norwegian Go-

vernment, it included a four-month module shared between the three countries, on theory and practice linking nutrition to human rights and governance. Interactive learning involved human rights, nutrition policy and governance experts and actors, including civil society organizations, enabling students to explore the role of governance and human rights as both determinants and facilitators of food and nutrition security. Diversified field visits and study visits to relevant government institutions, national parliaments, human rights commissions and international agencies, offered rich opportunities to interact with policy actors and other stakeholders.

Results: The module has given the students a unique basis for research for their nutrition master theses with an explicit human rights and governance orientation. The three-way learning platform has potential for further collaboration between government institutions, academic staff and practitioners.

Conclusions: Experience from this model should stimulate other universities to form interdisciplinary partnerships and, where possible, similar international networks to strengthen capacity for dealing with food security and nutrition through a human rights-based approach to tertiary education in nutrition and related subjects.

Key words: Human rights, Governance, Nutrition Policy, Capacity Development.

EFFECTIVENESS OF OFFERING KEYHOLE LABELLED MEALS IN IMPROVING THE NUTRITIONAL QUALITY OF LUNCH MEALS EATEN IN WORKSITE CANTEENS

A D. Lassen¹, A M. Beck², E. Leedo², E W. Andersen³, T. Christensen¹, H. Mejborn¹, AV. Thorsen¹, I. Tetens¹

¹Division of Nutrition, National Food Institute, Technical University of Denmark, Copenhagen, Denmark

²EFFECT, Main Kitchen, Herlev University Hospital, Herlev, Denmark

³Department of Applied Mathematics and Computer Science, Technical University of Denmark, Denmark

Background and objectives: In February 2012 the Danish Veterinary and Food Administration introduced the keyhole symbol to the restaurant and foodservice sector in Denmark. The keyhole labelling identifies the healthier options when eating out. The objective of this study was to evaluate the effectiveness of offering healthy keyhole labelled meals in improving the nutritional quality of lunch meals eaten in a Danish worksite canteen.

Methods: A pre-post quasi-experimental study design was used to evaluate the introduction of keyhole labelled meals in an intervention worksite canteen compared to a control worksite canteen. At baseline and end-point (six weeks from baseline) employees from both canteens were randomly selected to participate in the study during three consecutive days (n=180). Furthermore, a follow-up measure was obtained six months after end-point (n=90). A validated digital photographic method was used to estimate total intake and nutrient composition of the consumed lunch meals.

Results: Several significant positive nutritional effects were observed among the employees in the intervention canteen including a mean decrease in lunch intake of fat from 40 E% to 21 E% and an increase in mean fruit and vegetable content from 35 g/100 g to 45 g/100g. Also, mean energy intake decreased significantly from 2.5 MJ to 1.8 MJ per lunch meal eaten. Preliminary results of the follow-up measure suggest that the nutritional improvements of the lunch meals were sustained in the intervention worksite canteen a half year after end-point.

Conclusions: The present study provided insight into the effectiveness of a keyhole labelling in canteens. The study demonstrated that positive changes were achieved in the dietary lunch intake among customers at a worksite canteen by increasing the availability of healthy meals labelled with the keyhole symbol.

Key words: Worksite intervention, nutrition labelling, health promotion, canteen, lunch.

PO1436

STUNTING AND ANEMIA ARE PREVALENT IN CAMBODIAN SCHOOL CHILDREN AND AFFECT COGNITIVE PERFORMANCE

M. Perignon¹, M. Fiorentino¹, K. Kuong², K. Burja³, ME. Parker⁴, C. Chamnan², J. Berger¹, FT. Wieringa¹

¹UMR Nutripass, Institut de Recherche pour le Développement (IRD), Montpellier, France

²Dept Fisheries Post-harvest Technologies and Quality Control, Fisheries Administration, Phnom Penh, Cambodia

³World Food Programme, Phnom Penh, Cambodia

⁴PATH, Seattle, United States

Background and objectives: Micronutrient deficiencies remain a critical public health problem among children in developing countries. In Cambodia, more than half of children 6-59 months old were anemic and 40% were stunted in 2010. Many studies have assessed the prevalence or adverse outcomes of nutritional deficiencies among children <5yrs, but data on the impact of such deficiencies in school children on e.g. cogni-

tive development are scarce. The FORISCA project evaluates the effect of introducing fortified rice through the WFP school meal program on micronutrient status, health, and cognition among Cambodian school children. The present study investigated childhood anemia and anthropometric status, and their relation to cognitive performance.

Methods: The study sample consisted school children aged 5-15 yrs (N=2508) from 20 primary schools in Kampong Speu Province (KSP), Cambodia. Hemoglobin (Hb) concentrations were determined using HemoCue301+ system. Cognitive performance was assessed using Raven's Colored Progressive Matrices and two standardized tests from the Wechsler Intelligence Scale for Children (WISC): block design and picture completion. Anthropometric indices were calculated using the WHO 2006 standards.

Results: Anemia prevalence was 15.1%, with no significant differences between boys and girls or age. Anemia prevalence varied between 5% and 30% across the schools. Children with a Hb<115 g/L had lower scores on the Raven Test and Block design test (P<0.05 for both). The prevalence of stunting (HAZ<-2) was 42.5%, including 12.9% severe stunting (HAZ<-3). Stunting was a significant risk factor for lower cognition performance in Raven test (p<0.01), picture completion (p<0.01) and block design up to 12yrs (p<0.05).

Conclusions: Low hemoglobin concentration and stunting were significant risk factors for lower cognitive performance. Interventions to improve the nutritional status of Cambodian school children are urgently needed.

Key words: Anemia, stunting, cognition, schoolchildren, Cambodia.

PO1437

HOW DOES A SHIFT TOWARDS A MORE SUSTAINABLE FOOD CONSUMPTION PATTERN AFFECT NUTRIENT INTAKE OF DUTCH CHILDREN?

E H M. Temme¹, E. Bakker¹, M C C. Brosens¹, J. Verkaik-Kloosterman¹, M C. Ocke¹, J M A. van Raaij¹

¹National Institute for Public Health and the Environment (RIVM), Bilthoven, The Netherlands

Background and objectives: Food has a considerable environmental impact. Diets with less meat and dairy reduce the environmental impact, but may give nutritional challenges, especially in children. This modelling study investigates the impact of sustainable diets with less or no meat and dairy products on nutrient intakes.

Methods: Energy and nutrient intake, and environmental impact was assessed for observed consumption patterns (reference scenario) and two replacement scenarios. In the replacement scenarios, 30% or 100% of the dairy and meat consump-

tions were randomly replaced by plant-derived foods with similar use. Data of the Dutch National Food Consumption Survey Young Children (2005-2006) were used for the reference scenario. Food composition data were taken from the Dutch Food Composition Table 2011. For the evaluation of environmental impact, published data on global warming potential and land occupation were used.

Results: Full replacement of meat and dairy foods by plant-derived foods resulted in substantial lower environmental impact when compared to the reference. Saturated fatty acids intake was 26% lower and fiber intake 29% higher. After 100% meat and dairy replacement by plant foods, mean intakes of calcium, zinc and vitamin B1 decreased with 5-13%, and of vitamin B12 with 49%, while intake of iron was 10% higher. Calcium intake was below recommendations in all scenarios. In girls aged 4-6 y, 100% meat and dairy replacement resulted in 15 and 20% of children with inadequate intakes for zinc and vitamin B1.

Conclusions: Replacement of meat and dairy by plant-derived foods is beneficial for the environment and for children's health by lowering saturated fatty acids intake and by increasing the fibre contents of the child's diet. Alertness is needed for adequacy of zinc and vitamin B1 intakes of young girls.

Key words: consumption, children, sustainability, health, nutrient intake.

PO1438

PREVALENCE OF DISORDERED EATING AMONG MALAYSIAN ADOLESCENTS AGED 12 TO 19 YEARS OLD

Y S. Chin¹, S. Kaartina¹, R. Fara Wahida¹, F C. Woon¹, A. Siti Nadiah¹, MS. Zalilah¹, MT. Mohd Nasir¹

¹Universiti Putra Malaysia

Background and objectives: Disordered eating is known to be a growing nutritional issue among adolescents, particularly girls. To date, there is no publicly available nationally representative evidence on this issue among Malaysian adolescent population. This study aims to determine the prevalence of disordered eating among Malaysian adolescents aged 12 to 19 years old.

Methods: Using the stratified multi-stage sampling, a total of 9748 adolescents (male: 43.2%; female: 56.8%) from 67 selected secondary schools in all states of Malaysia participated in this study. Adolescents were required to fill in their socio-demographic characteristics and the Eating Attitudes Test-26 (EAT-26) that assessed disordered eating.

Results: The overall prevalence of disordered eating of the Malaysian adolescents was 30.7%. The prevalence of disorde-

red eating was higher among males (33.4%; 95% CI: 32.5, 34.3) than females (28.7%; 95% CI: 27.8, 29.6) at $\chi^2 = 25.033$, $p < 0.001$. About one-third of the adolescents aged 12 to 14 years old (34.9%; 95% CI: 34.0, 35.9) were having disordered eating, followed by 24.1% of adolescents aged 15 to 17 (95% CI: 23.3, 25.0) and 19.5% of adolescents aged 18 to 19 years old (95% CI: 18.7, 20.3; $\chi^2 = 130.289$, $p < 0.001$). The prevalence of disordered eating was higher among adolescents lived in rural area (32.7%; 95% CI: 31.8, 33.6) than adolescents who lived in urban area (29.2%; 95% CI: 28.3, 30.1) at $\chi^2 = 13.929$, $p < 0.001$.

Conclusions: The findings found that a high prevalence of disordered eating among Malaysian adolescents, particularly adolescents who were males, at younger age group and lived in rural area. Further studies are needed to determine factors associated with disordered eating in Malaysian adolescents.

Key words: Disordered eating, adolescents, Malaysia, eating disorders, secondary schools.

PO1440

RELATIONSHIP BETWEEN HABITUAL GRAINS CONSUMPTION AND THE PRESENCE OF NON-ALCOHOLIC FATTY LIVER DISEASE (NAFLD)

M. Kontogianni¹, N. Tileli¹, M. Georgoulis¹, A. Margarithi², E. Fragopoulou¹, M. Deutsch², D. Tiniakos³, R. Zafiropoulou², Y. Manios¹, G. Papatheodoridis²

¹Department of Nutrition & Dietetics, Harokopio University, Greece

²2nd Department of Internal Medicine, Medical School, National Kapodistrian University of Athens, Greece

³Laboratory of Histology & Embryology, Medical School, National Kapodistrian University of Athens, Greece

Background and objectives: Long term dietary habits have been suggested to contribute to the development of NAFLD. The aim of this study was to investigate associations between habitual food groups' consumption and the presence of NAFLD in a case-control study.

Methods: Fifty-eight NAFLD patients (inclusion criteria: steatosis on liver ultrasound and/or biopsy, elevated ALT and/or GGT, exclusion of other causes of liver injury) and 58 controls, adjusted for age, sex and BMI participated in the study. Food groups' consumption was estimated through a semi-quantitative food frequency questionnaire, while daily energy intake was estimated through three non-consecutive 24hour dietary recalls. Medical history, anthropometric indices, body composition analysis, physical activity data, biochemical parameters and inflammatory markers were available for all participants.

Results: Among all the food groups only grains (62.2±31.9 vs. 49.2±23.6 servings/ week, $p=0.028$) and refined grains (55.4±32.1 vs. 40.8±23.3 servings/ week, $p=0.022$) differed significantly between patients and controls. Consumption of grains was associated with higher likelihood of having NAFLD (OR=1.021, 95%CI=1.001-1.041, $p=0.045$), after adjusting for age, sex, daily energy intake, visceral fat, insulin resistance and LDL levels. A similar trend was also observed for refined grains' intake ($p=0.1$). Those with weekly grains' intake > 61 servings/ week had 4.2 higher odds of having NAFLD ($p=0.034$), compared to those with lower intakes.

Conclusions: Among several food groups higher grains' intake was associated with higher likelihood of having NAFLD, after controlling for several potential confounders.

Key words: non-alcoholic fatty liver disease, dietary habits, grains, case-control

PO1441

CLASSROOM TRAINING OF SCHOOLCHILDREN IN OBESITY PREVENTION: IMPLEMENTATION AND MONITORING OF THE PESOEH PROJECT

M. Galván¹, V. Granados², R. Balderrama³, I. Gerardo¹, A. Nájera¹, G. López-Rodriguez¹, T. Fernández-Cortés¹, A. Atilán¹

¹Institute of Health Sciences, Universidad Autónoma del Estado de Hidalgo, Mexico

²Ministry of Public Education of Hidalgo, Mexico

³System for the Integral Development of the Family of Hidalgo, Mexico

Background and objectives: It has been suggested that school-based interventions to prevent obesity may be more effective if introduced as part of the educational system. Our objective was to include in the 2011 curriculum of primary school children contents related to improvement of dietary and physical activity practices of school children from Hidalgo, Mexico (PESOEH project).

Methods: Childhood obesity was included as crosscutting topics of social relevance in official 2011 curriculum. Blocks and topics on healthy foods and physical activity were included in the curriculum. We applied methodology of training projects (TPs) based on the socio-educational model. The TPs were planned by a multidisciplinary group and learning activities by teachers ($n = 33$). The tracking of TPs was performed by observation in the classroom and interviewing teachers by trained professionals.

Results: We performed 5 TPs of healthy food and physical activity. The TPs were implemented (2012-2013) in two public and one private schools (800 students). During the first visit (1st) we found that 60% of teachers implemented the TPs and

the second (2nd) 70%. In 87% (1st) and 95% (2nd) the teaching situations were addressed as programmed; 96% (1st) and 88% (2nd) of the teachers used suggested materials. In 88% (1st) and 91% (2nd) didactic materials were visible in the classroom (posters, collages, drawings, etc.). In general, students showed interest, involvement and concentration; 48% (1st) and 52% (2nd) of the teachers indicated that TPs are relevant to the curriculum, and 28% (1st) and 69% (2nd) that impact on adoption of healthy lifestyle.

Conclusions: Teachers and students have accepted the TPs gradually, perceiving that the TPs are processes of teaching and learning differently. For teachers it has been useful to complete the content of the curriculum and address the consequences of a poor diet in schoolchildren.

Key words: childhood obesity, prevention, curriculum.

PO1442

COST ANALYSIS FOR INTEGRATED MANAGEMENT OF ACUTE MALNUTRITION IN UGANDA: CASE STUDY FOR PAJULE HEALTH CENTER IV PADER DISTRICT

R. Muhumuza¹, A. kasujja²

¹Diet Clinic Limited, India

²Department of Health Policy and Management, Kampala International Health Sciences University, India

Background and objectives: The Government of the Republic of Uganda is in the process of implementing integrated management of malnutrition. However, poor knowledge about costs of nutrition care services is perceived as a one of major obstacle towards effective and efficient nutrition service. The objectives for the study were: To establish cost of managing malnutrition in the different service points; To compare the cost of malnutrition services in the different cost centers for 2011 and To compare the cost of conventional approach to that of IMAM.

Methods: The study was exploratory in nature and covered financial year 2010– 2011. Data was collected through review of hospital record review and interviews using Questioners and extraction forms. Cost centres were identified according to the functional structure of the Nutrition unit and availability of reliable data.

Results: The study revealed that it costs \$ 241 per child averagely, however it was much more costly to manage a child from Inpatient Therapeutic Care (ITC) compared to \$ 78.8 of OTC for forty-eight days. The cost for managing a malnourished child with Vitamin A deficiency (VAD) was slightly higher (\$162.5) regardless of child's age than when the child is not having VAD. Majority, 42.2% of the children had no VAD but

had infections, and did not improve with in forty-eight hours. Averagely, the patients spent about half of the required ninety days on the program.

Conclusions: Feeds constitute the largest cost proportion, followed by personnel, laboratory, sundries, drugs and anthropometric equipment. The cost of management also varies widely from ITC to OTC but is generally highest in ITC regardless of the shorter length of stay compared to OTC. In addition, the cost in ITC could even be much higher depending on the presentation of the child's disease severity.

Key words: Average length of stay, Utilization.

PO1443

ALCOHOLIC BEVERAGE PREFERENCE AND DIET IN THE NETHERLANDS

D. Sluik¹, L. van Lee¹, A. Geelen¹, E. Feskens¹

¹Section Epidemiology & Public Health, Division of Human Nutrition, Wageningen University, the Netherlands

Background and objectives: The habitual consumption of a specific type of alcoholic beverage may be related to the overall dietary pattern. This cross-sectional study investigated associations between alcoholic beverage preference and diet in the Netherlands.

Methods: 2, 100 men and women from the Dutch National Food Consumption Survey 2007 – 2010 were studied. A general questionnaire assessed alcoholic beverage preference and two non-consecutive 24-hour dietary recalls assessed overall diet. Across categories of alcoholic beverage preference, mean nutrient and food group intakes, adherence to meal patterns and the Dutch Healthy Diet-Index, a measure of adherence to the 2006 Dutch Guidelines for a Healthy Diet, were calculated using generalized linear models. Adjustments were made for age, sex, education, smoking status, physical activity, energy intake, absolute alcohol consumption, and frequency of alcohol consumption.

Results: Although the majority of the population had no specific beverage preference (28%) or were non-consumers (30%), most contrasts were detected between persons who preferred wine (20%) and those who preferred beer (18%). Persons who preferred beer had higher absolute intakes of macro- and micronutrients, but also higher intakes of meat, margarine, deep frying fats, and snacks. Moreover, they displayed unhealthier meal patterns. Those who preferred wine had higher absolute intakes of vegetables, fruit, yogurt, and tea and adhered most to the Dutch Guidelines for a Healthy Diet.

Conclusions: Alcoholic beverage preference was associated with specific dietary habits in the Netherlands. As in other Northern-European countries, it was seen that persons with a

beer preference displayed less healthy dietary behaviour, especially compared to those who preferred wine.

Key words: Alcohol consumption, alcoholic beverage preference, dietary patterns, diet quality, Netherlands.

PO1444

WHAT AILS MICRONUTRIENT INTERVENTION PROGRAMMES IN KENYA?

A. Makokha¹

¹Jomo Kenyatta University of Agriculture and Technology, Kenya

Background and objectives: Recent national nutrition surveys in Kenya indicate a worrying trend of stagnation or even deterioration in some of the key malnutrition indicators, particularly for micronutrients. This situation prevails despite the existence of nutrition intervention programmes to alleviate these conditions. The objective of this paper is to discuss some of the factors that contribute to this situation.

Methods: Secondary data was obtained from the recent Kenya Demographic and Health Surveys, and a survey of health facilities in Nairobi, the Kenyan capital in a cross sectional descriptive study.

Results: The aspect of effective monitoring and evaluation stands out as particularly weak in many of the national micronutrient intervention programmes. Routine record keeping of the activities in some of the programmes appears to be a problem. In the integrated programmes the staff involved in the implementation of most of the programmes are often not nutritionists, and are thus unable to offer the services appropriately. There also appears to be very limited adequate involvement of the recipients of the services in planning and implementation of the programmes.

Conclusions: Among the key factors adversely affecting the micronutrient intervention programmes in Kenya include limited monitoring and evaluation, lack of staff, and lack of involvement of the recipients of the services. There is need to strengthen effective monitoring and evaluation of such programmes with a view to enhancing the delivery of the desired services and improving nutrition and health outcomes of the target populations.

Key words: Micronutrients, Monitoring, Evaluation, Interventions.

PO1445

FOOD ENVIRONMENT CHARACTERISTICS AND HEALTH IMPLICATION AMONG CHINESE ADULTS

W.W. Du¹, C. Su¹, H.J. Wang¹, Z.H. Wang¹, J.G. Zhang¹, J. Zhang¹, B. Zhang¹

¹National Institute of Nutrition and Food Safety, China CDC

Background and objectives: Obesity has been considered as a socioeconomic problem in worldwide. This study used data from wave2011 of a cohort study (China Health and Nutrition Study) to examine the possible risk factors of food environment characteristics to obesity among Chinese adults aged 18 to 65 years old at community level.

Methods: Local retail prices of 42 foods and beverages were obtained from supermarket and free market in 2011. Energy density of 16 food categories was calculated and energy cost was expressed as kcal/100g and £€/1,000kcal. Communities were stratified by tertiles of BMI and differences in local food prices were analyzed using Kruskal-Wallis test. Disparities in average numbers of food businesses operated in communities (per 10,000 persons) were examined between rural and urban area.

Results: Energy-dense foods, such as vegetable oil, rice, wheat, sugar, pork and wine, provided more energy at lower cost than those with low-energy-density, such as fruit, vegetable and milk. High BMI communities represented lowest prices in wheat, egg, oil, fruit, chicken, soybean curd, beer and cola, while highest price in mutton ($P<0.05$). Urban communities had more food businesses per 10,000 persons in fast food restaurants, indoor restaurants, outdoor fixed food stalls, mobile food carts that sell cooked food, bakeries and vendors that sell fried, twisted bread or other breakfast foods and cafes ($P<0.05$).

Conclusions: Disparities in access to food businesses and differences in energy costs may help explain obesity related dietary behaviors and food choices among Chinese adults, and indicated that food environment characteristics should be taken into account when designing policies for tackling obesity in China.

Key words: food price; energy cost; food environment; Chinese; adults.

PO1447**ASSOCIATION BETWEEN ENERGY DENSITY AND DIET COST IN CHILDREN**

A. P. Faria¹, P. Moreira^{1,2,3}, R. Rosário^{4,5}, A. Araújo¹, G. Albuquerque¹, V. Teixeira^{1,2}, R. Barros¹, O. Lopes⁶, A. Moreira^{7,8}, P. Padrão^{1,3}

¹Faculty of Nutrition and Food Sciences, University of Porto, Porto, Portugal

²Research Centre in Physical Activity, Health and Leisure, University of Porto, Porto, Portugal

³Institute of Public Health, University of Porto, Porto, Portugal

⁴Education School, Child Study Centre, University of Minho, Braga, Portugal

⁵Nursing School, University of Minho Braga, Portugal

⁶Tempo Livre, Sports Medical Centre, Guimarães, Portugal

⁷Department of Immunology, Faculty of Medicine, University of Porto, Porto, Portugal

⁸Department of Immunoallergology, Hospital of São João, Porto, Porto, Portugal

Background and objectives: Lower energy density diets are associated with higher diet quality, lower body weight and better health outcomes. However these type of diets are likely to cost more, which can be an obstacle to its consumption. To estimate the dietary energy density (DED) and to assess how the daily cost of diet is associated with DED in school children.

Methods: Children's data were obtained from a community-based survey selected from public elementary schools in Guimarães, Portugal. Of a total of 586 children attending these schools, 464 (51.5% girls), 6 to 12 years old, were studied. Dietary intake was assessed by a 24 hour recall between October 2007 and March 2008. DED (kcal/g) was calculated by three different ways: (1) with food and caloric/non-caloric beverages (DED1); (2) with food and caloric beverages (DED2); and (3) with food and no beverages (DED3). Energy adjusted diet cost (€/1000kcal) was calculated based on the collection of food prices available on a national leader supermarket website, and subjects were divided into tertiles according this variable. Anthropometric measures were taken and socio-demographic data was gathered from a questionnaire filled by parents. Logistic regression was used to estimate the association between diet cost and DED by sex, adjusting for age.

Results: Energy-adjusted diet cost was higher for children with the lowest DED. For boys, the energy-adjusted diet cost of the highest third of DED was lower, between 81% in the DED3 (p for trend <0.001) and 87% in the DED1 (p for trend <0.001), compared to the lowest third. Girls showed similar, but weaker associations between DED and diet cost.

Conclusions: Higher DED was associated with lower diet cost in children.

Key words: Energy-adjusted diet cost, dietary energy density and children.

PO1448**MICRONUTRIENT ADDED FOODS ANALYSIS IN COLOMBIA: VOLUNTARY FORTIFICATION CONTEXT**

E. Carvajal¹, I. Sotelo¹, M. Obregon¹

¹Universidad de la Sabana, Chía, Colombia

Background and objectives: The aim of this research was to analyze, for the retail distribution channel in Colombia, the trend of the voluntarily micronutrient fortified foods, from the Euromonitor International database.

Methods: The data were gathered in three large stores directly from the nutritional, ingredients, and claims labels from 34 packaged food categories, all from the International Euromonitor database. The information was statistically processed and analyzed according to Resolution 333 and ENSIN 2010.

Results: There were found 314 micronutrients added foods, which were organized in 24 fortified foods categories, it was established that the percentage share of the most commonly used vitamins in voluntary fortification in Colombia are: vitamin A 14%, vitamin C 13%, 11% vitamin B9, and the percentage share of the minerals used are: Iron 41%, Zinc 29% and 24% Calcium. The categories with the highest percentage of participation of fortified foods were: for foods, breakfast cereals 30%, pasta 13% and others 19%, and for drinks: soy beverages 20%, juices (up to 24% of fruit) 16%, and fruit flavored beverages 13%. It was found that only the pasta from one company has voluntary fortification with micronutrients: vitamin A, C, E, Selenium and Zinc, and that, apart from the mandatory fortification of flour, there is an additional voluntary fortification for micronutrients folate and Iron. It was found that the categories of breakfast cereal and flavored milks have some micronutrients added, which supply 100% of the recommended daily value.

Conclusions: there are many products with voluntary fortification in the Colombian market that may help to decrease Iron, Vitamin A and Zinc deficiencies, which is considering as a public health issue in the country. These products provide between 10 to 50% DV for Iron, 10 to 90% DV for Vitamin A and 10 to 96% DV for Zinc.

Key words: micronutrient, voluntary fortification, Euromonitor International.

PO1449

DOUBLE BURDEN OF MALNUTRITION AND DIETARY DIVERSITY IN SAME DISTRICT, TANZANIA

Y. Kolodziej¹, S. Msollo², J. Kinabo², M. Krawinkel¹

¹Institute of International Nutrition, Justus Liebig-University Giessen, Germany

²Department of Food Science and Technology, Sokoine University of Agriculture, Morogoro, Tanzania

Background and objectives: The double burden of malnutrition is documented in the Tanzania Demographic Health Survey 2010. Changes in diets and activity patterns play major roles in the increase of overweight and obesity, which already exceed rates of underweight in urban and rural settings. Dietary diversity increases, however, not among the healthy food choices. The current study assessed the prevalence of malnutrition and dietary diversity in an urban and rural setting in Same District, Tanzania in 2011.

Methods: This cross-sectional study included men and women, aged 25 to 55 years, without diagnosed nutrition-related disease. Demographic information was collected via standardized questionnaires. Malnutrition prevalence was calculated based on the following parameters: BMI, random blood glucose, blood pressure and clinical signs for vitamin A and iron deficiency. Dietary diversity was assessed with a dietary diversity score (DDS) based on data from a food frequency questionnaire.

Results: Of the 362 participants, 23% were overweight, 17% obese and 8% underweight. Significant differences for BMI were found between females and males (median 25vs. 21 kg/m²) and urban and rural participants (median 25vs. 22 kg/m²). Increased random blood glucose levels were found in 18% and frank diabetes mellitus in 6%. Around 37% had arterial hypertension. Clinical signs of micronutrient deficiency were apparent in up to 7%. Almost 70% of all participants had a high dietary diversity (DDS >6) and 6% a low dietary diversity (DDS <3). Fairly 100% of the participants consumed fats, 92% cereal products, and 37% sweets daily.

Conclusions: The double burden of malnutrition is present and already accompanied with secondary outcomes. Diets are dominated by fat and sugar but lack healthy diversity. Different prevalence rates among areas and sexes call for specific interventions to improve overall public health.

Key words: double burden, malnutrition, dietary diversity.

PO1450

THE EFFECTS OF PHYSICAL ACTIVITY AND DIETARY MANAGEMENT IN ADULTS WITH METABOLIC SYNDROME IN A RURAL DISTRICT IN MALAYSIA: AN INTERVENTION STUDY

WM. Wan Abdul Manan¹, WY. Wan Suria¹, WN. Wan Suriati¹, YY. Lee¹

¹Program in Nutrition, School of Health Sciences, Universiti Sains Malaysia, Kelantan, Malaysia

Background and objectives: The prevalence of obesity among adults in Malaysia is on the rise, while physical activity is on the decline, and at the same time there are increase cases of metabolic syndrome. Metabolic syndrome is associated with non-communicable disease such as diabetes mellitus, cardiovascular diseases and hyperlipidemia. The objective of this intervention study is to evaluate the effects of dietary management and physical activity on adults with metabolic syndrome after 6 months of intervention.

Methods: This is an intervention study which consisted of on 50 respondents each for both intervention and control groups in two health clinics in the rural district of Raub in Pahang, Malaysia. Assessment of nutritional status which include anthropometry measurements, biochemical and dietary assessment were measured during pre and post intervention.

Results: showed that there were significant difference in fat intake, body weight, waist circumference, fasting blood glucose, systolic blood pressure and diastolic blood pressure ($p < 0.05$) among subjects from the intervention group. Meanwhile, among respondents from the control group, no significant decrease was detected for all variables measured.

Conclusions: The reduction in measurements of metabolic syndrome such as waist circumference, fasting blood glucose, systolic and diastolic blood pressure among respondents from the intervention group was more pronounced as compared to respondents from the control group.

Key words: Metabolic syndrome, dietary management, physical activity, intervention study.

PO1451**CONTRIBUTION OF BEVERAGES TO ENERGY INTAKE AND BALANCE IN A SAMPLE OF GENERAL POPULATION IN GREECE**

M. Kapsokefalou¹, O. Malisova¹, V. Bountziouka¹, A. Zampelas¹

¹Agricultural University of Athens

Background and objectives: All beverages hydrate and most provide also nutrients and energy. Our objective was to evaluate the contribution of beverages to energy intake in summer and winter in a sample of the general population in Greece.

Methods: The Water Balance Questionnaire (WBQ), validated in the past to reflect water balance in the general population, was validated for recording energy intake with the method of three day diaries in 78 participants. Data from a stratified sample of the general population in Athens, Greece (n=984) collected using the WBQ were analysed for the contribution of beverages to energy intake.

Results: In winter, mean energy balance was 346±897 kcal/day, energy intake was 2082±892 kcal/day, energy intake from beverages was 479±286 kcal/day and energy loss 1860±390 kcal/day. In summer energy balance was 63±982 kcal/day, energy intake 1890±894 kcal/day, energy intake from beverages 492±499 kcal/day and energy loss 1830±491kcal/day. Energy intake from beverages in summer was higher than in winter (p<0.001) and in men higher than in women in both seasons (p<0.001 in summer and p=0.02 in winter). Coffee, coffee drinks, milk, chocolate milk and alcoholic beverages contributed approximately 75% of energy from beverages. Sugar-sweetened beverages, including soft drinks and fruit juice based beverages, as well as fruit juice were consumed less frequently contributing up to 25% of beverage energy intake.

Conclusions: Consumers have a variety of choices for their hydration; however their energy intake from beverages may vary according to dietary habits and the energy content of the beverage. At present, in the population tested, beverages contribute approximately 1/5 of total energy intake, with coffee drinks, dairy products and alcoholic beverages being the major contributors.

Key words: Water balance questionnaire WBQ, winter, summer, hydration, sugar-sweetened beverages, drink

PO1453**NUTRITIONAL CONTENT OF FOOD, AND NON-ALCOHOLIC BEVERAGES ADVERTISEMENTS BROADCASTED IN COLOMBIAN PUBLIC NATIONAL TELEVISION.**

D M. Mejía Díaz¹, I C. Carmona-Garcés¹, Ll. González-Zapata^{1,2}, P A. Giraldo-López¹

¹School of Nutrition and Dietetics, University of Antioquia, Medellín, Colombia

²Research Group in Social Determinants of Nutrition and Health status, University of Antioquia, Medellín, Colombia

Background and objectives: Eating habits are influenced by several factors, including food and advertisement of non-alcoholic beverages; therefore, strategies should be developed to reduce the advertisement's impact, especially on children. The objective of this research was to analyze the nutritional content of foods and non-alcoholic beverages advertised. Data were collected during morning hours in Colombian public national television by type of audience.

Methods and materials: A cross-sectional study was conducted including national channels Caracol and RCN. The recordings were performed simultaneously from 6:00 am to 12:30pm, for four days in July 2012, randomly selected, two on working days (Morning slot), and two on weekends (Morning children's slot). The nutritional characterization of the advertised foods was performed in a 100gr/ml sample of the product, taking as reference the Food Standards Agency criteria, the WHO recommendations, and the 333 Resolution issued by the Ministry of Social Protection of Colombia in 2011. We used the Chi 2 test and the SPSS software version 18. A p <0.05 was considered as relevant.

Results: Out of 52 hours of recording time, 23% consisted of food or non-alcoholic beverage advertisements. In both slots, advertisement of food with high sugar and sodium content (78.4% and 82% respectively) prevailed; more ads for foods with high sugar content were broadcasted on the morning children's slot than on the morning slot (93%). As for protective nutrients, ads for foods that are not a source of the evaluated nutrients, prevailed in both slots.

Conclusions: Advertisement for food and non-alcoholic beverages were characterized by products with high content of sugars, and sodium and low contribution of protective nutrients. This information is important to design new policies or strengthening the existing ones, following the recommendations proposed by WHO in the WHA63.14 Resolution.

Key words: Advertisement, foods, non-alcoholic beverages, nutritional value.

PO1454**TIME TRENDS CHANGES IN THE CONSUMPTION OF PROCESSED AND ULTRA-PROCESSED FOOD AND DRINK PRODUCTS DURING THE 20TH CENTURY IN CANADA**

J C. Moubarac¹, M. Batal², A P Bortoletto Martins¹, R. Claro¹, R.B. Levy³, G. Cannon¹, C. Monteiro¹

¹School of Public Health, University of São Paulo, São Paulo, Brazil

²Nutrition Program, University of Ottawa, Ottawa, Canada

³Faculty of Medicine, University of São Paulo, Brazil

Background and objectives: Food processing is an important determinant of the nature of dietary patterns and related states of health and well-being, at the personal and at the population level. The objective of this study is to use a new classification of foodstuffs based on the nature, extent and purpose of food processing, to assess changes in household food expenditures and dietary energy availability during much of the 20th century in Canada.

Methods: Food acquisitions from household food budget surveys from 1938-39, 1953, 1969, 1984, 2001 and 2011 were classified into (1) unprocessed or minimally processed foods; (2) processed culinary ingredients; and (3) ready-to-consume processed or ultra-processed products. Contributions of each group to household food expenditures (Can \$), and to dietary energy availability (kcal/per capita) were calculated. Shifts in household food expenditures and energy availability during 1938-2011 were assessed.

Results: Household expenditures have changed greatly since 1938-1939 in Canada. This was marked by falls in expenditure on both foods and culinary ingredients, and rises in ready-to-consume products. During this period, the share of foods (as defined here) fell from 34.3 to 25.6%, and of culinary ingredients fell from 39.6 to 12.8% of dietary energy, while the share of ready-to-consume products rose from 26.1 to 61.7% of dietary energy. More importantly, the share of ultra-processed products (as defined here) rose from 21.8 to 54.9% of dietary energy.

Conclusions: In Canada, in the course of the 20th century, ready-to-consume ultra-processed products have displaced food and culinary ingredients used together in the preparation of dishes and meals. The observed trend parallels the increase in the national prevalence of obesity in Canada. Public policy proposals are suggested.

Key words: food processing, ultra-processing, dietary patterns, obesity, public health nutrition, Canada.

PO1455**VERY LOW MICRONUTRIENT INTAKE ADEQUACY OF WOMEN IN RURAL BANGLADESH IS EXPLAINED BY LIMITED DIVERSITY OF NUTRIENT-RICH FOODS**

J. Arsenault¹, E. Yakes², M. Islam³, M. Hossain³, T. Ahmed³, C. Hotz⁴, B. Lewis⁵, A. Rahman³, K. Jamil³, K. Brown⁶

⁴Nutridemics, Toronto, Canada

⁵Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD

⁶Program in International and Community Nutrition and Department of Nutrition, University of California, Davis, CA, USA

Background and objectives: Documentation of micronutrient intake inadequacies among women in developing countries is important for planning food-based interventions. The objective of this study was to quantify and assess adequacy of micronutrient intakes of women in rural Bangladesh.

Methods: We measured 24-h dietary intakes using weighed food records and recall in homes on two non-consecutive days in a representative sample of 480 women who were a primary caregiver of a young child. We calculated the probability of adequacy of usual intakes of 11 micronutrients, an overall mean probability of micronutrient adequacy (MA), and evaluated dietary diversity by counting the total number of nine food groups consumed. The relationship between overall adequacy of micronutrient intakes and dietary diversity scores or food group indicators was determined using multivariate regression analyses.

Results: The overall mean prevalence of MA was 26% ± 10%. Fewer than 1% of women had adequate intakes of calcium, riboflavin, folate, and vitamin B-12, and <25% of women had adequate intakes of iron, zinc, vitamin A, and vitamin C. Overall MA was primarily explained by energy intake and diet diversity score. The only food groups that explained variance in MA were vitamin A-rich leafy greens and vitamin A-rich fruits and vegetables.

Conclusions: Micronutrient adequacy among women of child-bearing age in rural Bangladesh is alarmingly low, and targeted food-based interventions are warranted. Funding: HarvestPlus, Washington, DC, USA.

Key words: Micronutrient intake, women, Bangladesh.

PO1456**EVALUATION OF SODIUM CONTENT IN PROCESSED FOODS IN ARGENTINA**

L. Allemandi¹, L. Garipe¹, V. Schoj¹

¹Fundacion InterAmericana del Corazon-Argentina, Buenos Aires, Argentina

Background and objectives: In Argentina, hypertension is the first cause of cardiovascular events and salt intake is the main determinant. Although the recommended salt intake is 5gr/day, in Argentina there is a daily intake of 12gr. Two thirds of the salt intake comes from processed foods. This study is part of an international collaborative research study with over 29 countries to monitor nutritional composition of processed foods. The objective of this study is to evaluate sodium content in processed foods in Argentina over time in order to monitor the compliance of the policy changes.

Methods: pre- and post- comparison study design to evaluate sodium content in processed foods from selected food groups and categories. Sodium content was reported in mg/100gr of product. Baseline data collection was performed during August and December 2011 from food companies' websites. Baseline mean and range sodium values were calculated for each group and sub-category.

Results: Baseline results include 605 products from 9 groups of products: bread and bakery products, cereals and cereal products, dairy products, edible oils and emulsions, fish and fish products, meat and meat products, snacks, sauces and spreads, convenience foods. Baseline mean and range values for some sub-categories are: white bread 458mg (356-2000), crackers 686mg (11-1931), fresh ravioli 687, 5mg (396-1058), hard cheese 820mg (213-1166), butter 145mg (45-210), canned tuna 305mg (40-620), sausages 1200mg (87.5-1280), snacks 904mg (824-1104), sauces 533mg (413-698), mayonnaise 894.5mg (627-1040).

Conclusions: This project represents a first step to improve the quality of processed foods in Argentina. Our results show that most products, especially bread, meat and cheese, have salt amounts above reasonable benchmarks considering that a daily diet allows 2000mg/sodium. The variation between similar products shows that reformulation is feasible. This study provides baseline information to monitor future policy changes. **Key words:** sodium – processed foods – cardiovascular disease.

PO1457**CHANGES IN DAILY WATER INTAKE IMPACT MOOD OF HIGH AND LOW DRINKERS**

I. Guelinckx¹, E. Perrier¹, A. Klein¹, N. Pross²

¹Hydration and Health Department, Danone Research, Palaiseau, France

²Biotrial, Didenheim, France

Background and objectives: The effect of dehydration on cognition including mood has been examined in fluid deprivation studies. However, such study conditions are far from real life conditions. This inpatient crossover trial evaluated the effect of mild changes in water intake on mood in 22 high volume (HIGH; 2-4L/d; 25 ± 1 y) and 30 low volume drinkers (LOW; <1.2L/d; 25 ± 3 y).

Methods: During days 1 and 2 HIGH consumed 2.5L of water/d and LOW 1L/d. On Days 3 through 5, HIGH restricted water intake to 1L/d and LOW increased to 2.5L/d. Several mood scales (Bond & Lader VAS, Profile of mood states, Karolinska Sleepiness Scale, Thirst & Emotional VAS) were administered at different time points. An ANOVA model including treatment, time point and treatment x time as fixed effects on mean values (i.e.; baseline data vs mean of 3 intervention days) for each mood scale was performed.

Results: In LOW increased water consumption resulted in a significant decrease in fatigue (p<0.001), confusion (p=0.05) and thirst (p<0.001) and a trend to lower sleepiness (p=0.07) compared to baseline. In HIGH the restricted water intake resulted in a significant increase in thirst (p<0.001) and a decrease in contentedness (p<0.05), calmness (p<0.01), positive emotions (p<0.05) and vigor (p<0.001).

Conclusions: Increasing water intake has a beneficial mood effect, especially on sleep/wake feelings, whereas restricting water intake can deteriorate mood. Water consumption should not only be recommended because it fits within a healthy dietary pattern, but also because of the short term beneficial effect on mood. Improvements in sleep/wake feelings and well-being might also reduce the barrier to increased physical activity.

Key words: water, fluid intake, mood.

PO1458**FOOD INSECURITY, ACCULTURATION AND ASSOCIATED DEMOGRAPHIC FACTORS AMONG MIGRANTS TO AUSTRALIA***R. Ramsey¹, D. Gallegos¹*¹Queensland University of Technology, Queensland, Australia

Background and objectives: Food insecurity is the limited access to or availability of nutritious, culturally-appropriate and safe foods or inability to acquire such foods by socially-acceptable means. The major determinant of food insecurity is poverty, placing particular population sub-groups at risk, including migrants, who may also experience difficulty acquiring culturally-familiar foods in a new country. However, as individuals acculturate, changes may occur to traditional diets. This may have implications for food insecurity, with the prevalence decreasing with longer duration of residence. This study investigated associations between food insecurity, country of birth (COB), acculturation and sociodemographic factors among migrants to Australia.

Methods: Data (n = 14, 407) from the 2004-2005 National Health Survey (the most recent national survey to measure food security) were analysed using logistic regression, to investigate associations between food insecurity, COB, acculturation and sociodemographic factors.

Results: Independent of socioeconomic position, graded associations existed between food security and duration in Australia; those born in a country other than a major English speaking country were up to 90% more likely to experience food insecurity. This group exhibited higher rates of unemployment and a four-fold increase in receipt of lower household incomes compared to Australian-born counterparts. Each of these factors increased the risk of food insecurity by four and twelve times respectively. Increased duration residing in Australia was associated with increased rates of employment and higher household incomes. Findings suggest that sociodemographic factors are important, but not sole, determinants of food insecurity among migrants. Further investigation using a comprehensive food security assessment tool is warranted. Interventions to alleviate food insecurity among migrant groups may be enhanced by strategies to improve employment opportunities.

Conclusions: Migrants to Australia may be at higher risk of food insecurity, in part due to increased rates of unemployment and lower household incomes.

Key words: Food insecurity, migrants.

PO1459**ASSOCIATIONS BETWEEN FOOD INSECURITY, DIET AND OBESITY AMONG THE AUSTRALIAN POPULATION***R. Ramsey¹, D. Gallegos¹*¹Queensland University of Technology, Queensland, Australia

Background and objectives: Food insecurity is the limited availability of or access to nutritious, culturally-appropriate and safe foods or inability to obtain these foods by socially-acceptable means. Internationally, studies suggest that food insecurity may be associated with overweight and obesity, however existing evidence is conflicting. According to OECD data, Australia has the fastest rising food prices of any major developed nation. In particular, healthful foods are perceived as more expensive and 'less value-for-money', compared to their energy-dense counterparts. This study investigated the potential associations between food insecurity, fruit and vegetable intakes and weight status among the Australian population.

Methods: Data for 16, 428 participants from the 2004/2005 National Health Survey (the most recent national survey to assess food security) were stratified by gender and analysed using logistic regression to investigate associations between food insecurity, diet and weight status.

Results: Women from food insecure households were 30% more likely to be obese and 30% less likely to consume the recommended five servings of vegetables compared to their food secure counterparts. There was no association between food insecurity and weight status or vegetable intakes among men. Food insecurity was also associated with a two-fold increase in inadequate fruit intakes among both men and women. Consumption of adequate servings of fruits and vegetables was not associated with obesity among this sample. The positive association between food insecurity and obesity among women may not be mediated by intakes of fruits and vegetables. Further research investigating intakes of less healthful foods, and the eating patterns associated with food insecurity are warranted in order to understand and address the associations between food insecurity and obesity among women.

Conclusions: Women from food insecure households in Australia are at increased risk of obesity, however fruit and vegetable intakes do not appear to mediate this association.

Key words: Food insecurity, obesity.

PO1460**CONSUMPTION OF ULTRA-PROCESSED FOODS: EVIDENCE FROM MALAYSIA**

A. Ali^{1,2}, B. Margetts², P. Roderick², J-C. Moubarac³

¹Department of Food Science, Universiti Terengganu Malaysia (UMT)

²Department of Primary Care and Population Sciences, School of Medicine, University of Southampton, UK

³Département de Nutrition, Université de Montréal, Montréal, Canada

Background and objectives: The increase consumption of the processed foods brings a significant impact towards the nutritional status. The existing Malaysian dietary guideline suggests on the need of having to take minimally processed cereals however overlook the emerging of the whole processed foods. The aim of this study was to determine the consumption of ultra-processed foods in an urban area in Malaysia.

Methods: A total of 300 subjects living in Selangor, Malaysia, aged 20 to 59 years old were recruited. A semi-quantitative Food Frequency Questionnaire (FFQ) was used, and foods were grouped as: unprocessed or minimally processed foods (Group 1), processed culinary and food industry ingredients (Group 2), and ultra-processed foods (Group 3).

Results: showed that majority of these subjects were in the middle aged group, had received tertiary education, had household monthly income of more than RM3500 (GBP700) and encompassed household size of 3 to 5 persons. Total energy intake from the FFQ was 2435.85 kcal. Rice contributes 13.3% of total energy which is the highest contribution of energy in Group 1. Group 3 diets exceeded WHO upper limits for sodium, added sugar and saturated fat, with less fibre than recommended. Group 3 products taken together are more fatty, sugary, and salty than a combination of group 1 foods and group 2 ingredients. The food basket of the lowest quintile compared with the highest quintile is higher in fiber (1.76% compared with 1.1%); and is lower in added sugar (1.12% compared with 9.51%), saturated fat (7.71% compared with 12.02%), and sodium (1.12g/1000kcal compared with 1.98g/1000kg). There is a significant linear trend across all quintiles for all these indicators ($p < 0.01$).

Conclusions: The data presented support that diets high in or dominated by ultra-processed products cannot meet WHO and other dietary recommendations/guidelines designed to prevent and control obesity and diet-related disease (Monteiro et al., 2010).

Key words: Ultra-processed.

PO1461**INNOVATION IN HEALTH PROMOTION EDUCATION: TEACHING NUTRITION TO FUTURE PHYSICIANS**

S. Pati¹

¹Indian Institute of Public Health Bhubaneswar, PHFI

Background and objectives: Despite concerns raised for expanding nutrition training in health professional education, its implementation is below desired. The road to effective and efficient integration of nutrition in training of future physicians is still unpaved in developing countries. This is especially important in India where both under and over nutrition are the prime causes of morbidity and mortality. Objective: Present work is an innovative experiment in public health nutrition education for medical students. In India, physicians' training encompasses basic and clinical years.

Methods: It was attempted to provide the necessary orientation in first year when students get familiar to Biochemistry, Physiology and Community medicine with the objective of taking up nutritional inquiry when they move to clinical years. Intervention: The study was conducted in SCB Medical College, Orissa. Forty-four randomly selected first-year medical students were taught dietary behavior with a grounding on principles of medical anthropology and behavioral sciences; basics of nutritional assessment using anthropometrics and dietary intake assessment through FFQ. They calculated self anthropometric data, assessed own eating behavior from dietary intake analysis and compared the same with FAO's India-based dietary guidelines and ICMR-prescribed dietary recommendations. Next, using the data collected and consultations with registered dietitians working in hospital and faculty, these students were encouraged to develop dietary prescriptions to improve their overall nutritional wellness. Subsequently, they were given practicum where they applied the same skills to perform nutritional assessment and provide prescriptions to the patients.

Results: The experiment group students had better nutrition practice skills as assessed through OSCE performance outcome. A significant difference in knowledge and attitude were observed among intervention groups when compared to control.

Conclusions: Teaching nutrition to medical students in first year could prepare them adequately to impart effective nutritional counseling and support to their patient in clinical practice years.

Key words: nutrition education, innovation, medical student.

PO1462**INFANT AND YOUNG CHILD NUTRITION PROMOTION ACTIVITIES IN BURKINA FASO: ANALYSIS OF COVERAGE IN 2011**

L. Déart¹, B. Ndiaye², A. Challier¹, M. Brero², S. S³, A. Gartner¹, Y. Martin-Prevel¹

¹Institut de Recherche pour le Développement (IRD) - UMR204 Nutripass IRD, UM2, UM1, Burkina Faso

²UNICEF, Burkina Faso

³Programme d'Appui au Développement Sanitaire (PADS), Burkina Faso

Background and objectives: Optimal infant and young child nutrition (IYCN) practices are key to improve the nutritional status of children and reduce stunting. However, adequate IYCN is poorly practiced in Burkina Faso and stunting prevalence remains high (33% in 2012). To increase access to IYCN promotion activities by scaling up community interventions, the Government of Burkina Faso appointed a national network of 146 Communities-Based Organisations (CBOs). The objective of this study was to analyse the coverage of this national program in 2011.

Methods: In 2012, a questionnaire was sent to all 146 CBOs. Bottlenecks reducing the coverage of IYCN activities were identified using an adaptation of the Tanahashi method (1978). Different coverage indicators assessed the proportion of targeted mothers who were reached by CBO's (coverage indicator A); reached by CBOs delivering IYCN activities (B); actually offered to participate in IYCN activities (C); attending at least one activity (D).

Results: Coverage indicator A was good at national level (71.5%) but with regional disparities, from 33.6% to 100% (>60% in 11 out of 13 regions). As most of the CBOs delivered IYCN activities, coverage B (70.4%) was very close to coverage A. Coverage C was only 15.0%, reflecting a lack of resources to actually attain the targeted group. Finally, coverage D (11.0%) was close to coverage C, indicating that most of targeted mothers reached by the programme were willing to attend activities.

Conclusions: In all regions the main bottleneck was identified between the proportion of mothers living in areas covered by CBOs and those actually offered to participate in activities. In order to improve coverage, the government of Burkina Faso should increase the number of CBOs, and/or their human and financial resources, particularly in regions where initial coverage A and B were low.

Key words: Scaling up, Coverage, bottlenecks, Africa

PO1463**ASSOCIATION BETWEEN METABOLIC SYNDROME AND BREAST DENSITY IN PREMENOPAUSAL CHILEAN WOMEN**

A. Martínez^{1,2}, M.L. Garmendia¹, A. Pereira¹

¹Public Health Unit, Institute of Nutrition and Food Technology, University of Chile

²Department of Nutrition and Food, University of Valparaiso, Chile

Background and objectives: Metabolic syndrome (MS) has been associated with an increased risk of breast cancer (BC) in postmenopausal women. Mammographic density (MD) is the best predictor of risk of BC. There is little evidence about the association between MS and DM. To evaluate the relationship between metabolic syndrome and mammographic density in premenopausal Chilean middle and lower SES (socioeconomic status).

Methods: Cross-sectional. We studied 225 women (mean age 35 years, SD = 6.4), DERCAM cohort participants. Anthropometric (weight, height, waist), blood pressure and metabolic were assessed. Sociodemographic, gynecologic variables were registered in a questionnaire. We estimated mammographic density: dense volume (DV), non-dense volume (NDV), and density percentage (%D) through bilateral digital mammography, using the software Volpara. The MS was defined according to the NCEP ATP III criteria. The association between MS and DM (DV, NDV, %D) was estimated by linear regression models.

Results: The mean BMI was 28.2 kg/m² (SD=6.4), 62% had abdominal obesity and 78% low HDL. One in four women had MS. After adjusting for sociodemographic and gynecologic variables, the MS was associated with increased NDA (coef IC 263 149.02 to 377.03) and lower %D (coef -2.52 -4.14 IC to -0.91) however, these associations lost significance when adjusted by adiposity (BMI). No association with DV or crude or adjusted models.

Conclusions: Our results do not support the relationship between SM and DM. The relationship between adiposity and NDV and how this can influence the future risk of breast cancer should be deepened.

Key words: Mammographic density, Metabolic Syndrome. Funding: Fondecyt # 11100238

PO1464**AFRICAN STAKEHOLDER VIEWS OF RESEARCH OPTIONS TO REDUCE MALNUTRITION IN SUB-SAHARAN AFRICA**

M. Holdsworth¹, A. Kruger², E. Nago-Koukoubou³, P. Mamiro⁴, K. Smit², C. Garimoi-Orach⁵, Y. Kameli⁶, C. Lachat⁷, D. Roberfroid⁸, P. Kolsteren⁸

²Africa Unit for Transdisciplinary Health Research, North-West University, Potchefstroom, South Africa

³Faculté des Sciences Agronomiques, University of Abomey-Calavi, Cotonou, Benin

⁴Department of Food Science and Technology, Sokoine University of Agriculture, Morogoro, Tanzania

⁵School of Public Health, Makerere University, Kampala, Uganda

⁶NUTRIPASS, Institut de Recherche pour le Développement, Montpellier, France

⁷Department of Food Safety and Food Quality, Ghent University, Ghent, Belgium

⁸Child Health and Nutrition Unit, Institute of Tropical Medicine, Antwerp, Belgium

Background and objectives: Setting research priorities for nutrition in Africa is currently ad hoc and led by donors and funding bodies based in the Global North. There is a need to shift the status quo in the light of the continent's slow progress in reducing malnutrition (under and over-nutrition). This study explored African stakeholders' views on research priorities, to inform a nutrition research agenda that is better adapted to responding to malnutrition.

Methods: Using Multi Criteria Mapping, quantitative and qualitative data were gathered from 91 stakeholders from >15 sectors (health professionals, food industry, government, civil society, academics and research funders) in Benin, Mozambique, South Africa, Tanzania, Togo and Uganda. Stakeholders appraised six research options (ecological nutrition, nutritional epidemiology, community nutrition interventions, behavioural nutrition, clinical nutrition and molecular nutrition) for how well they could address malnutrition in Africa.

Results: Community interventions was ranked first by stakeholders, as it was seen as likely to have an impact relatively quickly, was inexpensive and cost-effective, involved communities and provided direct evidence of what works. Behavioural nutrition was the second most highly appraised research option. Many stakeholders, particularly academics and government were also optimistic about the value of ecological nutrition research in the long term. Research funders did not share this enthusiasm. Molecular nutrition was favoured least,

considered expensive, slow to have an impact and requiring infrastructure. Mozambique was the only country to prioritize research into ecological nutrition. South Africa ranked clinical and molecular nutrition the highest of all countries.

Conclusions: Research funders should redirect research funds towards the priorities identified by giving precedence to developing the evidence base for effective community nutrition interventions. Expanding research funding in behavioural and ecological nutrition were also valued and require multi-disciplinary collaborations between nutritionists, social scientists, agricultural and climate change scientists.

Key words: research policy, stakeholders, malnutrition, Africa.

PO1465**PHYSICAL BURDEN OF STUDENTS FROM THE MAIN SCHOOL OF FIRE SERVICE (MFSF) DURING "ADJUST TO WORKING TOGETHER" FIELD EXERCISES.**

J. Bertrand¹, A. Klos¹, W. Szymanska¹, B. Bertrand²

¹Military Institute of Hygiene and Epidemiology, Warsaw, Poland

²Health Department of Ministry of Interior, Warsaw, Poland

Background and objectives: Rescue activity is primarily a team work. Life of rescuers as well as rescued people depends on cooperation of all of them. The "Adjust to working together" exercises require from all participants maximum efforts up to the highest readiness. Time, precision and safety of exercises are assessed. The size of energy expenditure associated with carrying out different training activities by students of MFSF is a determinant that determines amount of daily energy expenditure. The aim of the work was to assess the size of energy expenditure during the "adjust to working together" exercises in field conditions.

Methods: Total of 24 students took part in the examination (eight in a group).

Results: The average age of examined students amounted to 19.8±1.2 years, body height and body mass amounted to 180.6±4.6 cm and 75.7±6.6 kg respectively. The BMI value was 23.2 ± 1.6 kg/m² in an average. The percentage fat content and lean body mass amounted to 12.9±1.8% and 65.9±5.5 kg respectively. Examination of energy expenditure was based on measurements of heart contractions frequency registered by the Polar Sport Tester 810 heart rate meters. The average time of each exercise was 54 minutes 37 seconds, during which the average energy expenditure amounted to 10.8 kcal/min (9.6 kcal/min – 11.6 kcal/min). The heart contractions frequency was 133.6±17.1 in an average.

Conclusions: According to the generally accepted classification for the assessment of work heaviness, both minute energy load and minute heart contractions frequency, allow to include the work performed by students to the category of very heavy works that can be done without a break for up to 1 hour.

Key words: military service, energy expenditure, nutritional status.

PO1466

MATERNAL EDUCATION AND DECISION MAKING POWER MODIFY HOW CHILDREN 0-24 MO BENEFIT FROM HOUSEHOLD DIETARY DIVERSITY IN EASTERN BURUNDI

J.L. Leroy¹, D. Olney¹, M. Ruel¹

¹Poverty, Health and Nutrition Division, International Food Policy Research Institute, Washington DC, USA

Background and objectives: Burundi is one of the 10 poorest countries of the world, with extremely high levels of child stunting. Research on the specific causes of stunting in this country is virtually non-existent. Our objectives were twofold: 1) to assess whether household dietary diversity (HDD) was associated with child dietary diversity (CDD) and stunting, respectively; and 2) to test whether maternal characteristics (literacy, years of schooling, health and nutrition knowledge and decision-making power) modified these associations.

Methods: Data were collected in 2010 on a sample of 2,562 children 0 to 24 mo of age from the eastern provinces of Cankuzo and Ruyigi. Linear regression was used to test the association between HDD and child height-for-age Z-scores (HAZ) and dietary diversity respectively, controlling for maternal characteristics and other covariates, and with relevant interaction terms included. Standard errors were adjusted for village clustering.

Results: More than 53% of children were stunted and both HDD and CDD were low (3.97±1.63 out of 12 groups; and 2.02±1.50 out of 7 groups, respectively). Higher HDD was associated with both child HAZ and CDD. There were significant interactions (p<0.05) between each of the maternal characteristics tested and HDD on both child outcomes; the associations between HDD and child outcomes were greater among households with better off mothers (literate, greater education, better knowledge and more decision-making power).

Conclusions: To maximize their impact on child nutritional status, interventions aimed at improving HDD and child nutrition outcomes need to be combined with efforts to improve women's literacy, nutrition and health knowledge and decision making power.

Key words: Burundi, child, malnutrition, maternal knowledge, decision making power.

PO1467

FOOD CHOICES AND PERCEIVED BARRIERS TO HEALTHY EATING IN EGYPT

S. Wahba¹, A. Mekkawy¹, A. Arrafa, R. Taha¹, W. Moheesen¹

¹National Research Center, Egypt

Background and objectives: Appropriate food choice is an essential factor in maintaining body function and health. Factors that influence healthful food choices are different and complex. This study was carried out to identify the major perceived influences on food choices and assess barriers to healthy eating among participants working in National Research Center, Egypt.

Methods: A cross sectional study was conducted using structured written questionnaires. A total of ninety hundred and fifty subjects aged 41.71±10.54 years (43.1% males and 56.9% females) participating in the study. Participants answered questions regarding social demographic characteristics. Food choices and perceived barriers to healthy eating were assessed.

Results: The major factors in food choices were: quality/freshness (77.3%), trying to eat healthily diet (68%), food preferred by family members (34.6%), taste (26.2%) and cost (18.2%). Lack of time was the most frequently barrier reported by 38.9%, followed by Resistance to change (26.1%), cost (23.6%), lack of knowledge (20.8%) and social influence (19.2%). Lack of knowledge and food prices were significantly higher among those who were singles and those with less than university level of education.

Conclusions: The findings suggest that food prices and nutritional knowledge must be addressed carefully when developing nutrition intervention.

Key words: Food choices, Barriers, Prices, Knowledge.

Acknowledgments: Funding support was provided by National Research Center in Egypt. None of the authors had a conflict of interest. Each of the authors made a direct contribution to this study. Thanks to all participants.

PO1468**TOLEDO AREA STUDY: RELATIONSHIP BETWEEN PHYSICAL ACTIVITY AND CARDIOVASCULAR RISK FACTORS IN ADOLESCENTS**

J M. Martínez-Sesmero¹, T. Guillén³, A. Aragonés², S. Bastida³, F J. Sánchez-Muniz³

¹Pharmacy Department (Virgen de la Salud Hospital, Toledo, Spain)

²Department of Pediatrics (Virgen de la Salud Hospital, Toledo, Spain)

³Nutrition Department Phaculty of Pharmacy (Complutense University of Madrid, Madrid, Spain)

Background and objectives: The Toledo Area Longitudinal Study (TALS) analyzes the possible influences of parents, birth status, diet and environmental factors on different lipoprotein markers and insulin resistance (IR) in children and adolescents of Toledo Health Area. The objective is to assess the relationship between physical activity (PA) and lipoprotein and anthropometric markers in adolescents aged 16-17 years.

Methods: 53 adolescents belonging to TALS completed a PA self-administered questionnaire based on the time in hours they spent half a day of activities qualified as rest, very light, light, moderate and intense. Cardiovascular risk variables were determined: total cholesterol (TC), HDL cholesterol (HDL-C), LDL cholesterol (LDL-C), apolipoprotein (Apo) A1 and ApoB. The anthropometric (weight, height and body mass index -BMI-). Descriptive statistics (median and interquartile range) and analytical (nonparametric tests) were performed by SPSS® 15.0.

Results: 12 adolescents (22.6%) performed a low-PA, 31 (58.5%) engaged in low to moderate-PA and 10 (18.8%) a high-PA. With the PA increased, decreased TG ($p = 0.012$), LDL ratios / HDL ($p = 0.086$), TG / HDL-C ($p = 0.001$) and TC / HDL-C ($p = 0.053$) and increased HDL-C ($p = 0.038$) and the ratio ApoA1/ApoB ($p = 0.069$). No significant differences in anthropometric parameters were found, although there was a trend to increasing BMI when PA degree increases.

Conclusions: Although adolescents PA is reduced, increasing PA induces lower LDL atherogenicity and better lipoprotein profile. In this adolescent sample, lipoprotein markers are more affected than anthropometric, probably because exercise promotes muscle development with relative increase in weight and BMI.

Key words: Physical activity, adolescents, cardiovascular risk markers.

PO1469**ASSOCIATIONS BETWEEN BODY MASS INDEX AND BREAKFAST CONSUMPTION IN CANADIAN ADULTS**

S I. Barr¹, L. DiFrancesco², V L. Fulgoni III³

¹Food, Nutrition & Health, University of British Columbia, Vancouver, BC, Canada

²Source Nutrition, Toronto, ON, Canada

³Nutrition Impact LLC, Battle Creek, MI, USA

Background and objectives: It has been suggested that breakfast consumption is associated with more favorable values for Body Mass Index (BMI; kg/m²); however, available data are inconsistent. Accordingly, we used data from the nationally-representative 2004 Canadian Community Health Survey (CCHS) to explore associations between BMI and breakfast status (no breakfast – NoB; breakfast containing ready-to-eat cereal – RTECB; other breakfast – OtherB).

Methods: Data were included from CCHS participants (age >19 y) who were not pregnant or lactating, had measured values for height and weight, and had completed a multiple-pass 24-hr diet recall. BMI was compared among NoB, RTECB and OtherB groups for all participants combined, men and women separately, and by age group (19-30, 31-50, 51-70, and 71+ y) within sex. Covariates in the analyses were age, sex, race, smoking status, physical activity, marital status, education, food security, language spoken at home, and dietary supplement use (n=11, 654).

Results: 11% consumed NoB, 23% consumed RTECB, and 66% consumed OtherB. Among the entire group, mean BMI was significantly lower in RTECB vs. OtherB (26.6 ± 0.2 vs. 27.2 ± 0.1 , $P < 0.01$), and was identical between NoB and OtherB (27.2 ± 0.3 vs. 27.2 ± 0.1). Among men, differences were not significant (27.6 ± 0.4 , 26.9 ± 0.3 , and 27.3 ± 0.2 for NoB, RTECB, and OtherB, respectively). Among women, RTECB had lower BMI than OtherB (26.2 ± 0.3 vs. 27.1 ± 0.2 , $P < 0.01$), but other pairwise comparisons were not significant. Differences by age group were more variable, but BMI of both men and women aged 71+ y was lower in RTECB than OtherB.

Conclusions: Among Canadian adults, the type of breakfast consumed was more consistently associated with BMI differences than was consumption versus non-consumption of breakfast. Overall, those who included RTEC at breakfast had lower mean BMI than those who consumed other breakfasts, and this was most apparent in women and older adults.

Key Words: breakfast, national survey, breakfast cereal, BMI.

PO1470**IMPACT OF NUTRITION IMPROVEMENT THROUGH COMMUNITY EMPOWERMENT (NICE) PROJECT ON NUTRITION INDICATORS IN MAKASSAR, INDONESIA**

A. Thaha^{1,2}, M. Minarto³, R. Soeharno⁴, J. Rodriguez⁵, A. Ilham⁶, A. Azikin⁷

¹School of Public Health, Kampus UNHAS Tamalanea, Makassar 90245, Indonesia

²Danone institute Indonesia, Jakarta, Indonesia

³Ministry of Health, Jakarta, Indonesia

⁴Indonesia Residence Mission/ADB Jakarta, Indonesia

⁵Pacific Rim Innovation and Management Exponents, Inc, Philipines

⁶Empowerment Family Welfare, Makassar, Indonesia

⁷District Health Office of Makassar, Makassar, Indonesia

Background and objectives: NICE Project is a loan from the ADB in collaboration with the MOH Indonesia started in 2008 and ended in December 2012. Makassar is one of the 24 districts of NICE location. The purpose of this study was to examine the impact of the NICE project on the management of the program by the community and nutrition indicators

Methods: NICE Project based on learning organization approach to community empowerment. It included three Community Nutrition Packages (CNP) in every village with USD 5, 000/package. Community Nutrition Group (CNG) was a core group to plan, implement and mobilize the community. Facilitated by Community Facilitator (CF) and supervised by multi-sector group. CNP proposal was developed based on the village's survey results and the village community meeting. Monthly financial and activity reports were based on accountability and transparency.

Results: 1.The process of the community-based nutrition improvement in Makassar occurred through the involvement of multi-sectors and integrated approach. 2.From 2008 to 2012: a.Coverage of program participation in NICE areas increased to 59%, 65%, 70%, 80%, and 89%, compared to Non-NICE areas are 65%, 61%, 67%, 70%, and 66% respectively. b.Coverage of program achievements in NICE areas increased to 67%, 69%, 75%, 82%, and 88%, compared to Non-NICE areas are 66%, 68%, 73%, 73%, 71% respectively. c.Prevalence of underweight decreased to 14.3%, 14.15, 11.8%, 9.85 and 7.1%, respectively. d.Coverage of iron-folic acid consumption by pregnant women increased to 32%, 33%, 37%, 46% and 79%, respectively e.Coverage of vitamin A increased to 69%, 74%, 85%, 86% and 97%, respectively.

Conclusions: NICE Project has successfully empowered communities to improve nutrition through multi-sector involvement with an integrated approach. Increase in output and outcome indicators was significant.

Key words: NICE, nutrition, multi-sectors, integrated.

³School of Agriculture, Makassar Moslem University, Makassar, Indonesia

⁴Department of Early Child Development, Makassar Moslem University, Makassar, Indonesia

Background and objectives: Indonesia has a strong commitment to the improvement of nutrition. However, the improvement has not been encouraging. The objectives of this study was to assess the nutritional status of children under five trends and possible achievement of MDG target.

Methods: Time series analysis on the Basic Health Research (BHR) data 2007 and 2010. Correlation analysis was performed between the prevalence of stunting and obesity.

Results: Prevalence of underweight, stunted, wasted and obesity of under-five in 2007 were 18.4%, 36.8%, 13.6% and 12.2% respectively; and in 2010 were 17.9%, 35.6%, 13.3% and 14.0% respectively. Accelerating decline in prevalence of underweight, stunted, and wasted was 0.17%/year, 0.4%/year, and 0.1%/year respectively. Conversely, an increase in the prevalence of obesity was 1.8%/year. With the same acceleration, the prevalence of underweight was only 17.05 in 2015, which is far above the MDG target (15.5%). There was a positive correlation between the prevalence of stunted and obesity ($R=0.379$ $p=0.000$). This indicates that Indonesia has experiencing double burden of childhood nutritional problems, with the occurrence of an increased prevalence of NCD in the future.

Conclusions: 1.Accelerating decline in the prevalence of underweight, stunted and wasting is very slow but prevalence of obesity increases quickly. 2.Indonesia has experienced a double burden of nutrition with increased prevalence of NCD risk in the future. 3.Without multi-sector intervention, Indonesia will not meet the MDG targets by 2015 and have to address the issue of malnutrition and NCD in the future.

Key words: Indonesia, nutritional status, MDG.

PO1472

IS SECULAR TREND IN HEIGHT DELAYING OVERWEIGHT RAISE AMONG ADOLESCENTS? THE BRAZILIAN CASE

W.L. Conde¹, A.E.M. Rinaldi², C.C. Enes³

¹Department of Nutrition, School of Public Health, University of Sao Paulo, Brazil

²School of Public Health, University of Sao Paulo/ School of Medicine – Federal University of Uberlandia, Brazil

³Nutrition School, Pontifícia Universidade Católica de Campinas, Brazil

Background and objectives: The body mass index (BMI) is used to evaluate overweight in population because the independency of weight and height. Such assumption is not widely confirmed to adolescents. To assess if secular trend in height is contributing to delay overweight raise among Brazilian adolescents.

Methods: Data are representative of Brazilian adolescents and come from four national surveys carried out from 1974/75 to 2002/2003. We considered as overweight adolescents with BMI equal to or greater than 25 kg/m². Changes in BMI mean over time were fitted using linear regression including as independent variables survey year, height, survey-specific income quintiles, age, and an interaction term height-survey year as explanatory variables. Changes in overweight prevalence over time were fitted using Poisson regression with overweight status as outcome.

Results: Mean values of height and BMI increased over the period, for both sexes and in all age range, except for girls from 14 to 19-years from 1989 to 2002/03. The average increment and mean rate of height was greater for 10-to-15-years old. The highest mean rate of height was between 1989 to 2002/03. The annual increment of height decreased from 2002/03 to 2008/09 in parallel of the increment in BMI rate. After fitting the regression model, interaction height-survey year and per capita income were strong vectors to increase BMI mean. Changes in increment rate of height played a protective role against overweight in the two last periods for both sexes, mainly for girls. Period of 1989 to 2002/03 was the strongest vector associated with overweight in boys and association decreased to the next period, from 2002/03 to 2008/09.

Conclusions: BMI and height increased in a different way over the last fourth years. These trends suggested height played a protective role in evolution of body mass mean and overweight indicators across time in Brazilian adolescents.

Key words: adolescents, obesity, secular trends.

PO1473

CHANGES IN THE PREVALENCE OF CHILD UNDER-NUTRITION AND OVERNUTRITION IN NIGERIA FROM 1990-2008

O. Adeyemi¹, R. Stoltzfus¹, D. Pelletier¹

¹Division of Nutritional Sciences, Cornell University, Ithaca, New York, U.S.A

Background and objectives: Malnutrition – undernutrition and overnutrition – is a major risk factor for morbidity. Knowing past prevalence of malnutrition and changes in prevalence with time can thus be vital for understanding and reducing morbidity. This study provides such knowledge for Nigeria, which bears a remarkable proportion of the global burden of morbidity.

Methods: Nationally representative cross-sectional data for children under five years of age from the 1990, 2003, and 2008 Nigerian Demographic Health Surveys were used. For each survey year, stunting, wasting, and overweight were defined, using the 2006 WHO standards, as height-for-age z-score <-2, weight-for-height z-score (WHZ) <-2, and WHZ >+2 respectively. Descriptive statistics were obtained using complex survey design in Stata 11.2.

Results: Nationally, there was a reduction in stunting from 48.7% prevalence in 1990 to 40.6% in 2008. In contrast, wasting prevalence increased from 10.8% in 1990 to 14% in 2008. Overweight prevalence also increased from 2.5% in 1990 to 8.8% in 2008. Similar trends were observed when the national prevalence of each indicator in 2008 was compared to that in 2003. However, when stratified by wealth quintile, the results showed important differences in levels and magnitude of changes in malnutrition between poor and rich children. From 1990 to 2008, stunting decreased from 36.7% to 24.2% among the richest children, but only from 53.7% to 52.3% in the poorest children. Likewise, while wasting increased from 7.1% to 9.1% among the richest, it increased from 13.9% to 20.7% among the poorest children. Yet, for both poorest and richest children, overweight increased from little over 2% in 1990 to 9% in 2008.

Conclusions: Unless measures are taken to reverse observed trends, poor Nigerian children are and will continue to be at the greatest risk of both undernutrition and overnutrition.

Key words: double burden of malnutrition, poverty.

PO1483

IMPACT OF SOLAR POWERED IRRIGATION ON FOOD SECURITY, WATER SECURITY AND INCOME IN THE DISTRICT OF KALALÉ OF NORTHERN BENIN

H. Alaofè¹, J. Burney², D. Taren¹

¹University of Arizona, College of Public Health

²University of California, San Diego, International Relations, Pacific Studies

Background and objectives: In spite of all efforts and investments in smallholder irrigation schemes to improve rural household food security through improved productivity in developing countries, pressing issues such as rural poverty, food insecurity and social problems still prevail, which results in the scheme being undermined. The main objective of the study was to evaluate the impact of solar powered drip irrigation (PVDI) systems on household food security and on lifestyle changes in the Kalalé District of Benin.

Methods: Solar-powered drip irrigation (PVDI) systems were installed in conjunction with local women's agricultural groups engaged in horticulture as a way to reduce poverty and impacts of climate adaptation, and to improve food security. Results were compared with other women groups in other villages and random samples of households in the same villages. A household questionnaire based on FAO food security pillars (access to food, availability of food, utilization of food and the overall factor of food stability) was used to evaluate food security before (n=244) and 1-year after (n=286) the PVDI systems were installed (2007-2008).

Results: Severe food insecurity decreased by 46% and severe water insecurity decreased by 32% in women's group with PVDI while it was unchanged in other households. Only women's groups decreased their health care insecurity but this was not associated with PVDI over this time period. Agricultural sales increased in all households over the 2-year period but greatest in women's groups who used PVDI (150%), compared with women's groups without PVDI (100%) and in 2 random samples of other households (58% and 41%).

Conclusions: The research findings depict that solar powered drip irrigation enhanced food security and household livelihood through access to water and income generation.

Key words: Food insecurity, solar-powered drip irrigation, livelihood, income.

PO1474

THE STRATEGIC CAPACITY TO ADDRESS THE DOUBLE BURDEN OF MALNUTRITION AND DISEASE IN NIGERIA

O. Adeyemi¹, D. Pelletier¹, C. Devine¹

¹Division of Nutritional Sciences, Cornell University, Ithaca, New York, U.S.A

Background and objectives: Overnutrition and noncommunicable diseases (NCDs) are significant problems in Nigeria. Yet, the country still bears an alarming burden of undernutrition and infectious diseases. Policy interventions have been recommended as an integral approach to simultaneously addressing these issues. However, strategic capacity is required to initiate and sustain the policymaking process. Strategic capacity is the ability of individual and institutional policy actors to envision, create, agree upon, and generate commitment to a long term approach to address an issue. This study assessed the strategic capacity for addressing NCDs in Nigeria in addition to ongoing efforts to address undernutrition and infectious diseases. Previous evidence from Nigeria had revealed notable policy awareness but no formal policy on NCDs.

Methods: Semi-structured interviews were conducted with 34 key, multisectoral, Nigerian policy actors identified through snowball sampling. Participants' views about NCDs, potential policy responses, and enablers/challenges for action were assessed. Interview transcripts were analyzed and aggregated using Atlas.ti 7.

Results: Each policy actor possessed a partial understanding of causes and potential long-term approaches for NCDs in Nigeria. When the responses of individual policy actors were aggregated, they presented a broad perspective on feasible policy responses. However, a primary constraint was that there were no formal or informal mechanisms through which policy actors could pool their knowledge, expertise and other resources to forge consensus on such policy responses. Furthermore, the strong leadership needed for building trust, organizing effective coalitions and moving forward with a coherent policy agenda did not exist.

Conclusions: Nigeria possesses human and institutional resources that could be mobilized to address NCDs but the strategic capacity for doing so does not presently exist. There is a need to recognize strategic capacity as a distinctive concept and to purposefully plan for and build this capacity.

Key words: strategic capacity, NCDs, nutrition policy.

PO1475

WHEN IS A HEALTHY DIET NOT A SUSTAINABLE DIET?

J. Macdiarmid¹, J. Kyle¹, G. Horgan¹, G. McNeill¹

¹University of Aberdeen, Aberdeen, UK

Background and objectives: One of the challenges facing public health nutrition today is to define a healthy and an environmentally sustainable diet and how to communicate this to consumers, as there are both synergies and conflicts between these issues.

Methods: Linear programming was used to create dietary scenarios to illustrate how widely the estimated greenhouse gas emissions (GHGE) associated with the diet can vary while still meeting UK dietary recommendations for health. Dietary scenarios were generated using the same basic meal structure (7-day menu), but changing some of the types or quantities foods within the meals. Four scenarios were created, with either healthy or unhealthy diets (either meeting dietary requirements or not) and high or low in associated GHGE.

Results: The different scenarios showed that making small changes to the foods in the diet but still meeting dietary recommendations could double the GHGE associated with the diet. It was also possible to create two diets with similar GHGE; one that met dietary recommendations for health and the other that met none of the recommendations.

Conclusions: This modelling exercise highlights one of the fundamental differences between dietary recommendations for health and GHGE associated with the diet, which is that dietary recommendations tend to be based the nutrient content of the diet and can usually be achieved from a relatively wide combination of foods, while GHGE associated with the diet are dictated by a small number of food items with no consideration of the nutrient content. This creates a challenge for providing simple a healthy sustainable diet since it cannot be assumed a healthy diet will have lower associated GHGE.

Key words: sustainable diets, healthy, greenhouse gas emissions, food, nutrients.

PO1476

COMMUNICATING THE CONCEPT OF HEALTH, ENVIRONMENTALLY SUSTAINABLE DIETS: DEVELOPMENT OF AN INTERACTIVE EDUCATIONAL TOOL

J. Macdiarmid¹, G. Horgan¹, G. McNeill¹

¹University of Aberdeen, Aberdeen, UK

Background and objectives: The concept of sustainable diets includes many different elements (e.g. health, environment, economic, social factors) and therefore is a complex issue to communicate. Current dietary intakes in the UK are neither sustainable for long term health nor the environment and the challenge is to communicate the combined dietary advice for healthier and more environmentally sustainable diets. The aim of this study was to develop an educational tool that incorporated the concept of both a healthy balanced diet and one lower in greenhouse gas emissions (GHGE).

Methods: In collaboration with the Global Food Security Programme, an interactive computer-based educational tool was developed using on the principles of the UK Eatwell plate. This is a plate divided into the five main food groups showing the relative proportions that make up a healthy diet. The tool allows the user to manipulate the proportions of the food groups on the plate, which is linked to two sliding scales (health and GHGE). Changing the proportions of the food groups alters the health score and GHGE score of the diet.

Results: The tool demonstrates how different elements of sustainability (i.e. health and GHGE) can work either together or against each other depending on the different proportions of the food groups chosen, e.g. increasing high fat/high sugar foods reduces the health score, but also lowers the GHGE. Initial testing of the tool found it to be acceptable and usable by the general public and cognitive testing is now being used to test the interpretation of the material.

Conclusions: The complexity of communicating the concept of a healthy and environmentally sustainable diet should not be underestimated and simple educational tools are needed to try and convey dietary changes needed for healthy and more environmentally sustainable diets.

Key words: sustainable diets, educational tool, healthy, greenhouse gas emissions.

PO1477**EFFECT OF PHYSICAL ACTIVITY AND NUTRITIONAL EDUCATION ON BLOOD PRESSURE AND LIPID PROFILE IN A PEDIATRIC POPULATION.**

J J. Muros¹, M. Zabala², M J. Oliveras-López³, P. Rodríguez-Bouzas⁴, H. López-García de la Serrana¹

¹Department of Nutrition and Food Science, University of Granada, Granada, Spain

²Department of Physical Education and Sports, University of Granada, Granada, Spain

³Department of Molecular Biology and Biochemistry Engineering, University Pablo de Olavide, Seville, Spain

⁴Department of Statistics and Operations Research, University of Granada, Granada, Spain

Background and objectives: The cultural and social changes of recent years have changed the eating habits and physical activity of children. The objective was to determine the effects of nutritional education and vigorous extracurricular physical activity on blood parameters on children in primary education.

Methods: The sample group consisted of 87 children (9-11 years) divided between three groups: 41 students in the control group (G0), 21 students in nutritional education group (G1), and 25 students in physical activity and nutritional education group (G2). The intervention program was carried out in 6 months of moderate to vigorous physical activity in 2 weekly lessons of 60 minutes, in addition to 6 sessions of nutrition education, held with the parents as well as the students, lasting approximately 2 hours each. The following parameters were measured: glycemia (GL) (mg/dl), total cholesterol (TC) (mg/dl), HDL cholesterol (cHDL) (mg/dl), LDL cholesterol (cLDL), triglycerides (TG) (mg/dl) and both systolic (SBP) and diastolic (DBP) blood pressure (mmHg). We performed T tests and Wilcoxon tests for two related samples to compare blood parameters changes. All analyses were conducted using the SPSS 19.0 statistics package.

Results: SBP increased in G0 and decreased in the rest of groups, without significant reductions. DBP increased in G0, was unchanged in G1 and decreased in G2 ($p < 0.05$). G0 achieved significant increases in TC ($p < 0.05$), G2 achieved significant reductions in GL ($p < 0.05$), cLDL and TC ($p < 0.001$). TG showed a significant reduction in G1 ($p < 0.05$) while the other groups showed significant changes.

Conclusions: The results of this study provide evidence that a school-based program incorporating vigorous physical activity and nutritional education for children and parents can improve blood parameters in children.

Key words: Nutritional education, Physical activity, Blood parameters, Children.

PO1478**FOOD SECURITY AND NUTRITIONAL STATUS AMONG ORPHANS AND OTHER VULNERABLE CHILDREN IN JOMORO DISTRICT, GHANA**

G. Otoo¹, G. Kudalor¹

¹Department of Nutrition and Food Science, University of Ghana, Legon, Accra, Ghana

Background and objectives: Orphans and other vulnerable children (OVC) are likely to experience food insecurity due to the absence of one or both parents from households. It is still difficult to determine whether the nutritional needs of orphans and other vulnerable children are different from that of other children. The main objective of this study was to determine association between OVC status and child nutritional status and household food security.

Methods: A cross-sectional survey employing purposive sampling was used to identify 168 female caregivers, with OVC (84) and without OVC (84). Sociodemographic and modified USDA household food security questionnaire was used to assess food security. Weight and height of the children were used to compute the WAZ, WHZ and HAZ using WHO Anthro v3.2.2. Bivariate Chi-square analysis and T-test were used to assess the relationship between food security and OVC status. Binary logistic was used to determine the predictors of food security.

Results: Only 25.6% of all households sampled where food secured. Households with OVC were less food secure (13.1%) compared to those without OVC (38.1%); ($p < 0.001$). Caregivers without OVC were significantly more likely to be employed ($p = 0.034$) and married ($p = 0.002$). Households without OVC were 3.7 times more likely to be food secured compared to those with OVC ($p = 0.003$). Households with only one child under 5 years were 2.6 times more likely to be food secure than those with more than one child. There was no clear association between underweight, stunting and wasting, and food security or orphan status.

Conclusions: Food security is a problem in the Jomoro district, with households with or without OVC being vulnerable to food insecurity and malnutrition. Further understanding of how low-income families manage limited food resources is necessary address food security in this district.

Key words: Food security, Orphans and vulnerable children, nutritional status.

PO1479

PHYSICAL ACTIVITY, BIOCHEMICAL AND ANTHROPOMETRIC PROFILE AMONG HEALTH-CARE PROFESSIONALS (UNIVERSITY OF ANTIOQUIA, COLOMBIA). LATINMETS STUDY

G. Deossa-Restrepo¹, Ll. González-Zapata^{1,2,3}, J. Monsalve-Álvarez^{1,2,3}, A J. Díaz-García^{1,3}, N. Babio^{3,4}, J. Salas-Salvadó^{3,4}

¹School of Nutrition and Dietetics, University of Antioquia, Medellín, Colombia

²Research Group in social determinants of nutrition and health status, Medellín, Colombia

³Latin American network for the study of Metabolic Syndrome –RIBESMET-

⁴Human Nutrition Unit, Research Institute Pere i Virgili, Universitat Rovira i Virgili; and CIBERobn, Institute Carlos III, Spain

Background and objectives: Cardiovascular disease is closely related to physical inactivity, body mass index (BMI), waist circumference, and lipid profile changes. This study correlates physical activity (in MET) to biochemical profile, BMI, and waist circumference among health care professionals.

Methods: Cross-sectional study conducted in 283 students and professors from the health-care area schools at University of Antioquia, Colombia (2010-2011). The Minnesota Leisure-time Physical Activity Questionnaire was used to define the levels of physical activity among participants (somewhat active (SA) <143 kcal/day, active (A) 143-283 kcal/day, and very active (VA) >283kcal/day). Blood chemistry and anthropometry assessment (BMI and waist circumference) were performed. A descriptive and analytical study was performed using χ^2 test and $\alpha = 0.05$. SPSS v.18

Results: 283 volunteers participated in the study, 71% female, 42, 8% teachers, 57, 2% students; according to physical activity level -PAL- SA 11, 3%, A 17% and VA 71, 7%. We found that both A and VA subjects showed lower (though not significant, $p > 0, 05$) levels of triglycerides, total cholesterol, and LDL cholesterol. Blood glucose showed a slight increase among A and VA participants compared to SA ($p > 0, 05$). Waist circumference was inversely associated to PAL ($p < 0, 05$).

Conclusions: Through PAL is possible to obtain a waist circumference level and some lipid profile variables closer to normal ranges. Cardiovascular risk in this population could be reduced by increasing physical activity levels, which should be encouraged through life. The World Health Organization (WHO) recommends 300 minutes of moderate physical activity or 150 minutes of intense physical activity every week in order to achieve greater health benefits.

Key words: Physical activity, body mass index, waist circumference, cholesterol, blood glucose.

PO1480

PROMOTING HEALTHY LIFESTYLE USING COMPLEX COMMUNITY-BASED APPROACH FOR AT-RISK POPULATIONS OF DIABETES IN THAILAND: FORMATIVE EVALUATION

K. Sranacharoenpong¹, S. Udomkarnjananan¹, M. Chirdkiatisak¹

¹Institute of Nutrition, Mahidol University, Nakhon Pathom, Thailand

Background and objectives: The ultimate goal is to promote healthy lifestyle for Thai people and to prevent the burden of diabetes among high-risk Thai populations, through the public health leadership, community linkages and innovative technologies for long-term outcomes. To achieve this goal, multiple cohesion stakeholders; community health care workers (CHCWs), health volunteers (HVs), at-risk people for diabetes (ARPD), and change agents (students) are involved to establish lifestyle modification program regarding diabetes prevention. To investigate barriers to and supports for implementing a healthy lifestyle to prevent diabetes for at-risk people in Chiang Mai province, Thailand.

Methods: We conducted formative evaluation at communities, healthcare centers and schools with stakeholders. Interviews were used to gather gaps and supports in services, program needed that suited for Thai health care system. We interviewed CHCWs (n=4), HVs (n=4), ARPD (n=5), teacher (n=5) and students' parents (n=3). Focus groups conducted to get insight key issues of barriers and opportunities for health promotion. HVs (n=21), ARPD (n=21) and students (n=22) were invited for focus groups. Coded transcripts from audiotaped interviews and focus groups were analyzed by hand and using NVivo software. Concept mapping illustrated findings.

Results: CHCWs, HVs, and ARPD identified potential barriers to program success as motivation for regular participation (e.g., physical activity program, school lunch program and quality management), lack of nutritional education and supporting healthy environments (e.g., junk foods and soft-drinks at schools and communities) and lack of health promotion policy supported for sustainability. However, CHCWs and teachers identified opportunities to integrate health promotion and disease prevention into their duties. HVs and ARPD suggested to integrate increasing physical activity into their lifestyle, e.g., traditional Thai dancing, walking, bicycle.

Conclusions: Formative research supports the need for the effective, sustainable lifestyle modification program to support ARPD in the communities.

Key words: health promotion, lifestyle modification program, Thailand.

PO1482**A HIGH FAT, HIGH GI, LOW FIBRE DIETARY PATTERN IS ASSOCIATED WITH INCREASED TYPE 2 DIABETES RISK IN BRITISH ADULTS**

S. Pastorino¹, M. Richards¹, M. Pierce¹, D. Kuh¹, G.L. Ambrosini²

¹MRC Unit For Lifelong Health and Ageing, London, UK

²MRC Human Nutrition Research, Elsie Widdowson Laboratory, Cambridge, United Kingdom

Background and objectives: Evidence suggests a protective role against Type 2 Diabetes (T2D) for some dietary factors, in particular, low glycaemic index (GI) foods, dietary fibre and a diet low in fat. However, few studies have considered these three dietary factors simultaneously, in relation to T2D risk. The objective of this analysis was to examine the relationship between a dietary pattern (DP) characterised by GI, fibre density and fat density and incident T2D risk in a British adult population.

Methods: Subjects were 1257 adults from the 1946 British Birth Cohort. Dietary intake was measured at age 53 using a 5-day diet diary. Reduced rank regression was applied to identify a DP characterised by high GI, low fibre-density and high fat-density. Each subject received a DP z-score measuring how much their intake reflected this DP. T2D incidence was identified using validated self-report, fasting blood glucose and haemoglobin A1c levels. Logistic regression models, adjusted for socio-economic class, education, smoking, body mass index (BMI), waist circumference (WC) and physical activity, were used to examine prospective associations between DP z-scores at 53 y of age and risk of T2D at 64 y of age.

Results: The DP was characterised by low intakes of fruit, vegetables, yogurt and high-fibre cereals and high intakes of white bread, chips, fried foods and butter. After 10 years of follow-up 119 people developed T2D. People in the highest tertile of DP z-scores had more than double the risk for T2D (OR=2.11, 95%CI: 1.08-3.09) compared to those in the lowest tertile. This association remained significant after adjustment for BMI and WC (OR=1.81, 95% CI: 1.01, 3.23).

Conclusions: A high-fat, high-GI, low-fibre dietary pattern may increase the risk of T2D in older adults predominantly via pathways that are independent of BMI and WC.

Key words: Type 2 diabetes; dietary patterns; diet.

PO1484**GLYCEMIC INDEX AND GLYCEMIC LOAD AND RISK OF MORTALITY: THE PREDIMED STUDY.**

²Ciber Fisiopatología Obesidad y Nutrición (CIBEROBN, CB06/03), Instituto de Salud Carlos III, Spain

³Department of Nutrition and Food Science, University of Granada, Spain

⁴Institute of Nutrition and Food Technologies, University of Granada, Spain

Background and objectives: Dietary fiber has been related with a lower risk of all cause mortality. However, there are different types of carbohydrates that have diverse glycemic response. Dietary glycemic index (GI) and glycemic load (GL) are indicators frequently used to assess this variation. The effect of GI and GL in all-cause mortality has not been sufficiently studied. To estimate the association between dietary GI/GL and risk of all-cause mortality in the PREDIMED study.

Methods: The PREDIMED study is a nutritional intervention trial for primary cardiovascular prevention in individuals at high cardiovascular risk. From 7, 447 participants from the PREDIMED trial we followed 3, 707 non-diabetic men and women (55-80 years) with complete and plausible dietary data. Dietary information was collected using a validated 137-item food frequency questionnaire (FFQ). We assessed baseline GI and GL values of each item by a 5-step methodology, using the International Tables of Glycemic Index and Glycemic Load Values. Deaths were ascertained through medical records and consultation of the National Death Index. Cox regression models were used to estimate multivariable-adjusted hazard ratios (HR) and 95% Confidence Intervals (CI) for mortality, according to quartiles of GI/GL adjusting for potential confounders.

Results: After a median of 4.65 year of follow-up, 123 deaths were observed. Participants in the highest quartile of baseline GI showed an increment in the risk of mortality [HR=2.04 (95% CI: 1.08-3.84)] as compared to those in the lowest quartile. Moreover, a significant dose-response relationship was observed [P for trend = 0.033]. Baseline dietary GL was not associated to mortality risk.

Conclusions: A direct association between baseline dietary GI and mortality was found within non-diabetic participants from the PREDIMED trial.

Key words: Glycemic index, Mortality, Elderly. Acknowledgements: CIBEROBN and RTIC 06/0045 are an initiative of the Instituto de Salud Carlos III, Science and Innovation Ministry, Spain.

LOW PHYSICAL FITNESS SCORE ASSOCIATED TO CARDIOVASCULAR HEALTH FACTORS IN CHILLEAN SCHOOL CHILDREN FROM SIX TO 14 YEARS OLD

G. Salazar Rodríguez¹, M. Suarez-Reyes¹, J. Meza¹, R. Burrows², F. Navarro³

¹Energy Metabolism Laboratory. Institute of Nutrition and Food Technology, University of Chile, Santiago, Chile

²Institute of Nutrition and Food Technology, University of Chile, Santiago, Chile

³Institute of Nutrition and Food Technology, University of Chile, Santiago, Chile

⁴Institute of Nutrition and Food Technology, University of Chile, Santiago, Chile

⁵Health Promotion, Metropolitan Health Secretariat, Ministry of Health, Santiago, Chile

Background and objectives: Chile faces increased obesity prevalence and low physical activity in children. Adequate physical fitness (PF) protects cardiovascular health (CVH). The objectives were: a) associate physical fitness to simple markers of CVH, b) detect children at risk, by generating a Z-Score composed of waist circumference (WC) blood pressure (BP), excess fat and associate it to tertiles of physical fitness in children.

Methods: In Santiago urban sector, a sample of 1686 children was selected from 17 state funded, semi-funded and private schools. Subjects were selected at random, by level and sex at schools. Standardized anthropometry, maturation, blood pressure, six minutes walk test (6MWT), standing long jump (SLJ) and grip strength (GRS) were measured.

Results: Obesity prevalence was 19, 7 % of obesity (22, 1% in girls and 17% in boys). CV risk expressed as WC>P90 occurred in 16, 5%, 3, 5% had PA >P90 and had 51, 3 23, 9 mm subcutaneous fat. Two z-scores were built and compared to PF test. Thus, children in the PF lowest tertiles, increased 2, 7 their CV risk. Children from state schools and girls had the worst PF and CV risks.

Conclusions: Excess fat, WC> P90 and BP> P90 were found in children with worst PF. Thus, with routine and easy measurements at schools, children at CHV risk could detect, without collecting blood samples. Low PF is a potent marker of CHV health risk in school children.

Key words: physical fitness, zscore, cardiovascular health.

PO1486

REDUCING ADDED SALT IN VEGETABLE SOUP: HEDONIC IMPACT IN ELDERLY AND PRE-SCHOOL CHILDREN

C. Gonçalves¹, S. Monteiro¹, P. Padrão¹, A. Rocha¹, S. Abreu², O. Pinho^{1,3}, P. Moreira^{1,2,4}

¹Faculty of Nutrition and Food Sciences, University of Porto, Portugal

²Research Centre in Physical Activity, Health and Leisure, University of Porto, Portugal

³REQUIMTE, Laboratory of Bromatology and Hydrology, Faculty of Pharmacy, University of Porto, Portugal

⁴Public Health Institute from the University of Porto, Portugal

Background and objectives: Reducing salt intake and implementing a strategy of small reductions is often advised. The objective of this study was evaluate the impact of a 30% reduction of the vegetable soup salt content on elderly and children's hedonic preferences.

Methods: This study took place in a natural setting (institutional canteens). Elderly subjects were 29 older adults (79.7±8.9 years, 20 females), who were recruited in two public nurseries (NH1 and NH2). The 49 children (4.5±1.29 years, 26 girls) were recruited from a public pre-school (PS). Through randomization and cross-over, the subjects tasted and evaluated a vegetable soup prepared as usual and a variant soup with a 30% salt reduction, in consecutive days. The order of presentation of the two soups was different across nurseries and schools. Salt content was determined using flame photometry method. A hedonic description of the food variants was performed; elderly evaluated hedonic perception using a visual analogue scale with 10 cm line scale (from "very good" to "very bad"), and children evaluated hedonic perception through perceived liking ranking using a five point facial scale.

Results: The mean baseline salt levels/100 g soup were 300.7 mg, 206.7 mg, and 147.0 mg, respectively in NH1, NH2, and PS; reductions of 30% were prepared on these values. Statistical significant differences on hedonic evaluation between reduced salt content soups and soups with usual salt levels were not observed. The results of hedonic evaluation, before and after reduced salt content were 0.7 and 0.8 in the elderly, and 4 and 4 in children.

Conclusions: No impact of a 30% decrease in salt content of vegetable soup was found either in children and elders. The reduction of 30% of added salt could be considered without suppressing the hedonic value of vegetable soups.

Key words: Elderly, Pre-school Children, Salt, Hedonic, Soup.

PO1487**THE COST OF HOME DELIVERY SCHEMES FOR LIPID-BASED NUTRIENT SUPPLEMENT PRODUCTS: A POLICY EXPERIMENT FROM RURAL MALAWI**

S. Vosti¹, J. Humber¹, T. Phiri², P. Ashorn³, K. Maleta⁴, K. Dewey⁵

¹Department of Agricultural and Resource Economics, University of California, Davis, Davis, CA, USA

²iLiNS Project, University of Malawi, Blantyre, Malawi

³Department of International Health, University of Tampere Medical School, Tampere, Finland

⁴Department of Community Health, University of Malawi College of Medicine, Blantyre, Malawi

⁵Department of Nutrition, University of California, Davis, Davis, CA, USA

Background and objectives: Public policy makers may play a role in promoting products demonstrated to be efficacious in addressing hidden hunger. Home delivery reduces the out-of-pocket costs of accessing these products, to zero if they are provided for free. However, home delivery is not cheap, especially in rural areas; little is known costs. This paper provides evidence based on a home-delivery scheme undertaken by the International Lipid-Based Nutrient Supplements (iLiNS) Project research team in rural Malawi.

Methods: Estimates of home delivery costs for lipid-based nutrient supplements (LNS), including product procurement, transportation, staffing and storage costs, are based on those faced by the iLiNS-DOSE Project. A cost model was developed and used to run a hypothetical five-year policy experiment to provide nationally produced LNS to 60% of the approximately 12, 000 young children aged 6-24 months. LNS is delivered bi-weekly to all children in the targeted age bracket; thus, older early-enrollees and young late-enrollees would not receive the full 18-month intervention.

Results: Total cost of the hypothetical five-year intervention would be approximately US\$3.3m. Cost per treated-child is US\$69; cost per fully-treated-child is US\$89. 63% and 21% of the total cost is attributable to product purchases and personnel costs, respectively.

Conclusions: Low effective demand for products proven to combat hidden hunger may prod delivery of these products directly to targeted children's homes. A five-year hypothetical policy experiment suggests that the cost of procurement, storage and weekly home delivery of a nationally produced LNS product can be large. Changes to intervention protocol (target population, frequency of delivery, etc.) will affect costs. The expected health and other benefits associated with each proposed intervention strategy would have to be compared to these costs in order to set priorities.

Key Words: Nutrient Supplements; Home Delivery; Malawi

PO1488**EFFECTS OF ALTERNATIVE SPATIAL DISTRIBUTION SCHEMES ON HOUSEHOLD ACCESS COSTS OF LIPID-BASED NUTRIENT SUPPLEMENTS: CASE STUDY IN RURAL BURKINA FASO**

S. Vosti¹, M. Hamilton², R. Guissou³, J. Ouedraogo⁴, K. Brown⁵, S. Hess⁵

¹Department of Agricultural and Resource Economics, University of California, Davis, Davis, CA, USA

²Department of Environmental Science and Policy, University of California, Davis, Davis, CA, USA

³Institut de Recherche en Sciences de la Santé, Bobo Djoulasso, Burkina Faso

⁴Institut de Recherche en Sciences de la Santé, Ouagadougou, Burkina Faso

⁵Department of Nutrition, University of California, Davis, Davis, CA, USA

Background and Objectives: Identifying cost-effective strategies for delivering efficacious nutrient supplements is a policy challenge, especially in rural areas. This paper examines the effects of alternative distribution outlet schemes on transportation costs of 3, 146 households in the Dandé health clinic catchment area (1, 600 sq. km), Burkina Faso, site of the International Lipid-Based Nutrient Supplements Zinc research project.

Methods: Spatially referenced data on households, hospitals, clinics and markets, and on the road networks that link them, are combined with the motorized transportation fare structure to construct a distance-based transportation cost overlay. This overlay is then used to estimate the household-specific, one-way transportation costs under alternative lipid-based nutrient supplement (LNS) distribution outlet schemes.

Results: If the full-service Bobo Dioulasso Hospital is the only outlet, there is a wide range of household-specific one-way transportation costs; average transportation cost is US\$ 1.96. Extending the distribution network to include the local, limited-service Dandé Hospital reduces the average transportation cost to US\$ 1.16; the spatial distribution of household access costs changes. Extending the network to include all health centers reduces average transportation cost to US\$ 0.60. Adding markets as distribution outlets does not further reduce average transportation costs. Results of this distance-based approach could be expressed in other metrics, e.g., walking time, without loss of generality but perhaps with different policy implications.

Conclusions: Full-service hospital-based (only) distribution is the most costly LNS distribution scheme to households.

Extending the network of outlets to include all hospitals, health centers and clinics reduces average households access costs by nearly 70%; doing so shifts the cost burden from households to other entities charged with managing this larger outlet network. Using this model, involving retail outlets offers no household transportation costs savings.

Key Words:Transportation Costs; Burkina Faso; LNS Acknowledgement Funded by the Bill & Melinda Gates Foundation.

PO1489

EPIDEMIOLOGY OF FOOD POISONING IN CHILDREN

F. Hadrya¹, H. Hami¹, S. Benlarabi², D. Benali¹, R. Soulaymani-Bencheikh^{2,3}, A. Soulaymani¹

¹Laboratory of Genetics and Biometry, Faculty of Sciences, Ibn Tofail University, Kenitra, Morocco

²Moroccan Poison Control Center (MPCC), Rabat, Morocco

³Faculty of Medicine and Pharmacy, Mohammed V University, Rabat, Morocco

Background and objectives: Food-borne diseases are a widespread and growing problem of public health. They spared no age, no country region and can happen at any time. One of the main vulnerable groups is the children. This study aims to determine characteristics of food poisoning among children aged less than 6 years old in Morocco, in order to better understand this problem to reduce the morbidity and mortality resulting from it.

Methods: A retrospective analysis of food poisoning cases occurred in Morocco, notified between 1992 and 2008 in the Moroccan Poison Control Center (MPCC), was performed.

Results: During this period, 2 589 cases of food poisoning among children under the age of 6 years have been reported to MPCC, 97% to the emergency department. According to reported data, boys were more exposed to poisoning than girls ($p < 0.01$). Of the 1 468 cases for whom the food has been identified, dairy products were the most accused. The mean consultation length was 9 hours. Most patients had shown digestive disorders accompanied by general, neurological and respiratory disorders. Of the 1719 cases for whom the evolution is known, 12 of them died and 2 children aged 2 and 6 years had developed sequelae. The health status of other children has improved under decontamination and symptomatic treatment.

Conclusions: The efficient treatment remains prevention focused on public awareness about the dangers of this type of poisoning, especially for those at risk, children and the elderly.

Key words: Food; Poisoning; Child; Epidemiology; Morocco.

PO1490

STAPHYLOCOCCUS AUREUS IN DAIRY PRODUCTS AND FOOD POISONING IN MOROCCO

F. Hadrya¹, H. Hami¹, S. Benlarabi², D. Benali¹, A. Elouardi³, S. Senouci³, R. Soulaymani-Bencheikh^{2,4}, A. Soulaymani¹

¹Laboratory of Genetics and Biometry, Faculty of Sciences, Ibn Tofail University, Kenitra, Morocco

²Moroccan Poison Control Center (MPCC), Rabat, Morocco

³Department of Microbiology and Food Hygiene, National Institute of Hygiene, Rabat, Morocco

⁴Faculty of Medicine and Pharmacy, Mohammed V University, Rabat, Morocco

Background and objectives: In Morocco, *Staphylococcus aureus* is the most common cause of bacterial gastroenteritis, due to consumption of contaminated food. The aim of this study is to describe the epidemiological and microbiological profile of dairy poisoning in the Rabat-Salé-Zemmour-Zaer region.

Methods: A retrospective study was conducted on food poisoning cases reported to the Moroccan Poison Control Center (MPCC), between 2004 and 2008, and data of dairy products samples (sold in small and large commercial surfaces) analyzed in Laboratory of Food Microbiology at the National Institute of Hygiene in Rabat, during the same period.

Results: During 2004-2008, the MPCC has recorded 141 cases of dairy poisoning whose 127 cases were from Rabat. Urban area was the most affected ($p < 0.001$). Nearly half of cases were recorded in autumn. The average age of victims was 7 years old. Milk and milk beverages were frequently involved (62%). Most patients had shown hepato-digestive disorders. Six cases were presented in addition, asthenia, cutaneous signs and dizziness. The health status of patients has improved under symptomatic treatment. Analysis of variance showed significant effects of age and consultation length on patients' health status. During the study period, 1 383 samples were analyzed, of which 677 dairy products samples were unfit for consumption. Enterotoxin-producing *Staphylococcus* were detected in 6% (41/677) of these samples at mean levels of 106 CFU.g⁻¹. Contamination peak was recorded in autumn (27%). Cream is the dairy product that has been most involved (34%).

Conclusions: Due to the universal standards, some dairy products had not a proper quality for use by consumers, even in times of cold weather. High levels of contamination by *S. aureus* may be due to bad storage mainly, and lack of equipment and staff hygiene.

Key words: Dairy; Poisoning; *Staphylococcus aureus*; Morocco.

PO1492

CONSTRUCTION AND ON-LINE PUBLICATION OF A DATABASE OF WORLDWIDE FOOD AND NUTRITIONAL GUIDES AND BENCHMARKS

G. Botelho^{1,2}, S. Rodrigues

¹Coimbra College of Agriculture, Polytechnic Institute of Coimbra, Coimbra, Portugal

²Department of Food Science and Technology, CER-NAS Research Unit, Coimbra College of Agriculture, Polytechnic Institute of Coimbra, Coimbra, Portugal

Background and objectives: In this research work, food and nutritional guides and benchmarks, from several countries around the world were identified and compiled. All collected documents are related to the food and nutrition education theme and to healthy lifestyles strategies, capable of reflecting the nutritional recommendations directed towards various target groups. This information refers to 64 countries and totalizes 601 food and nutritional guides and benchmarks.

Methods: For database construction, the documents were separated by continents and, for a better organization, 7 regions emerged: Europe, North America, Central America, South America, Africa, Asia and Oceania. In total, 66 tables were created, presenting 7 different sections: institution identification, guide/benchmark name, publication year, legal deposit (only available for Portugal and Spain), ISBN (only for countries with this information available), access link for the on-line document availability and, finally, the date when each document was first accessed.

Results: A database entitled “Food and Nutritional Guides and Benchmarks in the World” was built being freely available and downloadable in the official web site of the Public Higher Education Institution “Escola Superior Agrária de Coimbra” (Instituto Politécnico de Coimbra) through the electronic address www.esac.pt (in the banner entry “trabalhos de alunos”, translated in English as “students’ works”).

Conclusions: Recognizing that all this information will never be complete, this database is potentially a useful tool, not only for students, but also for researchers, teachers, educators, instructors and health professionals in the areas of food and nutrition sciences. Additionally, it is intended that the database should be seen as a dynamic instrument able to potentiate the interest due to its continuous update, encouraging the search for new knowledge.

Key words: guides, benchmarks, food, nutritional, on-line database.

PO1493

POLICY IMPLICATION OF QUALITATIVE EXPLORATION OF STAKEHOLDERS PERSPECTIVES ABOUT INTEGRATION OF ESSENTIAL NUTRITION ACTIONS/INTERVENTIONS INTO NIGERIA HEALTH SYSTEM

O. Anjorin¹, I. Akinyele¹

¹Department of Human Nutrition, University of Ibadan, Ibadan, Oyo State, Nigeria

Background and objectives: Significance of an enabling environment for nutrition has not been studied in Nigeria and contextual issues continue to affect scale-up of efficacious nutrition interventions. Within Nigeria health system, it is not clear how nutrition interventions are being integrated into critical contact periods. This study examined perceptions of key stakeholders involved with nutrition planning and implementation, to understand enabling environment for integrating essential nutrition actions/interventions (ENAs) into the Nigeria health system.

Methods: Semi-structured interviews were conducted with 30 nutrition stakeholders from donor agencies, federal and state ministries and agencies of health, academia and independent nutrition consultants who were recruited through snowballing technique. Interviews focused on respondents perception of nutrition as it relates to WHO’s six building blocks of the health systems. Thematic analysis was then conducted to identify common themes.

Results: In-depth analysis showed that most stakeholders perceived that leadership and governance for ENAs programmes in Nigeria is weak and characterized by poor- coordination, commitment and resource allocation and low-level of advocacy. Financing and supplies for ENAs in Nigeria are donor and development partners driven with very little government commitment. Human resources for nutrition were perceived as deficient since most personnel implementing ENAs are not trained nutritionists. Stakeholders further adjudged that ENAs implementation have not been systematically integrated into the primary health care system. Nutrition information systems in Nigeria were likewise considered as non-existent, with no harmonized method of data collection and integration.

Conclusions: In Nigeria, integration of ENAs is weak across the six building blocks of health systems. Stakeholders recommended that having a coordinating agency for nutrition directly under the Presidency is the best for integrating ENAs into the Nigeria health system. It is implied that engaging policy makers through advocacy is necessary to improve nutrition integration.

Key words: Nutrition interventions, Stakeholders perspectives, policy.

PO1494

SITUATIONAL ANALYSIS OF NATIONAL POLICY ON FOOD AND NUTRITION IN NIGERIA

O. Anjorin¹, I. Akinyele¹

¹Department of Human Nutrition, University of Ibadan, Ibadan, Oyo State, Nigeria

Background and objectives: Since the launch of the Nigerian National Policy on Food and Nutrition in year 2002, there has been no assessment of the state of implementation of its key elements. Indeed, although the active period of the document ends in four years (year 2016), it is not clear what has been achieved in its implementation. This study therefore assessed the nutrition policy performance through a desk review of nutrition related programmes documents in Nigeria.

Methods: Content analysis of the National Policy on food and Nutrition (NPFN), and the National Plan of Action for Nutrition (NPAN) were conducted with a focus on health related content. Performance of the health related nutrition interventions and activities were assessed based on availability of guidelines, training manuals and programmes implementation documents as well as technical reports.

Results: The NPFN had five specific objectives of which three were directly related to health sector implementation. As detailed in the NPAN, health sector tasks related to policy has been achieved through the Federal Ministry of Health (FMOH) with the development and dissemination of training manuals for IYCF and revision of these guidelines in the year 2011. Guideline on Nutritional Care and Support for People Living with HIV in Nigeria was also developed in year 2011. The National Primary Health Care Development Agency (NPHCDA) likewise developed the Maternal Newborn and Child Health Week training manual among others. Content analysis showed that actual interventions implementation has been fragmented and uncoordinated. Information about programme financing was also deficient, so it was not possible to assess policy and programmes financing. Available information showed high donor reliance in financing of nutrition activities.

Conclusions: Although certain health related elements of the nutrition policy have been implemented, they have neither been implemented at scale nor coordinated.

Key words: Nutrition Policy, Situation Analysis, Implementation.

PO1495

EFFECT OF MEDITERRANEAN DIET COMPONENTS ON SELECTED CARDIOVASCULAR RISK FACTORS, ALL-CAUSE MORTALITY AND CARDIOVASCULAR MORTALITY: SYSTEMATIC REVIEW

Y. Yuliana¹, M Y. Chan¹

¹Newcastle University, Newcastle, UK

Background and objectives: Mediterranean diet has been associated with lower risk of cardiovascular diseases. Objective: To evaluate the cardioprotective effect of some of the popular Mediterranean dietary components: olive oil, fish, fruits and vegetables, wholegrains and wine and to propose suitable recommended dietary dosage and frequency of the consumption.

Methods: A updated systematic review of observational and intervention studies in Scopus database (including Medline database) was performed. Inclusion criteria include English-publication studies published since 2001 up to 31 January 2013, adult participants (≥ 18 years old), interventions which stated frequency of consumption of each investigated component. For studies which showed at least one significant improvement of outcome was considered as cardioprotective.

Results: A total of 4,033 abstracts were obtained prior to title and abstract screening. Out of this, 67 original research studies were reviewed and 39 studies were included in the final rigorous list for review. Of these 39 studies, 34 had shown protective effects.

Conclusions: Current recent evidence showed that consumption of olive oil, nuts, legumes, fruits and vegetables, wholegrains, and moderate alcohol/wine consumption) could help to reduce the risk of cardiovascular disease and mortality.

Key words: Mediterranean diet cardiovascular risk all-cause mortality cardiovascular mortality

PO1497

WHAT IS THE OBESITY PREVALENCE OF NORTHERN CYPRUS?

C. Gezer¹, S. Dal¹, E. Ozer¹, S. Yucecan¹

¹Near East University, Faculty of Health Sciences, Department of Nutrition and Dietetics, Turkey

Background and Objectives: Obesity is a complex multifactorial chronic disease and its prevalence increases day by day on all around the world. Thus, in this study it's aimed to evaluate adult obesity prevalence of Turkish Republic of Northern Cyprus (TRNC).

Methods: The subjects were 1740 adults (738 males, 1002 females) aged 19-65 years (39.1 ± 13.3 year) who were selected

to constitute a representative Northern Cyprus population as a whole between June-July 2012. Height and weight were obtained using standardized equipment. Overweight was considered at BMI of 25 to 29.9 kg/m² and obesity at a BMI of >30 kg/m².

Results: The mean BMI was 27.2±4.5 kg/m² in men and 26.8±6.1 kg/m² in women. The prevalence of overweight and obesity was 34.4% and 26.4%, respectively in Northern Cyprus. This results significantly differs between five main area of country. Remarkably, Güzelyurt has the lowest (16.4%), Nicosia and Iskele have the highest (28.8%) prevalence. The prevalence of obesity increases by the age groups (19-30yr, 31-50yr, 51-65yr); 11.7%, 27.4% and 44.3%, respectively (p<0.05). There was statistically significant positive correlation between age and BMI. The prevalence of overweight and obesity in men was 40.2% and 25.7%, respectively. The corresponding percentages in women were 30.0% and 26.9%.

Conclusions: The prevalence of overweight and obesity in Northern Cyprus adult population is very high. A national plan of action to overcome obesity is urgently needed to reduce the economic and health burden of obesity in this country.

Key words: obesity, body mass index, nutrition.

PO1498

URBAN GHANANIAN CHILDREN WITH LESS PHYSICAL ACTIVITY ARE MORE PRONE TO OVERWEIGHT/OBESITY

E. Colecraft¹, A. Lartey¹, G. Marquis², G. Otoo¹

¹Department of Nutrition and Food Science, University of Ghana, Ghana

²School of Dietetics and Human Nutrition, McGill University, Canada

Background and objectives: Childhood obesity, a growing public health concern in developing countries, puts children at risk of serious health problems later in life. In Ghana, there is limited data on the magnitude and determinants of overweight/obesity in children to inform public health interventions. We aimed to determine the prevalence and determinants of overweight/obesity among school-age children in two major urban centers in Ghana.

Methods: Cross-sectional survey of 3, 089 pupils aged 9 to 15 years attending private or public schools in Ghana's two largest urban centers (Accra and Kumasi). Children and their mothers were interviewed on socio-demographic characteristics and the children's dietary intake and physical activity in the past week. Children's weight and height measurements were taken and their BMI for age and sex computed. Logistic regression was used to explore household and individual factors associated with overweight/obesity (WHO BMI Z-Score >1SD) in the children.

Results: More children were overweight/obese (14.7%) than underweight (3.9%). Female children were 2.4 (CI: 1.79, 3.13) times more likely to be overweight/obese than male children. Household factors associated with increased risk of overweight/obesity among the children included mother having completed post-secondary education vs. mother having no formal education (OR=1.84; 95% CI: 1.02, 3.32) and household in the third tertile of socioeconomic status vs. being in the first tertile (OR=.5; 95% CI: 1.12, 1.99). Children who never walked to school and children who engaged in a sporting activity fewer than 3 days a week had at least 36% higher odds of being overweight/obese compared to those who sometimes walked to school or engaged in a sporting activity at least 3 days a week.

Conclusions: Improving physical activity habits among school-age children is important for addressing overweight/obesity in this population. The study was funded by International Development Research Center (IDRC, Canada).

Key words: overweight, obesity, school-age children, Ghana.

PO1499

VOLUME AND PATTERNS OF PHYSICAL ACTIVITY IN RURAL CAMBODIAN CHILDREN AGED 15-MONTHS

M. Ogden¹, N. Roos¹, D. Faurholt-Jepsen¹, J. Skau¹, H. Friis¹, C. Ritz¹, S. Brage², C. Chamnan³

¹Department of Human Nutrition, University of Copenhagen, Copenhagen, Denmark

²MRC Epidemiology Unit, Institute of Metabolic Science, Addenbrooke's Hospital, Cambridge, United Kingdom

³Department of Fisheries Post-Harvest Technologies and Quality Control (DFPTQ), Fisheries Administration (FiA), Ministry of Agriculture, Forestry and Fisheries, Phnom Penh, Cambodia

Background and objectives: At present the physical activity of young children resided in low-income countries remains relatively unexplored. The main purpose of this study is to contribute to fill out a knowledge gap regarding the prevalence and patterns in young Cambodian children's physical activity.

Methods: 397 toddlers (M: n = 215, F: n = 182) wore accelerometers GT3X+ Actigraph accelerometers for six consecutive days. Outcomes were total activity, expressed as mean counts per minute (cpm), sedentary activity (SED; cpm < 100) and moderate-to-vigorous intensity physical activity (MVPA; cpm > 1676) and the percentage of children meeting the current recommendations of 180 minutes physical activity per day. Gen-

der differences in outcomes were tested in multiple regression models.

Results: Despite 25% and 11% of children presenting chronic and acute malnutrition, respectively, children expressed high levels of total activity (891cpm) and MVPA (18%). However, the majority of time was spent sedentary (64%) and roughly 55% of children met recommendations for daily physical activity. Despite similar hour-by-hour patterns between genders, girls were 2- 4% less sedentary between 8:00-9:00 PM whereas boys demonstrated significantly higher total activity and accumulated more MVPA over the whole day ($p < 0.001$).

Conclusions: Though gender discrepancies in physical activity are present at an early age, both genders displayed high-active-high-sedentary profiles. The results also indicate a need for early prevention of physical inactivity among Cambodian children and further provide information on specific time points in which opportunities for reducing SED may be more effective if each gender is targeted. Longitudinal monitoring of physical activity levels and changes in activity patterns are recommended from the onset of early childhood in order to assess a potential impact of the transition to school on physical activity levels.

Key words: Sedentary Behaviour, MVPA, Accelerometer, Early Childhood, Malnutrition.

lly processed foods (Group 1), processed culinary ingredients (Group 2) and processed and ultra-processed products (Group 3). Dietary indicators were calculated according to quintiles of the contribution of Group 3 products to the total energy intake.

Results: Food products supplied 30.5% of the total energy intake. Energy density and the percentage of total and saturated fat, trans fatty acids and free sugars, all significantly increased with increases in the contribution of Group 3 products to the diet, while the opposite was observed for dietary fiber, iron, zinc, potassium and vitamin C. These significant associations were not changed after control for income and other socio-demographic confounders. Group 3 products taken together were more fatty, sugary, salty and energy dense than a combination of Group 1 and Group 2 items. Only the 20% lowest consumers of food products were anywhere near reaching World Health Organization nutrient goals for the prevention of obesity and chronic non-communicable diseases.

Conclusions: The high energy density and the unfavorable nutrient profile of food products indicate their potential harmful effect on human health. Healthier diets involved low consumption food products and high consumption of meals based on minimally processed foods.

Key words: Food; Food processing, Nutrition; Nutrient profile.

INTAKE OF PROCESSED AND ULTRA-PROCESSED FOOD PRODUCTS IN BRAZIL AND THEIR IMPACT ON OVERALL DIET QUALITY

M.L. Louzada¹, A.P.B. Martins¹, D.S. Canella¹, L.G. Baraldi¹, R.B. Levy², R.M. Claro^{1,3}, J.C. Moubarac¹, G. Cannon¹, C.A. Monteiro¹

¹School of Public Health/University of Sao Paulo, Brazil

²Faculty of Medicine/University of Sao Paulo, Brazil

³School of Nursing, Department of Nutrition/Federal University of Minas Gerais, Brazil

Background and objectives: Increased consumption of industrially processed food products is a major cause of the current pandemic of obesity and related chronic non-communicable diseases. Potential mechanisms to explain this association include their high energy density and unbalanced nutrient profile. The objective of this study was to assess the intake of these products in Brazil in 2008-2009 and their impact on the overall quality of diets.

Methods: Data analyzed came from 24-hour food records applied to a probabilistic sample of 34,003 Brazilians aged 10 and older as part of the 2008-2009 National Household Budget Survey. Foods were classified as unprocessed or minima-

PO1501

NUTRITIONAL CONDITION, INTESTINAL PARASITOSIS AND LEUKOGRAM OF NURSERY CHILDREN IN SERRINHA, JUAZEIRO AND SALVADOR (BRAZIL)

M.F. Brazil dos Santos Souto¹, R. Brazil dos Santos Souto², M.L.P. Nascimento³, M.J. Rosales²

¹Estado de Bahia University, Brazil

²Granada University, Spain

³Fundação para Asistencias as Anemias Parasitosis e Desnutrição, Brazil

Background and objectives: Nutritional condition abnormalities bring immunologic deficiencies on children which makes leukogram abnormalities mainly. If there is intestinal parasitosis. Nutritional classification on children at Serrinha, Juazeiro and Salvador nurseries (Bahia-Brazil) in 2012 and results correlation with leukogram results and parasitosis presence.

Methods: It was valued 140 children of both sex between 2 to 6 years old from Serrinha, Juazeiro and Salvador (Bahia). They were valued by weight, height and sex using anthropometric evaluation through Epinut/Epi-Info, (3.5.2) and National Center for Health Statistics - NCHS standarts. Parasitologic exams were made from faece samples using Hoffman, Pons and

Janer methods. Leucograms were made by hematologic counter Pentra 120 Retic Horiba/ABX using EDTA preserved blood.

Results: it was analyzed 140 children (48 boys and 92 girls) which ages are between 2 to 6 years old. 74% (n=104) eutrophic children and 21% (n=29) children with low weight and 5% (n=7) children with obesity. 56% (n=78) of children were positive for intestinal parasitosis. It was monoparasitosis or polyparasitosis for protozoa and helminths like *Endolimax nana*, *Entamoeba coli*, *Entamoeba histolytica*, *Giardia intestinalis*, *Trichuris trichiura*, *Ascaris lumbricoides* and *Enterobius vermicularis*. 3 year old children presented the most frequency of parasitosis. Leukogram results were varied: total leukocytes (5,332 to 13,008 $\times 10^3/\mu\text{L}$), neutrophils (2,024 to 6,800 $\times 10^3/\mu\text{L}$), eosinophils (0,215 to 1,901 $\times 10^3/\mu\text{L}$), basophils (0,071 to 0,235 $\times 10^3/\mu\text{L}$), typical lymphocytes (2,050 to 4,182 $\times 10^3/\mu\text{L}$), atypical lymphocytes (0,067 to 2,120 $\times 10^3/\mu\text{L}$), monocytes (0,470 to 1,105 $\times 10^3/\mu\text{L}$).

Conclusions: Children were positive for intestinal parasitosis, most of them were eutrophic, but the rest had malnutrition and obesity. It exists leukocytosis and high eosinophilia on some children which must be caused by the pathologic agent presence. In order to reduce malnutrition and parasitosis a long-term intervention is needed.

Key words: Leucocytes. Malnutrition. Parasitosis.

PO1502

EFFECT OF RECOMMENDED PHYSICAL ACTIVITY DOSE ON OBSTETRICAL, NEONATAL AND MATERNAL METABOLIC OUTCOMES IN PREGNANT LATINA WOMEN

R. Ramírez-Vélez^{1,2}

¹Grupo GICAEDS. Facultad de Cultura Física, Deporte y Recreación, Universidad Santo Tomás, Colombia

²Programa de Fisioterapia, Facultad de Salud, Universidad Manuela Beltrán, Colombia

Background and objectives: To evaluate the influence of recommended physical activity dose on obstetrical, neonatal and maternal metabolic outcomes in pregnant latina women.

Methods: The study included Sixty-seven nulliparous in gestational week 16–20, attending for prenatal care at three tertiary hospitals in Colombia who were randomly assigned into one of two groups: 1) The experimental group took part in aerobic exercise at an intensity of 55–75% of their maximum heart rate for 60 min, three times a week for 12 weeks, 2) The control group undertook their usual physical activity. The primary outcomes were changes in immediately after the 12 weeks intervention on blood lipids, insulin sensitivity (HOMA-IR), body composition and cardiorespiratory fitness. Obstetrical

and neonatal outcomes measures were type of delivery, postpartum hemorrhage, newborns maternal and complications, gestational age, birthweight, fetal growth and APGAR score.

Results: At the end of the 12-week program, there was no difference in blood lipids or insulin sensitivity. The experimental group showed lower values in BMI, fat-free mass, body fat and skinfold thicknesses than did the control group, but these differentials were non-significant. Intention-to treat analysis revealed that the exercise group had a greater cardiorespiratory fitness at the end of the intervention, measured by VO_2 . Experimental group showed lower complications during delivery (postpartum hemorrhage moderate) than did the control group, (58% compared with 75%, $P = 0.05$) and lower complications in newborns (meconium, cyanosis or respiratory distress) than did the control group, (21% compared with 46%, $P = 0.01$).

Conclusions: The potential public health benefits of exercise are too great and this study supports existing guidelines indicating that latina women may begin or maintain an exercise program during pregnancy.

Key words: Physical Activity; Pregnancy; Newborns; Maternal complications.

PO1503

HOW MUCH LAND IS REQUIRED TO PRODUCE A HEALTHY DIET WITH REDUCED GREENHOUSE GAS EMISSIONS IN THE UK?

J. Kyle¹, S. Apariman¹, A. Hastings¹

¹University of Aberdeen, Aberdeen, UK

Background and objectives: One of the challenges facing public health nutrition today is changing peoples' dietary behaviour to meet dietary recommendations for health whilst ensuring environmental and economical sustainability. Recently there has been a focus on estimating the environmental impact of national diets and modelled diets, meeting nutrient requirements, based on dietary associated greenhouse gas emissions (GHGE). However, environmental sustainability is a multifaceted challenge encompassing not only reduction of greenhouse gas emissions, but also ensuring sufficient appropriate agricultural land is available to meet the requirements of a healthy GHGE reduced diet. The aim of the current study was to predict the area of land required in the UK to deliver a healthy, GHGE reduced diet for a woman.

Methods: Linear programming was used to create a sample food list for a seven day diet meeting UK dietary recommendations for an adult women and a 25% reduction of dietary associated GHGE (compared to 1990 levels). Assessment of land requirements was completed after conversion of food items to their equivalent raw food commodity weight, before annual per capita and UK population land areas were calculated.

Results: A diet meeting UK dietary recommendations for a woman achieving reductions in GHGE requires 0.412 hectares/person/year. Adjustment to the UK population indicates 28 million hectares would be needed to sustain a healthy, GHGE reduced diet annually. Cereal crops accounted for the largest acreage.

Conclusions: When compared to agricultural land in the UK (18.3 million ha), it would be impossible for the UK to be self sufficient in food production. When designing healthy diets the acreage demands on limited agricultural land to ensure food availability needs to be considered.

Key words: sustainable diets, healthy, greenhouse gas emissions, food, land use.

PO1504

FOOD ADVERTISING AND MEDIA: HOW DO THEY INFLUENCE DIETARY BEHAVIOR?

E. Alexiou¹

¹University of Thessaly, Greece

Background and objectives: Dietary behavior is formed by a combination of factors among which may also be included the media. The main aim of the study was to evaluate and compare the level of basic nutrition knowledge of three different age groups.

Methods: A new validated questionnaire was devised and completed by 371 subjects. It was divided in 3 main sections which tested 5 knowledge domains. Questions focused on areas of nutrition which interested both adolescents and adults.

Results: Carbohydrates and fiber related questions were the most known. Salt and white sugar were shown to be “guilty”, since most participants seem to believe that they should avoid their consumption because of their energy content.

Conclusions: For the interpretation of these findings, the researcher suggested that they could be partly correlated to the multiple advertisements of the grain industries as well as the mass media’s impact on the consumer’s nutrition update. Thus, although food advertising may be of considerable help for the public, it can be misleading too. Current data highlight the importance of providing the right message in the appropriate way to the suitable audience.

Key words: Nutrition behavior, food advertising, sugar.

PO1505

DESIGN OF A WORKPLACE INSTRUMENT FOR HEALTH MEASURE, HEALTHY LIFESTYLE PROMOTION, SURVEILLANCE OF CARDIOVASCULAR RISK FACTORS AND METABOLIC SYNDROME DIAGNOSIS

Z. López¹, S. Castillo¹, R. Mendizábal¹, M. Peña¹

¹Occupational Health and Safety Department, Cementos Progreso S.A., Guatemala, Guatemala

Background and objectives: Guatemala is currently on an epidemiological and nutritional transition with increasing prevalence of chronic diseases. Considering workplace as a priority for health promotion, the objective of the study was design an instrument of health measure, that represent in one indicator biochemical test and health status parameters, at the same time promotes healthy lifestyle, do surveillance of cardiovascular risk factors and identify the risk group by the diagnosis of metabolic syndrome, useful for planning effective intervention programs.

Methods: Cross sectional study in 2, 537 employees in the construction area. The instrument GS1 evaluate and score 10 parameters: body mass index, body fat percentage, waist circumference, fasting glucose, HDL cholesterol, triglycerides, maximum oxygen consumption, abdominal muscle strength and upper limb strength. Metabolic syndrome was diagnosed using AHA/NHLBI criteria, information on lifestyle was collected and healthy lifestyle promotion was provided. Linear regression was used on each indicator, to establish the score of GS1. Descriptive statistics and chi-square test for hypothesis testing was performed in PASW 18.0.

Results: 89% of the study population was male, with a mean of 36.35 years old (SD: 9.6). 57% of participants were classified in excellent -acceptable health. The score predicted correctly the overall value of the note (p: 0.000). The most prevalent cardiovascular risk factors were overweight and obesity (71.6%), high triglycerides (58.3%), low HDL cholesterol (61.5%), physical inactivity (70.2%) and low intake of fruits and vegetables (92.1 %). 35.8% of the study group presented metabolic syndrome, associated with poor performance on the instrument (p:0.000). Association with smoking was also presented.

Conclusions: A valid and practical instrument has been designed that properly score health status based on the established parameters, promotes healthy lifestyle, do surveillance of cardiovascular risk factors and identify the risk group.

Key words: Health Measure, Cardiovascular Risk Factors, Metabolic Syndrome, Healthy lifestyle promotion.

PO1506**ENTEROPARASITOSIS PRESENCE IN LOW RENT 2 TO 6 SIX YEAR OLD CHILDREN IN SALVADOR NURSERY (BAHIA)**

R. Brazil dos Santos Souto¹, M F. Brazil dos Santos Souto², M J. Rosales¹, I M. Sousa Souza², T. Telles Reis², V L. Fenandes², N R. Fonseca²

¹Granada University, Granada, Spain

²Estado de Bahía University, Brazil

Background and objectives: Enteroparasitosis represent a high public health problem, especially in developing countries. They appear on different ways: diarrhoea, intestinal proteic loss, malnutrition, anaemia and abdominal pain... Scholar children are especially vulnerable group, it means there are risk factor and physic and cognitive development disturbance. To determinate intestinal parasitosis frequency in public nursery children sample at lacking economic zone between October to December 2011.

Methods: Through quantitative methodology 50 children between 2 to 6 six years old were randomly selected from a nursery placed at Doron (Salvador, Bahia), prior authorization of Research Ethics Committee. Parasitologic exams were made from faece samples using Hoffman, Pons and Janer methods at parasitology laboratory of Department of life science of Estado de Bahía University. Data was analyzed through EpiInfo 3.5.2 software.

Results: 64% (n=32) of children were male and 36% (n=18) were female. Parasitosis presence was detected in the 60% (n=30) of them. 50% (n=15) of female children had protozoan parasitosis and 40% (n=12) of male children had monoparasitosis. Some of parasites found were: Giardia intestinalis 50% (n=15), Ancilostomideo 6, 7% (n=2), Blastocystis hominis 6, 7% (n=2), Endolimax nana 57% (n=17), Entamoeba coli 20% (n=6) and Entamoeba histolytica. 3, 3% (n=1). 50% of children had more than one parasite.

Conclusions: Results demonstrate the need of a good health education in this place.

Key words: Enteroparasitosis. Children. Financial support: Centro de Iniciativas de Cooperación al Desarrollo (CICO-DE)/Universidad de Granada (UGR).

PO1507**EFFECTIVENESS OF COMMUNITY INTERVENTIONS FOR THE REDUCTION OF DIETARY SALT INTAKE: A SYSTEMATIC REVIEW**

A. Christoforou¹, M. Land¹, L. Chan¹, B. Neal¹, J. Webster¹

¹Food Policy Group, The George Institute for Global Health, Sydney, NSW, Australia

Background and objectives: High salt diets are strongly linked to raised blood pressure which is a major risk factor for cardiovascular diseases, particularly stroke. Community based salt reduction strategies which usually have a strong focus on consumer education, have been employed in various settings to ameliorate the rising burden of salt related disease. The objective of this research is to provide a systematic assessment of such interventions and to identify key strategies of successful programmes.

Methods: Electronic databases were searched up to July 2012 using search terms “salt” or “sodium” and “community” in combination with “campaign”, “initiative”, “project”, “strategy”, “intervention” or “program”. Data from both evaluate and unevaluated interventions were included. Studies were assessed for quality, characteristics, intervention components and outcome measures by two independent reviewers.

Results: In total, 33 community programmes were identified. The settings for these were varied, ranging from whole communities (n=13), local groups (n=12), schools (n=5) and workplaces (n=3). The strategies employed within these programmes could be categorised into: nutrition education programs, public education campaigns, or other ‘novel’ approaches. Of the 15 studies that evaluated intervention effectiveness significant decreases were observed in terms of urinary sodium excretion (n=5) and Systolic Blood Pressure (n=5) and 3 reported positive changes in consumer behavior.

Conclusions: Current evidence suggests that community interventions to reduce dietary salt are possible in a range of settings. Scaling up consumer awareness initiatives in coordination with activities to reduce the large amount of unnecessary salt in the food supply would provide the most effective and sustainable reduction in salt intake.

Key words: Salt reduction, Community intervention, Cardiovascular disease.

PO1508**FAMILY FARMING AND SCHOOL FEEDING: STRATEGY FOR PROMOTING HEALTHY EATING?***CRPA. Teo¹, C.A. Monteiro²*¹Universidade Comunitária da Região de Chapecó/Unochapecó, Chapecó, Brasil²Universidade de São Paulo/USP, São Paulo, Brasil

Background and objectives: In Brazil, Law 11.947/2009 determines that 30% of funds transferred to municipalities by the Federal Government to support the National School Feeding Program (PNAE) must be applied in purchasing from family farming food that promote healthy eating. The objective of this study was to identify the profile of acquiring food from family farming for PNAE in a cutout of the western region of Santa Catarina state, southern Brazil.

Methods: Data about food quantities purchased from family farming in three cities in 2010 were obtained and converted into energy. The food acquisitions were classified according to a Brazilian researchers' proposal that considers the extent and purpose of food processing: fresh, unprocessed or minimally processed food (group 1); cooking ingredients (group 2); ultra-processed food (group 3). One of the three municipalities evaluated did not record purchases from family farming during the study period, despite the legislation. The following results are from two municipalities.

Results: The average share in total calories acquired from family farming was 55.8% for group 1 (acquisition of beans, meat, milk, fruit, vegetables, roots, tubers), 10.4% for group 2 (acquisition of animal fat, sugar, pasta, flours, starches), 33.8% for group 3 (acquisition of breads, cookies, jelly, salami, cheeses). Favorably, the average share of group 1 in total calories was significantly higher than that observed for the household availability of these foods in Brazil, while the share of group 2 was much lower, showing the potential of acquiring food from family farming for promoting healthier eating habits in school environment. However, the relevant share observed of processed food high in saturated fat, sugar and sodium (group 3) lead us to conclude that the opportunity to promote healthy eating through the largest Brazilian public program of food and nutrition is being underutilized.

Acknowledgements: CNPq/Brasil (102231/2011-7).

Key words: Public health nutrition, Public policies, Nutrition programs and policies.

PO1509**THE PRICE OF FOOD FROM FAMILY FARMING CAN INHIBIT THEIR PARTICIPATION IN PUBLIC SCHOOL MEALS***CRPA. Teo¹, CA. Monteiro²*¹Universidade Comunitária da Região de Chapecó/Unochapecó, Chapecó, SC, Brasil²Universidade de São Paulo/USP, São Paulo, SP, Brasil

Background and objectives: Brazil has recently introduced a new model of public procurement with a view to health promoting and local development, easing the process of buying food from family farming to the National School Feeding Program (PNAE). The aim of this study was to evaluate the influence of food price from family farming on its participation in PNAE.

Methods: The amounts of food purchased from family farming and from conventional suppliers between 2008 and 2010 were obtained in three municipalities in Santa Catarina state, southern Brazil, and converted into energy. Foods were classified in fresh foods, minimally processed or unprocessed (group 1), culinary ingredients (group 2), ultra-processed food (group 3).

Results: The price of food purchased was expressed in U\$/1000 kcal. The average price of food from family farming was U\$1.11; the average price from conventional suppliers was U\$0.79. By year, food prices from family farming were U\$1.06 (2008), U\$1.14 (2009) and U\$1.11 (2010); prices from conventional suppliers were U\$0.87, U\$0.79 and U\$0.74. According food group, the average prices from family farming were U\$1.36 (Group 1), U\$0.48 (Group 2), U\$0.99 (Group 3); prices for conventional suppliers were U\$1.32, U\$0.30 and U\$0.82. The prices from family farming were always higher, inhibiting its greater participation in PNAE, to the detriment of local development and healthy eating. The price difference between both kinds of suppliers increased during the study period. The relative decrease in the price of products from conventional suppliers may represent a coping strategy of reducing the volume of sales to the school feeding due to the implementation of simplified purchase from family farming.

Conclusions: We conclude that the price of food from family farming may be inhibiting the full deployment of this new Brazilian public policy. **Acknowledgements:** CNPq/Brasil (process number 102231/2011-7).

Key words: Public health nutrition. Public policies. Nutrition programs and policies.

PO1510**A STUDY ON LIFESTYLE AND DIETARY BEHAVIORS OF ELEMENTARY STUDENTS INVOLVED IN EXTRACURRICULAR ACTIVITIES IN KOREA***K.J. OH¹, M.H. Kim², M.H. Kim³, M.K. Choi³*

¹Major in Nutrition Education, Graduate School of Education, Kongju National University, Yesan, Chungnam, South Korea

²Department of Food and Nutrition, Kangwon National University, Samcheok, Gangwon, South Korea

³Division of Food Science, Kongju National University, Yesan, Chungnam, South Korea

Background and objectives: Parents in South Korea are known for their high educational zeal for their children. As a result, their children usually take extra classes in institutions as well as participate in other extracurricular activities such as sports and music. The purpose of this study was to examine the lifestyle and dietary behaviors of Korean elementary students involved in such activities.

Methods: The number of total subjects was 550 fourth to sixth graders in elementary schools in Sejong, Korea.

Results: Of the total subjects, 88.0% were involved in extracurricular classes or other activities for an average of 7.34 hours/week. The subjects were assigned into one of four groups based on the degree of extracurricular activities: No extra-class (n=66), Low extra-class (1; taking time < 5 hour/week, n=118), Medium extra-class (5; taking time < 10 hour/week, n=184), and High extra-class (taking time ≥ 10 hour/week, n=182). More subjects of the High extra-class group went to bed late (p < 0.01), were under stress, and skipped breakfast than those in the other groups (p < 0.01). The reasons for skipping breakfast were mostly 'no time' and 'no appetite'. The ratio of the students who answered 'I go to an institute without a meal', 'I prepare a meal for myself', or 'I go out before going to an institute' was higher in the High extra-class than in the Low extra-class with a significant difference (p < 0.001). The frequency of eating fast food in the High extra-class was higher than that in the other groups.

Conclusions: These results indicate that a high amount of extracurricular studies may affect the children's lifestyles and dietary behaviors in a negative way. Therefore, this study alerts parents to the potential harm of excessive extracurricular activities to their children's health.

Key words: Dietary Behaviors, Elementary Students, Extracurricular Activities.

PO1511**BARRIERS TO VITAMIN A CAPSULE COVERAGE IN HARD TO REACH AREAS: FINDINGS FROM THE CHITTAGONG HILL TRACTS, BANGLADESH***E. Roy¹, D. Chakma¹, P. Ryland²*

¹Helen Keller International, USA

²Columbia University Mailman School of Public Health, USA

Background and objectives: Vitamin A-related morbidity has decreased dramatically in Bangladesh, primarily through distribution of Vitamin A Capsules (VAC). However, pockets remain where VAC coverage is inadequate and Vitamin A deficiency (VAD) continues to affect approximately one in five pre-school age children nationwide. Coverage is worst in hard-to-reach areas such as the Chittagong Hill Tracts (CHT), where poor infrastructure, a scattered population and often ethnic exclusion limit access to services. As part of a VAC program in the CHT, Helen Keller International (HKI) conducted a qualitative study to assess challenges in hard-to-reach areas.

Methods: Data was collected through key informant interviews and focus group discussions (FDGs) involving health facility managers and 20-24 community members in each of nine CHT sub-districts. Approximately 60% of FDG respondents were female.

Results: Reported VAC coverage varies, with health facilities reporting 94% coverage and FDGs reporting 87% coverage. Most community members were not aware of VAC's benefits, with only 15% reporting VAC improves children's health and 16% reporting VAC prevents night blindness. Barriers in accessing VAC included transport and/or road infrastructure (87%), engagement with agricultural tasks (25%) and superstitions (25%). Challenges with the delivery system were also highlighted, with 14% of community members reporting that VAC had run out by the time they reached the health center and several health facility managers reporting difficulty in reaching remote locations.

Conclusions: Coverage levels indicate that some children remain beyond the reach of health workers, and that systems to determine the number of eligible children and provide sufficient capsules still face challenges. Results highlight the need to develop innovative strategies for overcoming barriers to this life-saving intervention, including ensuring services are provided in the most remote locations (to address transport barriers) and families are mobilized to participate in VAC campaigns.

Key words: Vitamin A Capsule, Vitamin A Deficiency.

PO1512**DIGITAL FOOD GUIDE: MOBILE APPLICATION TO INCORPORATE HEALTHY FOOD CHOICES**

S. Caivano¹, MCR. Camargo², T. Anunciato², SMA. Domene¹

¹Department of Public Policies and Collective Health, Federal University of São Paulo, Brazil

²Instituto Nutra e Viva, Brazil

Background and objectives: There is an increasing prevalence of obesity, and this epidemic raises the budgets of health systems. In Brazil, 50.1% of adults are overweight and 12.4% are obese. A key strategy for the prevention of chronic diseases is to change the eating pattern. The increased interest and access to information technology is an opportunity to promote healthy food choices. This study presents the Digital Food Guide (DFG), in the form of smartphone mobile application and aims to evaluate the app as a resource to promote healthy food choices.

Methods: Retrospective cohort study through the analysis of food intake and body weight reported by application users, ages ranging from 19 to 50 years.

Results: Among the 442 subjects in the sample, there was a positive shift pattern of 31.45% in diet quality; 60% of users experienced a weight loss.

Conclusion: The application allows the reprogramming of food choices with the help of digital language and is an additional resource to disseminate food education with the aim of encouraging the individual to consume food consciously, favoring the prevention of chronic diseases and promoting a healthy diet.

Key words: Nutrition education. Dietary Guidelines. Cellular phone.

PO1513**ASSOCIATION BETWEEN ENVIRONMENTAL FACTORS OF SHOPPING AND NUTRITIONAL STATUS IN JAPANESE AGED OVER 65 YEARS**

Y. Kimura¹, H. Kuwada¹, M. Fuchigami¹

¹Department of Nutrition and Life Science, Fukuyama University, Fukuyama, Hiroshima, Japan

Background and objectives: Insufficient nutritional status is a frequent problem in elderly people. Objective of this study was to determine the relationship between environmental factors of shopping and the nutritional status in women aged over 65 years.

Methods: A cross-sectional study was carried out in 2012 for 107 elderly women living independently in Fukuyama, Ja-

pan. A dietary assessment was conducted using a brief self-administered diet history questionnaire (BDHQ) for the previous month. Subjects were divided into group A (65~74 years old) and group B (75~89). An analysis of covariance (ANCOVA) was used to examine the association between nutrient intake and environmental factors such as living alone and the shopping environment.

Results: The 64 group A, and 43 group B subjects' average ages were 69.5±2.7 and 79.8±3.8, respectively. The ratio of the subjects that felt shopping was inconvenient was significantly higher in group B (25.6%) compared with group A (9.4%) (p=0.03). The percentage of licensed drivers in group A was 57.8% (including 7.8% who were drivers in name only) and 11.6% in group B (P<0.001). Some 28.0% of subjects who live alone (average age, 77.5±6.5) was significantly higher than that of other subjects (72.2±5.0) (p<0.001). There was no difference in the intake of energy, protein or carbohydrate of all subjects. However, the intake of vitamin C was significantly lower for living alone subjects (p=0.002) after an adjustment for age and living area. The intake of vitamin C had no significant difference at subjects that felt shopping was inconvenient.

Conclusions: Environmental factors may affect the nutritional status of elderly Japanese women. This study showed an association between living alone and a lower intake of vitamin C. It might be beneficial to support elderly people who must shop but cannot drive to shopping.

Key words: nutritional status, shopping status, aging, cross-sectional study, epidemiology.

PO1514**HEALTHY FEEDING IN TEENAGERS: HOW TO PROMOTE IT? INTERDISCIPLINARY EDUCATIONAL EXPERIENCE MADE FROM COLLEGE TO THE COMMUNITY, SANTA FE, ARGENTINA**

G. Blaser¹, L. Ortigoza^{1,2}

¹Facultad de Bioquímica Y Ciencias Biológicas, UNL, Santa Fe, Argentina

²Facultad de Ciencias Médicas, UNL, Santa Fe, Argentina

Background and objectives: In Argentina there is plenty of food, yet few people have access to sufficient and varied amounts. Others lack the knowledge to make a diet that contributes to improving their quality of life. In both cases a poor diet can lead to diseases. The Nutritional Feeding Education is conceived as a tool for the exercise of autonomy, self-care and responsibility, being vital its application in children and teenagers. Argentine universities consider a priority to contribute to the promotion of The Nutritional Feeding Education.

Methods: In this research, we worked with 161 adolescents aged between 15-16 years, attending the 3rd. year of secondary school in Argentina. We followed a qualitative interpretive model through surveys, interdisciplinary workshops and interviews in depth. The questions that guide the process help to identify knowledge and social representations that this age group has about the concept of healthy feeding, so that then we can design and implement interdisciplinary educational activities, with the aim of promoting from the school, a reflective and self-critical attitude in participants. After the implementation of these strategies we investigated theoretical categories such as: - Alternative Conceptions - Theoretical knowledge- Eating Habits - Importance and Appropriation of the concept - emerging from the analysis of the stages mentioned above.

Results: There was a high percentage of students - 62% - with solid knowledge when making the diagnosis; and after the workshops, 48% of the surveyed modified their eating behavior.

Conclusions: The pre and post activities evaluations show a significant advance in the incorporation of water as a key element of the Argentine Oval Feeding: from 4% in the diagnostic test to 22% in the post-test.

Key words: Nutritional Feeding Education, Teenage years, Healthy Feeding, theoretical categories.

PO1515

EATING BEHAVIOR AND BODY IMAGE AMONG MEDICINE STUDENTS

M.L. Bosi¹, J.A.D. Nogueira², K.Y. Uchimura³, R.R. Luis⁴

¹Faculty of Medicine, Federal University of Cear, Brazil

²Faculty of Physical Education, University of Brasilia, Brazil

³Faculty of Nutrition, Fepar, Curitiba, Brazil

⁴Public Health Institut, Federal University of Rio de Janeiro, Brazil

Background and objectives: Eating disorders are defined as deviances on eating behavior that may lead to serious physical and psychological consequences. The onset of eating disorders appears to happen around 16 to 20 years of age, especially in women. Female university students are a high-risk population, but there is little scientific information regarding eating disorders in this group, especially from health related courses. This study aims to characterize eating habits, body shape image and their relation as risk factors for eating disorders among medicine students.

Methods: This is a cross-sectional study with a significant sample of 189 female undergraduate medicine students, aged 18 to 22 years. Body Mass Index (BMI) was calculated consider-

ring self-reported weight and height and the Bulimic Investigatory Test Edinburgh (BITE), Eating Attitudes Test (EAT-26), and Body Shape Questionnaire (BSQ) were applied. Descriptive statistics and correlation Spearman test were used; significance was set at $p < 0,05$.

Results: Mean (SD) age and BMI were 20.8 (2.2) years and 21.5 (2.6) Kg/m². BITE results showed prevalence of medium (some abnormal behavior) and high (risk for bulimia) scale symptoms of 31.7% and 6.3%, respectively. For severity, 6.3% of the girls presented moderate and 1.6%, intense symptoms. EAT-26 showed 19% prevalence for positive result (>21 points) associated with risk of developing eating disorders; and 27, 7% presented some body distortion by BSQ. Significant association ($p < 0.001$) was observed between BMI classification and abnormal eating behavior.

Conclusions: Although mean BMI was eutrophic, female undergraduate medicine students may represent a high-risk group for sub-clinical compulsive eating habits or an initial stage of bulimia. Although the majority of cases were not severe, attention must be given to eating behavior in this population; future health professionals may have their health and practice impaired in cases they present risk for eating disorders.

Key words: Eating disorders, body image, public health.

PO1516

CHILEAN SCHOOLCHILDREN WITH THE LOWEST SOCIOECONOMIC LEVEL HAVE THE WORST NUTRITIONAL STATUS AND PHYSICAL FITNESS

M. Suarez-Reyes¹, J. Meza Jara¹, R. Burrows¹, F. Navarro², G. Salazar¹

¹Institute of Nutrition and Food Technology, University of Chile

²Health Promotion, Metropolitan Health Secretariat, Ministry of Health

Background and objectives: Nutritional status (NS) and physical fitness (PF) are determinant factors of children and adolescents' health. Low socioeconomic level (SEL) affects eating habits and physical activity level. In Chile, SEL is related to the school type, those with low, medium and high SEL attend to Public (Pub), Subsidized (Sub) and Private (Pri) schools, respectively. School type is a SEL marker. The aim was to compare the NS and PF between children and adolescents, attending to different school types.

Methods: Schoolchildren were measured (N=1656; 29% Pub, 57% Sub, 14% Pri). BMI, waist circumference >90th percentile (WC>p90) and 4-skinfold sum (FAT) were used as NS markers; while the 6-minute walk test (6MWT), dynamometry and standing long jump as PF markers. Chi-square test established associations by the school type, sex and school levels.

Results: Pub schoolchildren had the highest overweight/obesity prevalence and WC>p90 ($p<0.05$). After sex analysis, differences were observed only in girls. Pub girls presented the highest FAT values ($p<0.01$). When both sex and levels were considered, differences in WC>p90 and FAT were present in girls from the oldest school levels ($p<0.01$). In muscular strength tests, the lowest performances were identified in Pub schoolchildren ($p<0.05$). By sex analysis, differences were found in girls, mainly from oldest school levels ($p<0.01$).

Conclusions: The results demonstrated an association between SEL (according to school type) and both NS and PF. The lower the SEL, the worse NS and PF. This relationship was mainly found in the oldest schoolgirls.

Key words: socioeconomic status, physical fitness, overweight.

PO1517

SUGAR CONSUMPTION AMONG CHILDREN AGED 3-6 YEARS OLD AND ITS RELATED FACTORS IN JAKARTA 2011

S. Bardosono¹, R. Sekartini¹, T. Wiguna¹

¹Medical Research Unit, Faculty of Medicine University of Indonesia, Jakarta, Indonesia

Background and objectives: Indonesian Basic Health Research 2007 found that 12.2% of children under-fives and 6.4-9.5% of school-children were obese. There is no study yet aiming to observe linked to this condition. This study aims to evaluate child sugar intake from foods and beverages consumption among Indonesian children aged 3-6 years, and its relationship to overweight-obese, tooth-decay and cognitive function status.

Methods: A cross-sectional study was applied to get the amount and food sources of sugar intake and its related factors among children aged 3-6 years from kindergarten and playgroup in Jakarta. Data on demographic characteristics, nutrients intake, anthropometric measures and cognitive function test by using standardized methods were collected. Descriptive and analytic statistics were performed accordingly.

Results: One-hundred children aged 3-6 years were recruited in 2011. This study revealed that based on body-mass-index indicator, 5% and 19% of the subjects were overweight and obese, respectively. Accordingly, based on waist-circumference indicator, 26% was classified as having central-obesity. Tooth-decay and/or loss of tooth was found in 76% of the subjects. Low average and extremely low cognitive-function status was 26%, 17% and 17% based on verbal IQ, performa IQ and full-scale IQ, respectively. Forty-three percent of the subjects had energy intake status of more than 120% of Indonesian RDA, and 99% of the subjects had sugar intake of more than 10% of total energy intake.

Conclusions: This study failed to show significant relationships between sugar intake, overweight-obese status and low cognitive status of the subjects.

Key words: Indonesia, sugar-intake, toddler.

PO1519

EFFECT OF BLACK-RICE EXTRACTS INTAKE AND EXERCISE ON THE BODY COMPOSITION OF RAT

T. Watanabe¹, T.Sato², S. Igawa³

¹Department of Human Health Science, Hachinohe Gakuin University, Hachinohe, Japa

²Department of Human Environmental Sciences, Jissen Women's University, Tokyo, Japan

³Department of Health Science, Nippon Sport Science University, Kanagawa, Japan

Background and objectives: It is known as a health food that black-rice is including many vitamins and minerals as compared to white rice. In addition, exercise is important to spend on health throughout life. Purpose of this study was to investigate the effect of black-rice extracts intake and exercise on body composition of rat.

Methods: Male Wistar rats were individually housed in cages at temperature of 23 ± 1 degree centigrade, and 40-60% humidity. After basically 5 weeks breeding, 20 rats were divided 4 groups each 5 rats and were fed standard powder diet and water and rest (C), standard powder diet, water and training (CTr), standard powder diet include black-rice extract and water and rest (B), standard powder diet black-rice extract and water and training (BTr) a certain time once a day. Also, CTr and BTr were trained running (230 m/s) on treadmill to 1 hour per day, during the experimental period of 9 weeks. This animal experiment was carried out in accordance with the Japanese law, which allows experiments on laboratory animals in Nippon Sport Science University accordance to the principle of laboratory animal care.

Results: Result of this study, body weight of B was higher than C, and BTr was higher than CTr. Fat around kindly of B showed the highest value compared to the other groups. But it was not significant difference between fat around kindly of BTr and CTr. In addition, there was no significant difference in the weight of heart, liver, kidneys and brain between all groups.

Conclusions: This result suggests that it is possible to healthy life not only the including black-rice extract but also continuous exercise.

Key words: black-rice, exercise

PO1520**INTENSIVE COUNSELING BY HEALTH WORKERS IMPROVED INFANT AND YOUNG CHILD FEEDING KNOWLEDGE AND PRACTICES IN A LARGE-SCALE PROGRAM IN BANGLADESH**

K. Saha¹, R. Rawat², A. Khaled¹, R. Haque³, K. Afsana³, T. Sanghvi⁴, M. Ruel², P. Menon⁵

¹International Food Policy Research Institute (IFPRI), Dhaka, Bangladesh

²IFPRI, Washington DC, USA

³BRAC, Dhaka, Bangladesh

⁴FHI360, Dhaka, Bangladesh

⁵IFPRI, New Delhi, India

Background and objectives: In Bangladesh, the Alive & Thrive (A&T) initiative aims to improve infant and young child feeding (IYCF) practices of mothers through intensive counseling by skilled frontline health workers (FHWs) and a mass media campaign. Well-trained and supervised FHWs counseled mothers of children 0-24 months of age on IYCF through regular home visits – 6 visits between 0-6 months and 6 between 7-24 months. We studied the early impacts of the intervention on mothers' IYCF knowledge and practices.

Methods: We conducted a program theory-driven process evaluation within a cluster-randomized impact evaluation design comparing A&T intensive and A&T non-intensive interventions (10 subdistricts in each group). In 2012, a survey was conducted in 10 subdistricts (5 subdistricts in each group) to gather data on interim outcomes. Data on IYCF knowledge and practices were compared for mothers of children 6-24 months at baseline (2010) and in 2012. We examined trends over time and compared outcomes between groups in 2012.

Results: At baseline, maternal IYCF knowledge and practices were not different between the two areas. At follow-up, maternal knowledge about breastfeeding (initiation, exclusivity and continuation) and complementary feeding (timing of introduction, frequency and quantity) improved in both groups. Improvements in IYCF indicators were greater in A&T intensive compared to A&T non-intensive areas. In 2012, feeding of iron rich foods (66% vs. 42%) and minimum dietary diversity (52% vs. 34%) were higher ($p < 0.05$) in A&T intensive than A&T non-intensive areas.

Conclusions: It is feasible to integrate IYCF counseling by skilled FHWs into a large-scale health program and thereby improve mothers' IYCF knowledge and practices. Funding: Bill and Melinda Gates Foundation, through Alive & Thrive, managed by FHI360.

Key words: IYCF knowledge, IYCF practices, frontline health workers, Alive & Thrive, Bangladesh.

PO1521**A COMPREHENSIVE TRAINING AND SUPERVISION PROGRAM IMPROVED FRONTLINE HEALTH WORKERS' KNOWLEDGE OF INFANT AND YOUNG CHILD FEEDING IN RURAL BANGLADESH**

⁴FHI360, Dhaka, Bangladesh

⁵IFPRI, New Delhi, India

Background and objectives: In Bangladesh, the Alive & Thrive (A&T) initiative aims to improve infant and young child feeding (IYCF) practices of mothers through intensive counseling by frontline health workers (FHWs) and a nationwide mass media campaign. A comprehensive IYCF training and performance improvement package (3-day classroom discussion, 3-day field practice, monthly refreshers, routine supervision and performance-based incentives) for FHWs was developed based on formative research. We evaluated the impact of this performance improvement package on FHWs' knowledge of IYCF.

Methods: We conducted a process evaluation in the context of a cluster-randomized impact evaluation design comparing A&T intensive (A&T-I) and A&T non-intensive areas (A&T-NI) (10 subdistricts each). FHWs in A&T-I areas received IYCF training and supervision; FHWs in both areas were exposed to mass media campaign. Data were collected from FHWs in 2010 and 2011 in these 20 subdistricts to capture FHWs' IYCF knowledge over a year.

Results: At baseline, FHWs' IYCF knowledge was low with no significant difference in A&T-I and A&T-NI areas, with little exposure to IYCF topics at pre-service (5.5%) or refresher (2.0%) training. At follow-up, IYCF was a key topic of discussion in A&T-I areas (91.0%). In A&T-I areas, FHWs' IYCF knowledge improved significantly. Knowledge of early initiation of breastfeeding increased from 27.1% to 63.2%, knowledge of timing of introduction of complementary foods improved, particularly for animal source food (mean age 9.6±2.6 months at baseline vs. 6.8±1.4 months at follow-up). Similarly, knowledge of frequency and quantity of complementary feeding at different ages improved in A&T-I areas.

Conclusions: Comprehensive training with performance improvement package improved FHWs' IYCF-related knowledge, thus assuring that a critical point in the impact pathway for this intervention was in place. Funding: Bill and Melinda Gates Foundation, through Alive & Thrive, managed by FHI360.

Key words: IYCF, frontline health workers, Alive & Thrive, Bangladesh.

PO1522**FORMATIVE RESEARCH FOR THE DEVELOPMENT OF A HOME FORTIFICATION PROGRAMME FOR CHILDREN IN ZAMBIA***Z. Daly¹, M. Suter¹, A. Aongola², J. McLean¹*

¹Department of Food, Nutrition & Health, Faculty of Land & Food Systems, University of British Columbia, Vancouver, British Columbia, Canada

²Ministry of Health, Lusaka, Lusaka Province, Zambia

Background and objectives: In response to the high prevalence of anaemia in Zambia, the Ministry of Health plans to introduce home fortification with Micronutrient Powders (MNP) for children 6-23 months. International recommendations for new MNP programmes include formative research to ensure the intervention package is culturally acceptable. Therefore, the objectives of this research were: 1. To investigate attitudes and practices on complementary feeding and the potential for home fortification with MNP; 2. To develop culturally acceptable MNP communication and training materials; 3. To evaluate the acceptability of MNP.

Methods: Focus groups (n=10) and key informant interviews (n=60) were conducted regarding infant and young child feeding, anaemia, and the feasibility of home fortification, prior to a 30-day MNP trial with 60 mother-child pairs. Mothers were interviewed at baseline, Day 10 and Day 30 regarding perception of changes in the child, ease of MNP use, and acceptability. Sample packaging and training materials were field-tested.

Results: Most mothers had heard of anaemia, although knowledge of iron-rich foods was low and dietary iron sources limited. Almost all mothers reported family members were supportive of MNP although fewer reported community support, indicating neighbours associated MNP with Satanism. Almost 80% of mothers reported positive changes in their child's health or behaviour. All mothers said they would continue giving MNP and 78% said they would pay a small amount to purchase MNP.

Conclusions: The results of the formative research provided support for home fortification with MNP in Zambia. Acceptability and utilization were high in the trial as mothers found the MNP easy to use and perceived health benefits for their children. The importance of educating the whole community on MNP was widely apparent. Importantly, there is the potential for charging for MNP, which could increase sustainability.

Key words: Home fortification, micronutrient powders

PO1523**SALT INTAKE AND EDUCATION LEVELS IN ADULTS OF MONGOLIA***B. Jamiyan¹, E. Batsaikhan¹, J. Webster², M. A. Land²*

¹National Center of Public Health, Ulaanbaatar, Mongolia

²George Institute of Global Health, Sydney, Australia

Background and objectives: The Government of Mongolia has been taking several actions to reduce the incidences of NCD and their related mortalities in recent years, and a number of projects and programs are being implemented with the support of WHO and the Millennium Challenge Account. The objective of this study is to determine actual salt intake adults of Mongolia and compared to education levels of the population.

Methods: A total of 1,034 people in the age range of 25 to 64 years old were randomly selected from the 4 economic regions of Mongolia. A 24 hours urine sample was collected from each participant for determine sodium intake.

Results: There was a 95.8% response rate. According to the survey, 24.9% (male were 35.8%, and female were 20.4%) of participants had no formal schooling and incomplete secondary school, 38.2% (male were 34.5%, and female were 39.7%) had complete secondary school, 36.9% (male were 29.8%, female were 39.9%) had completed college/university ($p < 0.001$). The participants 24 hours urine sample contains 11.1g (SD 7.7g/d.) salt on average, and 83.2% (95% CI 80.6-85.5) of participants consume more than 5g salt per day. Salt intake was who has none and incomplete primary education level were 11.9g/d, St. dev 8.4g/d, participants who has completed secondary education level were 10.9g/d, St. Dev 6.9g/d, and who has college and higher education level were level 10.7g/d, St. Dev 7.9g/d ($p < 0.01$).

Conclusions: Salt intake in adults of Mongolia was two times higher than WHO recommended. The comparison of education status by gender demonstrated that the education level of females was higher compared to men, which shows females could have a positive effect on trainings and promotional activities towards salt reduction awareness among the population.

Key words: non-communicable diseases, salt intake, education level.

PO1524**PREVALENCE OF METABOLIC SYNDROME IN MEXICAN ADULTS. RESULTS OF THE NATIONAL HEALTH AND NUTRITION SURVEY OF STATE WORKERS AND RETIRED**

M A. Ortiz-Rodríguez¹, T. Villalobos⁶, L. Yáñez-Velazco², A. Carnevale³, S. Romero-Hidalgo³, D. Bernal², C. Aguilar-Salinas⁴, R. Rojas⁵, A R. Villa Romero¹

¹Departamento de Salud Pública, Facultad de Medicina, Universidad Nacional Autónoma de México

²Instituto de Seguridad y Servicios Sociales de los Trabajadores del Estado.

³Instituto Nacional de Medicina Genómica

⁴Instituto Nacional de Ciencias Médicas y Nutrición

⁵Instituto Nacional de Salud Pública

⁶Departamento de Nutrición y Bromatología I, Facultad de Farmacia, Universidad Complutense de Madrid

Background and objectives: Metabolic syndrome (MS) has been associated with coronary heart disease, stroke and diabetes type 2. In Mexican adult population, MS has been reported with a high prevalence which is increasing in the time. To describe the prevalence of MS and its main associated factors in Mexican adult population with data derived of the National Health and Nutrition Survey from State Workers and Retired during 2007 (NHANSSWR-2007).

Methods.: A national representative sample of 4595 adults, 20 years and older, was surveyed. They were questioned about chronic diseases including diabetes, hypertension, coronary heart disease, cancer, renal disease and obesity. Seric levels of glucose and lipids were determined. Blood pressure and anthropometry were taken. Definitions of MS included: National Cholesterol Education Program (NCEP-ATPIII), American Heart Association/National Heart Lung and Blood Institute (AHA/NHLBI), and International Diabetes Federation (IDF). Prevalence (%) and 95% confidence intervals are reported. Exact Fisher's test was applied to statistical significance. Statistical software SPSS v20 was used.

Results. The national prevalence of MS was 44.0, 48.8 and 57.4% according with definitions NCEP-ATPIII, AHA/NHLBI, and IDF, respectively. The prevalence of MS was higher in man than women, independently of the definition, due mainly to higher levels of glucose, triglycerides and blood pressure. The prevalence of MS increased with age, poor educational level and central region of the country.

Conclusions: The prevalences of MS found in the NHANSSWR-2007 are higher than those reported in the general population of the National Health and Nutrition Survey in 2006. These results do mandatory the necessity to install primary and secondary preventive programs conducted to the State sector with more than 10 millions of beneficiary population.

Key words: metabolic syndrome, national survey, Mexican population.

PO1526**LOW PREVALENCE OF INTRA-INDIVIDUAL DOUBLE BURDEN OF MALNUTRITION IN URBAN TUNISIAN CHILDREN**

J. El Ati^{1,2}, A. Gartner³, P. Traissac⁴, H. Aounallah-Skhiri⁴, C. Ben Rayana^{1,2}, C. Beji^{1,2}, J. Berger³, F. Delpeuch³

¹National Institute of Nutrition and Food Technology, Tunisia

²LR12SPO5: Nutritional Surveillance and Epidemiology in Tunisia

³Institut de Recherche pour le Développement (IRD), UMR 204 NUTRIPASS, IRD-UM2-UM1, Montpellier, France

⁴National Institute of Public Health (INSP), Tunis, Tunisia

Background and objectives: In the context of nutrition transition, North-African countries are facing rapid increases in overweight/obesity while under-nutrition such as anaemia and iron deficiency (ID) remains highly prevalent. This study aimed at describing the magnitude of this double burden of over- and under-nutrition both at population and individual levels among Tunisian urban children and exploring the relationship between these nutritional co-morbidities within subjects.

Methods: The nutritional status of 1134 children (562 boys; 572 girls), 6mo to <10y old living in Great Tunis was assessed through a cross-sectional survey (stratified two-stage clustered sample). Overweight/obesity were defined by age and sex specific BMI z-scores (2007 WHO). Anaemia was defined by age specific WHO cut-offs and ID by serum ferritin concentration (<12µg/L or <15µg/L in those <5y and ≥5y of age, respectively), after correction for inflammation (CRP>5mg/L and/or orosomucoid>1g/L). Relationships between overweight/obesity and anaemia/ID status were estimated by logistic regression analysis with sex interaction.

Results: Nutritional status did not differ between sexes. Overweight and obesity were more prevalent (P<0.0001) in school-age children (≥5y) (19.1%[15.7-23.1]; 7.6%[5.7-10.1], respectively) vs. preschool-age (<5y) (9.6%[6.8-13.4]; 2.4%[1.3-4.5]). Anaemia prevalence was higher (P<0.0001) in preschool-age (33.1%[29.0-37.6]) compared to school-age (19.2%[15.3-23.7]) whereas ID prevalences were high and similar in the two age-groups (19.4%[14.5-25.4]; 20.5%[17.0-24.5], respectively). ID anaemia affected the tenth child and inflammatory was higher in preschool-age (18.8%[15.1-23.1]) vs. school-age (9.6%[7.5-12.1]; P=0.023). Coexistence of overweight/anaemia or overweight/ID was low in preschool-age (3.8%[2.2-6.5]; 1.8%[0.8-4.0], respectively) and school-age (2.7%[1.6-4.6]; 3.8%[2.3-6.1]). The prevalence of obesity/ID was rare in preschool-age (1.8%[0.8-4.0]) but doubled in school-age (3.8%[2.3-6.1]; P=0.023). Anaemia/ID prevalence was not associated with overweight/obesity among children.

Conclusions: Despite a high prevalence of overweight/obesity and anaemia/ID in young urban children, the intra-individual double burden was rare and the risk of anaemia or ID was not increased when overweight/obesity.

Key words: overweight; anaemia, iron status; children; North-Africa.

PO1527

ASSOCIATION BETWEEN PHYSICAL ACTIVITY AND LIVER ENZYMES IN ADOLESCENTS: THE HELENA STUDY

J. Ruiz¹, I. Labayen², F. Ortega¹, L. Moreno³, G. Rodriguez³, C. Breidenassel⁴, Y. Manios⁵, A. Kafatos⁶, D. Molnar⁷, S. de Henauw⁸, F. Gottrand⁹, K. Widhalm¹⁰, M. Castillo¹, M. Sjöström¹

¹University of Granada, Granada, Spain; and Karolinska Institutet, Stockholm, Sweden

²University of the Basque Country, Vitoria, Spain

³University of Zaragoza, Zaragoza, Spain

⁴Rheinische Friedrich-Wilhelms Universität Bonn, Germany

⁵Harokopio University, Athens, Greece

⁶University of Crete, Heraklion, Crete, Greece

⁷University of Pecs, Hungary

⁸Ghent University, Ghent, Belgium

⁹University of Lille, Lille, France

¹⁰University of Vienna, Vienna, Austria

Background and objectives: We aimed to examine the association between physical activity (PA) and liver enzymes levels in adolescents from 9 European countries (10 centers).

Methods: The study comprised 718 adolescents (397 girls) participating in the HELENA cross-sectional study. PA was measured by accelerometry and expressed as total PA (counts/min), and time (min/d) engaged in moderate to vigorous intensity PA (MVPA). We measured serum levels of alanine aspartate aminotransferase (AST), alanine aminotransferase (ALT), and γ -glutamyltransferase (GGT), and the AST/ALT ratio was computed. We also measured waist circumference and skinfold thickness, and computed the fat mass index (FMI, fat mass in kg divided by height in squared meters).

Results: There was an association between MVPA and AST and AST/ALT (age, sex and center adjusted $R=0.096$, 95% confidence interval (CI): 0.016 to 0.118, $P=0.011$; and $R=0.090$, 95% CI: 0.006 to 0.112, $P=0.029$, respectively). Meeting the PA recommendations (60min/d of MVPA) was associated with higher AST and AST/ALT ($P=0.002$ and $P=0.003$, respecti-

vely), which persisted after further adjusting for sedentary time ($P=0.003$ and $P=0.002$, respectively), and FMI ($P=0.002$ and $P=0.009$, respectively) or waist circumference ($P=0.002$ and $P=0.003$, respectively).

Conclusions: Our findings support that meeting the current PA recommendations of 60min/d of MVPA is associated with higher levels of AST and AST/ALT regardless of time spent sedentary as well as total and central body fat in European adolescents.

Key words: Aspartate aminotransferase, alanine aminotransferase, γ -glutamyltransferase (GGT), youth, exercise.

PO1528

PCBS AND HEAVY METALS EXPOSURE AMONG FISHERMEN IN MALAYSIA

A. Azlan¹, A. Mohamad¹, M Y. Adon², M R. Razman³

¹Universiti Putra Malaysia

²Institute of Medical Research, Ministry of Health Malaysia

³Universiti Kebangsaan Malaysia

Background and objectives: Fish as source of high-quality protein also contribute to vitamins and important fat such as essential fatty acids (EPA and DHA). Besides being an important source of nutrients, fish also may contribute to exposure to organochlorine and heavy metals that can harm health.

Methods: In this study we determined exposure to PCBs and heavy metals via dietary intake of fish and shellfish among fishermen ($n=90$). Dietary intake of fish and shellfish was measured using food frequency questionnaire (FFQ) while exposure to contaminants was estimated by multiplying amount of fish intake with concentration of individual contaminants in each species (previously determined) per body weight of subjects.

Results: The mean age of fishermen (Malay, 55.6%; Chinese, 43.3% and Indian, 1.1%) was 47 ± 10.60 years old. Generally, mean dietary exposures to PCBs, Hg, As, Cd and Pb were within tolerable daily intake by WHO (2005) at 2.77 ± 0.261 pg/kg bw/day, $0.017 + 0.003$, $4.517 + 0.400$, $0.090 + 0.009$ and $0.453 + 0.037$ $\mu\text{g}/\text{kg}$ bw/day, respectively.

Conclusions: Although exposures to the contaminants were relatively low at present, continued monitoring of the contaminants in food, especially fish and shellfish is warranted especially for vulnerable groups (children and pregnant/ lactating women) as well as the general population.

Key words: Fish, Shellfish, Dietary exposure, Fishermen.

PO1529**DECLINING OF HOUSEHOLD INCOME LEADS TO A CHANGE IN NUTRITION - FINDINGS FROM CASE STUDIES OF GIESSEN, GERMANY***J. Yildiz¹, I U. Leonhaeuser¹*

¹Department of Nutrition Education and Consumer Behaviour, Institute of Nutritional Sciences, Justus-Liebig-University of Giessen, Germany

Background and objectives: The widening gap between rich and poor in Germany leads to unequal nutrition and health security. Surveys identify vulnerable households (e.g. unemployed or retired) but do not contribute to a deep understanding of coping strategies and individual impacts of recent financial restrictions on food consumption. Gender-oriented research and its results concerning underlying attitudes and motives are needed for social and nutrition policies.

Methods: The study is based on mixed-methods using a sequential design starting with a quantitative secondary analyses of available data by the second German National Nutrition Survey. Based on the results of the secondary analysis (n=7490) guideline-based face-to-face interviews were done surveying in depth women (n=11) and men (n=3) who actually had a decrease of income (job losses/retirement).

Results: Regarding the dimensions of food deprivation (FEICHTINGER) the respondents (n=14) face constraints in material, psychological and socio-cultural quality. For some of them healthy eating can no longer be realised. Due to financial limitations food purchasing fail individual preferences and common recommendations, e.g. fresh fruits, vegetables, fish and meat. Respondents are forced to buy low status food and feature a lack of choice (supermarkets vs. discounter). The socio-cultural quality is pointed out by them, besides invitations/celebrations eating out is missed the most. Financial restriction leads to more consciously handling with food: there are less food wasted, more attention is paid on labels/information on food packages, prices and package sizes. Spontaneous purchases are reduced.

Conclusions: Benefits for unemployed or retired people need to be improved to allow a healthy eating. To prevent food deprivation education programmes for low income groups should include not only healthy eating but also consider women's and men's readjustment to the new financial situation (mental, social wellbeing). Positive modifications like increased awareness of food purchasing should be strengthened.

Key words: Food purchasing, food deprivation.

PO1531**PHYSICAL ACTIVITY OF STUNTED, UNDERWEIGHT AND WASTED MALAWIAN CHILDREN***A. Pulakka¹, YB. Cheung^{1,2,3}, U. Ashorn¹, K. Maleta⁴, P. Ashorn^{1,5}*

¹Department of International Health, University of Tampere, Tampere, Finland

²Centre for Quantitative Medicine, Duke-National University of Singapore Graduate Medical School, Singapore, Singapore

³Department of Biostatistics, Singapore Clinical Research Institute, Singapore, Singapore

⁴Department of Community Health, College of Medicine, University of Malawi, Blantyre, Malawi

⁵Department of Pediatrics, Tampere University Hospital, Tampere, Finland

Background and objectives: Nutrition intervention trials for young children have traditionally measured growth as the main outcome and a marker for overall wellbeing. Physical activity offers a potential new outcome but its relationship with growth outcomes is not well characterized. This study tested a hypothesis that children who are stunted, wasted or underweight are physically less active than their normally nourished counterparts.

Methods: The study was done in rural Malawi, among 18-month-old children who had participated for one year in a nutrition intervention trial (www.ilins.org). To assess physical activity, 1350 children wore an accelerometer (ActiGraph GT3X+) for seven days in their normal home environment. Activity was expressed as mean daytime activity counts/15 seconds. Participants who had a minimum of six hours of acceptable accelerometer data per day on at least four days were included. Anthropometric measures were taken using standardized methodology. Anthropometric indexes were calculated with the latest WHO standards. Stunting, underweight, and wasting were defined as a z-score below minus two z-score units. The hypotheses about a difference in mean activity counts between participants with low and normal z-scores were tested with Student t-test.

Results: A total of 1085 (80%) children had sufficient anthropometric and physical activity data. Mean (SD) activity for all children was 300 (64) counts/15 seconds. Stunted children (n=460, 44%) were less active than non-stunted children (difference 11 counts/15 seconds, 95% CI 3 to 19, p=0.006). Underweight children (n=199, 19%) were slightly less active than non-underweight children (difference 11, 1 to 21, p=0.03). Wasted children (n=57, 5%) were also less active than non-wasted children, but this difference was not statistically significant (difference 14, -3 to 31, p=0.10).

Conclusions: Undernourished children are physically less active than children who are not undernourished.

Key words: physical activity, stunting, wasting, underweight
Funded by the Bill & Melinda Gates Foundation.

PO1532**TEMPERAMENT TRAITS AND FOOD INTAKE IN THE HELSINKI BIRTH COHORT STUDY**

A. M. Tiainen^{1, 2}, S. Männistö¹, J. Lahti, M. Lahti³, K. Rääkkönen³, K. Heinonen³, A. K. Pesonen³, E. Kajantie¹, J. G. Eriksson^{1, 2, 4, 5}

¹Department of Chronic Disease Prevention, National Institute for Health and Welfare, Helsinki, Finland

²Folkhälsan Research Centre, Helsinki, Finland

³Department of Psychology, Institute of Behavioral Sciences/University of Helsinki, Helsinki, Finland

⁴Department of General Practice and Primary Health Care, Institute of Clinical Medicine/University of Helsinki, Helsinki, Finland

⁵Vasa Central Hospital, Vasa, Finland

Background and objectives: The temperament traits novelty seeking (NS), harm avoidance (HA), reward dependence (RD), and persistence (P) are associated with health behaviors, but their associations with the whole diet remain to be explored. Our objective was to study the associations between temperament traits and food intake.

Methods: Subjects (n= 1681, mean age 61, 5 y) from the Helsinki Birth Cohort Study filled in the Tridimensional Personality Questionnaire and a validated 128- item food frequency questionnaire. We tested separately in men and women using linear regression analysis, whether temperament traits are associated with food intake while adjusting for age, education, and energy intake.

Results: In men, HA was associated with higher total fruit intake (29.7 g/d for every 1 SD increase in the temperament score, P= 0.01) and NS with higher soft drink intake (4.1 g/d, P= 0.02). In women, RD associated with lower intakes of meat and meat products (-2.4 g/d, P= 0.001), red meat (-1.3, P= 0.02), and poultry (-1.1, P= 0.01), and a higher intake of fruits, berries and fruit juices (8.5 g/d, P= 0.01). These results are in line with a previous study finding high RD and HA to associate with a healthy eating pattern and high NS to associate with an unhealthy eating pattern.

Conclusions: In general there were only few statistically significant results, but they support the hypothesis that temperament traits are associated with food intake (e.g. HA was associated with fruit intake).

Key words: food intake, temperament, food frequency questionnaire.

PO1533**ECOLOGICAL RISK FACTORS OF OVERWEIGHT WOMEN IN INDONESIA: IMPLICATIONS FOR NUTRITION AND WELLNESS CHANGING BEHAVIORS**

R. Diana¹, Hardinsyah¹, I. Tanziha¹

¹Department of Community Nutrition, Faculty of Human Ecology, Bogor Agricultural University, Indonesia

Background and objectives: Overweight including obesity is now so common and be a rapid growing threat to health of global population. Amongst all age-sex groups in Indonesia, women aged 30-49 years (WTY) has the highest prevalence of overweight; while very limited data available on the ecological risk factors of overweight WTY in Indonesia. The aim of this study is to analyze ecological risk factors of overweight amongst WTY in Indonesia based on the current nation-wide survey data.

Methods: A current national health survey data set collected by the Health Research and Development Institute of the Ministry of Health was used and analyzed. The electronic files data consist of 38319 WTY. Overweight subject was identified by BMI more than 25. Based on the availability of the data, a logistic regression model was applied to suspected ecological risk factors of overweight such as energy adequacy from carbohydrate (EAC), energy adequacy from sugary sweetened foods (ESF), energy adequacy from fat (EAF), physical activity, family income, education level, and marital status.

Results: One-third (35.3%) of the WTY is overweight. The ecological risk factors of the overweight WTY in Indonesia are marital status (OR for married=1.751, CI: 1.604-1.911), family income (OR for high income =1.543, CI: 1.467-1.623), urban-rural settlement (OR for living in urban=1.255, CI: 1.193-1.321), physical activity (OR for sedentary=1.445, CI: 1.361-1.534), ESF (OR for ESF>10%=1.117; CI: 1.038-1.202), EAC (OR for EAC >55%=1.111; CI: 1.043-1.185), and education level as a proxy of nutrition education level (OR for senior high school and above =0.890, CI: 0.843-0.939).

Conclusions: Controlling overweight amongst WTY in Indonesia should focus on major changeable ecological risk factors such as physical activity, energy adequacy and nutrition education, which implies the important of nutrition and wellness changing behaviors.

Key words: overweight women, risk factors, ecological factors, physical activity, energy adequacy.

PO1534**FACTORS ASSOCIATED WITH NUTRITIONAL STATUS IN ELDERLY LIVING IN TWO CITIES OF CENTRAL AFRICA: THE EDAC STUDY.**

P. Jésus^{1,2,3}, M. Guerchet^{1,2}, A M. Mouanga⁴, P. Mbeleso⁵, P M. Preux^{1,2,6}, J.C. Desport^{1,2,3}

¹NSERM UMR1094, Tropical Neuroepidemiology, Limoges, France

²Univ Limoges, School of Medicine, Institute of Neuroepidemiology and Tropical Neurology, CNRS FR 3503 GEIST, Limoges, France

³Dept. of Nutrition, CHU, Limoges, France

⁴Dept. of Psychiatry, Brazzaville University Hospital, Brazzaville, Republic of Congo

⁵Dept. of Neurology, Amitié Hospital, Bangui, Central African Republic

⁶Dept. of Medical Information & Evaluation, Clinical Research and Biostatistic Unit, CHU, Limoges, France

Background and objectives: Nutritional status has been scarcely investigated in elderly living in Sub-Saharan Africa compared to younger populations. However, identifying factors associated with nutritional status could be of importance in order to prevent malnutrition in ageing populations.

Methods: Two cross-sectional population-based studies were carried out in capitals of Central African Republic (CAR) and Republic of Congo (2008-2009). Participants aged >65 years old were included and underwent nutritional assessment including the following measurements: weight, height, waist circumference, arm circumference and triceps skinfold thickness. A food investigation was also conducted. Nutritional status was defined according to the WHO BMI classification (BMI < 18.5 for malnutrition and BMI > 30 for obesity). After full description of the characteristics of the population, multinomial regression analysis was realized in order to identify factors associated with nutritional status.

Results: Above 1055 elderly contacted in both Bangui and Brazzaville, 1016 accepted to participate to the study. Unfortunately, height or weight measurements were impossible for 26 of those participants due to bad physical condition. Considering both settings, prevalence of malnutrition was estimated to 19.2% (95%CI [16.8-21.8]) and prevalence of obesity to 8.8% (95%CI [7.1-10.7]). Adjusted on study site, increasing age (OR=1.59 (95%CI=[1.09-2.31])) for 75-84 years compared to 65-74 years, and OR=2.57 (95%CI=[1.36-4.83]) for 85+ years old), occupation (farmer/breeder, OR=2.17 (95%CI=[1.11-4.22])), smoking (OR=1.71 (95%CI=[1.14-2.56])) and low sugar consumption (OR=1.72 (95%CI=[1.11-2.65])) were significantly associated with malnutrition whereas female gender (OR=4.97 (95%CI=[2.24-10.98])) was significantly associated with obesity.

Conclusions: The prevalence of malnutrition is high in the elderly population of these countries. These new data concerning African elderly nutritional status need to be implemented by further investigations, particularly comparing urban and rural areas.

Key words: denutrition, obesity, elderly, risk factors, Africa.

PO1535**NUTRITION KNOWLEDGE AND FOOD CHOICE BEHAVIOUR AMONG GHANAIS: IMPLICATIONS FOR HEALTHY LIFESTYLE PROMOTION**

F. Hayford¹, M. Steiner-Asiedu², E. Sakyi-Dawson²

¹Department of Dietetics, School of Allied Health Sciences, University of Ghana, Korle-bu, Accra-Ghana

²Department of Nutrition and Food Science, University of Ghana, Legon, Accra-Ghana

Background and objectives: Proliferation of shopping malls and supermarkets in major cities in Ghana, coupled with the globalization of our food market systems are clear evidence that consumers now have a wider choice of food products. Given the increasing prevalence of diet, nutrition and health related diseases, there is the need for greater nutrition knowledge and understanding of factors underlying consumers' food choice behaviour to facilitate outcome of successful interventions. The objective was to determine Nutrition Knowledge and its influence on Food Choice Behaviour among Ghanaians in the Greater Accra Region.

Methods: A cross-sectional survey, mainly by questionnaire, was used to source information from randomly selected consumers between the ages of 18-75 years, who patronize some super markets and shopping malls. Logistic regression analysis was used to examine and establish associations. 'P' value less than 0.05 was considered statistically significant.

Results: Majority (70%) of the respondents had good knowledge about healthier food choices. Higher educational level was a key determinant of nutrition knowledge. Advertisement of product and use of Nutrition and Diet Books were key determinants of food choice behaviour. Advertisement of product on mass media was more likely to influence respondents with poor level of nutrition knowledge (vs. good nutrition knowledge, OR, 9.53; 95% CI, 1.12—81.41; P= 0.039).

Conclusions: Though Nutrition knowledge was generally good and a link established between it and some determinants of food choice behaviour, the studies did not find significant associations between nutrition knowledge and dietary behaviour. This is because knowledge about healthy food choices does not lead to direct action when individuals are unsure how to apply their knowledge. Accurate and consistent messages through

various media are needed to educate consumers to use the knowledge to impact positively on their food choice behaviour.

Key words: Nutrition knowledge, food choice behaviour, Healthy lifestyle, Ghana.

PO1537

LAW AND LAW PROJECTS REGARDING HEALTHY SNACK STAND REGULATION IN ARGENTINA

P. Gomez¹, M.E. Zapata¹, E. Carmuega¹

¹Centro de Estudios Sobre Nutrición Infantil (CESNI), Ciudad Autónoma de Buenos Aires, Buenos Aires, Argentina.

Background and objectives: As a consequence of the increase in the prevalence of overweight and obesity in infant population, Argentina needs regulation of school snack stands. The aim of this work was to evaluate the legislation on healthy snack stands at national and regional level in Argentina.

Methods: A descriptive-cross-sectional study was conducted. To learn about the projects of law and existing laws for the regulation of healthy-snack-stands, nutrition schools and province associations were contacted through the Argentinian Federation of Nutrition Graduates (FAGRAN) and consulted on the current regulations in their jurisdiction. At the same time a systematic internet search was conducted and the national and provincial houses of representatives and senates were contacted to inquire about the status of projects and laws.

Results: In 2008 a national law was sanctioned focuses on eating behavior with special attention on healthy-snack-stands (N°26.396/08) but it did not specify its implementation and responsibilities. Nowadays the national House of Representatives had sent to the Senate a national law about healthy-snack-stands. In Argentina 83% (20) of the provinces have some regulation or project concerning healthy-snack-stands. Twenty-five percent (6) of them have regulated laws, 13% (3) have sanctioned and promulgated laws and 25% (6) have law projects. Twenty-nine percent (7) of the provinces have municipal ordinances and 17% (4) have projects of municipal ordinances.

Conclusions: This study shows the complexity of the instauration of a national health legislation in the context of a federal country. Laws concerning healthy-snack-stands were enacted by provinces. Many laws have been enacted since 2008, but with complex regulations and implementation processes. It is very important to analyze the regulatory aspects to accelerate changes in the marketing and communication of foods which are associated with the childhood-obesity epidemic.

Key words: Healthy snack stand, Law and Project law, regulation.

PO1538

MILK AND DAIRY PRODUCTS CONSUMPTION IN ARGENTINA

M.E. Zapata¹, A. Rovirosa¹, E. Carmuega¹

¹Centro de Estudios Sobre Nutrición Infantil (CESNI), Ciudad Autónoma de Buenos Aires, Buenos Aires, Argentina.

Background and objectives: Milk and dairy products are important sources of calcium, high quality proteins and vitamins and are included in Argentinean Food Guidelines. Our aim was to assess the consumption of milk and dairy products in Argentinean population.

Methods: A cross-sectional nutrition survey was conducted on a random probabilistic sample considering age, sex and region quotas, in the main cities of Argentina. Analysis was based on 1137 individuals (563men and 574women), aged 2-65 years using a self-administered 7-day questionnaire. One serving size was defined as: 200ml of milk, 200ml of yogurt, 50g of fresh cheese, 60g of spread cheese and 15g of hard cheese. Data were compared with the dietary guidelines for the Argentinian population. Total calcium intake was estimated as the sum of dairy products calcium and calcium from other sources taken food balance sheets. Total calcium was compared to EAR by sex and age.

Results: The mean daily servings of dairy products for the population was 2.1±1.2. For children (2-4yo) 3.3±1.3, for scholar-age children (5-12yo) 2.6±1.0, for adolescents (13-18yo) 2.0±1.0, for young adults (19-30yo) 1.7±0.9, for middle-age adults (31-50yo) 1.7±1.0 and for older adults (51-61yo) 1.6±1.1. Compared with the dietary guidelines: 45% of children (2-4yo), 72% of scholar age children, 87% of adolescent were below the 3 recommended servings per day, and 65% of young adults (19-30yo) and 69% of adults older than 31yo were below the 2 recommended servings which is consistent with the 16% of children, 76% of scholar-age-children, 97% of adolescent, 87% of young adults (19-30yo) and 90% of adults older than 31yo were below calcium estimated average requirement.

Conclusions: The consumption of dairy products falls sharply in scholar age children and stays low throughout adulthood. Therefore its consumption habits should be promoted from early ages.

Key words: milk, dairy product, dietary guidelines.

PO1539

EXCLUSIVE BREASTFEEDING. EFFECT ON GROWTH AMONG CHILDREN BELOW TWO YEARS IN MALAWI

J. Kuchenbecker¹, I. Jordan¹, A. Reinbott¹, J. Herrmann¹, J. Theresa², B. Mtimuni³, M B. Krawinkel¹

¹Justus Liebig University Giessen, Germany

²Food and Agriculture Organization of the United Nations, Nutrition Division (ESN), Economic and Social Department, Italy

³Bunda College of Agriculture, Malawi

Background and objectives: Exclusive breastfeeding for the first six months of life is considered best even in HIV/AIDS affected countries like Malawi. In September 2011, a cross-sectional nutritional baseline survey was conducted in Kasungu and Mzimba District of Malawi within the IMCF research project to assess the nutritional status of children below two years and its determinants.

Methods: In total 1041 randomly selected households with children below two years were interviewed based on a standardized questionnaire. Anthropometric measurements were taken from both parents and the child. In order to analyze the effect of exclusively breastfeeding, predominant breastfeeding and mixed feeding on height-for-age-Z-score, an ANCOVA was performed in the age group 0 < 6 months only (n=205) with age of child, BMI and height of mother as covariates.

Results: Prevalence of stunting among the children below 6 months of age was 29% (mean = -1.41). Most mothers (n=180) and all fathers (n=18) who had been measured had a normal BMI (87% and 100%, respectively). Exclusive breastfeeding was less common (43%) than predominant breastfeeding and mixed feeding taken together (21% and 36%, respectively). Influence of breastfeeding pattern on HAZ, adjusted for age of child and height of mother, was significant (p<0.05). Exclusively breastfed children had higher mean HAZ compared to mixed fed children (-1.16 versus -1.61; p<0.05). There were no significant differences in HAZ between exclusively breastfed and predominantly breastfed children and between predominantly breastfed and mixed fed children.

Conclusions: The results show the need to continue the promotion of exclusive breastfeeding and a timely introduction of adequate complementary foods in Malawi to prevent stunting among children below 6 months of age.

Key words: Exclusive Breastfeeding, Predominant Breastfeeding Growth, HAZ, Malawi.

PO1540

COMPLEMENTARY FEEDING PRACTICES AND THEIR POTENTIAL DETERMINANTS IN INDONESIA: A REVIEW OF LITERATURE

J. Febrihartanty¹, S. Sukotjo², S. Blaney³

¹EAMEO Regional Center for Food and Nutrition (RECFON) Universitas Indonesia

²UNICEF Indonesia

³UNICEF Senegal

Background and objectives: Around 36% of Indonesian underfive children are stunted. Appropriate complementary feeding is recognized to be highly effective to reduce undernutrition. Only 41% of children 6-23 months are fed as recommended. Yet, national aggregates hide disparities between locations. To fill the gap, studies have been conducted to assess child feeding practices as well as their underlying factors in different locations of Indonesia. Nevertheless, no attempt has been made to reconcile available literature to identify gaps in current knowledge. The aim of the paper is to provide a comprehensive review of the current literature on feeding practices among children above 6 months of age and their potential determinants.

Methods: A systematic literature research was conducted in several databases using combinations of different search terms: feeding, child, Indonesia, MPASI/complementary food, gizi/nutrition, factor, determinant, praktek/practices. The review of all documents was conducted using a 3-step procedure to assess content appropriateness and research quality. Information was analysed using a conceptual framework for behaviour change.

Results: In all studied areas, child feeding practices are not optimal. Available data on individual factors underlying those practices relate mostly to mother's attributes, namely knowledge, attitudes, beliefs and skills which are positively linked to better feeding practices. Although, literature on group factors does not provide a full picture of their contribution to child feeding practices as it is limited to health services, home and peer environment, it shows that such support is conducive to good practices. Literature on societal factors affecting childhood complementary feeding is limited to cultural norms with some of them detrimental to optimal practices.

Conclusions: The results stress the need to strengthen research on child feeding and its underlying determinants. Results are useful for providing guidance to nutrition program to improve overall child's well-being.

Key words: children, feeding, factors, review, Indonesia.

PO1541

DOUBLE BURDEN OF MALNUTRITION IN CASABLANCA

A. Jafri¹, M. Jabari², M. Dahhak³, A. Derouiche¹

¹Ben M'sik Faculty of Science, Université Hassan II Mohamedia Casablanca

²Division d'Hygiène de Sidi Othmane, Casablanca

³Direction of Statistics of Casablanca

Background and objectives: The epidemiological situation in developing countries is rapidly switching to a model where obesity and associated diseases are becoming a major public health concern. Unfortunately, other deficiency issues are still persistent in prevalent, we are now noticing both malnutrition aspects among the same populations, sometimes in the same households, and sometimes even in the same person. **Objectives:** This study aimed to assess the severity of malnutrition among women and children from Casablanca, and the prevalence of households with overweighted mothers and undernourished children, also, to see if mothers' level of education is associated to these aspects of malnutrition.

Methods: A survey was carried out in 6 neighborhoods of Casablanca, 426 adult women and 240 preschoolers were randomly selected using a cluster sampling. Anthropometric parameters were measured according to the guidelines of the World Health Organization (WHO). Obesity in adults was determined using the body mass index cutoffs from the WHO. Underweight, stunted and obesity in children were determined using the WHO child growth standards.

Results: Results showed 47% obesity and 36% overweight among women, while 19% children were underweight and 15% were stunted, we also noticed 8% obesity among children. Data also showed that 13.7% households had obese mothers and malnourished children, while 9.8% households had obese mothers and children. Obesity, underweight, and stunting were not associated with mothers' level of education, age, or marital status.

Conclusions: Results allowed us to assess the severity of the double burden of malnutrition in low and middle income households from Casablanca, The fact that we found it in a considerable part of the population is an indicator of other possible malnutritions. It is becoming imperative to conduct a thorough study of the food behavior of these households to understand the complexity of this phenomenon.

Key words: Malnutrition, Casablanca.

PO1542

DETERMINANTES OF CHILD CHRONIC MALNUTRITION IN THE PROVINCE OF VILCASHUAMAN IN THE CENTRAL PERUVIAN HIGHLANDS

L. Espejo¹, A. Vargas¹, J. Díaz¹, J. Silva¹, B. Gillespie¹, H. Torres¹, A. Fernández¹, R. Ruiz²

¹Technical Department, Action Against Hunger Spain, Lima, Peru

²Technical Department of Intersocial, Lima, Peru

Background and objectives: Child malnutrition is a serious public health problem in Peru, affecting children's academic performance and future economic productivity. This study analyzes the determinants of chronic malnutrition in Vilcashuaman, Ayacucho.

Methods: The study used quantitative and qualitative methods, including a two stage sample with a 95% level of confidence and 5% accuracy to measure malnutrition rates in 496 children under 3 years of age. A survey covered the situation for health, nutrition, water and sanitation and food security. A further part included focus groups, interviews and observations with 50 families.

Results: 64.4% of children under 6 months are exclusively breast fed. 65.3% of those from 6 to 35 months receive balanced complementary foods, with local products and adequate frequency, usually characterized as soups. 46.3% of children from 18 to 35 months have complete vaccinations. 51.7% of those under 3 suffered respiratory problems and 15% had diarrhea in the preceding two weeks. 38% of municipalities aim to reduce child malnutrition, but have not assigned a corresponding budget. 74.2% of dwellings have running water, but the majority is not chlorinated. 73% of dwellings have latrines. Subsistence agriculture takes place in small plots, irrigated by rain, with low yields, and animal herds are small. In January and February 30% of families face food scarcity. Prevalence of chronic child malnutrition is 31.5% in those under 3, with higher rates in children with mothers with only primary education compared to those whose mothers attended secondary school.

Conclusions: Chronic malnutrition in children under 3 is high, affected by factors such as limited food diversity, high prevalence of infections, deficient health services, low quality basic services, limitations in agricultural production and lack of attention to cultural issues. There is an inverse relationship between mothers' education and child chronic malnutrition.

Key words: malnutrition, agriculture, education.

PO1543**INEQUALITIES IN THE AVAILABILITY OF FOOD STORES AND FOOD ACQUISITION PATTERN OF FAMILIES LIVING IN URBAN AREAS OF SANTOS, BRAZIL***G M. Vedovato¹, M A. Oliveira², P A. Martins³*¹Nutritional Epidemiology Laboratory, Federal University of Sao Paulo, Santos, SP, Brazil²Nutritional Epidemiology Laboratory, Federal University of Sao Paulo, Santos, SP, Brazil³Nutritional Epidemiology Laboratory, Department of Human Movement Science, Federal University of Sao Paulo, Santos, SP, Brazil

Background and objectives: To assess household food acquisition patterns and its relation to the geographical distribution of food stores in urban neighborhoods.

Methods: A cross-sectional survey was conducted in four administrative region of Santos City (2010). Households were selected by random sampling of 36 census tracts. Families were interviewed (n=538) to collect the household food acquisition in the last month (31 food/beverage groups) and socioeconomic data. All food stores in the study area were audited using a validated instrument to assess food availability, quality and price. Stores were classified as More or Less Healthy Eating Promoter (MHEP; LHEP) according to the degree of industrial processing and food nutrient content. Per capita food acquisitions in grams were log transformed, and scores were attributed to the quartiles of distribution (1–4;0=no acquisition). Principal Component Analysis (orthogonal rotation/varimax method) was performed to achieve patterns of food acquisition (factors). The internal consistency of the items that comprised the pattern was evaluated by Alpha Cronbach coefficient (P>0.6). Geographical distribution was used to compare the neighborhoods availability of stores.

Results: Seafont and Intermediate regions showed a higher economic level. Northwest and Downtown presented lower socioeconomic and education levels. Maps illustrated that the higher availability of MHEP stores was related with high-income areas. Three patterns were retained in analysis. Seafont and Intermediate showed a similar pattern, based on fruits, vegetables, tubers and unprocessed meat (P=0.80 for both). Less healthy patterns were identified in low-income areas: Northwest based on refined grains, flour, pasta, beans, fats and sugar (P=0.82); and Downtown on fruits, vegetables and soft drink (P=0.70).

Conclusions: Neighborhood disparities in food environment are a concern due to their potential to influence purchase behaviors, dietary intake and obesity. Interventions are needed to increase the availability and access to healthy food.

Key words: food acquisition; food environment; food stores; urban health.

PO1544**SEASONAL UNCONDITIONAL CASH TRANSFERS AND WASTING IN NIGER***B. Fenn¹, D. Trepel², C. Dolan¹, J. Shoham¹, V. Sibson³*¹Emergency Nutrition Network, Oxford, UK²Department of Health Sciences, University of York, York, UK³Save the Children, London, UK

Background and objectives: The use of unconditional emergency cash transfers (CTs), prior to and during annual seasons of poor food security are becoming increasingly popular amongst agencies involved in tackling undernutrition. Yet there is little evidence of their impact on childhood nutrition outcomes, even with improvements in dietary diversity and calorie intake. The Moderate Malnutrition cash Study (MMS) attempts to understand why CTs may not directly impact on nutritional status by examining potential synergies and barriers within the causal framework.

Methods: The MMS was a prospective community-based cohort study of a Save the Children CT programme in Maradi region, Niger. 453 households, with a non-wasted child 6–36 months, were enrolled at baseline and followed for 5 months. Exit from the study was detection of wasting; weight-for-height z score (whz) <-2, Mid-upper arm circumference (MUAC) <125mm or bilateral pitting oedema. Pre-distribution baseline data were collected on community, household, mother and child variables; time variant data was collected monthly. Data was analysed by adjusted Cox proportional hazards survival regression.

Results: The final adjusted model showed significant associations with wasting remained for; poorer socio-economic status (2.78, p<0.001), baseline whz (0.36, p<0.001), disease incidence (1.86, p=0.01), expenditure on medical care (1.39, p=0.01; expenditure controlled for disease: 0.74, p=0.01), and younger age group (0.97, p<0.03). Distance to medical services was weakly significant in the final model (HR= 1.56; p=0.06). Improvements in household food security and dietary diversity, and children's dietary diversity and food expenditure were similar across the sample.

Conclusions: These results suggest that if cash transfers benefits are to be maximised to help prevent the occurrence of wasting in under-fives then attention needs to focus on removing health-related barriers. This will require enhanced coordination across the health, Water Sanitation and Hygiene (WASH), livelihoods and nutrition sectors.

Key words: Cash transfers, Niger, Wasting, Cohort, Pathways.

PO1545**CORRELATES OF FRUIT AND VEGETABLE CONSUMPTION AMONG 11-YEAR OLD SCHOOLCHILDREN: RESULTS FROM THE PRO GREENS PROJECT IN PORTUGAL**

B. Pereira¹, B. Franchini¹, R. Poínhos¹, M. Vaz de Almeida¹

¹Faculty of Nutrition and Food Sciences, University of Porto, Porto, Portugal

Background and objectives: To investigate which personal, social and environmental factors were more strongly correlated with fruit and vegetable intake after an intervention program to promote their consumption in a sample of 11-year-old Portuguese schoolchildren.

Methods: A cross-sectional survey was performed, both at baseline and follow-up, as part of the Pro Greens cross-Europe survey in order to assess the effect of a one-year intervention on the frequency of fruit and vegetable consumption and to identify potential correlates of consumption. A total of 690 Portuguese children participated, divided into intervention (n=310) and control (n=380) groups. Data was analysed using t test and Spearman's correlation coefficients with SPSS® version 20.0; statistical significance was established at $p < 0.05$.

Results: Regarding the mean frequency of intake of fruit and vegetables at the follow-up period, the intervention group revealed some small but significant differences compared with the control group (Fruit: 0.93 vs. 1.11 times per day, $p = 0.006$; Vegetables: 1.46 vs. 1.67 times per day, $p = 0.038$). In the intervention group, daily fruit and daily vegetable intake were significantly correlated with liking, positive self-rated intake and attitudes, habit, intention and parental encouragement, demand and allowance.

Conclusions: This study shows that interventions to promote fruit and vegetable consumption must take into consideration various personal and social correlates. The modest albeit significant effect reinforces the need for longterm and sustained promotion of F&V intake.

Key words: fruit and vegetables, schoolchildren, correlates.

PO1546**TEACHERS' PERCEPTIONS OF AN INTERVENTION PROGRAM TO PROMOTE FRUIT AND VEGETABLE CONSUMPTION IN SCHOOLCHILDREN**

B. Pereira¹, B. Franchini¹, R. Poínhos¹, M. Vaz de Almeida¹

¹Faculty of Nutrition and Food Sciences, University of Porto, Porto, Portugal

Background and objectives: Intervention programmes within the school setting require an extended collaboration from teachers in order to be carried out and to be effective. The aim of the present study was to examine the perceptions of school teachers regarding an intervention program to promote fruit and vegetable consumption in 11-year-old schoolchildren – the Pro Greens project - in two Portuguese schools.

Methods: Data derived from a follow-up self-administered questionnaire, filled out by teachers belonging to the intervention schools of the Pro Greens project. The questionnaire included questions regarding the overall program quality, activities and support materials made available to teachers and children and also questions about the impact of the program on the awareness concerning fruit and vegetable intake. Descriptive statistics were performed using SPSS® version 20.0.

Results: All teachers involved in the project have completed the survey. A total of 16 (87.5% female) teachers have completed the questionnaires. 43.8% considered Pro Greens intervention very good, and 75% said that the perception of students on the program was good. Most of the participant teachers (87.5%) considered the overall quality of the classroom curriculum of the project good. Regarding teachers' manual provided by the project, 25% considered it very good. 50% of the teachers consider that Pro Greens intervention has contributed, to a large extent, to increase children's awareness about fruit and vegetable intake, whereas 62.5% believes that to some extent, the intervention has contributed to increase his/her own awareness and interest about this issue.

Conclusions: These findings provide useful information to work on the improvement of such programs in order to create more appetitive and useful materials and activities for teachers and that fit better on the school curricula, which could therefore result in a more effective program.

Key words: schoolchildren, intervention program, fruit and vegetables, teachers.

PO1547**FOOD, BELIEFS AND THEMATIC APPEALS IN ADVERTISEMENTS OF BRAZILIAN MAGAZINES**

M. Costa^{2,3}, M C. Carvalho¹, S. Prado², J. Soares³

¹Universidade Federal do Rio de Janeiro, Universidade do Estado do Rio de Janeiro, Brasil

²Instituto de Nutrição, Universidade do Estado do Rio de Janeiro, Brasil

³Instituto de Psicologia, Universidade do Estado do Rio de Janeiro, Brasil

Background and objectives: The study of advertisements can show social practices, meanings of life and forms of relationships throughout history. The objective was to analyze beliefs, thematic appeals and quality of products in advertising campaigns.

Methods: We selected four magazines per year of *Seleções Reader's Digest* (1944-1948) and *Claudia* (2004-2008). Only the ads of food and beverage (non-alcoholic drinks) with the figure of the female body were submitted to semiotic analysis.

Results: The statements in the ads were grouped into two categories: attributes (flavor, smell, color, texture and yield) and benefits (health, nutrition, welfare; body shape, energy; love, friendships; pleasure, satisfaction, convenience). The thematic appeals were classified into six categories based on the central idea of the ad: fun/joy; love/feeling; appetite; status/prestige; relaxation/vacation; and humor. We found 82 food and beverage ads, 33 of *Seleções* and 49 of *Claudia*. In *Seleções*, the attributes of the products were more valued and the appetite appeal was more frequent. In *Claudia*, the benefits were more important, without strong evidence of a specific appeal, the fun/joy appeal was more common. Among the products of *Seleções*, the main representative was the refrigerants. Fruits and vegetables were not announced. However, more than half of the ads of *Claudia* presented specific versions of the product such as light/diet/zero, skimmed, rich in fibers, soy-based, whole grains and fast food.

Conclusions: The increase of obesity, characteristic of the nutritional transition process, is related to dietary practices of the individual in society. The exchange of technical-scientific Knowledge of Nutrition with the discourse of Advertising can provide important information to the consumers to decide about their food, based on the cultural standard, to ensure health and well-being for the individual and society.

Key words: Food. Nutrition. Advertising. Beliefs. Appeals.

PO1548**SCHOOL FOOD POLICY AND EVIDENCE – AN INTERNATIONAL APPROACH**

M. Nelson¹, J. Breda²

¹Children's Food Trust, Sheffield, UK

²WHO Regional Office for Europe, Copenhagen, Denmark

Background and objectives: Schools provide an excellent platform from which to promote good child nutrition and health, including social and financial safety nets through engagement with local communities and food providers. (1) Better integrated evidence is needed internationally to support policy development worldwide.

Methods: An international workshop hosted in London in January 2012 by the Children's Food Trust and WHO Regional Office for Europe (2) brought together a group of experienced researchers and policy leads from 20 middle- and high-income countries to discuss how to improve the evidence base for school food policy development. The workshop covered current school food policy across Europe, United States, Brazil, and China, and links between evidence and policy development.

Results: The workshop developed recommendations to strengthen links between evidence and policy: conduct a review of school food research; develop a map showing links between policy, evidence, and tools for workforce development; develop a regularly updated repository of research and guidance relevant to school food policy; establish an international network for experts involved in strengthening school food policy, spanning government representatives, experts in education, school principals, civic organizations, public health nutritionists, caterers.

Conclusions: Organizers and participants from the London workshop met in Israel in March 2013 to discuss the assembly of a European network to promote better school food policy development and implementation through sharing of methodologies, building a strong evidence base, garnering political support for school food regulation, and facilitating the sharing of learning outcomes and training.

Key words: school food policy (1) Bundy D et al (2009). Rethinking School Feeding. World Bank (2) Nelson M, Breda J. School Food Research: building the evidence base for policy. Public Health Nutrition 2013

PO1549**PREDICTORS OF INFANT OVERWEIGHT IN A RURAL AND URBAN AREA OF THE ECUADORIAN HIGHLANDS**

J. Ortiz^{1,2}, S. Wijaya¹, S. Donoso², J. Van Camp¹, B. de Meulenaer¹, L. Huybregts^{1,3}

¹NutriFOODchem unit, Department of Food Safety and Food Quality, Faculty of Bioscience Engineering, Ghent University, Belgium

²Faculty of Chemical Sciences, Cuenca University, Cuenca, Ecuador

³Child Health and Nutrition unit, Department of Public Health, Institute of Tropical Medicine Antwerp, Belgium

Background and objectives: Recently in developing countries, the proportion of overweight children has increased considerably in all age groups. This study aimed to identify and compare the socio-demographic determinants of overweight of infants aged 0-24 months between an urban and a rural area of the Ecuadorian highlands.

Methods: A cross-sectional study was conducted between June to September 2008 in a sample of 227 infants from a rural and 476 from an urban canton of Azuay province, Ecuador. Household key indicators (KPC survey); socio-demographic characteristics (questionnaire on Unsatisfied Basic Necessities), and anthropometric measurements were collected. The WHO 2006 growth standard references were used to estimate the BMI-for-age index.

Results: The prevalence of overweight children was higher in the urban area than in the rural area (12.4% vs 8.8%); while the prevalence of obesity was similar (5.7% and 6.2%, respectively). Compared to the rural area, there was a significantly higher assisted delivery (96.6% vs 53.7%; P -value<0.001) and a higher preference to frequent medical centers (85.1% vs 76.7%; P -value=0.006) in the urban canton. Unassisted delivery was found as significant predictor for infant overweight in both urban (OR: 0.29; 95%CI: 0.10, 0.81) and rural setting (OR: 0.48; 95% CI: 0.23, 1.01). Only in the rural setting child's age was positively/negatively associated with infant overweight (EFFECT=0.046), whereas in the urban setting older maternal age at birth of the first child appeared protective against infant overweight (OR: 0.94; 95%CI: 0.89, 0.99).

Conclusions: Infant overweight was associated with different factors in urban and rural in Ecuador. In contrast to the large cultural and socio-economic differences, only maternal status and frequentation to medical services was significantly associated with infant overweight.

Key words: Overweight, infants, rural-urban differences, socio-demographic determinants.

PO1550**FACTORS ASSOCIATED WITH NUTRITIONAL SUPPLEMENTS CONSUMPTION BY EXERCISE PRACTITIONERS IN SÃO LUIS, BRAZIL**

H J F. Veloso¹, F M Moura L. Alves¹, N A L. Cabral¹, E V. Hortegal¹

¹UniCEUMA, Brazil

Background and objectives: Sports nutrition aims to establish dietary strategies to improve performance and ergogenesis. This study aimed to analyze factors associated with nutritional supplements consumption among exercise practitioners in health club at São Luis, Northeast of Brazil.

Methods: A convenience sample was defined by considering the number of health clubs in operation in São Luis. The dependent variable was the use of supplements and the explanatory variables were how long one has been practicing exercise, schooling, weekly attendance at the health club, gender, age, self-perception of weight, smoking, goal of exercise, training session duration, self-awareness of training intensity and self-perception of own power. The association of variables was analyzed using Poisson regression, adopting a significance level of 0.05.

Results: The final sample consisted of 723 exercise practitioners, of which 64.7% reported using some type of supplement. A higher proportion of men (52.6%) was observed. Age between 20 to 39 years-old was more frequent (74.4%). Regarding schooling, 24.1% had post-graduation degree, 41.1% superior graduation degree, 30% had completed high school and 2.8% elementary school. Smoke was observed in 3.5% of participants. Most respondents (46.1%) were physically active for over a year. Variables associated with nutritional supplements consumption were self-evaluation of below the ideal weight (p <0.001), smoking (p <0.001), practicing exercise for 7-12 months (p = 0.028) or for more than 1 year (p <0.001), practice exercise for more than two hours each session (p = 0.053) and self-evaluation of training to be moderate (p = 0.024).

Conclusions: Socioeconomic, demographic and own power do not interfere in the decision regarding the consumption of supplements that are strongly associated with the characteristics of the training and dissatisfaction with body weight.

Key words: Nutritional Supplement, Physical Exercise, Poisson Regression.

PO1551**CONSUMPTION OF PROCESSED AND ULTRA-PROCESSED FOOD AND DRINK PRODUCTS IN THE USA, 2007-08**

L G. Baraldi¹, E S. Martinez¹, R C. Claro¹, A P B. Martins¹, M L C. Louzada¹, D S. Canella¹, R B. Levy¹, J C. Moubarrac¹, G. Cannon¹, C A. Monteiro¹

¹Department of nutrition, Universidade de São Paulo, São Paulo, São Paulo, Brazil

Background and objectives: Increased consumption of processed food products is a major cause of the current pandemic of obesity and related chronic non-communicable disease. The objective of this study was to assess processed and ultra-processed products consumption in the US in 2007-08.

Methods: Dietary data analyzed came from the 2007-08 National Health and Nutrition Examination Survey-NHANES conducted on a probabilistic sample of 10, 149 people of all age groups. Breastfed children were not included. Food items were converted into dietary energy and assigned to: (1) unprocessed or minimally processed foods and freshly prepared dishes made up mostly from these foods, or (2) ready-to-consume food products. This second group is of processed products, manufactured by adding substances such as salt, sugar, or oil to whole foods; and ultra-processed products, formulated mostly or entirely from industrial ingredients, typically containing little or no whole foods. The contribution of ready-to-consume products to the diet, expressed as a percentage of total dietary energy, was calculated.

Results: The average contribution of ready-to-consume products to dietary energy was 69.6%. This was made up from 4.9% from processed products and 64.7% from ultra-processed products. The most consumed processed product was cheese (3.0%). The main ultra-processed products were: pre-prepared ready-to-eat or to-heat mixed dishes (16.8%), candies (sweets) and desserts (7.8%), sugar sweetened soft drinks (7.6%), breads (6.9%), sweetened pastries and cakes (5.2%), and salted snacks (4.2%). The overall US figure of 69.6% is slightly higher than in Canada (62.0 %) and the UK (63.4%), somewhat higher than in Chile (55.4%), and much higher than in Brazil (27.8%).

Conclusions: The US diet is dominated by ready-to-consume food and drink products, almost all of which are ultra-processed.

Key words: Diet, Food Processing; ultra-processed food products; NHANES.

PO1552**VALIDATION STUDY OF WEIGHT CONCERNS SCALE APPLIED TO COLLEGE STUDENTS**

J. Dias¹, J. Campos²

¹Department of Food and Nutrition, Faculty of Pharmaceutical Sciences of Araraquara - State University Julio de Mesquita Filho, Brazil

²Department of Social Dentistry, Faculty of Dentistry Araraquara - State University Julio de Mesquita Filho, SP, Brazil

Background and objectives: The Weight Concerns Scale (WCS) proposed in the english language, aims to evaluate the degree of concern with body weight. Objective: perform cultural adaptation of the instrument to portuguese and estimate its reliability and validity in college students.

Methods: 343 college students (female) from a Brazilian public university were participated. The validity of the scale was measured by means of factorial and convergent validity. Then, the confirmatory factor analysis was conducted using as the fit indices the χ^2/df , the CFI, GFI and RMSEA and estimated the average variance extracted (AVE) and composite reliability (CR). The factorial invariance was estimated by analyzing multigroups considering the groups as "eutrophic" and "non-eutrophic" defined from the body mass index of the participants. The internal consistency was estimated by Cronbach's alpha (α).

Results: 442 participants performed the Health course and 655 the Humanities course. The average age was 20.9 ± 6 years and 6.7% were underweight, 74, 8% were normal weight, 9.9% were overweight and 7.2% were obese. The portuguese version of the WCS showed adequate factorial adjustment in the total sample ($\chi^2/df=0, 55-0, 78$; $f^2/df=9, 06$; CFI=0, 98; GFI=0, 98; RMSEA=0, 09). The convergent validity (AVE=0.49, CR=0.83) and internal consistency were adequate ($\alpha=0.77$). The simultaneous adjustment of the groups was excellent ($\chi^2/df=0.55-0.79$; $f^2/df=5.21$; CFI=0.95; GFI=0, 96; RMSEA=0, 06) with invariance of the models ($\chi^2/df=4.58$; $p=0.33$; Cov: $\chi^2/df=12.10$; $p=0.03$; Res: $\chi^2/df=48.09$; $p=0.00$).

Conclusions: the portuguese version of the Weight Concerns Scale applied to female college students showed adequate reliability and validity.

Key words: validity; college students; reliability; body weight. Grant number FAPESP: 2010/13475-4

PO1553**ULTRA-PROCESSED FOOD AND DRINK PRODUCTS AND OBESITY: A NEW HYPOTHESIS, AND EVIDENCE**

C.A. Monteiro¹, R.B. Levy¹, R. Claro¹, A.P.B. Martins¹, M.L. C. Louzada¹, L.G. Baraldi¹, D.S. Canella¹, J.C. Moubarac¹, G. Cannon¹

¹Department of nutrition, Universidade de São Paulo, São Paulo, São Paulo, Brazil

Background and objectives: Increased consumption of industrially processed food products is considered to be an important cause of the current pandemic of obesity. However, direct evidence linking the intake of these products to obesity is restricted to a few products such as soft drinks. This is in part because criteria to define and classify foods according to industrial processing have not yet been agreed. This study proposes that one increasingly consumed group of processed foods, ultra-processed food and drink products, are an important cause of obesity, and presents supportive preliminary evidence.

Methods: We used a new food classification based on the nature, extent and purpose of industrial food processing. This defines ultra-processed products as formulations mostly or entirely of industrial ingredients, typically containing little or no whole foods. The purpose of ultra-processing is to create durable, accessible, convenient, and highly-palatable products. These include sugared breakfast cereals; many baked goods; chips and several snack products; soft cola and 'energy' drinks, and ready-to-heat products such as pre-prepared pizza and pasta dishes, burgers and hot dogs, and poultry and fish 'nuggets' or 'sticks'.

Results: Population-based studies on national-representative samples of adolescents and adults in Brazil indicate that higher consumption of these products (upper quintile) increases the risk of obesity by 20-30%. There are many reasons why ultra-processed products are likely to increase the risk of obesity. They are energy-dense (added fat and sugar, reduced water). They increase accessibility (they are convenient, packaged, with long shelf life). They favor snacking and mindless eating (they are readily accessible, minimal utensils needed). They are liable to be over-consumed (they are highly palatable and often aggressively marketed).

Conclusions: Preliminary epidemiological evidence and other evidence indicate that the increase in the consumption of ultra-processed food products is one cause of the obesity pandemic.

Key words: Obesity, diet, food processing.

PO1554**WORLDWIDE FOOD AND NUTRITIONAL PICTORIAL REPRESENTATIONS**

S. Rodrigues¹, G. Botelho^{1,2}

¹Coimbra College of Agriculture, Polytechnic Institute of Coimbra, Coimbra, Portugal

²Department of Food Science and Technology, CER-NAS Research Unit, Coimbra College of Agriculture, Polytechnic Institute of Coimbra, Coimbra, Portugal

Background and objectives: The food and dietary guidelines related to the food education theme can be transmitted in the form of guidelines or through pictorial representations. In this work 40 worldwide pictorial representations of food and nutritional guides available in 23 countries are presented and discussed.

Methods: An Internet search about food and nutritional guides and benchmarks and also nutritional plans, policies and strategies of a healthy lifestyle worldwide was conducted systematically. The search was done only in recognized institutional and official institutions web sites of each country or global organizations (such as World Health Organization or Food and Agriculture Organization). The intention was to include all regions of the world and their different development stages.

Results: The main goal, found in all of the 40 pictorial representations evaluated, was similar - to educate the target public regarding proper eating habits and nutrition education, promoting a culture of food education and encouraging healthy lifestyles. It was intended to instill rules, guidelines and nutritional advice, gathering the foods and classifying them so as to teach the relative proportions of food ingestion.

Conclusions: The pictorial representations for each country are presented as symbols representing a familiar image to the target population. The written messages associated with the pictures are simple, direct, clear and flexible in order to transform the message more effectively and spread it more efficiently. It is also clear that the food availability, culture, religion, social and economic environment are relevant factors that affect food choices and the image display of each pictorial representation is taken into account.

Key words: pictorial representations, food, nutrition, country.

PO1555**CHILDREN AND MOTHERS' PERCEPTION ON ACTUAL AND DESIRED HEALTHY BODY SHAPE IN URBAN INDONESIA**

H. Hardinsyah¹, C. Dwiriani¹, C. Au², M. Lwin³, M. Aries¹, S. Nababan¹

¹Food and Nutrition Society of Indonesia, and Department of Community Nutrition, Bogor Agricultural University, Kampus IPB, Jl Raya Darmaga, Bogor, Indonesia

²Mondelez Asia Pacific Singapore and Kraft Food Indonesia

³Wee Kim Wee School of Communication and Information, Nanyang Technological University, 31 Nanyang Link, Singapore 637718

Background and objectives: The prevalence of overweight amongst children in developing countries has increased. Recent studies in developed countries showed that perceived body image is one of factors related to overweight, but no study has been done to examine this in Indonesia. This study aimed at assessing the nutritional status of school children (SC) and perception of children and their mothers on children's actual (ABS) and desired healthy body shape (DBS).

Methods: A cross-sectional study was conducted in SC (N=524, 8–10 years old) from different socio-economic status (SES) in urban Jakarta and Bogor. Data collected include SC body weight and height, perceived ABS and DBS by SC and mothers. SC nutritional status was assessed using BMI/age (underweight, normal, overweight), and body image perception was assessed using seven levels of silhouette charts designed for SC.

Results: Prevalence of underweight and overweight groups amongst SC was 7.3% and 8.1% respectively. Prevalence of overweight SC in high SES was double of low SES. While 30.7% of SC perceived their actual body shape to be underweight, 50.1% of mothers perceived their ABS to be underweight. A positive correlation was found between SC nutritional status and their perceived ABS categories ($r=0.50$), suggested some SC correctly assessed their ABS. However 44.8% SC perceived their DBS is overweight; and 23.3% of mothers perceived their children's DBS is overweight. They shared the same perception that the DBS for children should be larger than the ABS.

Conclusions: Overweight is higher amongst urban high SES children. SC and mothers are more likely to expect a larger body shape for SC to be identified as healthy children. This implies that the perceived body image by children and mothers can be unrealistic and shall be addressed in nutrition education to prevent childhood obesity.

Key words: Overweight children, body image, Indonesia

PO1556**HOUSEHOLD DETERMINANT OF MALNOURISHED IN PREGNANCY DUE TO LOWER ENERGY AND PROTEIN INTAKE (REANALYZED INDONESIAN BASIC HEALTH SURVEY IN 2007 DATA)**

D. M. Dachlan¹, A. R. Thaha¹, Wahiduddin¹, S. Riskiyan¹

¹SPH, Hasanuddin University, Indonesia

Background and objectives: Approximately 20% pregnant in Indonesia are malnourished not only caused by low intake of protein and energy but also related to household determinant. Objectives: To analyze determinant of household toward malnourished pregnancy due to low intake protein and energy from the data Indonesian Basic Health Survey in 2007.

Methods: Case control approach are using to Analyze the risk factor, which were 1435 malnourished pregnancy as a case, and control were 2947 pregnant in normal, with matching on age and cluster census. Indicator risk if: intake energy and protein <80 % RDA and stratification analysis by household determinant (household expenditure, mother's state and residential) Results Pregnancy with intake energy <80 % RDA are OR: 1.305 (CI 95%: 1.008-1.565), and intake protein <80 % RDA are OR: 1.338 (CI95%: 1.120-1.559). Stratification risk analysis for malnourished pregnancy due to low energy-protein intake, Household expenditure, educational level of mothers, working mothers and rural-urban residential are confounders risk factors.

Conclusions: Intervention only Intake energy and protein without any intervention about household determinant, cannot effective to solve malnourished in pregnancy.

Key words: Malnourished Pregnancy, Energy-Protein intake, household determinant.

PO1557**ESTIMATE OF THE NUTRITIONAL STATUS AND DIETARY INTAKE OF ADULT PEOPLE LIVING WITH HIV/AIDS IN DHAKA**

K. Ferdouse¹, S K. Roy¹, K. Jahan¹, A. Rahman², S. Israt¹, S S. Saliheen Sultana², S B. Salam¹, T. Ahmed¹

¹Bangladesh Breastfeeding Foundation, Institute of Public Health, Dhaka, Bangladesh

²Department of Food and Nutrition, Home Economics College, Azimpur, Dhaka, Bangladesh

Background and objectives: People living with HIV/AIDS (PLHIV) are vulnerable to poor nutritional status due to increased nutrient requirements. PLHIV need adequate

nutritional support prevention of HIV related infections and maintain good nutritional status. According to the estimation of UNAIDS, 11, 000 people living with HIV in Bangladesh. However there is lack of information on the nutritional status and food intake of the PLHIV in Bangladesh. This research was conducted to estimate the nutritional status and assess dietary intake of adult PLWHA of Dhaka.

Methods: It was a cross-sectional study, conducted during November-December, 2009 in Dhaka. About 65 adult PLHIV were selected randomly from Infectious diseases Hospital, Icdhr'b and Ashar Alo Society. Height and weight was measured to calculate the BMI of the subject to estimate their nutritional status. Dietary intake, frequency of taking food, Dietary habit, personal hygiene and other related data was collected with semi-structured questionnaire.

Results: This study found that nutritional status of 55.4 % PLHIV was normal, 30.8% were underweight (BMI less than 18.5kg/m²) and 13.8% were overweight. BMI was lower than 16 kg/m² among 18.5% PLHIV. About 54% of the subject's were unemployed and 12 % dependent on their relatives to meet their basic need of life. Mean calorie intake of the subjects was 1588 (± 329) kcal/day which was 29% less than their calorie requirement (P <.001). Most of the subjects were sick with various diseases like fever, caught, frequent diarrhea, TB, asthma, skin diseases.

Conclusions: Study found that nutritional status of most of the PLHIV was normal. However they are highly vulnerable to be malnourished due to low calorie intake and frequent exposure to diseases.

Key words: Nutritional status, Dietary intake, malnourished, PLHIV.

PO1558

RISK FACTORS ANALYSIS FOR MALNUTRITION OF PLHIV OF BANGLADESH

K. Ferdouse¹, SK. Roy¹, S S. Saliheen Sultana², K. Jahan¹, S. Israt¹, SB. Salam¹, T. Ahmed¹

¹Bangladesh Breastfeeding Foundation, Institute of Public Health, Dhaka, Bangladesh

²Department of Food and Nutrition, Home Economics College, Azimpur, Dhaka, Bangladesh

Background and objectives: People living with HIV/AIDS (PLHIV) are vulnerable to poor nutrition status due to increased body requirements. The objective of the study was to identify risk factors for malnutrition in HIV-AIDS subjects.

Methods: It was a cross-sectional study. To identify the risk factors 85 male and female HIV positive people aged 18 to 50years were interviewed by semi-structured questionnaire.

The subjects were randomly selected from a national NGO Ashar Alo Society and Infectious Diseases Hospital who provide health care service to the PLHIV in Bangladesh.

Results: The study found that Mean (± SD) age of underweight HIV positive subjects was 33 (± 9) years, Mean (± SD) height was 160 (± 8) cm, mean weight was 44 (± 5.6) kg and mean BMI was 17.2 (±1.3) kg/m². Study also recognized that less calorie intake was highly associated with underweight condition (OR=27.5). Calorie intake of the underweight PLHIV was 25% less than their daily requirement. Less protein intake was also associated with underweight (OR=2.80). Nausea (OR=2.60), Vomiting (OR=2.02), change in smell or taste (OR=2.70), Fever (OR=3.05), cough/cold (OR=2.50), diarrhea (OR=2.83), anorexia (OR=3.23) were also associated with the poor nutritional status of the subject. Some other factors i.e. unemployment, low income, low food intake, presence of diseases, social stigma, fasting or less food intake due to lack of money and poor appetite were significantly associated with poor nutrition status of PLHIV.

Conclusions: Nutrition is a fact which influence with many other factors like nutrition knowledge, socio-economic condition, body mechanism, mental condition etc. For longevity of PLHIV and decrease diseases progression, proper nutritional support should be provided through effective nutrition program.

Key words: Risk Factors, Nutritional status, HIV/AIDS, PLHIV.

PO1559

PERCEPTION AND INVOLVEMENT OF WOMEN'S GROUPS IN FOOD MANAGEMENT TOWARDS CREATING A HEALTH TOURISM COMMUNITY

N. Sikhiram¹, S. Poosawang¹

¹Home and Community Division, Faculty of Humanities, Chiangmai University, Thailand

Background and objectives: The study was conducted at Ban Tha-Gu, Mae Tha District, Lamphoon, Northern Thailand. This community is being supported by the Thai government health ministry to develop their skills in able to create and offer health tourism. The community currently practices organic farming and have created food security through practice of sufficiency economy theory. The study focused on four women groups in the community who are involved with food preparation and management in order to assess the acceptance, collaboration and preparation of health food for community health and tourism purposes.

Methods: The study was carried out as a participatory study which included seminars and workshops on healthy food preparation, basic and applied nutrition concepts, food safety handling, and food display and service management.

Results: The women groups did not have basic knowledge of the nutritional values of food whereas most recipes were prepared contained high saturated fat and high sodium content. Women groups were eager to learn how to prepare and manage food for health. They acknowledged that food is important for health and took part in analyzing the problems such as reliance on MSG as the major flavoring in food preparation. Another issue was preparing meals for themselves and tourist based on keeping cost to the minimum without understanding of nutritional value, quality and appropriate quantity. The researchers along with the women groups created standard recipes in order to improve food management and nutritional value.

Conclusions: Standard recipes are currently prepared for home consumption as well as for tourism. A change in the community eating habits is observed which in turn can be used as a promotional factor towards offering the community as a health tourism destination.

Key words: Health tourism community, Food management, Promoting nutritional value, Women group, Collaboration.

PO1560

RELATIONSHIP BETWEEN HAND WASHING WITH SOAP AND STUNTING AMONG CHILDREN <2 YEARS FROM BANGLADESH

L. Unicomb¹, C. Stewart², A. Halder¹, T. Huda³, P. Ghosh¹, S. Luby⁴

¹International Centre for Diarrhoeal Disease Research, Bangladesh

²Program in International and Community Nutrition, University of California, Davis, CA, USA

³Department of Disease Control, Faculty of Infectious and Tropical Diseases (ITD), London School of Hygiene and Tropical Medicine, London, UK

⁴Infectious Diseases and Geographic Medicine, Center for Innovation and Global Health Stanford University, San Francisco, CA, USA

Background and objectives: Hand washing with soap has been shown to reduce diarrhea in low income settings. Frequent enteric infections impact on child growth in such settings, thus good hand washing practices, by reducing diarrhea may impact on child growth. We examine the relationship between hand washing and nutrition status.

Methods: Credible hand washing practice data were collected through 5 hour structured observations for 417 households with at least one child <2 years in rural Bangladesh in 2007. We measured their height and weight. We compared length-for-age z-scores (LAZ) with categorical hand washing variables ranging from no hand washing to washing both hands with

soap. We controlled for wealth, parent education, child age and sex using a generalized estimated equation regression model and adjusted for households clustering.

Results: Among the 417 households, 169 of 432 (39%) children <2 were stunted. There were 8, 872 handwashing events observed. Of the 142 events recorded after latrine use, hand washing with soap was detected for 23(16%). Soap was used among 48 of 229 (21%) events of cleaning a child's anus, 5 of 783 (0.6%) during food preparation, 72 of 2, 821 (3%) before eating, and 14 of 1155 (1%) before feeding a child. Nutritional status, indicated by LAZ, was associated with wealth but not with washing both hands with water or soap when controlling for wealth, education, age and sex.

Conclusions: In this cross sectional study no association between nutrition status and hand washing during food-related or fecal-related events. Prospectively exploring an association of observed good hand washing practices on growth when dietary intake data are included is worthy of investigation. Acknowledgements; The UK Department for International Development funded the study

Key words: stunting, hand washing with soap.

PO1561

COMPARISON OF THE NUTRIENT DENSITY OF LUNCHESES EATEN BY FRENCH CHILDREN ACCORDING TO MEAL LOCATION: SCHOOL CANTEEN OR HOME

C. Dubuisson¹, S. Lioret¹, J.L. Volatier¹, D. Turck², L. Lafay¹

¹Risk Assessment Department, French Agency for Food, Environmental and Occupational Health and Safety (ANSES), Maisons-Alfort, France

²Department of Paediatrics, Jeanne de Flandre Children's Hospital and Lille University Faculty of Medicine, Lille, France

Background and objectives: School nutrition policies are considered as an appropriate way to promote healthier dietary habits in the paediatric population. In France, two thirds of French children and adolescents eat lunch provided by school canteen at least once weekly. Several guidelines on the composition of school meals have been published since 1999, in order to improve children intakes in lipids, sugar, fibre, vitamin C, calcium and iron. This study investigated whether nutritional intakes at lunch were different at school canteen and at home.

Methods: Data from the second French cross-sectional dietary survey (INCA2), performed in 2006-07 among a representative sample of 3-17 year-old children were used. Dietary intake and meal location were collected with a 7-day food record. A total of 4615 weekday lunches eaten at school canteen or at home by 1068 children attending school during the sur-

vey week were selected. Energy content and nutrient density (macronutrients, vitamins and minerals) were assessed using the French food composition database. Comparisons between school canteen and child's home were performed using a mixed regression linear model with child as random effect. Analyses were stratified according to school type (junior or secondary schools).

Results: Energy intake at lunch was 100 kcal higher at school canteen. For every 100 kcal, school lunches contained more proteins, starch, fibres, poly unsaturated fatty acids and sodium and less total carbohydrates, sugars, saturated fatty acids, calcium and vitamin C. Other results were school-type specific: school lunches contained more lipids and beta-carotene for junior-school children, and less iron, retinol, vitamin E and folate for secondary-school children. The food-groups contributing to these intakes also differed with lunch location.

Conclusions: Nutritional intake at lunch varies with location, suggesting that nutrition policies on school lunches may contribute to improve nutritional intake of children.

Key words: school lunch, nutrient intake, nutrition policies.

PO1562

HEALTHKICK: VALIDATION OF KNOWLEDGE, ATTITUDES AND BEHAVIOUR CONSTRUCTS RELATING TO HEALTHY EATING AND PHYSICAL ACTIVITY IN SOUTH AFRICAN SCHOOL CHILDREN

Z. Abrahams¹, N. Steyn¹, A. de Villiers², C. Draper³, J. Fourie², L. Dalais¹, J. Hill², E. Lambert³

¹Population Health, Health Systems and Innovation, Human Sciences Research Council, Cape Town, South Africa

²Chronic Disease of Lifestyle Unit, Medical Research Council, Tygerberg, South Africa

³UCT/MRC Exercise Science and Sports Medicine Research Unit Department of Human Biology, University of Cape Town, South Africa

Background and objectives: Evidence from North America and Europe has shown that school-based interventions can be effective in changing health behaviour. There is a scarcity of evidence from low and middle income countries. HealthKick is a primary school-based nutrition and physical activity (PA) intervention programme. A key tool used to assess learners healthy eating and physical activity knowledge, attitudes and behaviours (KAB) was developed and validated to be used as a measure of the efficacy of the programme.

Methods: Learners from 16 schools in the Western Cape Province were included in the survey (N=865). The questionnaire was administered in a classroom by trained field workers,

in learners' home language. Scores were based on the number of correct answers, and questions were grouped for nutrition and physical activity knowledge, self-efficacy, social support, barriers and behaviour. Multiple correspondence analysis (MCA) was conducted to identify valid constructs under these categories using the Burt matrix approach. The percentage of variability in the first two dimensions of each score was assessed. Questions that contributed very little to the variability were dropped from the model. Additionally, item-analysis was conducted to determine the internal reliability of the constructs.

Results: The final scores for knowledge consisted of 14 questions that contributed 87.7% to the variability; while 7 questions contributed 89.17% to the variability of the social support score and 13 questions captured 90.5% of the variability of the barriers score. Separate nutrition and PA scores were needed for self-efficacy and behaviour. 13 nutrition self-efficacy questions captured 89.6% of variability and 3 PA questions contributed 96.4% to the variability. Similarly, 6 nutrition and 2 PA behaviour questions contributed 77.6% and 100% respectively. Similar results were obtained when item-analysis was used.

Conclusions: MCA has been shown as an effective statistical technique.

Key words: nutrition, physical activity, validation, school-children.

PO1563

LONG-TERM ACCEPTABILITY OF LNS (LIPID-BASED NUTRIENT SUPPLEMENTS) FOR INFANTS IN MALAWI

U. Ashorn¹, N. Phiri², K. Maleta², K. Dewey³, M. Arimond³, P. Ashorn¹

¹Department of International Health, School of Medicine, University of Tampere, Tampere, Finland

²Department of Community Health, College of Medicine, University of Malawi, Blantyre, Malawi

³Department of Nutrition, University of California, Davis, USA

Background and objectives: The effectiveness of complementary feeding interventions depend on efficacy and acceptability. This descriptive study aimed to investigate mothers' experiences about providing lipid-based nutrient supplements (LNS) for extended periods to their infants.

Methods: The study is part of an intervention trial which provided LNS for 12 months to 6-18 month old infants in rural Malawi (www.ilins.org). After six months in trial (infant age 12 months), mothers' accounts were collected with in-depth interviews and KAP (knowledge, attitudes, practices) survey and analyzed for emerging themes and frequency of perceptions.

Results: KAP data were available from 1250 and in-depth interviews from 30 participants. Mothers reported having fed LNS to the child on an average of five days during previous week. 77% (95% CI 75 to 80%) of the infants were reported to have consumed LNS on the day preceding the interview, mostly in two feedings. Most mothers reported that their children liked LNS. However, 19% (16 to 21%) indicated some difficulties with feeding LNS. Typically, the child either refused all meals or declined to eat porridge containing LNS. LNS was shared with siblings in 12% (10 to 14%) and with other children in 14% (12-16%) of families. In-depth interviews suggested wider sharing among extended family. Selling or bartering was rare. The interviewed mothers perceived that LNS gave their infants strength and prevented illnesses. Only 9% (8 to 10%) thought that their child had growth problems and poor growth was seldom reported as a reason to consume LNS.

Conclusions: Long-term acceptability of LNS for infants is relatively good in rural Malawi. KAP survey suggests some deviation from recommended ways of feeding the products. In-depth interviews give a more detailed picture of acceptability. Funded by the Bill & Melinda Gates Foundation

Key words: Complementary feeding, LNS products, acceptability, Malawi.

PO1564

LUNCH-MEAL CHOICES; IMPLICATIONS TO HEALTH OF CORPORATE WORKERS COMPARED TO ARTISANS

R K. Steele-Dadzie¹, D Y. Larvie¹

¹Department of Dietetics, School of Allied Health Sciences, University of Ghana

Background and objectives: Lunch meals are often eaten away from home. Consumption of food prepared away from home has been associated with increased sodium, fat and calorie intake. Obesity and insulin resistance are also implicated. The variation in socioeconomic status of Corporate Workers and Artisans in Ghana could potentially influence their lunch meal choices. This study aimed at identifying the lunch meal choices of Corporate Workers compared with Artisans in Accra to identify individuals at risk of diet-related morbidity and mortality.

Methods: Study design was cross sectional. Participants were randomly selected from 4 Corporate Institutions and Artisan Worksites in Accra. A food frequency questionnaire was administered to obtain the choice and frequency of lunch meals eaten in a typical week. Daily energy, fibre and macronutrient intake were obtained using a 3-day 24 hour recall. Anthropometric measurements (bmi, waist and hip circumference) as well as total body fat and visceral fat (VF) were also measured.

Correlations between anthropometry, body composition and nutrient intake were determined using SPSS version 20.

Results: Corporate workers and Artisans had similar lunch meal choices. BMI, WHR, WC and VF were significantly higher among Corporate Workers ($p = 0.01$; $p < 0.01$; $p < 0.01$ and $p < 0.01$ respectively) compared with Artisans. Calorie contribution of lunch to total daily calorie intake was 42.9% and 46.2% respectively. Convenience was the major reason that influenced lunch meal choices.

Conclusions: Management of Corporate Institutions and Artisan shops need to scale-up their worksite health promotion programs to include provision of canteens where healthy meals would be provided.

Key words: lunch-meal, Artisans, Corporate Workers, Obesity.

PO1565

EVALUATING THE IMPACT OF A SCHOOL-BASED INTERVENTION ON THE DIETARY ADEQUACY OF LEARNERS FROM LOW-INCOME SETTINGS IN SOUTH AFRICA

Z. Abrahams¹, R. Ehrlich², A. de Villiers³, E. Lambert⁴, C. Draper⁴, J. Fourie³, L. Dalais¹, J. Hill³, N. Steyn¹

¹Population Health, Health Systems and Innovation, Human Sciences Research Council, Cape Town, South Africa

²School of Public Health and Family Medicine, University of Cape Town, South Africa

³Chronic Disease of Lifestyle Unit, Medical Research Council, Tygerberg, South Africa

⁴UCT/MRC Research Unit for Exercise Science and Sports Medicine, Sports Science Institute of South Africa, Newlands, South Africa

Background and objectives: HealthKick was a school-based nutrition intervention programme which took place in low-income primary schools in the Western Cape, South Africa. The intervention was designed to promote the adoption of healthy lifestyle behaviour, with the aim of reducing non-communicable disease (NCD) risk factors in disadvantaged communities. This paper reports on the impact of a “healthy lifestyle” intervention on the dietary adequacy of learners after 18 months of intervention.

Methods: The sample consisted of 8 intervention and 8 control schools. At baseline, 613 primary school learners were selected and 784 at follow-up. The intervention comprised a curriculum component and assistance in creating a healthy school environment. Learner’s nutrition knowledge, attitudes, dietary intake and anthropometric measurements (height and

weight) were assessed, and again after 18 months. Dietary adequacy was measured using dietary diversity score as a proxy measure.

Results: While both intervention and control schools showed a significant increase in the percentage of learners achieving an adequate diet, the increase was greater in the intervention schools. The most significant predictors of dietary adequacy at intervention and control schools, at baseline and follow-up were the number of meals eaten by learners and whether they had consumed food from the government school feeding programme. Dietary adequacy appeared to be largely reliant on socio-economic determinants.

Conclusions: Interventions implemented at schools in low income settings need to take into account that schools have many serious immediate priorities which rate higher than education on NCDs.

Key words: Dietary adequacy, healthy lifestyle, nutrition, intervention.

PO1566

PERCEPTIONS OF BODY WEIGHT AND HEALTH RISKS AMONG PRIMARY SCHOOL EDUCATORS IN THE WESTERN CAPE, SOUTH AFRICA.

L. Dalais¹, N. Steyn¹, A. de Villiers²

¹Population Health, Health Systems & Innovation, Human Sciences Research Council (HSRC), Cape Town, South Africa

²Chronic Diseases of Lifestyle, Medical Research Council (MRC), Tygerberg, South Africa

Background and objectives: The global problem of overweight and obesity is disturbing judging by the World Health Organization 2008 statistics which estimate that 1.4 billion and 500million adults are overweight and obese. The HealthKick study, a school-based nutrition and physical activity intervention programme in the Western Cape, S.A., showed that educators were at high risk for NCDs because of their high levels of obesity. This study aimed to describe primary school educators' perceptions regarding body weight, related health risks and barriers to weight management.

Methods: A qualitative approach was used to collect data and included focus group discussions, in-depth individual interviews and anthropometric measurements. A total of thirty one male and female educators from four schools participated in the seven focus group discussions and four in-depth interviews. Male and female focus group discussions and in-depth individual interviews were conducted separately. Thematic data analysis was conducted with the use of ATLAS ti 6.1 computer software.

Results: Educator perceptions regarding their own body weight varied slightly from the actual weight. Positive and negative weight loss experiences and feelings regarding their own body weight were expressed. Educators appeared knowledgeable of overweight/obesity and its health risks particularly regarding NCDs. Educators identified barriers relating to the school environment which were of particular interest. These were too little time, a heavy workload and many school responsibilities. A recommendation to prevent these time-related factors from being obstacles in a health and wellness programme, was that a programme should either be incorporated into the school programme or it should be implemented after school or on special/specific days with specific involvement of the Department of Education.

Conclusions: Several factors emerged which could be used beneficially to develop an educator weight management programme in schools.

Key words: Educators, obesity, body weight, health risks.

PO1567

IMPLICATIONS OF FREQUENT LIVER CONSUMPTION AMONG PREGNANT WOMEN FROM A LOW SOCIO-ECONOMIC SOUTH AFRICAN COMMUNITY

M. Van Stuijvenberg¹, S. Schoeman¹, J. Nel², M. Dhan-say¹

¹South African Medical Research Council, Cape Town, South Africa

²Northern Cape Department of Health, South Africa

Background and objectives: Excessive intake of vitamin A during pregnancy may lead to teratogenicity; the WHO recommends the consumption of not more than 25000 IU (7576 µgRE) vitamin A per week. Liver is a concentrated source of vitamin A, containing 7800 µgRE/100g, and intake during pregnancy should therefore be limited. This study aimed to determine liver intake and post-partum serum retinol levels in pregnant women from an impoverished South African community where liver is frequently eaten and vitamin A deficiency known to be absent.

Methods: Blood was obtained from 201 post-partum mothers. Information on liver intake during pregnancy was retrospectively obtained by questionnaire.

Results: Liver was eaten by 87.6% of mothers, with 75.1% having eaten liver at least once a month, and 20.9% at least once weekly. Mean serum retinol was 29.3±11.6 µg/dL, with 21.4% having concentrations <20 µg/dL. Elevated CRP concentrations (>8 mg/L) were found in 43.7% of mothers, with a significant negative correlation between serum retinol and CRP (-0.273; p<0.0001). The traditional cut-off value for serum retinol may

not apply to the post-partum period, as serum levels may be influenced by factors other than vitamin A status e.g., the haemodilutional effect of pregnancy, and the acute phase response induced by the birth process, as suggested by the raised CRP.

Conclusions: A concern in this community is the risk of teratogenicity in those women who consume liver once a week or more, and thereby exceeding the WHO recommendation for vitamin A intake during pregnancy. Health authorities in certain countries advise pregnant women to limit liver intake. No such recommendations exist for culturally diverse South Africa, and should be considered, especially for areas where liver is an available and affordable source of meat, and frequently consumed by the poor.

Key words: liver intake; pregnancy; excessive vitamin A intake; teratogenicity risk

PO1568

EFFECTING IMPROVEMENT IN FOOD BEHAVIOUR THROUGH AN EDUCATIONAL INTERVENTION: RESULTS OF AN IN-DEPTH STUDY IN SCHOOL CHILDREN

D. Prakash¹, J. Prakash¹

¹DOS, Food Science and Nutrition, University of Mysore, Mysore, India

Background and Objectives: The study explores the impact of nutrition education based on social cognitive theory on the cognitive performance, biochemical indices and food behaviour of urban school children (6-11 years, n=630) in Bangalore, India.

Methods: The study had a nutrition education intervention to the children and parents of the experiment group and a pre and post-test assessment of nutrition knowledge scores, cognitive performance scores, food behaviour in both experiment and control groups. The data was analysed using appropriate statistical techniques. **Results:** A statistically significant improvement was seen the cognitive performance and food behaviour parameters assessed in the experiment group and an impact of gender was seen in digit backward scores in girls ($p<0.011$). Biochemical indices was assessed in pre and post-test in a sub-sample of the experiment group; a statistically significant improvement in serum ferritin ($p<0.001$) was observed in the post-test. An impact of gender was seen in the post-test food frequency of the experiment group; girls consumed more sprouts ($p<0.006$), green leafy vegetable ($p<0.003$) and boys more eggs ($p<0.007$). The changes in food behaviour indicated lesser families watching television while eating ($p<0.001$), more families encouraging fitness ($p<0.001$) and a better dietary diversity of whole grain, plant proteins, fruits and vegetables in the experiment group. A converse change was observed

in the control group, with continued subscription to television while eating and increase in selection of high simple carbohydrate and fat; with poor dietary diversity in the control group. A positive association of plant protein, whole grains, fruits and vegetables was observed with improved cognitive performance in the experiment group.

Conclusions: The study concludes that the nutrition intervention was successful in improving nutrition knowledge, cognitive performance, iron status and food behaviour of children.

Key Words: Nutrition education, children, cognitive performance, food behaviour.

³National Institute of Health, Rome, Italy

⁴Department of Epidemiology, Regional Health Service, Lazio, Italy

⁵National Research Institute for research on food and Nutrition, INRAN, Italy

⁶Department of NonCommunicable Disease Epidemiology, London School of Hygiene & Tropical Medicine, London, UK

Background and objectives: Age-related decline of immune function and longevity may be partially due to extrinsic factors such as life-style behavior. This study investigated the role of walking outdoors on longevity, controlling for individual and other life-style factors as possible confounders

Methods: A 10-year cohort study was conducted with 152 self-caring and mobile, mean age 80 years, were enrolled in the study. Information on socio-demographic characteristics, clinical and biochemical data, diet, physical activity, smoking, depression status, cognitive status and anthropometrics measurements, were obtained for all participants. Cox proportional-hazards models were used to determine independent predictors of longevity.

Results: During the 10-years of follow-up, 96 (63%) died. Old age, chronic diseases, smoking, depression, CD4/CD8 ratio and coffee consumption were significantly predictors of mortality. Over-all survival was highest for subjects walking at open air for 4 times weekly for at least 15 minutes in compa-

ri-son to subjects walking less than 4 times weekly (40% versus 22%). After adjusting for confounders, elderly people walking at open air for four times weekly had 40% decreased risk of mortality that individuals who walked less than four times weekly [relative risk (RR) = 0.53; 95 % confidence interval (CI)= 0.32-0.88, p=0.01].

Conclusions: Findings suggest an independent and protective effect of walking on mortality and supports the encouragement of physical activity in advanced age for increasing longevity.

Key words: elderly, longevity, walking, life-style, immunity

RELATIONSHIP BETWEEN NUTRITIONAL STATUS AND SLEEP DURATION IN CHILEAN SCHOOL-AGE CHILDREN

S. Durán¹, G. Cediel², J. Brignardello¹

¹Universidad Autónoma de Chile, Department of Health, Santiago, Chile

²PhD (c), Nutrition and Food Program, University of Chile

³Universidad Autónoma de Chile, Department of Health, Santiago, Chile

Background and objectives: Sleep and healthy diet are important aspects in growth, maturation and health in scholar age. Inadequate sleep duration is a risk factor for obesity; this issue needs more attention in public health policies related to nutrition, especially during early ages. To establish the relationship between sleep duration, nutritional status and caffeinated beverages consumption patterns in school-age children.

Methods: The study was conducted in 805 school-age children, between 6 to 10 years old from 6 areas of Santiago de Chile. Parents filled out a questionnaire, which considers the sleep duration, physical activity and food intake. Anthropometric measurements were evaluated in school-age children.

Results: 52.6% of school-age children were obese and 46.4% slept the recommended time (>10 hours). Normal weight subjects slept more hours than obese 9.8 ± 0.9 vs 9.6 ± 0.9 (p<0.05). Sleep duration during the week was inversely associated to obesity (OR: 3.5, IC 95% 1.3 a 9.2), the beverage intakes during the night were caffeinated soft drinks (52.2 %), coffee and/or tea (32.6%) and 21.2 % caffeine beverages (caffeinated soft drinks, coffee or tea).

Conclusions: Sleep duration in the school-age children sample was less than recommended (>10 hours) specially, in the obese group. The intake of caffeine products in particular, caffeinated soft drinks, was higher during the night in both groups.

Key words: sleep; obesity; children.

PO1573

HEALTH PROMOTING LIFESTYLE OF UNDERGRADUATES AT SELÇUK UNIVERSITY, TURKEY

N. Aktas¹, B. Akin², M A. Cebirbay¹

¹Department of Nutrition Education, University of Selcuk, Konya, Turkey

²Department of Nursing, University of Selcuk, Konya, Turkey

Background and objectives: The World Health Organization signifies that the quality of an individual's health and life depends on his/her behavior and lifestyle. Health-risk behaviors are activities that increase a person's vulnerability or susceptibility towards negative health outcomes (1). The aim of this study is to determine the relationships between health promoting lifestyles and demographic characteristics of undergraduates.

Methods: This cross-sectional and descriptive study was conducted with 420 undergraduates at Selçuk University, Konya. The data was collected by using a socio-demographic questionnaire and the Turkish version (2) of Health Promotion Lifestyle Profile (HPLP-II) (3). The HPLP II has 52-item that consist of health responsibility, physical activity, nutrition, interpersonal relations, spiritual growth, and stress management.

Results: The participants were 73% girls; 60% of nursing and 40% of nutrition education undergraduates, one-half of the undergraduates (50%) lived in urban, perceived their economical situation as middle (69%), the education level of mother were primary school (60%) and, the undergraduates were lived in dormitory(80%). Living in rural areas and economically being well were found as significant factors affecting the HPLP (p<0.05). Education of mothers and gender of undergraduates were not an important factor for HPLP (p>0.05).

Conclusions: The supporting nursing and nutrition education undergraduate programs with subjects and activities about health behaviors and healthy lifestyle could affect HPLP of undergraduates.

Key words: Healthy lifestyle, health promotion, undergraduates.

PROMOTING HEALTHY LIFESTYLES: CULTURAL AND PARTICIPATORY APPROACH

R. Zárate¹, D. Castañeda¹

¹Universidad Industrial de Santander UIS, Bucaramanga, Santander, Colombia

Background and objectives: Health problems related to lack of enabling environments, strengthening community action, social participation and personal skill development for health promotion from the interplay of social, political, economic, cultural and environmental hinders promoting healthy lifestyles. However they are crucial for community development and thus for improving the quality of life of the population. Being the Colombian state responsible for ensuring fundamental rights since the 1127 Act of 2007, it provides the formulation of healthy public policies aimed at creating a supportive environment that will enable people to lead healthy lives towards improving the quality of life dignity. Taking into account the nurturing behaviors, healthy behaviors and practices from the promotion of a participatory culture, the Industrial University of Santander developed the project 'Promotion of lifestyles and healthy living environments in 100 families of the township of Yarima and sidewalks to Colorados, Rancho Chile and La Ye', in order to strengthen protective factors to reduce the occurrence of behaviors that influence the health of families.

Methods: The methodology was based on stages such as: recognition of habits and customs, ancestral resizing, learning together and resignifying behaviors to achieve a better quality of life based on approaches from social determinants and Human Rights.

Results: As a result, it was developed a certain group of teaching strategies evidenced in 75% of the studied population.

Conclusions: The promotion of healthy living from a cultural and participatory approach was established as a training strategy aimed at developing processes and activities of individual and collective empowerment, to modify risk behaviors and to adopt healthy lifestyles.

Key words: Quality of life, healthy lifestyles, health determinants.

DIAGNOSIS OF NUTRITIONAL AND FOOD STATUS OF THE STOCKS OF COLORADO AND INFLUENCE AREAS AT CAMPO ESCUELA COLORADO PROJECT – PARTICIPATORY ACTION RESEARCH (PAR) PORPUSE FROM UNIVERSIDAD INDUSTRIAL DE SANTANDER - COLOMBIA

C. Monsalve¹, R. Zárate¹, M. Peña¹

¹Universidad Industrial de Santander UIS, Bucaramanga, Santander, Colombia

PROMETEO research Group with eleven (11) years of investigative experience, assigned to the Industrial University of Santander (UIS) Bucaramanga - Colombia, in accordance with the policies of University Social Responsibility (USR), has focused on understanding and promote alternatives for change to complex food and nutrition situation of the population living in CAMPO ESCUELA COLORADO and its area of influence (CEC), administrative agreement UIS-ECOPETROL 2006 to 2016, San Vicente de Chucurí, Santander department. Thus PROMETEO aware of the importance of articulating the communities in the research process and in the development of the region, especially women heads of households, from a Participatory Action Research (PAR) made the project 'Promotion of lifestyles and healthy environments'. Where the advice of OBUZINGA Corporation, recognized by the local and national context for its experience in conducting studies in food and nutrition problems of rural populations; developed the food security component, empowering seven (7) leaders in the comprehension of the nutritional status of their communities by providing them conceptual and methodological tools for understanding and developing the nutritional profile of villages Los Colorados, Rancho Chile and La Ye, promoting empowerment and community building the Route to Action and management of food and nutrition security of the micro-region, influence area of CAMPO ESCUELA COLORADO project. Finally main risk factors were identified, such as malnutrition both deficit and weight excess in each of the population groups.

Key words: food security, university social responsibility, lifestyles and healthy environments..

PO1576**NUT CONSUMPTION AND DECREASED RISK OF TOTAL MORTALITY IN THE SUN PROJECT**

A. Fernandez Montero¹, M. Bes Rastrolle², J. J. Beunza², M. T. Barrio Lopez², C. de la Fuente Arrillaga², L. Moreno Galarraga³, M. A. Martinez Gonzalez²

¹Department of Occupational Medicine, Universidad de Navarra, Pamplona, Navarra, Spain

²Department Preventive Medicine and Public Health, Universidad de Navarra, Pamplona, Navarra, Spain

³Department of Pediatrics, Hospital de Navarra, Pamplona, Navarra, Spain

Background and objectives: Our aim was to assess the association between nut consumption and total mortality in the SUN Project.

Methods: The SUN Project [Seguimiento Universidad de Navarra, University of Navarra Follow-up] is a prospective cohort study, formed by Spanish university graduates. Information is gathered by mailed questionnaires collected biennially. A subsample of 17, 184 participants from the SUN Project was followed-up for 5 years. Nut consumption was collected by self reported data, using a validated 136-item food frequency questionnaire (FFQ) and participants deaths were identified by various means. Information on overall mortality (all-causes death) was collected from permanent contact with participants and their families, postal authorities and the National Death Index. The association between baseline nut consumption and overall mortality was assessed using Cox proportional hazard model during the first five-year period of follow-up. Nut consumption was categorized in two different ways, in a first analysis subjects were divided in quintiles based on baseline nut consumption (measured in g/d) adjusted for total energy intake using the residuals method. In a second analysis subjects were categorized in four groups according to nut consumption (servings/day). Both analyses were adjusted for possible confounding factors.

Results: Participants who consumed nuts twice or more per week had a 58% lower risk of overall mortality than those who never / or almost never consumed nuts (HR: 0.42 95% CI: 0.22-0.82) after adjusting for relevant confounders.

Conclusions: Nut consumption was significantly associated with reduced risk of death after the first five years of follow-up in the SUN Project.

Key words: nut consumption, total mortality, SUN Project.

PO1577**THE COST OF MEETING DIETARY GUIDELINES IN LOW-INCOME FAMILIES OF BRAZIL**

C. Borges¹, R. Claro², B. Slater¹

¹School of Public Health, Sao Paulo, Brazil

²University of Minas Gerais, Sao Paulo, Brazil

Background and objectives: A nutritionally balanced and healthy diet consists of fresh foods, grains, pulses and almost always has a high costs, unfeasible to low-income Brazilians. In fact, foods with high quantity of sugar and fat are generally cheaper and yet more accessible. We aimed to analyze the cost of following National Dietary Guidelines for low-income families in Brazil.

Methods: Data from the Brazilian National Household Budget Survey 2008-09 conducted by IBGE were used. Food purchases were recorded during seven consecutive days in 55,970 households. A subset composed only by low-income families (income \leq €US\$1.00 per capita/day) was used for the analysis. We estimated per capita calorie availability, total expenditure and food prices/1,000kcal aggregated into 8 food groups based on the Guidelines for the Brazilian population. The participation of each food group in total calories was estimated and compared to the recommendations.

Results: Actual acquisitions exceeded the recommendation for pulses, oils/fats, sweets/deserts, meat/eggs, and unmet for fruits, vegetables, dairy products, cereals. Meeting the recommendations would increase food expenditures in 58.1% (from US\$0, 91pc/day to US\$1.46pc/day) for an isoenergetic diet of 1, 943kcal (the exact guideline recommendation). The cost /month of the ideal diet according to the Brazilian Dietary Guide should be of US\$ 47.7/month for an individual living in a low-income family. Therefore, if the diet recommended was adopted by Brazilian low-income, the percentage to your total income would be compromised 54.2% more than is currently compromised (an increase of US\$16.00/month to US\$ 46.26/month).

Conclusions: Following diet recommendation would demand a large increase in food expenditure by low-income families. In this sense, meeting current dietary guidelines would necessarily demand an increase in the income of these families or a policy of food prices reduction.

Key words: low-income families, diet recommendation, food expenditures

PO1578**THE ROLE OF DIETARY PATTERNS IN CORONARY ARTERY DISEASE IN URBANISED BLACK SOUTH AFRICANS**

R. Dolman¹, E. Wentzel-Viljoen¹, J. Jerling¹, L. Ntyintyane², F. Raal², K. Sliwa³, A. Kruger⁴, M. Pieters¹

¹Centre of Excellence for Nutrition (CEN), North West University, Potchefstroom, South Africa

²Carbohydrate & Lipid Metabolism Research Unit, Division of Endocrinology & Metabolism, Department of Medicine, Faculty of Health Sciences, University of the Witwatersrand, South Africa

³Hatter Institute for Cardiovascular Research in Africa & IIDMM, Cape Heart Centre, University of Cape Town, South Africa

⁴Africa Unit for Transdisciplinary Health Research Health Research (AUTHeR), North West University, Potchefstroom, South Africa

Background and Objectives: To investigate the role of dietary intake as a risk factor in urbanised black South African CAD patients through the analysis of nutrients as well as of food group consumption patterns.

Methods: Dietary habits, including use of ultra-processed foods, of urbanised CAD patients were compared with those of healthy volunteers from an urbanised reference population (PURE). Urban areas in Soweto and North West Province, South Africa. Black CAD patients from Charlotte Maxeke Johannesburg Hospital and Chris Hani Baragwanath Hospital (n=91) and apparently healthy volunteers (n=534) from urban group of South African PURE study population at very low risk of developing CVD.

Results: Although the CAD patients consumed significantly higher protein, SFA and MUFA as percentage of energy, their diet was still considered prudent. In general, they had higher micronutrient intakes than the reference group. Both groups, however, met the DRIs for most micronutrients, except for calcium, vitamin C, magnesium and potassium. The CAD patients, furthermore, consumed more fruit and vegetables, dairy products, total meat products and eggs, as well as more ultra-processed foods than did the reference group.

Conclusions: The CAD patients' diets can be considered prudent, but are still not adequate in micronutrients owing to their low intake of foods such as fruit and vegetables and dairy products. Furthermore, they consumed more ultra-processed foods, providing evidence for a link between food processing and disease. The use of the analysis of food groups, including ultra-processed foods, greatly enhances the interpretation of nutrient data.

Key words: CAD, urbanisation, dietary patterns.

PO1579**UNDERNUTRITION IN COLOMBIAN SCHOOL CHILDREN WITH INTESTINAL PARASITES**

N. Muñoz¹, L. Valencia¹, C. Velasco¹

¹Grupo de Investigación GASTROHNUP, Universidad del Valle, Cali, Colombia

Background and objectives: The undernutrition defined how body mass index (BMI) < 1 standard deviation (SD) according OMS tables in school children with intestinal parasites (IP) is a major cause of morbidity and mortality. Objective: To determine the prevalence of undernutrition by BMI in Colombian school children with IP and associations potential.

Methodology: Prevalence study in 93 rural area school children in Cali, Colombia with IP (*Ascaris lumbricoides*, hookworms, *Trichuris trichiura* and *Giardia lamblia*). Were considered clinical (weight, height), paraclinical (hemoglobin Hb, coprology) and demographics (sex) variables. Statistical analysis included estimating the prevalence of thinness in school children and their corresponding 95%CI, the estimate of other descriptive measures of interest and association analysis by multiple logistic regression.

Results: Mean age 7.3±1.7 years; mean Hb 13.4±0.5 g/dl; mean BMI -0.48±0.67 SD; found a prevalence for undernutrition of 15% and for IP of 69.9%, dominance males and none with anemia (Hb < 11 gr/dl). Undernutrition was associated with IP (OR = 1.1 95%CI 0.27-5.23 p=0.02), and giardiasis (OR = 1.03 95%CI 0.21-4.08 p=0.00). Possible associated factors finally were younger and male sex.

Conclusions: Almost one fifth of Colombian school children with IP presented undernutrition and this was found to be associated with age and sex of the child.

Key words: Undernutrition, Intestinal parasites, School children

PO1580**BODY MASS INDEX IN CHILDREN WITH ATIPIC GASTROESOPHAGEAL REFLUX DISEASE GIVEN BY OTOLARYNGOLOGY**

N. Muñoz¹, M. Pérez¹, C. Velasco¹

¹Grupo de Investigación GASTROHNUP, Universidad del Valle, Cali, Colombia

Background and objectives: The nutritional status of children with gastroesophageal reflux disease (GERD) may be compromised, especially if occur with otolaryngology symptoms. We aimed too identify the nutritional status through the body mass index (BMI) in children with GERD and OLR manifestations.

Methods: We included 32 children with 1 to 12 years 6 months of age (average 5 years 3 months \pm 3 years 1 month), 17 male, diagnosed with GERD by pH monitoring 24-hour ambulatory intraesophageal (pH-24h) and one or more OLR manifestations (12 of recurrent otitis, 11 chronic sinusitis, 4 obstructive apnea and 3 dysphonia), whose mean weight was 19.0 ± 7.3 kg (range 10-37), mean length = 109.5 ± 20.4 cm (range 75-166) and mean BMI = -0.29 ± 1.89 (range -4.95 and 4.51).

Results: 17 children presented malnutrition (6 risk of undernutrition, 3 undernutrition, 2 severely underweight, 2 risk of overweight, 3 overweight and 1 obese) with 0.35 times more likely to be male gender (95%CI 0.06-1.81 $\times 2 = 2.08$) without any possible risk factor ($p < 0.05$).

Conclusions: The nutritional status of children diagnosed with GERD by pH-24h and OLR manifestations was involved in 53.1%, having more opportunity to be male sex, but without any possible risk factors.

Key words: Undernutrition, Atipic gastroesophageal reflux disease, Otolaryngology symptoms, Children.

psychosocial stimulation in target audience. Using this data, nutrition and psychologist experts created curriculum and module. Subsequently, the curriculum was tested for its applicability by conducting focus group discussions among mothers and educators.

Results: The curriculum emphasizes the role of mother-child relationship in feeding practices and creating a more stimulating learning environment in their home. Lesson components consist of 6 session that cover knowledge of food groups, cooking, food safety, feeding behavior, and a hands-on approach to improve children verbal, social-emotional, gross and fine motor developments. Mothers found that lessons were very helpful and increase their knowledge. Educators considered the hands-on activities were useful in engaging the mother, and believed the lessons and handouts were appropriate for target audience.

Conclusions: The results suggest that the FIRST curriculum was well accepted by the educators and mothers. Findings demonstrate the potential positive impact of education on feeding-practices and psychosocial stimulation for mothers and their children.

Key words: food-based intervention, psychosocial-stimulation, mother's education

PO1581

DEVELOPMENT OF FIRST (FOOD-BASED INTERVENTION AND PSYCHOSOCIAL STIMULATION) CURRICULUM FOR MOTHERS WITH CHILDREN UNDER 2-YEARS IN LOMBOK, INDONESIA

R. Kolopaking^{1,2}, U. Fahmida¹, O. Santika¹

¹SEAMEO RECON (Regional Center for Food and Nutrition), Universitas Indonesia, Indonesia

²Faculty of Psychology, Universitas Islam Negeri Syarif Hidayatullah Jakarta, Indonesia

Background and objectives: The role of mothers has been identified as a primary factor in creating home-environment that supports children's growth and development. Food-based intervention and psychosocial stimulation (FIRST) Program is an educational intervention which was designed to enhance the quality of parenting behavior and optimize their children's nutritional status and development. This study objective is to describe the development of FIRST curriculum for mothers with children aged less than 2 years in East Lombok, West Nusa Tenggara Province, Indonesia. Theory of Plan Behavior (TPB), Social-cognitive Learning Technique, and Ecological Framework were used to develop the curriculum.

Methods: Curriculum development began with in-depth interview, environmental assessment, literature study of child development and feeding practices, conducting linear/goal programming approach to develop complementary feeding recommendation (CFR) to identify key nutrition messages and test the cultural relevance of the food-based intervention and

PO1582

EGGS, IODINE AND IRON SUPPLEMENTATION IMPROVE COGNITIVE ABILITY OF ELEMENTARY SCHOOL CHILDREN WHO SUFFER IODINE DEFICIENCY DISORDERS IN INDONESIA

T. Sudargo¹, H. Hadi¹, W. Lestariana¹, A. Kumara²

¹Department Nutrition and health, Faculty of Medicine, Gadjah Mada University, Yogyakarta, Indonesia

²Faculty of Psychology, Gadjah Mada University, Yogyakarta, Indonesia

Background and objectives: Not only do elementary school children who live in iodine deficient areas have lower cognitive abilities than children from iodine sufficient area, but they also suffer from protein deficiency and iron deficiency. Supplementation of egg combined with iodine and iron is considered as an appropriate strategy for combating iodine, protein and iron deficiency in children with iodine deficiency disorders in order to improve their cognitive abilities. This study aimed at investigating the effect of supplementation of egg with iodine and iron on the cognitive ability (IQ score) of elementary school children.

Methods: This is a randomized double-blind controlled trial involving 109 elementary school children aged 8-13 years in endemic iodine deficient District, Kismantoro, in Wonogiri

(Central Java) Indonesia. Subjects were divided into 4 groups which are group A (iodine + iron + eggs); B (iron + eggs); C (iodine + eggs); and D (eggs) and supplementation were given for 16 weeks. Cognitive abilities (IQ score) were examined by using CFIT (culture fair intelligence test) at pre- and post- intervention.

Results: There is a significant difference on cognitive abilities (IQ within group of intervention after 16 weeks of intervention ($p < 0.05$). In cognitive abilities, children who received egg alone or in combination with iodine and iron have the highest cognitive abilities compared to the ones who got supplementation of egg with iron. In addition, children who received egg alone or combination with iron and iodine can increase the IQ score by 12 points and 13 points, respectively.

Conclusions: Supplementation with egg alone or in combination with iodine and iron improve the cognitive abilities (IQ score) of primary school children who suffer from iodine deficiency disorders.

Key words: Egg, iodine, iron, cognitive ability, children, iodine deficiency disorders.

PO1583

URBAN AGRICULTURE AS A STIMULUS TO URBAN PLANNING IN DEVELOPING CITIES FOR SUSTAINABLE FOOD AND NUTRITION SECURITY

V. Obatolu¹, S. Speak²

¹Obafemi Awolowo University Institute of Agricultural Research and Training, Ibadan, Nigeria

²School of Architecture, Planning and Landscape, Newcastle University, Newcastle upon Tyne, UK

Background and objectives: This paper presents the findings of a three year British Council/Development for International Development sponsor project in Ibadan, Nigeria. The broad study objective is to support Millennium Development Goals (MDG 1); poverty and hunger reduction and environmental preservation (MDG 7), and HEI capacity building.

Methods: Quantitative and qualitative survey, workshops and seminal were used to identify ways in which urban planning (UP) can support urban agriculture (UA) to improve sustainable urban livelihoods and food production and set intervention in motion. Advocacy and lobbying was also used to raise awareness and informs decision makers and planners of the different aspects of urban agriculture, which entails a broad range of activities.

Results: The initial survey shows that despite urban agriculture known strategic livelihood benefits, many still perceived it to be detrimental to public health and urban environments. Thus, urban planning seldom supports it and frequently seeks to eliminate it. In interviews with urban households, about

53.8% of the respondents were aware of what urban agriculture meant while 46.2 % were not. Reason for respondents engagement in urban agriculture include to 'clear the environment' (30.8 %), 'feed the household' (38.5 %) and for 'economic reasons' (38.5 %). UA still remains economically unimportant and an illegal practice; yet to be integrated in agricultural policies or urban planning. Final survey and workshop evaluation report analysis shows that support of urban agriculture could act as a relevant intervention point for urban planners in pursuing directly the MDG 1 and 7 for especially the urban poor people.

Conclusions: UA can be an innovation to UP in developing cities to enhance adequate access to sufficient, safe and nutritious food for healthy life as well as being a strategy to right based approach to food and nutrition security.

Key words: Urban, Agriculture, Planning, Food security.

PO1584

ENERGY AND MACRONUTRIENTS INTAKE IN BRAZIL: RESULTS OF THE FIRST NATIONWIDE INDIVIDUAL DIETARY SURVEY

R. Pereira¹, R. Souza¹, E. Yokoo², R. Sichieri³

¹Departamento de Nutrição Social e Aplicada, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil

²Instituto de Saúde da Comunidade, Universidade Federal Fluminense, Niterói, Rio de Janeiro, Brazil

³Departamento de Epidemiologia, Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil

Background and objectives: Dietary patterns in Brazil have undergone intense changes; nevertheless, until recently the country had no information on food consumption at individual level. The first nationwide individual dietary survey was carried out in subsample of 2008-2009 Household Budget Survey. The objectives were to characterize energy and macronutrient consumption and to compare with general dietary guidelines.

Methods: The analysis included a countrywide representative sample of individuals 10 years old and more, except pregnant and lactating women ($n = 32,749$ individuals). Energy and nutrient intake was estimated from means of two non-consecutive food records (deattenuated by the Multiple Source Method). Mean and 95% confidence interval of energy and macronutrients intake were estimated for age-gender strata, geographical regions, and per capita monthly family income quartiles. Statistical analyses considered the complex sampling design.

Results: Men presented higher mean energy intake than women (2126 vs. 1721 kcal; $p < 0.01$), but women reported higher contribution of added sugar to total energy intake than

men (13.8 vs. 12.5%; $p < 0.01$). Compared to adults (1.26) and elderly (1.19), adolescents presented higher energy-dense diet (1.33). Although mean total fat contribution to total energy intake (27%) was according to recommended limits, the lipids profile was unfavorable: there was high consumption of saturated fat (9.2% of total energy intake) and reduced intake of beneficial fats - polyunsaturated fat mean contribution to energy intake was about 6% and omega-6/omega-3 ratio was equal 8. Moreover, mean fiber intake was under the recommend limits (20g). The diet of individuals in the highest quartile of family income was characterized by high contribution of added sugar (14%) and saturated fat to total energy consumption (10%).

Conclusions: Overall characteristics of Brazilian dietary intake are compatible with the increased prevalence of obesity and non-transmissible chronic diseases that have been observed in Brazil.

Key words: energy intake, macronutrients intake, dietary guidelines

PO1585

CLUSTERING OF RISK FACTORS RELATED TO LIFESTYLE AMONG ADOLESCENTS FROM CUIABÁ, CENTRAL-WESTERN BRAZIL

R. Pereira¹, P. Rodrigues¹, R. Gonçalves-Silva²

¹Departamento de Nutrição Social e Aplicada, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil

²Faculdade de Nutrição, Universidade Federal de Mato Grosso, Mato Grosso, Brazil

Background and objectives: Lifestyle and dietary habits are modifiable risk factors commonly associated with non-communicable chronic diseases (NCCD). The aggregation of these factors is frequent among adolescents. This study aimed to estimate the prevalence and clustering of five NCCD risk factors among adolescents from the Brazilian Central-Western region.

Methods: Cross-sectional, school-based study ($n=1.139$; age=14-19 years old), in Cuiabá, Brazil. The occurrence of smoking, sedentary lifestyle, inadequate fruit-and-vegetables consumption, irregular habits of breakfast consumption, and unsatisfactory meals consumption pattern was investigated by means of a structured questionnaire. The meals consumption pattern was evaluated from scoring points assigned to the frequency of main meals consumption (daily=0; 3-6 times/week=1; 1-2 times/week=2; never=3 points). Scores > 3 indicated unsatisfactory meals consumption pattern. The intake of fruit-and-vegetables $< 400\text{g/day}$ was considered inadequate. The chi-square test was used to assess the association between variables. Multivariate logistic regression models were applied to estimate the chance of aggregation of risk factors.

Results: Prevalence of inadequate fruit-and-vegetables consumption was 32%. Smoking was more frequent among boys than among girls (9 vs. 4%, $p < 0.01$). Unsatisfactory meals pattern (66 vs. 53%), irregular consumption of breakfast (59 vs. 45%), and physical inactivity (32 vs. 9%) were more frequent among girls than among boys ($p < 0.01$). Cigarette smoking was associated with greater chance of inadequate fruit-and-vegetables consumption (OR=1.8, 95%CI=1.1, 3.0) and unsatisfactory meals pattern (OR=2.4, 95%CI=1.4, 4.3). There was higher chance of inadequate fruit-and-vegetables consumption among sedentary adolescents (OR=2.4, 95%CI=1.9, 3.8) and among those who were insufficiently active (OR=1.5, 95%CI=1.1, 2.0). There was greater chance of skipping breakfast (OR=1.5, 95%CI=1.1, 2.1) among sedentary adolescents.

Conclusions: There was high prevalence and aggregation of risk factors among the studied adolescents, indicating high vulnerability to the development of NCCD. Physical inactivity seems to be a marker of other risk behavior among adolescents.

Key words: Adolescent; lifestyle; meals pattern.

PO1586

SODA CONSUMPTION AMONG ADOLESCENTS FROM PUBLIC AND PRIVATE SCHOOLS, RIO DE JANEIRO, BRAZIL

R. Pereira¹, R. Fernandes¹, P. Freitas², ML. Rosa², RA. Souza¹, G. Veiga¹,

¹Departamento de Nutrição Social e Aplicada, Universidade Federal Do Rio de Janeiro, Brazil

²Instituto de Saúde da Comunidade, Universidade Federal Fluminense, Brazil

Background and objectives: Soda consumption is often associated with weight gain and seems to favor the development of metabolic disorders. In Brazil, high levels of soda consumption are frequently observed in adolescents. This study aimed to describe soda consumption and its association with social and demographic characteristics in adolescents.

Methods: Cross-sectional study analyzing data from the baseline survey of the Longitudinal Study on Nutritional Assessment of Adolescents (ELANA). In 2010, the survey examined 805 elementary and 1,015 high school students (10 to 19 years old) of selected public and private schools in the metropolitan region of Rio de Janeiro. Data on soda consumption were collected with a self-administered food frequency questionnaire. Soft drink consumption was classified as high (at least five times per week) or moderate (up to four times per week). The association between variables was assessed by estimating the odds ratio and 95% confidence interval.

Results: Fifty percent of the adolescents reported to have sodas at least five times per week. For elementary school stu-

dents, the chance of high consumption of soda among those from public schools was twice as much as those from private schools (OR = 2.1, 95% CI = 1.5, 2.8). The same was observed for high school adolescents: compared to private school students, those from public schools presented greater chance of high consumption of sodas (OR = 1.6, 95% CI = 1.3, 2.1). No differences were observed between students of elementary and high school according to the frequency of consumption of sodas.

Conclusions: Higher soda consumption was observed in adolescents from public schools than among those from private schools, regardless of grade level.

Key words: sugar sweetened beverages, adolescent, socioeconomic factors, odds ratio

AWAY FROM HOME EATING AND SKIPPING MEALS AND DIETARY SALT AND OIL INTAKES OF ADULTS IN BEIJING, CHINA

F. Zhang¹, X. Zhao¹, H. Lin¹

¹Department of Nutrition and Food Safety, Fangshan District Center For Diseases Control and Prevention, China

Background and objectives: Away from home eating and skipping meals may impact intakes of salt and oil.

Methods: A subsample of 954 adults aged 18 years old and older from the China Health and Nutrition was used. Dietary intake data were determined by three consecutive 24-hour recalls and food weighing method. Multivariate logistic regression was used to determine the impacts of meal patterns on salt and oil intake.

Results: Of the 954 participants, 6.7% skipped breakfast, 1.9% skipped lunch, and 1.3% skipped dinner. Participants had 24.5% of breakfasts, 20.1% of lunches, and 6.2% of dinners eaten away from home. Average salt consumption was 8.9 grams/day (g/d) and 89.8% of participants consumed > 6 g/d of salt. Average oil intake was 33.8 g/d and 56.4% participants consumed > 25 g/d of oil. Adjusted by age, education, gender, and income, adults who ate away from home were more likely to have high salt intake (OR=1.50, 95% CI: 1.09-2.07) and high oil intake (OR=1.56, 95% CI: 1.13-2.14). Skipping meals did not have significant impacts on salt and oil intake.

Conclusions: Skipping meals may have no effect on dietary salt or oil intake, but away from home eating significantly increased salt and oil intake.

Key words: Away from home eating, meal patterns, dietary salt intake, dietary oil intake.

PO1588

EFFECTS OF DIETARY RESTRICTION ABOVE PHYSICAL ACTIVITY

V. Aguilera¹, C. Flores², C. Santos², A. López-Espinoza¹

¹Behavioral Feeding and Nutrition Research Center University of Guadalajara- University Center From The South, Mexico

²Centro de Estudios e Investigaciones en Comportamiento Universidad de Guadalajara – Centro Universitario de Ciencias Biológico Agropecuarias, Mexico

Background and objectives: A balanced diet and physical activity are conditions for a healthy life. However, when these conditions are excessive or deficient people manifest diseases related to feeding behavior. Therefore is important determine the conditions to establish an adequate interaction between activity and feeding. The aim of this study was to identify the effects on activity in situations of ad libitum feeding and poor feeding in animal models.

Methods: Nine females albino rats of six months age at the start of the study were exposed during 30 days an condition ad libitum feeding and 60 minutes to activity wheel. Later the rats were assigned to three groups consisting of three rats each and were exposed to dietary restriction and 60 minutes to wheel running for 30 days. Group 1 dietary restriction was to the 90%; Group 2 dietary restriction was to the 70% and Group 3 dietary restriction was to the 50%.The body weight, activity, food consumption and water were measured daily.

Results: The results showed a positive correlation between dietary restriction and activity level, to low food restriction reduced activity at higher food restriction increased activity.

Conclusions: These findings corroborate that activity is determined by the consumption of food.

Key words: feeding, activity, health.

PO1589

CHINESE DIET BALANCE INDEX AND DIETARY QUALITY AMONG ADULTS IN BEIJING, CHINA

J. Qin¹, J. Yu¹, N. Zhang¹

¹Department of Nutrition and Food Safety, Xuanwu District Centre For Disease Prevention and Control, China

Background and objectives: To evaluate the overall diet quality of adults in Beijing.

Methods: A subsample of 1, 053 adults aged 18 years old and older who had completed three 24-hour dietary recalls in

the China Health and Nutrition Survey in Beijing. Diet quality was evaluated by using Chinese Diet Balance Index (DBI) scoring and evaluating system. Diet Quality Distance (DQD) was calculated to reflect the dietary quality. Multivariate linear regression models were used to identify factors characterizing imbalance intake.

Results: Dietary imbalance existed in a large proportion of the residents in Beijing. 40.1% adult were in moderate or severe deficit of food intake, while 29.0% in moderate or severe surplus of food intake. Intakes of milk, soybean, vegetables, and fruits did not reach the Recommended Daily Allowances. Intake of cereal, oil, and salt exceeded the recommended levels. Smoking, low income level, and low physical activity level were associated with dietary imbalance.

Conclusions: Dietary imbalance is common in Beijing. Residents consume more oil and salt and less milk, vegetables and fruits than recommended levels.

Key words: Chinese Diet Balance Index, dietary quality.

PO1590

TRENDS AND PATTERNS OF HEALTH BEHAVIORS IN LIAONING, CHINA, 1991-2006

Z. Zhao¹, D. Luan¹, S. Li¹, H. Li¹, Z. Liu¹, X. Li¹, X. Liu¹

¹Institute of Nutrition and Food Safety, Liaoning Center For Disease Control and Prevention, China

Background and objectives: To analyze trends and patterns of physical activity and soft drinks consumption in Liaoning, China.

Methods: Data on 1,039 adults aged 18 years old and older from 480 households participated in the China Health and Nutrition Survey were used. A multistage stratified cluster random scheme was used to draw the sample in Liaoning. Soft drinks consumption data were collected by using food frequency questionnaire and three consecutive 24-hour recalls. Detailed physical activities were self-reported in different categories.

Results: From 1991 to 2006, regular physical activity increased from 6.3% to 16.5% (p-trends < 0.0001) among adults but decreased from 46.5% to 32.1% in children and adolescents (p trends=0.011). Screen time increased from 13.0 to 20.5 hours per week among adults (p-trends = 0.021) and from 9.5 to 13.0 hours per week among children and adolescents (p-trends < 0.0001). Soft drinks consumption did not change over time among adults but significantly increased among children and adolescents from 2000 to 2006. The proportion of alcohol drinkers and smokers decreased while amount of drinking or smoking increased significantly from 1991 to 2006 (p-trends < 0.0001).

Conclusions: Physical activities are increasing but still low among adults and are decreasing quickly among children and

adolescents. Soft drinks consumption is increasing rapidly among children.

Key words: Physical activity, soft drink consumption, children and adolescents, lifestyle.

PO1591

NUTRITION TRANSITION IN JIANGSU, CHINA, 1989-2009

B. Yuan¹, Y. Dai¹, Y. Luo¹, H. Zuo¹

¹Department of Nutrition, Jiangsu Center For Disease Prevention and Control, China

Background and objectives: To study the secular trends of dietary pattern among residents in Jiangsu Province, China.

Methods: A multistage stratified cluster random scheme was used to draw the sample in Jiangsu for the China Health and Nutrition Survey cohort. Dietary intake data were determined by three consecutive 24-hour recalls and food weighing method. Blood pressure and anthropometric data were measured with standard protocols.

Results: Cereal consumption decreased significantly, while animal food consumption, dairy product consumption, energy from fat increased rapidly. Calcium intake was increasing but still much lower than the recommended intake level. Prevalence of overweight and obesity (BMI>24) increased from 9.4% in 1989 to 41.1% in 2009 among men. Prevalence of hypertension increased from 7.8% in 1989 to 37.6% in 2009 among men and from 4.8% to 30.8% among women during the same time period.

Conclusions: People in Jiangsu province are experiencing a quick nutrition transition toward high fat diet. Overweight, obesity, and hypertension are increasing tremendously.

Key words: nutrition transition, calcium, overweight and obesity

PO1592

AWAY FROM HOME EATING IN HUNAN, CHINA, 1989-2009

J. Liu¹, G. Li¹, D. Jin¹, M. Lin¹, Z. Fu¹

¹Department of Nutrition and Chronic Disease Prevention, Hunan Center For Disease Control and Prevention, China

Background and Objectives: To explore the patterns and changes of away from home eating (AFHE) in Hunan, China.

Methods: A multistage random cluster sampling method was used to draw the sample for the China Health and Nutrition Survey in Hunan. A subsample of 1,300 adults aged 18 years old and older was used in this study. Dietary data were collected by using 3 consecutive 24-hour recalls in combination with weighing methods. Away from home eating was defined as food prepared at restaurants and food stalls.

Results: AFHE increased from 0.1% in 1989 to 9.9% in 2009 in Hunan province. It increased faster in urban areas than in rural areas. In 2009, 16.8% of urban residents and 6.0% of rural residents ate away from home. AFHE slightly increased before 2000 and increased quickly thereafter. AFHE breakfast increased from below 5.0% in 2000 to 21.0% in 2009, lunch from 1.9% to 7.7%, and dinner from 1.6% to 3.7% during the same time period. AFHE significantly increased sodium intake and fat intake in this study, even though they were underestimated. As a result, overweight and obesity, hypertension, and other nutrition-related diseases increased rapidly in past 20 years.

Conclusions: Away from home eating is increasing quickly in Hunan province, particularly in urban areas. More studies are needed to observe and study the detrimental effects of away from home eating.

Key words: away from home eating, overweight and obesity, hypertension.

PO1593

AN INTERVENTION STUDY ON REDUCING ANIMAL FOOD INTAKE AND INCREASING PHYSICAL ACTIVITY

S. Zhao¹

¹Institute of Nutrition and Food Safety, Guizhou Center For Disease Control and Prevention, China

Background and objectives: To develop strategies to prevent and control overweight and obesity at community level.

Methods: Two urban neighborhoods and two rural villages with similar economic status and transportation were randomly selected and assigned to intervention and control groups. Intervention protocols were developed based on Chinese dietary Pagoda. Dietary data, physical activity, and blood samples were collected at baseline and at the end of 1-year follow-up. Multivariate linear regression and variance analysis were used to compare the differences between baseline and follow-up and between intervention group and control group.

Results: At baseline, animal food intake, physical activity, and BMI were not different between intervention group and control group. At the end of the study, animal food intake decreased in both groups. It was significantly lower in intervention group than in control group. Physical activity increased in the

intervention group and was significantly higher than in the control group. BMI and blood cholesterol were significantly lower in the intervention group than in the control group.

Conclusions: Promoting physical activity and reducing animal food consumption may be practical in terms of preventing and controlling overweight and obesity at community level.

Key words: Animal food, physical activity, intervention, overweight, obesity.

PO1594

EFFICACY OF DIFFERENT FORTIFIED GRUELS ON THE RECOVERY FROM MODERATE ACUTE MALNUTRITION IN BURKINABE 6-23-MONTH-OLD CHILDREN

T. Traore¹, C. Mouquet-Rivier², C. Kabore¹, O. Bruyeron³

¹GRET, NUTRIFASO Program, Ouagadougou, Burkina Faso

²Institut de Recherche pour le Developpement, UMR 204 Nutripass, IRD/UM1/UM2, Montpellier, France

³GRET, Paris, France

Background and objectives: Moderate acute malnutrition (MAM) is still a public health problem in developing countries and research is needed to define optimal fortified foods for its management. This study aimed at comparing the efficacy of the regular consumption of 3 fortified complementary foods on recovery from MAM in Burkinabe children.

Methods: The study was conducted in 11 rural health centers in Fada n'Gourma district in Burkina Faso. 330 children aged 6 to 24 months, affected by MAM ($-3 < \text{WLZ} < -2$) were randomly assigned to 3 groups receiving gruels prepared from one of the three following locally processed fortified flours: the two first (Energy density = 150 kcal/100g) were formulated according to specific recommendations for MAM (Golden, 2009), one with 8% dried milk (MAM-FFM), the second without milk (MAM-FF), and the third (ED = 100 kcal/100g) was the Miso-la (MIS) flour formulated according to recommendations for healthy children (Lutter and Dewey, 2003). Each child consumed two meals of experimental gruels per day for 12 weeks.

Results: The energy intakes from gruels were significantly higher ($p < 0.001$) in MAM-FFM and MAM-FF groups (47.5 ± 26.0 and 45.6 ± 26.4 kcal/kg BW/day, respectively) than in MIS group (38.1 ± 19.6 kcal/kgBW/day). The weight gain from baseline was greater in children from MAM-FFM and MAM-FF groups than in the MIS group (mean \pm SD = 1.09 ± 0.80 , 1.18 ± 0.83 , 0.92 ± 0.67 kg, respectively, $p < 0.01$). Recovery from MAM ($\text{WLZ} > -2.0$ or $\text{MUAC} > 12.5\text{cm}$) was higher in MAM-FF

and MAM-FFM groups compared to the MIS group (70% and 60% vs 50%), but only the difference between MAM-FF and MIS was significant ($p < 0.01$).

Conclusions: MAM-FF and MAM-FFM seem to be more effective than MIS. When considering product costs, MAM-FF is cheaper than MAM-FFM. Both flours can be easily produced locally.

Acknowledgments: WFP funded the study.

Key words: wasting; processed cereal-based flour; complementary food

INTERVENTION IN RURAL SCHOOL TO PROMOTE HEALTHY LIFESTYLES

C. Valenzuela¹, M.L. Gonzalez¹, B. Vielma¹

¹Nutrición y Dietética, Facultad de Farmacia, Universidad de Valparaíso, Valparaíso, Chile

Background and objectives: The prevalence of malnutrition due to overweight that affects child population, plus the high levels of sedentary behavior characteristic of the Chilean population, has focused the attention of the authorities in creating and implementing programs to promote healthy lifestyles. The aim of this study was to implement an educational intervention to promote healthy eating habits and physical activity encouragement for the prevention of overweight and obesity.

Methods: The educational program called "Healthy Eating + Physical Activity: Play, eat and have fun healthy", was carried out on a total population of 94 students in first through fifth year of primary school belonging to the basic F-372 of Pumanque, VI Region, Chile. The sessions planning was focused on age and maturity of the students using participative, creative and ludic methods, to acquire meaningful learning; in order to gain useful tools for their daily life. The program designed included 8 educational sessions.

Results: The malnutrition due to overweight reaches 45, 7% of the sample (Risk of obesity: 22, 3%; Obesity: 23, 4%). The range of age of the sample varies between 6 and 10. Obesity decreased by 2.1% after the educational program. There was a decrease of 10.6% of students who ate breakfast twice. The prevalence of schoolchildren who took a snack from home, and also bought another at school decreased by 12.8%. First grade was the level that obtained the highest average difference in the final assessment tool, increasing by 6.71 points score.

Conclusions: An intervention based on an educational program of healthy eating habits and regular physical activity could contribute to improving the nutritional status and lifestyles in children belonging to rural schools, projected as a useful tool in favor of the decrease rates of overweight that affect the child population in Chile.

Key words: intervention study; lifestyle; nutrition; children.

PO1596

LIFESTYLE AND DIETARY FACTORS ASSOCIATED WITH THE EVOLUTION OF CARDIOMETABOLIC RISK OVER FOUR YEARS IN WEST-AFRICAN ADULTS: THE BENIN STUDY

C. Sossa¹, H. Delisle², V. Agueh¹, R. Sodjrou³, G. Ntandou⁴, M. Makoutode¹

¹Regional Institute of Public Health, Ouidah, Benin

²University of Montreal, Montreal, Canada

³Unicef, Ndjamen, Chad

⁴Bioversity International, Cotonou, Benin

Background and objectives: Several studies reported that the metabolic syndrome (MetS) does not give a proper measure of cardiometabolic risk (CMR) profile in Blacks. We therefore examined the Framingham risk score (FRS) along with the MetS to assess in adults from Benin changes in CMR and the effects of diet and lifestyles.

Methods: The four-year longitudinal study included initially 541 apparently healthy subjects aged 25-60 years and randomly selected in the largest city, a small town and rural areas. Along with CMR factors, socioeconomic, diet and lifestyle data were collected in individual interviews. A food score based on consumption frequency of four "sentinel" foods groups (meat and poultry, dairy, eggs and vegetables) was developed. Lifestyle included physical activity, alcohol and tobacco use. Complete data at last follow-up was available in 416 subjects.

Results: Among the subjects with four-year follow-up data ($n=416$), 13.5% were at risk at baseline, showing MetS or $FRS > 10\%$. The incidence of MetS and $FRS > 10\%$ during follow-up was 8.2% and 5%, respectively. CMR deteriorated in 21% of subjects. The combination of MetS and the FRS depicted more at-risk subjects than the use of either tool alone. Diet and lifestyle mediated location and income effects on CMR evolution. Low "sentinel food" scores (foods that may reflect the protective effect of the diet against CMR): meat, poultry, milk and milk products, eggs and vegetables; and inactivity increased the likelihood of CMR deterioration: $RR = 5.6$ (CI 95%: 1.9-16.4) and $RR = 6.3$ (CI 95%: 3.0-13.4), respectively.

Conclusions: Combining MetS and FRS might be appropriate for surveillance purposes in order to better capture CMR and inform preventive measures. The results of the present study call for urgent measures to reduce CMR deterioration focusing on more active lifestyle and dietary inadequacies.

Key words: Cardiometabolic risk, diet, sub-Saharan Africa.

PO1597**RAPID ASSESSMENTS ON REFERRAL LINKAGE BETWEEN OTP AND TFU IN OROMIA REGION, ETHIOPIA**

M. Nakamori¹, T. Desta², K. Watanabe¹, Z. Habtamu², S. Deba²

¹JICA COBANA Project, Addis Ababa, Ethiopia

²Oromia Regional Health Bureau, Addis Ababa, Ethiopia

Background and objectives: The JICA project has supported to strength the linkage between Health Post(HP) and Health Center(HC) for the management of severe acute malnourished children(SUM) in Oromia Region, Etiopia, since September 2008 for a period of five years.

Methods: A rapid referral assessment: a cross sectional study design including records review and interviews with caretakers and health providers, was conducted in March 2012 to gather programmatic information on referral care processes at the community and facility levels in a timely and cost-effective way for the purpose of program design.

Results: Coverage of Outpatient Therapeutic Program(OTP) training among health providers at HPs and HCs was high (98%) and majority of HPs (98%) had OTP services. According to the report obtained during the last 12 months, overall cure rates (91-93%) and default rate (3-4%) of OTP services satisfied the SPHERE standards. However, only 25% of the established Therapeutic Feeding Unit (TFU)/Stabilized Center(SC) were functioning. Contrary to perception held by the service providers (82%), the actual compliance rate for referrals was low (27%). The most common responses of the non-compliance among caretakers were difficulty to get permission of husband (48%). Although almost all of the referral cases were given referral slips, they did not necessarily help prioritization of the patients at the referral site. In addition, feed back slips were never received at HPs from referral sites. Although OTP service was performed efficiently, establishment and operation of TFU/SC had several constrains that need further support for rehabilitations. There were large rooms for improvement in terms of communications for referral linkage.

Conclusions: The information on the referral status between HP and HC should be shared regularly in a structural way. BCC activities at community levels should include urgent needs of SAM children with medical complications at TFU/SC.

Key words: SUM, OTP, TFU, Referral-Linkage

PO1598**WHOLE-GRAIN AND FIBER INTAKE AND COLORECTAL CANCER; NEW RESULTS FROM THE HELGA AND EPIC COHORTS**

A. Olsen¹, C. Kyrø², G. Skeie³, A. Tjønneland⁴

¹Danish Cancer Society Research Center, Copenhagen, Denmark

²Danish Cancer Society Research Center, Copenhagen, Denmark

³Department of Community Medicine, University of Tromsø, Norway

⁴Danish Cancer Society Research Center, Copenhagen, Denmark

Background and objectives: Recently, World Cancer Research Fund stated that intake of dietary fiber is convincingly related to lower risk of colorectal cancer. When looking into sources of dietary fiber, cereals emerged to be the food group showing the strongest association. The content of dietary fiber constitutes one of the main differences between refined grains and whole grains. The association seen with cereal fiber may consequently partly be assigned as evidence for whole grains. None of the published cohort studies on wholegrain intake and colorectal cancer have been able to evaluate the potential different effects of the main cereals: wheat, rye and oats. Un-detailed baseline information about whole-grain intake makes studies of associations to disease a challenge in most existing cohorts, using a biomarker to estimate whole-grain intake can overcome this problem.

Methods: In this presentation associations between dietary fiber and whole-grain intake and incidence of colorectal cancer, by use of detailed questionnaire information in a Nordic cohort (HELGA) and by use of the biomarker alkylresorcinols in a European cohort (EPIC) will be shown.

Results: In the HELGA cohort intake of dietary fiber, especially from cereal sources, and whole grains was found associated with lower colorectal cancer incidence. The strongest association was seen for whole grain wheat, with non-significant associations for oats or rye. In the EPIC cohort, whole-grain intake was measured by plasma levels of the phenolic lipids alkylresorcinols that is a validated biomarker for whole-grain wheat and rye intake. Plasma levels of alkylresorcinols were not found related to overall colorectal cancer, but lower incidence of distal colon cancer was seen among those with highest levels.

Conclusions: These studies confirm that whole grains may play a role in colorectal cancer prevention. The results are, however, preliminary and must be interpreted as such.

Key words: Whole grains, Dietary fiber, Alkylresorcinols, Colorectal cancer, Epidemiology.

PO1599

CREATING AND CALIBRATING MODELS OF FOOD-BORNE EPIDEMICS

T. Nowicki¹, R. Pytlak², R. Waszkowski¹, T. Zawadzki², W. Migdal³, J. Bertrand⁴

¹Military University of Technology, Warsaw, Poland

²Warsaw University of Technology, Warsaw, Poland

³Institute of Nuclear Chemistry and Technology, Warsaw, Poland

⁴Military Institute of Hygiene and Epidemiology, Warsaw, Poland

Background and objectives: The paper discusses models of food-borne epidemics and the numerical procedure for finding parameters of these models. These models include activities of sanitary inspection teams.

Methods: We consider two types of models. In the first approach we model decisions, events and human activities as workflow. In the second approach we apply Forrester's approach (for modeling business processes) to create differential equations describing epidemics. In this approach we start with the casual loop diagram which depicts the main variables which should be used in the model of epidemic and the relationships between them. Based on the diagram the process equations are built.

Results: Having a model of the epidemic its parameters are found by solving an optimal control problem described by ordinary differential equations. The objective functional of the problem measures the discrepancy between real data and trajectories resulting from the model. The problem is solved by using an approach based on adjoint equations. At each iteration of the numerical procedure system and the corresponding adjoint equations are integrated. The unique feature of the procedure is that initial conditions for model equations are allowed to be model parameters. The procedure is implemented with the help of highly efficient procedures: for integrating differential equations – SUNDIALS package; for performing optimization steps – IPOPT package and for applying automatic differentiation - ADOL-C package.

Conclusions: Using these packages guarantees that: system equations are accurately integrated; optimization steps are performed by the method which refers to second order information of functions describing the model; the user does not have to provide the jacobian of the model equations. As an example a model of E-cola epidemic is considered. The work reported in the paper was partially supported by The National Centre for Research and Development partially by grant PBS1/A7/6/2012.

Key words: foot-borne epidemic, business processes, sanitary inspection.

PO1600

THE METHOD FOR FINDING OPTIMAL SANITARY INSPECTORS SCHEDULES

T. Nowicki¹, R. Pytlak², R. Waszkowski¹, J. Bertrand³

¹Military University of Technology, Warsaw, Poland

²University of Technology, Warsaw, Poland

³Military Institute of Hygiene & Epidemiology, Warsaw, Poland

Processes of different types of disease epidemics are connected with activities of several professional groups. The present work is related to modeling processes associated with sanitary inspectors work. Food-borne diseases caused by different pathogens are very common disorders. Sometimes such a disease gives rise to an epidemic. In that situation patients are examined by medical personnel. Medical doctors are obligated to register the type of disease and report about it to District State Sanitary Inspectorate (SDSI). Then tests are performed in order to recognize a specific pathogen causing the disease. After finding by sanitary inspectors what and where patients were eating they should organize several controls in the potential origins of spread of the epidemic. Thus SDSI have to determine not only the schedules of interviews, but also schedule of activities which aim at finding potential origins of the spread of the epidemic. Generally two types of sanitary inspectors teams are created: some of them carry out interviews; the others look for potential origins of an epidemic. It is assumed that sanitary inspectors must reach the patients wherever they are. Interview duration is a random variable with its mean value equal to a few hours. We also assume that looking for potential origins of spread of the epidemic lasts longer. These time estimates follow from the fact that inspectors must reach patients or a potential origin of spread of the epidemic. In this paper we show how to find optimal schedules for sanitary inspectors who have to do interviews with individual patients and inspect various potential origins of spread of the epidemic. The work reported in the paper was partially supported by The National Centre for Research and Development under grant PBS1/A7/6/2012.

Key words: foot-borne disease, optimal schedule, sanitary inspectors

PO1602**IMPACT EVALUATION OF THE NUTRITIONAL SUPPORT PROGRAM (PAL BY ITS SPANISH ACRONYM) ON FOOD DIVERSITY AND CONSUMPTION OF IRON-RICH OR IRON-FORTIFIED FOODS IN 6-23 MONTH-OLD CHILDREN**

M.J. Ramirez¹, T. Gonzalez de Cossio², S. Rodriguez², M. Unar², J. Rivera²

¹Ministry of Health of Ecuador, Ecuador

²National Institute of Public Health-Mexico, Mexico

Background and objectives: Micronutrient deficiencies in the first two years of life have adverse health effects. Part of the cause is complementary feeding (CF) of low nutritional quality and poor CF practices. In order to prevent malnutrition in the most vulnerable individuals, the Mexican state has implemented the Nutritional Support Program, which is directed towards small communities with fewer services and includes conditional distribution of food or monetary transfers and education. The impact of PAL was evaluated in minimum dietary diversity and consumption of iron-rich or iron-fortified foods indicators.

Methods: A longitudinal sample of 168 communities was analyzed using the double-difference method with fixed and random effects at the community level. Baseline values for children aged 6-23 months of (n=664 children, 591 households) were compared with values for children aged 6-23 months who live in the same communities after 18 months from the start of the intervention (n=478, 368 homes).

Results: PAL, in its 'provisions with special education' modality, increased the prevalence of consumption of iron-rich foods by 31 percentage points (PP), (p<0.01) and by 25 PP (p<0.01) for minimum dietary diversity in children aged 6-23 months when compared to the control group.

Conclusions: Social programs based on conditioned provision of foods that are fortified with iron and multiple micronutrients contribute to improving Complementary Feeding practices.

Key words: nutrition, foods, children.

PO1603**DIETARY TRANS FATTY ACIDS INTAKE AND ITS RELATION TO LIPOPROTEIN (A) LEVEL IN A SAMPLE OF ADULTS IN WEST JAVA, INDONESIA**

R. Sartika¹

¹Department of Public Health Nutrition, University of Indonesia, Indonesia

Background and objectives: In Indonesia, cardiovascular disease (CVD) as a public health problem had become the single major cause of death. One cause of high death rates is lifestyle, especially diet. Diets high in fat, saturated fatty acids and trans fatty acids may increase lipoprotein (a). The purpose of this study was to determine the mean intake of trans fatty acid and its relation to lipoprotein (a) concentration in a sample of Indonesian adults.

Methods: A cross-sectional study was conducted on a total of 156 adult male and female aged 30-55 years living in rural areas (Bogor) and urban areas (Depok) in West Java, Indonesia.

Results: The results showed the mean intake of trans fatty acid was 0.37% calories (rural 0.36% and urban 0.38% calories). The main source of trans fatty acid among the subjects was fried foods, followed by ruminant products and margarine/HVO products. Deep-frying cooking is one of the most common cooking methods in Indonesia. The proportion of Lp (a) 'not normal' in the subjects was 29% (rural 28.6% and urban 30.0%). There was no significant association between Lp (a) level in urban and rural areas (p>0.05). There was a statistically significant association between trans fatty acid intake and levels of lipoprotein (a) (p<0.05).

Conclusions: Further studies are recommended to determine the intake of trans fatty acids and its relation to other lipoproteins.

Key words: trans fatty acid, lipoprotein (a), urban, rural.

PO1604**PROTEIN DENSITY, BODY WEIGHT, ECONOMIC STATUS AND MOTHERS HEIGHT ARE RISK FACTORS OF STUNTING AMONG INDONESIAN YOUNG CHILDREN**

A.W. Hayati¹, H. ², F. Jala³, S. Madanijah², D. Briawan²

¹Nutrition Department of Pontianak Health Polytechnic, Indonesia

²Department of Community Nutrition, Bogor Agricultural University, Indonesia

³Faculty of Medicine, Andalas University, Indonesia

Background and objectives: Stunted is a major under-nutrition problem in developing countries; and it might be related to the quality of the children's diet, such as protein density. We

aimed to analyze protein density, economic status, birth weight and mothers height in relation to the stunting status of young children (YC) in Indonesia.

Methods: An electronic data file of the National Basic Health Survey consists of 3 095 cleaned records of young children 0-23 months was use and analyzed in this study. The variables used include socio-demography, economic status, food intake, children's body weight, body length and born weight, and mothers height. The data were processed using the WHO AnthroPlus 2007, Excel 2007 and SPSS 16.0 for windows. Logistic regression was applied to analyze the associations based on odd ratios.

Results: Children consumed low protein density diet are more likely suffered from stunting than children consumed high protein density diet (OR=1.32). Underweight children (-2 Z-score) are more likely suffered from stunting (OR=3.07) than other children. Children with low family economic status is more likely suffered from stunting (OR=1.26) than children from middle-high family economic status. Moreover, children born less then 2 500 g is more likely suffered from stunting (OR=1.81) than children born with body with more than and equal to 2 500 g. Children with mothers height <145 cm is more likely suffered from stunting (OR=1.68) than children with mothers height > 145 cm.

Conclusions: Stunting among Indonesian young children status is negatively associated with protein density, body weight, birth weight, economic status and mothers height. The prevention of stunting of the young children should be done by improving the food quality, especially protein and micro-nutrients rich foods, and increasing the income of the families.

Key words: stunting, birth-weight, protein density.

PO1605

COMMUNITY AND PROGRAM PERFORMANCE IN THE SUPPORT OF BREASTFEEDING PRACTICES IN PASEBAN VILLAGE, PERI URBAN, CENTRAL JAKARTA

A. Dwita¹, J. Februhartanty²

¹Seameo- Recfon, Jakarta, Indonesia

²Seameo- Recfon, Jakarta, Indonesia

Background and objectives: Mother's knowledge and attitude may not be a clue for successful breastfeeding (BF) practices. BF practice is multi complex behavior that needs support from the environment, in order to facilitate the improvement of breastfeeding practices. Community in this study described as all channels and contacts to mothers that can be a prospective source influence to promote optimal breastfeeding practice. Exposure of negative or positive information about breastfeeding practice should be known to identify whether the posi-

tive information can be reinforced and negative information should be changed. The purpose of the study is to determine the community and the existing BF program that supports the BF practice.

Methods: This study investigated, through a structured interview, in- depth interview with twelve mothers and three cadres, the determinants of such BF practices and sources of information was involved. In-depth interview with mothers focused on questions about what, why, how BF information and programs were influenced the BF practice.

Results: BF practice had associated with exposure to channels of information from friends, family, and neighbor, and peer and family influences (P< 0.05). BF program through lactation counseling in Posyandu (integrated health post) was coming from stakeholders. Low of mother's participation in the BF program due to they had felt not satisfied with the cadres service. Cadres had low self efficacy to give counseling about lactation to mothers.

Conclusions: Strengthen the cadres capacity with training counseling skill about BF are needed and family empowerment in knowledge and attitude to BF practice through family nutrition education are essential.

Key words: breastfeeding information, promotion, support.

PO1606

NUTRITIONAL CARE IN BRAZILIAN PUBLIC HEALTH SYSTEM: DEVELOPMENT OF AN INSTRUMENT TO ASSESS ACTIONS IN PRIMARY HEALTH CARE

M A Tavares de Medeiros¹, N. Spina², A S. Laporte³, F C. Braga-Campos¹, P A. Martins⁴, L T O. Zangirolani¹

¹Department of Health, Clinical and Institutions, Universidade Federal de São Paulo, Brazil

²Graduate Study Program in Nutrition, Universidade Federal de São Paulo, Brazil

³Graduate Study Program in Teaching in Health Sciences, Universidade Federal de São Paulo, Brazil

⁴Department of Movement Sciences, Universidade Federal de São Paulo, Brazil

Background and Objectives: Primary Health Care is a privileged scenario to develop Nutrition Policies. This paper describes the formulation of an Instrument to assess nutrition actions in Primary Health Care in the municipality of Santos, SP, Brazil, from the perspective of managers of Primary Health Care Units PHCU).

Methods: Through a cross-sectional design, qualitative and quantitative data were collected. Managers from the whole of 28 PHCU of the municipality were interviewed. For the cons-

truction of this instrument, three steps were fulfilled: Study of the National Food and Nutrition Policy and the protocols from Ministry of Health, emphasizing: management of nutritional care and food and nutrition surveillance, aiming to identify the actions of healthy nutrition promotion (HNP). Review of scientific literature, to identify categories used in analyzes of the actions of HNP in Primary Health Care. Construction of categories collating those identified in the literature with official documents.

Results: The questionnaire consists of 133 open and closed questions to evaluate: the quality of nutritional care; the character of the actions (individual or collective); case discussion meetings and interdisciplinary teamwork. There are 10 blocks of issues including: general data, infrastructure, team composition and working process, food and nutrition surveillance and management of nutritional care, in the following topics: obesity, diabetes and hypertension, prenatal and postpartum, children and elderly. To validate the instrument, a pretest was carried out and it was necessary to reduce the number of questions and the time duration of the interview, by 50%.

Conclusions: As the results point to the improvement of internal consistency of the instrument, according to expertizes, the instrument proved to be useful to support the evaluation of nutritional care in Primary Health Care, to plan and redirect actions of healthy nutrition promotion.

Key words: Primary Health Care. Nutrition, Public Health. Nutrition Programs and Policies.

INTERACTION OF PHYSICAL ACTIVITY AND NUTRITION STATUS OF CHILDREN OF PUBLIC AND PRIVATE SCHOOLS IN MEXICO

C. Calvo¹, V. Melo², L. Cervantes¹, M. García², S. Macín²

¹Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, México, D.F., Mexico

²Universidad Autónoma Metropolitana-X, Mexico, D.F., México

Background and objectives: One of the problems affecting population nowadays in Mexico, is the increased amount of young generation with overweight and obesity among of school children. The quality of nutrition and nutrition status in them, shows the presence of the risk factors which can be in connection with the unbalanced diet of the most vulnerable period of school children grow. An adequate diet combined with physical activity is crucial for a future healthy life style and to prevent diseases, such as overweight and obesity. The aim of this study is to evaluate food quality and intake of an administered 7 day dietary habitual record and physical activity at the same period of time of children aged 6 to 10.

Methods: Nutritional quality was assessed at the level of nutrients and food groups, and expressed as energy percent (E%) and macronutrients from milk, milk products, eggs, cereals, vegetables, fruits, poultry, meat, fish, sweets and tidbits were used as nutrient indicators of nutritional status. Results and

Conclusions: The main characteristics of school children nutritional status, are unbalance of meal composition, low intake of milk and milk products, fruit and vegetables, are high in sweets, snacks and fast food. Inadequate rhythm of exercise therefore, correct nutrition and physical activity promotion with prevent disorders in obesity of children in grow age and promote a good health and future well-being.

Key words: children nutrition, physical activity, overweight, obesity.

PO1608

GENETICALLY REDUCED PHYTATE STAPLE CEREAL GRAINS TO INCREASE IRON AND ZINC INTAKE IN SUB-SAHARAN AFRICA – THE CASE OF SORGHUM

J. Kruger^{1,2}, J. Taylor¹, A. Oelofse², B. Lönnerdal³

¹Institute for Food, Nutrition and Well-being and Department of Food Science, University of Pretoria, Pretoria, Gauteng, South Africa

²Department of Human Nutrition, University of Pretoria, Pretoria, Gauteng, South Africa

³Department of Nutrition, University of California, Davis, California, USA

Background and objectives: Iron and zinc deficiencies are highly prevalent in rural sub-Saharan Africa. Phytate in staple cereal grains such as sorghum chelates essential minerals, reducing the bioavailability of non-haem iron and zinc. While the value of traditional lactic acid fermentation in reducing the phytate content of sorghum foods has long been recognised, genetic modification (GM) is currently being used to develop sorghum lines with lower phytate contents. We evaluated the effect of reducing sorghum phytate content through traditional fermentation and GM on iron and zinc availabilities in porridges using three different assay procedures: in vitro dialysability, Caco-2 cell uptake assays and in vivo suckling rat pup model.

Methods: Two sets of GM low phytate non-tannin (30-40% and 80-90% reductions), a set of tannin-containing sorghum varieties (30-40% reductions), and their respective null controls were processed into thick unfermented and fermented porridges.

Results: The fermentation increased the iron and zinc availabilities in the non-tannin sorghums. The inhibitory effect of the tannins on mineral availability seemed to prevent any

increase in in vitro iron and zinc bioaccessibilities regardless of the level of phytate reduction. The 30-40% GM phytate reduction did not result in increased iron and zinc availability. However, the additive effect of 30-40% GM phytate reduction in combination with phytate reduction through fermentation as well as the 80-90% GM phytate reduction caused substantial increases in iron and zinc availabilities. Both the magnitude of phytate reduction and the final phytate content affect iron and zinc availabilities.

Conclusions: It is recommended that non-tannin GM sorghum with a phytate reduction above 85% and phytate content below 200 mg/100 g wholegrain flour would be most appropriate to be subjected to a human bioavailability study to evaluate the efficacy of the biofortification by determining the biological impact on iron and zinc status under controlled conditions.

Key words: Iron, Zinc, Phytate, Sorghum.

PO1609

LOW CALORIE- AND CALORIC-SWEETENED PRODUCTS: DIETARY QUALITY AND DIETARY PATTERNS OF U.S. HOUSEHOLD CONSUMERS FROM 2000-2010

C. Piernas¹, B.M. Popkin¹

¹Department of Nutrition, University of North Carolina, Chapel Hill, USA

Background and Objectives: The U.S. food supply is currently facing rapid changes such as the increased use of caloric-sweeteners (CS) combined with low-calorie sweeteners (LCS) in newly reformulated products. Using a novel identification approach that uses ingredient lists of each food/beverage, we have reported important increasing trends in products containing LCS and both LCS&CS. This study explored the dietary quality and patterns of U.S. consumers of products containing LCS and CS from 2000-10.

Methods: We analyzed food/beverage purchases from the Homescan longitudinal dataset 2000-10 (n=140, 352 households; 408, 458 individuals); and dietary intake from the National Health and Nutrition Examination Surveys (NHANES) 2003-10 (n=34, 391). Because soda-type beverages were the main sources of LCS and CS, to investigate dietary quality/patterns we defined these consumer profiles: LCS-soda consumers; CS-soda; LCS&CS-soda; non-consumers. Multivariable linear/longitudinal random-effects models were used to investigate the associations between each consumer profile and total energy/macronutrients in each dataset separately. Factor analysis and applied factor scores were used to derive longitudinal dietary patterns to investigate the association between each profile and the different patterns that emerged.

Results: Compared to non-consumers and LCS-soda consumers, CS- and LCS&CS-soda consumers had significantly higher total daily energy and % carbohydrates and % sugars. LCS-soda consumers had significantly higher % kcal from snacks, whereas CS- and LCS&CS-soda consumers had significantly higher % kcal from fast-foods and desserts. Compared to non-consumers, consumers of LCS-, CS- and LCS&CS-soda were significantly more likely to follow a Western dietary pattern, but significantly less likely to follow a Prudent dietary pattern.

Conclusions: As LCS- beverages appear to be displacing those with CS over the last 10 years, this study shows that LCS-, CS- and LCS&CS-soda consumers are still more likely to follow an unhealthier dietary pattern than those with no consumption of soda-type beverages.

Key words: low-calorie sweetener, caloric-sweetener, dietary patterns, dietary quality, soda.

PO1610

PROFILE OF THE PUBLIC HEALTH NUTRITION WORKFORCE IN FIVE HIGH BURDEN STUNTING COUNTRIES: CONSTRAINING AND ENABLING FACTORS

M. Tharaney¹, M. Anson², S. Lamstein², K. Kappos², A. Narayan¹, H. Nekatebeb³

¹SPRING Project, Helen Keller International, Arlington, USA

²John Snow Research and Training, USA

³Save the Children

Background and objectives: A skilled, motivated, and competent workforce is the backbone of any private or public service delivery system. Most countries with the highest burden of stunting have a severe shortage of human resources and are unable to deliver quality, basic nutrition or health services. A profile analysis of the nutrition workforce is underway in five high burden stunting countries. The objective of the analysis is to outline which frontline workers are tasked with implementing the high-impact nutrition interventions defined in the Lancet Series on Maternal and Child Undernutrition (2008). The analysis looks at the types of providers across health, agriculture and other sectors as well as the size of the nutrition workforce and their skill-mix in working at national and sub-national levels.

Methods: Five countries across different regions were selected to provide a wide range in geographic location as well as to understand the various contexts of workforce development. The SPRING project developed a web-based database that will be used to collect, analyze and report the data and map trends and patterns across countries.

Results: Initial findings suggest that a wide range of health providers, community workers and agriculture extension workers are involved in delivering high-impact nutrition services in the five countries. However, much is not known about skill-mix, the attributes and the competencies of these workers. One reason is the scarcity of such data at the country level. Another reason is the lack of clarity and guidelines on the types of activities that are classified as “public health nutrition” by health, agriculture and community development workers.

Conclusions: System strengthening, in particular workforce development represents a key element to address in nutrition programming as it allows countries to provide evidence-based systematic approaches with sufficient numbers of skilled workers with high competencies to serve communities with diverse nutrition needs.

Key words: public health, nutrition, stunting.

PO1611

SUPPLEMENTATION WITH LOW-DOSE, LIPID-BASED NUTRIENT SUPPLEMENTS INCREASES IRON RESERVES AND HEMOGLOBIN, BUT NOT VITAMIN A STATUS, OF YOUNG BURKINABE CHILDREN

S. Abbeddou¹, S Y. Hess¹, E. Yakes², W J. Some⁰, Z P. Ouedraogo³, J B. Ouedraogo³, K H. Brown¹

¹Department of Nutrition, University of California Davis, Davis, California, USA

²Department of Individual, Family, and Community Education: Nutrition/Dietetics Program, University of New Mexico, Albuquerque, New Mexico, USA

³Institut de Recherche en Sciences de la Santé Direction Régionale de l'Ouest, Bobo-Dioulasso, Burkina Faso

Background and objectives: Lipid-based nutrient supplements (LNS) can enhance the micronutrient content of local complementary foods, but there is little information on their impact on young children's micronutrient status.

Methods: In a partially masked, placebo-controlled, randomized trial, communities were assigned to immediate (II) or delayed intervention (DI). 2469 eligible II children were randomized to receive 20g LNS/d with varying contents of zinc, same contents of iron (6mg/d) and vitamin A (400ig/d), and treatment of malaria and diarrhea from 9-18 months of age. DI Children (n=797) did not receive LNS or other treatment. At 9 and 18 mo, hemoglobin (Hb) was evaluated in all children from capillary blood. Venous blood was collected in a subgroup (n=597) for assessment of plasma ferritin (pF), soluble transferrin receptor (sTfR) and retinol-binding protein (RBP). C-reactive protein and alpha-1 acid glycoprotein were measured to adjust pF, sTfR and RBP for inflammation.

Results: At baseline, pF, sTfR, Hb and RBP did not differ among groups. Geometric mean (95%CI) pF was 26.8±22.2ig/L in all groups combined; and 23% were iron depleted (pF<12ig/L); at 18 mo, pF increased in II, but decreased in DI (P<0.001). Mean sTfR was 17.4±9.1mg/L at 9 mo and 87% had tissue iron depletion (sTfR>8.3mg/L). sTfR decreased more in II than DI (P<0.001). Mean baseline Hb was 8.9±1.5g/dL, and >90% were anemic (Hb<11.0g/dL). At 18 mo change in Hb was greater in II than DI (+0.80 vs -0.02g/dL, P<0.001), but 79% of II were still anemic. Mean RBP was 1.0±0.3imol/L at 9 mo, and 30% of children had values <0.83imol/L. RBP did not change in any group at 18 mo.

Conclusions: LNS along with malaria and diarrhea treatments improved the children's iron status and hemoglobin, but not vitamin A status.

Key words: LNS, hemoglobin, iron, vitamin A. Funded by the Bill & Melinda Gates Foundation.

PO1613

MATERNAL ACTIONS AND PROBLEMS IN MANAGING THE CHILD'S WEIGHT AND THEIR ASSOCIATION WITH THE MATERNAL PERCEPTION OF THE CHILD'S WEIGHT IN MEXICAN DYADS

Y. Flores-Peña¹, P M. Trejo-Ortiz², H. Avila-Alpirez³, V M. Cárdenas-Villarreal¹, A. Ugarte-Esquivel⁴, J. Gallegos-Martínez⁵, R M. Cerda-Flores¹

¹Universidad Autonoma de Nuevo Leon - Facultad de Enfermería, Mexico

²Universidad Autonoma de Zacatecas - Area de Ciencias de la Salud, Mexico

³Universidad Autonoma de Tamaulipas - Unidad Académica Multidisciplinaria Matamoros, Mexico

⁴Universidad Autonoma de Coahuila - Escuela de Licenciatura Torreon, Mexico

⁵Universidad Autonoma de San Luis Potosi - Facultad de Enfermería, Mexico

Background and objectives: Associate actions and problems in managing child's weight with the mother's perception of child's weight (MPCW) in pairs (mother-child 2 to 17 years of age) who reside in 5 States in north eastern Mexico.

Methods: 2840 pairs participated. Mothers answered: What have you done in managing your child's weight? What has made it difficult for you in managing your child's weight? I believe that my child is... Weight and height of the child were measured.

Results: Mothers of Overweight (OW)-Obese (OB) children do not carry out actions 50.2% (n = 150) & 21.3% (n = 81) (÷2 = 171.788, p <.001), do not have problems to control it,

79.6% (n = 238) & 60.1% (n = 229), $\div 2 = 58.11$, $p < .001$ and do not have an adequate perception of the child's weight.

Conclusions: Actions and problems in managing weight of OW-OB children are associated with MPCW.

Key words: body weight, weight perception, obesity, overweight, mother-child relations.

PO1614

IMPACT OF NUTRITION EDUCATION INTERVENTION ON APPROPRIATE FOOD SELECTION OF RURAL MOTHERS IN EHA-AMUFU, ISI-UZO L.G.A I

O. Mbah¹, N. Ene-Obong, P. Eme

¹University of Nigeria, Nsukka, Nigeria

²University of Calabar, Nigeria

Background and objectives: Inadequate feeding practices, including poor knowledge of appropriate food for infants and cultural practices contribute to the high prevalence of malnutrition among infants and young children in developing countries. This study compared the impact of nutrition education intervention on food selection practices of mothers/caregivers.

Methods: Sixty (60) mother/caregiver child pairs were purposefully chosen. The selected mother/caregiver child pairs were randomly assigned (by balloting) to three treatment groups: one control and two intervention groups. The nutrition education program was carried out for a total of six (6) weeks. Children in the control and interventions groups were dewormed and given vitamin A at the beginning, for ethical reasons and to isolate the other elements of intervention from the effects that may be due to deworming and low serum vitamin A. The two intervention groups attended classes for four weeks. One received intensive education only while the other received intensive education with additional cooking demonstration. Data obtained were analyzed using descriptive statistics. Comparison between control and intervention groups was done using Student t-test.

Results: It revealed that the increase in scores of mothers/caregivers after intervention on selection of energy-giving foods for the control and intervention groups were (20% vs 40% and 40%) ($p=0.072$) and body-building foods (20% vs 20% and 40%) ($p=0.193$). There was a significant ($P<0.05$) increase in scores of mothers/caregivers on selection of protective foods: calcium-rich foods ($p=0.031$), iron-rich foods ($p=0.022$), vitamin A rich foods ($p=0.011$), zinc rich foods ($p=0.012$) and iodine-rich foods ($p=0.021$).

Conclusions: Based on the findings, nutrition education intervention improved mothers' selection ability of appropriate foods for their children.

Key words: Impact, nutrition education package, food selection, rural mothers, Eha-Amufu.

PO1615

DEVELOPMENT OF NUTRITION EDUCATION PACKAGE ON CHILD CARE AND FEEDING PRACTICES FOR RURAL WOMEN IN ENUGU STATE, NIGERIA: A POSITIVE DEVIANT APPROACH

O. Mbah¹, N. Ene-Obong, P. Eme

¹University of Nigeria, Nsukka, Nigeria

²University of Calabar, Nigeria

Background and objectives: The burden of nutrition related disease is greatest among the vulnerable and disadvantaged groups including rural women. The study describes the development of 12-lesson based nutrition education package for rural women in Enugu State.

Methods: The study involved 91 mothers in a community of Eha-Amufu, Enugu State. Mothers were classified as Positive Deviants (PDs) and Non Positive Deviants (NPDs) based on the nutritional status of their infants. Structured questionnaire was used to collect information. Summary findings from the Positive Deviant Inquiry (PDI) were used to develop the package. Data was analysed using descriptive statistics.

Results: More than half of the respondents (78.7%) and 21.3% were classified as NPDs and PDs respectively. The PDs had better feeding, caring and health-seeking practices than the NPDs. The nutrition education package developed had the following lessons: Growth monitoring, Malnutrition, Food Selection Techniques, Body building foods, Energy-giving foods, Protective foods, Infant nutrition, Management of childhood diarrhea, Immunization, Hygiene and Sanitation, Family Planning and Feeding during illness.

Conclusions: This developed package can be used in communities during intervention programmes on child-care and feeding practices.

Key words: nutrition education package, child care, feeding, rural women, Enugu

PO1616**CAPACITY DEVELOPMENT (CD) IN NUTRITION IN CENTRAL AND EASTERN EUROPE (CEE)**

M. Gurinovic¹, M. Glibetic¹, A. Oshaug², E. Dupouy³, R. Novakovic¹, P. Finglas⁴

¹Centre of Research Excellence In Nutrition and Metabolism, Institute for Medical Research University of Belgrade, Serbia

²Oslo and Akershus University College of Applied Sciences, Oslo, Norway

³FAO Regional Office for Europe and Central Asia (REU), Budapest, Hungary

⁴Institute for Food Research, Norwich, UK

Background and objectives: The Network for CD in Nutrition in CEE (NCDNCEE) (<http://www.agrowebcee.net/ncdn/>) established in 2005 with the general objective to stimulate relevant CD in CEE countries. NCDNCEE has joined several EC funded projects, including EuroFIR (www.eurofir.org), EURRECA (www.eurreca.org) and EuroFIR-Nexus.

Methods: NCDNCEE meetings were arranged for identifying specific challenges and training needs; developments tools and implementing workshops; establish collaboration for collection recommendations and nutrition grey literature; identification on dietary methodology; Food Composition Data Base (FCDB) status and training needs inventory.

Results: Much of the results are published in scientific journals; cross-cutting themes were academic training, workshops, networking, and types of methodology in nutritional research and sharing of experiences. CD workshops (2005-2013) included collection and use of grey literature for nutritional status evaluation in CEE; overview of micronutrient recommendations; media communication training; FCDB workshops; identification and prioritization of nutrition education needs. Nutritional tools creation and presentation: (NutriRecQuest) web tool -micronutrient recommendations; web based application Food Composition Data Management (FCDM) for creating a FCDB; DIETASSES for nutritional assessment and planning diet. EuroFIR-Nexus and NCDNCEE initiated a Balkan food platform to foster regional FCDB development using web-based software FCDM; Memorandum of Understanding signed with several CEE countries. The need for additional tailor-made training on nutrition identified. A follow-up of NCDNCEE launched as CAPNUTRA.

Conclusions: An impressive amount of CD activities was achieved in each country, guided by the plans, frameworks, leadership and the implementation of CD. CD had an essential role in stimulating research and is useful for harmonization relevant research in CEE. The network was a tool to foster regional involvement and development of education and research.

EuroFIR-Nexus; Ministry of Education and Science Republic of Serbia project 41030; NCDNCEE; FAO REU Budapest, Hungary

PO1617**PUBLIC PRIVATE SECTOR PARTNERSHIP ON SUPPORTING THE SCALING UP NUTRITION (SUN) MOVEMENT: PROPOSE MODEL FOR INDONESIA**

A. Riyanti¹, A. Usfar¹

¹Indonesian Danone Institute Foundation, Jakarta, Indonesia

Background and objectives: United Nations led, multi-stakeholder movement the Scaling Up Nutrition (SUN) launched in 2010 globally, was translated into a 1000 days movement (1000 Hari Pertama Kehidupan) in Indonesia, launched in 2012. The private sector engagement, a less utilized resource in the national context, would improve the effectiveness of existing nutrition program by enhancing partner collaboration, as well as bringing in specific expertise, innovative approaches and technologies.

Methods: A review of private public partnership programs was conducted to evaluate its contribution toward increasing nutrient intakes, improving nutritional status, water and sanitation, increasing knowledge, and community empowerment.

Results: The three main areas of private sector engagement proposed are: provision of nutritional products, facilitate the improvement of water and sanitation facility, and provision of educational materials. The following activities could be pursued: provision of macro and multiple-micronutrient supplementation, provision of height measurement tables and monitoring cards, improvement of transport facility to the health centers, facilitate the improvement of monitoring and information system, and providing fund for training and socialization. Activities can be channeled through the current existing government program at the household or community level. All programs should follow the three positioning principles of mutual benefit, equity, and transparency.

Conclusions: Public private partnership will bring the much needed extra efforts in combating the double burden of malnutrition present in Indonesia.

Key words: Scaling Up Nutrition, public private partnership, private sector, nutrition, Indonesia.

PO1618**WASHING THE FOODSTUFFS OF SEEDS, PROMOTING THE HEALTH LEVEL, A PROPOSAL FOR LEGISLATION OF NATIONAL STANDARD OF FOOD SAFETY**

X. Han-You¹

¹China Academy of Management Science, Clinical Institute, Workers Hospital of Nanyang Textile Corporation, Nanyang City, Henan Province, China

Background and objectives: As the bad situation of pollution in the foodstuffs of seeds in and outside of China is more and more serious and critical. There is not any concrete regulation or national process standard of food safety to eliminate or reduce the pollution in the foodstuffs of seeds round the world. The children are much too easy to be harmed by polluted food. It is imperative to eliminate the danger pollution factors in the foodstuffs of seeds for promoting people's health, including the children health, around the world before the pollution factors are eat and harm the human-being.

Methods: Summarize the bad situation of pollution in the foodstuffs of seeds around the world.

Results: Washing the foodstuffs of seeds to eliminate the danger pollution factors in the foodstuffs of seeds, promoting the health level, and a proposal for legislation of national standard of food safety was created.

Conclusions: The proposal for washing the foodstuffs of seeds, promoting the health level, a legislation of national standard of food safety was suggested to promote health food and health people around the world. Which the new breakthrough can promote the children health greatly if the proposal was accepted by China and world.

Key words: Proposal; legislation; National standard of food safety; Foodstuffs of seeds; Health promotion.

PO1619**FAMILY FEEDING PRACTICES IN 0-4 CHILDREN WITH PREVENTABLE PATHOLOGIES BACKGROUND**

E. A. Garcia¹, N. Garrote², M. E. Santos¹, L. de Gracia¹, I. Corfield¹, M. Raffart¹, N. Reverdito¹

¹Facultad de Bromatología, Universidad Nacional de Entre Ríos, Gualeguaychú, Entre Ríos, Argentina

²Facultad de Ciencias Médicas, Universidad Nacional de Rosario, Rosario, Santa Fe, Argentina

Background and objectives: Abstract Feeding is a cultural activity and it is present in the actions of the individual in the social and family area. Thus, it is possible to speak of a health/sickness/feeding process. Among the child pathologies, diarrhea, undernourishment and anemia were chosen since they are preventable and prevalent and because prevention and attention consists, mainly, in providing adequate feeding, considering the family and environmental situation. We aimed to characterize the feeding practices of mothers, both exclusive breast-feeding and timely complementary feeding.

Methods: Exploratory, descriptive, cross sectional during 2010-2011 with casual sampling. The participants were 23 families with children up to 4 years old with background of diarrhea, undernourishment and anemia. Semi-structured surveys were used, interviews and focus group. Socio-demographic variables were evaluated, related to: child health, exclusive breast-feeding practices and timely complimentary feeding. Excel and SPSS were applied, differences verified, chi square coefficient, t student, confidence level 95%.

Results: Sixty-one percent of nuclear families: 81% receive feeding plans; 47, 8% of children received exclusive breast-feeding; 52, 2% received other liquids from the age of 2 months; 47, 8% received solid food before 6 months of age; 83% are controlled monthly; 78% of mothers are housewives, do not work outside the home; 95% of mothers do not study; 92% have tap water and sewer; 40% live overcrowded; mothers admitted rare experience in culinary practices.

Conclusions: Mothers admitted the environment was adverse. Feeding practices relate to life conditions. Mothers always see the doctor and say they respect indications, but this does not stop repeated episodes. They assign a particular sense to being "housewives" without the preparation of meals being a part of it. It would be necessary to strengthen the promotion policies of good feeding and nutritional practices.

Key words: feeding practices, diarrhea, undernourishment and anemia, promotion policies.

PO1620**EFFECT OF A FORTIFIED OIL AND FLOUR PROGRAM IN COTE D'IVOIRE ON MICRONUTRIENT STATUS OF PRE-SCHOOL CHILDREN AND WOMEN**

⁵Institut National de Santé; Publique, Abidjan, Côte d'Ivoire

⁶Helen Keller International, Abidjan, Côte d'Ivoire

⁷Helen Keller International, Regional Office for Africa, Dakar Senegal

⁸Department of Biological Anthropology, University of Cambridge, Cambridge, UK

Background and objectives: Anemia and micronutrient deficiencies are widespread in sub-Saharan Africa but the impact of food fortification on addressing such deficiencies on a program scale is still debated. We aimed to estimate the iron and vitamin A status of pre-school age children (pre-SAC) and women of reproductive age (WRA), and folate status in WRA in households consuming fortified oil and wheat. Design: The survey was cross-sectional. Twenty-six clusters each were selected independently by a two-stage process in an urban and rural area; total of 52 clusters. Data on demographics, socio-economic status and access to fortified foods were collected at households. Hemoglobin, retinol binding protein (RBP), ferritin, soluble transferrin receptors (sTfR), folate, sub-clinical inflammation and Plasmodium spp. infection were determined among pre-SAC and WRA.

Results: In pre-SAC vitamin A deficiency (VAD) was prevalent (15% with RBP < 0.7 μmol/L) but for each 1 mg RE/kg oil consumed, RBP increased by 0.37 μmol/L (p=0.03). The relationship was stronger in those 24-59 months (RBP increased by 0.58 μmol/L; p = 0.004). In WRA, there was no significant VAD in the population (0.7%). Anemia was found in 92.2% of rural and 56.3% of urban pre-SAC (p<0.001). Pre-SAC with access to adequately fortified flour had hemoglobin concentrations 15.7 g/L higher than those without (p<0.001); significance remained after correction for Plasmodium parasites (p<0.001). Hemoglobin levels increased by +0.238 g/L per mg/kg increase in iron fortification levels (p<0.001). Seventy-eight percent of rural and 45% of urban women were anemic. Only minor positive effects were found in association with folic acid for-

tification of wheat flour, because adequacy of folic acid flour fortification was poor.

Conclusions: Micronutrient status was better in pre-SAC accessing fortified vegetable oil with vitamin A and wheat flour with iron and folic acid, provided through the national fortification program.

Key words: fortification, hemoglobin, vitamin A, folate.

¹Medecins Sans Frontieres, Vienna, Austria

²Medecins Sans Frontieres, New Delhi, India

Background and objectives: Community perceptions of health and illness, and how traditional and allopathic medical providers are viewed, determine how effectively medical non-governmental organisations such as Medecins Sans Frontieres (MSF) can provide care. Since February 2009, MSF has implemented a community-based nutritional programme in Biraal Block - an area in Darbhanga, in the rural state of Bihar, east India. Darbhanga is one of the most disadvantaged of Bihar's 38 districts. The programme has admitted more than 12, 000 children, but has a relatively high defaulter rate of 35%. We undertook a qualitative study to assess perceptions and the understanding of childhood malnutrition, and associated health-seeking behaviour, in Biraal Block.

Methods: In 2010, 58 qualitative semi-structured and narrative interviews dealing with malnutrition were undertaken with families of both malnourished children and nonmalnourished children (mothers, fathers, in-laws), and healthcare workers (traditional healers, traditional health practitioners, midwives, hospital nurses, doctors). 150 people were interviewed in individual and group discussions.

Results: Malnutrition did not tend to be viewed as a disease, meaning that people were unlikely to consult health workers if a child was 'only skinny'. Traditional beliefs tended to inform understanding of disease. People regularly consulted Hindu and Muslim priests or other non-allopathic traditional health practitioners who were easier to access than conventional health facilities. Findings did not differ between families of children with and without malnutrition. Senior family members and village elders had significant influence over the parents of the malnourished child in terms of decisions to seek treatment and type and location of treatment sought.

Conclusions: Health education programmes are needed to inform people about malnutrition in this context, and improve awareness that it is a disease that can be treated. Programmes

must engage individuals and communities, including traditional healers, so they can develop a holistic approach within existing social structures.

Key words: Malnutrition, perceptions, health-seeking-behaviour.

PO1623

NUTRITIONAL STATUS OF WOMEN OF REPRODUCTIVE AGE AND PREGNANT AND LACTATING WOMEN (PLW) IN BIRAUL BLOCK, DARBHANGA DISTRICT, BIHAR, INDIA.

E. Marino¹, S. Burza¹, N. Salse², C. Casademont², R. Mahajan¹

¹Medecins Sans Frontieres, New Delhi, India

²Medecins Sans Frontieres, Barcelona, Spain

Background and objectives: Since 2009 MSF's CMAM programme in Darbhanga district has admitted over 12000 children <5yrs. Given the strong correlation between maternal and child nutritional status, a needs assessment was undertaken to investigate the nutritional status of women of reproductive age (19-49 years), including pregnant and lactating women (PLW), in Biraoul block (population 300,000).

Methods: Two-stage cluster sampling was used to select populations from the smallest sampling unit (tolas) within Biraoul Block. Women of reproductive age (19-49 years) living in the selected households were included in the assessment. Information was collected through structured questionnaires by a team of enumerators previously trained on anthropometry and field practices. Nutritional status was determined using MUAC and a cut-off of <220mm indicating malnutrition.

Results: The overall prevalence of acute malnutrition defined as MUAC <220mm in women 19-49 years (n=341) was 17.0% (58/341). Stratified by PLW status, the prevalence was 23% (7/31) among pregnant women, 17.5% (25/143) in lactating woman and 16.3% (28/172) in non-PLW. A diet diversity score calculated using the FAO Individual Diet Diversity Score (IDDS, 2007) demonstrated a mean score of 7.1 (out of 14 food groups). No significant difference in score was detected between PLW (7.1±1.8) and non-PLW (7.2±1.8, p=0.7457), or malnourished (7.0±1.7) and non-malnourished women (7.1±1.7, p=0.5575). A significant difference (p<0.005) was found between castes, with those belonging to Scheduled Castes being lower (6.5±1.5) than those of higher castes (8.1±1.7).

Conclusions: The 17% prevalence acute malnutrition among women of reproductive age was found lower than shown in the government Bihar state National Family Health Survey-3 of 45% based on a BMI <18.5kg/m². Using a lower MUAC cut-off <210mm resulted in lower overall prevalence (5.9%), with significantly lower prevalence among pregnant women (3.6%)

but not lactating women (6.3%) or non-PLW (5.8%). This suggests that <220mm is more sensitive in detecting malnutrition in pregnant women. Further studies with larger sample sizes and outcome investigation are needed.

Key words: Mid-Upper-Arm-Circumference (MUAC), Pregnant & Lactating women (PLW).

PO1624

EFFECT OF CHANGING ADMISSION CRITERIA FROM W/H <-3 AND/OR MUAC <110MM TO EXCLUSIVELY MUAC <115MM ON CMAM PROGRAMME INDICATORS IN BIHAR, INDIA

S. Burza¹, R. Mahajan¹, N. Salse², C. Casademont², E. Marino¹

¹Medecins Sans Frontieres, New Delhi, India

²Medecins Sans Frontieres, Barcelona, Spain

Background and objectives: Between 2009-2010 MSF's CMAM programme in Bihar admitted children between 6-59 months with a W/H z-score of <-3SD and/or MUAC of <110mm, and discharged once achieving W/H >-2SD and MUAC >110mm (known henceforth as criteria A). To facilitate wider screening coverage and simplicity, the admission criteria was changed in 2010 to exclusively MUAC <115mm and discharge criteria to MUAC >120mm (known henceforth as criteria B).

Methods: All data was collected as part of routine operations on an excel based database which was retrospectively cleaned and analysed for epidemiological characteristics and programme indicators for both time periods. Oedematous children (0.5%, n=57) were excluded from this analysis.

Results: 3647 and 6484 children were admitted and exited under criterion A and B respectively. 57.7% and 66.9% of admissions were female under criterion A and B respectively. When stratified by age ranges 6-12 months, 12 to <24 months, 24 to <36 months and ≥36 months: 21.1%, 54.1%, 15.5% and 9.3% compared to 30.4%, 53%, 11.7% and 5% were admitted under criterion A and B respectively. Mean W/H at admission (-3.3±0.8 for both) and discharge (-1.5±0.7 vs -1.5±0.8) were similar for both criterion. Although there was minimal change in average MUAC gain between criterion (14.2mm +/- 7.4 vs 14mm +/- 6.3), the Average Weight Gain (g/kg/day) appeared significantly higher in criteria B (5.2 vs 4.8, p<0.005). Similarly, the average Length Of Stay in the programme prior to cure (days) was lower in criteria B (49 vs 57.6, p<0.005). In-programme mortality remained similar in both (0.7% vs 0.6%).

Conclusions: MUAC <115mm as an admission criteria appears to be more sensitive towards children <24 months (particularly between 6-12 months) and females when compared to W/H <-3SD and/or MUAC <110mm in this context. The

change in criteria appeared to have no effect on average W/H by z-score on admission or discharge, nor on in-programme mortality. Introducing the new criterion may have contributed to increased AWG and decreased LOS.

Key words: MUAC, CMAM, malnutrition, SAM, W/H.

PO1625

EFFECT OF W/H Z-SCORE ON DEMOGRAPHIC, ANTHROPOMETRIC AND PROGRAMME INDICATORS OF SEVERE ACUTE MALNOURISHED(SAM) CHILDREN ADMITTED WITH MUAC<115MM IN COMMUNITY-MANAGEMENT-OF-ACUTE-MALNUTRITION (CMAM) PROGRAMME IN BIHAR, INDIA

S. Burza¹, R. Mahajan¹, N. Salse², E. Marino¹, C. Casademont²

¹Medecins Sans Frontieres, New Delhi, India

²Medecins Sans Frontieres, Barcelona, Spain

Background and objectives: Between July 2010 and December 2012 MSFs CMAM programme, treating children with Severe Acute Malnutrition (SAM) in Bihar, India, admitted children with exclusively MUAC<115mm and discharged with MUAC >120mm. This abstract compares characteristics and outcomes of children within this cohort who had W/H Z-scores <-3SD and W/H Z-scores >-3SD.

Methods: All data was collected as part of routine operations on an Excel based database which was retrospectively cleaned and analysed for epidemiological characteristics and programme indicators. Oedematous children (0.5%, n=36) were excluded from this analysis.

Results: 6484 children were admitted with MUAC<115mm, of which 63.2% had a Z-Score <-3SD and 36.8% >-3SD. 60.3% and 78.4% of admissions were female comparing <-3SD and >-3SD respectively. When stratified by age ranges 6-12 months, 12 to <24 months, 24 to <36 months and >=36 months: 27.7%, 52.4%, 13.9% and 6% compared to 34.8%, 54%, 7.9% and 3.2% contrasting Z-score<-3SD and Z-score >-3SD respectively. Mean Z-scores were -3.8+/-0.6 and -2.4+/-0.5 at admission and -1.8+/- 0.8 and -1.2+/- 0.7 at discharge comparing <-3SD and >-3SD respectively. In-programme mortality was higher in those children with Z-score <-3SD (0.9% vs 0.2%, p<0.005; Risk Ratio 5.1, CI 1.8-14.3). AWG and LOS was slightly worse in children with Z-scores<-3SD, however average MUAC gain was significantly higher at 15.1mm vs 12mm (all p<0.0005).

Conclusions: In children admitted using the sole criteria of MUAC<115mm, interestingly there appears to be a significantly higher proportion of females and children <24 months in those with W/H Z score >-3SD. In-programme mortality appears to be higher in those with W/H Z score <-3SD, however

other programme response indicators appear to be relatively unchanged.

Key words: MUAC, CMAM, malnutrition, SAM, W/H

PO1626

SCALING UP NUTRITION IN TANZANIA: ACHIEVEMENTS, CHALLENGES AND WAY FORWARD

J. Kaganda¹, F. Magambo¹, B. Jeje¹, G. Mulokozi²

¹Tanzania Food and Nutrition Centre, Dar es Salaam, Tanzania

²Feed the Future, Tuboreshe Chakula Project, Dar es Salaam, Tanzania

Background and objectives: The Government of Tanzania believes that freedom from malnutrition is a moral imperative and a basic human right. Good nutrition is essential for enhancing immunity and hence reducing morbidity and mortality. Furthermore, good nutrition contributes to increased education, productivity, household and national income. Because of its belief, Tanzania has committed itself to scaling up nutrition within the country.

Methods: Reviewed of different country reports on progress towards scaling up nutrition in Tanzania.

Results: Tanzania has developed a National Nutrition Strategy and its Implementation Plan that state its priorities for the period of five years from 2011 to ensure that its people are properly nourished. A National Food Fortification Alliance has been established and is building a Private Public Partnership in food fortification to advance the fortification agenda in the country. A High Level National Steering Committee for Nutrition which includes senior representatives from the Government, Development Partners, Private Sector and Civil Society has been established and similar committees are being established at sub-national level. Nutritionist to plan and coordinate nutrition activities have been recruited to all regions of the country. Other nutrition interventions including promotion of breastfeeding, control of iodine deficiency disorders, twice yearly vitamin A supplementation have been promising. Challenges including inadequate linkages with programs and projects between various sectors that could provide synergistic services to address the underlying causes of malnutrition and limited financial resources for nutrition activities do exist.

Conclusions: Tanzania needs enhanced capacity, resource mobilization, commitment of decision makers and a multi-sector multi-stakeholder structure in place and functioning to coordinate the national, regional and districts response to improve nutrition. Documentation of lessons learned and positive partnerships between government and CSOs and the private sector with regards to nutrition is also crucial.

Key words: Tanzania, scaling up nutrition.

PO1627**IS THE BODY WEIGHT LOSS PREDICTED BY THE NEGATIVE ENERGY BALANCE PRESCRIBED?***M.A. Rojo-Tirado¹, P.J. Benito¹*

¹Department of Health and Human Performance, Technical University of Madrid, Madrid, Spain

Background and objectives: Teixeira et al. (1) stated that the ability to lose a significant amount of weight is dependent on the level of caloric restriction. The aim of this study was to evaluate if the real body weight (BW) loss is similar to predicted in a six-month diet intervention.

Methods: Forty people, with BMI 25-34.9 kg•m⁻², aged from 18 to 50 years, participated in the study during 6 months. All participants followed a 25-30% calorie restriction diet. The predicted BW loss was calculated assuming that a kilogram of body mass is equal to 7770 calories (2). A paired Student's t test was used to compare the predicted and the real BW loss. Probability level for statistical significance was set at $\alpha=0.05$.

Results: If we converted the calorie restriction during the six-month intervention into body mass, the mean body weight loss should have been -17.01 ± 4.78 kg. However, the real BW loss was significantly lower (-8.47 ± 5.06 kg) than expected ($t_{39}=9.109$; $p<0.001$), being this difference of 8.54 ± 5.63 .

Conclusions: The real BW loss is lower than expected by the level of caloric restriction. This should be taken into account in tailoring intervention advice.

Key Words: Caloric restriction, body weight loss.

PO1628**BASAL METABOLIC RATE: VALIDATION OF A POPULATION-SPECIFIC EQUATION FOR BRAZILIANS***V. Wahrlich^{1,2}, L. Anjos^{1,2}, T. Teixeira²*

¹Departamento de Nutrição Social, Universidade Federal Fluminense, Niterói, Brasil

²Pós-graduação em Saúde Coletiva, Universidade Federal Fluminense, Niterói, Brasil

Background and objectives: Estimation of energy requirements depends on reliable values of basal metabolic rate (BMR). Internationally recommended BMR prediction equations (Schofield - SCHO) have been shown to be inadequate for groups of Brazilians. The purpose of this study was to vali-

date population-based sex-specific equations to estimate BMR developed for the Brazilian adult population (BRA) against measured BMR in a sample of adults (age ≥ 20 years) living in Niterói, Rio de Janeiro (RJ), Brazil.

Methods: A total of 172 subjects (109 women) participated in the study. BMR was measured in a controlled environment early in the morning with the subject having fasted for 10-12 hours. Body mass (BM), stature (S) and percent body fat (%BF) by DXA were obtained following the BMR measurements. BMR was estimated with the SCHO and BRA equations (kcal/day): $8.95(\text{BM})+8.87(\text{S})-0.70(\text{Age})-814.3$ (Women) and $9.99(\text{BM})+7.14(\text{S})-2.79(\text{Age})-450.5$ (Men).

Results: Average (\pm SD) age was 38.3 (16.9) years (range 20.0-97.0y). Women were older, heavier, shorter, and had higher %BF than men but similar BMI (24.4 ± 4.8 and 24.6 ± 3.3 kg/m² for women and men, respectively). Measured BMR (1151.7 ± 164.8 and 1478.2 ± 189.1 kcal/day) was significantly lower than estimated by SCHO (1352.8 ± 129.8 and 1756.7 ± 176.2 kcal/day) but not different from BMR estimated by BRA equations (1154.4 ± 130.5 and 1452.2 ± 153.8 kcal/day, representing 1.0 ± 9.2 and $-1.0\pm 10.1\%$). Individual accuracy was greater for BRA (73.4% of women and 60.3% of men had predicted values within $\pm 10\%$ of measured BMR) than SCHO (22.0 and 15.9%).

Conclusions: The data indicate that the FAO/WHO internationally recommended predictive equations are not appropriate for Brazilian adults living in Niterói. It is suggested that the newly developed equations be used in the Brazilian population.

Key words: Basal metabolism, Brazil, Validation studies.

PO1629**DIETARY INTERVENTION IMPROVES HEALTH AND NUTRITIONAL STATUS OF HOSPITALIZED CHILDREN WITH PROTEIN ENERGY MALNUTRITION***M. Ismail¹, L. El bedewy², A. El shafie³, A. Ghanem⁴*

¹Faculty of Home Economics, Minufiya University, Egypt

Background and objectives: Protein energy malnutrition (PEM) is common in young children in developing countries and consider as a major public health problem. This study aimed to improve the nutritional status of infants and children with PEM.

Methods: A sample of 40 Infants and young children with PEM and who admitted Shebin El-Kom University Hospital for treatment were enrolled in the study. The children were classified into four equal groups; 1st control group (CG) in whom children were received the regular hospital meals without any modification; 2nd modified diet group(MDG) in whom chil-

dren fed the modified diet from admission till leaving; 3rd double protein group (DPG) in whom children fed the hospital meals with multiple amount of protein from admission till leaving; 4th formula group (FG) in whom children fed the hospital meals besides high protein formula. Each group received the menu for at least 14 consecutive days.

Results: The results showed that the served hospital for treatment of PEM was very low in energy, iron, vitamin C, vitamin A. The results showed that dietary intervention resulted in significant increase in body weight among CG and DPG groups. On the other hand the dietary intervention caused significant improvement of other blood parameters.

Conclusions: Modifying hospital diet can be improve health and nutritional status of children with PEM.

Key words: PEM, Malnutrition, Children, Infants, Protein

PO1630

DETERMINANTS OF OVERWEIGHT AMONG INDONESIAN TEENAGE FEMALES

V. Melani¹, Hardinsyah.¹, D. Briawan¹

¹Department of Community Nutrition, Faculty of Human Ecology, Bogor Agricultural University, Bogor, West Java, Indonesia

Background and objectives: Prevalence of overweight has increased globally, and be a serious public health concern because of it is associated with chronic diseases such as diabetes and cardiovascular diseases. However, very limited information available on its determinants factors among Indonesian teenage females (ITF). Objective: To analyze the prevalence of overweight and its determinants especially in the context of social economic and food factors among ITF.

Methods: The electronic files data of the Riskesdas 2010 – a national health survey consisted about 11.000 ITF aged 13–18 years were analyzed. Overweight subject was identified by BMI/age (WHO, 2007). The suspected determinants factors encompass age, fathers and mothers educational levels, family income levels, fathers and mothers occupations, fruit and vegetable intake, energy adequacy, percentage of energy intake from sugary sweetened beverages, percentage of energy intake from carbohydrate, fat and protein. A logistic regression model was applied to analyze the determinants of the overweight.

Results: The prevalence of overweight among ITF was 10.2% which is relatively low; it was higher in the younger age and higher family. The result of the logistic analysis showed that the determinants of the overweight were age (OR for aged 13-15=0.755; CI: 0.642 – 0.887), female education level (OR for basic education=0.769; CI: 0.653 – 0.904), and family income level (OR for high income=1.487; CI: 1.272 – 1.739). None of the food factors considered as determinants in this study,

possibly because of the low prevalence of overweight and the weaknesses of the 24 hr food recall method to be used in the regression/correlation analysis.

Conclusions: The prevalence of overweight among ITF is low; and the determinants factors of it are age, education and family income levels, which need to be considered in preventing overweight among ITF.

Key words: Indonesian females, overweight determinants, overweight female

PO1631

EFFICACY OF IRON FORTIFIED RICE IN VIETNAM

T. Pham Van¹, H. Le Thi², Y. Nakanishi³

¹NIN, Hanoi, Vietnam

²NIN, Hanoi, Vietnam

³ILSI-CHP, Japan

Background and objectives: Rice as a stable food is consumed daily by almost of Vietnamese population could be a food vehicle for fortification program. The study evaluated the efficacy of iron fortified rice (IFR) in improving iron status of reproductive age women (RAW).

Methods: It was a randomized, double-masked study of 244 women, in two groups. A meal based on IFR (SunActive® FeP80) was served 6 days/week with 15mg premix per 150g rice-Iron fortified group (FG) or 0.75mg Fe/day and no added iron-Control group (CG). Concentrations of hemoglobin (Hb, g/l), serum ferritin (SF, mcg/l), transferrin receptor (rTfR, mg/l) were measured at baseline (T0), 3 mo. (T3) and 6 mo. (T6). After intervention, in FG, concentrations of Hb, SF were significant higher Hb0: 123.5±10.8; Hb6: 125.9 ± 8.9 (p=0.009); SF0: 32.0±35.2; SF6: 43.7±53.1 (p<0.001); TfR were lower: 6.3±2.2; 5.1±1.6 (p<0.001); prevalence of anemia decreased from 30.3% to 17.6%; prevalence of iron deficiency from 40.7% to 24.4%. In CG, Hb0: 125.6±13.8; Hb6: 126.2 ± 11.7 (p=0.7); SF0: 36.2±27.2; SF6: 38.7±31.0 (p=0.1); TfR0: 6.2±3.7; TfR6: 5.3±2.4 (p<0.001); prevalence of anemia changed from 29.5% to 27.1%; of iron deficiency was 21.3%.

Conclusions: Regular consumption of IFR during 6 mo. significantly reduced the prevalence of iron deficiency anemia in RAW. Fortified rice is a potential strategy for control of Iron deficiency anemia in Vietnam.

Key words: anemia, fortification, rice, Vietnam

PO1632

COMPETENCY REQUIREMENTS OF PUBLIC HEALTH NUTRITIONISTS: STABILITY OF CONSENSUS OVER A DECADE

R. Hughes¹

¹Bond University, Gold Coast, Australia

Competency standards provide the architecture for workforce development and serve to inform workforce preparation, continuing professional development and quality assurance via registration and credentialing systems. Developing consensus on competency requirements for the developing global public health nutrition workforce is therefore an important strategic initiative. This study aimed to compare consensus derived from 3 international Delphi studies conducted regarding the essential competencies required for effective public health nutrition practice. Three modified Delphi studies were conducted in 2003, 2009 and 2012 involving 3 rounds of questionnaires administered amongst panels (n=24, 52 and 44 respectively) including public health nutrition leaders from government, academic and professional jurisdictions. The emphasis of the consensus development process was identification and prioritization of essential competency requirements for the future public health nutrition workforce. In each Delphi study, ratings and open-ended responses to over 180 separate competency elements derived from the white and grey literature were categorised into 14 competency areas including enabling knowledge, analytical, nutrition science, public health systems, food and nutrition systems, communication, management, leadership, nutrition education, nutrition assessment, nutrition monitoring and surveillance, capacity building, intervention management and professional competency categories. This comparative study demonstrates that there is strong international agreement about the competency requirements for public health nutrition and this consensus has been very stable over the last decade. Essential competency units identified have been used to develop competency standards for public health nutrition by the World Public Health Nutrition Association, which form the basis for its practitioner certification system.

Key words: Competency, public health nutrition, consensus

KNOWLEDGE AND PRACTICES OF COMMUNITY HEALTH AGENTS: HEALTHY EATING AND WALKING IN PREGNANCY

M B. Malta¹, M Y. Takito², M H D A. Benício³, M A B L. Carvalhaes⁴

¹Department of Public Health, Botucatu Medical School, UNESP, Botucatu, Brazil

²Department of Body Human Movement, School of Physics and Sport Education Institute, USP, São Paulo, Brazil

³Department of Nutrition, Public Health Medical School, USP, São Paulo, Brazil

⁴Department of Nursing, Botucatu Medical School, UNESP, Botucatu, Brazil

Background and objectives: The Community Health Agents (CHA) find themselves in an good position to encourage the development of healthy lifestyles. Pregnant women are particularly vulnerable to these influences, whether to receive frequent home visits by the CHA during the prenatal period, or in order to his willingness to change. Objective: identifying knowledge and practices related to healthy eating (HE) and walking (WA) in pregnancy of CHA working in primary health care in Botucatu/SP/Brazil.

Methods: Cross-sectional study. All CHA have answered questionnaire on recommendations and guidelines given in home visits about HE and WA during pregnancy. Descriptive statistical analyzes have been performed using SPSS.

Results: The 50 CHA were on average 34.2±8.1 years old, and most had never attended training on HE (96.1%) or physical activity (92.2%) in pregnancy. Most of the CHA reported they don't always/very often approach the topic HE on his home visits to pregnant women: 97% said they don't talk about fruits and vegetables, 27.5% haven't mentioned the consumption of beans and 40% the consumption of soft drinks and biscuits. Concerning the amount of daily servings, 44% were unaware of the recommendation of fruit, 56% vegetables, 72% beans and almost 7% biscuits and soft drinks. Concerning the subject WA prenatal, 33.3% of ACS always/very often stimulated the pregnant woman to perform WA. Concerning the knowledge on WA recommendations, only 5.9% knew the recommendation for the 1st pregnancy trimester, 3.9% for the 2nd and 2% for the 3rd.

Conclusions: The subjects WA and HE, although quite important in defining the mother/son health outcomes, are not addressed at all home visits to pregnant women. Moreover, there are significant gaps in their knowledge regarding current recommendations for pregnant women about these behaviors, justifying interventions focusing on training these professionals.

Key words: Community health agent, healthy eating during pregnancy, walking during pregnancy.

PO1634**DEVELOPMENT OF FOOD PYRAMID FOR VEGETARIAN IN INDONESIA**

A. Setiarini¹, D M. Utari¹, W K Y. Putra¹, M. ¹, T. Sudiarti¹, S. ²

¹Department of Public Health Nutrition, Faculty of Public Health, University of Indonesia

²Indonesian Vegetarian Society, Indonesia

In Indonesia, number of vegetarians is increasing from year to year along with the increasing awareness of health. Vegetarian diet is believed as one of the alternative healthy diet for the people of Indonesia. However lack of information about healthy and balance diet for vegetarian can make them prone to the deficiency or excess of nutrients. Therefore, a food pyramid for vegetarian needs to be develop to give them guideline about healthy and balance vegetarian diet. This study was a prototyping research and used cross-sectional design with both quantitative and qualitative approaches. Data were collected from literature review and interview to vegetarians male and female from various age groups (children, adolescent, adult and elderly) using a structured questionnaire. The number of sample in this study was 160 vegetarians obtained with non-probability sampling method using consecutive sampling technique. Information that collected from subjects was type of food consumption using Food Frequency Questionnaire, then categorized in to food group, analyzed nutrient content using Nutrisurvey and counted based on Indonesian recommended dietary allowance to determine the portion. After these steps, development food pyramid for vegetarian was done by buying all food that consumed and made photos. Pilot test of food pyramid was done among vegetarian people in Centre of Education and Training Buddha, Maitreyawira, West Jakarta and getting input from expert such as academics and dietitian. The output from this study was Food Pyramid for two types of vegetarian, i.e vegan and lacto-ovo vegetarian. We hope that these Food Pyramids could be a guidelines for vegetarians in Indonesia in regard of choosing and consuming healthy and balance food.

Key words: food pyramid, vegetarian, vegan, lacto-ovo vegetarian

PO1635**THE EFFECT OF TRAINING DELIVERY METHOD ON THE COMPETENCIES OF COMMUNITY HEALTH WORKERS IN COMMUNICATING SAFE COMPLEMENTARY FEEDING**

D N. Iswarawanti¹, S. Muslimatun¹, E. Basuki², H P. Ahmad³

¹Southeast Asian Ministers of Education Organization (SEAMEO) Regional Center for Food and Nutrition (RECFON), University of Indonesia, Indonesia

²Department of community medicine, Medicine Faculty, University of Indonesia, Indonesia

³State University of Jakarta, Indonesia

Introduction and objectives Caregivers need support to sustain appropriate young child feeding practices from Community Health Workers (CHW). Limited and ineffective training may impact CHWs' performance particularly in nutrition counseling. Therefore, it is necessary to assess the effect of training which has developed through a systematic and scientific approach to their competencies. The study aimed to assess the effect of training method delivery on CHWs' competencies in communicating safe complementary feeding to caregivers of 6-24 months children. Methods The study was conducted in Bekasi, Indonesia. It used a non-equivalent pre-post test control group design. Both groups obtained 6 topics on communicating safe complementary feeding. The intervention group (n=70) received the materials in a 3-day training consisted of 24 hours learning session using adult learning approach. The comparison group (n=68) received the material in a half day seminar session. Results Cognitive competency (C). The "application competency" of CHWs who received training was significantly higher than those who attended seminar. Affective competency (A). The "responding competency" of CHWs who received training was significantly higher than those who attended seminar. Psychomotor competency (P). The "set competencies" of CHWs who received training was significantly higher, and they have potential to be psychomotor-competent 9.1 times more than who attended the seminar. Composite competency (30% C+30% A+40% P). The proportion of CHW who were competent in composite competency in the training group was significantly higher than the counterpart (74.3% vs 36.8). and they have potential to be composite-competent 6.9 times more than who attended the seminar. Conclusions Training can improve the CHWs' competencies in communicating safe complementary feeding. A half day seminar could improve the lower level of cognitive competencies but fail to improve the affective and psychomotor competencies. Acknowledgement is delivered to The Nestle Foundation.

PO1636**TELEVISION VIEWING: IMPACT ON BODY MASS INDEX AND FOOD INTAKE AMONG SCHOOL CHILDREN IN MALAYSIA***R A. Talib¹, R. Sharif², W N. Wan Nazir¹*

¹School of Health Care Sciences, Faculty of Health Sciences, The National University of Malaysia, Malaysia

²Department of Mass Communication, Faculty of Creative Industries University Tunku Abdul Rahman Petaling Jaya Campus, Malaysia

Background and objectives: This cross-sectional study was conducted to determine the relationship between duration of television viewing and body mass index (BMI), energy and nutrient intake.

Methods: A total of 180 Malay school children from five primary schools in Wilayah Persekutuan Kuala Lumpur as urban area and Daerah Hulu Langat in Selangor as rural area participated in this study. The children consisted of 73 boys and 107 girls, aged 10 to 12 years old. The anthropometric data including body weight, height, BMI and waist circumference were measured using standard measurement. Data on television viewing habit was collected using questionnaire developed specifically for this study whereas data on energy and nutrient intake were collected using 2 days 24 hour dietary recall.

Results: This study found higher prevalence of overweight/obesity among urban children (42.2%) compared to rural children (34.4%). Prevalence of underweight was slightly higher among rural children (6.7%) compared to urban children (5.6%). During weekend and weekdays, most of the children in urban area watched television > 2 hours per day, 56.7% and 46.5% respectively. Besides, most of the children in rural area watched television < 2 hours per day during weekend (58.4%) and weekdays (77.4%). Both energy and protein intake were higher ($p < 0.05$) among girls in urban compared to rural area. For boys, the protein intake was higher ($p < 0.05$) in urban, as compared to rural area. This study found positive correlation between duration of television viewing and BMI during weekend ($r = 0.212$, $p < 0.05$) and weekdays ($r = 0.201$, $p < 0.05$). However, this study found no significant correlation between energy and macronutrient intake with duration of television viewing among children.

Conclusions: This study showed that duration of television viewing has affected body mass index but not the energy and macronutrient intake of school children in Malaysia.

Key words: Television, BMI, school children, food intake

PO1637**DIFFERENCES ON WHO INDICATORS FOR ASSESSING INFANT AND CHILDREN FEEDING PRACTICES ON PUBLIC AND PRIVATE HEALTH CENTERS IN ROSARIO, ARGENTINA***M E. Zapata^{1,2}, S. Padrós², E. Palanca², A. Venecia², J. Fortino², C. Palmucci², E. Carmuega¹*

¹Centro de Estudios Sobre Nutrición Infantil (CESNI), Ciudad Autónoma de Buenos Aires, Buenos Aires, Argentina

²Licenciatura en Nutrición, Facultad de Química, Universidad del Centro Educativo Latinoamericano, Rosario, Santa Fe, Argentina

Background and objectives: The World Health Organization (WHO) and partners have released new and updated indicators for assessing infant and young children feeding practices for use in population based surveys. The indicators reflect current recommendations for proper infant and young children feeding and provide important new information on feeding practices in children 6 to 23 months of age. The aim of this study was to assess infant and young children feeding practices based on the new indicators from WHO, in a public and a private health center of Rosario, Argentina.

Methods: A cross-sectional study was carried out and evaluated 400 mothers and children from a public and a private health center of downtown Rosario. Analysis is based on 391 children (191 public and 199 private) less than 24 months. To assess the indicators a general questionnaire was administered and a 24h recall. Differences were evaluated by Chi-square test.

Results: Early breastfeeding initiation was 83, 3 vs 83, 9% (NS) at public and private health center respectively; exclusive breastfeeding under 6 months was 79, 1 vs 43, 8% ($P < 0.001$); continued breastfeeding at 1 year was 29, 4 vs 36, 8% (NS); introduction of solid, semi-solid, or soft foods was 71, 4 vs 100% ($P < 0.01$); minimum dietary diversity was 45, 3 vs 70, 9% ($P < 0.001$); minimum meal frequency was 74, 5 vs 98, 1% ($P < 0.001$); minimum acceptable diet was 41, 5 vs 70, 9% ($P < 0.001$); and consumption of iron-rich or iron-fortified foods was 66, 0 vs 94, 2% ($P < 0.001$).

Conclusions: In the public health center outcomes in complementary feeding indicators were worse, this may be related to the lower socioeconomic status of the population attending this centers. There were indicators different from breastfeeding in public and private sector involved with the primary care of children in Argentina and that should motivate the ways of education and promotion in both sectors.

Key words: indicators, breastfeeding, feeding practices

PO1638

URBAN AGRICULTURE AS STRATEGY TO PROMOTE FOOD AND NUTRITION SECURITY.

D. Coelho¹, M. Garcia¹, M. Salandini¹, C. Bógus¹

¹Faculdade de Saúde Pública, Universidade de São Paulo, São Paulo, Brasil

Background and objectives: Urban Agriculture (UA) developed through agroecological approach contributes to generating productive and ecological cities, by respecting social and cultural diversity. It is, therefore, an important strategy to sustainable development and to promote food and nutrition security. This work evaluates the role of UA activities developed in Primary Care Units as promoters of food and nutrition security among participants.

Methods: Qualitative study carried out in the city of Embu das Artes (Sao Paulo/Brazil), through workshops of Systematization of Experiences with participants of an UA project. The workshops were analyzed according to thematic content analysis.

Results: The discourses were organized based on Brazil's definition of food and nutrition security, from the new National Food and Nutrition Policy, according to the following categories: improvement of conditions to food access (growing vegetables and fruits for own consumption; local sale; community donation); food quality (organic production and consumption; greater food variety), environmental sustainability (use of household waste to produce organic fertilizer); healthy eating practices that respect cultural diversity (rediscover the ancestors food growing methods; social exchanges; community meals prepared with produce from the garden; development of culinary skills); production of knowledge (knowledge exchange within the community; understanding healthy eating benefits). Other important ideas have been identified, but they were not categorized for not fitting directly into the definition of food security and nutrition. Thus, we found that participants of the UA activities felt encouraged to develop home gardens in their homes. We also found a conscious awakening of the participants to self-perceived feeding and to perception of feeding in a broaden social and environmental context.

Conclusions: The practice of Urban Agriculture with an agroecological approach is a powerful strategy to promote food and nutrition security, as it implicates on food, health, environment and social development.

Key words: Urban Agriculture; Food and Nutrition Security.

PO1639

MALNUTRITION STATUS AND INFLUENCING FACTORS IN LEFT-BEHIND CHILDREN WITH MIGRANT WORKER MOTHER IN POOR AREAS IN CHINA

D. Yu¹, A. Liu¹, W. Yu¹, F. Jia¹, J. Li¹, L. Zhao¹

¹Institute of Nutrition and Food Safety, China CDC, Beijing, China

Background and objectives: Poor rural left-behind children, a vulnerable population that emerged with the economic and social transition in China, will exist for a long time. The study was to explore the malnutrition status and influencing factors in left-behind children with migrant worker mother in poor areas of 13 provinces*.

Methods: Survey data was from the program of Public Health Emergency Response and Operation Mechanism-Establish the monitoring and information system on nutrition and health and related risk factors in 0-5 children in 2009 which funded by China CDC. Multistage stratified random cluster sampling method used in the national survey was performed. The contents of the investigation included questionnaire survey, anthropometric measurement, biochemical tests and dietary survey. The subjects of the study were 2161 children no more than 18 months in the survey. Z-scores were calculated according to WHO growth standards (2006). Data processing and multiple factors analysis were finished by non condition logistic regression in software SAS 9.12.

Results: There were 9.3% children whose mother were migrant workers in the target population. The prevalence of stunting and underweight in left-behind children was 15.5% and 6.0%. Excluding other influencing factors, the results suggested that low birth weight (OR=2.543; 95%CI=1.481-4.365); minority nationality (OR=1.661; 95%CI=1.274-2.165); mother is migrant worker (OR=1.602; 95%CI=1.085-2.367), the nearest medical institution at a distance of ≤ 1 km (OR=1.308; 95%CI=1.008-1.696), and unsanitary toilet (OR=1.311; 95%CI=1.017-1.689) are the most important independent factors among 0-18 months young children.

Conclusions: Malnutrition in left-behind children with migrant worker mother in poor areas should not be ignored. Enhance the monitoring and adopt comprehensive improvement are useful to improve the growth of children.

Key words: left-behind children, malnutrition, influence factors.

PO1640**COMPARISON OF PREVENTIVE AND THERAPEUTIC ZINC SUPPLEMENTATION PROGRAM EFFECTS ON DIARRHEA AND FEBRILE ILLNESSES AMONG YOUNG CHILDREN: A RANDOMIZED TRIAL**

E. Becquey^{1,2}, C.T. Ouedraogo³, S.Y. Hess², N. Rouamba³, L. Prince⁴, S.A. Vosti⁴, J.B. Ouedraogo³, K.H. Brown^{1,2}

¹Helen Keller International, New York, NY, USA

²Department of Nutrition, University of California, Davis, CA, USA

³Direction Regionale de l'Ouest, Institut de Recherche en Sciences de la Sante, Bobo-Dioulasso, Burkina Faso

⁴Department of Agricultural and Resource Economics, University of California, Davis, CA, USA

Background and objectives: WHO/UNICEF recommend including zinc supplementation in the treatment of diarrhea. We hypothesized that in an area with high risk of zinc deficiency, daily or intermittent preventive zinc supplementation might provide greater reduction of diarrhea morbidity than just therapeutic zinc, while also possibly decreasing morbidity from febrile illnesses.

Methods: 6, 246 rural Burkinabe children 6-30 mo old were randomly assigned to one of 4 treatment groups for 16, 32 or 48 wks: 7 mg zinc/d and ORS+placebo for diarrhea (daily supplementation); 10 mg zinc/d for 10d/16wks followed by daily placebo and ORS+placebo for diarrhea (intermittent supplementation); daily placebo and ORS+20mg zinc/d for 10d for diarrhea (therapeutic supplementation); or no daily supplementation and ORS for diarrhea (control). Morbidity surveillance was performed through weekly home visits; free community-based treatment was provided for uncomplicated diarrhea (>3 liquid/semi-liquid stools/d), confirmed fever (axillary temperature \geq 38°C) and malaria (reported or confirmed fever (RCF) and positive rapid diagnosis test). Any group-wise differences in baseline characteristics were accounted for in logistic regression analyses. Group codes are still masked.

Results: Reported adherence to daily supplementation (97 \pm 5%) did not differ by group. Overall, diarrhea (0.5%), RCF (1.2%) and malaria (0.3%) incidence were low. Diarrhea incidence decreased progressively during the three 16-wk rounds (OR=0.86 for round 3 vs round 1, $p=0.009$), while RCF (OR=1.44; $p<0.0001$) and malaria (OR=4.13; $p<0.0001$) incidence increased. All supplemented groups had moderately lower diarrhea (OR=0.83-0.87; $p=0.0009$ -0.003) and RCF (OR=0.77-0.80; $p<0.0001$) but not malaria ($p=0.36$) incidence than the control group. Treatment groups effects differed across rounds of supplementation for diarrhea ($p=0.10$ for the interaction).

Conclusions: Zinc supplementation reduced diarrhea and RCF in this population. The effects of different supplement

delivery strategies may vary according to the duration of the supplementation program. Supported by: Thrasher Research Fund and Canadian International Development Agency.

Key words: diarrhea, fever, malaria, zinc supplementation

PO1641**FOOD SECURITY AMONG HOUSEHOLDS WITH NO DRINKING WATER AND ELECTRICITY.COMUNA 3 CASE.MEDELLÍN-COLOMBIA. 2011**

C. Mejía¹, C. Arango¹, Y. Cataño¹

¹Faculty of Public Health, University of Antioquia, Medellín, Colombia

Background and objectives:The lack of drinking water and electricity has worsened in the last decades in Medellín, especially in the poorest areas where displaced families whose basic needs are not fulfilled have come to try to make a living in the outskirts of the city, places where both water and electricity supply is weak thus affecting the quality of life. **Objective:**Describe the food security and nutrition status among households with no access to drinking water and electricity.

Methods:Cross-sectional study involving 250 households and 541 subjects selected by convenience sampling. A descriptive analysis was performed, the OR with $P = 0.05$ test was used to estimate the association between malnutrition and socioeconomic characteristics, odds ratio results and multiple correspondence analysis were used to establish households' socioeconomic and feeding profiles.

Results: 92, 7% of households showed food insecurity, 15, 5% showed malnutrition duality, i.e., obesity among adults while children are malnourished. A food insecurity profile household was found where changes in the diet are made due to lack of money to buy food; they live in inadequate conditions. Malnourishment among children was associated to overcrowding, income, and type of house.

Conclusions:The major problem found was stunting among under 18-year-old subjects, most showing some type of malnutrition; one in six households showed malnourishment among some of the children and overweight among adults. Basic groceries these households shop for supply mostly carbohydrates and have a low nutritional density.

Key words: Households, malnutrition, food insecurity, drinking water and electricity.

PO1642**CONTRIBUTION TO THE STUDY OF TOXICOLOGICAL AND NUTRITIONAL EDIBLE OILS HEATED: IMPACT ON HEALTH***O. Aouacheri¹, S. Saka¹, M. El-Farra¹*

¹Applied Biochemistry and Microbiology Laboratory, Department of Biochemistry, Faculty of Sciences, Badji Mokhtar University - Annaba, Algeria

Background and objectives: In this study we try to focus on the evidence that the wrong use of oil in food cooking should lead to health problems. High temperatures associated with repeated use of the same oil would lead to the breakdown of some fatty acids forming numerous toxic polymer compounds and peroxides.

Methods: 54 male rats (Albino Wistar) were fed with a diet containing 10 % of sunflower oil. The control group was fed by ordinary oil (OO); the second lot was fed by continuously heated oil (CHO) for 10 hours at 220 C° and the last lot was fed by frying oil (FO). The animals were killed by decapitation, respectively after three, five and seven weeks from the beginning of the diet.

Results: The chemical dosages demonstrated great ratios of polymer, polar and peroxide compounds in heated oil for 10 hours at 220 C° (CHO) and frying oil (FO). The biochemical studies have shown a significant decrease in hepatic glutathione (GSH) ratio in CHO and FO lots in comparing the control group (OO). A combined significant increase in glutathione peroxidase (GPx) and glutathione reductase (GR) activities appears also along the time of diet in CHO and FO groups compared to control.

Conclusions: The high temperatures associated with repeated use of the same oil lead to the production of high contents of dangerous compounds: free oxygen radicals, polymer compounds, peroxides etc. The combined relationship between the decreased glutathione ratio and the increased GPx and GR activities in rats feed on CHO and FO confirms the participation of glutathione redox system in the detoxifying reactions of continuously accumulated toxic peroxides.

Key words: Glutathione, glutathione peroxidase, glutathione reductase, peroxides, heated oils.

PO1643**EFFECT OF INCREASING VOLUNTARY FOLIC ACID FORTIFICATION ON DIETARY FOLATE INTAKES AND ADEQUACY IN REPRODUCTIVE AGE NEW ZEALAND WOMEN***L. Houghton¹, S. Evans¹, V. Mygind¹, M. Peddie¹, J. Miller¹*

¹Department of Human Nutrition, University of Otago, New Zealand

Background and objectives: Mandatory fortification of breads with folic acid in New Zealand was put on hold for 3 years in 2009. In the interim, bread manufacturers were requested to adopt greater voluntary fortification and agreed to add folic acid to approximately one third of their bread range. We sought to evaluate the potential impact of increased voluntary fortification of bread and the proposed mandatory fortification programme on folate intake adequacy of reproductive age women.

Methods: This study used baseline dietary data from 125 healthy non-pregnant New Zealand women (18-40 years) enrolled in folate intervention trial conducted in 2008. Three-day weighed food records were used to collect dietary data, and folate intakes [folic acid, natural food folate and dietary folate equivalents (DFEs)] were determined based on the following 3 fortification scenarios: i) voluntary fortification of bread as of 2008 (6 breads); ii) increased voluntary fortification of bread as of 2011 (34 breads), and iii) mandatory fortification of all breads. Estimates of participants' usual intakes adjusted for within-person variability were generated for each scenario, and the prevalence of folate inadequacy was calculated using the EAR cut-point method.

Results: Usual median folate intake of participants in 2008 was 362 µg DFE/d. Adoption of greater voluntary bread fortification lead to a significant albeit marginal increase in folate intakes (394 µg DFE/d), and a decline in inadequacy from 37% to 29%. Simulated mandatory fortification resulted in an increase of 89 µg folic acid/d, which substantially shifted the distribution of overall folate intakes, and produced a marked reduction in the prevalence of inadequacy to 5%.

Conclusions: Our results show that increased voluntary bread fortification efforts are far inferior to mandatory fortification as a reliable public health intervention.

Key words: folate intake adequacy, folic acid fortification, reproductive-age women.

PO1644**AN EVALUATION OF ANTHROPOMETRIC MEASUREMENTS, KNOWLEDGE, ATTITUDE, AND PRACTICES SCORES OF DIET AND NUTRITION AT DIFFERENT TYPE WORKSITES IN TAIWAN***H M L. Chin¹, H C. Chiu², P L. Hsu³*¹Taipei City Hospital; Fu-Jen Catholic University, Taiwan, China²Taiwan Dietetians Association, Taiwan, China³Taipei City Hospital, Zhongxing Branch, Taiwan, China

Background and objectives: For a workplace health promotion programme to be effective, it should address their needs before intervention. This study was undertaken to evaluate whether the anthropometric measurements, knowledge, attitude, and practices (KAP) scores regarding diet and nutrition have differences among different type worksites.

Methods: Eight workplaces from Taiwan East, South, North and Middle area were selected. Body weight and waist circumference (WC) were measured, and a pre-tested KAP questionnaire comprising of 51 questions (knowledge 15, attitude 10, and practice 26) was administered to those employees. One-Way ANOVA and Duncan's multiple range tests were used for statistics.

Results: Two high-tech companies, four government agencies and two operating factories with total of 840 subjects, 376 males and 455 females completed the KAP questionnaire and related measurements. Data indicated that KAP scores varied among 3 different type workplaces significantly ($p < 0.0001$ for both K and P scores and $p < 0.01$ for A score), and also between male and female employees ($p < 0.0001$ for P score and $p < 0.05$ for both K and A scores). Operating factories has the lowest K and A score, and both high-tech companies and operating factories have lower P score than government agencies. After age and sex weighted, employees in high-tech companies have the highest WC although their BMI and total body fat are similar to the other workplaces employees ($p < 0.05$).

Conclusions: This study demonstrated that diet and nutrition knowledge is limit in certain type workplaces like operating factories, and for the other type workplace like high-tech companies, to set up a supportive environment may be the most important.

Key words: KAP scores, workplace, body weight, waist circumference.

PO1645**THE POTENTIAL FOR NUTRITION-ORIENTED VALUE CHAIN ANALYSES TO INFORM DIET-RELATED CHRONIC DISEASE PREVENTION: AN AUSTRALIAN PERSPECTIVE***L. Hattersley¹, J. Dixon¹, S. Friel¹, J. Coveney²*¹National Centre for Epidemiology and Population Health, The Australian National University, Canberra, ACT, Australia²School of Medicine, Flinders University, Adelaide, South Australia, Australia

Background and objectives: Nutrition-oriented value chain analysis involves mapping the processes, actors, and value-adding activities involved in specific agri-food chains, analysing actor relations, power, and governance dynamics, and identifying the implications for nutrition. The approach offers significant potential for identifying leverage points within agri-food systems to integrate nutrition goals, and therefore as an upstream approach to reducing the global malnutrition burden, including the rapidly growing burden of diet-related chronic diseases. To-date, nutrition-oriented value chain studies have focused on relatively short food chains within rural communities, and have been minimally applied to long, processed food chains crossing international borders.

Methods: A nutrition-oriented global value chain framework was applied to a case-study of Australia's canned deciduous fruit supply. The case study encompassed both domestically-supplied and imported canned and packaged deciduous fruit products retailed through Australia's two major supermarket chains. Data from semi-structured interviews conducted with fifty-five key informants in Australia and South Africa, including primary production, processing, retail and government sector representatives, were analysed using thematic coding together with secondary data from industry and government sources.

Results: The analyses identified increasing concentration and tighter vertical coordination of the canned deciduous fruit value chain, increased international competition, an increasingly dominant role of retailer private labels, shifting government priorities, and changing consumer demands for processed fruit products. These dynamics have converged to drive processor and retailer sourcing, product development, and marketing strategies. The nutrition implications are not straightforward. While there has been some healthier product formulation, there has been growing emphasis on the promotion of convenience products, snacking, and expanding eating occasions, with greater potential for over-consumption.

Conclusions: Processed foods are a major component of Australian diets. Value chain analyses can contribute important insights into the multiple, inter-related forces shaping processed food chains, food environments and diets.

Key words: Processed foods, chains, chronic diseases

PO1646**NUTRITIONAL STATUS OF CHILDREN 6-59 MONTHS BY SOCIO-ECONOMIC GROUPS IN THE PHILIPPINES: POLICY IMPLICATIONS**

G M. Gironella¹, I. Angeles-Agdeppa¹, M. Capanzana¹, L. Dasco¹

¹Department of Science and Technology, Food and Nutrition Research Institute, Taguig, Philippines

Background and objectives: The Food and Nutrition Research Institute conducts every 5 years National Nutrition Surveys to determine the nutritional status of different population groups and related factors like socio-economic index. This study aims to determine the association of socio-economic index and nutritional status of children.

Methods: The study used the data from the 2008 National Nutrition Survey. Nutritional status of children were determined using WHO-Child Growth Standards while the household's economic status was measured using wealth index. Multivariate statistical analysis was used to determine the wealth index of the household using easily measured variables such as household amenities, characteristics of housing unit and household head characteristics. Wealth index were then grouped into quintilesto associate to the nutritional status of children.

Results: Nutritional status of the children differs by wealth quintile. Prevalence of underweight and underheight decreases as the wealth quintile increases, while the prevalence of overweight increases as the wealth quintile increases. Prevalence of underweight among 6-59moschildren at the 1st and 5th quintile were 32% and 7.2% respectively while underheight were 51% and 12.7%, respectively. Overweight were 1.8% and 10.3% among the 1st and 5th quintile, respectively.

Conclusions: Children at the lower socio-economic status had higher prevalenceof underweight and underheightthan that of thehigher socio-economic status. Prevalence of overweight was higher among children in higher socio-economic groupsthan those in the lowerstratum. Program policies on improving nutritional status of the poor must be coupled with poverty alleviation programs for better sustainability. Intensive programs in improving lifestyle practices among the rich people must be installed.

Key words: wealth index, underweight, underheight, overweight.

PO1647**INVERSE ASSOCIATION BETWEEN SOY PRODUCTS CONSUMPTION AND INSULIN RESISTANCE IN JAPANESE ADULTS.**

M. Nakamoto¹, T. Sakai¹, H. Uemura¹, S. Katsuura¹, M. Yamaguchi¹, K. Arisawa¹

¹University of Tokushima

Background and objectives: To examine the association between soy food consumption and insulin resistance among Japanese population.

Methods: This cross-sectional study included 409 men and 145 women, with age of 35–69 y, living in Tokushima prefecture, in Japan, during 2005–2010. The authors obtained information about life style characteristics including soy food intake and self-reported medical history using a structural self-administered questionnaire, and fasting blood samples. The prevalence of insulin resistance at baseline was calculated. Insulin resistance was evaluated using the index which is the homeostasis model assessment of insulin resistance (HOMA-IR). In HOMA-IR, the person with insulin resistance was defined as person with HOMA-IR \geq 2.5. The level of insulin resistance was also compared among the groups with regard to differences in soy product intake. Multiple logistic regression models were used for analyzing the association between soy product intake and prevalence rate of insulin resistance.

Results: Total unsweetened soy product and total soy product intake showed significant inverse dose-response relationships with insulin resistance, after adjustments for potential confounders. Soy product intake had inverse association with insulin resistance in Japanese adults, significantly. Furthermore, this association was shown only among Japanese population with BMI $<$ 25kg/m².

Conclusions: The present findings suggest that total unsweetened soy product and total soy product intake was associated with reduced risk of insulin resistance. The results also support the idea that soy product, especially total unsweetened and non-fried soy product, reduced risk of type 2 diabetes through improving insulin resistance among subjects with BMI $<$ 25kg/m².

Key words: Insulin resistance, Soy product intake, Medical checkup, a cross-sectional study.

PO1648

MONITORING CORPORATE INFLUENCE: AN ASSESSMENT OF THE POLICIES AND ACTIONS OF PRIVATE SECTOR ORGANISATIONS WITH RESPECT TO FOOD ENVIRONMENTS

G. Sacks¹, B. Swinburn^{1,2}

¹WHO Collaborating Centre for Obesity Prevention, Deakin University, Melbourne, Victoria, Australia

²School of Population Health, University of Auckland, Auckland, New Zealand

Background and objectives: Private sector organisations play a critical role in shaping food environments; however, their actions are not currently systematically monitored. This paper proposes a monitoring framework and reports results of an assessment of the extent to which the policies and actions of private sector organisations are affecting food environments and influencing obesity prevention efforts. The framework has been developed by the International Network for Food and Obesity/NCD Research, Monitoring and Action Support (INFORMAS) that is setting benchmarks for creating healthy food environments.

Methods: The corporate accountability literature and previous studies that have monitored food companies were reviewed, and a step-based approach to monitoring private sector policies and actions proposed. Using the proposed approach, pilot study data was collected and analysed for a selection of large food companies in Australia and New Zealand.

Results: 'Minimal' monitoring activities assess the extent to which the publically-available, nutrition-related policies of selected private sector organisations in each country compare to current good practice. 'Expanded' monitoring activities assess nutrition-related actions (including nutrient composition of products, and marketing and labelling activities) of private sector organisations. 'Optimal' monitoring activities assess other commercial activities that influence food policy and action, such as political lobbying and sponsorships. Results from the 'minimal' step for Australia and New Zealand show that many of the largest food companies either do not have nutrition policies or they are not publically-disclosed. Where they exist, company policies are typically weak and are unlikely to improve public health.

Conclusions: It is imperative that private sector organisations are held to account for their role in influencing food environments and contributing to obesity prevention. A structured, standardised approach to monitoring will enable international benchmarking and comparisons of private sector policies and actions.

Key words: obesity, food environment, monitoring, private sector.

PO1649

SODIUM LEVELS IN PRIVATE LABEL FOODS COMPARED TO NATIONAL BRANDED PRODUCTS IN AUSTRALIA

H. Trevena¹, E. Dunford¹, J. Sundstrom¹, J. Webster¹, B. Neal¹

¹The George Institute For Global Health, Sydney, NSW, Australia

Background and objectives: Reducing sodium levels in processed foods is proposed to reduce the risk of cardiovascular disease. An increasing proportion of Australian processed foods are private label products manufactured for grocery retailers. We compared average sodium levels of private label and national branded foods.

Methods: Sodium data for packaged foods in five Australian supermarkets were collected from product labels in 2008 and 2011. The change in mean sodium content between years was calculated for private label and national branded products and compared. Analyses were done overall and for 10 food categories.

Results: Data were available for 7016 products in 2008 and 7641 in 2011. 23% and 27% were private label products in each year, respectively. The overall mean sodium content for private label products was not significantly different between 2008 and 2011 (405mg/100g vs. 381mg/100g; $p=0.15$) but rose for national brands (492mg/100g vs. 567.17mg/100g; $p<0.001$) ($p=0.001$ for difference between private label and branded products). In 2011 the mean sodium content of private label products was 186mg/100g ($p<0.001$) lower. That year, private label products had significantly lower sodium levels for 4 of the 10 categories studied (bread and bakery, cereals, fish products, sauces and spreads; all $p<0.010$) and national branded products for two (meat products, edible oils and emulsions; both $p<0.02$). There were no significant differences for convenience foods, snackfoods, fruit and vegetables, or dairy.

Conclusions: Overall, private label are less salty than national branded products. How the grocery retailers have achieved lower salt levels in their products, or why it has been achieved for some food categories and not others is unclear. It is, however, unlikely to be chance and working with the retailers may provide an opportunity to improve the quality of the Australian food supply.

Key words: Private label, national brands, sodium.

PO1650

WEIGHT CONTROL ATTEMPTS IN UNDERWEIGHT KOREAN ADULTS: KOREA NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEY, 2007-2010

Y.G. Cho¹

¹Department of Family Medicine, Seoul-Paik Hospital, College of Medicine and Institute of Clinical Nutrition, Inje University, Republic of Korea

Background and objectives: Underweight refers to the weight range in which the health risk can increase, since the weight is lower than the healthy weight. Negative attitude towards obesity and socio-cultural preference for thinness could induce even underweight persons to attempt weight control. This study was conducted to investigate factors related to weight control attempts in underweight Korean adults.

Methods: This was a cross-sectional study on 690 underweight adults aged 25-69 years using data from the Korea National Health and Nutrition Examination Survey, 2007-2010. Body shape perception, weight control attempts during the past one year, various health behaviors, history of chronic diseases and socioeconomic status were surveyed.

Results: Underweight women had a higher rate of weight control attempts than underweight men (25.4% vs. 8.1%; $P < 0.001$). Among underweight men, subjects with the highest physical activity level (OR: 8.03), subjects with physician diagnosed history of chronic diseases (OR: 6.76) and subjects with other jobs (OR: 9.42 with reference to manual workers) had a higher likelihood of weight control attempts. Among underweight women, subjects who did not perceive themselves as thin (OR: 4.95), subjects with the highest household income level (OR: 2.16) and unmarried subjects (OR: 1.99) had a higher likelihood of weight control attempts.

Conclusions: This study shows that numbers of underweight Korean adults have ever tried to control weight, especially women. Seeing that there are gender differences in factors related to weight control attempts in underweight adults, gender should be considered in helping underweight adults to maintain a healthy weight.

Key words: underweight, body shape, weight control, Korea National Health and Nutrition Examination Survey, socioeconomic status.

PO1651

THREE YEAR-OLD HEAD START PRESCHOOLERS LEARNED AND SHARED POSITIVE BEHAVIORS WITH THEIR CAREGIVERS AT SCHOOL AND AT HOME

V. Zoumenou¹, L. DaSilva², T. Gong³

¹Department of Human Ecology, Cooperative Extension, University of Maryland Eastern Shore, USA

²Department of Natural Sciences, Cooperative Extension, University of Maryland Eastern Shore, Princess Anne, Maryland, US

³Department of Agriculture, University of Maryland Eastern Shore, Princess Anne, Maryland, US

Background and objectives: In contribution to childhood obesity prevention strategies, this project focused on preschoolers and their caregivers. The objectives are to: Implement teaching strategies easy to be remembered by the preschoolers; assess the influence of storytelling and songs on the consumption overtime of fruits and vegetables among the preschoolers in school and home environment.

Methods: A 2-year longitudinal study at Head Start, Princess Anne, Maryland, involved: 102 three-year old preschoolers, 6 classrooms, 17 children per classroom, 6 teachers, 1 cafeteria staff, 50 parents, food demonstrations, and gardening activities. Cooperative Extension educators taught, each semester, the Eagle Books Series stories (4books) published by the Center for Disease Control. Three menu cycles were offered per year. Three, five, and four F&V items were introduced in the lunch menu respectively in cycle 1, 2, and 3; each item was repeated twice. The plate method helped to measure the F&V consumption. Qualitative data, pre and post survey, descriptive statistics, one way ANOVA (SPSS.20), and content analysis were used for data collection and analysis.

Results: Approximately 90% of preschoolers improved their knowledge in nutrition and gardening. F&V consumption percentage is calculated as the average consumption of each food over its initial weight. The top five are: Strawberries 72%, Clementine 67%, Spinach 62%, Cucumber 62%, and Broccoli 58%. One-way ANOVA and POSTHOC analysis at ALPHA (0.05) indicated an average consumption increased for Spinach, clementine, and broccoli by respectively 20, 30, and 28%. At least there was one significant difference between two classrooms per F&V item. Qualitative analysis indicated two main patterns: "Sharing messages"; and "Initiating positive behavior changes."

Conclusions: The preschoolers' preferences, consumption, and ability to identify F&V increased through storytelling and songs. An impact on their caregivers' F&V consumption was observed. A larger sample size is needed to confirm the results.

Key Words: Preschoolers, caregivers, nutrition, behavior.

PO1652**NUTRITION EDUCATION PROGRAM TO PROMOTE HEALTHY DIETARY HABITS AMONG ELEMENTARY STUDENTS.**

E. Sakai¹, A. Morioka¹, M. Nagasima², K. Sueda¹

¹Department of Health and Nutrition, Aichi-Gakuin University, Japan

²Department of Food and Nutritional Sciences, Chubu University, Japan

Background and Objectives: In order to investigate nutrition education programs to promote healthy dietary habits among early elementary school students, we aimed to determine sequence effects on learning, i.e., the influence of switching the order of lecture- and activity-based sessions within a program on students' comprehension and practice of the learning content.

Methods: The study was conducted with 61 second-grade elementary school students (32 boys and 29 girls) at schools Y and T (33 and 28 students, respectively). The students at school Y were first given lecture- and then activity-based sessions with the program theme 'Eat vegetables at breakfast,' while those at school T were given in the reverse order. These students filled out questionnaires before and after the program regarding their eating practice and feedback about the program, and the responses were analyzed for sequence effects.

Results: 1. In school Y, in which the students were first given a lecture-based session, the number of students who reported 'having more than three vegetables they disliked' increased after the program ($p < 0.05$). 2. In school T, in which the students were first given an activity-based session, the number of students who reported 'having eaten foods from the 'Red Food Group,' including protein-rich foods such as meat, fish, and eggs' increased after the program ($p < 0.05$). 3. In school T, the students reported a significantly greater 'number of vegetables ever eaten at home' after the program ($p < 0.05$), suggesting that greater familiarity with the names of vegetables through the food experience may lead to an increase in the number of vegetables reported.

Conclusions: These results suggest that elementary school students' interest and motivation can be greatly enhanced when they are given an activity-based session first, as well as their participation in the subsequent lecture-based session.

Key words: Nutrition Education Programs, Sequence, Elementary School Students.

PO1653**INFANT AND YOUNG CHILD NUTRITION IN BANGLADESH: COUNTRY SITUATION ANALYSIS**

F. Shabnam¹

¹EEP/Shiree, Dhaka, Bangladesh

Background and objectives: Bangladesh has nearly succeeded in achieving the Millennium Development Goal particularly in reducing child mortality but improvement in overall child nutritional status has been slow over the years, it is increasingly facing challenges of population growth, climate change impacts, vulnerability of price shocks and persistent poverty, food insecurity and malnutrition. The objective is to discuss the background of practices, achievements and way forward of Infant Young Child Nutrition in the community of Bangladesh.

Methods: This study is obtained through reviewing the available primary source documents.

Results: Bangladesh Demographic & Health Survey 2011 data represents that, 41 % of children under five are stunted and 36% were underweight. Age-specific data on stunting, underweight and wasting show a significant increase in the first 2 years of age, with little change thereafter. Anemia peaks at 6-11 months of age, demonstrating the importance of first 2 years age window for interventions. The prevalence of under nutrition amongst extreme poor household is higher; about 23% of children and close to 50% is wasted and stunted. There has been an apparent increase in exclusive breastfeeding, from 43 % in 2007 to 64 % in 2011. However the problems of complementary feeding remain. Around 40% of children are receiving an adequately diverse diet and consuming iron-rich foods in their complementary foods. Overall, 21 % of children age 6-23 months is fed appropriately according to recommended 3 IYCF Practices. In a proactive response to the situation, the Government of Bangladesh made nutrition as a priority for The Health, Population and Nutrition Sector Development Programme.

Conclusions: There is still significant room for acceleration in programming to improve infant and young child nutrition. This includes both increasing and sustaining good breastfeeding practices as well as interventions to improve complementary feeding.

Key words: Stunting, Wasting, underweight, IYCF.

PO1654**HEALTH SECTOR STRATEGY FOR ADDRESSING MATERNAL UNDERNUTRITION IN NEPAL: FROM CAUSAL ANALYSIS TO STRATEGIC APPROACHES**

M. Devkota¹, R. Pokharel², S. Uprety³, S. Karn⁴, P. Dahal⁵, S. Aryal⁶, K. Dearden⁷

⁵Unicef Nepal Office, Lalitpur, Nepal

⁶Family Health Division, DoHS, Ministry of Health and Population, Nepal

⁷SUSAHARA/Helen Keller International in Nepal

Background and objectives: Eliminating maternal under-nutrition still remains a challenge in Nepal, as many women continue to suffer from chronic energy and micronutrient deficiencies. The efforts till date to address it have been fragmented and focus mainly on micro-nutrient supplementation. The strategies, approaches and programme options for improving the nutritional status of women have not clearly been defined. This paper describes the process through which a comprehensive health sector strategy for addressing maternal undernutrition was developed for the country.

Methods: The Ministry of Health and Population, formulated a core group, comprising of researchers, program managers and experts, under the Nutrition Technical Committee, to review and compile the global and national evidence, lessons learnt and gaps in existing interventions. Detailed contextual causal analysis lead to the identification of strategic approaches, which were unique and relevant to the local context. Stakeholders' ownership was garnered through series of meetings and two national workshops.

Results: A causal analysis explored four dimensions, dietary factors, care and practices, health and environment, and socio-cultural norms. It identified adolescent girls, pregnant and breastfeeding women as priority groups. Factors beyond the purview of health sector were listed under cross cutting issues to be addressed through involvement of other sectors in-line with the Multi-sectoral Nutrition Plan of the Government. Based on the above exercise, five major strategic approaches were identified namely, building institutional as well as human resource capacity, integrating maternal nutrition in the existing key health programmes and beyond, including community based approaches, improving communication and strengthening nutrition monitoring and surveillance. The strategy is currently in the process of being endorsed by the government.

Conclusions: This strategy will improve nutritional status and health of adolescent girls, pregnant and breastfeeding wo-

men, through accelerating and sustaining reductions in chronic under-nutrition and micronutrient deficiencies.

Key words: Maternal Undernutrition, Causal Analysis, Strategy, Nepal.

PO1655**PREVALENCE AND DETERMINANTS OF METABOLIC SYNDROME AMONG POST MENOPAUSAL WOMEN IN RURAL AREA OF NORTHERN BANGLADESH**

F. Ara¹, F.S. Saleh¹, K.J. Jahan², L.A. Ali³

¹Dept of Community Nutrition, Bangladesh Institute of Health Sciences (BIHS), Bangladesh

²Institute of Nutrition and Food Science, University of Dhaka, Bangladesh

³Dept of Biochemistry & Cell Biology, Bangladesh Institute of Health Sciences (BIHS), Bangladesh

Background and objectives: Postmenopausal period creates special risk for diabetes and cardiovascular diseases due to various physiological, socioeconomic and psychological factors. The present study was aimed to explore the prevalence and determinants of metabolic syndrome (MS) among postmenopausal women in rural area of northern Bangladesh.

Methods: A total of 316 postmenopausal women, amenorrhea for >2 years and non user of HRT were selected from 27 villages of two randomly selected unions of Pirganj sub district.

Results: The overall prevalence of MS was found 7.6%, 41.5% and 26.9% according to WHO, ATP III and IDF. Prevalence of hypertension were 35.1%, 42.7%, 42.7%; diabetes were, 100%, 49.6%, 40.0%; hypertriglyceridemia were 66.7%, 71.0%, 61.2% and low HDL-C were 54.2%, 91.6%, 89.4% using the criteria of WHO, ATP III and IDF. Subjects with MS consumed huge rice (93.5% for 2-3 times/day), low protein (animal source >90%, never/week) and (plant source 50%, 1-2 times/week), low green leafy vegetables and fruits (>40%, 3-6 times/ week). According to WHO, women of 10-15 years since menopause were 4 times and >15 years were 5 times increased the risk of MS {OR (95% CI): 4.070 (1.02- 16.23), p= 0.04 and 5.626 (1.06- 29.85)}. In ATP III criteria, family history of hypertension {OR (95% CI): 0.299 (0.09- 0.91) p= 0.03} were involved in the development of MS though family history of CVD 3 times increased the risk of MS [OR (95% CI): 3.8 (1.3-11.2) p=0.01].

Conclusions: The data indicate an alarmingly high prevalence of metabolic syndrome in rural area of northern Bangladeshi postmenopausal women using the modified ATP III and IDF definition. More than 10 years since menopause onset, family history of CVD and hypertension seem to be the determinants for development of metabolic syndrome among this population.

Key words: Metabolic Syndrome, Postmenopausal women.

PO1656**SEPARATING SATIETY AND SATIATION IN APETITE CONTROL: EFFECT OF EXERCISE IN OVERWEIGHT AND OBESE ADULTS**

P. Caudwell¹, C. Gibbons¹, M. Hopkins¹, E. Näslund², G. Finlayson¹, J. Blundell¹

¹Institute of Psychological Sciences, University of Leeds, Leeds UK

²Department of Medical Sciences, Gastroenterology and Hepatology, Uppsala University, Sweden

Background and Objectives: Exercise influences mechanisms of appetite control. This study examined the impact of 12 weeks supervised exercise on 2 aspects; meal size (satiety) and the postprandial effects of food (satiety) under high and low energy density conditions.

Methods: Overweight and obese participants matched for BMI, age and sex completed 12 weeks of supervised exercise (EX n=15) or 12 weeks of no exercise (NEX n=15). The exercise program was designed to expend 2500kcal/wk at 70% HRmax. Appetite control was examined using separate validated procedures to assess satiety and satiation. Satiety was assessed using a test meal paradigm with energy density (ED) manipulated using high or low fat meals. Satiety was measured using appetite ratings adjusted for energy intake to calculate the satiety quotient (SQ). Measures were also made of appetite-related peptides (e.g. fasting PYY, GLP-1) and body composition (FM, FFM).

Results: The 12 week program led to significant reductions in body and fat mass (EX, -1.7±2.8 and -2.2±2.7kg) compared with (NEX 0.49±2.4 and 0.06±3.1kg) (p<0.0001). There was a significant effect of ED on meal size and total daily energy intake in both groups (p<0.0001), but no difference between EX and NEX. Therefore, exercise did not influence satiation. However, there was a significant increase in SQ with EX but not NEX (p=0.041). Exercise induced body fat loss was associated with increases in PYY (25.6±12.3 ng/L) (p=0.025) and GLP-1 (11.1±5.0 ng/L) (p=0.05).

Conclusions: Satiety and satiation are independent components of appetite control. Exercise (but not NEX) increased the SQ indicating upregulation of post-meal satiety signalling. Satiety was strongly determined by the energy density of meals but was not affected by exercise.

Key words: Satiety, Satiation, Appetite control, Exercise, Peptides.

Funding: Biotechnology and Biological Sciences Research Council (BB/G005524/1) and European Union 7th Framework Programme (FP7/2007-2012; 266408).

PO1657**DIET QUALITY, WATER AND TOILETS: WHAT ROLES FOR CHILD UNDERNUTRITION IN INDIA?**

P. Menon¹, S.Cyriac¹, S J. Coates², V M. Aguayo²

¹International Food Policy Research Institute, New Delhi, India

²UNICEF, New Delhi, India

Background and objectives: Infant and young child feeding (IYCF) practices are critical to child nutrition. Emerging evidence is suggesting important roles for water, sanitation and hygiene (WASH) too. Less is known, however on the intersection of these two inputs. We studied the joint effects of IYCF and WASH on child nutrition in India using national data.

Methods: We used data from ~18, 463 children 0-23.9 month old from the 3rd round of India's National Family Health Survey. Outcomes: child height-for-age, weight-for-age, weight-for-height z-scores (HAZ, WAZ and WHZ), stunting, underweight and wasting. Main predictor variables: IYCF indicators (breastfeeding and complementary feeding) and WASH indicators (water source, toilet type, disposal of child stools). Linear and logistic regression analyses were used, accounting for clustering. We tested for interactions between IYCF and WASH variables, adjusting for child, maternal and household characteristics and state and urban/rural residence.

Results: Toilet type (TT), child stool disposal (CSD) and diet diversity (DD) were independently associated with nutritional outcomes; drinking water or breastfeeding were not. The effects of DD and TT indicators are not independent, though; better DD and access to improved toilets together led to better nutritional outcomes. Also, improved DD was protective for HAZ and WAZ where TT was unimproved. However, for some combinations of IYCF-WASH, there is a larger main effect of improved sanitation; for others, IYCF is more strongly associated with nutritional outcomes than the sanitation indicators.

Conclusions: In summary, a positive synergistic effect of better complementary feeding and better toilets is seen for all anthropometric indicators, but not for improved drinking water or better ways of disposing child stools. Additionally, IYCF is protective against poor sanitary conditions for most outcomes. Interventions that address IYCF and sanitation constraints to child growth simultaneously can have greater impact than either alone.

Key words: India, child growth, IYCF, sanitation.

PO1658

ENABLING POLICY ENVIRONMENTS FOR INFANT AND YOUNG CHILD FEEDING AND NUTRITION: THE ROLES OF ACTORS, NETWORKS, NARRATIVES AND DATA

P.Menon¹, N.L. Aberman¹, J. Harris¹, P.H.Nguyen¹

¹International Food Policy Research Institute, Washington, DC, USA

Background and objectives: Policy support and advocacy can help to shape the environment for infant and young child feeding in developing countries. Alive & Thrive aims to improve IYCF through community-based behavior change communications, supported by policy advocacy in Bangladesh, Ethiopia, and Vietnam. Using a framework to assess factors contributed to issue ascendance on policy agendas, we assessed the policy environment in 2010 to be able to capture shifts in the policy environment at a later point.

Methods: We gathered data on four enabling factors for issue ascendance on policy agendas: actors, ideas and narratives, policies, and issue characteristics. A participatory stakeholder network-mapping methodology generated data on actor networks and actor power. Stakeholder interviews and document reviews generated data for the other framework domains.

Results: Characteristics of policies and policy environments for IYCF varied across the 3 countries. Actor networks were more complex in Bangladesh, where IYCF has been on the agenda for years, less cohesive in Ethiopia, where attention has been on acute malnutrition and famines, and characterized by clear differences between national and international actors in Vietnam. Data highlighted the poor understanding of IYCF and nutrition among opinion leader, and the role of issues like marketing of breast milk substitutes. The poorer status of all IYCF indicators in Bangladesh and Ethiopia suggested that both breastfeeding and complementary feeding would be amenable to insert into the policy discourse. In Vietnam, indicators were not as poor, except for exclusive breastfeeding.

Conclusions: The framework used demonstrated strong utility for a policy environment assessment and highlighted critical areas in the policy environments to move the IYCF and nutrition agenda forward. The stakeholder network-mapping tool, specifically, illuminated the critical role of individuals, agendas, and network characteristics in enabling movement of the IYCF agenda.

Key words: IYCF policy, enabling environment, Alive & Thrive, Bangladesh, Vietnam, Ethiopia.

PO1659

MENU LABELING IN “OUT-OF-HOME” SECTOR: OPPORTUNITIES, BARRIERS, AND NEEDS WITH RESPECT TO USE OF HEALTH COMMUNICATION IN RESTAURANTS

A.J.C. Roodenburg¹, I.A.J. Payens¹, C. Vrijhof¹

¹Department of food technology, HAS university of applied science, Den Bosch, the Netherlands

Background and objectives: about 30% of the energy intake in the Netherlands is consumed in the “out-of-home” sector. Although commonly used in supermarkets and part of the “out-of-home sector”, health logos are not used in traditional restaurants. This study investigates the possibilities of menu labeling (ML) in restaurants as a tool to facilitate a healthy choice.

Methods: 4 restaurants and 90 potential guests participated in 2 qualitative studies. 1) Rogers “Diffusions of Innovations Theory” of (restaurant tenants, chefs and serving personnel) and 2) Rogers “Theory of Planned Behavior”(potential guests) were used for a systematic questionnaire.

Results: the restaurant tenants considered “competitiveness” an opportunity of ML. For chefs “creativity” was an opportunity, and for serving personnel, it was “the easy supply of health information” to guests. Barriers for using ML were “complexity”, and the fact that restaurants are often visited for indulgence reasons. The most important needs with respect to ML were: “central coordination” (tenants), “help in recipe calculation” (chefs) and allergen /sustainability information (serving personnel). Restaurant stakeholders indicated a preference for symbols, rather than calorie content. Potential guests indicated that ML would help them to make healthier choices. Their interest, however, depended on the reason for eating out: in a business setting guests were more interested in ML than in a social setting.

Conclusions: The study showed opportunities for menu labeling as a way to facilitate a healthy choice for consumers. “Competitiveness” and “creativity” are possible opportunities for restaurant stakeholders, “complexity” and “indulgence as reason to eat out” potential barriers.

Key words: menu labeling, health communication, out-of-home, restaurants.

PO1660

COMPLEMENTARY AND ALTERNATIVE MEDICINE USE AMONG PEOPLE LIVING WITH HIV AND AIDS (PLWHA) IN LEBANON

J. Abou-Rizk¹, M. Alameddine², L. Nasreddine¹, F. Naja¹

¹Department of Nutrition and Food Sciences, American University of Beirut, Beirut, Lebanon

²Department of Health Management and Policy, American University of Beirut, Beirut, Lebanon

Background and objectives: Although the antiretrovirals have improved the quality of life of HIV/AIDS patients and reduced morbidity and mortality, these drugs are not always accessible and pose significant side effects. Therefore, PLWHA are increasingly seeking alternative and complementary medicine (CAM). Only few reports on CAM use among HIV-infected patients are available in the Middle East and North Africa Region. The objective is to assess the prevalence and determinants of CAM use among PLWHA in Lebanon.

Methods: A cross-sectional survey design was used to carry out face-to-face interviews with 116 HIV infected patients attending various NGO in Lebanon. The questionnaire comprised three sections: the socio-demographic, disease characteristics, and information on CAM use, its types and modes. Data analysis employed descriptive statistics, t-test, and chi-square.

Results: Overall, 46.6% of the participants reported using one or more CAM therapies since diagnosis with HIV/AIDS. CAM users had a higher education level as compared to non-users (68.5% vs 32.3% had a high school/university degree, $P < 0.01$). The most commonly used CAM therapies included vitamins and minerals (61.1%) and herbs/natural products (63.0%). Most of survey participants used CAM as a complementary basis (79.6%). A major proportion of the participants did not report using CAM to a health care professional (44.4%). The main reason for not reporting was that participants did not need the doctor's approval to purchase the CAM (70.6%).

Conclusions: A significant number of HIV patients are using CAM in Lebanon. In addition, an alarming proportion of these patients did not report using CAM to a health care professional. Therefore, efforts should be made to increase awareness of health care professionals on risks of CAM therapies in order to provide proper advices and recommendations to PLWHA.

Key words: HIV, AIDS, complementary and alternative medicine (CAM), Lebanon.

PO1661

NATIONAL SURVEY OF INSTITUTIONALIZES SOCIALLY DEPRIVED CHILDREN AGED 0-3 YERS IN BULGARIA

L. Ivanova¹, K. Angelova², D. Ovcharova², M. Vukov³, K. Kostadinova²

¹Sofia University 'KI.Ohridski' Faculty of Medicine, Sofia, Bulgaria

²National Centârof Public Health and Analyses, Sofia, Bulgaria

³National Cancer Register, Sofia, Bulgaria

Background and objectives: Institutionalization has proven negative impact on all aspects of children's development -intellectual, physical, behavioral and social emotional. Reducing the number of children in orphanage is a priority of the Bulgarian government. At the time of this study there were 32 social institutions with a total number of 3550 infants and young children aged 0-36 months. The aim was to identify key nutritional and developmental problems of children aged 0-3 years reared on institutions to support public policies of deinstitutionalization.

Methods: A national survey on a representative sample of 449 children aged 0-36 months distributed across the four age groups 0-6, 6-12, 12-24 and 24-36 months in eight orphanages in Bulgaria was conducted. The sample size was determined based on the expected prevalence of anemia in infants with a relative precision of 5% and confidence level of 95%. The study involved assessment of nutrition and complimentary feeding, anthropometric and psychological measurements, hemoglobin and iodineuria.

Results: The mean Z-scores of H/A, W/A and W/H for all children were -1.31, -0.45 and -1.29 being lower among boys. The prevalence of H/A below 2 Z-scores was 26.1% among boys and 32.4% among girls. The highest level of stunting was found among children 24-36 months both sexes. Significant difference ($p < 0.05$) was observed between mean H/A and W/A z-scores and Development Quotient of the low (<2500 g) and normal birthweight group (>2500 g) persisting until the end of third year. The prevalence of anemia was 32.3% being 52.3% among children 0-6 months. Iodineuria among 3-year old group was 111.5 µg/L.

Conclusions: Although in Bulgaria institutions for children up to three years are under the health authorities there were identified serious nutritional and development problems due to deprivation and inappropriate care and feeding practices.

Key words: infants and young children, institutions, malnutrition, Bulgaria.

PO1662**DRUG – NUTRIENT INTERACTIONS: EFFECT OF FOLIC ACID FORTIFIED DIETS ON THE EFFICACY AND TOXICITY OF METHOTREXATE**

E. Alonso-Aperte¹, R.M. Ausín Sáiz¹, M. Achón y Tuñón¹, E. Carrera Puerta¹, M.P. González¹, G. Varela-Moreiras¹

¹Department of Pharmaceutical and Food Sciences, Facultad de Farmacia, Universidad CEU San Pablo, Spain

Background and objectives: Mandatory Folic Acid (FA) food fortification can be associated to multiple potential unknown effects. Within them, raising folate status in patients may modify the response to therapy by antifolate drugs used in the treatment of chronic disease. Such is the case for Methotrexate (MTX), a “gold standard” in the treatment of Rheumatoid Arthritis. Hypothesis: Long term exposure to FA fortified diets modifies the efficacy and toxicity associated to low dose MTX treatment. The alterations are mediated by the effect of extra FA on folate metabolism, particularly on dihydrofolate reductase activity (DHFR), and the effect on xenobiotic metabolising enzymes.

Methods: Female Sprague Dawley rats (n=40) were fed either a standard diet (2 mg FA/kg diet) or a supplemented diet (60 mg FA/kg diet). After 4 weeks, animals were injected MTX (0, 2 mg/kg, i.p. every two days) for 8 weeks. Saline was used for controls.

Results: Animals fed a standard diet and treated with MTX exhibited significant weight reduction, reduced intake, inactivity, hair loss and low response to stimuli, as compared to controls. MTX treatment also provoked a significant reduction in haemoglobin and erythrocyte concentrations (86% and 82%) and a 78% reduction in haematocrit ($p < 0.001$ Anova and Tukey tests). Animals treated with MTX but fed a FA supplemented diet did not show apparent adverse effects and reductions in haematological parameters were significantly lower (35%, 25% and 21% reduction in haemoglobin and erythrocyte concentrations, and haematocrit, as compared to controls and other MTX treated animals ($p < 0.005$ Anova and Tukey tests)). Preliminary data show no influence of FA supplemented diets or MTX treatment on CYP 450 hepatic concentrations.

Conclusions: Long term exposure to FA supplemented diets reduces anaemia and adverse effects induced by MTX treatment. Acknowledgements: this project is financed by Universidad CEU San Pablo.

Key words: Folic acid, methotrexate, fortification, drug-nutrient interactions.

PO1663**DEVELOPMENT OF NUTRITION EDUCATION PACKAGE ON CHILD CARE AND FEEDING PRACTICES FOR RURAL WOMEN IN ENUGU STATE, NIGERIA: A POSITIVE DEVIANT APPROACH.**

O. Mbah¹, N. Ene-Obong, P. Eme

¹University of Nigeria, Nsukka, Nigeria

²University of Calabar, Nigeria

Background and objectives: The burden of nutrition related disease is greatest among the vulnerable and disadvantaged groups including rural women. The study describes the development of 12-lesson based nutrition education package for rural women in Enugu State.

Methods: The study involved 91 mothers in a community of Eha-Amufu, Enugu State. Mothers were classified as Positive Deviants (PDs) and Non Positive Deviants (NPDs) based on the nutritional status of their infants. Structured questionnaire was used to collect information. Summary findings from the Positive Deviant Inquiry (PDI) were used to develop the package. Data was analysed using descriptive statistics.

Results: More than half of the respondents (78.7%) and 21.3% were classified as NPDs and PDs respectively. The PDs had better feeding, caring and health-seeking practices than the NPDs. The nutrition education package developed had the following lessons: Growth monitoring, Malnutrition, Food Selection Techniques, Body building foods, Energy-giving foods, Protective foods, Infant nutrition, Management of childhood diarrhea, Immunization, Hygiene and Sanitation, Family Planning and Feeding during illness.

Conclusions: This developed package can be used in communities during intervention programmes on child-care and feeding practices.

Key words: nutrition education package, child care, feeding, rural women, Enugu.

PO1664**NUTRITIONAL RISKS RELATED TO DIETARY WEIGHT-LOSS PRACTICES**

S. Wetzler¹, P. Nadaud¹, L. du Chaffaut-Koulian¹, I. Margaritis¹, E. Kalonji¹

¹Unité d'évaluation de la nutrition et des risques nutritionnels - The French Agency for Food, Environmental and Occupational Health & Safety (ANSES) – Maisons-Alfort, France

Background and objectives: Today, the cult of the body is a social reality which pressurises the individual into accepting

aesthetic canons and social norms regarding the body. Moreover, overweight and obesity, which affect respectively 32% and 15% of people over 18 years of age in France, are a major public health problem. Our study enables an assessment of the risks related to dietary weight-loss practices.

Methods: First of all, we estimated the intakes (energy, macro and micronutrients) of the 15 weight-loss diets (WLDs) which are popular in France. Secondly, we conducted a review of the literature to identify the biological effects of possible nutritional imbalances, and the pathophysiological and psycho-behavioural consequences of WLDs.

Results: This original work highlights the inadequate nutritional intakes (INI) of certain phases of WLDs when compared with recommended intakes, in particular concerning protein, dietary fibre, calcium and sodium. This INI can lead to different types of risks: High protein diets and sodium overload, in extreme situations, can cause metabolic acidosis result in urinary calcium leak; Very low-calorie diets may induce cardiac arrhythmia with a consequent risk of sudden death; Low-carbohydrate diets are often associated with transient gastrointestinal disorders, particularly constipation. Moreover, some risks are independent of the type of WLD followed: Weight-loss practices have a detrimental effect on bone integrity; weight regain affects 80% of subjects after one year and increases over time; depression and loss of self-esteem are common psychological consequences of repeated failures in dieting.

Conclusions: Following a WLD is not a trivial act. Adverse short-, medium- or long-term consequences of following these diets should not be neglected, especially since they are unbalanced, associated with severe behavioural eating disorders, and may eventually lead to possibly irreversible weight gain.

Key words: Diets, weight-loss, risk assessment.

PO1665

CARDIORESPIRATORY FITNESS CHANGES AFTER A WEIGHT LOSS PROGRAM: EFFECTS ON HEMOGLOBIN AND HEMATOCRIT VALUES. RESULTS FROM THE PRONAF STUDY

P.J. Benito¹, A.B. Peinado¹, F.J. Calderón¹, M.A. Rojo-Tirado¹, V. García-Zamorano¹, M. González-Gross^{1,2}

¹Department of Health and Human Performance, Technical University of Madrid, Madrid, Spain

²CIBER: CB12/03/30038 Fisiopatología de la Obesidad y la Nutrición, CIBERobn, Instituto de Salud Carlos III (ISCIII), Spain

Background and objectives: Maximal oxygen uptake (VO₂max) is an important indicator of cardiovascular health¹. Epidemiological studies have shown a strong relationship with cardiovascular diseases². The purpose of this study was to evaluate

if the change in cardiorespiratory fitness, hemoglobin and hematocrit values depends on the type of exercise developed during a six-month intervention program.

Methods: Two hundred obese and overweight subjects aged 18–50 years were randomly assigned to a strength training group (S), an endurance training group (E), a combined strength + endurance training group (SE) or a diet and physical activity recommendations group (C). The intervention period was 22 weeks (training groups trained 3 times/wk during 22 weeks) and 2 weeks for pre and post evaluation tests. All subjects followed a hypocaloric diet (25–30% energy restriction)³.

Results: VO₂max, hemoglobin and hematocrit values were not different between groups at baseline (p>0.05). At the end of the intervention, it was the SE group the one which showed greater % changes in the VO₂max in absolute values (13±15.8%), and relative to the final weight (24.7±17.4%) and the final FFM (13.7±15.6%), compared to the rest of groups (p<0.05). The values obtained by SE group are the highest (41.02±8.59 ml/kg/min) compared with S (35.90±8.43 ml/kg/min), E (36.33±7.26 ml/kg/min) and C (36.17±7.28 ml/kg/min) (p<0.05) in all cases. However, no changes in hemoglobin and hematocrit values were observed (p>0.05).

Conclusions: Our results suggest that the combined strength + endurance intervention is the most suitable to increase the oxygen consumption in a six-month exercise and caloric restriction program. However, the increment was not due to changes in hemoglobin or hematocrit values.

Key Words: Oxygen uptake, weight loss intervention, obesity, overweight.

PO1666

THE MEDIA AND PUBLIC'S REACTION TO SCIENTIFIC EVIDENCE: A BREASTFEEDING CASE STUDY

D. Marais¹, S. Watt¹

¹University of Aberdeen UK

Background and objectives: When new scientific evidence is published, it is important that the public is made aware of these findings and recommendations. This usually involves the media as a translator to put the scientific evidence into layman's language. The accuracy of this translation is vital as demonstrated during the MMR vaccine and swine flu scares. This study aimed to investigate the media's translation of a review of the evidence of the effects of exclusive breastfeeding for six months (Fewtrell et al., 2011) in the British Medical Journal and to explore the reaction of the lay public.

Methods: A search was conducted to identify and quantify online television and newspaper reports, magazine articles and blogs/forum postings that discussed the Fewtrell article in the UK, over a three month period after publication of the journal.

The identified media were analysed qualitatively by identifying common themes.

Results: Seven online newspaper articles, four television channel website reports, six online forums and one online magazine blog were identified and investigated to establish themes. Seven common themes were identified relating to the media's interpretation of the evidence and the lay public's reaction. These included sensationalism, misinterpretation and contravention of codes from the media. Demonisation of industry was a theme for both the media and the public, whereas the mistrust of science, wanting to disproving evidence using personal stories and concerns about the implication of their own practice when following recommendations, were themes highlighted in the public discussion forums.

Conclusions: This case study highlights the vital role that the media plays in correctly translating scientific literature into layman's terms. If this does not happen as in this case, it is the trust in science that is questioned by the public, not the reliability of the journalists.

Key words: Media, Breastfeeding, Lay public, Online, UK.

PO1667

FAMILY FARMING AND THE QUALITY MENU OF THE NATIONAL SCHOOL NUTRITION PROGRAM (PNAE) IN BRAZIL

J. Yumi Toyoyoshi¹, R. Oliveira¹, M. Sineide Neres dos Santos², F. Dias Bellão¹, D. Behar¹, A. Polo Galante¹

¹Course of nutrition, Centro Universitário São Camilo, São Paulo, Brazil

²ONG Action Fome Zero, São Paulo, Brazil

Background and Objectives: The nutrition transition, which Brazil passed, was influenced by several factors, increasing demand for fast foods. Industrialization led to the development of agriculture, breaking with traditional methods of cultivation. National policies, such as the National School Nutrition Program (PNAE), appear as possible to assist in addressing the issues related to food production and consumption. The objective is analyze the relationship between the acquisition of the family farming food genre and the quality of the menu provided by PNAE, according to the methodology Award Efficient Public Manager of School Meals 2012 of Action Fome Zero.

Methods: This was a descriptive study, performed by database manager of the Award Efficient Public Manager of School Meals 2012.

Results: The South stands out in number of actions aimed inducement the Family Farming, with 7.1% having the maximum number of actions. The Northeast had the lowest prevalence for all these actions, with only 1.1%. Despite the greater incentive of family farming, the southern was the region with

the highest prevalence of low grades (5.5%) and the South East was the region with top grades of the menu, but with a prevalence of 1.8% of actions family farming, indicating no direct relationship between acquisition of the family farming food genre with the quality of the menu offered to students.

Conclusions: There was no relationship between the amount of actions for the inducement of family farming with the quality of the menu offered to students, because even in regions such as the South, the quality of the menu was not better, compared to other regions of Brazil. This fact reveals the need for guidelines that point what foods should be purchased of Family Farming.

Key words: Food consumption. Food production. School feeding.

PO1668

LEVERAGING A NUTRIENT SUPPLEMENT TRIAL TO IMPROVE HANDWASHING BEHAVIOR

K. Jannat¹, L E. Unicomb¹, C P. Stewart², S. Ashraf¹, M. Rahman¹, P K. Ghosh¹, S P. Luby¹

¹International Center For Diarrheal Disease and Research, Bangladesh, India

²Program in International and Community Nutrition, University of California, Davis, CA, USA

Background and objectives: A conducive environment helps to establish new habits. Handwashing with soap is a difficult habit to develop in settings where soap and water is not conveniently available. We investigated the uptake of handwashing behavior as part of a lipid-based nutrient supplement (LNS) pilot trial.

Methods: Households (N=120) from a low income rural setting in Bangladesh, having at least one child aged 6-21 months, received LNS and handwashing promotion, which included handwashing stations, a device that provided soap and water together. Self reported LNS feeding practices and handwashing behavior were measured using surveys. We used spot checks to measure the proxy handwashing indicator- availability of soap and water at handwashing stations near kitchens. To examine the uptake of handwashing behavior, we calculated the relative difference (RD, 95%CI) from baseline to six months follow-up.

Results: Among caregivers, 78% reported feeding LNS using fingers, 5% mixed LNS with food, and 17% fed it directly from sachets. Caregiver's reported handwashing before feeding increased from 10% to 97% (RD=87%; CI:81, 93). Availability of soap and water at the handwashing stations near kitchens increased from 1% to 83% (RD=82%; CI:75, 90). Caregivers who fed LNS with fingers were more likely to have observed soap and water at handwashing stations near kitchens (88%) than caregivers who mixed LNS with food or fed directly from sachets (68%, RD=20%; CI:0, 41).

Conclusions: Using hands to feed infants is common in Bangladesh. An intervention promoting handwashing with soap during child feeding was effective in improving handwashing, as indicated by soap and water presence near kitchens. Feeding of LNS in the presence of a handwashing station can provide cues to support the development of a handwashing habit.

Key words: nutrient supplement, handwashing.

PO1669

ENGAGING THE MEDIA FOR EFFECTIVE NUTRITION EDUCATION

A. Botwe¹

¹Broadcast Journalism Department, National Film and Television Institute, Ghana

Background and objectives: Although the mass media is effective for nutrition education, little nutrition-related issues appear in the Ghanaian media. This study was undertaken to determine the extent to which the Daily Graphic, Ghana's official and most widely circulated newspaper, paid attention to nutrition issues within a two-year period: 2006 to 2007.

Methods: The composite week sampling technique was used to select 144 editions out of a universe of 625 from 2006 to 2007 for content analysis. Straight news stories, features (including columns), editorials and letters to the editor were analysed for the coverage of nutrition issues. Coding was done for variables such as prominence, source, category and framing of nutrition stories.

Results: The Daily Graphic gave some attention to nutrition issues although coverage was not extensive. Out of 10, 624 stories in the editions sampled only thirty-three (0.31%) were nutrition related. Also, even though the Daily Graphic gave appreciable prominence in terms of space, headline sizes and accompanied photographs to the stories it published, the nutrition stories were unfavourably placed, as no nutrition story appeared on the front page and centre spread of the editions sampled. Straight news stories dominated; with relatively few in-depth feature stories. The largest story source came from invited events/programmes where mostly public servants or experts spoke. None of the stories came from a pressure/advocacy group.

Conclusions: To make impact on nutrition, professionals and nutrition educators should play more advocacy roles in engaging the media for nutrition education, as even brief episodes of news coverage can influence the public's health-related behavior.

Key words: Media, nutrition coverage, Ghana.

PO1670

USING THE MEDIA IN NUTRITION EDUCATION IN GHANA-THE CHALLENGES AND OPPORTUNITIES

A. Botwe¹

¹News Department, Radio XYZ, Accra, Ghana

Background and objectives: The mass media is a vibrant medium for delivering nutrition education messages and has several advantages over other channels. However, little nutrition-related issues appear in the Ghanaian media. Given the growing prevalence of obesity and diet-related chronic diseases, concurrent with the continued high burden of malnutrition in Ghana, there is need for nutrition professionals to play a more active role in educating the general public on nutrition issues. I aim to share journalistic experiences on challenges and opportunities to effective nutrition communication through the mass media and highlight efforts to increase visibility of nutrition in the mass media in Ghana.

Methods: Literature review of the scientific and grey literature on topics related to nutrition education and the media in Ghana. This was supplemented with journalistic field notes and observations from interactions with nutrition professionals from 2005 to date.

Results: In 2009 only 0.31% of the news items in the largest state-owned newspaper were nutrition related. More recently it was found that only two of the 38 radio stations in the capital, Accra, carry nutrition programmes. Factors contributing to lack of media attention to nutrition include: nutrition professionals not being proactive in involving the media and shying away from media attention; journalists' preference to report on sensational stories and journalists often having difficulty understanding and translating nutrition information into meaningful news items.

Conclusions: Given growing public interest in diet/nutrition issues, there is need to address challenges faced by nutrition professionals and journalists in disseminating nutrition information through the mass media to enhance media coverage of nutrition issues.

Key words: Media, nutrition coverage, Ghana.

PO1672**SPORT AND PHYSICAL ACTIVITY MODIFICATION AND ITS RELATIONSHIP WITH RISK FACTORS IN A COHORT OF UNIVERSITY STUDENTS**

M G. Alvear-Galindo¹, L. Yamamoto-Kimura¹, C. Morán-Alvarez¹, A Rodríguez-Pérez², C Solís-Torres³

¹Universidad Nacional Autónoma de México, Mexico

²Servicios de salud Pública del D.F, Secretaría de Salud del Gobierno del Distrito Federal, Mexico

³Dirección General de Servicios Médicos, Universidad Nacional Autónoma de México, Mexico

Background and objectives: Increased physical inactivity in regards to age is associated with health problems in the population. Unfortunately, global data regarding cardiovascular risk factors in the young are limited. Therefore the objective of this study was to analyze the change in the practice of sport and physical activity and its relationship with risk factors in students who entered the first year of high school (2007) and admission to Medicine College (2010).

Methods: The Universidad Nacional Autónoma de México applies the comprehensive survey of health to all their students. We analyzed the sport and physical activity, body mass index, smoking and alcohol consumption in the cohort of students who entered school in 2007 and three years later, when entering Medicine College.

Results: A total of 593 students (180 men) participated with a mean age at onset of 15.1 years old. The prevalence of physical inactivity in 2007 was 38.3% and increased to 39.9% in 2010. The results show that men are more physically active than women ($p < 0.05$). The change in BMI mean in men was from 22.3 to 23.4 ($p < 0.01$) and in women from 22.1 to 22.8 ($p < 0.01$). Overweight prevalence in sedentary men increased, and obesity decreased, contrary to what occurred in sedentary women in which overweight decreased but obesity increased. In the sedentary population, smoking increased in 4.9% and 36.7% in alcohol consumption. There was a 23% decrease of medical students who ran and 21.7% in soccer.

Conclusions: The change in sport and physical activity in a cohort of young people shows important changes in a short follow-up time; therefore, it is necessary in addition to their follow up, to promote health programs in this population.

Key words: Physical inactivity, BMI, University students.

PO1673**CHANGES IN RISK PROFILE FOR CHRONIC DISEASES IN UNIVERSITY STUDENTS FROM THE UNIVERSIDAD NACIONAL AUTÓNOMA DE MÉXICO**

M G. Alvear-Galindo¹, L. Yamamoto-Kimura¹, C. Morán-Alvarez¹, A. Rodríguez-Pérez², C. Solís-Torres³

¹Universidad Nacional Autónoma de México, Mexico

²Servicios de salud Pública del D.F, Secretaría de Salud del Gobierno del Distrito Federal, Mexico

³Dirección General de Servicios Médicos, Universidad Nacional Autónoma de México, Mexico

Background and objectives: During the term, university students modify their eating and physical activity habits, with differences in risk conducts. The present study has as objective to contrast the behavior of some risk factors for chronic diseases in students from the Universidad Nacional Autónoma de México (UNAM), in high school and medical students.

Methods: To recognize the risk profile of students a survey on integral health values in high school (2007) and medical students (2010). Previous health problems were taken in consideration, as well as the intake of alcohol, smoking, overweight, obesity, and familial health problems.

Results: In total 593 students participated, 69.9% were women. Age range in high school was of 13 to 37 years. 97.3 % coursed high school in three years and the rest in four. 1.54 referred high blood pressure during high school, and 1.69 in medical students, 11.5% was considered as obese. The highest difference in BMI was in high school between 14 and 16 years of age. In three years, consumption of alcohol increased in 32% and smoking in 11.5%. During the periods, hypertension in relatives went from 24.1% to 30.4%, obesity from 27.6% to 31.3%, smoking from 24.5% to 24.9%, and type 2 diabetes mellitus from 12.8% to 16.2%, $p < 0.01$.

Conclusions: Changes in risk factors those regarding the student population and those regarding their relatives during the study term, point out towards a higher risk for chronic diseases; it is vital to reduce these, acting upon the young may reduce future health damages.

Key words: Risk profile, Chronic diseases, Students.

PO1674**COMMUNITY-BASED MANAGEMENT OF SEVERE-ACUTE MALNUTRITION IN CHILDREN IN NON-EMERGENCY CONTEXT: EVIDENCE FROM A RETROSPECTIVE STUDY IN GHANA**

R. Akparibo¹, J. Harris¹, L. Blank¹, S. Adu-Afarwuah²

¹School of Health and Related Research, University of Sheffield, UK

²Department of Food Science and Nutrition, University of Ghana, Ghana

Background and objectives: In 2007, the WHO recommended that community-based (CB) strategies were a more appropriate alternative to previous clinical programmes for treating children with severe-acute malnutrition. Evidence from the literature suggests that CB programmes have been implemented in many emergency situations and have proven effective. However in non emergency situations, very little evidence exists to inform integration and scale-up of programmes. This study analysed longitudinal data from Ghana to measure the outcome of CB programmes to treat severe-acute malnutrition in children under five years of age in a non-emergency, routine primary health services context.

Methods: Outcome data were obtained retrospectively through review of children's records. This include mortality, dropouts, recovery status and length of time spent in programme. The programmes were implemented in selected rural and urban settings in Ghana. In total, the records of 525 children who benefited from the programme between June 2010 and March 2011 were reviewed. Data from 488 children were included in the final analysis. The main primary outcome (recovery from severe-acute malnutrition) was compared with Sphere standards.

Results: The acceptable recovery rate (Sphere standards) for therapeutic programme effectiveness is 75% or more, with <10% mortality and <15% default rates. The current programme achieved 69.2% recovery (95% CI: 67.0; 75.1), 28% dropout (95% CI: 24.1; 32.1) and 0.8 % mortality (95% CI 0.02; 1.6). Length of stay (Mean \pm SD) was 4.8 \pm 1.7 weeks (95% CI 4.6; 5.2). Daily weight gain (Mean \pm SD) was 3.1 \pm 0.9 (95% CI 2.9; 3.3). We found that children's baseline weight and MUAC were strong predictors of weight gain.

Conclusions: The findings suggest that CB programmes can be replicated in non-emergency context with high recovery success, although dropouts are likely to be high which could affect overall programme impact.

Key words: Children, severe malnutrition, community-based programmes, treatment, non-emergency.

PO1675**HEALTH EFFECTS AFTER A TRAINING PROGRAM OF EXERCISE IN PREPUBERTAL BOYS**

F J. Llorente-Cantarero¹, G M. Quintana-Navarro², N. Saldaña-García¹, M. Medina-Martínez¹, J L. Pérez-Navero¹, M. Gil-Campos¹

¹Department of Pediatrics/ University Reina Sofia Hospital/ IMIBIC, Cordoba, Spain

²Lipids and Atherosclerosis Unit, Department of Medicine, IMIBIC/Hospital Universitario Reina Sofia/ Universidad de Cordoba, Cordoba, Spain

Background and objectives: The low physical activity (PA) may be a risk factor for cardiovascular disease even in children. The aim of this study was to assess the effect of a moderate intensity regulated PA on cardiorespiratory fitness (CRF) in a group of prepubertal children. Methods 18 healthy prepubertal boys 8-13y from a basketball club were selected. CRF was assessed by the Eurofit battery test, and PA by accelerometry. A training program during 10 months was developed: Anthropometric measurements by bioimpedance, blood pressure and biochemical parameters were measured at the beginning (pre-competition), and at the end of the program (optimal CRF for competition).

Results: Comparing basal and final measurements, children decreased body mass index ($p < 0.005$), percentage of body fat ($p < 0.001$), and blood pressure levels ($p < 0.02$ systolic, $p < 0.008$ diastolic) and increased percentage of fat-free mass ($p < 0.012$). Blood count, renal and liver function, and plasma lipid profile, were normal in all cases in both, basal and at the end of the program. Some children also improved serum iron levels or insulin. Regarding the sedentary habits, no significant differences were observed between baseline and the end of time, showing that 90% of children continued being sedentary. However, there was a significant improvement in oxygen consumption ($p < 0.001$) and in the test speed values ($p < 0.001$) and in the overall strength, improving their CRF.

Conclusions: The scheduled PA may improve CRF and health in prepubertal children. However, further studies are needed in children of different ages to establish the type of exercise, intensity and duration, which would improve fitness and cardiovascular and metabolic health, and also decrease sedentary habits.

Key words: Training program, exercise, fitness.

PO1676**ASSOCIATION BETWEEN STRESS AND DIETARY BEHAVIOUR AMONG FIRST YEAR UNIVERSITY STUDENTS IN AUSTRALIA***F. Ahmed¹, J. Wiseman¹, K. Papier¹, P. Lee¹*¹School of Public Health, Griffith University, Gold Coast, Australia

Background and objectives: Studies have shown that a significant proportion of university students in Australia suffer from stress. Although many studies have reported an association between psychological stress and dietary behaviour, findings remain inconclusive. To date, data on the relationship between stress and dietary behaviour of university students in Australia are scanty. This study was designed to examine the relationship between stress and total dietary intake and food selection patterns among first year undergraduate students in an Australian university.

Methods: A total of 391 (173 males and 215 females) first year students attending Gold Coast Campus of Griffith University participated in this cross sectional study. Data were collected using a self-administered survey consisting of three sections: socio demographic questions, stress measures and a food frequency questionnaire.

Results: About 45% of the participants were found to suffer from some level of stress, with relatively more (54%) females than males (32.4%). In males, level of stress was found to be significantly ($p < 0.05$) positively associated with frequency of consumption of cereal ($r = 0.17$), brown bread ($r = 0.19$), chicken ($r = 0.18$), canned fish ($r = 0.15$), protein powder ($r = 0.22$), tea and coffee ($r = 0.16$), wine ($r = 0.19$), spirits ($r = 0.20$) and mixed alcoholic drink ($r = 0.30$). In females, level of stress was significantly ($p < 0.05$) positively associated with the frequency of consumption of nuggets ($r = 0.14$), hot chips ($r = 0.25$), chocolate/muesli bar ($r = 0.16$), pure fruit juice ($r = 0.15$), energy drinks ($r = 0.18$) and fizzy drinks ($r = 0.18$), while leafy vegetables ($r = -0.15$), unsalted nuts ($r = -0.17$) and unsweetened yogurt ($r = -0.16$) consumption were negatively associated.

Conclusions: The results show a clear difference in food selection pattern between male and female students under stress condition. This difference could not be explained from the present study. Further research is ongoing using a qualitative approach to understand how stress affects eating behaviour among university students in order to develop appropriate interventions.

Key words: stress, nutrition.

PO1677**SMOKING HABITS IN PARENTS IS ASSOCIATED WITH HIGHER PREVALENCE OF OVERWEIGHT / OBESITY IN THEIR OFFSPRING. ALADINO STUDY***A M. López-Sobaler¹, J M. Perea², E. Rodriguez-Rodriguez³, N. Pérez-Farinós⁴, R M. Ortega¹*¹Department of Nutrition, Faculty of Pharmacy, Universidad Complutense de Madrid, Madrid, Spain²Universidad Alfonso X El Sabio, Villanueva de la Cañada, Madrid, Spain³Departamental Section of Analytical Chemistry, Faculty of Pharmacy. Universidad Complutense de Madrid, Madrid, Spain⁴Agencia Española de Seguridad Alimentaria y Nutrición (AESAN), MSSI, Madrid, Spain

Background and objectives: To study the prevalence of overweight/obesity in Spanish schoolchildren, and to analyze the influence of the smoking habits of their parents.

Methods: We studied a representative sample of 7659 6-9-year-old Spanish children (3841 boys and 3818 girls). Weight, height, waist and hip circumference data were taken, and then calculated BMI, waist/hip and waist/height ratios. Overweight and obesity were defined according to the WHO Reference 2007 Growth Standards. Parents reported their smoking habits, and also the food frequency and activity patterns of their children.

Results: The 54.7% of children have non smokers parents (NS) compared to 15.6% with both smoker parents (2S) and 29.8% with only one smoker parent (1S). 2S children have higher BMI (18.3 ± 3.3 kg/m²) than NS children (17.8 ± 2.8 kg/m², $p < 0.05$). 16.4% NS children are obese versus 19.2% in 1S group and 22.8% in 2S ($p < 0.05$ in all cases). NS children declared a higher consumption of fruits, vegetables, cheeses, eggs, breakfast cereals and bread, and lower of legumes, soft drinks, milkshakes, snacks, sweets, pastries and ready-to-eat and fast-foods than children with at least one smoker parent ($p < 0.05$ in all cases). A higher percentage of NS children participate in extracurricular sports activities, and spend less time watching television.

Conclusions: The smoking habits of parents are associated with a higher prevalence of obesity in their offspring. This could be explained by the worst dietary habits and lifestyle of the children of smokers, especially when both parents are smokers. It is probably that smokers parents were less concerned about health and nutrition issues, and they could be adversely influencing on the health of their offspring.

Key words: Overweight, obesity, schoolchildren, smoker parents.

PO1678

SPANISH SCHOOLCHILDREN WHO SOMETIMES SKIP BREAKFAST HAVE POORER BREAKFAST QUALITY AND POOR DIETARY HABITS IN THE WHOLE DAY. ALADINO STUDY

A M. López-Sobaler¹, N. Perez-Farinós², A. Aparicio¹, M. Mascaraque¹, B. Navia¹

¹Department of Nutrition, Faculty of Pharmacy, Universidad Complutense de Madrid, Spain

²Agencia Española de Seguridad Alimentaria y Nutrición (AESAN), MSSI, Madrid, Spain

Background and objectives: To study the influence of breakfast frequency on the quality of this meal and on dietary habits in Spanish schoolchildren

Methods: We studied a representative sample of 7659 6-9-year-old Spanish children (3841 boys and 3818 girls). Parents answered a questionnaire about the frequency, quality of their children's breakfast in a typical week, and the place where the children usually have this meal. The results were tabulated and analyzed using SPSS (v.19.0)

Results: 9.5% of schoolchildren usually skip breakfast at least one day in a normal week (NB), considering both parent and children answers. More children between those who eat breakfast every day (B) include in this meal a dairy product (81.4% versus 58.8% in NB), a cereal product (72.5% vs. 56.8%) and fresh fruit or natural juice (13.4% vs. 10.2%, $p < 0.05$ in all cases). 50.9% of B children included two basic foods in their breakfast (out of dairy, cereal or fruit) versus 47.2% in NB group ($p < 0.05$), and 40.3% includes only one or none (compared to 48.2% in NB group, $p < 0.05$). The food frequency consumption of fruits, vegetables, dairy products, fish, breakfast cereals and bread is lower in NB children, while is higher for sodas, smoothies, snacks, candy and ready-to eat and fast food ($p < 0.05$ in all cases). Only 8.1% of children who have breakfast at home on schooldays skipped sometimes their breakfast, compared to 20.0% of those who have breakfast at school ($p < 0.001$).

Conclusions: Skipping sometimes breakfast is associated with breakfast of poor quality and with more unbalanced dietary habits. It is still necessary to promote this meal from an early age, and looking for strategies to encourage proper eating habits not only in the family but also in the school.

Key words: breakfast, schoolchildren, dietary, habits.

PO1679

UNDERSTANDING SUSTAINABLE DIETS: PAST, PRESENT AND FUTURE EFFORTS TO ADVANCE SUSTAINABLE DIETS

J. Johnston¹, J. Fanzo², B. Cogill³

¹School of International and Public Affairs, Columbia University, New York, New York, USA

²Institute of Human Nutrition, Columbia University, New York, New York, USA

³Nutrition and Marketing Diversity Programme, Bioversity International, Maccaresse, Italy

Background and objectives: Global dietary patterns have changed dramatically in just one generation, presenting both a boom and a threat to the health and wellbeing of populations everywhere. Today, people are overeating foods that pose the greatest negative impacts for their health and the environment. The confluence of population, economic development, environmental pressures resulting from increased globalization and industrialization reveal an increasingly resource-constrained world where all the predictions point to the need to do more with less and in a "better" way. Sustainable diets present an opportunity to successfully advance commitments to sustainable development and the elimination of poverty, food insecurity and poor health outcomes.

Methods: The study examines three broad determinants of sustainable diets: social-economic, health, and environmental. A descriptive analysis of these areas was delineated and a causal model was established. The study also examined the considerations and tradeoffs for developing and promoting innovative strategies for understanding, measuring and promoting sustainable diets in human health and nutrition.

Results: The major determinants of sustainable diets fall into five categories: Agriculture, Health, Socio-cultural, Environmental, and Socio-Economic. When factors or processes are changed in one category, such changes affect other determinant categories, and in turn the level of "sustainability" of a diet. There are tradeoffs including the consumption of foods that are affordable, culturally appropriate and nutritious, yet harmful to environmental sustainability.

Conclusions: The complex web of the determinants of a sustainable diet make it challenging for policy makers to understand the benefits and considerations for promoting and consuming such diets. To advance such processes, measurement mechanisms must be developed to assess the various determinants and understand the level of sustainability of a diet, and the tradeoffs associated with recommendations to increase the "sustainability" of a particular diet.

Key words: diets, sustainable development, consumer behavior.

PO1680**CARDIOVASCULAR RISK PROFILE AND DIET DIVERSITY IN RURAL ZIMBABWEANS**

N. Mathe¹, S T. Johnson^{1,2}, J. Gandy³

¹Alliance For Canadian Health Outcomes Research In Diabetes, 2-040 Li Ka Shing Centre, University of Alberta, Edmonton, Alberta, Canada

²Centre for Nursing and Health Studies, Faculty of Health Disciplines, Athabasca University, Athabasca, Alberta, Canada

³School of Health and Emergency Professions, University of Hertfordshire, Hatfield, Hertfordshire, UK

Background and objectives: Cardiovascular diseases (CVD) prevalence is increasing in Sub-Saharan Africa. Diets of limited diversity, usually high in energy and low in micro-nutrients, have been linked to CVD. However, little information is available on the CVD risk profile of rural populations in Sub-Saharan Africa. This study describes risk factors for CVD including diet diversity (proxy for nutrient adequacy) in rural Zimbabweans.

Methods: Cross-sectional study assessed CVD risk factors, including overweight and obesity, anthropometry-height, weight, skinfolds and waist circumference (WC), blood pressure (BP), low-density lipoprotein (LDL), smoking and dietary intake recorded by 24-hour recall in 163 adults from rural Nkayi, Matabeleland, Zimbabwe.

Results: Results are presented for men (n=55) and women (n=108), mean age (SD) 40.2 (13.2) and 41.6 (12.2) years respectively. Thirty-three percent of rural females were overweight (BMI 25-29.9kg/m²), mean WC was 76.6 (7.2) for men and 77.1 (10.1)cm for women, mean percent body fat was 8.4 (3.7) and 24.0 (9.1) for men and women respectively. Fourteen percent of men and women had BPs above the recommended level (140/90mmHg) and 19% of men and 15% of women had non-fasting-LDL cholesterol >3.0mmol/l. More men (28%) than women (7%) were current smokers. Dietary intake showed limited variety. Isitshwala, (maize meal staple) was the most frequently reported food (1.8 times/person/day), followed by kale/greens (1.1 times/person/day), tea (0.7 times/person/day), rice (0.6 times/person/day) and fried tomatoes (0.2 times/person/day). Cereals dominated the diets of this population; of the ten most frequently reported foods, five were cereals. Meat consumption was limited (0.6 times/ person/ day) and no fruit consumption was reported.

Conclusions: This study described risk factors for CVD in a rural Zimbabwean population, which were lower than the national averages. Limited diet diversity in this population may negatively impact the quality of diets, increasing the risk of CVD.

Key words: Diet diversity, CVD, Sub-Saharan Africa, rural

PO1681**TOOLS FOR ASSESSING NUTRITION ASSESSMENT, COUNSELING AND SUPPORT SERVICES AT THE FACILITY AND COMMUNITY LEVELS**

S. Lamstein¹, K. Kappos², M. Tharaney³, H. Nekatebeb⁴, A. Mokori⁵, A. D'Agostino¹, N. Racine⁶, R. Exume⁶, C. Lyons²

¹The SPRING Project / JSI, 44 Farnsworth St., Boston, MA 02210, USA

²The SPRING Project / JSI, 1616 Fort Myer Dr., 16th Floor, Arlington, VA 22209, USA

³The SPRING Project / HKI, 1616 Fort Myer Dr., 16th Floor, Arlington, VA 22209, USA

⁴The SPRING Project / Save the Children, 1616 Fort Myer Dr., 16th Floor, Arlington, VA 22209, USA

⁵The SPRING Project / Uganda, Mbarara Plot 295, Block 01, Kakiika, Kacence Zone, Mbarara, Uganda

⁶The SPRING Project / Haiti, JSI/Haiti, 41, Rue Borno, Petion-Ville, Haiti

Background and objectives: International public health systems do not systematically integrate nutrition into existing services. The Nutrition Assessment, Counseling, and Support (NACS) approach is being used to bring together existing nutrition services, protocols and actors to ensure the prevention and treatment of malnutrition among all populations and across the continuum of care. The SPRING Project is strengthening NACS services globally and specifically in Haiti, Nigeria, and Uganda.

Methods: Working with local counterparts, SPRING developed tools and conducted assessments to better understand the capacity of health facilities and communities to deliver NACS services in Uganda and Haiti. With the experiences and findings from these assessments, SPRING set out to develop a refined and streamlined package of tools. Tools from Haiti and Uganda were reviewed and lessons learned were documented. In addition, we methodically reviewed existing tools and consulted with experts in the field on their definitions of nutrition assessment, counseling, and support as well as existing job aids, protocols, and supervisory tools. Based on this information, SPRING prioritized a core set of indicators and revised assessment tools accordingly.

Results: SPRING now has a refined NACS Services Capacity Assessment package including a sample protocol, sampling plan, application for ethical review, and tools for key informant, health worker, and client exit interviews, provider observations, site quality checklists, record reviews, focus group discussions, and mapping of community support services. In addition, the package provides guidance for adapting the tools to specific country contexts.

Conclusions: Momentum for the NACS is growing. Assessing NACS at the facility level is an important first step in sca-

ling up NACS and encouraging facilities to take ownership of nutrition integration. The SPRING package of tools provides users with a streamlined set of tools for doing this.

Key words: assessment, counseling, support, health facility.

CARDIOLOGIC FINDINGS, BODY MASS INDEX AND BLOOD PRESSURE IN APPARENTLY HEALTHY ADOLESCENTS

R. Valdes-Ramos¹, A L. Pérez-Huitimea¹, J. Alanis-Tavira², J de J. Muñoz-Murguía³, G G. Mendieta-Alcántara⁴, P. Tlatempa-Sotelo¹, B E. Martínez-Carrillo¹, R. Oros-Pantoja¹

¹Center For Res and Grad Studies In Health Sciences, UAEM, Mexico

²Center For Res and Grad Studies in Dentistry, UAEM, Mexico

³Centro Universitario de Investigaciones Biomédicas, UCOL, Mexico

⁴Hospital del Niños, IMIEM, Mexico

Background and objectives: Exercise related energy expenditure values used in questionnaires for adolescents are usually extrapolated from adult data, it is thus necessary to obtain measured data in order to analyze physical activity adequately. As part of an initial evaluation for the analysis of energy expenditure with varying types of exercises, we evaluated apparently healthy adolescents for weight status, blood pressure and heart condition.

Methods: Thirty-five apparently healthy adolescents from public schools in Toluca in Mexico, were evaluated by a pediatric cardiologist; weight and stature for BMI, waist circumference (WC) and systolic (SBP) and diastolic (DBP) blood pressure were measured by a trained sports specialist. Analysis was done in SPSS.

Results: Sixteen boys and nineteen girls with a mean age of 12.7±1.1 (range = 11-16). All were apparently healthy and their BMI was 20.3±4.5 (range: 15.7-35.7); SBP was 110±8.8 mmHg (range: 90-130) and DBP was 67.5±8.4 mmHg (range: 55-80). Only 13 showed no cardiologic abnormalities, while the resting 24 had one of the following: sinus arrhythmia, tricuspid regurgitation, hypertension, interatrial communication, pulmonary insufficiency, tachycardia, ventricular extrasystole.

Conclusions: Although not every cardiologic abnormality is life threatening, some may be so, particularly when initiating a physical activity program. We can conclude that a cardiologic evaluation is absolutely necessary in healthy, overweight or obese adolescents before initiating any kind of physical activity intervention, as abnormalities may be under-diagnosed in this

age group. These findings are very important, particularly as an increase in physical activity has been recommended at all levels for the general public.

Key words: Adolescents, BMI, physical activity, cardiology.

PO1683

STUNTING AND ENVIRONMENTAL QUALITY AMONG URBAN AND RURAL HOUSEHOLDS IN NIGERIA

F. Samuel¹

¹Department of Human Nutrition, University of Ibadan, Nigeria

Background and objectives: An important determinant of childhood undernutrition is the quality of the physical environment in which children live. The dynamics of how this relationship plays out in urban as compared to rural communities is the focus of this study.

Methods: Stunting was determined in a sample of 370 under-five children from households in three urban communities (low, medium and high-income), and one rural community in Oyo State, Nigeria. A structured questionnaire and an observation checklist were used to collect data. A composite environmental quality index (EQI) combining four indicators (water, sanitation, housing, waste disposal/drainage) was developed to describe the physical environment of children's households. Using regression analysis, we projected hypothetical scenarios of stunting ahead under three different assumptions of environmental quality.

Results: Overall stunting prevalence was 29.7%; the low-income urban community had the highest prevalence (44.4%) followed by the rural community (30%). EQI was lowest for the rural community (mean = 44.2% ± 11.01), and highest in the low-density urban community (76.5% ± 17.76). There was moderate and negative but highly significant association between the EQI with height-for-age ($r = -.437$, $p = .000$). Regression analysis showed that the EQI explained 15.5% of the variability in stunting in the urban, but only 1.8% for the rural children. Mean height-for-age z-scores increased with hypothetical improvements in EQI. For a 10% hypothetical improvement in EQI, mean z-scores increased by 7.3% for urban and 5.1% for rural. A larger increment of 20% in EQI yielded more improvement for urban (44.4%) than for the rural sample (11.7%).

Conclusions: Household environmental improvements have potential in reducing stunting in children in both urban and rural locations. However, this may play a greater role among urban than rural children possibly due to differentials in the quality of the physical environment and higher population density.

Key words: Stunting, environment, urban, rural.

PO1685**COMBINED EFFECT OF TRADITIONAL AND NON-TRADITIONAL HEALTH BEHAVIORS ON MORTALITY IN SPANISH OLDER ADULTS**

D. Martinez-Gomez¹, P. Guallar-Castillon², L. M. Leon-Muñoz², E. Lopez-Garcia², F. Rodriguez-Artalejo²

¹Department of Physical Education, Sports and Human Movement, Faculty of Teacher Training and Education, Universidad Autónoma de Madrid, Madrid, Spain

²Department of Preventive Medicine and Public Health, School of Medicine, Universidad Autónoma de Madrid, IdiPAZ – CIBER of Epidemiology and Public Health (CIBERESP), Madrid, Spain

Background and Objectives: Data on the combined impact of lifestyles on mortality in the elderly have generally been collected from highly selected populations and have been limited to traditional health behaviors. In this study, we examined the combined impact of three traditional (smoking, physical activity, and diet) and three non-traditional health behaviors (sleep duration, sedentary time, and social interaction) on mortality among older adults.

Methods: A cohort of 3, 465 individuals, representative of the Spanish population aged 60 years and older, was established in 2000/2001 and followed-up prospectively through 2011. At baseline, the following positive behaviors were self-reported: never smoking or quitting tobacco >15 years, being very/moderately physically active, having a healthy diet score >median in the cohort, sleeping 7-8 h/d, spending <8 h/d in sitting time, and seeing friends daily. Analyses were performed with Cox regression and adjusted for the main confounders.

Results: During an average 9-year follow-up, 1, 244 persons died. Hazard ratios (95% confidence interval) for all-cause mortality among participants with 2, 3, 4, 5, and 6 compared to those with 0-1 positive behaviors were, respectively, 0.63 (0.46-0.85), 0.41 (0.31-0.55), 0.32 (0.24-0.42), 0.26 (0.20-0.35) and 0.20 (0.15-0.28) (P for trend <0.001). The results were similar regardless of age, sex, and health status at baseline. Those with 6 vs. 0-1 positive health behaviors had an all-cause mortality risk equivalent to being 14 years younger. Adding the three non-traditional to the four traditional behaviors improved model fit (likelihood ratio test, P<0.001) and the accuracy of mortality prediction (c-statistic: +0.0031, P=0.040).

Conclusions: Adherence to some traditional and non-traditional health behaviors may substantially reduce mortality risk in older adults.

Key words: aging, elderly, mortality, cohort study, lifestyles. **Acknowledgements:** This work was funded by grants from the FIS (12/1166), and the 'Plan Nacional sobre Drogas' (06/2010).

PO1686**SELF-REPORTED LEVELS OF PHYSICAL ACTIVITY DURING SCHOOL RECESS IN SPANISH ADOLESCENTS: THE AFINOS STUDY**

D. Martinez-Gomez¹, O L. Veiga¹, B. Zapatera², S. Gomez-Martinez², D. Martinez-Hernandez³, A. Marcos²

¹Department of Physical Education, Sport and Human Movement, Faculty of Teacher Training and Education, Universidad Autónoma de Madrid, Madrid, Spain

²Immunonutrition Research Group, Department of Metabolism and Nutrition, Institute of Food Science, Technology and Nutrition (ICTAN), Spanish National Research Council (CSIC), Madrid, Spain

³Department of Preventive Medicine and Public Health and History of Science, Faculty of Medicine, Complutense University, Madrid, Spain

Background and Objectives: The morning recess period during school days represents a regular opportunity to accumulate physical activity (PA). However, the contribution of recess to PA guidelines (60 min/day in moderate-to-vigorous PA [MVPA]) in adolescents is unknown.

Methods: This study comprised 1065 Spanish adolescents (550 girls), aged 13 to 17 years. Adolescents completed a validated Recess PA Recall in 2007-2008. Differences in levels of PA during the recess period were analyzed by gender, age group, type of school, school location, immigrant status, weight status, fitness levels and eating snacks during recess.

Results: Adolescent boys spent more time in MVPA (7.7 vs. 6.4 min in MVPA, P=0.009) than girls during the recess period. Also, a higher percentage of adolescent boys than girls spent at least the 40% (35.1 vs. 28.9%, P=0.029) and 50% (32.0 vs. 24.9%, P=0.010) of recess time engaged in MVPA. In boys, only the youngest age group and with the school located in cities were more active than their peers (all P<0.05). In girls, there were no differences in levels of PA during recess by all the descriptive characteristics (all P>0.05).

Conclusions: These findings suggest that recess in Spanish secondary schools may contribute to the daily recommended MVPA for adolescents, but greater efforts must be implemented to increase PA levels among adolescent girls during this school period.

Key words: playgrounds, physical activity, correlates, adolescents.

Acknowledgements: This study was supported by the Spanish Ministry of Education and Science (DEP2006-56184-C03-02/PREV), the Spanish Ministry of Education and Science (AP2006-02464), and E.U. funding (FEDER).

PO1687**INFLUENCE OF BODY SHAPE ON THE DIAGNOSIS OF ACUTE MALNUTRITION BY ANTHROPOMETRIC INDICATORS***B. Guesdon¹, M.A. Aissa¹, D. Roberfroid²*¹Action Contre La Faim, Paris, France²Institute of Tropical Medicine, Antwerp, Belgium

Background and objectives: Two anthropometric indicators, Mid Upper Arm Circumference <125 mm (MUAC125) and Weight-for-Height Z-score <-2 (WHZ-2), are widely accepted proxies to identify 6 to 59 months old children suffering from non-oedematous acute malnutrition. Current debate around the validity of these indicators includes the possible influence of the sitting-standing height ratio (SSR) on WHZ diagnosis. Our aim was to test this hypothesis.

Methods: In November 2012, weight, standing and sitting height, and MUAC were measured in all under-5 children (N=3843) of the 2 refugee camps of Kutupalong and Nayapara, Bangladesh. SSR Z-score were computed by strata of 6 months of age within study population. The association between having longer legs for a given height (being in the lower vs. the two upper tertiles of SSRZ) and the diagnosis of acute malnutrition by MUAC125, WHZ-2 and MUAC-for-Age Z-score <-2 (MUACAZ-2) was investigated by multivariate logistic regressions adjusted for sex, age and stunting. The clustering by blocks and camps was accounted for in multilevel modelling.

Results: Only 25% of malnutrition cases by either MUAC125 or WHZ-2 were diagnosed by both indicators. Being aged <24 months and being stunted were factors increasing more strongly the probability of malnutrition diagnosed by MUAC125 than by WHZ-2. Being a female was also a predictor of diagnosis by MUAC125, whereas the opposite was observed for WHZ-2. Having longer legs was associated with an increase in WHZ-2 (OR=2.21; 95%CI: 1.84; 2.65) and MUACAZ-2 (OR=1.68; 95%CI: 1.43; 1.97) but not in MUAC125 (OR=1.19; 95%CI: 0.91; 1.55).

Conclusion: While confirming the hypothesis of an influence of SSR on WHZ diagnosis, our results challenge the idea of a body shape-related bias which would be peculiar to WHZ-2 by displaying a similar relation between SSR and MUACAZ-2.

Key words: Acute malnutrition, diagnosis, body shape.

PO1688**PREVALENCE RISK FACTORS AND PROTECTION FOR CHRONIC DISEASES TRANSMITTED IN NO CAPITAL OF BRAZIL IN 2011***N. Cabral¹, A. Maia¹, H. Veloso¹, E. Hortegal¹*¹Department of Nutrition, University CEUMA, Sao Luis, Maranhão, Brazil

Background and objectives: This study aimed to determine the prevalence of risk factors and protective for chronic diseases in the capital of Brazil in 2011.

Methods: This was a descriptive study. Secondary data pertaining to Surveillance System Risk and Protective Factors for Chronic Diseases of the Ministry of Health, which made data collection through telephone interviews conducted in 2011. The variables analyzed were the risk factors and protective, presented by variables of lifestyle, dietary intake and presence of injuries to health, stratified by gender and education.

Results: It was found that the highest prevalence of risk factors belonged to men, except for the presence of diabetes and hypertension and those with eight years of schooling or less. Protective factors for the higher prevalence of consumption of fruits and vegetables were among women and the consumption of milk fat and physical activity was higher among men. Regarding schooling, vegetable consumption and physical activity was higher among those who had twelve or more years of study and consumption of milk with full-fat content was higher among those who had nine to 11 years.

Conclusions: We conclude that there are differences in the distributions of factors associated with chronic diseases, it is important to be considered for adoption promotion and health prevention.

Key words: Chronic Disease. Risk Factors. Life Style.

PO1689**CLIMATE VARIABILITY ON CAREGIVER'S MENTAL HEALTH AND CHILD NUTRITIONAL STATUS***A. Christian¹, A. de-Graft Aikins, A. Lartey*¹Regional Institute For Population Studies, University of Ghana, Legon & Carolina Population Center, University of North Carolina, Chapel Hill, USA²Regional Institute For Population Studies, University of Ghana, Legon, Ghana³Department of Nutrition and Food Science, University of Ghana, Legon, Ghana

Background and objectives: Current research on the influence of caregiving practices on children's nutrition status

and well-being have often overlooked the importance of the caregivers' mental health, and even when taken into account, seasonal and environmental factors are not considered. Although researchers concur that climate change will have both direct and indirect effects on mental health, no integrative or comprehensive framework to guide research or policy on the impact of climate change on mental health exist. Understanding the psychological impact of climate change on caregivers and its effect on their children's well-being particularly their nutritional status, entails recognizing the complexity of the various environmental stressors on the livelihoods of rural communities; and recognizing mediators and moderators of impacts.

Methods and Results: Based on a current review and synthesis of research evidence from low and middle income countries using the socio-ecological framework, this presentation shows how climate change (acute or traumatic effects of extreme weather events) can affect directly and indirectly the psychological health of caregivers and ultimately affecting the nutritional status of their children. Granting the various methodological challenges identified in reviewed studies, results suggests that seasonal climatic variability are associated with the mental health of caregivers' and with household food insecurity. The mechanisms linking these variables are however not clearly understood. Few studies however, were explicitly designed to test pathways in which climatic stressors such as heat and precipitations impact on caregivers' mental health, caregiving practices and their children's nutritional status.

Conclusions: This presentation concludes by identifying gaps in the literature, implications, and some research priorities. Recognizing clearly how climate change impact on the psychological health of individuals, particularly women and children nutritional status has the potential to lead to more productive mitigation and adaptation activities.

Key words: Climate change, Caregivers, Mental health, Children's Nutritional Status.

PO1690

CAROTENOID CONSUMPTION AMONG BENEFICIARIES OF A CASH TRANSFER PROGRAM IN BRAZIL

A. Sartori¹, M. Vieira¹

¹Department of Agroindustry, Foods and Nutrition, Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo, Piracicaba, Brazil

Background and objectives: Bolsa Família Program, maintained by Brazilian government, supported more than 13 million families in poverty in 2012. The target of the cash transfer's Program are persons who are frequently exposed to food insecurity. This study aims to evaluate the diet of this population by

analyzing carotenoid consumption, which has been associated with decreased prevalence of chronic diseases.

Methods: The sample, part of the "Pesquisa de Orçamentos Familiares" budget survey, conducted by the Brazilian Institute for Geography and Statistics (Instituto Brasileiro de Geografia e Estatística) in 2008-2009 is composed of 34, 003 persons (10 years old or more) and is representative of all Brazilian states; of both urban and rural areas; and of all socioeconomic status. Food consumption was obtained by the food diary method. To obtain carotenoid composition of foods, it was used reference tables from Brazil and United States. The daily prudent ingestion for carotenoids recommended by the Institute of Medicine were used as reference (beta-carotene: 3, 000 to 6, 000 µg; lycopene: 5, 000 to 10, 000 µg; provitamin A carotenoids: 5, 200 to 6, 000 µg; and total carotenoids: 9, 000 to 18, 000 µg). It were made statistical analysis of the daily carotenoid consumption (grams per person) among beneficiaries and non beneficiaries.

Results: The quantity per person of total carotenoids consumed among beneficiaries (3, 244 µg/day) was less than among non beneficiaries (4, 300 µg/Day). Similar trends were identified for beta-carotene (beneficiaries: 1, 396 µg/day and non beneficiaries: 1, 916 µg/day); lycopene (beneficiaries: 716 µg/day and non beneficiaries: 929 µg/day); and provitamin A carotenoids (beneficiaries: 1, 794 µg/day and non beneficiaries: 2, 452 µg/day).

Conclusions: The ingestion, especially among Program's beneficiaries, is smaller than the recommended and can be partially conditioned by the lack of access to fruits and vegetables.

Key words: carotenoids, cash transfer program, consumption

PO1691

CHILD AND MOTHER NUTRITION SURVEY OF BANGLADESH(CMNS), 2012

A. Islam¹, AH. Pasha¹, K. Ferdouse², K. Jahan², S. Israt², S. Roy²

¹Bangladesh Bureau of Statistics, Parishankhyan Bhaban, E-27/A, Agargaon Sher-e-Bangla Nagar, Dhaka-1207, Bangladesh

²Bangladesh Breastfeeding Foundation, Institute of Public Health, Mohakhali, Dhaka, Bangladesh

Background and objectives: Child and Mother Nutrition Survey (CMNS) of Bangladesh was carried out in March, 2012. The main objective of this survey was to assess the nutritional status of children aged less than 5 years and their mothers and to examine underlying causes of malnutrition and comparing with the findings of previous surveys.

Methods: The CMNS2012 was carried out among 4112 children aged 0-59 months and their 3521 mothers who were living in 3484 households in 64 districts of Bangladesh.

Results: Using the WHO 2005 MGRS, 34.4% of children aged <5 years were underweight, 41.2% were stunted, 13.4% were wasted and 4.1% were overweight/obese. The prevalence of underweight sharply increased between 18-23 months and in 48-59 months. Children of rural area was significantly more underweight (35.2% vs. 31.7%) and more stunted (42.7% vs. 36.4%) than urban area. The prevalence of underweight, stunting and wasting was inversely associated with the education status of mothers and wealth quintile. Stunting and wasting or overweight were more in children of mothers aged less than or equal to 18 years. Children of housewife mothers were less likely to be wasted than the children of working mothers. The mean weight of the mothers was 48.9 kg, mean height was 150.9 cm, mean MUAC was 258 mm and mean BMI was 21.4 kg/m². The prevalence of underweight was almost double in rural mothers, while the prevalence of overweight/ obesity was considerably higher in urban areas (35.2% vs. 13.1%). Between 2004 and 2012, prevalence of overweight/ obesity among mothers increased from 15.4% to 26.0.

Conclusions: The findings clearly demonstrate the presence of double burden of malnutrition in Bangladesh. Problems of both under-nutrition and over-nutrition needed to address simultaneously.

Key words: Stunted, Underweight, CED, Overweight/Obesity.

PO1692

RISK FACTORS ANALYSIS FOR MALNUTRITION IN PEOPLE LIVING WITH HIV/AIDS

K. Ferdouse¹, SK. Roy¹, K. Jahan¹, SS. Saliheen Sultana², S. Israt¹, SB. Salam¹, T. Ahmed¹

¹Bangladesh Breastfeeding Foundation, Institute of Public Health, Dhaka, Bangladesh

²Department of Food and Nutrition, Home Economics College, Azimpur, Dhaka, Bangladesh

Background and objectives: People living with HIV/AIDS (PLHIV) are vulnerable to poor nutrition status because their body's food requirements are increased. Due to lack of knowledge they often become malnourish or become sick with other nutritional deficiency diseases and infections. The objective of the study was to identify risk factors for malnutrition in HIV-AIDS subjects.

Methods: It was a cross-sectional study. To identify the risk factors 85 male and female HIV positive people aged 18 to 50 years were interviewed by semi-structured questionnaire

from the member of a national NGO Ashar Alo Society and Infectious Diseases Hospital who provide health care service to the PLHIV in Bangladesh.

Results: The study found that Mean (\pm SD) age of underweight HIV positive subjects was 33 (\pm 9) years, Mean (\pm SD) height was 160 (\pm 8) cm, mean weight was 44 (\pm 5.6) kg and mean BMI was 17.2 (\pm 1.3) kg/m². Study also recognized that study recognized that less calorie intake was highly associated with underweight condition (OR=27.5) and underweight PLHIV intake 25% less calorie than their daily requirement. Less protein intake was also associated with underweight (OR=2.80). Nausea (OR=2.60), Vomiting (OR=2.02), change in smell or taste (OR=2.70), Fever (OR=3.05), cough/cold (OR=2.50), diarrhea (OR=2.83), anorexia (OR=3.23) were also associated with the poor nutritional status of the subjects. Some other factors i.e. unemployment, low income, low food intake, presence of diseases, social stigma, fasting or less food intake due to lack of money and poor appetite significantly associated with nutrition status of underweight PLHIV.

Conclusions: Nutrition is a fact which influence with many other factors like nutrition knowledge, socio-economic condition, body mechanism, mental condition etc. For longevity of PLHIV and decrease diseases progression proper nutritional support must be provided through effective nutrition program.

Key words: Risk Factors, Nutritional status, HIV/AIDS, PLHIV

RELATIONSHIP BETWEEN PREFERENCE FOR JAPANESE SOUP STOCK (DASHI) AND DIETARY HABITS IN UNIVERSITY STUDENTS

Y. Higashine¹, T. Okuda², N. Tanaka³, J. Kang⁴, Y. Asano⁵, I. Hamaguchi⁶, H. Shinohara⁷

¹Faculty of Health Science, Osaka Aoyama University, Minoo, Japan

²Faculty of Human Sciences, Tezukayamagakuin University, Sakai, Japan

³Faculty of Home Economics, Kobe Women's University, Kobe, Japan

⁴Department of Nutrition, Hyogo NCC College, Nishinomiya, Japan

⁵Faculty of Health Science, Kio University, Nara Pref, Japan

⁶Faculty of Human Sciences, Konan Women's University, Kobe, Japan

⁷Faculty of Education and Culture, University of Miyazaki, Miyazaki, Japan

Background and objectives: The aim of this study was to investigate a relationship between a preference for Japanese soup stock (Dashi) and dietary habits in university students.

Methods: A sensory evaluation was performed in 323 university students (54 males and 269 females). The subjects tasted five kinds of soup stock made from kelp, dried bonito, mixture of kelp and dried bonito, dried small sardines, and monosodium glutamate. The relationship between the preference for soup stock and dietary habits was assessed with a questionnaire, which asked their dietary habits, frequency of tasting soup stock, and ingredients of soup stock at home in four grades.

Results: In the five kinds of soup stock, the soup stock made from mixture of kelp and dried bonito was the most preferred (3.4 ± 1.2), but the monosodium glutamate soup stock was the least (1.8 ± 1.0). No difference between the sexes was observed. An umami taste, a pleasant aftertaste and a good body were prominent in the soup stock made from mixture of kelp and dried bonito. In contrast, an acid taste was prominent in the dried bonito soup stock, and the dried sardine soup stock had stronger fishy smell compared with the other four. The pleasantness of aftertaste and smell, and the strength of umami taste were desirable factors, but the strengths of bitter taste and acid taste were undesirable ones. The group in which the subjects had soup stock from natural ingredients frequently had tendencies to masticate their food well, to eat boiled vegetables often, to favor Japanese food, and to have confidence in their health.

Conclusions: These findings suggested that the preferential and frequent tasting of soup stock from natural ingredients would impact on a preference for Japanese food, healthy dietary habits and an interest in cooking.

Key words: Japanese soup stock (dashi), sensory evaluation, dietary habits, questionnaire

COMMUNITY INTERVENTION TRIAL PROMOTE HEALTHY BEHAVIORS IN FARMERS IN TIANJIN, CHINA

G. Jiang^{1, 2}, M.L. Boulton^{3, 4}, Z. Wang¹, J. Li¹, W. Li¹, D. Wang¹, H. Liu¹, W. Zheng¹, Y. Yang¹, G. C¹, F. Zhang⁵, J.P. Montgomery³

¹Tianjin Centers For Disease Control and Prevention, Tianjin, China

²Tianjin Medical University, School of Public Health, Tianjin, China

³University of Michigan School of Public Health, Ann Arbor, MI, USA

⁴University of Michigan School of Medicine, Ann Arbor, MI, USA

⁵Jinnan County Centers for Disease Control and Prevention, Tianjin, China

Background and objectives: To assess a community intervention trial promoting healthier lifestyles in rural Chinese farmers using the stage of change health behavior model.

Methods: A community intervention trial utilized an intervention and control village with farmers as study subjects. The intervention village (n= 549) participated in a stage-specific interventions while the control village (n=557) received general health education messages. Farmers in both villages were initially categorized using the stage of change model and observed for attitudinal and behavior changes over one year. Data collection included dietary habits, physical activity, anthropomorphic measures, and biomarkers at baseline, mid-point, and study termination.

Results: The intervention group demonstrated greater progress in moving from awareness to the action stage in their adoption of healthier behaviors. Total cholesterol, homocysteine, blood pressure and urine sodium decreased while blood and urine folic acid increased in intervention subjects only.

Conclusions: The first documented use of the stage of change model in rural Chinese farmers was successful at increasing healthier eating and physical activity in an infrequently studied population. Given China's escalating burden of chronic diseases, the stage of change model should further be evaluated in promoting healthier behaviors and addressing lifestyle related illness in the world's most populous nation.

Key Words: farmers, nutrition intervention, vegetables, fruit, physical activities

PO1698

DOES SOCIO-ECONOMIC FACTORS DETERMINE THE POSITIVE OUTCOME OF FRUITS AND VEGETABLES CONSUMPTION?

C.T. Anyakee¹, O.B. Ogunba¹

¹Department of Family, Nutrition and Consumer Sciences, Faculty of Agriculture, Obafemi Awolowo University, Ile-Ife, Osun State, Nigeria

Background and objectives: It is important to understand the relationship between food consumption and culture among other influential factors, which is the issue of understanding food consumption for health. Fruits and vegetables (FV) are great sources of vitamins, antioxidants, and other components with great functional properties. Objectives: The study explores the linkages among age, income, educational level, ethnicity, household size, sex, number of children, religion, marital status and (FV) consumption

Methods: Using a descriptive cross-sectional survey, male and female undergraduates (n=200) aged 16-29 years were randomly selected for the study. Structured interviews and questionnaires suitable to meet research objectives were used to eli-

cit relevant information on socio-economic characteristics of respondents. The data collected were analyzed using SPSS program version 17 and multivariate logistic analysis was used to examine and establish association between variables of interest.

Results: Age has a negative relationship with fruits consumption ($p < 0.05$, $r = -0.0908$). Sex ($X^2 = 21.800$, $df = 2$, $c = 0.000$) and ethnicity ($X^2 = 18.476$, $df = 2$, $c = 0.05$) had significant relationship with fruits consumption. Also, there exists a strong positive and significant relationship ($p = 0.01$, $r = 0.208^{**}$) between the educational level of respondents and vegetables consumption. It also showed that age, increase in number of children and household size influenced vegetables consumption negatively

Conclusions: Social and economic factors to a significant extent influence different levels of (FV) consumption therefore, there is an urgent need to create a sustainable means to promote (FV) consumption, in order to eradicate the preventable deaths attributed to low (FV) consumption worldwide.

Key words: Respondent, socio-economic, consumption, fruits, vegetables.

PO1699

ENERGY DENSITY AND FEEDING FREQUENCY OF COMPLEMENTARY FOODS AFFECTS MEAL-SPECIFIC FOOD CONSUMPTION AND DURATION BY HEALTHY, BREAST FED BANGLADESHI CHILDREN

M. Islam^{1,2}, M. Khatun¹, J. Peerson², T. Ahmed¹, A. Mollah³, K. Dewey², K. Brown

¹Centre for Nutrition and Food Security, International Centre For Diarrhoeal Disease Research, Bangladesh (icDDR, b), Dhaka 1212, Bangladesh

²Program in International and Community Nutrition, University of California, Davis, CA 95616, USA

³Department of Pediatrics, Dhaka Medical College Hospital, Dhaka 1000, Bangladesh

Background and objectives: Appropriate complementary feeding of infant and young children is necessary, information is lacking on the effects of dietary energy density (ED) and feeding frequency (FF) of complementary foods on food consumption during individual meals and the amount of caregiver time expended in child feeding. To evaluate the effects of varied ED and FF of complementary foods on food intake and time required for child feeding during individual meals.

Methods: During 9 separate, randomly ordered dietary periods lasting 3-6 days each, we measured self-determined intakes of semi-solid cereal porridges by 18 healthy, breastfed children 8-11 mo of age who were fed coded porridges with EDs of 0.5, 1.0 or 1.5 kcal/g, during 3, 4, or 5 meals/d. Complementary food intake was measured by weighing the feeding bowl before and after every meal.

Results: Children consumed greater amounts of complementary foods per meal when they were receiving diets with lower ED ($p = 0.044$) and fewer meals per day ($p < 0.001$). Food intake was less during the first meal of the day than the other meals. Greater time was expended per meal when fewer meals were offered. The time expended per meal did not vary by dietary ED, but the children ate the lower ED diets faster ($p = 0.019$). Food intake velocity was also greater when more meals were offered per day ($p = 0.005$).

Conclusions: We conclude that the ED and FF of complementary foods affect meal-specific food intake. FF also influences the duration of individual meals, but ED does not. These results provide further evidence of young children's ability to regulate their energy intakes, even during infancy; and they convey information on factors that affect the amount of time that caregivers must devote to child feeding.

Key words: complementary foods, energy density, feeding frequency, meal, breastfed children.

PO1700

LEVELS OF ANEMIA AMONG CHILDREN IN TRIBAL INDIA

S. Sharma¹, J. Bir Singh², R. Rani³

¹Institute of Health Management Research (IIHMR), India

Background and objectives: Despite exceptional economic growth in India, the public health problems status still remains grim. One of the major problems in India, by which the children of India suffer is, Malnutrition. According to National Family Health Survey- III, in 2005-2006, conducted by Ministry of Health and Family Welfare, Government of India, 7 out of every 10 children age 6-59 months in India were anemic.

Methods: To study the levels of anemia among children residing in backward and tribal area, a cross sectional study was done in three blocks of Udaipur district of Rajasthan, a province of India, namely: Salumber, Sarada and Jhadol. The hemoglobin (Hb) level of a sample of 468 U-5 children was measured and recorded. The data was entered and analyzed using SPSS 16.0. The anemia level has been analyzed using WHO (International) and NFHS III 2005-2006 (India) reference values.

Results: Only 6% of children were found with normal Hb level while the percentage of children suffering from mild, moderate and severe anemia were 37%, 49% and 8% respectively. The mean Hb level of the children in all the blocks comes to be 9.6 g/dl. More male children (11%) were found suffering from severe anemia than female children (6%). **Conclusions:** The result shows the high percentage of anemia among children, thus, interventions such as strengthening of health programmes are recommended.

Key words: Nutrition, Anemia, Children, India

PO1701**LESSON LEARNED 'IODINE VILLAGE' DEVELOPMENT FOR SUSTAINABLE IDD CONTROL AND PREVENTION IN THAILAND**

N. Viriyautsahakul¹, W. Kongnoo¹, N. Saiwongse¹, S. Chotivichien¹, N. boonmongkol¹

¹Department of Health, Ministry of Public Health, Thailand

Background and objectives: Ever since 2010, Health Department and Department of Local Administration have encouraged nationwide villages to create Iodine Village in an effort to control and prevention of IDD.

Methods: At least 38, 663 villages (53.13%) have been certified Iodine Villages applying social measures to permit only qualified iodized salt to be sold in the villages. Quality of iodized salt will be inspected two times per year. Iodized salt will be continuously communicated to villages via local radio network, home visit, campaign etc. for sustainable self reliance in IDD control.

Results and Conclusions: After three years IDD control, it found that household coverage of iodized salt (≤ 30 ppm.) increased from 77.4% in 2009 to 93.5% in 2011. The proportion of IDD in pregnant women decreased from 59.0% in 2009 to 39.5% in 2011. The key success include 1) Awareness creation through an information on linkage of IDD with child cognitive development. 2) Potential development of related workers to be able to transform the IDD knowledge to practice with emphasis on applying simple local wisdom for sustainable development. 3) IDD ambassador appointment among health volunteers to create direct contact among IDD risk groups. 4) Development of tools for self - assessment. 5) Empowerment supervision to identify local intervention and facilitation. 6) Provision of communication materials and I-kit for iodized salt examination. 7) Media advocacy development through national festivals. 8) Lesson learned development, plague presentation, good model village communication 9) Merit, success and cooperation acknowledgement among all concerned well help inspiration to practice better the iodine village.

Key words: Iodine Village Development /Sustainable IDD Control and prevention

PO1702**DEVELOPMENT OF INNOVATION FOOD AND NUTRITION EDUCATION TOOL FOR BETTER NUTRITION IN PRIMARY SCHOOL, THAILAND**

W. Kongnoo¹, S. Damapong, N. Saiwongse, S. Khunsanong, N. Thongbuasirilai

¹Bureau of Nutrition, Department of Health, Ministry of Public Health, Thailand

²The Project to Develop Systems and Mechanisms for Age-Appropriate Nutrition for Thai Children, Thailand

³Department of Health

⁴Institute of Nutrition, Mahidol University

⁵Regional Health Promotion Centre 5, Nakhon Ratchasima Province

Background and objectives: The objective is a tool for teachers to apply integrated food and nutrition in school curriculum for children to have skills in food and nutrition in life style practice.

Methods: The methodology is the process of participatory development of the tool among teachers, educators, nutritionists, communicator etc, on the proposal and acceptability must be acceptable to teachers prior to actual application in primary school. The issues include a) nutrition flag b) vegetables and fruits c) reduce sugar, fat, and salt in foods d) overweight will be incorporated into health physical education occupation and technology, social and culture sciences, mathematic, Thai language, foreign language and arts.

Results: The key success indicated that 52.12% of 253 schools in the project areas regularly implement the innovative food and nutrition while the others implement only some parts. It found that the number of children with good consumption behavior was 1.12 times higher especially in the issues of the daily vegetable and fruit consumption behavior, non carbonated drinking behavior, lower high sugar, fat and salty sweet consumption, practices of adding fish sauce and sugar in cook food as well as lower overweight children. It also found that the satisfaction among teacher and children as the education tool were joyful to teaching and learning and easy to apply for good food and nutrition behavior change. Besides, more novel food and nutrition had been created among teacher, children and parents.

Conclusions: However it was recommended that content and element should be adopted and applied to meet the needs of users at each level for application at national level of Thailand.

Key words: food and nutrition, education tool, primary school.

PO1703**LESSON LEARNED: IMPROVEMENT OF FOOD QUALITY IN SCHOOL AND CHILD DEVELOPMENT CENTER FOR SUSTAINABLE CHILD NUTRITION**

S N. Damapong¹, W. Kongnoo, P. Monarumit

¹The Project To Develop Systems and Mechanisms For Age-Appropriate Nutrition For Thai Children, Thailand

²Bureau of Nutrition, Department of Health

³The Project To Develop Systems and Mechanisms For Age-Appropriate Nutrition For Thai Children, Thailand

Background and objectives: Since the Thai government have transferred its administrative authority to local government it found nutrition in local school and child development center (CDC) is not up to par.

Methods: Hence the Health Department together with The Nutrition Association of Thailand under the royal patronage of Her Royal Highness Princess Maha Chakri Sirindhorn had organized a study to find ways and means to strengthen the management capability of the local government, school, CDC, community and social network to be able to develop good nutrition practices for child optimal growth. Five strategy applied were; a) Food and nutrition surveillance of which the information would be utilized for policy planning. b) Potential development on food and nutrition practice, c) Support innovation food and nutrition materials based on FBDG to administrator, child care attendants, cook, food seller, school child teacher, parent, worker. d) Forum for exchanging view and experiences. e) Empowerment supervision and monitoring. It founded 39.2% CDC and 28.8% school were able to develop quality nutritious lunch with vegetable and fruit served daily. The practice had good impacted to child nutrition as stunt and obesity decrease remarkably.

Results: The key success issue included 1) The increase cost of CDC and school lunch to Baht 15 – 20 from Baht 13 per person per meal by the local government. 2) Application of nutritionist to be responsible in food and nutrition or the responsible party including administrator, teacher, cook, school child leader, parent would be trained on food and nutrition regularly. 3) School and CDC. lunch specification be employed for food caterer to be followed. 4) Local central kitchen. 5) Vegetable garden for lunch program.

Conclusions: Key mechanism of the success is a capacity building of the local government for public policy planning on food and nutrition.

Key words: Improvement of food quality/sustainable child nutrition

PO1704**A FOLLOW-UP SURVEY IN JAPANESE FEMALES: CHANGES OF BONE MINERAL DENSITY AND LIFESTYLE RELATED FACTORS**

N. Nakashima¹, M.Arimatsu², I. Kawakami³, N. Kitano¹, T. Kitano⁴

¹Faculty of Environmental and Symbiotic Sciences, Prefectural University of Kumamoto, Kumamoto, Japan

²Department of Fundamental Nursing, School of Health Sciences, Kumamoto University, Kumamoto, Japan

³Department of Nutrition Science Faculty of Living Science, Shokei University, Kumamoto, Japan

⁴Department of Public Health, Graduate School of Life Sciences, Kumamoto University, Kumamoto, Japan

Background and objectives: To clarify the relationship between bone mineral density (BMD) and lifestyle related factors in Japanese females.

Methods: The subjects were 214 females aged 19-21 years. In 1992-1995, we have measured their BMD (of lumbar spine (L2-4), total body, arms and feet), body habitus, and lifestyle related factors self-reported questionnaire. To compare these values with the ones of themselves at the other points, as a time-series, we intended to measure again the values. 80 subjects of them were actually measured in 2006-2010, hence we investigated them in this study. Note that for each 80 subjects, we have a pair of the values whose distance is in at least 14 years. We used paired-t test in the following. We compared the pairs BMD at the baseline and follow-up. Also, we classified 80 subjects under tertiles, by body mass index (BMI) at the baseline. For each tertiles, we used the values at the two points. Besides, we did by bone-free lean tissue mass index (LMI) as same as above.

Results: On the case of no classifying, we recognized significant differences in BMD of total body, arms, feet ($p < 0.001$), while no difference in L2-4. On the highest tertiles by BMI, we estimated that with respect to L2-4, their BMD increased significantly ($p < 0.05$). On the highest tertiles by LMI, we obtained a similar result as the case of BMI. The other result was that LMI associated significantly with several lifestyles ($p < 0.05$).

Conclusions: We estimated that BMD of some parts had increased from the baseline to the follow-up. We also asserted that, it was important for BMD to keep both body weight and fat-free mass appropriate, in particular, during early life.

Key words: Bone mineral density, Young Japanese females, Body composition.

PO1705**MALNUTRITION AND THYMIC HYPOPLASIA IN THE INFANCY***E. Castellanos¹*¹Department of Allergy and Immunology, University Hospital, Cuba

Background and objectives: The thymus is an organ primary linfoide; decisive for the thymopoiesis and development of system inmunitario in the early childhood, the nutritional lacks, result in thymus structural and functional changes and in the appearing of infectious complications.

Methods: In this study longitudinal prospective were studied 125 patients undernourished in during 6 moths with thymic hypoplasia and recurrent sepsis among 1-7 years old. The patients stratified in working groups according to the measurement of thymic area for ultrasound themselves: Critical (less than 500mm²), moderated (501-999 mm²) and normal (100-1500 mm²). We realized correlation test between groups.

Results: We found a positive correlation among the malnutrition and the thymic hypoplasia, being more significant in the critical respect to the ones that having the normal thymic area and had a positive correlation also among the malnutrition and the appearing sepsis complicated in the infants, with significant changes in the critical and moderated in relation to them with normal thymic area.

Conclusions: Our results show that the malnutrition result in altered thymic activity in early life, therefore, its monitoring in the infants is very important in the development and functioning of thymus, for the opportune intervention in the fight against the infectious illnesses.

Key words: Thymic hypoplasia, Nourishment, Sepsis, Infant, Malnutrition

PO1706**GROWTH AND BODY COMPOSITION CHANGES IN INDIAN UNDERNOURISHED CHILDREN***U. Deshmukh¹, S. Joshi¹, C. Joglekar¹, E. Rush², A. Kurpad³, C. Yajnik¹*¹King Edward Memorial Hospital and Research Centre, Australia²Faculty of Health and Environmental Sciences, Auckland University of Technology, Auckland, New Zealand³Division of Nutrition, St John's Medical College, Bangalore, India

Background and objectives: Early life nutrition is linked to later life disease risks. India has the highest number of under-

nourished children in the world. Body composition and growth of undernourished children in community-based management of acute malnutrition (CMAM) is not investigated before.

Methods: Children from nutrition rehabilitation centres who met the WHO weight-for-height-Z-score (WHZ) categories: severe-acute-malnutrition (SAM, n=57), moderate-acute-malnutrition (MAM, n=29) and average (n=25) were measured at baseline (aged 30±16.8 months), and followed for 18 months. Measurements included standard of living, morbidity, dietary intake, anthropometry; bioimpedance and total body water (TBW) by the stable isotope technique of deuterium oxide dilution. The Institutional Review Board and the local health authorities provided study approval.

Results: As expected the SAM compared with average children had lower anthropometric Z-scores (weight, height, head and mid-upper arm circumference, triceps and sub-scapular skin folds) and lower fat free mass (FFM) and fat mass (FM) at baseline. After 18 months, SAM children had a significant increase in body fat%, yet WHZ-scores had improved from -3.8 to -1.8. Fat mass contributed to 18% of the weight gain in SAM, as compared to 8% in Average children. Younger age was associated with greater increases in TBW, FFM and FM; and low WHZ-scores at baseline predicted a higher body fat % at 18 months.

Conclusions: The children showed composite growth failure. Follow-up of undernourished children showed differential catch-up and growth faltering patterns for weight, height, head circumference and adiposity. Recovery from undernutrition was marked by increase in adiposity, which may persist in later life and contribute to the risk of chronic diseases like metabolic syndrome and type 2 diabetes. The nutrient profile and role of nutrients, in foods provided in CMAM needs to be investigated further.

Key words: Body composition, children, CMAM, undernutrition, chronic disease.

Funding agency: International Atomic Energy Agency, Vienna, Austria.

PO1707**EVALUATION OF THE ACQUISITION OF THE FAMILY FARMING GENRE: DATA ANALYSIS OF AWARD EFFICIENT MANAGER OF SCHOOL MEALS 2011.***J.Y. Toyoyoshi¹, R. de Oliveira¹, M Sineide. N dos Santos², M. Santiago Galisa¹, A. Polo Galante¹*¹Centro Universitário São Camilo, São Paulo, Brazil²Organização Ação Fome Zero, São Paulo, Brazil

Background and objectives: The Award Efficient Manager of School Meals organized by non-governmental organization

Ação Fome Zero, identifies and rewards best practices of municipalities with municipal public administration of the National School Nutrition Program (PNAE). The purpose of this study was to evaluate the acquisition of the family farming food genre by municipalities awarded the Prize.

Methods: The study used data from the 8th edition of the Prize 2011 (percentage of the purchase of family farming and the types of food purchased).

Results: 19 municipalities made the purchase of family farming, but only 18 municipalities declared the percentage purchase and cited the foods that are purchased. Only 8 counties achieved the goal of 30% of purchase family farming, 8 of the winners found themselves slightly below the percentage and 2 much lower than recommended one. The food groups most commonly bought by 83% of municipalities were fruits / pulps and vegetables, the candy group was purchased by 67% of municipalities. Despite the group of cereals, tubers and roots occupy the 4th position, only 2 municipalities reported buying rice, most of this group purchase were potatoes and cassava.

Conclusions: These data demonstrated that some municipalities may even have reached 30% of food genre coming from the family farming, but this does not guarantee that there is variety in the types of food purchased and neither guarantee that the already purchased are products that encourage healthy eating habits.

Key words: Food consumption. Food production. School feeding.

Methods: Sampling stratified by sex and nationality. Trained interviewers investigated: 1) anthropometry, socio-demographic data, and food preferences; 2) nutritional assessment by double weighted; 3) acceptability of the usual menu, and 4) perception of the process of assistance. The scales used were hedonic and perceptions facial type, of 7 points, in Arabic and French. Acceptability and the overall assessment were also scored with a note (0-10). The nutritional goal was set at the 40% of daily needs.

Results: Users: 200; N = 50 (45 men); 14 nationalities, 5 alimentary groups: Spanish, Maghrebians, Eastern Europeans, South American and African; Average: 46 years old; There are not underweight, 58% excess weight; 30% limited chewing capacity, 10% do not make another meal a day. Sensory evaluation of 13 dishes of the menu is acceptable (5, 8) and correlates with the percentage remains uneaten. Found deficient texture of rice and pasta. The usual menu has a high acceptability (5, 65) correlating with the overall rating of service (8, 62); The best accepted are dairy products, fruit and legumes, and the worst fish. There are differences between acceptability by nationality. Intake: 813 kcal/meal (deficit: 327 kcal/meal), 31% fat, 19% protein. Negative perception of the amount, the behavior of other users, and noise.

Conclusions: Excellent assessment, with improvement areas: Increase energy and amount, improve the textures and tastes consider. Sensory analysis and perceptions allow you to design menus and services that maximize satisfaction, nutritional intake and minimize remains.

Key words: Homeless, Food Services, Sensory evaluation

PO1708

SENSORY AND NUTRITIONAL EVALUATION OF A MUNICIPAL SERVICE OF COMMUNITY KITCHEN FOR POOR AND HOMELESS PERSONS

B. Patiño Villena¹, A. Navarro García², M.J. Periago Castón³, A. Rodríguez Tadeo³, A. Duarte López², G. Ros Bermejo³, E. González Martínez-Lacuesta¹

¹Municipal Health Services, Department of Social Welfare and Health, Local Government of Murcia, Murcia, Spain

²Prevention and Social Integration Section, Municipal Service of Social Services, Local Government of Murcia, Murcia, Spain

³Nutrition and Food Science, Veterinary School, University of Murcia, Murcia, Spain

Background and objectives: Local government of Murcia has a service of community kitchen for homeless. It is necessary to adapt the resources and provide of monitoring indicators facing to the increasing demand in the currently economic crisis. The objective is to optimize the supply of menus in order to ensure the health of the users and the efficiency.

PO1709

CONCERN ABOUT HIS BODY, SELF-ESTEEM AND DISORDERS OF EATING IN YOUNG

I C. Moran-Alvarez¹, V.Cruz-Licea¹, L T. Yamamoto-Kimura¹, M G.Alvear-Galindo¹, C. Urbina¹

¹Departamento de Salud Pública, Facultad de Medicina, Universidad Nacional Autónoma de México, Mexico

Background and objectives: In the last years, it has been sought to understand why youngsters try to diminish their body weight through a variety of mistaken eating and exercising behaviors. These, added to the concern for their body and low self esteem, may turn into a Eating Behavior Disorder (EBD). The purpose of this work was to measure self-esteem, preoccupation regarding body image and EBD, in youngsters in a high school (middle school) in Mexico City.

Methods: To 47 adolescents, 61% women and 49% men, with an average age of 14 years old, three tools were applied: Eating Attitude Tests (EAT-26) to measure FBD, Body Image

Anxiety (BIAS), modified to measure the concern towards the body, and Assessment Questionnaire self-esteem Evaluation to measure adolescents' self esteem, validated in this population. Weight was recorded in kilograms and height in centimeters to calculate Body Mass Index (BMI) in adolescents. A statistical analysis was performed to calculate frequencies, correlations and associations with a statistical significance $P < 0.05$, using the SPSS computer program.

Results: FBD frequency was of 10.6%, low self-esteem was found in 93.6% and 75.3% are concerned about their body. No statistically significant differences were found, although frequency was higher in women. Overweight and obesity in women were 34.5% for each and 6.9% for morbid obesity. Overweight and obesity in men were 61.1% and 11.1% respectively. Higher FBD, low self esteem and concern towards body frequencies were found in groups with overweight and morbid overweight both in men and women. No statistically significant associations were found.

Conclusions: Despite the small sample, a high risk frequency for EBD was found, in a three women to one man rate. It is necessary to continue with this line for it is a high risk group.

Key words: FBC, self esteem, body image, eat-26.

PO1710

DOUBLE BURDEN OF MALNUTRITION IN BURKINA FASO, A GENDER AND LIFE STYLE BOUND UP PROBLEM RELATED TO EDUCATION AND POVERTY

A N. Zeba¹, H. Delisle², G. Renier³

¹Institut de Recherche en Sciences de la Santé-
Direction Régionale de L'Ouest Bobo Dioulasso,
Burkina Fasso

²Département de Nutrition, Faculté de Médecine,
Université de Montréal, Montréal, Canada

³Centre Hospitalier Universitaire de Montréal,
Département de Médecine, Université de Montréal,
Montréal

Background and objectives: Evidence suggests that nutrition transition with a progressive shift in diet and lifestyle factors plays a crucial role in the increasing cardio-metabolic factors (CMRF). While CMRF are escalating in the developing countries, global and micronutrients malnutrition remain highly prevalence even among adults, portraying the double burden of malnutrition, within a population, household and even within the same individual. This study examined the relationship between nutritional deficiencies, cardio-metabolic risk factors (CMRF) with lifestyle habits in adults.

Methods: We randomly selected 330 households stratified by income tertile. In each income stratum, 110 individuals

aged 25-60y and having lived in Ouagadougou for at least six months were randomly selected, and underwent anthropometric measurements and blood sample collection. Lifestyle habits were also assessed with dietary intake computed in dietary patterns using cluster analysis.

Results: Two distinct dietary patterns were identified - 'urban' (29% of subjects) and - 'traditional' (71%). Women, low income and none educated subjects, were significantly aggregated in 'traditional' cluster whereas men, high income and more educated subjects were significantly in 'urban' cluster. Anaemic, iron and vitamin A deficient subjects were significantly more prone to have 'traditional' diet. The 'urban' cluster was characterised by a higher intake of fat, and sugar, whereas a higher intake of protein, carbohydrate and fibres was in the 'traditional'. Both patterns exhibited no difference for CMRF prevalence's. Subjects in 'traditional' diet had more active time and those in 'urban' had significantly higher sedentary time. The 'traditional' diet, poverty, female gender and sedentary time have been founded to be the most contributing factors to the double burden of malnutrition.

Conclusions: The rapid nutrition transition is reflected in this co-occurrence of CMRF and nutrition deficiencies, stressing the need for prevention strategies addressing both ends of the nutrition spectrum.

Key Words: Double nutritional burden, diet and lifestyle.

PO1711

THE KUWAIT NUTRITION SURVEILLANCE SYSTEM: AN EXAMPLE FOR OTHER COUNTRIES

M. Alsumaie¹

¹Ministry of Health, Kuwait

Background and objectives: The Kuwait Nutrition Surveillance System (KNSS) is a nation-wide Nutrition Surveillance system which was established in 1995. KNSS main aim is to provide timely data for monitoring the health and nutritional status of the Kuwaiti population. Identify the functioning of the KNSS as an example for the region.

Methods: The KNSS is designed as a sentinel data collection for "purposive" sampling. The target population covers children under 5 years old and women of child bearing age from the health centers of all the governorates. The school aged children are chosen from sentinel schools. The adult sample is chosen from the Medical Council, Public Authority for Social Security, universities and colleges. The KNSS collects information on the following indicators: weight, height, hemoglobin for all age groups, in addition cholesterol, blood glucose and data on life style including intake of fruits & vegetables, smoking and physical activity patterns for adults. Infant feeding practices data are also collected for children less than two years.

Results: The KNSS data are analyzed annually and reported to the public through media, and to stake holders at MOH who use the information for policy making, policy changes, and to help in guiding and shaping public health programs.

Conclusions: The system is simple, sustainable and tailored to the needs of the country and within the health care system. KNSS provides useful information on trends which can alert the health authorities and trigger policy changes. The KNSS can be considered as an example for the region.

Key words: Kuwait, Nutrition Surveillance, example.

PO1712

DISCREPANCY BETWEEN TWO METHODS OF A QUESTIONNAIRE TO MEASURE FOOD FREQUENCY

E. Ramos^{1,2}, E. Curiel³, A. Castro^{1,2}, A. Salinas^{1,2}, G. Nuñez^{1,2}, E. Ramírez^{1,2}

¹Universidad Autonoma de Nuevo Leon, Mexico

²Facultad de Salud Pública y Nutrición

³Maestría en Ciencias en Salud Pública

Background and objectives: The frequency questionnaire of food consumption (CFCA) is a relatively economical, fast and easy-to-apply dietary assessment tool. It allows information of the habitual consumption in the long run in large populations, used as the main instrument for the calculation of dietary intake in age groups. The CFCA, is a fragile methodological part in nutritional epidemiology based on information that reports the person memory. The hypothesis is that there is discrepancy in results in the same instrument by submitting it to two methods. Objective : Set if there is difference in the information obtained in the CFCA final when you follow up on the diet of the school in relation to that obtained for first intention (initial CFCA).

Methods: Pre experimental study, observation units were selected on the basis of invitation, were 242 CFCA applied to 121 mothers of three cities in Mexico.

Results: 108 Included food, 12 (11%) have difference in the amounts consumed ($p < 0.05$). Vegetable oil was the only one with values higher in the CFCA final ($p < 0.00$). The total number of food consumed in the CFCA final was lower ($p < 0.000$). The number of food from cereals, fruits, fats and oils and pulses was lower in the initial CFCA ($p < 0.05$). In the initial CFCA, dietary intake of carbohydrates and proteins were higher ($p < 0.05$) and lower lipids ($p < 0.05$) with respect to the final CFCA.

Key words: food, food consumption.

Findings: Dietary information obtained a CFCA is different when the mother was tracking to the diet of the school compared to that obtained for first intention.

PO1713

FOOD FREQUENCY, PHYSICAL ACTIVITY AND SEDENTARY LIFE STYLE OF OVERWEIGHT AND OBESE SAUDI YOUNG WOMEN

L. AL-Oboudi¹, H. Abuhaimed¹

¹Princess Nora Bint Abdulrahman University, Saudi Arabia

Background and objectives: Obesity is considered as epidemic health problem among Saudi women, thus it is important to determine some of the factors associated with overweight and obesity for planning the appropriate intervention to improve the health status of the community. The aim of the study was to determine the food frequency, Physical activity (FA) and sedentary life style of overweight and obese Saudi young women and its relationship to body weight status.

Methods: 182 overweight and obese (BMI > 25) Saudi young women (18-25years) completed a self report questionnaire, Physical activity (FA) was assessed using the official Arabic form of IPAQ, followed by questions about food consumption frequency per week.

Results: The study demonstrated that overweight Saudi young women do not engage in any physical activities except climbing stairs two times per week (21.1%) and house work 3 times/week (20.3%). While the most common physical activities (FA) among obese Saudi young women were walking once a week (33.3%), followed by doing house work every day (24.1%) and climbing stairs once a week (20.4%) and. Both overweight and obese Saudi young women do not eat healthy food such as fish, egg, and yogurt. They consume vegetables and fruits, sweets, juices, and fast food 2-3 times/week. Overweight Saudi young women spend 3hours watching TV or video (22.7%) and two hours using computer (21.9%) and 8 hours sleeping(24.2%). While obese Saudi young women spend 2hours watching TV or video (25.9%) and 1 hour using computer (22.2%) and 9 hours or more sleeping(25.9%).

Conclusions: The study indicated a high level of inactivity among overweight and obese Saudi young women, and low consumption of healthy food.

Key words: Food frequency, Physical activity, overweight obese, Saudi young women.

PO1714

THE GRADUATE FROM AGRICULTURE TECHNICAL COURSE AND HIS RELATIONSHIP WITH FOOD AND NUTRITION SECURITY: A WORRYING SITUATION

H. Oliveira¹, M. Ávila¹, H. Silva¹, S. Neves¹, V. Silva¹

¹Instituto Federal de Educação, Ciência e Tecnologia Do Ceará - Campus Crato, Crato, Ceará, Brazil

Background and Objectives: The Professional Agricultural Technician, among other functions, can plan and monitor all phases of agricultural development projects, administer rural properties and act in programs of technical assistance and agricultural extension next to small producers. In actions that promote Food and Nutrition Security (FNS), it is supposed to be a profession of great importance. The Brazilian government has implemented them on different axes like policies directly linked to the production and distribution of food and local development. The objective is to assess the knowledge of students Federal Institute graduated from the agriculture technical course in the perspective of professional practice with FNS.

Methods: It was applied to 101 graduates a semi-structured questionnaire whose options responses could be 'yes' or 'no and justified'. The variables analyzed were knowledge about: FNS, governmental programs related to the relationship between the profession Agricultural Technician and food security of population.

Results: The analysis showed that 45.5% of agricultural technicians trained by the institution reported had never heard about SAN. Among the 29 students (34.6%) who reported knowledge of SAN government programs, 83% exemplify them properly. For 94.1%, the profession is related to FNS. However, 61.4% of them only related FNS to Good Manufacturing Practices, to the detriment of the social and political context in Brazil. They did not show reasonable knowledge about the topic and not associated it with their professional development, reducing their potential as agents of health promotion and performers of government programs.

Conclusions: The study demonstrated the need to include discussion of political and social content of food security to reorder the curriculum and its linkage with other programmatic contents, allowing the knowledge to Agricultural Technician for the work socially engaged and promoting local development.

Key words: Food Security, Agricultural Technician; Vocational Education; Development Site.

PO1715

NUTRITIONAL STATUS AND DIETARY PATTERNS IN SCHOOLCHILDREN OF THE WAYUU ETHNIC GROUP FROM MARACAIBO, VENEZUELA

D. Villalobos¹, A.Bravo¹, M. Duque¹, T. Rincón¹, J. Puentes¹, S. Sequera¹

¹Laboratory of Research and Development in Nutrition (LIDN), University of Zulia, Venezuela

Background and objectives: Malnutrition in early childhood is an important health problem, it causing stunted growth, as well as a limited mental and physical development of schoolchildren. The aim of this study was to determine the nutritional status and dietary patterns in schoolchildren of the Wayuu ethnic group.

Methods: The study was descriptive and cross-sectional, which was evaluated a random sample of 100 children aged 6-9 years, of both genders, from a public school located in the community of Laguna "Las Peonias" in Maracaibo city, Zulia State, Venezuela. Assessment of anthropometry was performed through the combination of indicators (weight/height, height/age and weight/age), according to the WHO criteria. A dietary assessment (food frequency) was also applied. For diagnosis of socioeconomic status was used the modified Graffar method.

Results: Anthropometric analysis showed that 68% of schoolchildren had normal nutritional status, while 32% were malnourished (11% deficit and 21% excess). The frequency of consumption showed a daily intake of pasta, rice and corn flour (80%), banana (81%), sugar (92%), oils and margarine (75%) and eggs, dairy products (72%). The economic assessment showed that 82% of families were living in poverty (56% in relative poverty and 26% in extreme poverty).

Conclusions: We conclude that in this indigenous community there are a lot of social, cultural and environmental factors that adversely compromise the nutritional and feeding of the children in growing period.

Key words: Nutritional status, anthropometry, schoolchildren, Wayuu, dietary assessment.

PO1716**THE NATIONAL EVALUATION PLATFORM: A NEW WAY TO EVALUATE NUTRITION PROGRAMMING IN MALAWI**

R. Heidkamp¹, M. Kanyuka², E. Hazel¹, A. Amouzou¹, J. Bryce¹

¹Institute for International Programs, Johns Hopkins Bloomberg School of Public Health, MD, USA

²Malawi National Statistics Office, Malawi

Background and objectives: Recent global initiatives promote nationally-coordinated multi-sectorial efforts to address malnutrition at scale. Direct and indirect approaches hold promise for accelerating impact but are difficult to evaluate. IIP-JHSPH is implementing a three-year, four-country project in collaboration with in-country institutions to test the National Evaluation Platform (NEP) approach for evaluating Maternal Child Health and Nutrition programs. The NEP consolidates validated district-level data from existing cross-sector sources (e.g., census, routine information systems, surveillance, household surveys) with ongoing district-level documentation of program implementation and contextual factors. The NEP supports longitudinal assessment of multiple programs, using several analytical approaches to generate findings that support local, national and global decision making. Since 2010, IIP-JHSPH and local partners in Malawi have implemented a NEP design to evaluate the Rapid Scale-Up of Integrated Community Case Management (iCCM) programs in 17 of the country's 28 districts. We examined the feasibility of extending the NEP to incorporate nutrition-specific interventions and outcomes nationally.

Methods: We considered multiple dimensions of feasibility: 1) fit with national policy and implementation landscape; 2) availability of appropriate cross-sector data; 3) availability of valid documentation tools; and 4) data storage, accessibility, and utilization issues. Methods included document review and key informant interviews.

Results: Malawi is a Scaling Up Nutrition (SUN) country with high-level government and donor support for the NEP. Periodic nationally-representative health, nutrition, agriculture and food security surveys are available, but cross-survey indicators are not identical and require quality checks. iCCM documentation tools for community health workers can be modified for nutrition programs. The National Statistics Office is well situated to manage the NEP database.

Conclusions: The cross-sector NEP is feasible and well-suited for evaluation of multi-sectoral nutrition programs in Malawi. Lessons learned will apply to other NEP countries. Funding support: Canadian International Development Agency.

Key words: program evaluation, Scaling Up Nutrition, Malawi

PO1717**SELECTION OF FOOD IN A DINING ROOM AT UNIVERSIDAD IBEROAMERICANA, MEXICO CITY**

I. Cruz¹, C. Martínez¹, E. Escalante¹, M. Mier¹, K. Dominguez¹

¹Health Department, Universidad Iberoamericana, Mexico City, Mexico

Background and objectives: The selection of food on population groups can be characterized primarily by Genetics and culture to which belongs the group. The decisions of food choices are influenced by several factors, such as past experiences, the environment, choose habits and age (in age groups also influences the context, psychology, tastes, among others).

Methods: In order to describe food choice in one of the dining rooms at the Universidad Iberoamericana, we conducted a transversal and descriptive study of a sample of 397 users, men (60%) and women (40%). We interviewed students, teachers, administrative and service staff of both gender and different ages. We took a picture of the selected food dishes. The menu includes a choice of soup soupy, dry soup, main course with garnish, salad, fruit and/or dessert, bread and/or tortilla. Each time includes at least two options.

Results: 80% of the group selected liquid soup, 78% choose dry soup. 45% prefer rice and 33% pasta. For the main course, 25% opt for chicken; this option generally includes foods of animal origin (93%). 37% consumed beans and 55% prefer salad as garnish; the male population consumed less vegetables. 67% preferred dessert instead of fresh fruit, this is more frequent among students.

Conclusions: We found that selection of food is similar to that described in national surveys and other studies. Characterization by age, sex and working group will allow us to set appropriate interventions by taking into account the specific cultural parameters to establish sustainable actions and promote healthy lifestyle.

Key words: Food selection, preferences.

PO1718**STUDENT CONSUMPTION OF ALCOHOLIC AND ENERGY-DENSE BEVERAGES ACCORDING TO TIME OF CLASS ATTENDANCE IN A PRIVATE UNIVERSITY**

R F. Simony¹, C. Pikelaizen¹

¹Mackenzie University, Sao Paulo, Brazil

Background and objectives: Young people represent one of the largest groups of consumers of alcoholic beverages and sugary drinks, which makes the study of their patterns of con-

sumption relevant in the context of prevention of disease and older age health complications. The aim of this study was to compare potential differences in the drinking behavior of students attending morning, afternoon and evening classes and its impact on their nutritional status and macronutrient intake.

Methods: In this cross sectional study a sample of college students attending morning, afternoon and evening classes answered a questionnaire about food and beverage consumption that also included a 24-hour dietary recall. Nutritional status was determined by self-reported weight and height.

Results: Students who attended morning-only courses reported the lowest alcohol consumption. Afternoon-only students were the highest consumers of alcohol, which resulted in excessive carbohydrate intake for 73% of the group. Processed fruit juice was the most consumed beverage in all groups (37% morning and afternoon, 47% evening), followed by sodas (13% morning and 20% evening). Overweight was more prevalent among evening-only students (30%) and the highest prevalence of obesity was detected in the morning-only group (6, 7%). Both these groups presented fat intakes above the recommendations (33% evening and 27% morning).

Conclusions: Although the overall majority of the sample was normal-weight (BMI 18.5 - 24.9 kg \cdot Mm²), overweight and obesity were more frequent among the morning and evening groups, the highest consumers of fats. Carbohydrate intake in the afternoon group was greatly impacted by sugary drinks and alcohol. It is important to adopt strategies that emphasize the benefits of healthy eating and reducing the consumption of beverages with high sugar and alcohol content.

Key words: university students, food consumption, sugary drinks, alcoholic beverages.

PO1719

IMPACT OF A MULTISECTORAL PUBLIC HEALTH AGRICULTURE INTERVENTION IN A POST-EMERGENCY SETTING IN HAITI.

D. Sanou¹, Y. Philizaire², B. Arcens³, P.M. Ndoye³, J.P. Foschia⁴, M.P. Elisme⁴, E. Blain⁵, J.E. Saint Fleu⁵, E. Pauze¹, M. Batal¹, A. Yao³

³Food and Agricultural Organization, Haiti country office, Port au Prince, Haiti

⁴Medecins du Monde France – Haiti country office, Port au Prince, Haiti

⁵United Nations International Children Emergency Funds – Haiti country office, Port au Prince, Haiti

Background and objectives: Since the 2010 earthquake, several international organizations are active to providing emergency nutritional interventions, and exploring options for more sustainable food systems in Haiti. This paper reports the impact of a multisectoral intervention implemented by Food and Agricultural Organization, Medecins du Monde France and German Red Cross and aimed at improving food and nutrition security and household resilience.

Methods: The study included a quantitative knowledge attitudes and practices (KAP) survey and focus groups. The KAP survey included 529 households (intervention group = 255 and control group=274). We collected data on food security, dietary practices and dietary diversity, infant and young child feeding practices and sanitation.

Results: The intervention has strengthened operational capacity for managing malnutrition in 7 health centers, provided agricultural equipments and inputs to 1200 households, and supported 800 home gardens and 200 livestock farms. Mothers exposed to the intervention have better practice for breastfeeding and appropriate management of diarrhea. The dietary diversity score in the intervention group increases from 4.9 to 6.8. Fruit/vegetable consumption was higher in intervention group as compared to control group (86% versus 67%) but no difference was observed for animal products. Food insecurity was still highly prevalent (68%) in both groups and was still higher in intervention group. Focus group discussions suggest that overcrowding, poverty, single parent status, emigration, dependency on foreign aid created by distribution of food stamps and some food taboos were potential barriers to the program effectiveness even when the mothers gain the appropriate knowledge. The recurrence of natural disasters was also a potential treat.

Conclusions: The project highlights the possibility to combining emergency initiatives that meet the immediate nutrition

needs and development interventions that enhance the resilience capability of the more vulnerable households and provide more sustainable solutions.

Key words: food security, Haiti, public health, nutrition, emergency.

PO1720

FOR THE DEVELOPMENT OF STRATEGIES TO PREVENT THE RISE OF OBESITY IN MOROCCO

Bour¹, A F. Derouiche², Y. Kameli³, M. Holdsworth⁴, A. Gartner³, E. Landais³, S. Goumi¹, F. Delpeuch³

¹Faculty of Sciences, Ibn Tofail University, Kenitra, Morocco

²Hassan II University, Mohammedia – Casablanca, Morocco

³UMR204 NUTRIPASS, IRD, Montpellier, France

⁴SCHARR, Faculty of Medicine, Dentistry and Health, University of Sheffeld, UK

Background and objectives: policy makers in most countries are aware of the growing social and economic costs of obesity if nothing is done to change the trend. The causes are many and the answer must be multifactorial.

Objective: To explore the views of key stakeholders towards a range of public policy options to prevent obesity in Morocco using a multi-criteria mapping methodology (MCM). **Methodology:** MCM is based on a 2 to 3 hour structured interviews using MCM mapper software. Stakeholders appraised a set of pre-defined options by reference to criteria of their own choosing and provided relative weights to their criteria, and overall rankings of the policy options. Twelve public policy options were proposed for evaluation by 37 respondents from 33 sectors..

Results: The 12 options were all accepted. Behavior change through education got broad consensus. The same goes for those aiming to promote and enhance physical activity at school. Control of advertising is preferred to nutrition labeling. In each group of options, those aimed at children are preferred: curriculum and nutrition, physical activity at school, controlling advertising and marketing in schools. The performances of many options were considered dependent on education but also on a prior sensitization to the problem of obesity

Conclusions: In Morocco, obesity seems not recognized as a problem, and when it is, it is seen as a priority issue, neither of health nor for society. Advocacy with policy makers and the awareness of the population are needed with emphasis on educational measures and those for children.

Key words: Obesity, policy, policy makers, decision making, Morocco. Study funded by CORUS (France), IRD (France) and INNNTA (Tunisia)

PHYSICAL ACTIVITY AND NUTRITIONAL STATUS OF WOMEN IN PROCREATIVE AGE IN MOROCCO AND THEIR RELATIONSHIPS WITH SOCIO-DEMOGRAPHIC CHARACTERISTICS

Bour¹, O. Ayyat¹, A. Gartner², E. Landais², J. El Ati³, B. Maire², P. Traissac², H. El Hsaini¹, Y. Al Karim¹, F. Delpeuch²

¹Faculty of Sciences, Ibn Tofail University, Kenitra, Morocco

²UMR204 NUTRIPASS, Institut de Recherche pour le Développement-IRD, Montpellier, France

³Institut National de Nutrition et de Technologie Alimentaire (INNTA), Tunis, Tunisia

Background and objectives: Obesity and related chronic diseases have grown rapidly in Morocco, particularly among women. The objective is to describe patterns of physical activity (PA) and energy expenditure (EE) of urban Morocco women and relationships with socio-demographic characteristics.

Methods: A cross-sectional survey in Rabat (2009-2010) conducted on a representative sample of 895 women (20-49y). PA was assessed by validated frequency questionnaire (12 categories of PA). Body Mass Index=weight/height² defined overweight ($\geq 25\text{kg/m}^2$) and obesity ($\geq 30\text{kg/m}^2$). The management of data files and calculation of derived variables were performed using the adequate methods.

Results: Overweight affected the 2/3 of women, obesity nearly the 1/3 and abdominal obesity nearly the half. Activities that contribute to EE (kcal/d) were, in descending order: sleeping, walking, seating, light housekeeping and cooking. Low-intensity activities contributed to 57.5% of the EE; those with moderate-intensity to 21.0%, and high-intensity to 2.6%. Only 2% of women had a very inactive lifestyle; almost half of the women (45%) had a sedentary lifestyle and the third an active one. Only 14% of women had an important activity, and 3% were extremely active. The proportion of women with a higher activity among working women and in women who have a children.

Conclusions: In the study area, the duration of activities is related to certain environmental characteristics, social, cultural and family, regardless of economic status. Such results are useful to consider in the implementation of targeted and tailored to specific population groups to promote physical activity and the fight against inactivity.

Key words: Energy expenditure, obesity, sedentary, urban area, North Africa. Obe-Maghreb 6028: Study funded by CORUS (France), IRD (France) and INNNTA (Tunisia)

PO1722**PLASMATIC LEVELS OF COPPER AND ZINC, NUTRITIONAL ANTHROPOMETRY AND LIPID PROFILE IN AN INDIGENOUS POPULATION BARI FROM VENEZUELA**

N. Martínez¹, I. Túnez², A. Bravo³, T. Mesa³, S. Linares³, D. Villalobos³, Y. Hernández³

¹Nutrition Research Coordination, National Institute of Nutrition (INN), Venezuela

²Department of Biochemistry and Molecular Biology, University of Cordoba, Spain

³Laboratory of Research and Development in Nutrition (LIDN), University of Zulia, Venezuela

Background and objectives: Copper (Cu) and zinc (Zn) are essential trace elements involved in different biological functions, such as growth and development, blood cell formation, energy metabolism and immune response. The aim of this study was to establish a relationship between the plasma levels of copper and zinc with nutritional status and lipid profile in an indigenous population Bari from Venezuela.

Methods: Blood samples were collected in 90 indigenous people who live in the community Bari “Kumanda” located in the Mountains of Perija, Venezuela. The nutritional status in children was assessed by mean of combining anthropometrical indicators (weight/age, weight/height, and height/age) and by mean of the body mass index (BMI) in adolescents and adults. Plasmatic Zn and Cu were determined by flame atomic absorption spectrometry and total cholesterol (TC), triacylglycerol (TAG) and HDL cholesterol (HDL-C) by enzymatic methods.

Results: The 72.7% of Bari children presented undernutrition, in 65.2% of adolescent and adult the nutritional status was normal and 30.4% was found with overweight. Plasma levels of trace elements (mg/ml) in children were 0.32 ± 0.23 (Zn) and 0.78 ± 0.35 (Cu), while in adolescents and adults were found levels of 1.03 ± 0.17 (Zn) and 1.15 ± 0.47 (Cu). The 92.1% and 62.5% of children were deficient in Zn and Cu, respectively. In adolescents and adults the overweight was associated with higher levels of TAG and VLDL-C ($P=0.042$). Children with low plasmatic Zn were found with TAG and VLDL-C higher in comparison with those children who had normal levels of Zn ($P=0.001$), but adolescents and adults indigenous people with subnormal levels of Cu showed decreased levels of TAG, VLDL-C ($P=0.027$) and HDL-C ($P=0.017$).

Conclusions: These results demonstrate that Cu and Zn status could affect plasma lipid metabolism in different age groups of indigenous Bari.

Key words: Copper, zinc, lipid profile, nutritional anthropology, indigenous Bari.

PO1723**CONCENTRATION OF HEAVY METALS AND ESSENTIAL TRACE ELEMENTS IN SCALP HAIR OF INDIGENOUS CHILDREN BARI FROM VENEZUELA**

A. Bravo¹, Y. Hernández¹, B. Montilla², M. Colina², D. Villalobos¹, M. Duque¹, N. Martínez³, S. Linares¹, D. García¹

¹Laboratory of Research and Development in Nutrition (LIDN), University of Zulia, Venezuela

²Laboratory of Environmental Chemistry (LQA), Department of Chemistry, University of Zulia, Venezuela

³Nutrition Research Coordination, National Institute of Nutrition (INN), Venezuela

Background and objectives: Determination of some chemical elements, such as heavy metals and essential trace elements in human hair has a great value as these evaluations allow scientific knows if some groups of people have been exposed to toxic elements or have been presented nutritional deficit. The objective of this research was to determine the concentration of some heavy metals (mercury, lead, aluminum, chromium, uranium), and essential trace elements (zinc, copper, selenium, manganese) in hair samples of indigenous children Bari.

Methods: We performed a cross-sectional and analytic study, which a total of 40 scalp hair samples were collected from children (2-12 years-old) belonging to the ethnic group Bari that live in the community “Kumanda”, located at the Mountains of Perija, Venezuela. Hair samples were rinsed thoroughly with nonionic detergent and deionized water, then were mineralized in an acid medium using Parr digesters. The elemental analyses were performed by Inductively Coupled Plasma Mass Spectrometry (ICP-MS).

Results: Scalp hair samples showed the following levels (ug/g) of heavy metals: Hg 1.72 ± 2.01 , Pb 15.52 ± 14.96 , Al 70.90 ± 38.79 , Cr 3.47 ± 4.06 , U 0.32 ± 0.42 . Essential trace elements were found in the following concentrations (ug/g): Zn 107.40 ± 68.78 , Cu 6.79 ± 4.19 , Se 3.19 ± 4.34 , Mn 25.33 ± 14.21 . Values of Hg, Pb, Cr, and Al were higher than those reported in the literature for human scalp hair. A significant correlation was found between Hg and Cr content in hair samples ($r=0.923$, $p<0.001$). Zn and Cu values presented an order of magnitude lower than that reported in the literature for human scalp hair, while Se and Mn levels were higher.

Conclusions: We conclude that there is a source of exposure to heavy metals in this indigenous community, as well as a deficit of some essential trace elements in Bari children.

Key words: Heavy metals, essential trace elements, scalp hair, Bari children, ICP-MS.

PO1724**MATERNAL BMI IN MID-PREGNANCY AND INSULIN LEVELS IN OFFSPRING AT AGE 4 Y.**

Y. Gutierrez-Gomez^{1,2}, U. Ramakrishnan³, A D. Stein³, R. Martorell³, C. Aguilar⁴, I. Romieu⁵, J. Rivera¹

¹Centro de Investigación en Nutrición y Salud, Instituto Nacional de Salud Publica, Cuernavaca, Mexico

⁴Departamento de Endocrinología y Metabolismo, Instituto Nacional de Ciencias Medicas y Nutrición Salvador Zubirán, Ciudad de Mexico, Mexico

⁵Nutrition and Metabolism Section, International Agency for Research on Cancer, Lyon, France

Background and objectives: Evidence suggests that maternal prepregnancy body mass index (BMI) and gestational weight gain may be associated with cardiometabolic risk factors in offspring later in life. However, little is known about the effects of maternal BMI during pregnancy on metabolic markers in early childhood. We examined the association of maternal overweight in mid-pregnancy with markers of lipid and glucose metabolism in offspring at age 4y.

Methods: Study subjects were the offspring of women who participated in POSGRAD, a double-blind, randomized, and controlled trial in Mexico in which women were supplemented with 400 mg/d DHA or placebo from mid-pregnancy to parturition. We measured maternal weight and height at baseline (18-22 wk gestation), and classified women as overweight if their BMI > 26.0 kg/m² using a Latin American reference. We obtained non-fasting blood samples from 524 (53.9% of the birth cohort) offspring at age 4 y and analyzed these for glucose, insulin, and lipids.

Results: Prevalence of women overweight at baseline was 46.8%. In offspring, mean+ SD of the biomarkers were: total cholesterol (157.9 +25.3mg/dl), LDL-C (83.0 +21.9mg/dl), HDL-C (51.7 +10.1mg/dl), Apo B (76.9 +15.2mg/dl), triglycerides (122.1 +67.4mg/dl), glucose (93.7 +10.9mg/dl), insulin (9.7 +11.2iU/ml), and the glucose/insulin ratio (14.8 +14.2). Offspring of women who were overweight in mid-pregnancy had higher insulin levels (2.15 iU/ml; 95%CI 0.29, 4.01) and reduced glucose/insulin ratio (-2.75; 95% CI: -5.19, -0.31) compared to those born to women who were not overweight, adjusted for prenatal intervention group, fasting hours and offspring BMI. There were no significant differences in lipid and glucose levels.

Conclusions: Maternal overweight during mid-pregnancy is associated with higher insulin levels and hence, reduced glucose/insulin ratio in offspring at age 4.

Key words: pregnancy, overweight, preschool, glucose, insulin, lipid. Funded by NIH (HD043099).

PO1725**INFLUENCE OF OVERALL MEAL SENSORY CHARACTERISTICS ON SCHOOL LUNCH ACCEPTANCE**

M. Liz Martins^{1,2}, SSP. Rodrigues^{1,2}, LM. Cunha^{2,3}, A. Rocha^{1,2}

¹Faculty of Food Science and Nutrition, University of Porto, Portugal

²REQUIMTE, University of Porto, Portugal

³DGAOT, Faculty of Sciences, University of Porto, Portugal

Background and objectives: Food intake at school is an important source to nutritional daily intake. School meals sensory characteristics determine meals acceptance, influencing children food consumption. The present study aims to evaluate children's satisfaction with meal sensory characteristics and its influence on school lunch acceptance.

Methods: A stratified clustered sample of 463 fourth-grade children, aged 9 to 10 years old, chosen from 20 public primary schools in the city of Porto were evaluated. Satisfaction with school lunch in relation to overall sensory characteristics: taste; smell; appearance and temperature, was determined using a questionnaire with a 4-point scale, ranging from "dislike" to "like a lot". School lunch acceptance was assessed by plate waste measurement. Weighing of individual meals and leftovers was performed and plate waste (%) was determined based on individual food servings.

Results: Sensory characteristics of soup were less satisfying than the ones of both main dish and dessert. Boys were significantly more dissatisfied with taste, appearance and smell of the main dish than girls. Children receiving free school lunch were more satisfied with sensory characteristics of all meal components than children with partial or no financial support for school lunch. Average plate waste of soup and main dish was 21.6% and 27.5%, respectively. Assuming that served portions are balanced with children's nutritional needs, these were not being achieved. Rejection of school lunch, expressed by higher plate waste values, was negatively correlated with satisfaction towards taste, smell and appearance of soup ($r=-0.223$; $r=-0.197$; $r=-0.194$) and main dish ($r=-0.168$; $r=-0.126$; $r=-0.110$, all significant at a 99% confidence level).

Conclusions: Children dissatisfaction with school meal overall sensory characteristics was associated with lower acceptance of school lunch, pointing to the need of improving taste and appearance of meals.

Key words: children satisfaction; meal acceptance; plate waste; school lunch.

PO1726**CARDIOVASCULAR RISK IN HEALTH CARE PROVIDERS WORKING IN ROTATING SHIFTS AND DAYTIME JOBS IN THE HERMINDA MARTIN HOSPITAL, CHILLÁN, CHILE**

M. Cifuentes Muñoz¹, M. Ruiz de la Fuente¹, J. Parra Flores¹, A. Rodríguez Fernández¹

¹Departamento de Nutrición y salud Pública, Universidad del Bío-Bío, Chillán, Chile

Background and objectives: The study was carried out in the city of Chillán, Chile, and its objective was to identify the presence of cardiovascular risk factors in health care workers in the Herminda Martín Hospital in order to evaluate and compare factor prevalence, stratifying the risk of a cardiovascular event.

Methods: The sample corresponded to 138 workers, 108 in rotating shifts and 30 in daytime jobs. The Framingham Table was applied to evaluate the cardiovascular risk factors and the risk score was obtained following Framingham. Additionally, a survey was applied to determine sleep habits and alterations.

Results: Men over 45 years and post-menopause women are strongly associated to turnicity. A large percentage of both types of workers studied were overweight or obese and also had total cholesterol over 200 mg/dl. The risk score of presenting a cardiovascular event in 10 years was 2.89 ± 3.37 and 1.58 ± 1.33 for workers with rotating shifts and daytime jobs, respectively, which was significantly different. The variables that significantly predict the Framingham score for workers with rotating were: age, smoking habit, total cholesterol, HDL cholesterol, and systolic arterial pressure.

Conclusions: For workers with daytime shifts, the variables that significantly predict the Framingham score are: smoking habit, total cholesterol, systolic arterial pressure, age when began working, and years in the present job.

PO1727**EFFECTIVENESS OF A LOCALLY PRODUCED READY-TO-USE-THERAPEUTIC FOOD FOR THE TREATMENT OF CHILDREN WITH ACUTE MALNUTRITION IN VIET NAM**

T T. Nga¹, M. Nguyen², R. Mathisen³, D T B. Hoa¹, H N. Minh¹, L T. Hop¹, J. Berger², F T. Wieringa²

¹National Institute of Nutrition, Ministry of Health, Hanoi, Vietnam

²Institut de Recherche pour le Developpement (IRD), UMR204 NutriPass, IRD-UM2-UM1, Montpellier, France

³UNICEF, Hanoi, Vietnam

Background and objectives: Peanut-based Ready-To-Use-Therapeutic Foods (RUTF) were shown to have a low acceptability in SE-Asia. Therefore, a RUTF was developed in Viet Nam by NIN, IRD and UNICEF based on locally available ingredients, which showed promising acceptability and impact on nutritional status among preschool children. The present study assessed the effectiveness of this RUTF on weight gain and recovery rates in children with acute malnutrition using the RUTF in a home-based treatment program.

Methods: Community-based, randomized intervention trial with a local RUTF (LOC) and a standard available RUTF (STD) in 150 children, aged 6–59 months, with acute malnutrition, enrolled in a home-based treatment program in Kon Tum province in Central Vietnam.

Results: After 8 weeks intervention, nutritional status of all children was significantly improved ($p < 0.001$). Mean weight gain was higher for STD group than LOC group, with increments in WHZ of $+1.04 (\pm 0.97)$ and $+0.69 (\pm 1.01)$ respectively ($p = 0.04$). Height also improved significantly and was not different between the groups, with a mean increase of $27.1 (\pm 28.8)$ mm after 8 weeks, resulting in a mean increase in HAZ-scores of $0.43 (\pm 0.99)$. The recovery rate from acute malnutrition with RUTF as home-based treatment was 70.8%, and not different between the 2 interventions. Acceptance (taste and palatability) of the LOC tended to be higher than of the STD.

Conclusions: LOC was effective in the treatment of severe acute malnutrition, and can be used successfully in Integrated Management of Acute Malnutrition programs (IMAM). This study also suggests that IMAM with RUTF can have a positive impact on height of wasted children, including those above 2 years of age. The study supports the current efforts in Viet Nam to include IMAM and therapeutic foods into the National Targeted Program and National Health Insurance scheme.

Key words: children, malnutrition, RUTF, IMAM

PO1728**REFERENCE VALUES OF URINARY HYDRATION BIOMARKERS OF MEN AND WOMEN**

D. Bougatsas¹, S. Kavouras^{1,2}, A. Hasanou¹, K. Manolopoulou¹, D. Panagiotakos¹

¹Department of Nutrition and Dietetics, Harokopio University, Athens, Greece

²Department of Health, Human Performance and Recreation, University of Arkansas, USA

Background and objectives: Reference values for hydration status are not well established either in men or women, as there are few publications that have addressed the issue.

Methods: 341 apparently healthy Greek women (n=141, age: 45 ± 14.4y, mass: 70.7 ± 16.1kg, height: 1.62 ± 0.06m, BMI: 26.6 ± 5.9kg/m²) and men (n=200, 47.2 ± 13.5 y, mass: 86.8 ± 14.8 kg, height: 1.76 ± 0.07 m, BMI: 27.8 ± 4.2 kg/m²) provided first morning urine sample which was analyzed for urine color (Ucol) with the use of the eight-point scale, urine specific gravity (USG) and urine osmolality (Uosm). Volunteers also completed a food frequency questionnaire with the help of a trained investigator. Urine Samples were not received while women were on menstruation.

Results: Means and 95% confidence intervals Uosm, Ucol, USG, water consumption and water intake per kg of body weight were 640 mOsm/kg (596-685), 2.8 (2.6-3), 1.018 (1.017-1.019), 1376 ml (1263-1490) and 20.3 ml/kg (18.5-22.2) for women and 734 mOsm/kg (699-768), 3.1 (2.9-3.2), 1.020 (1.019-1.021), 1456 ml (1353-1559) and 17.0 ml/kg (15.8-18.2) for men, respectively.

Conclusions: These data provide reference values derived from various urinary hydration markers that can be used by dietitians, nutritionists, and clinicians in order to provide guidelines for men and women regarding their hydration status.

Key words: Hydration Markers, Urinary, Reference Values

PO1729**REFERENCE VALUES FOR HYDRATION BIOMARKERS OF CHILDREN 8-14 YEARS**

S. Kavouras¹, D. Bougatsas², G. Arnaoutis², E. Perrier³, L. Armstrong⁴, S. Tsipouridi²

¹Department of Health, Human Performance and Recreation, University of Arkansas, USA

²Department Nutrition and Dietetics, Harokopio University, Athens, Greece

³Danone Research, Palaiseau, France

⁴Department of Kinesiology, University of Connecticut, USA

Background and objectives: Reference values for hydration markers do not exist in children. Also there is a lack of studies describing drinking habits of children.

Methods: 152 Greek healthy boys and girls (29 girls, 8-10 y (G8-10); 36 girls, 11-14y (G11-14); 41 boys, 8-10 y (B8-10); and 46 boys, 11-14 y (B11-14)) were asked to collect their urine for 24 hours while conducting normal daily activities. They were also instructed to record the fluids they consumed in a diary specially designed for children, for two consecutive days. Urine samples were analyzed for color (Ucol) via an eight-point scale, urine specific gravity (USG) via refractometry, and urine osmolality (Uosm) via a freezing point depression osmometry.

Results: Means and 95% confidence intervals for TBW, Uosm, USG, Ucol, total fluid consumption and water consumption were for G8-10: 21.2 L (23.1-19.3), 647 mOsm/kg (727-567), 1.018 (1.02-1.015), 2.8 (3-2), 1432 mL (1644-1219) and 976 mL (1178-774); for G11-14: 27.2 L (28.5-25.9), 615 mOsm/kg (680-549), 1.016 (1, 018-1.015), 2.6 (3-2), 1918 mL (2139-1697) and 1197 mL (1392-1003); for B8-10: 21.7 L (23.5-20.6), 686 mOsm/kg (757-615), 1.018 (1.02-1.017), 2.9 (3-2), 1586 mL (1766-1407) and 972 mL (1153-792); for B11-14: 30.8 L (32.3-29.2), 791 mOsm/kg (864-718), 1.020 (1.022-1.019), 3.3 (4-3), 1964 mL (2219-1710) and 1296 mL (1519-1073).

Conclusions: These data provide reference values for children aged 8-14 years, derived from 24-h fluid intake and urinary hydration markers.

Key Words: Reference Values, Children, Hydration Markers

PO1730**ADDRESSING THE CAUSES OF UNDERACHIEVEMENT OF USI AND IDD ELIMINATION IN COUNTRIES WITH IDD-FREE STATUS: LESSONS FROM IRAN**

M. Daniali¹, E. Girerd-Barclay²

¹School of Population Health - University of Queensland, Brisbane, Queensland, Australia

²Humanitarian Section, International Department, Save The Children Sweden, Stockholm, Sweden

Background and objectives: Iodine deficiency is the most important preventable cause of impaired brain development and subsequent mental retardation. While Universal salt iodisation (USI) has proven to be successful in eliminating IDD, if monitoring fails or iodised salt processes, distribution and consumption are inadequate, IDD may re-occur. In 2000, Iran achieved IDD-free status, with a total goiter prevalence of 6.5%. Two decades later, a goiter prevalence of >10% and decrease in median urinary iodine values were observed among school children in five provinces. The study sought to identify the causes of persisting pockets of IDD in Iran, and to formulate feasible solutions.

Methods: A literature review and case study were carried out in 2010, including the compilation and analysis of existing empirical data from 1989-2007, provided by Iran's Ministry of Health, an analysis of Iran's IDD and Iodised Salt policy documents, and semi-structured interviews with IDD/USI experts.

Results: Inconsistent training for health workers has resulted in wide variations in IDD assessment capacity. Inadequate public knowledge about iodized salt, and its proper storage and use is widespread in areas with the highest goiter prevalence. The absence of a quality assurance system and production of low quality iodized salt in some provinces contribute to underachievement of IDD elimination.

Conclusions: To address persisting pockets of IDD in Iran, quality assurance and public awareness of IDD and USI must be improved. In addition to social and behaviour change communication (SBCC), improved monitoring of IDD status, enhanced quality assurance of iodized salt, and establishing a system to ensure the sustainability of the iodized salt programme are needed. Recommendations may serve as lessons for any country achieving IDD free status, yet experiencing high levels of IDD amongst limited population groups.

Key words: USI Underachievement, Quality Assurance, Sustainability.

PO1731**OVERWEIGHT AND OBESITY, AN INCREASING PROBLEM IN LIMA, PERÚ; THE NUTRIMOVIL PROGRAM**

M R. Liria¹, M. Abad¹, K. Meza¹, H M. Creed-Kanashiro¹

¹Instituto de Investigación Nutricional, La Molina, Lima, Perú

Background and objectives: Overweight and obesity are public health problems worldwide. Peru continues to have problems of stunting and anemia but now also has high rates of overweight and obesity. This study evaluated the prevalence of overweight and obesity in a population served by the Nutrimovil program in Lima and Callao during 2004-2008.

Methods: Since 2004, Nestlé Perú has implemented the Nutrimovil programme (an itinerant nutrition service). Nutritional status was measured in 64,470 subjects at 4 cross-sectional time points (2004-5; 2005-6; 2006-7; 2008). Nutritional status for subjects under 19 years was classified according to Z-scores of the WHO 2006 reference data: undernutrition <-2sd; normal 2 to 1.49sd; overweight 1.5 to 1.99sd and obesity > 2sd. For adults (19 to 59 years) nutritional status was classified as: underweight BMI <18.5; normal 18.5 to 24.9; overweight 25 to 29.9 and obesity > 30 and in the elderly (> 60 years) underweight BMI < 23; normal 23 to 27.9; overweight 28 to 31.9 and obesity > 32.

Results: The prevalence of overweight and obesity increased significantly in all age groups: under 2 years: from 24.9% to 35.7%; 2 to 5 years: from 14.8% to 26.0%; 5 to 9 years: 21.8% to 30.1%; 10 to 18 years: from 15.7% to 22.2%; adult men: from 47.4% to 60.0%, adult women: from 52.8% to 63.2%: elderly men: from 23.1% to 39.4% and elderly women: from 39.8% to 45.9%.

Conclusions: Overweight and obesity has increased in Lima and Callao by 7-11 percentage points per year in subjects under 19 years and by 6-16 percentage points in adults. The causes of overweight and obesity in this population need to be studied in order to develop public health strategies to prevent and reduce this problem.

Key words: Overweight, obesity, Peru Financial support: Nestle Peru.

PO1732**PERINATAL AND POSTNATAL ANTIOXIDANT NUTRITIONAL STATUS INFLUENCE ATOPIC DERMATITIS IN 3-YEAR-OLD CHILDREN***S O. Kwon¹, H.S. Park², J.Y. Jung¹, S Y. Oh¹*¹Department of Food and Nutrition, Kyung Hee University, Seoul, Korea²Department of Preventive Medicine, School of Medicine, Ewha Medical Research Center, Ewha Womans University, Seoul, Korea

Background and objectives : Perinatal and early life dietary factors may induce atopic dermatitis. We examined the role of perinatal and postnatal antioxidant nutrition on the risk of atopic dermatitis (AD) in Korean children at 3 years.

Methods: Our 311 participants were the 3 year old children with mother-child pair data in our prospective study. We assessed the perinatal antioxidant nutrition by maternal blood antioxidant levels during pregnancy and the postnatal nutrition by the dietary intake of the children at 3 years. Maternal antioxidant biomarkers (retinol, α -tocopherol, β -carotene, and vitamin C) were measured at 26 months of pregnancy. For children, atopic dermatitis was assessed by the ISSAC questionnaire and dietary intake by 2-day 24-hour recalls. Results : After controlling for potential confounders, maternal antioxidants such as blood α -tocopherol and retinol were inversely associated with the risk of AD in children at 3 years. Perinatal urinary MDA levels and postnatal antioxidant nutrient intakes (vitamin A [OR=0.36, 95% CI=0.18-0.72], retinol [OR=0.40, 95% CI=0.21-0.81], vitamin C [OR=0.43, 95% CI= 0.21-0.86]) had positive and negative relationships regarding the AD risk of our children, respectively.

Conclusions: In conclusion, the results from our cohort study provide the evidence that perinatal and postnatal antioxidant nutritional status play a role as predictors of atopic dermatitis in early childhood.

Key words: atopic dermatitis, antioxidants, ISSAC, pregnancy, children, oxidative stress

PO1733**EFFECTS OF 'TAKE SPORTS ONE HOUR A DAY' POLICY IMPLEMENTATION IN CHINESE STUDENTS***J.J. Li¹, M. Yang¹, L. Wang¹, L B. Li¹*¹Institute of Child & Adolescent Health, School of Public Health, Peking University Health Science Center, Beijing, China

Background and objectives: A national physical activity (PA) promoting policy was issued by the Chinese government

in 2007 for encouraging students to take at least one hour of intensive physical activity in each school day. The aim of this study was to evaluate the effects of the policy in PA participation and changes in body mass index (BMI) in Chinese students.

Methods: 1) 3211 students in grade 4 to 12 were selected using a randomized clustered sampling method from urban and rural areas of Beijing, Liaoning and Guizhou provinces in China from 2007 to 2009. Data relating PA participation were collected by using a self-filling questionnaire. Logistic regression was used for identifying potential risk factors. 2) Three national data sets (in 2000, 2005 and 2010) were used for assessing BMI changes before and after the policy implementation.

Results: 1) About 53.8% of urban and 45.2% of rural participants met the national recommendation for physical activity (one hour a day). ($p < 0.05$) 54.8% of boys and 34.3% of girls met the recommendation. Students met the recommendation in primary school, middle school and high school were 60.2%, 50.8%, 32.7%, respectively. ($p < 0.05$) Logistic regression analysis showed that girls (OR, 95% Confidential Interval: 1.83, 1.57-2.13, $p = 0.00$), higher age groups (2.13, 1.93-2.35, $p = 0.00$), and higher SES (1.42, 1.33-1.50, $p = 0.00$) were the independent risk factors for less PA participation. 2) Average BMI increase in 6-22-year boys were 0.3 kg/m² and 0.4 kg/m² before and after the policy implementation. And the BMI increase was curbed in 6-22-girls (0.2 kg/m² in both of the two durations).

Conclusions: Gender, age, and family SES affected PA participation in Chinese students. PA promoting policy is effective in curbing BMI increase.

Key Words: physical activity, policy intervention, Chinese student.

PO1734**HEALTH BENEFITS OF WHOLEGRAIN – A SYSTEMATIC REVIEW OF THE SCIENTIFIC EVIDENCE TO PROPOSE A DAILY INTAKE***A. Chanson-Rollé¹, J. Lappi², A. Meynier³, K. Poutanen^{3,4}, S. Vinoy³, V. Azais-Braesco¹*¹VAB-Nutrition, Clermont-Ferrand, France²Dpt Clinical Nutrition, University Eastern Finland, Kuopio, Finland³Nutrition Research, Mondelez France, Saclay, France⁴VTT, Kuopio, Finland

Background and objectives: Recommendation to include wholegrain (WG) in the daily diet is widespread but is rarely quantitative. This work attempts to systematically review the published human studies to identify the daily intake of WG associated to favorable health outcomes.

Methods: Highest caution was put in confirming the nature and the amount of WG and WG food in each study. Overall mortality, obesity, cardiovascular diseases, type-2 diabetes and associated risk factors to both were the considered health outcomes. Databases were searched from 1993 to 2012 and the retrieved papers were screened independently by two trained nutrition PhD. The lowest amount of WG intake associated to an effect for each considered health outcome was determined in each relevant study.

Results: More than 2200 papers were retrieved by the initial search and less than 100 were fulfilling all selection criteria. Most studies, especially the ones on prospective cohorts, concerned US populations who consume low amounts of WG. Intervention studies usually focus on a specific cereal, test only one daily dose for a limited duration and consider risk factors rather than final outcomes; they were used as supporting evidence. Observation studies do not distinguish between the cereal types that constitute WG and consider the whole range of intakes across the population. These studies seem more relevant to identify potential effective doses. There is evidence of a favorable effect for each one of the considered health outcome, while the lowest WG intake needed varies across effects.

Conclusions: Reviewing systematically the data relating WG intake amounts to favorable health outcomes is a prerequisite for a quantitative recommendation of use. Taken the existing evidence, it is important to continue developing whole grain foods, and communicating about their use. For this, estimates about effective doses are important.

Key words: Wholegrain, dietary intake recommendation, mortality, cardiovascular health, type-2 diabetes.

PO1735

PREVALENCE OF OVERWEIGHT AND OBESITY, AND STATUS OF CHRONIC NON-COMMUNICABLE DISEASES AND SOME RELATED RISK FACTORS AMONG EGYPTIAN ADOLESCENTS

N. Aboul Ella¹, D. Shehab¹, M. Ismail¹

¹National Nutrition Institute, Cairo, Egypt

Background and objectives: The prevalence of obesity has been steadily increasing; and the number of obese children has nearly tripled and is more likely to have risk factors for cardiovascular disease, such as type 2 diabetes high cholesterol or high blood pressure. Research objectives were to study the current prevalence of overweight and obesity among adolescents in Egypt from 2000 to 2008, to estimate the prevalence of glucose disorders, hypertension, lipid profile, and metabolic syndrome, and to investigate some related risk factors among 10 to 18 years old school adolescents.

Methods: For assessing prevalence rates of overweight and obesity among adolescents, data from reports of other cross-

sectional studies carried out by National Nutrition Institute (2000 to 2005) and Egypt Demographic and Health Survey (2008) were compared. To estimate the prevalence of glucose disorders, hypertension, lipid profile, and metabolic syndrome, a randomized stratified cluster-sample of preparatory and secondary school students was used. Body mass index was calculated and referred to corresponding international reference values for age and sex. A fasting blood sample was drawn to assess lipid profile and fasting plasma insulin.

Results: Overweight and obesity are prevalent among Egyptian adolescents of both sexes, and at least, for girls, the prevalence has increased in the last few years. Pre-diabetic state was present among 16.4% of adolescents. The crude prevalence of hypertension is 1.4%. The overall proportion of adolescents with high total cholesterol is 6.0%; the proportion with high lower density lipoprotein is 7.5%, with high triglycerides of 8.2%, and low higher density lipoprotein of 9.4%.

Conclusions: overweight and obesity, type 2 diabetes mellitus, hypertension and cardiovascular risk factors in young are serious in terms of morbidity and mortality, suggesting that they are an appropriate target for screening.

Key words: Prevalence, overweight and obesity, chronic non-communicable diseases, Egyptian adolescents.

PO1736

INFLUENCE OF SELECTED FACTORS ON FRAILTY SYNDROME AMONG THE ELDERLY: A PILOT STUDY

K. Rolf¹, B. Pietruszka¹

¹Department of Human Nutrition, Warsaw University of Life Sciences WULS-SGGW, Poland

Background and objectives: Elderly people are at high risk of malnutrition due to physical, social, and medical factors. Nutrients deficiency can cause health problems, including frailty; and frailty is responsible for a higher number of falls, hospitalization and mortality. Moreover, frailty may develop other risk factors, which in turn may cause malnutrition. The aim of the pilot study was to evaluate the relationships between the frailty status and selected health and nutritional factors in a group of elderly people.

Methods: The study was conducted among 77 community-dwelling elderly people (age 59-96; 51 women, 26 men) from Warsaw, Poland. All data were collected by questionnaires. The frailty status was assessed according to Fried et al. (2001) criteria and the nutritional risk was identified using the Dietary Screening Tool (DST) (Bailey et al, 2009). A Chi2 analysis was performed to examine significant associations, with the p value set at $\alpha=0.05$.

Results: The majority of the subjects were categorized as either pre- or non-frail (88% in total), and as being at nutri-

tional risk (over 66%). No statistically significant relationship between frailty and nutritional risk was observed. However, non-users of supplements were at higher nutritional risk than supplements users and women were at higher risk than men as far as nutritional risk is concerned. Statistically significant relationships were found between frailty syndrome and marital status, physical activity level and self-reported health status (those living alone, with low physical activity and worse health status were frail more often).

Conclusions: There was a stronger relationship between frailty and health factors than between frailty and nutritional risk. Moreover we conclude that further research is needed and other methods for identifying persons with nutritional risk should be applied to allow for better differentiation between those with frailty and other subjects.

Key words: elderly, frailty, nutritional risk, lifestyle.

PO1737

SOCIO-DEMOGRAPHIC DETERMINANTS OF CHILD MALNUTRITION IN NORTHERN GHANA

M N. Adokiya², A K. Edusei¹

¹Institute of Public Health, University of Heidelberg, Germany

²Department of Allied Health Sciences, School of Medicine and Health Sciences, University for Development Studies, Box TL 1350 Tamale, Ghana

³Kwame Nkrumah University of Science and Technology, School of Medical Sciences, Department of Community Health, Kumasi, Ashanti Region, Ghana

Background and Objectives: Malnutrition remains a major public health problem particularly in developing regions such as sub-Saharan Africa. The first two years of life offers an opportunity for preventing child malnutrition. In inadequacies of nutrition, children are susceptible to frequent illness and other diseases leading to death. The objective was to determine child malnutrition prevalence and the relationship to socio-demographic determinants in northern Ghana.

Methods: A cross-sectional descriptive study was conducted in northern Ghana among 380 mothers with young children (6-23 months of age) in 20 communities (19 children per community). The participants were selected randomly using the Navrongo Health and Demographic Surveillance System. The data was analyzed using Stata12 version to determine the levels of stunting, underweight, and wasting, maternal malnutrition and its associated socio-demographic determinants.

Results: Child undernutrition was (15.26% underweight, 15.53% stunting and 8.42% wasting). Prevalence of malnutrition was found to be highest among the aged group 12-17 months: underweight (50.00%, OR=4.69, CI=1.58-13.93 and

P=0.005), stunting (44.07%, OR=17.27, CI=2.29-129.95 and P=0.006) and wasting (53.13%, OR=4.68, CI=1.05-20.90 and P=0.043). Maternal malnutrition: underweight 39 (10.26%), overweight 47 (12.37%) and obese 9(2.37%). The study also found the following determinants to be associated with child underweight (mothers age p=0.040, mother's weight p=0.000, and mother's height p=0.031), stunting (mother's weight p=0.000, and mother's height p=0.001) and wasting (mother's age p=0.050, number of children per woman p=0.002 and mother's weight p=0.000) using regression.

Conclusions: The study found high prevalence of child undernutrition with increasing age. The findings also depict the presence of underweight and overweight among the mother. The socio-demographic factors independently associated with child undernutrition included sex of child, age of child, number of children per woman, education, ethnicity, mother's age, present breastfeeding status, maternal height, maternal weight and religious denomination.

Key words: Malnutrition, sex, child, ethnicity, maternal.

PO1738

DIETARY SODIUM INTAKE AMONG TURKISH ADULTS

Z. Buyuktuncer-Demirel¹, M. Kizil¹, B. Aksoy¹, N. Rakioglu¹, G. Samur¹, E. Yildiz¹, S. Mercanligil¹, A. Ayaz¹, G. Pekcan¹, H. Gokmen-Ozel¹, G. Ersoy¹, M. Aksoy¹, H T. Besler¹

¹Department of Nutrition and Dietetics, Faculty of Health Sciences, Hacettepe University, Ankara, Turkey

Background and Objectives: Reducing dietary sodium intake has been recommended by health authorities in order to prevent chronic diseases such as hypertension, cardiovascular disease and some cancer types. SALTURK study, conducted on Turkish population, showed that daily salt intake was 18 g, and recommended to promote national health strategies for reducing daily sodium intake. Detailed information on the main food sources of dietary sodium was necessary in the process of developing national strategies. Therefore, this study aimed to obtain the major sources of dietary sodium in Turkish population.

Methods: In a cross-sectional, population based survey, 2965 subjects (1231 male, 1734 female), aged 19-64 years, living in Ankara, Turkey were enrolled. Dietary sodium intake was investigated using a food frequency questionnaire which examined the consumption frequency and amount of 55 sodium-rich food items in the last four weeks. Table salt consumption was not assessed, only, participants were asked whether they add salt at the table or not.

Results: Dietary sodium intakes from food sources were skewed, with a median intake of 2785 mg/d and 5th-95th percentile range of 1396-5775 mg/d. A significant difference was obtained between males (3163 mg) and females (2559 mg) in terms of daily sodium intake ($p < 0.001$). The food sources providing the highest amount of sodium were bread and bakery products (34%), dairy products (25%), olives and pickles (15%), meat and meat products (6%), ready-to-eat foods (5%) and sauces (5%). In addition to food sources, 57.5% of the participants stated that they add salt to their meals at table.

Conclusions: In terms of reducing dietary sodium intake, consumers should pay attention to the hidden food sources of sodium such as bread and bakery products, and dairy products, in particular cheeses, as much as table salt.

Key Words: sodium, food sources, Turkish diet.

PO1739

AN AUDIT OF VENDING MACHINES IN PUBLIC PLACES IN REGIONAL NSW, AUSTRALIA

V. Flood¹, A. Carrad¹, A. Alshukri¹, J. Louie¹, B. Kelly², H. Yeatman¹, L. Tapsel¹

¹School of Health Sciences, University of Wollongong, Wollongong, NSW, Australia

²School of Molecular Biosciences, University of Sydney, Sydney, NSW, Australia

Background and objectives: Vending machines are widespread in public spaces, providing ready access to predominantly high-energy food and beverages. This study aimed to describe the type and frequency of foods available in vending machines in selected public spaces in regional NSW.

Methods: A quantitative audit of vending machines in Wollongong Hospital, University of Wollongong campuses, and surrounding suburbs was completed using a survey tool adapted from a similar audit of train station platforms in NSW. Information on the type of and cost of food and drink products available, and signage on the exterior of machines was collected. Healthy food items were defined as those with less than 600 kJ per serve, and healthy beverages as those with less than 300 kJ per serve.

Results: Wollongong Hospital contained 21 vending machines with 498 occupied slots for food or beverages. Among the 498 slots, 48.2% were beverages and 51.8% were snack foods. Among the beverage items, 71.8% were classified as healthy beverages; and among the snack foods, 49.6% were classified as healthy. On UOW campuses and 6 surrounding suburbs, 55 vending machines were identified. Among the 1662 slots, 61.8% of slots were beverages, and 38.2% were snack foods. Among the beverage items, 39.2% were classified as healthy beverages (mostly water); and among the snack foods, only 3.4%

were classified as healthy snack foods (most unhealthy snack foods were chips, chocolate and confectionary).

Conclusions: Vending machines in public places may cumulatively contribute to excess energy consumption and poor diet quality as many available items are energy dense and nutrient poor. Interventions are required in public places to improve the public's access to healthy food and beverages.

Key words: food environment, food availability, food promotion, vending machines.

PO1740

USING LOCAL FOODS TO MEET NUTRIENT REQUIREMENTS OF 6-23 MONTH OLD INFANTS IN DEVELOPING COUNTRIES: A REVIEW OF THE EVIDENCE

S J M. Osendarp^{1,2}, E. Klassen¹, M J. van Liere², L M. Neufeld¹

¹The Micronutrient Initiative, Ottawa, Canada

²Global Alliance for Improved Nutrition (GAIN), Geneva, Switzerland

Background and objectives: The WHO recommends that energy and nutrient dense complementary foods be introduced to all infants at age 6 months with an emphasis on the use of suitable locally available foods. However, there is debate whether 6-23 mo children will be able to obtain all of their nutrient requirements from local foods. Several studies have addressed this question using modeling techniques. We performed a review of the evidence to address the question whether the macro- and micro-nutrient requirements of infants and young children can be met with local foods.

Methods: Studies were identified using Scopus, by crosschecking referenced articles and through local contacts in the MI and GAIN program countries. Criteria for inclusion were (1) features locally available foods and nutrient requirements, (2) observational or controlled interventions, (3) age range of 6-23 months, (4) in Africa, Asia, or Latin America, (5) from 2007 to 2012. Relevant studies and reports were reviewed by 2 independent reviewers. A total of 32 of these met all of the inclusion criteria.

Results: Overall, the results indicate that it is possible to meet most of the nutritional needs of older infants and young children with low-cost locally available complementary foods, if provided in the correct quantities and if animal-source foods are included as part of the daily diet. However, there are important exceptions for critical micronutrients (iron, zinc, calcium, folate, vitamin A) and perhaps essential fatty acids.

Conclusions: This review confirms the difficulty of meeting all of the nutritional needs of 6-23 mo old children with local foods alone. In addition, in many settings the ingredients nee-

ded to ensure that complementary foods are rich in micronutrients may not be accessible or affordable to the local population, stressing the need for additional cost-effective strategies.

Key words: complementary foods, local foods, nutrient requirements

PO1741

SYSTEMATIC REVIEW OF OBSERVATIONAL STUDIES WITH DOSE-RESPONSE META-ANALYSIS BETWEEN FOLATE INTAKE AND FOLATE STATUS MARKERS IN ADULTS AND ELDERLY

R. Novakovic^{1,2}, D. Ristic-Medic¹, M. Nikolic¹, O W. Souwerein², A. Geelen², C. Dullemeijer², H. McNulty³, M. Duffy³, L. Hoey³, M. Gurinovic¹, M. Glibetic¹, L. de Groot², P. van't Veer²

¹Centre of Research Excellence in Nutrition and Metabolism, Institute for Medical Research University of Belgrade, Serbia

²Division of Human Nutrition, Wageningen University and Research Centre, Wageningen, The Netherlands

³Northern Ireland Centre for Food and Health, School of Biomedical Sciences, University of Ulster, Coleraine, Northern Ireland, UK

Background and objectives: Dietary reference values for folate intake vary widely across Europe. Data from observational studies on the association between folate intake and biomarkers of folate status (plasma folate, erythrocyte folate and homocysteine) provide estimates of a dose-response relationship which can be used to derive folate intake reference values.

Methods: A systematic review was conducted on prospective cohort, nested case-control and cross-sectional studies in healthy adult and elderly populations which provided data on folate intake and biomarkers of folate status. An intake-status regression coefficient (r) was calculated for each individual study and the overall pooled x and SE established using random effects meta-analysis on a double log scale.

Results: Based on the data from 18 studies, the pooled dose-response relationship between folate intake and biomarkers of folate status showed that for every doubling of folate intake there was an increase in serum/plasma folate by 26%, erythrocyte folate by 21%, and a decrease in homocysteine by 17%.

Conclusions: These findings, combined with data obtained from randomized controlled trials may aid in setting folate intake recommendations as a basis for nutrition policies.

Key words: folate intake-status; dose-response; dietary recommendations. Acknowledgements: The work reported herein has been carried out within the EURRECA Network

of Excellence (<http://www.eurreca.org>), which is financially supported by the Commission of the European Communities, specific Research, Technology and Development (RTD) Programme Quality of Life and Management of Living Resources, within the Sixth Framework Programme, project no. FP6 036196-2. This report does not necessarily reflect the Commission's views or its future policy in this area. FUNDING FOR DISTRICT-LED NUTRITION ACTIVITIES IN TANZANIA: BASELINE SCALING UP NUTRITION DATA

T. Mkumbwa¹, M. Benjamin¹, R. Stevenson², G. Mulokozi³, C. Nyhus Dhillon¹

¹Helen Keller International Tanzania, Tanzania

²USAID Tanzania, Tanzania

³Tanzania Food and Nutrition Center, Tanzania

Background and objectives: Malnutrition is a major problem in Tanzania, where 42% of children under five are stunted, and 8 in 10 infants and 6 in 10 <5s are anemic. District health sector budget guidelines (in decentralized Tanzania) have not had a specific budget lines for nutrition to facilitate allocation of funds for district-led nutrition. In an effort to scale up nutrition in Tanzania, the government in 2011 created a budget line for nutrition and instructed all districts to ensure nutrition is integrated into district health budgets. Objective: To determine funding allocations for the district-led nutrition activities in Tanzania in 2010/2011, as a baseline for scaling up nutrition activities.

Methods: District health budgets (FY 2010/11) from all 133 mainland Tanzania districts were reviewed and allocations for nutrition activities were recorded in an excel-based data collection tool designed to systematically collect nutrition activities, their budget allocation and funding source.

Results: Only 12 independent nutrition activities were identified in the budgets across the 133 districts in the country. Remarkably, funding for the twice yearly VASD (Vitamin A Supplementation and Deworming) events were allocated by all districts. In 123 districts (92.5%), no additional nutrition activities were budgeted. Infant feeding was the second largest nutrition activity, budgeted by 10 districts (7.5%), followed by screening for and management of severe acute malnutrition and purchase of iron and folic acid tablets in 9 districts each (6.8%).

Conclusions: Districts have shown efforts in allocating funds for VASD, although there are inconsistencies of implementation budgets across and within district budgets. Other nutrition activities, however, are not being budgeted at scale in the country. Guidance on identification of specific nutrition

activities, as well as tools for planning and budgeting for nutrition activities is still heavily needed in Tanzania.

Key words: District budget, nutrition funding, vitamin A supplementation and deworming, scaling up nutrition.

PO1744

RELATIONSHIP BETWEEN CARDIORESPIRATORY FITNESS, PHYSICAL ACTIVITY AND NUTRITIONAL STATUS IN CHILEAN SCHOLARS

J. Soto^{1,2}, M. Cano^{1,3}, A. White¹, F. López², M. San Martín², V. Reyes²

¹Laboratorio de Ciencias de la Actividad Física, Programa de Fisiología, Facultad de Medicina, Universidad de Chile, Chile

²Laboratorio de Ciencias de la Actividad Física, Departamento de Educación Física, Universidad de Playa Ancha, Chile

³Escuela de Kinesiología, Facultad de Medicina Universidad de Chile, Chile

Background and objectives: In children has been observed that there is a negative association between aerobic capacity (as a biological predictor of morbidity) with obesity, insulin resistance, dyslipidemia and metabolic syndrome. Because a lower aerobic capacity is related to a sedentary behaviour, obesity can be considered a risk factor for cardiovascular disease at early age. The aim of this work is to study the relationship between cardiorespiratory fitness, physical activity and nutritional status in Chilean scholars.

Methods: In representative sample of public schools of 213 children (including 154 girls), between 12 and 13 years old was determined its cardiorespiratory fitness through EUROFIT 20 m shuttle run test, its nutritional status by BMI, according the Chilean recommendation and its physical activity was estimated by a validated questionnaire for Chilean children. The statistical software SPSS 20.0 was used.

Results: we found that prevalence overweight or obesity was the 78% and 65.7% as a lower performance in the cardiorespiratory fitness (all: 26.05 +/- 1.69; boys 26.7 +/- 3.1 and girls: 25.7 +/- 0.16 mlO₂/kg/min, P <0.001), physical activity (all: 4.77 +/- 1.32 boys: 5.19 +/- 1.3 and girls: 4.61 +/- 1.3 points P <0.001). Nutritional status was associated with cardiorespiratory fitness (P <0.001) and physical activity (P <0.001).

Conclusions: the results of cardiorespiratory fitness and physical activity are lower than international investigations, but de level of overweight and obese are majors than others

country and its relation with nutritional status on paediatrics populations is a big public health in the present on Chile, is urgently needed, physical activity interventions in schools.

Key words: Children, Cardiorespiratory fitness, overweight, obesity, physical activity.

PO1745

QUALITY OF CARBOHYDRATES OF FOODS BEING ADVERTISED TO CHILDREN ON CHILEAN TV

C. González¹

¹Departamento de Nutrición y Alimentos, Facultad de Farmacia, Universidad de Valparaíso, Chile

Background and objectives: The evidence shows that quality and type of carbohydrates of food, Glycemic Index (GI), Glycemic Load (GL), sucrose and fructose are possibly related to childhood obesity. These foods are widely offered to children on television advertising.

Objetives: Analyze the quality of carbohydrates in foods advertised to children through Chilean television.

Methodology: This descriptive research has a cross-sectional design. Programs broadcast by Four Chilean TV stations on days randomly selected were recorded. Advertised foods were identified. The information from the nutrition labelling of packaging was recorded. The GI of similar foods was obtained from the International Table of Glycemic Index and Glycemic Load Values 2002. The GL was estimated according to carbohydrates available per portion of advertised foods. Statistical analyses were made with Stata11.0.

Results: 509 food commercials were shown. Of these, 302 were aimed at children (P-value= 0.0000294 (CI95% 1.218397-1.749717) daily average 25.16 SD +/-11.82). The foods with higher number of repetitions were breakfast cereals, dairy products, non-alcoholic beverages and fast food. Information about the GI of 17 foods, being these the most advertised, was obtained. Of these, 23.6% had high GI. According to the size of the offered portion, 41.2% of the foods had a medium or high GL (17.6% high GL (>=20), 23.6% medium GL (11 to 19)). No products had information about sucrose or fructose.

Conclusions: An important part of the foods offered to children through TV advertisement has high GI and GL, which could be associated with childhood obesity. Studying the GI of all the advertised food on TV and legislating so the mandatory nutrition labelling of prepackaged food includes qualitative declaration about GI, GL, sucrose and fructose content are required.

Key words: obesity, glycemic index, television advertising.

PO1746**FRUIT AND VEGETABLES ON PRESCRIPTION: A BRIEF INTERVENTION IN PRIMARY CARE**

Z. Buyuktuncer-Demirel^{1, 2}, M. Kearney³, C. Louise Ryan¹, M. Thurston⁴, B. Ellahi¹

¹Department of Clinical Sciences, University of Chester, Parkgate Road Chester, UK

²Department of Nutrition and Dietetics, Faculty of Health Sciences, Hacettepe University, Sıhhiye, Ankara, Turkey

³Primary Care & Public Health Advisor Respiratory Programme, Department of Health, Room Wellington House, London, UK

⁴University of Chester, Faculty of Applied Sciences, Parkgate Road Chester, UK

Background and objectives: Increasing fruit and vegetable consumption is a goal for the UK. Therefore, the effectiveness of a fruit and vegetable voucher scheme coupled with key 'five-a-day' consumption messages as a brief intervention in primary care consultations was assessed in the present study.

Methods: One thousand one hundred and eighty-eight vouchers as a prescription for fruits and vegetables were routinely distributed to patients attending a primary health care centre in a deprived area, and 124 volunteer patients routinely attending the centre were included. Telephone-based questionnaires were used to examine changes in consumption over the short and medium term. Other key aspects assessed in the evaluation related to fruit and vegetable purchasing behaviour, knowledge relating to what constitutes a portion size, the relationship between food and health, and barriers to consumption.

Results: Although 76.2% of participants used the prescription vouchers when purchasing fruits and vegetables, a significant change in the consumption or purchasing behaviour was not observed ($P > 0.05$). Participants' level of knowledge relating to the number of portions recommended and the portion size of different fruits and vegetables showed a moderate increase from baseline over the short and medium term. The primary barriers to fruit and vegetable consumption were reported as 'the quality of fresh fruits and vegetables' and 'the money available to spend on food'.

Conclusions: The use of 'the fruit and vegetable on prescription' scheme was an effective method of engaging participants in improving awareness of key diet-related health messages. However, further intervention is required to produce a significant impact on the actual behaviour change.

Key words: fruit and vegetable prescription, mainstreaming prevention, health settings

PO1747**EFFECT OF MEDITERRANEAN DIET COMPONENTS ON SELECTED CARDIOVASCULAR RISK FACTORS, ALL-CAUSE MORTALITY AND CARDIOVASCULAR MORTALITY: SYSTEMATIC REVIEW**

M.Y. Chan¹, Y. Yulianna¹

¹Newcastle University, UK

Background and objectives: Mediterranean diet has been associated with lower risk of cardiovascular diseases. Objective: To evaluate the cardioprotective effect of some of the popular Mediterranean dietary components: olive oil, fish, fruits and vegetables, wholegrains and wine and to propose suitable recommended dietary dosage and frequency of the consumption.

Methods: A updated systematic review of observational and intervention studies in Scopus database (including Medline database) was performed. Inclusion criteria include English-publication studies published since 2001 up to 31 January 2013, adult participants (≥ 18 years old), interventions which stated frequency of consumption of each investigated component. For studies which showed at least one significant improvement of outcome was considered as cardioprotective.

Results: A total of 4,033 abstracts were obtained prior to title and abstract screening. Out of this, 67 original research studies were reviewed and 39 studies were included in the final rigorous list for review. Of these 39 studies, 34 had shown protective effects.

Conclusions: Current recent evidence showed that consumption of olive oil, nuts, legumes, fruits and vegetables, wholegrains, and moderate alcohol/wine consumption) could help to reduce the risk of cardiovascular disease and mortality.

Key words: Mediterranean diet, cardiovascular risk, cardiovascular mortality.

PO1748**NUTRITION AND METABOLIC SYNDROME: DISSEMINATION OF EVIDENCE BASED KNOWLEDGE FROM RESEARCH TO PRACTICE IN BANGLADESH**

K. Natasha¹, L. Ali¹

¹Bangladesh Institute of Health Sciences, Bangladesh

Background and objectives: Local context of knowledge, attitude and practice (KAP) is of central importance to reduce the public health disasters (including metabolic syndrome) and thus designing of proper strategies to improve health in a population requires sufficient data which are scanty in Bangladesh. Therefore a project was designed an attempt to start a solution

by BIRDEM And WDF (Jan06- Aug11). To build up a database and disseminate research and evidence based knowledge regarding MS absolutely from local perspective of Bangladeshi people and create awareness and specially a significant impact on health professionals and policy makers.

Methods: The TEAM contacted with each and every single institute/university/organization over the whole country to collect primary/secondary - chemical, biological and sociocultural data from research on MS or nutrition relevant to Bangladeshi race and society authorised by them. Data on about 1000 food items and 12000 socioeconomic related KAP were summed, compiled and edited for database. Then a substantial volume of culturally sensitive health promotional/educational tools enriched by accumulated findings was developed, piloted and improvised. Publication and circulation of a number of health articles, special issues of a magazine, a calendar, 2 categories of Leaflets and 1 Alphabet book. Distribution of 'Clay-models' (20 food-items). Dispersion of thousands of Mini-display-boards. Training of health professionals (>30 sessions) • Special Classes for patients (337) 'Series of Dissemination Seminars' for all (15) Launching of website www.pushti.org Broadcast of 3 minidocudramas through >12 satellite channels.

Results: The follow-up study says after promotional activities the KAP level is significantly improved. Benefitted people: 3000000Patients and Relatives, 1200Doctors, 600Paramedics, 800Nurses, 100Dieticians/Educators, 60000000Mass people.

Conclusions: Allied persons are now giving the second thoughts to design, run or implement new endeavour focusing the key findings of this project.

Key words: Healthpromotion, Research, Masscommunication

PO1749

PARASITOSIS PRESENCE AND ITS POSSIBILITY OF WORSENING NUTRITIONAL STATEMENT AND ANAEMIA ON 0 TO 10 YEARS OLD POOR CHILDREN IN BAHIA.

M de F. Brazil dos Santos Souto¹, M de LP. Nascimento², R. Brazil dos Santos Souto³

¹Estado da Bahia University, Brazil

²Fundação para Asistencias as Anemias Parasitosis e Desnutrição, Brazil

³Granada University, Spain

Background and objectives: Parasites are one of the mainly health problems in developing countries. Its presence increases the risk of to contract others diseases. Anaemias and malnutrition, diseases which could bring fisiopathologic abnormalities and, in consequence, it makes easy to contract others

diseases. Objectives: To indentify nutritional statement of 0 to 10 years old children of Bahia.

Methods: It was chosen various schools and nurseries of Bahia. It was evaluated 626 children under parents' authorization. Data collect was made by clinic evaluation, faeces parasitologic evaluation using Hoffman, Pons and Janer and Faust methods from the same sample and nutritional evaluation according to National Center for Health Statistics (NCHS). Data was analyzed using statistic program Epi-Info 3.5.2 version.

Results: 68, 2% of children was positive to one or more helmint parasite, the most common was *Ascaris lumbricoides* (49, 5%). 14, 4% was positive to some type of protozoo. 30, 1% (n=190) of children had protein energetic deficiency, 15, 3% (n=96) had malnutrition risk, 1, 3% (n=8) had obesity and 53% (n=332) was eutrophic. Abdominal pain and diarrhoea were the most frequent symptoms. Abnormalities presence in ocular mucose or palm color were clear at 30, 5% of cases.

Conclusions: Anaemia and nutritional statement of positive evaluated children predispose the rise of parasitic charge and new infection susceptibility which could bring serious malnutrition condition and chronic anaemias.

Key words: Anaemia. Malnutrition. Parasitosis. Health problem.

PO1750

THE IMPACT OF FAMILY VIOLENCE ON CHILDHOOD GROWTH

M H. Hasselmann¹, A C. Lindsay, P. Surkan, G. Werneck

¹Institute of Nutrition, State University of Rio de Janeiro, Brazil

²Nutrition Department, Harvard School of Public Health, USA

³International Health, Johns Hopkins Center for Global Health, USA

⁴Institute of Social Medicine, State University of Rio de Janeiro, Brazil

Background and objectives: Although the role of family violence on early childhood growth is of increasing interest, few longitudinal studies from developing countries have assessed such putative associations. Objective: The aim of our study was to examine whether intimate partner violence (IPV) adversely affects growth of children in the first years of life.

Methods: We used a cohort study of 592 children in the second month of life ($\mu = 35.6$ days; $SD = .35$) attending four primary health care units in Rio de Janeiro, Brazil. Conflict Tactics Scales (CTS1) were used to assess IPV (exposure). Children were considered to have inadequate growth (outcome-stunting) when they were below -2SD based on the WHO length-for-age standards median, measured at the third and fifth

months of life. Associations between variables were expressed as prevalence ratios (PR, baseline) and risk ratios (RR, follow-up), with their respective 95% confidence intervals (95%CI), estimated by Poisson regression models with robust variance.

Results: Children living in families experiencing IPV were at higher risk of stunting in the third month of life (RR=5.77; 95%CI: 1.45–22.96). IPV was not associated with stunting in the fifth month of life (RR=0.73; 95%CI: 0.10–5.43).

Conclusions: Although the estimates are imprecise due to the small number of cases of stunting observed, results indicate that violence in the family might be an important element in the genesis of inadequate infant growth.

Key words: child growth, stunting, intimate partner violence, cohort, Brazil.

sustainability, transfers should be linked to interventions to facilitate behavioural changes that will empower mothers and families to ensure adequate child feeding prepared at home from local resources wherever appropriate.

Conclusions: Social protection systems should provide essential assistance in the short-term and support livelihoods in the long-term. Supplementary feeding, when organised as part of nutrition policies aimed at realising the human rights to adequate food for young children and to social protection for women in vulnerable situations, would enhance the capability of deprived mother's to ensure their children's health on a continuing basis.

Key words: Social Protection, Food Security, Supplementary Feeding, CFS.

PO1751

SOCIAL PROTECTION FOR FOOD SECURITY: THE RIGHT OF VULNERABLE MOTHERS TO SOCIAL ASSISTANCE PROMOTING ADEQUATE SUPPLEMENTARY FEEDING FOR YOUNG CHILDREN

W B. Eide¹

¹Department of Nutrition, University of Oslo, Norway/Project Team Member For The UN Committee On World Food Security's High Level Panel of Experts, Report On Social Protection For Food Security

Background and objectives: Food insecurity refers to both the inability to secure an adequate diet today and the risk of being unable to do so in the future. "Social protection" is a menu of policy instruments addressing poverty and vulnerability, through social assistance, social insurance and efforts at social inclusion. Besides conditional or non-conditional cash transfers, adequate supplementary feeding for young children should also be regarded as part of vulnerable mothers' right to social assistance for their children's food and nutrition security.

Methods: The reformed Committee on World Food Security (CFS, housed in FAO) established a High Level Panel of Experts on food security and nutrition (HLPE, 2009) to strengthen world-wide knowledge about emerging trends in food security. The HLPE report Social Protection for Food Security (HLPE, 2012) reviewed nine social protection instruments, including Supplementary Feeding, that should complement longer term development efforts.

Results: The HLPE report on SPFS (2012) made recommendations to governments and CFS. Regarding food supplementation they include attention both to the impact on children's height and weight, and to the actual forms of feeding programmes. In line with human rights principles and the growing interest in the right to adequate food and concerns regarding

PO1752

SOCIOECONOMIC AND FOOD CONSUMPTION FACTORS ARE ASSOCIATED WITH OVERWEIGHT IN MIDDLE-AGED INDONESIAN ADULTS

G. Yasmin¹, D. Briawan¹, H. Hardinsyah¹

¹Department of Community Nutrition, Faculty of Human Ecology, Bogor Agricultural University, Bogor, West Java, Indonesia

Background and Objectives: Very limited information available on the risk factors of overweight among Indonesian adults (IA). This study was aimed at analyzing socioeconomic and food consumption factors of overweight among IA.

Methods: This study used electronic files data of Basic Health Research 2010 of the Health Research and Development Agency of the Ministry of Health, which was design as a cross sectional survey. A total of 12196 adults aged 50-55 years were selected for the analysis. Overweight was defined using Body Mass Index (BMI) more than 25 kg/m². A logistic regression was used to analyze socioeconomic and food consumption factors of overweight.

Results: The result showed that 28.03% of IA were overweight (include obese). The significant socioeconomic factors (p<0.05) of overweight among IA are sex (OR for women=2.026, CI 95%:1.856-2.213), education level (OR for higher education=1.413, CI 95%:1.268-1.575), household income (OR for high income=1.650, CI 95%:1.501-1.815), urban-rural settlement (OR for living in urban=1.463, CI 95%:1.333-1.605), and physical activity (OR for sedentary=1.703, CI 95%:1.540-1.885). Marital status is predictor of overweight only in women (OR for married=1.197, CI 95%:1.021-1.404). The significant food consumption factors are protein intake (PI) (OR for PI>15%=1.292, CI 95%:1.033-1.616) in men and energy adequacy level (EAL) (OR for EAL>110%=1.277, CI 95%:1.041-1.567) in women.

Conclusions: This implies that health awareness on balance diet and physical activity is important for prevention of overweight among IA.

Key words: overweight, middle-aged, socioeconomic, food consumption.

PO1753

DIETARY AND PHYSICAL ACTIVITY HABITS IN ITALIAN AND SPANISH SCHOOL-AGE YOUTH WITHIN THE PROJECT MISSION X: TRAIN LIKE AN ASTRONAUT

D. Cañada¹, J. Valtueña¹, G. Galoforo², R. Tagliamonte², S. Hartevelt³, J.C. Ortiz¹, M. González-Gross^{1,4}

¹ImFINE Research Group, Department of Health and Human Performance, Universidad Politécnica de Madrid, Madrid, Spain

²Italian Space Agency, Roma, Italy

³Directorate of Human Spaceflight and Operations Promotion Office (Education Unit), European Space Agency, Noordwijk, The Netherlands

⁴CIBER: CB12/03/30038 Fisiopatología de la Obesidad y la Nutrición, CIBERobn, Instituto de Salud Carlos III (ISCIII), Spain

Background and objectives: There is strong evidence dealing with the effects of regular physical activity (PA) and adequate nutrition on several health and behavioural outcomes in school-age youth. Following PA recommendations, school-age youth should participate daily in 60 minutes or more of moderate to vigorous physical activity, limiting screen time to a maximum of 2 hours/day. Objective: The aim of the present abstract is to describe daily PA and dietary habits in two different populations of children and adolescents within the MX project: train like an astronaut, developed to encourage proper PA and nutrition.

Methods: In the frame of the project, a total of 422 (149 Italian and 252 Spanish) school children with an age range of 9-13 yrs, were assessed by means of an online questionnaire, before starting the project at school. Daily habits for nutrition and PA were included. Descriptive characteristics of the studied sample were assessed by SPSS v 19.0.

Results: Only 18% of the Italian and 25% of the Spanish subjects meet the PA international guidelines. Physical Activity is practiced less than 2-3 times per week by 31% of the Italian and 25% of the Spanish children. Both Italian and Spanish subjects show the same levels of sedentary behavior with an average screen time of 1-2 hour. Spanish children report lower daily vegetable intake than Italian ones (9% vs. 26%, respectively). Regarding sugar beverage intake, higher consumption was reported by Spanish students than by Italian ones (35% vs. 9%).

Conclusions: A high percentage of school-age youth does not meet current recommendation for PA in both countries. Spanish students show higher levels of daily PA, higher sugar beverage intake and lower daily vegetable intake when comparing with Italian ones. Both Spanish and Italians meet current recommendation for daily screen time.

Key words: health promotion, school-based intervention, physical activity, nutrition.

PO1754

NATIONAL SURVEY OF CHILDHOOD OBESITY IN SWEDEN - INDIVIDUAL AND SOCIETAL ASPECTS

A. Sjöberg^{1,2}, L. Moraeus², A. Yngve³, L. Lissner²

¹Department of Food and Nutrition, and Sport Science, University of Gothenburg, Gothenburg, Sweden

²Department of Public Health and Community Medicine, Public Health Epidemiology Unit, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden

³Unit for Public Health Nutrition, Karolinska Institutet, Stockholm, Sweden

Background and objectives: To correctly assess the national prevalence of overweight and obesity in children highly representative data are required. Measuring the children in schools is expected to result in high participation, while family questionnaires which are required to get data about individual socio-economy (SES) and lifestyle are more demanding. This project permitted comparison of area- and individual level approach when analysing prevalence and how the urban-rural gradient in overweight and obesity was related to SES.

Methods: Anthropometric data from 4538 children in grades 1 and 2 in a nationally representative sample were collected in 2008. School areas were classified to be urban, semi-urban or rural based on population density, and as low, medium and high SES based on proportion of the population with university degree. Individual SES based on parental educational level was available from questionnaires for 3721 children. Overweight and obesity was classified by IOTF.

Results: The overall prevalence of overweight (including obesity) was 16.6% (3.0%) and 15.6% (2.6%) for children with family questionnaire. Prevalence differed significantly between subjects with and without family questionnaire. The urban-rural gradient was similar when area and individual approach was used but there was a difference in explanatory value of SES factors between the designs. Parental weight status was the strongest marker for child weight status.

Conclusions: Asking for detailed information results in a more selected population and affects the prevalence. Area and

individual education levels and parental weight status are markers for a cluster of lifestyle factors that differ between individuals and groups.

Key words: paediatric obesity, socio-economic status, level of urbanization
Acknowledgements: This study was financed by the Swedish Research Council and The Swedish Council for Working Life and Social Research.

MULTISECTOR ACTION TO PROMOTE NUTRITION SECURITY IN FIVE COUNTRIES IN ASIA

Dorothy Foote¹, K. Paintal², Adriana Zarrelli², France Begin¹

¹UNICEF East Asia and Pacific Regional Office EA-PRO, UNICEF, Australia

²UNICEF Regional Office for South Asia (ROSA)

Background and objectives: One billion people in the world suffer from chronic hunger; two-thirds of them live in Asia. This crisis has far-reaching effects, and robs millions of children of their full potential for growth and development. "Nutrition security" is more than food security; it's the outcome of good health, clean environment, and good caring practices. The Maternal and Young Child Nutrition Security Initiative in Asia (MYCNSIA, 2011-14, EU/UNICEF) aims to improve nutrition security among women and children through an evidence-based, multi-sector approach. Targets for impact include 5 percentage point reduction in stunting, and one-third reduction in anaemia among young children and pregnant women.

Methods: MYCNSIA is implemented in five countries (Bangladesh, Lao PDR, Indonesia, Nepal, Philippines). Action is under four programme Pillars: (1) strengthening upstream policies and awareness, (2) capacity development, (3) data and knowledge sharing, (4) scaling-up direct interventions. Direct interventions include Iron-folic acid in pregnancy; early (within 1 hour) and exclusive (for 6 months) breastfeeding; micronutrient powders for children 6-23 months; IYCF Counselling; vitamin A supplementation; zinc for diarrhoea management; fortification of staple foods; improved water and sanitation; home production of food and animal products; nutrition services with social-protection and cash-transfer programmes.

Results: Baseline data from 2011 revealed stunting from 29-41%, child anemia 39-78%, and anemia in pregnancy 18-53%. To date, seven new or revised nutrition policies have been adopted; over 17, 000 people have been trained on Community IYCF Counselling; process and behavioural indicators have improved (e.g. minimum acceptable diet improved from 31%

to 40% in selected areas); impact evaluation is expected 2014.

Conclusions: In line with the global Scaling-Up Nutrition (SUN) movement and the "1, 000 Days" approach, there is great need and potential to reduce chronic malnutrition (stunting) by enacting a multi-sector approach from health, agriculture, social protection, education.

Key words: Stunting; Anemia; Multi-sector nutrition action; 1, 000 Days.

PO1757

PHYSICAL ACTIVITY LEVEL AND OBESITY STATUS OF FACTORY WORKERS IN OGUN STATE, SOUTH-WESTERN NIGERIA

O. Adewuyi¹, T. Atinmo¹

¹Department of Human Nutrition, University of Ibadan, Nigeria

Background and objectives: The aim of this study was to assess the physical activity level and obesity status of some factory workers in south-western Nigeria. Adults with varying working conditions were randomly sampled from two factories (A food company and a Pharmaceutical company).

Methods: Physical activity level was estimated using the long format of the International Physical Activity Questionnaire (IPAQ). Diagnosis of obesity and abdominal obesity was done using the WHO standard recommended method of determining of body mass index (BMI) and waist circumference (WC) and subjects were classified into 3 BMI groups underweight, Normal and overweight/obese. A total of 150 adults were recruited.

Results: In women, the prevalence of overweight/obesity (BMI ≥ 25 kg/m²) is 41.9%, higher than in men 39.5%. The prevalence of abdominal obesity (waist ≥ 88 cm in women and ≥ 102 cm in men) was higher in women than in men (45.2% vs. 9.2%). The overall overweight/obesity was 40%. Overall level of physical inactivity in the study was 24.0%. Thirty six (24.0%) of the subject had no physical activity (PA), 19 (12.7%) had insufficient physical activity, 58 (38.7%) had moderate PA, while 37 (24.7%) had high physical activity. There existed a relationship between the recreation physical activity level (PAL) values and the BMI groups ($P < 0.05$). However, there was no statistical relationship between Total PAL and BMI groups

Conclusions: A 40% prevalence of obesity/overweight and a 36.7% prevalence of low/insufficient physical activity amongst adults working in the factory can be reduced by introducing occupational physical activity to work place. This would help worker lead a healthier lifestyle in their day to day activities and the overall quality of life improved.

Key words: Physical activity(PA), obesity, overweight, BMI

PO1758

HEALTHY LIFESTYLE FOR THE PREVENTION OF CHILD OVERWEIGHT AND OBESITY IN THE COMMUNITY PHARMACY WITHIN A PUBLIC HEALTH MULTIDISCIPLINARY APPROACH

C. Pardo¹, A. Paré¹, M.J. Alonso¹, L. Torres¹, G. Piera¹, AM. Andrés¹, M. Iracheta¹, G. Tribó¹, A. Santamaria¹, C. Pardo¹, I. Puigdueta¹, M T. Bovet¹, N. Francés¹, M. Rius¹, P. Palacio¹, M. Estrada¹, C. Rodríguez¹, R. Guayta¹, M. Casamitjana¹, A. Bach-Faig¹

¹Col.legi de Farmacèutics de Barcelona, Spain

Background and objectives: The Working Committee of Prevention and Community Health (COPISC) is created by integrating the different professionals that carry out preventive and community health promotion in Barcelona. The prevention of overweight and obesity in children is a priority given the current rates (25.7% and 16.8%, respectively). Families need to be supported to make informed choices about their diet and their levels of physical activity. Pharmacy teams are ideally placed to offer this support. Moreover, for those people who do not routinely access primary care services, pharmacists might be the only healthcare professional seeing them on a regular basis.

Methods: A pilot intervention (6 months) is designed for the prevention of child and youth overweight and obesity (0-16 years) in the community pharmacy. The study area are two basic health areas' pharmacies. Homogeneous and consensual (minimums) messages to develop the interventions thought out the different health professionals were formulated after a review of effective interventions. Tools were developed around dietary counseling (including sugary drinks and fast food occasional consumption, breakfast composition, relevance of family meals, serving-size control). and physical activity promotion (60'/day, <2 h/d of screen (TV, computer...) exposure and 9-hour sleep). To not use drugs and the involvement of families is stressed in the program. Community pharmacies are widely accessed by families, and can inform and support family members and carry measurements of body mass index, weight circumference and body fat percentage.

Results: A protocol is applied with an algorithm to describe the interaction between pharmacist and other health professionals to detect, follow-up and referral if needed to dietetic services and medical services.

Conclusions: The community pharmacy's intervention in preventing child overweight and obesity through promoting healthy lifestyles is a possible additional strategy in coordination with other health professionals.

Key words: child, obesity, overweight, pharmacy, public health

MEDIATING ROLE OF GENDER IN DYNAMICS BETWEEN CASH CROPPING AND FOOD AND NUTRITION SECURITY IN BURKINA FASO

C. Maisonneuve¹, K. Ouattara², C. Nana³, T. Desrosiers¹, D. Sanou³

¹Department of Food Science and Nutrition, Université Laval, Québec, Canada

²Institut de l'Environnement et de Recherches Agricoles, Centre national de la Recherche Scientifique et Technologique du Burkina Faso, Saria, Burkina Faso

³Interdisciplinary School of Health Sciences, Faculty of Health Sciences, University of Ottawa, Ontario, Canada

Background and objectives: International community is increasingly advocating for approaches that integrate agriculture, nutrition and health. However, the impact of some agricultural interventions such as cash cropping on food and nutrition security and the mediating role of women remain ambiguous in literature. Objectives: To determine the implications of cotton cropping in Burkina Faso on the daily activities of women and household food security and child nutrition.

Methods: A mixed methods study was conducted in four villages of Hauts-Bassins, the leading cotton producing region of Burkina Faso. A questionnaire on the impacts of cotton on women's role and household food security was completed by 275 women. Twelve focus groups were conducted with 44 men, 40 women and 39 representatives of stakeholder organizations.

Results: In this region, cotton farms were mostly owned by men. Household incomes seemed to increase with cotton production. However, the cash flow was annihilated by the high cost of agricultural inputs. Overall, 67.3% of households were food insecure, 35.3% of their children were stunted, 17.8% underweight and 5.3% wasted. Women farmers felt that cotton was causing food insecurity and child malnutrition in their area due to lack of control over cotton income due to local social norms. Cotton women worked in average 41.6 ± 7.3 hours per week in cotton activities, and 81.3% felt that they had less time to rest because of cotton workload. Working time was negatively associated with food security score. Participants in the focus groups mentioned that these changes in women daily activities have reduced time for caring of children and to do income generating activities.

Conclusions: Cotton farming seems to affect women empowerment and increase exposure to food insecurity and gender inequalities. Increased in women workload worsens the cotton-child nutrition dynamics.

Key words: cotton cropping, food insecurity, child nutrition, women, Burkina Faso

PO1760**HEALTHY RESTAURANT MENUS: OFFER AND DEMAND. THE EUROPEAN BAROMETER FOOD - SPANISH RESULTS**

M. Asla¹, P. Pascual¹, N. Bertrand², N. Renaudin², B. Roldán³, A. Bach-Faig³

¹Edenred S.A. Spain, Spain

²Edenred S.A. France, France

³Mediterranean Diet Foundation, Barcelona, Spain

Background and objectives: The European Barometer is a tool that was created within the FOOD (Fighting Obesity through Offer and Demand) project to promote healthy eating habits of employees and make balanced meals available in restaurants. A balanced diet is linked to health and well-being for employees and as well results in an increased productivity; and in turn decreases the rates of absenteeism.

Methods: A study aiming at following and understanding any needs and changes in the habits of employees and restaurants, was conducted through the European Barometer FOOD which numbered 6, 324 employees and 832 restaurants' answers from the seven participating countries (Belgium, Slovakia, Spain, France, Italy, Czech Republic and Sweden) in 2012.

Results: The study on eating habits reveals that 79% of European consumers believe that the nutritional quality of the meals is a decisive factor when choosing a restaurant, even ahead the proximity to workplace. Spanish consumers are more demanding on the nutritional quality: 88% of them prefer restaurants that offer healthy meals. Furthermore, 83% of them believe it is crucial that the restaurants offer varied meals. The survey shows that 70.4% of European employees have a lunch break every working day and it is in Spain where employees are the most often going to a restaurant (48.3%) for their break, while the European average is 28.4%. For Spanish consumers, factors for their meals' choice are the distance, the speed of service, a friendly atmosphere, abundance of vegetables, presence of foods steamed, grilled or baked, providing local and seasonal foods, and/or that the menus meet their individual dietary needs.

Conclusions: For employees who are going to a restaurant at lunch time the nutritional quality of the offer is a decisive factor. Spanish consumers are the most demanding on this issue.

Key words: Workplace, restaurants, employees, healthy menus

PO1761**IMPACT OF A DIABETES EDUCATION PROGRAM ON KNOWLEDGE, ATTITUDE AND PRACTICE IN BANGLADESHI TYPE 2 DIABETIC SUBJECTS**

F. Afnan¹, F. Ara¹, S.J. Mumu², F. Saleh¹

¹Department of Community Nutrition, Bangladesh Institute of Health Sciences (Bihs), Bangladesh

Background and objectives: knowledge-based education is the most feasible strategy to prevent diabetes and its complications in this low resource society. The present study was to see the impact of diabetes education program in terms of knowledge, attitude and practice (KAP) among Bangladeshi type 2 diabetic subjects.

Materials and Methods: Total 500 type 2 diabetic subjects (male 43%, female 57%) attending the structured diabetes education program in different health care centers under BADAS were included. Baseline data were collected before providing education and the followup data were collected after 12 months of providing diabetes education.

Results: In follow up, fasting (mean±SD, mmol/l 9.8±4 vs 8.2±3; p=0.0001) and ABF (mmol/L, 14±5 vs 11.8±4; p=0.0001), serum glucose were significantly reduced. KAP scores of the subjects, (% 56±15 vs 68.4±11, 78±5 vs 85.8±6, 38.9±14 vs 67.9±18, respectively; p=0.0001) were significantly increased after intervention. Before intervention better knowledge was associated with better attitude (r=0.29, p=0.0001) and practice (r=0.49, p=0.0001). After intervention these associations {knowledge vs attitude (r=0.23; p=0.0001); knowledge vs practice (r=0.28, p=0.0001)} became stronger. Age (r=-0.09, p=0.04) showed a significant negative association with knowledge score. Year of education (r=0.27, p=0.0001) and diabetes education (r=0.13, p=0.01) showed a significant positive association with knowledge score. Diabetes education (r=0.21, p=0.0001) and number of education class (r=0.11, p=0.03) showed significant positive association with attitude score. Age (r=0.14, p=0.003) showed significant positive association with practice score though monthly income (r=-0.09, p=0.04) showed significant negative association with practice score.

Conclusions: Diabetes Education Program is associated with improved glycemic control and increased Knowledge, Attitude and Practice. The present data also show that better knowledge leads to better attitude and practice and a diabetes education program is positively associated with knowledge and attitude.

Key words: impact, education, diabetes

PO1762**PROCESS EVALUATION OF NUTRITION EDUCATION PROGRAM IN GREEK PRIMARY SCHOOLS**

N. Efstathiou¹, G. Risvas¹, M. Kapsokefalou¹, A. Zampelas¹

¹Agricultural University of Athens, Athens, Greece

Background and objectives: Process evaluation of nutrition education programs has been scarcely reported in the literature, leading to a lack of adequate data on how interventions are implemented and whether program goals are met. The aim of the study was to evaluate the application of a nutrition education program in Greek primary schools, which was delivered through active learning techniques.

Methods: Three hundred twenty two students, aged 8-10 years old (157 boys and 165 girls) were voluntarily enrolled in the study from eleven primary schools of Attica district. The nutrition education program incorporated theatrical play sessions by specially trained life scientists, with the participation of the teacher. Intervention monitoring was undertaken by Regional Health Education Authority personnel on-site, during program delivery. The evaluation tool was a questionnaire, which measured adherence to the curriculum, realization of aims, teacher participation and active learning techniques used.

Results: 48.8% of the classroom teachers participated in the program. 66.1% of these personnel were adequately prepared for each session, while 62.2% met the aims described in the curriculum. Adherence to delivery plan reached 68.5% while 29.9% of the students were fully responsive and cooperative. Active learning techniques were implemented in 44.9% of cases. Our data suggest that only half of the teachers were included in the classroom team, 2/3 of which were adequately prepared. Consequently, 3 out of 10 students were fully exposed to the activities planned.

Conclusions: Nutrition education through active learning can operate effectively, when the classroom teacher is involved in the curriculum. Moreover, the personnel must be adequately prepared to adhere to program plan and apply the techniques that will mobilize the students. Therefore, our program should be better prepared to meet the needs of the trainers, besides addressing the needs of the students.

Key words: process evaluation; nutrition education; children

PO1763**PARENTAL KNOWLEDGE AND PRACTICES OF VITAMIN SUPPLEMENTATION IN YOUNG CHILDREN, AND ITS RELATIONSHIP TO MALNUTRITION**

S. Ratanachu-Ek¹

¹Department of Pediatrics, Queen Sirikit National Institute of Child Health, Thailand

Background and objectives: Vitamins are micronutrients that play an important role in the human metabolism. Vitamin supplementation has been used to improve children's appetite and growth. Although vitamin preparations are available over-the-counter, many children received vitamin supplementation from clinics and hospitals. However, few cases of vitamin overdose have been reported. This study was performed to evaluate the parental knowledge and practices of vitamin supplementation in young children (1-5 years) and its relationship to under-nutrition status, at QSNICH.

Methods: A cross-sectional study was performed at the Well Child Clinic, QSNICH, from 1st – 31st May, 2005. Five hundred parents of young children, aged 1-5 years were interviewed about demographic data, knowledge and practices of vitamin supplementation by trained health personnel using the questionnaire. Weight and length/height were measured and assessed for nutritional status using Thai growth reference. The relationship between vitamin supplementation and malnutrition was analyzed using Chi-square test and $p < 0.05$ was considered statistically significant.

Results: Regarding parental knowledge, 57% knew the benefits of vitamin supplementation, 74% did not know the toxic effects. Prevalence of vitamin supplementation was 75.6%, including vitamin C 62%, multi-vitamin (MTV) 35%, and cod-liver oil 20%. Vitamin supplementation was obtained from over-the-counter in 59%, health services 40%, and friends 1%. The reasons for vitamin supplementation were poor feeding 63%, under-weight 23% and unhealthy status 14%. MTV supplementation was significantly higher in malnourished children ($p < 0.001$).

Conclusions: The prevalence of vitamin supplementation was high, especially MTV in malnourished children. Parents should be educated and warned about the dangers of excessive vitamin consumption.

Key words: Vitamin supplementation, Knowledge, Practices, Malnutrition, Children

PO1764**BIOMARKERS OF OXIDATIVE STRESS AFTER STRENUOUS PHYSICAL EXERCISE.**

M.D. Barnuevo Espinosa¹, C.J. Contreras Fernandez¹, A.J. Luque Rubia¹, F.J. López¹, J. Mulero², P. Zafrilla Rentero²

¹Department of Physiology of exercise, Catholic University of San Antonio, Murcia, Spain

²Department of Food Technology and Nutrition, Catholic University of San Antonio, Murcia, Spain

Background and objectives: Numerous studies indicating that exercise of sufficient intensity and duration increases the formation of reactive species and that antioxidant mechanisms cannot scavenge them, thus resulting in oxidative stress. The aim of this study was to analyze biomarkers of oxidative stress after performing strenuous physical exercise.

Methods: A group of 25 sportsmen participated in the study. 90 min rectangular test were performed on a bicycle ergometer at 70% of the VO₂max. Protein carbonyl groups were determined by an ELISA kit (Biocell Corporation Ltd, New Zealand) according to the manufacturer's instructions. 8-OHdG analysis was carried out with an ELISA kit (Japan Institute for the Control of Aging, Fukuroi, Shizuoka, Japan). Reduced and oxidized Glythatione were determined by colorimetric determination (OxisResearch™ Bioxytech GSH/GSSH-412™ Burlingame, USA). Differences with p less than 0, 05 were considered statistically significant. Calculations were performed with SPSS software v. 17, 0.

Results: Initially mean values of carbonyl groups are 38.5±11.5 μmol/mg. After performing strenuous physical exercise these values increased (41.8±10.8 μmol/mg), and significant differences were observed (p<0.05). After 24 hours these values decreased (37.7±10.8 μmol/mg) and significant differences were found. According to the 8-OHdG results (damage DNA), after strenuous physical exercise the levels of 8-OHdG decreased, but no significant differences were observed. At 24 h the mean values increased, and significant differences were observed. According to the GSH/GSSH results, average values were higher immediately after exercise (9.4±2.4 μM vs 8.9±2.1 μM) although no significant differences were found. At 24 hours these values increased.

Conclusions: performing strenuous physical exercise modifies oxidative stress biomarkers analyzed.

Key words: physical exercise, oxidative stress, rectangular test, protein carbonyl.

PO1765**QUANTIFICATION OF VITAMIN A IN FORTIFIED OILS USING A FAST AND SIMPLE PORTABLE DEVICE: EVALUATION AND COMPARISON TO HIGH-PERFORMANCE LIQUID CHROMATOGRAPHY**

S. Avallone¹, C. Renaud¹, B. Jacques¹, A. Laillou²

¹UMR NutriPass, IRD Centre de Montpellier, France

²Global Alliance for Improved Nutrition, Geneva, Switzerland

Background and objectives: Vitamin A deficiency is one of the major public health's problems in developing countries. In order to improve vitamin A status of population, food fortification programs have been widely developed this last decade. Oils are considered as a good matrix for food fortification because of the fat soluble properties of vitamin A. Oil fortification is increasing all around the world and controls are needed for companies and state commissions. The most commonly used methods for vitamin A quantification are High Pressure Liquid Chromatography (HPLC) and spectrophotometry. Even though these methods have proved their reliability, it required qualified personnel to lead time-consuming experiments. Furthermore, high volumes of solvents necessary pose a problem not only of cost but also of environment. Testing alternative methods involving lower investment and reducing ecological consequences is interesting.

Methods: A rapid test kit with a portable device (iCheck™ CHROMA and iEx™ ELAN) was compared to a reference high liquid chromatography method (HPLC), for three types of vegetal oils (colza, groundnut and soya).

Results: The iCheck™ device presented a good linearity from 3 to 30 mg retinol equivalents per kg (mg RE.kg⁻¹) and a limit of quantification of 3 mg RE.kg⁻¹ in colza and groundnut oil, and 4 mg RE.kg⁻¹ in soya oil. The inter and intra-assay precision ranged from 1.48% to 3.98%. Accuracy, estimated by root mean squares error (RMSE), ranged from 3.99 to 5.49 reveals a lower precision than HPLC (from 0.40 to 2.25). An underestimation for groundnut oil and an overestimation for soya oil were noted. Although a lack of precision, the portable device offers a rapid approximation of vitamin A in a range of 3 to 15 mg RE.kg⁻¹ in fortified oils.

Conclusions: This range corresponds to the international recommendation of oil fortification (5 to 15 mg RE.kg⁻¹).

Key words: Vitamin A, oil, chromatography.

PO1766

HEALTH WORKERS EFFECTIVENESS IN DELIVERING NUTRITION COUNSELLING AT PRIMARY HEALTH FACILITIES IN FCT ABUJA, NIGERIA

I. Chima¹, B. Adebisi¹

¹Helen Keller International, Nigeria

Background and Objectives: Nutrition indicators in Nigeria are some of the worst in Africa with 41% of children less than five years of age stunted, 14% wasted and 23% underweight. Poor infant and young child feeding (IYCF) practices resulting from inadequate knowledge and conflicting local beliefs were identified as major contributory factors. Health workers are expected to be knowledgeable in IYCF since caregivers rely on them for guidance. Research was conducted to evaluate the IYCF knowledge base of health workers (HWs).

Methods: Data was collected from primary health centers (PHC) using the Rapid Health Facility Assessment (RFHA) method. Multistage sampling technique was used to select interviewed PHCs. Nutrition knowledge of PHC HWs was collected using a structured interviewer administered questionnaire. Eighteen PHCs across 3 Area Councils in the Federal Capital Territory Abuja were assessed.

Results: HWs knowledge on IYCF practices showed that 95% were knowledgeable on breastfeeding issues while 69% and 52% respectively knew the correct time to introduce and right quantity of complementary foods to give each day. Almost all (82%) the HWs did not know the correct age to introduce complementary foods to children. About 62% are involved in food demonstration activities while 74% promote continued breastfeeding with complementary feeding. Only 55% have heard about vitamin A fortified foods however 44% are unable to identify the vitamin A fortified food's logo.

Conclusions: The survey shows HWs inadequate knowledge on complementary feeding. Timely introduction of complementary foods and the quality of foods to be given seems to be a problem with majority of the HWs opting to introduce watery pap with little nutritional value. Providing refresher training to health workers to correct their misunderstandings and reinforce their counseling skills is essential to ensuring the quality of nutritional counseling and reducing malnutrition

Key Words: Knowledge, complementary feeding, health workers.

PO1767

NUTRITIONAL STATUS AND DIETARY HABITS AMONG PHARMACY STUDENTS IN SERBIA

S. Sobajic¹, B. Vidovic¹, J. Timic¹, S. Milovic¹, I. Djuricic¹, N. Ivanovic¹, V. Todorovic¹, U. Cakar¹

¹Department of Bromatology, Faculty of Pharmacy, University of Belgrade, Serbia

Background and objectives: Dietary habits have important role in providing optimal nutritional status and chronic diseases prevention. The aim of this study was to assess the dietary habits and nutritional status among the students of the Faculty of Pharmacy in Belgrade.

Methods: A total of 264 female students with the mean aged 23, 2 ± 1, 6 participated in this study. The data related to eating, drinking and smoking habits were obtained based on self-administered questionnaire. The height, body weight, body fat percentage, waist and hip circumference were measured, and body mass index (BMI) and waist-to-hip ratio (WHR) were calculated.

Results: According to BMI, 81, 8% of students had a normal BMI and 13, 6% were underweight. Dietary habits of the students showed that 46, 6% reported taking meals regularly. Approximately 48% of the students skip their breakfast daily. Only 31, 3% of students reported daily intake of vegetable, while 37.3% reported consuming fruit every day. About 18, 6% of the students consume fast food daily, and the highest percentage consumes it 3–4 times a week (42, 9%). Alcohol intake and smoking were not common among students.

Conclusions: In this study we have demonstrated that many students have unhealthy dietary habits. Educational interventions should be planned to decrease the health risks attributable to their eating behaviors.

Key words: nutritional status, dietary habits, students. This work was supported by the Ministry of Education, Science and Technological Development, Republic of Serbia, Project No III-46001

PO1768

RELATIONSHIP BETWEEN STUNTING TO DISEASES, PATERNAL EDUCATION, AND SOCIAL ECONOMY IN INDONESIAN CHILDREN

S. Sandjaja¹

¹Persatuan Ahli Gizi Indonesia, Indonesia

Background and objectives: SEANUTS is a comprehensive nutrition survey conducted in four South-East Asian Countries namely Indonesia, Malaysia, Vietnam and Thailand. The study collected anthropometry, biochemical parameters, die-

tary intakes, health status, and socio-economic status of child's family. In Indonesia, SEANUTS is run by Persagi (Indonesian Nutrition Association) in 7, 211 children aged 0.5-12 years selected randomly from 48 districts all over Indonesia in 2011. The objective of this presentation is only part of the SEANUTS particularly on stunting and associated risk factors

Methods: Height of children were measured by trained enumerators using length measuring board and stadiometer. Date of birth was recorded based on birth certificate and age was calculated. Stunting is defined as <-2.00 a-score using WHO Child Growth Standard. Risk factors of child characteristics and morbidity in previous month, and family socio-economic status were collected by using questionnaires, blood analysis, 24-hour dietary recall.

Results: The results showed that the prevalence of stunting was the highest among four countries 32.7 percent, higher in rural (38.8%) than urban areas (24.6%), lowest in youngest age group (> 2 year old) (28.8%), and no clear difference by gender. Risk factors of stunting was strongly associated with lower parents' education, poor family as measured by score of valuable goods owned, poor score of child morbidity, low birth weight, and poor dietary intakes.

Conclusions: Stunting in Indonesia is high and associated with family and child characteristics, morbidity and dietary intakes

Key words: stunting, nutritional status, Indonesian children

PO1769

CONSUMPTION OF NON CALORIC SWEETENERS IN UNIVERSITY POPULATION

MJ. García-Meseguer¹, F. Cervera Burriel², C. Vico García³, M. Milla Tobarra⁴, R. Serrano Urrea⁵

¹Departament of Nursing and Physiotherapy, University of Castilla-La Mancha, Campus of Albacete, Spain

²Health Service of Castilla-La Mancha, Motilla del Palancar, Cuenca, Spain

³Center of Primary Care, Health Service of Castilla-La Mancha, Albacete, Spain

⁴General Hospital, Health Service of Castilla-La Mancha, Talavera de la Reina, Toledo, Spain

⁵Departament of Mathematics, University of Castilla-La Mancha, Campus of Albacete, Spain

Background and objectives: Non-nutritive sweeteners are one option for maintaining sweet taste through reducing the energy content diet of children and young people. However, several epidemiologic studies suggest that consumption of products containing non caloric sweeteners may promote ex-

cessive intake and body weight gain by weakening a predictive relationship between sweet taste and the caloric consequences of eating. It may be associated with a decrement in the ability of sweet taste to evoke reflex responses which are thought to help maintain energy balance by interfering with fundamental homeostatic, physiological processes. Knowledge about consumption habits of non caloric sweeteners can contribute to plan educational interventions in this way. The objective of this work is to determine the habitual consumption of non caloric sweeteners and its relationship to some possible conditional factors in a university population

Methods: A Cross-sectional observational study has been conducted on a sample of 604 students from University of Castilla-La Mancha (Campus of Albacete). A questionnaire was self-administered which reported information about habitual intake of non caloric sweeteners besides some sociodemographic and anthropometric factors.

Results: The average age of students was 20, 63 ± 4 , 45 years, 50, 33% women ($n = 304$) and 49, 67% men ($n = 300$). Habitual consumption of non caloric sweeteners in females was twice (20, 93% than in male (10, 28%), being normal weight BMI majority in both sexes. Only 1, 06% of women and 3, 4% of men were obese. Positive significant correlation ($p < 0, 01$) between BMI and non caloric sweetener consumption while negative significant correlation ($p < 0, 05$) between BMI and number of daily meals have been found.

Conclusions: Taking into account that young people often take low calories beverages besides added non caloric sweeteners, the regular intake of non caloric sweeteners could be an important factor to promote obesity in the future in this healthy population.

Key words: caloric sweeteners, obesity, BMI.

PO1770

PROGRAM ACTIVITIES FOR THE OBESE PATIENT (PAPO)

S. Freire¹, T. Tormena¹, C. Carvalho¹, L. Garcia², M S. Vitalle¹, M. Fisberg¹

¹University Federal of Sao Paulo, Sao Paulo, Brazil

²University of Sao Paulo, Sao Paulo, Brazil

Background and objectives: Searching increase the effectiveness of the interdisciplinary treatment of obesity in adolescence, the Division of Adolescent Medicine, Department of Pediatrics UNIFESP developed 15 years ago the PAPO. This study aims to assess the impacts of changes in feeding behavior of obese adolescents.

Methods: Were selected 16 girls from 13 to 16 anos age, BMI > 85 th, to participate in the program that consists of complementary areas (Physical Education, Nutrition Education,

Psychology and Sports Modalities. These activities occur in groups three times a week, one hour per week per area for four months. Nutrition in adolescents were instructed to perform three goals; eat each 3 hours without repeating a portion and without nipping the intervals, and other targets with the aim of balancing food intake. The dietary questionnaire was designed to assess the behavior, stipulating a number expected by the end of the program for each item. To compare the anthropometric data was used the Student t test for dependent samples and dietary habits we used the marginal homogeneity test.

Results: There were no statistically significant changes in anthropometric measurements. In relation to eating habits, some changes were statistically significant, with a reduction in the number of girls who: consume sweet and fatty foods in more than three days a week; fast-food consume more than twice per month; repeated portions more than one day per week; nip between meals in over three days of the week; not eat each three hours at least six days a week, and eat their meals in front of the TV or computer more than three days a week.

Conclusions: The PAPO is efficient to stimulate change in eating behavior of obese adolescents.

Key words: behavior, dietary goals, obesity.

PO1771

DEVELOPMENT OF ANAEMIA ASSESSING INDEX (AAI) TO ASSESS THE RISK OF ANAEMIA AMONG 6 TO 24 MONTHS OLD CHILDREN

J. Arun¹, K.M. Rathnayake², D.R. Peiris³

¹School of Population Health, Faculty of Medicine, the University of Melbourne, Australia

²Department of Applied Nutrition, Faculty of Livestock, Fisheries and Nutrition, Wayamba University of Sri Lanka, Makandura (60170), Sri Lanka

³World Vision Lanka, Colombo, Sri Lanka

Background and objectives: Early identification of the anaemic risk children is important to develop appropriate interventions to reverse the high prevalence of anaemia among young children. The aim of the present study was to develop an anaemia assessing index (AAI) to assess the risk of anaemia among 6 to 24 months old children.

Methods: This study was conducted as a cross-sectional study in Sri Lanka. A sample of 456 children aged between 6 to 24 months was selected using cluster random sampling method. A comprehensive literature review was done to identify the risk factors associated with anaemia among children. A pre-tested interviewer administrated structured questionnaire was used to develop the AAI. The HaemoCue method was used to measure haemoglobin concentration, and anaemia was defined as haemoglobin < 11 g/dl. Socio economic (SE),

child feeding practices (CFP), mothers' nutrition knowledge (MNK), communicable diseases on previous month (CDPM), water, sanitation and home gardening practices (WSH), and mother and child nutrition status (MCN) were identified as six main indicators. A composite AAI was developed by discriminant analysis using identified six main indicators. **Results:** The developed index was $AAI = -4.8 - 0.7 * SE + 2.3 * WAH + 3.1 * CFP + 1.6 * MNK + 0.8 * MCN + 1.3 * CDPM$. The overall prevalence of anaemia among the study group was 79% and 4% was severely anaemic. SE, CFP, MNK, CDPM, WSH, MCN indicators were identified as risk factors for anaemia and they were significantly associated ($P < 0.01$) with low hemoglobin levels among the children.

Conclusions: A composite AAI was developed to assess the risk of anaemia among 6 to 24 month old children. Sensitivity and specificity of the AAI were 80.6% and 80.2%, respectively.

Key words: Index, anaemia, children, indicators

PO1772

THE TYPE OF DISEASE AFFECTS DIETARY ADHERENCE

E. Fappa¹, M.Yannakoulia¹

¹Department of Nutrition and Dietetics, Harokopio University, Athens, Greece

Background and objectives: The role of diet in the prevention and management of various chronic diseases is established. However, patients' adherence to the proposed regime is a prerequisite. Various factors affect dietary adherence, including age, sex or nutritional knowledge of the individual. Aim of this analysis was to explore whether the type of the disease [Metabolic Syndrome (MetSyn) or Rheumatoid Arthritis (RA)] or the type of intervention affects dietary adherence of patients receiving similar lifestyle intervention.

Methods: Ninety patients with RA (n=32) or MetSyn (n=58) (41% men, mean age: 23 to 81 years) received a 6 month lifestyle intervention program, based on the principles of the Mediterranean diet, participated in the study. The intervention was delivered either by telephone or face to face contact. All participants were underwent anthropometric, dietary and physical activity evaluation at baseline and at the end of the intervention. Dietary adherence was assessed through the Mediterranean Dietary Score (MedDietScore). The score ranges from 0 to 55: higher values indicate greater adherence to the Mediterranean diet.

Results: At baseline, patients with MetSyn, compared to RA patients, were younger and they, had greater BMI and MedDietScore values (all $p < 0.001$). Repeated measures analysis that the type of disease ($p = 0.001$), but not by the type of intervention ($p = 0.374$), was significantly associated with chan-

ge in dietary adherence, as evaluated by MedDietScore. No interaction between disease and type of intervention was found ($p=0.667$). Further adjustment for age, sex or BMI did not change the results.

Conclusions: These findings indicate that the type of the disease may affect adherence to a dietary intervention. More research is warranted on the specific characteristics of the diseases that affect adherence and potential interactions with biological factors.

Key words: dietary adherence, metabolic syndrome, rheumatoid arthritis.

PO1773

THE EFFECT OF NUTRIBUTTER SUPPLEMENTATION ON COMPLEMENTARY FEEDING PRACTICES AMONG YOUNG CHILDREN IN AN URBAN SLUM OF HAITI

L. Iannotti¹, S. Jean-Louis², C. Lesorogol¹, J. Green¹, N. Nickerson³

¹Washington University In St. Louis, USA

²Notre Dame de la Sagesse School of Nursing, Justinien Hospital, Haiti

³Konbit Sante, Justinien Hospital, Haiti

Background and objectives: In Haiti since the January 2010 earthquake, high-energy dose food supplementation programs have been implemented with little regard for populations in transition and infant and young child feeding (IYCF) practices. We hypothesized that a low-dose (108 kcal) micronutrient-fortified food, Nutributter[®], offered within a package of integrated health services would preserve IYCF and promote linear growth.

Methods: Healthy, singleton infants ages 6-12 months ($n=589$) were randomized to: control group; Nutributter[®] for 3 m; and Nutributter[®] for 6 months. Children were followed monthly for 6 months, and again 12 months from baseline to test for sustained effects. Diet was examined through 24-hour recall of frequency of complementary foods and breastmilk consumption. Dietary diversity was defined as number of different foods consumed in a day. Changes in IYCF, uptake of health services, and Nutributter[®] acceptability and uses were assessed at each visit and through qualitative methods of in-depth interviews and focus groups.

Results: Panel regression analysis, generalized least squares (GLS) with random effects, showed that Nutributter[®] supplementation significantly increased dietary diversity by 0.23 (± 0.07 SE) after controlling for child age, baseline diversity score, maternal education, and household income ($p<0.001$). Breastfeeding frequency was reduced in the Nutributter[®] groups, but the effect did not interfere with linear or somatic

growth. Qualitative findings showed that despite apprehension to buy peanut butter in the market, mothers trusted the fortified paste delivered through the healthcare system.

Conclusions: This mixed-methods RCT demonstrated that low-dose food supplementation not only maintained, but improved some IYCF practices. Efforts are needed to change perceptions about breastfeeding and poverty in this context and redirect complementary feeding programs towards low dose, micronutrient fortified foods.

Key words: Breastfeeding, supplements.

PO1774

INFORMING SCHOOL MEAL POLICY THROUGH USE OF A NOVEL WEB-BASED DATA COLLECTION METHOD IN SWEDEN

E. Patterson¹, L. Schäfer Elinder¹

¹Dept of Public Health Sciences, Karolinska Institutet, Stockholm, Sweden

Background and objectives: School meal policies have the potential to improve public health nutrition. Sweden is one of very few countries with a policy of providing free meals to all school children regardless of parental income. National guidelines for school meals exist but adherence varies widely. The lack of a national monitoring system has meant that the quality of school meals, the factors related to it, and its effects on public health has long gone undocumented. We developed an innovative, validated instrument 'School Food Sweden' (www.SkolmatSverige.se) to overcome these problems. The instrument is web-based and consists of three levels, covering topics from meal choice/provision, nutritional quality, hygienic food practices, meal service and related pedagogic activities, environmental impact and organisational factors.

Methods: In the course of developing the instrument we invited 695 primary schools to test it (spring 2011); 191 completed the compulsory first level. 'Nutritional quality' is a summary variable indicating whether meals met the nutritional recommendations for iron, saturated fat, vitamin D and fibre. 'Lunch quality' summarises the number and type of warm meals and salad buffet offered. Cross-tabulations were performed against school size, type (municipal/private), geographical region, and reported access to a catering dietician.

Results: "Lunch quality" was positively associated with school size, with municipal schools and with the eastern region of Sweden ($P<0.05$). Nutrition recommendations for all four nutrients were met in only 6% of schools. "Nutritional quality" was significantly associated with lunch quality ($P<0.005$) but not directly with any of the other variables.

Conclusions: These results are an important first step in understanding the complex determinants of school meal qua-

lity. The instrument is now available to all primary schools and means that school meal policy can in future be informed by relevant and timely data.

Key words: school meals, children, monitoring.

PO1775

OBJECTIVELY MEASURED PHYSICAL ACTIVITY IN NORMAL WEIGHT/OVERWEIGHT, NON-STUNTED/STUNTED GUATEMALAN CHILDREN AND ADOLESCENTS

E R. Close¹, T.S. Mustafa², M. Ramirez-Zea¹

¹INCAP Comprehensive Center for the Prevention of Chronic Diseases (CIIPEC), Institute of Nutrition of Central America and Panama (INCAP), Panama

²Faculty of Bioscience Engineering, Ghent University, Belgium

Background and objectives: Prevalence of childhood overweight is rising in developing countries, where stunting is still a public health issue. Data on physical activity (PA) is scarce when both conditions coincide. Our objective was to assess PA in normal weight non-stunted (NW-NS) and stunted (NW-S) and overweight non-stunted (OW-NS) and stunted (OW-S) school-age children.

Methods: 37 NW-NS (BMI-Z < +1; HA-Z > -1), 88 NW-S (BMI-Z < +1; HA-Z > -1), 50 OW-NS (BMI-Z < +1; HA-Z > -1) and 46 OW-S (BMI-Z < +1; HA-Z > -1) subjects (112 girls/109 boys, 6.7 - 17.7 y old) were recruited in 9 low-income, urban schools from Guatemala City. Subjects wore an accelerometer (Actigraph) on the waist up to seven days (epoch set at 60 seconds). Records were considered as valid when there was at least 660 minutes of continuous recording and data on at least one weekend day and two weekdays. PA is reported as total counts/day and minutes/day doing moderate to vigorous physical activity (MVPA, >2100 counts/minute, mean ± SD).

Results: Boys were more active than girls (658 ± 218 vs 560 ± 222 counts/day, 66 ± 38 vs 49 ± 33 minutes/day MVPA, p<0.01). There were no differences in counts/day among nutritional status groups (p=0.08). MVPA was lower in NW-S (53 ± 37) and OW-S (52 ± 35) compared to NW-NS (74 ± 42).

Conclusions: Stunting impaired daily physical activity, particularly of moderate to vigorous intensity, regardless of weight status.

Key words: Obesity, stunted, physical activity. Acknowledgements: Funding was received from the International Atomic Energy Agency and the National Institutes of Health (R01 MH067981-04, NHLBI HHSN-268200900028C)

PO1776

NUTRIENT INTAKE AND TELOMERE LENGTH AMONG JAPANESE AND KOREAN POPULATIONS

M. Masaki¹, S. Yabuta¹, Y. Shidoji¹, H.J. Yoon², S.K. Lee²

¹University of Nagasaki, Nagasaki, Japan

²Kyungpook National University, Daegu, Korea

Background and objectives: Telomere length may be affected not only by physical aging but also by life style factors including dietary intake. This study clarifies the relationship between nutrient intake and telomere length among Japanese and Korean populations.

Methods: Telomere length was measured by monochrome multiplex quantitative PCR (MMQPCR) method with buccal swab that is a low-invasive material for sampling. The telomere length was finally expressed as a relative telomere length (RTL) comparing with reference sample. The subjects of this study consist of 135 men and women (92 Japanese and 43 Koreans) voluntarily recruited with a written informed consent. The participants were mostly officer for Japanese and those of having medical checkup for the Korean. Age distribution of both populations indicated that Japanese was younger when compared to the Korean. The data of nutrient intake was obtained by validated food frequency questionnaire (FFQ) for both populations. Logistic regression analysis was used to identify the important nutrients affecting RTL.

Results: The values of RTL were negatively correlated with age only for Korean population (r=-.318, p=.04). For nutrient intake, RTLs were positively correlated with values of Fe, beta-carotene, folic acid, and fiber and negatively with fat and Mg in both populations. Korean females showed a greater value of RTL than that of Japanese regardless of its elderly sample. Logistic regression analysis indicated that value of beta carotene was significantly associated with RTL after adjusting age, sex, and other confounding variables.

Conclusions: Intake of nutrients suggesting of anti-oxidative activity may be effective in preventing telomere shortening among Asian populations.

Key words: telomere, nutrient, Japanese, Korean

PO1777

GLOBAL MALNUTRITION CAPACITY BUILDING ENABLED BY ELEARNING AND SOCIAL MEDIA

T. Pickup¹, R. Annan², S. Choi¹

¹Medical Education, Faculty of Medicine, University of Southampton, Southampton, United Kingdom

²Department of Biochemistry and Biotechnology, College of Science, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana

Background and objectives: The outcomes of severe malnutrition in children can be significantly improved by providing training to those undertaking the management of children with malnutrition. Making standardised and accessible training available globally could play a major role in reducing childhood mortality by malnutrition. Access to Internet is improving at a great rate across the world, offering a huge potential for technology enabled training in the developing world. Utilising the technology to offer such training, in 2010 the International Malnutrition Task Force and University of Southampton developed a high quality training course, called "Caring for Infants and Children with Severe Acute Malnutrition". After its successful field test in Uganda, it was introduced to the health communities, agencies and professional bodies at international events. However, bringing the course to those who needed it most was slow.

Methods: To increase its uptake, from October 2012 marketing strategies using social media were devised to promote the course widely. Their effectiveness was investigated in January 2013.

Results: For 4 months 1200 people from over 100 countries, including Haiti and N.Korea, enrolled the course, indicating 3,000 per annum. There now is a global demand for the course, with 10 people a week enrolling via Google, 20 responding to posts in LinkedIn/Facebook, and many others responding to "word of mouth" recommendations. Most are health professionals, for whom training is directly relevant but unavailable through other means. It has also begun to be used by academic institutions, embedded within curricula, and NGOs for community-based training.

Conclusions: The malnutrition course has great potential for providing training globally, directly to those who need it. Feedback is very positive, describing improved knowledge and competency in malnutrition management required in work places. Social media can provide the opportunity to bring learners and learning together.

Key words: eLearning, Malnutrition, training, Social media.

PO1778

MORTALITY DUE TO MALNUTRITION AMONG UNDER 5-YEAR-OLD CHILDREN AND ITS RELATION TO SOCIOECONOMIC INDICATORS IN COLOMBIA

C. Arango¹, C. Molina¹

¹National School of Public Health, University of Antioquia, Medellín, Antioquia, Colombia

Background and objectives: The child health situation in the Americas has improved in the last years thanks to social and economic development and better health-care coverage. In Colombia, however, problems such as respiratory infections, diarrhea, malaria, and malnutrition persist. Objective: To analyze the structure and trend of malnutrition mortality among under 5-year-old children in Colombia from 1985 to 2006 and establish its relation to socioeconomic indicators.

Methods: Descriptive, ecological study based on official mortality records from the Colombian Vital Statistics System. Net and adjusted rates, mortality standardized reasons, and Poisson regressions for trend analysis were obtained. A multiple linear regression model was built to estimate the relation between the malnutrition mortality rate and socioeconomic indicators.

Results: The analysis included a 22-year period in which 370,136 deaths of under 5-year-old children were registered, 4,1% due to malnutrition. The trend analysis showed two significant inflection points in 1994 and 2000, the first one decreasing, the second one, increasing. The unfulfilled basic needs index, the human development index, and the prevalence of breastfeeding explained 37% of variations in malnutrition mortality rates.

Conclusions: The increasing trend in malnutrition mortality rates starting in 1994 highlight the fact that the implementation of the Colombian Health-Care System did not have the expected effect, quite the contrary health care has deteriorated. Higher mortality rates appeared between 2000 and 2001, just when poverty levels in Colombia worsened.

Key words: Malnutrition, mortality rate, Colombia.

PO1779**NEPAL'S NATIONAL IRON INTENSIFICATION PROGRAM IMPROVED IFA COVERAGE FOR PREGNANT WOMEN AFTER 5 YEARS AND AFTER 10 YEARS PROTECTED AGAINST ANEMIA**

M L. Roche¹, R. Pabayo², M R. Maharjan³, R. Pokharel⁴, L M. Neufeld¹

¹Micronutrient Initiative, Ottawa, Ontario, Canada

²Harvard School of Public Health, Boston, Massachusetts, USA

³Micronutrient Initiative, Kathmandu, Nepal

⁴Nutrition Section/Child Health Division, Department of Health Services, Ministry of Health and Population, Kathmandu, Nepal

Background and objectives: The global health community has looked to Nepal's Iron Intensification Program (IIP) as a successful scale-up of a national iron folic acid (IFA) supplementation program for pregnant women. The IFA coverage increased from 23% to 59% between 2001 and 2006 and to 80% in 2011. Contradictory to the improved coverage of IFA for pregnant women, the anemia rates increased from 42.4% in 2006, to 47.6% in 2011. These unexpected results highlighted the need for further study of the IIP and implications for IFA coverage and anemia.

Methods: We estimated the possible impact of exposure to the ten year IIP on IFA supplementation coverage and anemia in mothers through multiple regression modelling of the 2006 and 2011 Demographic Health Surveys controlling for IIP district exposure, age, pregnancy status, wealth, religion, parity in the last 5 years, weight status, education, and ecological region. Sampling weights were utilized and data analysed using multilevel modelling because respondents were nested within districts.

Results: In the 2006 and 2011 surveys, 4, 693 and 2, 168 women provided blood samples respectively. In 2006, women who lived in districts with IIP implemented were more likely to receive IFA supplements in comparison to those who lived in districts without IIP (OR=1.85, 95% CI=1.16, 2.94). Similar results were obtained in 2011. Multiple regression analyses indicated that in 2006, women who lived in IIP districts were not significantly less likely to have moderate or severe anemia. However, in 2011, women who lived in IIP districts were marginally significantly less likely to have moderate or severe anemia (OR=0.56, 95% CI=0.30, 1.03).

Conclusions: The IIP increased IFA coverage and may protect against anemia. Further studies, both qualitative and quantitative are still underway to explore how the program can be further strengthened in Nepal.

Key words: Iron Folic Acid Supplementation, Pregnant Women, Anemia, Nepal, Scale-up.

PO1780**WHEN RESEARCH STUDY AND NUTRITION PROGRAM IMPLEMENTATION TIMELINES CLASH – A CASE REPORT ON VITAMIN A SUPPLEMENTATION FROM SOUTH AFRICA**

M A. Dhansay^{1,2}, S E. Schoeman¹, J. Nel³, M. Le roux³, M E. Van Stuijvenberg¹

¹Nutritional Intervention Research Unit, South African Medical Research Council, Cape Town, South Africa

²Division of Human Nutrition, University of Stellenbosch, Cape Town, South Africa

³Northern Cape Department of Health, Kimberley, South Africa

Background and Objectives: Public health (nutrition) decisions are taken with communities or entire countries as the unit of intervention. However, there may be contextual differences within countries that need to be recognised. The policy implications of the need for vitamin A supplementation (VAS) in the Northern Cape Province (NCP) of South Africa (SA) have been presented elsewhere. That study was done in collaboration with the local health department and dietitians. An impasse arose when the research was halted because of the imminent implementation of a VAS campaign in the study town, threatening the findings of the study. The objective of the presentation is to describe the events prior to the deadlock between research team and decision-makers, the resolution of the problem, and make recommendations for avoiding similar situations.

Methods: A narrative description of the events leading to the impasse between the research team and decision makers at national and provincial level, as well as the agreement that was reached.

Results: The research study was approved by the IRB and the NCP Health Department and intended evaluating vitamin A status before the under-fives received VAS. The imminent campaign would impact the results of the study. Representation was made to the IRB, which ruled that the long-term benefits of completing the study were higher than the risk of deficiency - the children were consuming preformed vitamin A and preliminary results showed no immediate need for vitamin A. Approval for postponement was sought and received from the National Nutrition Department and the NCP Health Department, after intense, prolonged telephone and email communication.

Conclusions: The "distance" between researchers and policy makers/ programme implementers/decision-makers is crucial, so that any problems affecting the conduct of research studies may be addressed timeously, and preferably pre-empted.

Key words: Researchers; decision-makers; programme implementation; partnerships.

⁹Unidad de Coproctología. Hospital Universitario San Cecilio de Granada, Spain

¹⁰Instituto de Biomedicina (IBIOMED), Universidad de León, León, Spain

Background and objectives: It has been hypothesized that elevated meat consumption may increase risk of general obesity, indirectly contributing to risk of obesity-related chronic diseases. Despite research linking meat consumption to dietary patterns such as higher intakes of energy and reduced intakes of low energy-dense foods such as vegetables, evidence of a link to obesity remains limited and inconsistent.

Methods: This cross-sectional analysis included 2600 adults aged 24-85y (mean 62y) recruited between 2007- 2012 from the general population as controls in a multi-case control study of cancer from 10 Spanish regions. Dietary intakes were assessed using a previously validated food frequency questionnaire. Logistic regression was used to assess associations between higher proportions of meat consumption (g/100 kcals) and odds of overweight, obesity and elevated waist circumference (WC >88cm women, 102 cm men), adjusting for age, sex, region, education, smoking, and alcohol intake.

Results: Meat consumption (mean intake 4.6g/100 kcals) was positively associated with energy intake. Women in the

top tertile of meat intake had increased odds of overweight (OR=1.6; 95%CI=1.0-2.4), obesity (OR=2.5; 1.6-3.9) and elevated WC (OR=1.4; 1.1-1.9). These associations were stronger for cured/processed and red meats than for poultry/white meats. However, associations in men were null, both for meat intakes as a whole and for meat subtypes. Excluding low energy reporters, adults <45y, or additionally adjusting for intakes of seafood, fruits and vegetables, had no meaningful effect.

Conclusions: Though findings are consistent with an increased risk of obesity and excess energy intakes related to meat consumption in women, evidence was lacking in men. Further research is needed to assess to what extent associations between meat consumption and obesity may be linked to correlated dietary patterns which may vary by gender or food culture, and whether such patterns are prospectively related to excess weight gain.

Key words: Meat consumption, central obesity, BMI.

PO1782**POSSIBLE CAUSES OF HIGH RATES OF NON-RESPONDENTS IN COMMUNITY MANAGEMENT OF ACUTE MALNUTRITION (CMAM): THE SCI NORTH NIGERIA EXPERIENCE**

D. Ekele¹, F. Joseph¹, A. Oseni¹, A. Okekunle²

¹Nutrition Project, Save The Children International, Katsina field Office, Katsina State, Nigeria

²Department of Human Nutrition, University of Ibadan, Oyo State, Nigeria

Background and objectives: Non-respondent's cases in the Community Management of Acute Malnutrition (CMAM) project by Save the Children International with funding from European Commission for Humanitarian Aid Office (ECHO) in Northern Nigeria as a major concern. This is largely due to a number of factors, Malnutrition and child mortality remains an issue of public health significant in Northern Nigeria and high cases of non-respondents remains a major source of concern in terms of program quality. This study accesses factors responsible for the high cases of non-respondents in CMAM.

Methods: Qualitative data was compiled from 4 Local Government Areas (LGA) with high non-respondents. 5 patients' cards were randomly selected from 15 facilities (static/fluctuating weight, referrals, physical examination and Drug administration). Visits were made during clinic days to observe the dispensing of Ready To Use Therapy Food (RUTF). 40 household caregivers and village-heads were also interviewed to get information on RUTF usage and consumption at home.

Results: Qualitative analysis shows that 90% of the non-respondents had regular attendance during their treatment in the facilities, 82% did not receive vaccinations for measles

and other illnesses, 85% for anti-malaria drugs at any time during their treatment. Interview information gathered showed that non-respondents patients were not given correct doses of RUTF at home (50% of RUTF rations was shared with non-SAM patients and there were cases of sales of RUTF). 95% were not visited by the Community Volunteers (CVs) to guide them on the usage of RUTF and 70% of facilities did not give key messages on RUTF consumption to the caregivers.

Conclusions: the survey on possible reasons for non-respondent to SAM revealed poor management of clients. The effective management of SAM requires careful and systematic medical treatment to complement treatment with RUTF and adequate community participation.

Key words: CMAM, RUTF, Non-respondents and Caregivers.

PO1783

THE CHRONIC EFFECTS OF COFFEE INGESTION ON HYDRATION STATUS: A COUNTERBALANCED CROSS-OVER STUDY IN A FREE LIVING POPULATION

S. Killer¹, A. Blannin¹, A. Jeukendrup¹

¹University of Birmingham, Edgbaston, Birmingham, UK

Background and objectives: It is often suggested that coffee causes dehydration and its consumption should be avoided or reduced to maintain fluid balance. The aim of this study was to compare the chronic effects of moderate coffee consumption against water ingestion across a range of hydration assessment techniques.

Methods: In a counterbalanced cross-over design, 50 habitual coffee-drinking males participated in two conditions; coffee (C) or water (W). Each condition consisted of two consecutive days during which participants consumed 4x200 g coffee (4 mg/kg caffeine) or water. All food and fluids were provided to participants during each trial. Total body water (TBW) was calculated via ingestion of deuterium oxide and analysis with Isotope Ratio Mass Spectrometry to observe fluid balance. Nude body mass (BM) was measured daily. Urinary (USG, osmolality, 24 h volume, sodium (Na⁺), potassium (K⁺) and creatinine) and haematological hydration markers (haematocrit, serum osmolality, total plasma protein, creatinine, blood urea nitrogen, serum Na⁺ and K⁺) were recorded daily throughout both conditions. Plasma was collected daily for analysis of caffeine for compliance.

Results: There were no changes in TBW from beginning to end of either trial and no differences between trials (p>0.05). No differences were observed between trials across any haematological markers. No differences were observed between trials

in 24 h urine volume, USG, osmolality or creatinine (p>0.05). No differences in serum Na⁺ concentrations were observed between trials (141.2±2.5 and 141.2±2.4 mmol/L for C and W, respectively), although mean urinary Na⁺ excretion was higher in C than W (p=0.02). No significant differences in BM were found between trials, although a small but progressive daily fall was observed within both conditions (0.39±0.5 kg; p<0.05).

Conclusions: These data suggest that coffee, when consumed in moderation by caffeine-habituated males contributes to daily fluid requirement and does not pose a detrimental effect on fluid balance.

Key words: Fluid balance, Coffee, Hydration.

PO1784

EFFECTS OF WEB-BASED INTERVENTION ON KNOWLEDGE ATTITUDES AND BEHAVIORS RELATING HEALTH EATING IN CHINESE SCHOOL CHILDREN

L. Wang¹, J.J. Li¹, M. Yang¹, L.B. Li¹

¹Institute of Child & Adolescent Health, School of Public Health, Peking University Health Science Center, Beijing, China

Background and objectives: To evaluate the feasibility and efficacy of a web-based family oriented nutrition intervention in knowledge, attitudes and behaviors relating healthy eating in Chinese children.

Methods: A three-month parallel trial was conducted in two primary schools in a rural-urban fringe zone of Beijing, China, including one intervention and one control school. Children in grade 4 and grade 5 and their parents participated in the study. The target website was just provided to the intervention group. We used questionnaires to evaluate the effect of intervention. The web-logging on rate in the intervention group was estimated by using group interview in children and a phone call report in part of the parents (n=40).

Results: about 423 families participated in the study. After three months of intervention, the increase in children's healthy eating related knowledge was significantly higher in the intervention school than that in the control school (P<0.05). The changes in scores of healthy eating related attitude, self-efficacy and behaviors of children were not significantly different between the two schools (P>0.05). The score of parents' knowledge in the control group decreased significantly more than that in the intervention group (P<0.05). The changes in scores of availability of healthy foods at home and parental modeling were not significantly different between the two groups (P>0.05). The reported logging-on rate in children and parents were just about 20% and 15%, respectively.

Conclusions: The web-based and family oriented nutrition intervention can improve the healthy eating relating knowledge of children and parents, but didn't promote the attitudes, self-efficacy, behaviors and home nutrition environments. The web-logging rates were very low both in parents and children. Further study is needed in improving the logging-on rate in web-based nutrition intervention in Chinese children.

Key words: Children; Healthy eating; Nutrition environment; Web-based nutrition intervention.

PO1785

FOOD CONSUMPTION AMONG BRAZILIAN BENEFICIARIES OF "BOLSA FAMÍLIA" PROGRAM

M. Vieira da Silva¹, A. Sartori¹

¹Department of Agroindustry, Foods and Nutrition, Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo, Piracicaba, Brazil

Background and objectives: Aiming to reduce poverty and, consequently, ensure food security, over 13 million Brazilian families have been supported by Federal cash transfer program "Bolsa Família" (BFP) per year. This study aims to describe energy consumption (average) among beneficiaries of the Program.

Methods: The data used were obtained from the Brazilian Household Budget Survey microdata (POF 2008-2009), carried out by the Brazilian Institute of Geography and Statistics (IBGE), and related to the sample composed by 34, 003 persons (10 years old or more). From this total, 7, 600 were identified as BFP beneficiaries. The method used to obtain food consumption data was food diary.

Results: The average energy consumption among BFP beneficiaries was 1855.8 kcal/day (sd=826.39). The others (non beneficiaries) ingested 1917.48 kcal/day (sd= 832.91). Discriminating analysis in geographic regions/states it was identified that only in São Paulo state the beneficiaries ingested more energy (1907.07 kcal; sd=1639.48) when comparing with non beneficiaries (1868.1 kcal; sd=1318.11). Observing results for macronutrients, outstands the average lipid ingestion, systematically smaller among beneficiaries in general. The exception was beneficiaries living in São Paulo state, that achieved the bigger quantity of lipids ingested per day per person in the entire country (60.4g; sd=65.28).

Conclusions: The results of energy consumption were not excessive among beneficiaries and non beneficiaries. Data from São Paulo state (the richest state) needs attention, especially regarding to lipid ingestion. Considering the increase on overweight and obesity prevalence in Brazil, it is recommended the food consumption monitoring and the adoption of healthy life habits for population.

Key words: diet, energy consumption, social programs.

PO1786

AVAILABILITY OF ULTRA-PROCESSED FOOD IN THE NEIGHBORHOOD IS RELATED TO BMI IN WOMEN LIVING IN AN URBAN AREA OF BRAZIL

P. Martins¹, G. Vedovato¹, M. Oliveira¹

¹Department of Human Movement Sciences, Federal University of São Paulo, Santos, São Paulo, Brazil

Background and objectives: There are few studies in developing countries assessing the effects of food environment on nutritional status. The aim of this study was to evaluate whether there are differences in Body Mass Index (BMI) of women living in neighborhoods with different ultra-processed food availability.

Methods: Though a cross-sectional design, 531 women with children under 10 years of age were sampled from 36 randomly selected census tracts in the urban area of Santos, Brazil. Nutritional status of women and socioeconomic data were collected in household interviews. Concomitantly, availability of food in all stores of the census tract neighborhood (a buffer with 500m radius) was assessed. The stores were classified according to the percentage of ultra-processed foods sold, using the median as the cutoff point, and census tracts were also classified according to the predominance of food stores with varying availability of ultra-processed items. BMI values of women living in the two groups of neighborhoods were compared using t-test and a significance level of 5%.

Results: The percentage of stores classified as having greater availability of ultra-processed foods was 76% in the neighborhoods with the highest concentration of these stores and 51% in the neighborhoods with lower concentration. The BMI of women who lived in census tracts with greater availability of ultra-processed foods was significantly higher compared to those with lower availability (26.4 x 25.1 kg/m², respectively, $p = 0.017$). This results was further adjusted for socioeconomic status in a linear multiple regression model ($p=0.03$).

Conclusions: the nutritional status of women may be related to the availability ultra-processed food in the neighborhoods of residence. These results suggest the need for public policies in the food supply chain articulated the intervention actions on the environment, to increase the availability of minimally processed foods.

Key words: food environment, ultra-processed food, urban areas.

PO1787**ASSESSING THE IMPACT OF INTEGRATED HEALTH, NUTRITION, AGRICULTURE AND ECONOMIC EMPOWERMENT PROJECTS ON THE NUTRITIONAL STATUS OF LIBERIAN REFUGEES CHILDREN IN BUDUBURAM CAMP, GHANA.**

A. Sandow¹, C. Amuzu-Addo¹, J. Haynes², B. Abu³

¹Point Hope Ghana

²Point Hope Inc.

³Department of Nutrition and Dietetics, Faculty of Health Sciences, University of the Free State, Postal box 339, Bloemfontein 9300, South Africa

Background and objectives: Refugee settlements are characterized by food insecurity, malnutrition, health and sanitation problems. Services provided to address these issues are mostly sectorial and parallel activities. Point Hope, an NGO operational in the Buduburam Refugee Camp integrated the Health, Nutrition, Agricultural and Economic Empowerment services it provided to Liberian refugees at the camp in Ghana. The approach is to address the underlying causes of malnutrition within the household and prevent relapse of malnutrition.

Methods: Refugee households of malnourished children or persons are identified and enrolled in any of the three different programmes 1.) A Nutrition Programme focused on rehabilitation of malnourished children/persons 2) Agriculture skills training programme, established to simultaneously produce food to feed into the Nutrition programme and to train food insecure household members on agriculture. 3) Skills trainings programmes for household members. Baseline information on child anthropometric indicators, household food security and frequency of illness were collected in 2008 prior to the start of the integrated programme. Indicators were then monitored till 2012, when all components of the model were in place.

Results: Of an average population of 4000 refugee children under five years of age, Global Acute Malnutrition reduced from 11.9% in 2008 to 5.6% in 2012. General report of sickness of children under five years to the camp clinic has reduced by 60%. 804 malnourished refugee children's households have received a kind of support in nutrition or skills training among which 303 refugee households became self-reliant and have repatriated to Liberia. Of the camp population of 3,000 refugees, 21% were at risk or food insecure in 2008, which was reduced to 15% in 2012.

Conclusions: Causes of malnutrition are multi-factorial, the integrated programmatic approaches may reduce malnutrition, reduce relapse, and solve the diverse but basic causes. The approach could be helpful in refugee management.

Key words: Refugee, integrated programmatic approach, malnutrition.

PO1788**NEGATIVE WEIGHT EVOLUTION AMONG NORMAL BIRTH WEIGHT BRAZILIAN INFANTS: A NEW APPROACH TO NATIONAL DEMOGRAPHIC AND HEALTH SURVEYS**

J.A. Silveira², F.A. Colugnati², A.P. Poblacion¹, J.A. Taddei¹

¹Departament of Pediatrics, Universidade Federal de São Paulo, São Paulo, São Paulo, Brazil

²Division of Nephrology, Universidade Federal de Juiz de Fora, Juiz de Fora, Minas Gerais, Brazil

Background and objectives: The first two years of life are characterized by accelerated growth and development, especially considering that, by this time, both are more strongly determined by environmental factors than by genetic characteristics. These environmental factors are interlinked through a multidimensional chain of cultural, socioeconomic and biological determinants. The study aim was to describe the prevalence and identify social determinants for negative weight evolution (WEZ) in normal-birth-weight (NBW) infants.

Methods: Data was from the latest Brazilian Demographic and Health Survey-2006/07. We selected children between 0-23 months (n=1482), living in the same house with their mothers. WEZ was calculated subtracting the survey's and birth's weight-for-age z-score, considering this variable a biological indicator capable to identify environmental influences on infant's growth, given that poor anthropometric outcomes reflect poor health status. To quantify associations, WEZ was dichotomized in negative and positive. A negative WEZ indicates that a child fell from the expected weight gain pattern. Multivariate models were used to estimate the prevalence ratio of negative WEZ determinants, based on the UNICEF's Conceptual Framework of Malnutrition.

Results: Almost 42% of infants with NBW experienced negative WEZ. From eight variables significantly associated with negative WEZ in the bivariate analysis, these were the independent determinants in the fitted model: living in less developed regions, residing in households with moderate or severe food insecurity and having mothers with education lower than 8 years.

Conclusions: About 1.8 million infants were exposed to environments that impaired their growth. We found that macro environmental determinants had more influence than proximal ones for negative WEZ. This approach to health surveys was sensitive to characterize inequalities among different socioeconomic contexts and to identify risks for negative WEZ in different levels of determination. Acknowledgement: Silveira JA receives a scholarship from Fundação de Amparo à Pesquisa do Estado de São Paulo.

Key words: Infants; Surveys; Nutritional Disorders.

PO1789**LONG-TERM EFFECT OF A WORKPLACE HEALTH&WELLNESS PROGRAM ON BODY WEIGHT, RELATED METABOLIC AND HEMODYNAMIC MARKERS IN MEXICO EMPLOYEES**

M. Alvarez¹, A. Rullan¹, J. García¹, J O. Talavera^{2, 3}, P. Clark^{2, 4}

¹Pepsico Mexico, Mexico city, Mexico

²National University of Mexico (UNAM), Mexico city

³Epidemiology Unit, S. XXI Medical Center, Mexico city

⁴Clinical Epidemiology Unit, Mexico Children Hospital, Mexico city

Background and objectives: Prevalence of non-communicable diseases in Mexico has become a public health problem, with high economic impact due to diseases associated and presence of early mortality at high productivity ages. For adults, workplace is the ideal venue of intervention, reason why this study shows the long-term effect of a workplace-promoted health and wellness program (VIVE SALUDABLE-ADN), on body weight and related metabolic and hemodynamic markers.

Methods: From 2003 to 2009, 2341 administrative employees from the PepsiCo Mexico, voluntarily participated in the program comprising physical activities, personalized nutritional counseling and rest activities. Anthropometric, clinical and biochemical measures were done, baseline and after 6 months of intervention. 1560 participants' data were analyzed. Means were compared by years using ANCOVA analysis adjusted by age, gender, business area, job level and previous participation in the program.

Results: Metabolic syndrome prevalence observed in this population was 7% in 2006, 8.3% in 2007, 8.4% in 2008 and 4.4% in 2009. No significant changes in weight and BMI were observed, but an increase in body fat percentage in women from 2006 to 2008, with a plateau in 2009 ($p=0.001$). Similar results were observed in other variables in 2006(1), 2007(2), 2008(3) and 2009(4); BP: Females SBP: ($p=0.003$ (3vs1, 2, 4)), DBP: ($p=0.001$ (3vs1, 2, 4; 2vs4)), Males SBP: ($p=0.24$ (3vs4, $p=0.0503$)), DBP: ($p=0.022$ (3vs1, 2, 4)); Glucose(mg/dL): Female: 76.92 ± 0.83 , 79.66 ± 0.63 , 86.62 ± 0.75 and 86.02 ± 0.66 ($p=0.0001$ (1vs2, 3, 4; 2vs3, 4)); Males: 83.83 ± 0.95 , 86.21 ± 0.74 , 90.55 ± 0.90 and 89.16 ± 0.85 ($p=0.0001$ (1vs3, 4; 2vs3, 4)); HDL-C(mg/dl), Females: 50.54 ± 1.17 , 54.21 ± 0.94 , ($p=0.016$, 3vs4); Males: 40.11 ± 0.87 , 42.50 ± 0.74 ($p=0.04$, 3vs4); Triglycerides(mg/dl): Females, 106.07 ± 6.57 , 140.73 ± 5.10 , 126.24 ± 5.90 and 112.05 ± 5.29 ($p=0.0001$ (1vs2, 3; 2vs4)); Males, 150.84 ± 8.87 , 182.91 ± 7.10 , 159.00 ± 8.48 and 167.49 ± 8.00 ($p=0.037$ (1vs2; 2vs3)).

Conclusions: Study shows that it takes a continued effort, 3 to 4 years, to see beneficial results with a reduction in the progression and even a reversion of parameters associated with increased body weight, such as metabolic and hemodynamic abnormalities in workplace health and wellness programs.

Key words: Workplace, lifestyle, promotion.

PO1790**PREVALENCE OF OVERWEIGHT AND OBESITY AMONG ECUADORIAN WORKERS AND THEIR ASSOCIATION WITH LIFE STYLE FACTORS, EXERCISE, AND EATING HABITS**

P. Mogrovejo¹

¹Escuela de Nutriología, Universidad Internacional del Ecuador, Quito, Ecuador

Background and objectives: Personal characteristics can determine eating and exercise behaviors leading to greater risk of overweight and obesity. To study the relationship between overweight and obesity prevalence with socio demographic data, related illness, physical activity level, eating and exercise habits and the relationship between self efficacy and physical activity.

Methods: A cross sectional study conducted on 917 Ecuadorian private employees (663 men and 254 women). Surveys were conducted to obtain life style information, anthropometric data, eating habit (Fruit and Vegetable Stage of Change questionnaire), physical activity habit (Physical Activity Stages of Change and self efficacy questionnaire) and physical activity level (International Physical Activity Questionnaire). Statically, descriptive statistics, chi-squared test and multiple correspondence factorial analysis were used.

Results: Prevalence of overweight and obesity was 40% and 9.4%, respectively; higher in males ($p<0.001$), married ($p=0.000$), primary education level ($p=0.024$) and increases with age ($p<0.000$). Overweight and obesity were associated with hypertension and dyslipidemia ($p<0.001$). Overweight, obesity, abdominal obesity, high percentage of body fat and hypertension were associated ($p<0.000$). Individuals (83%) who fulfilled fruit and vegetable consumption recommendation were classified in maintenance stage of change. Conversely, most individuals who did not fulfilled fruit & vegetable recommendation were at the lower stages of change. Most of individuals (65.3%) were sedentary. Exercise stage of change was associated with physical activity level ($p=0.000$). Most of sedentary subjects were in contemplation stage of change. In contrast, active and very active subjects were in maintenance stage. Lower self efficacy was associated with obesity.

Conclusions: Overweight and obesity were more prevalent in men. Overweight, obesity and abdominal obesity were associated with cardiovascular disease. Employees need a healthy diet and physical activity promotion. Stage - based interventions would be appropriate, with focus on lower stages of change.

Key words: Obesity; exercise; eating; behavior.

PO1791

EVALUATING THE BEHAVIORAL EFFECT OF JUNK FOOD ADVERTISING AND BRAND PLACEMENT ON CHILDREN

A. Fuentes-García¹, R. Uribe²

¹School of Public Health, University of Chile, Chile

²Faculty of Economics and Business, University of Chile, Chile

Background and objectives: In the context of increasing obesity, previous studies have analyzed the influence of advertising in children's preferences demonstrating a modest but consistent effect on children's wishes. These have rarely focused on either brand-placement, or the combined-effect (synergy) with advertising. Seeking to orient public nutrition policies, this research evaluates the separate and joined-effect of advertising and placement on children's preferences, and whether it may change across age.

Methods: We did a 3x3 factorial experiment, with promotional tools (advertising, placement and synergy), and age (9, 12 and 15) as factors. The dependent variables were the behavioral disposition toward the product category (junk food) and the advertised brand (McDonalds). The sample was 382 children (57% women) distributed across the nine combinations. Children were exposed to a film clip (with/without McDonalds placement scene) including a commercial break (with/ without McDonalds advertisement). A self-administered questionnaire was answered where the dependent variable and covariates (sex, prior exposure and appreciation of the film) were examined.

Results: Covariates were equally distributed across conditions. Two-way ANOVA evaluating the disposition toward the product category ($F=3, 090, p=0, 047$) and for the brand ($F=3, 347, p=0, 031$) show a main effect for promotional tool but neither for age nor for the interaction of both. The combined use of advertising and placement increased the disposition toward the category and brand. Advertising and placement performed similar in both dependent variables.

Conclusions: This study shows the similar persuasive effect of advertising and placement, and the amplified effect of using both together. These findings suggest that public nutrition policies should regulate not only advertisement of food but also placement since these tools are used in an isolated or a combined way. The absence of a significant effect of age opens the question about the acquisition of new cognitive defenses after 9 years-old.

Key words: Obesity, Children, Advertising, Placement

PO1792

NUTRITIONAL RISK AND FUNCTIONAL IMPAIRMENT IN THE ELDERLY (NURSING HOMES AND FREE-LIVING) YUCATAN, MEXICO

L. Gonzalez¹, E. Gomez¹, A. Castellanos¹

¹School of Nutrition, Universidad Anáhuac Mayab, Mexico

Background and objectives: The present study examines the association of nutritional status and functional capacity (hand grip strength) in institutionalized and free-living elderly in Yucatan, Mexico.

Methods: 121 women (40 in nursing homes and 81 free-living) and 37 men (19 in nursing homes and 18 free-living), agreed to participate in the study. The age range was 60 to 97 years. Body Weight (kg) Height (m), triceps skinfold (mm), arm circumference (cm) were collected using standard methods and nutritional indicators were calculated using validated equations. Grip strength in both hands was measured using a mechanical dynamometer.

Results: Findings show differences ($P < 0.001$) in body weight (53.8 vs 62.4), BMI (kg/m^2) (26.2 vs 29.5), arm circumference (26.4 vs. 29.4), arm fat area (cm^2) (22.7 vs. 28.5) among nursing homes and free-living women. For its part, the indicators that showed differences between free-living and nursing homes men were ($P < 0.05$): triceps skinfold (11.7 vs. 9.1) and arm fat area (25.2 vs 21.3). Grip strength in both hands, was higher only in free-living women ($P < 0.05$), no difference was found in males.

Conclusions: We conclude that nutritional indicators fat and muscle mass are better in free-living women, while in males, body fat is higher in institutionalized subjects. Further research is required grip strength in males as an indicator of nutritional risk.

Key words: nutrition, handgrip strength, elderly.

⁴Viet Nam National Assembly Institute for Legislative Studies, Hanoi, Viet Nam

⁵Maternal & Child Health Department, Viet Nam Ministry of Health, Hanoi, Viet Nam

⁶GMMB, Seattle, USA

Background and objectives: Across infant and young child (IYCF) interventions, maternity leave entitlements and restrictions on marketing of breast milk substitutes (BMS) are two policies that help create an enabling environment for families to follow recommended child care practices. Research shows that longer maternity leave can positively impact rates of exclusive breastfeeding, and that stronger marketing restrictions can decrease use of formula for infants and young children. Beginning in 2009, a coalition of government, multilateral, and non-governmental partners in Vietnam initiated advocacy efforts with two objectives: (i) Lengthen paid maternity leave for all mothers to six months; and (ii) More closely align Vietnam's legislation with the International Code of Marketing of Breast Milk Substitutes and subsequent World Health Assembly resolutions.

Methods: A methodical process, starting with stakeholder analysis, was used to build political commitment and generate consensus for policy change. The highly collaborative effort included conducting research early and thoroughly to build the case for change; creating tailored and localized advocacy materials to package the evidence base; leveraging the comparative advantages within a broad stakeholder network to create change; and strategically using champions and the media. These approaches became part of an iterative process that created political momentum and pathways to influence decision-makers and build consensus for the two policy changes.

Results: In June, 2012, Vietnam's National Assembly voted in favor of expanding paid maternity leave to six months and ban marketing of BMS for children under 24 months, including feeding bottles and teats. Both laws passed with over 90 percent of the vote.

Conclusions: Using best practices for policy change can effectively influence policymakers' understanding of the role IYCF policies play in protecting health and nation develop-

ment, and can ultimately influence legislative decisions to create an enabling environment for IYCF.

Key words: maternity leave, BMS Code, IYCF, policy, advocacy.

PO1794**PERSEO PROJECT: PROCESS EVALUATION, LEVEL OF IMPLEMENTATION AND EFFECTIVENESS**

C. Perez-Rodrigo¹, V. Calderón², J. Campos Amado², J. Aranceta¹

¹Sociedad Española de Nutrición Comunitaria (SENC)

²Agencia Española de Seguridad Alimentaria y Nutrición (AESAN)

Background and objectives: PERSEO is a school based community intervention Project aimed to promote healthier food and physical activity habits among primary school children. In this paper we analyze the influence of the degree of implementation of the project on effectiveness.

Methods: Six Spanish Autonomous Regions (Andalucía, Canarias, Castilla-León, Extremadura, Galicia, Murcia), Ceuta and Melilla participated in PERSEO Project. 67 primary schools were recruited and randomly assigned to the intervention (n=34; 5646 children) and control group (n=33; 6139 children). The intervention was implemented during school years 2007-2008 and 2008-2009. A specific process evaluation protocol was designed previous to implementation. Based on process evaluation, a intensity of implementation score was calculated (0-10). The implementation score was included in logistic regression analysis for effectiveness evaluation.

Results: Mean implementation score for intervention schools was 4, 32 ± 1, 81; median 5 (highest 8). On average, 50% of the program was implemented as planned. Significant differences were observed in implementation score between schools, between classes within schools and between school grades. There were significant differences in implementation score by region as well. Adjusting for baseline BMI, OR for being obese at the end of the project was 1, 56 (95IC% 1, 03-2, 36) for the control group. Considering as reference a high level of project implementation, OR for being obese was 1, 15 (95IC% 1, 10-1, 20) for low level of implementation.

Conclusions: Results highlight the need to ensure a high level of implementation to reach the intended objectives, reinforcing teachers involvement and sustainability of policies adopted in schools.

Key words: schoolchildren obesity food habits physical activity

PO1795**BASELINE EVALUATION OF A CONTINUING EDUCATION PROGRAM FOR HOME DELIVERED CARE SUPPORT PROVIDERS: NUTRITION RISK***J. Aranceta¹, C. Perez-Rodrigo¹*¹Community Nutrition Unit, Bilbao, Spain

Background and objectives: A continuing education program for workers in the public home delivered support care service was designed with the aim of increasing awareness and motivation about the relevance of food and nutrition care for the wellbeing of the clients of the service. In this paper results of baseline evaluation regarding nutritional risk of users of the service is presented.

Methods: A 20 hour education program was designed. As part of the evaluation, a protocol for baseline assessment was designed including determinant factors of nutrition risk, food habits and physical activity of clients.

Results: In the first phase of the project 75 people providing care in two city districts were involved. About 600 clients receive care in these districts. Data were collected for 218 users. Mean age of clients was 76, 89 yr for men and 81, 19 yr for women. Consuming more than 3 drugs daily, eating alone and limitations for buying, preparing or consuming food and beverages were key determinant factors of nutrition risk in the group. Prevalence of malnutrition was estimated 5% and 37, 5% were likely at risk of malnutrition according to MNA screening.

Conclusions: Prevalence of risk of malnutrition is high among home delivered support care. Awareness and adequate training for care providers should be essential for a high quality service.

Key words: Continuing education; nutrition risk; home delivered care; elderly

PO1796**EARLY CHILDHOOD STIMULATION IMPROVES GROWTH OF DISADVANTAGED CHILDREN IN RURAL MEXICO***L. Neufeld^{1,2}, A. Garcia-Guerra², A C. Fernandez-Gaxiola², A D. Quezada², A. Hernandez-Cabrera²*¹Micronutrient Initiative²Instituto Nacional de Salud Publica, Cuernavaca, Mexico

Background and objectives: Despite positive impact of the conditional cash transfer program, Oportunidades on child growth, the prevalence of stunting remains high in rural areas

of Mexico, particularly in the south. Early childhood stimulation (ECS) may improve child growth. We evaluated the impact of combining 2 large-scale programs in Mexico (Oportunidades and the Initial Education ECS program) on child growth and development in a large randomized effectiveness trial and report here the effects on growth.

Methods: This cluster randomized controlled effectiveness trial was implemented in southern Mexico in small rural communities with a high prevalence of chronic malnutrition and was stratified by indigenous and non-indigenous communities. Eligible communities were randomly assigned to the ECS program or comparison group. All Oportunidades beneficiary children 0 to 4 y of age were eligible to participate in the study; we report here results for a longitudinal sample of those 0 to 2 y of age at baseline. The ECS program was implemented after baseline and the effects assessed after 2.5 y of implementation. Program effects were assessed with a difference in differences estimator using a multilevel model.

Results: Groups were well balanced at baseline within strata but the prevalence of stunting was significantly higher in indigenous (46.5%) than non-indigenous (26.9%) communities. In non-indigenous communities, the prevalence of stunting did not change significantly from baseline to follow-up in the ECS group (+3.1 percentage points, PP; 95%CI -2.6, 8.8), while there was a large increase in the control group (+16.1 PP; 8.6, 23.6) (p=0.007).

Conclusions: The addition of ECS to the benefits provided by Oportunidades can provide a further benefit to child growth among in non-indigenous communities in southern Mexico. Further analyses are underway to understand limitations that may have limited impact in indigenous communities.

Key words: early stimulation, Mexico, impact evaluation.

PO1797**MONITORING NUTRITIONAL STATUS OF CLIENTS OF BASIC HEALTH UNITIES IN THE STATE OF SÃO PAULO***Al. Cruz Perez¹, T. Zillesg, M. Shirassu, A. Ribeiro, S. Coria, M A. Moraes*¹Secretaria de Estado Da Saude de São Paulo, Brazil

Background and objectives: The Nutritional and Alimentary Surveillance System (SISVAN) allows performance descriptive/analytic diagnosis of nutritional situation of Brazilian population. Objectives: To verify nutritional state of clients of the Basic Health Unities of the State of São Paulo, employing data obtained from SISVAN implanted by the General Coordination for Foods and Nutrition (GCAN) according to the guidelines of the National Policy for Food and Nutrition (PNAN) regarding the warranty of adequate health conditions for the Brazilian population.

Methods: This research was developed from information on the nutritional state of people monitored by the SISVAN.

Results: The number of registers in relation to the total population is considered to be very low, meaning that less than 3% of the population is registered at SISVAN. The amount of children with low weight wavers around more or less 1%; nevertheless the amount of children with very low weight, in a percentage between 6, 7/10, 1%, representing an average of 8, 7% (DP +1, 9). From the percentage of adolescents registered, in average, 2, 8% present thinness/marked thinness; 72, 9% are eutrophic and 57% present excessive weight; among these, 31, 3% are overweight and 26, 1% (DP+1, 63) were classified as being obese. Among the elderly, only 34, 2% are eutrophic, while 10, 9% present low weight and 55, 9% (DP+4, 80) are overweight.

Conclusions: Regardless of the low rate of registers at SISVAN, results of this study show an alarming situation regarding nutritional status, registered, in proportion, a high number of persons overweight in all age brackets. Strategies for health promotion and prevention must receive more attention and subsidies by the public organs, at municipal, state and federal levels, in order to reach a higher level of efficacy of the actions designed to avoid the worsening of morbid situations and reducing the evolution of hazards that may demand more complex attention.

Key Words: Nutritional State. Monitoring. Food and Nutrition Surveillance System

PO1798

EFFECTIVENESS OF A LARGE-SCALE FOOD BY PRESCRIPTION PROGRAM IN ETHIOPIA ON RECOVERY FROM MALNUTRITION AND HIV PROGRESSION AMONG HIV+ ADULTS

K. Sadler¹, E. Bontrager², J. Coates², S. Ghosh³, D. Suri³, B. Lorge Rogers², Y. Kidane²

¹Valid International, USA

²Tufts University, Friedman School of Nutrition Science and Policy, USA

³Nevin Scrimshaw International Nutrition Foundation

Background and objectives: Determine effect of food supplement provided to malnourished HIV+ adults (BMI <= 18.5) also receiving standard ART care on recovery from malnutrition, HIV disease progression and survival.

Methods: RUTF, assessment, and counseling were provided to MAM or SAM subjects that were pre ART or ART for up to 6 months at 15 clinics (n=1956), with 8 matched comparison clinics (n=639). Longitudinal nutritional and HIV status data were collected. Recovery was defined as having a BMI >= 18.5 recorded for 2 or more consecutive visits.

Results: In treatment and comparison groups, respectively, rates were as follows: recovery 11.3% and 7.4% (p=0.005), non-response 15.9% and 31.9% (p<0.001), default 70.6% and 59.6% (p<0.001) and died 1.5% and 0.8% (NS). Controlling for baseline variables, participants in treatment gained 0.75 more BMI points on average than comparison if MAM (16<=BMI<18.5) at baseline (p<0.001), and 0.92 points more if SAM (BMI<16) (p=0.004). Median change in CD4 count was 29 cell/uL (IQR=114) in treatment group versus no change (IRQ=99) in the comparison group (p=0.015).

Conclusions: Adding a therapeutic food ration to an ART regimen for malnourished adults with HIV in Ethiopia led to improved BMI, recovery from malnutrition, CD4 count and functional status compared to a similar group that did not receive food assistance, demonstrating a quantitative benefit of macronutrient supplementation on HIV health and nutrition outcomes beyond that of ART alone. Issues of default from program need to be given consideration.

Key words: malnutrition, HIV.

PO1799

NATIONAL SCHOOL MEALS PROGRAM AND THEIR INTERFACE WITH FAMILY FARMING: THE BRAZIL CASE

P M O. Machado¹, B A S. Schmitz², F A G. Vasconcelos², A C T. Corso², D A. González-Chica²

¹Postgraduate Program in Nutrition, Federal University of Santa Catarina, Brazil

²Collaborating Center for Feeding and Nutrition of Scholar, Federal University of Santa Catarina, Brazil

Background and objectives: In Brazil, in 2009, a new legislation was approved about the National School Meals Program (PNAE – Programa Nacional de Alimentação Escolar) related to their conceptions and guidelines, which establishes that at least 30% of the financial resources must be channeled to purchase food from familiar farming (AF – Agricultura Familiar). The objective of the study was to obtain a panoramic view of the achievement of this type of purchasing in Brazilian school meals in the year of 2011, describing the limits and progress made since the implementation of the new legislation.

Methods: This research was carried out in 2012 and it is a cross-sectional study. Electronic questionnaires have been sent to all education secretaries of the 5564 Brazilian cities. Descriptive analysis with absolute and relative frequencies has been used.

Results: 93.2% of the Brazilian cities have answered the questionnaire (n=5184), of which 73% have purchased food from familiar farming, and more than 30% of the cities declared purchase organic food. Examples of reported difficulties are

insufficient amount of food to supply all school meals (n=2300) and the lack of variety of food facing the needs raised by the menu (n=2278).

Conclusions: It might be highlighted the expressive acceptance of the cities to the incentive measures in favor of familiar farming in Brazil, promoted by the National School Meals Program, since the new legislation has covered a short period of time.

Key words: School Meals, Familiar Farming, Purchasing of food.

PO1800

AFTER-SCHOOL NUTRITION EDUCATION, AND PARENTS' AND PEERS' INFLUENCE CAN IMPROVE FRUIT AND VEGETABLE CONSUMPTION AMONGST INTERNATIONAL SCHOOL CHILDREN IN DENMARK

S. Thapa¹, R.Dangol¹, E. Girerd-Barclay²

¹Institute of Public Health, University of Southern Denmark, DK 5000 Odense, Denmark

²Save The Children Sweden, S-10788, Stockholm, Sweden

Background and objectives: Children in Europe are increasingly at risk of nutritional disorders due to inadequate diets, especially those low in fruits and vegetables (FV). While EU member countries currently implement a variety of health education programmes designed to improve nutrition in school age children, including increasing fruit and vegetable intake, the results of such programmes are mixed. Objective: A study was carried out among 5-12 year-old international school students attending an after school program in Copenhagen to identify determinants promoting or inhibiting FV consumption and assess the outcomes of an educational intervention to promote FV consumption and to meet the Danish recommended daily intake (RDI).

Methods: Using a pre-test/post-test experimental study design, 53 study participants were selected at random from two age groups (ages 5 to 7, ages 8 to 10) attending an after school programme from 18 different countries were selected to participate in the study. The children completed food frequency questionnaires (FFQ), followed by questionnaires to determine knowledge, attitudes and practices of nutrition and FV consumption. A 15-day education intervention was administered. Students' lunches were observed and recorded one week before and after the nutrition education intervention. The Body Mass Index (BMI) of students was recorded.

Results: Post-test results demonstrated increased FV consumption by children in both age groups, with various reasons

cited including family and peer influence, and taste preference. Nutrition education interventions for children influenced them to consume more FV. Parents and teachers also influenced and motivated children to taste new FV by encouraging them to eat more and varied FV.

Conclusions: Further research is needed to determine which interventions are most effective in promoting increased FV consumption. After school programmes provide ideal opportunities to improve nutrition knowledge and practice.

Key words: Fruits and vegetables, School-based nutrition interventions.

PO1801

CHILD UNDER NUTRITION, A CROSS SECTIONAL STUDY OF THE ASSOCIATED FACTORS AMONG CHILDREN ATTENDING CHILD WELFARE CLINIC IN CAPE COAST METROPOLIS

K K A. Pereko¹, E.Turkson¹

¹University of Cape Coast, Ghana

Background and objectives: Child under nutrition is common with children under age five in Cape Coast Metropolis despite the effort of the Health sector. To understand the menace, there is the need to assess the factors associated with this problem. This study was aimed at assess the factors associated with child under nutrition in the Cape Coast Metropolis.

Methods: This was a cross sectional study involving 100 mother / caregiver child pairs selected from the 3 major child welfare clinics in the metropolis. Data collected included child anthropometric measures, socio demographic Characteristics of mothers and breastfeeding.

Results: Mean age of 1.74 SD 0.80 Completed months was recorded for children in this study. Mothers were found to earn a median amount of \$261.8 (104.7, 316.7) of this amount, mothers indicated spending a median amount of \$104.7 (52.4, 157.0) on food. Mild (23.7%) to Moderate (8.2%) wasting and mild (19.6%) to moderate (6.2%) stunting rates were recorded. Significant association was found with current breastfeeding status and length for age, marital status and weight for age and mother/caregiver educational status, length for age and weight for age.

Conclusions: Malnutrition is common among the children.

Key words: undernutrition, children.

PO1802**EVALUATION OF NUTRITION SURVEYS IN FLOOD AFFECTED AREAS OF PAKISTAN: SEEING THE UN-SEEN**

S M. Hossain¹, M. Talat², E. Boyd³, S. Rafique⁴, E. Soofi⁵, E. Hussain, I. Ahmed, R. Salam

¹UNICEF Afghanistan

²Save the Children, Pakistan

³UNICEF NYHQ

⁴Punjab Bearu of Statistics, Pakistan

⁵Aga Khan University Karachi, Pakistan

Background and objectives: In July and August 2010, Pakistan experienced the worst floods recorded in its history. The floods affected more many million people with thousands lives lost. Nutrition assessment surveys were conducted in flood affected areas of the two largest provinces (Punjab and Sindh) led by United Nations Children Fund (UNICEF) to assess nutrition status of children between 6 – 59 months while Aga Khan University (AKU) undertook a parallel assessment including micronutrient status in their project areas within Balochistan, Sindh and Punjab.

Methods: Standardized Monitoring & Assessment of Relief and Transition (SMART) methodology was used for all the surveys in Punjab and Sindh. A total of 881 children from Sindh, 1143 from Punjab and 817 from AKU project areas were measured for anthropometry and their households being interviewed. All three data sets were entered into ENA for z-score calculation and prevalence of malnutrition.

Results: Global Acute Malnutrition (GAM), defined as low weight for height (less than – 2 z-score and or oedema) was found to be 21-23% in Sindh, 14% in Punjab and 16% in AKU project areas. The other notable finding was widespread evidence of Chronic Malnutrition (Stunting) which was 52-54% in Sindh, 47-53% in Punjab and 48% in AKU project areas.

Conclusions: The findings indicated that while immediate life-saving interventions were needed, there was a wakeup call to address chronic malnutrition as well. Through wide and high level dissemination of the survey results, treatment and importantly prevention of malnutrition has become a visible priority for provincial and federal government in Pakistan and overseas development aid.

Key words: Nutrition Survey, Floods, Chroning Malnutrition.

PO1803**SOCIO-HISTORICAL STUDY OF A FEDERAL FOOD POLICY FOR WORKERS**

J. Costa-Souza¹, L M. Vieira-da-Silva¹

¹Ufba, Brazil

Background and objectives: in 1976, Brazil initiated a new subsidizing companies model that offered food to employees through the Fiscal Incentive Program to Food Worker (FI-PFW). The menu must follow nutritional parameters established by the government and to have a nutritionist as responsible. Currently, the program benefits 169.000 companies, covering 16 million workers and involves 19% of Brazilians nutritionists. To understand the possibility conditions for its social construction, it was conducted a sociohistorical study supported in the Pierre Bourdieu reflexive sociology.

Methods: it was performed documentary analysis, 21 in-depth and 3 structured interviews. The documents were obtained in the institutions and from internet. For the provisions in-depth study, it was selected an intentional sample of agents involved in the program genesis, identified through the snowball strategy.

Results: it was noted that the program has emerged within the bureaucratic field, but in conjunction with the economic field agents, mainly major industries and catering corporations executives. The program was idealized by a physician and nutrition specialist David Luiz Boianvsky who, converting his social capital in bureaucratic capital, enabled the program start. The most important capitals for the program genesis were the Ministry of Work political capital and the bureaucratic, private and militant administrative capitals, potentiated by the social capital.

Conclusions: the FIPFW represented the previous model rupture, by shifting the worker food control from the State to inside the companies. It was possible to identify a specific social space development, where are disputed the fiscal benefit forms and amounts and who is responsible for setting the menu. Health and nutrition issues occupy a secondary position, which helps to understand the high chronic diseases prevalence identified by numerous studies about Brazilian workers.

Key words: Worker food; nutrition policies; sociogenesis; Brazil; fiscal benefits; Pierre Bourdieu.

PO1804**NUTRITION ASSESSMENT AND RESPONSE IN FLOOD AFFECTED AREAS OF PUNJAB- CRISIS AND HOPE**

M. Talat¹, S.Rafique², S. Sharif³, SM M. Hossain

¹Save The Children, Pakistan

²Punjab Bureau of Statistics

³Eycon Solutions

⁴UNICEF, Afghanistan

Background and objectives: Pakistan experienced on of the world flood in history during 2010 that affected all 4 provinces of Pakistan. UNICEF in collaboration with the Punjab Bureau of Statistic (BOS) and Health Department Government of the Punjab conducted a nutrition survey in the flood affected areas of the most populous province of Pakistan during November-December 2010 to assess the impact on level of malnutrition and coping mechanism of the population.

Methods: SMART methodology was applied for the survey designing and sampling procedure while WHO growth standards were used as reference to classify malnourished children. The survey was conducted in two different strata: Severely and Moderately Affected Areas during November and December 2010. 1200 (600 in each survey area) households were interviewed and all children between 6 to 59 months of age were measured.

Results: Prevalence of Global Acute Malnutrition (GAM) was found to be 14.0% (with 95% CI 11.4 – 17.0%) and severe acute malnutrition (SAM) of 3.6% (with 95% CI 2.4 – 5.3%). Chronic Malnutrition (Stunting) affected more than 50% children. 40% had taken a loan since the flooding and another 40% had started selling valuable assets. 35% families had received some financial assistance and about 90 percent of them received from Government sources- an amount of PKRs. 20, 000 or above. In addition, there was association of between wasting and living in kacha households, taking a loan with interest, wealth quintile and the geographical areas.

Conclusions: Acute malnutrition in flood affected areas was not much higher than the national prevalence but the study revealed a very high rate of chronic malnutrition and the impact of flood across all socio-economic groups. Coping mechanism was alarming of a very deteriorating situation but the response and rehabilitation program was very encouraging.

Key words: Floods, Assessment, Malnutrition, Coping Mechanism.

PO1805**SNACKS THAT INTERPERSE MEALS: SMALLS IN GRAMS IS NOT EQUAL SMALL IN CALORIES.**

NM. Altoe¹, GM. Mainardi², WL. Conde³

¹Master of Preventive Medicine At School of Medicine, University of São Paulo, Brazil

²Master of Public Health Nutrition at School of Public Health, University of Sao Paulo, Brazil

³School of Public Health, University of Sao Paulo, Brazil

Background and objectives: Some studies have observed an inverse relationship between daily eating frequency and body weight. We have no evidence of this effect at population level without intervention. Brazilian Food Guide recommends at least three meals interspersed with snacks daily. In this study we describe Brazilian eating frequency separated by meals and snacks, and investigate its relationship with total daily calories.

Methods: We used data from Pesquisa de Orçamentos Familiares 2008-2009 (POF-2009) modulus 7, where 34, 003 people (≥ 10 y) filled out a 24h food registry. Daily eating episodes were divided in ≤ 2 , 3, 4, 5, 6 e ≥ 7 and classified into small snack (≤ 200 grams), medium snack (>200 to ≤ 350 grams), large snack (>350 to ≤ 500 grams) and meal (> 500 grams). Household income was stratified into fifths. Food composition was estimated based on the IBGE-TACO (Brazilian Food Composition Reference).

Results: Increase eating episodes is correlated to proportion of small snacks ($r=0.37$), daily caloric intake ($r=0.32$) and daily gram of food intake ($r=0.43$). The proportion of daily calorie filled by snacks increases with the number of snacks ($r=0.67$). Correlation among eating episodes and daily calories is higher in poorest ($r=0.32$) than in richest ($r=0.29$) and among eating episodes and proportion of small snacks is stronger in richest ($r=0.37$) than in poorest ($r=0.35$).

Conclusions: Brazilian Food Guide recommendation of intersperse main meals with small snacks has increased daily total calorie consumption more than contributed to balancing calories through daily eating episodes.

Key words: eating frequency; caloric intake; snacks.

PO1806**ESTIMATING THE IMPACT OF GENDER ON NUTRITIONAL OUTCOMES AMONG EXTREME POOR PROJECT PARTICIPANTS IN BANGLADESH***E. Roy¹, J. Waid¹, T. Chowdhury*¹Helen Keller International, Bangladesh

Background and objectives: Almost half of children under five years of age are malnourished in Bangladesh (48%). This high level malnutrition has been linked to both poverty and poor child feeding practices. Helen Keller International – Bangladesh, with support from DFid, developed an intensive, nutrition and gender sensitive poverty alleviation program in two unions of one of the least developed areas of Bangladesh (Chittagong Hill Tracts). This three year program dramatically reduced stunting among pre-school aged children of project participants, from 51% to 40%. Additional analysis was used to determine if this reduction was more closely related to income gains or increased empowerment and collaboration within participant households.

Methods: Panel data, from before, during, and after the program was collected from 440 households participating in the program. Of these 440 households, 240 had a child from whom anthropometric measurements were taken.

Results: Program results indicated large increases in household and women's dietary diversity and sizable increases in women's empowerment indicators. Additionally, household per capita income increased from 8 taka per person per day at baseline to 39 taka per person per day at end line. Women reported increased support with household tasks over the course of the project. Increased women's and household's dietary diversity was correlated with several measures of women's empowerment. In addition, households with stunted and severely stunted children reported not being able to freely discuss household finances with their spouses, and reporting that their husband was a higher priority for food consumption. Multivariate models indicate that household support was the largest driver of the improved child growth outcomes. Indicators related to female mobility showed poor correlation with nutrition, likely because women from poorer households were more mobile.

Conclusions: Integration of gender into income and equity programs can increase impact.

Key words: extreme poor, gender, stunting.

PO1807**NUTRITIONAL STATUS AND LIFE STYLE FACTORS ASSOCIATED TO CARDIOVASCULAR DISEASE RISK IN ECUADORIAN WORKERS***P. Moreno¹, M. de la Torre¹, A. Moncayo¹, P. Mogrovejo¹*¹Escuela de Nutriología, Universidad Internacional del Ecuador, Quito, Ecuador

Background and objectives: Cardiovascular diseases (CVD) are growing contributors to worldwide and Ecuador mortality, a country that is experiencing a rapid health transition. Nutrition has been extensively investigated as risk factor for major cardiovascular diseases and is also linked to other cardiovascular risk factors. To study cardiovascular (CV) risk prevalence and to assess the relationship between nutritional status and cardiovascular risk prevalence in Ecuadorian university employees.

Methods: In 2011 a cross sectional study conducted on 132 (72 men and 60 women) Ecuadorian individuals working at Universidad Internacional del Ecuador, aged 20 y 74 years, with no previous history of cardiovascular disease or diabetes. Individuals who consented to participate complete a questionnaire including: nutritional screen, life style information, anthropometric data. Cardiovascular risk level for estimating 10-years Risk of having a heart attack was calculated using Framingham Risk Equation. Statically, descriptive statistics and chi-squared test were used.

Results: Prevalence of overweight and obesity was 45% and 13%, respectively; higher in males, married and tertiary education level. Central obesity was prevalent in women ($p=0.000$). Most of the subjects (93%) were classified in low risk of having a heart attack in the next 10 years, whereas 5.3% were in moderate risk and 1.3 in high risk. High CV risk was found in male ($p<0.018$) with tertiary level of education, married, aged from 51 years or more who worked mainly at university administrative area. More individuals (44%) with CV risk were overweight. A 66% of individuals with CV disease risk had dyslipidemia and CV risk was associated with visceral fat ($p<0.033$).

Conclusions: Overweight and obesity were more prevalent in men. Central obesity was prevalent in women. CV disease risk was associated with visceral fat. Employees need a healthy diet and physical activity promotion.

Key words: Obesity; Nutrition, Cardio vascular risk.

PO1808**BENEFITS OF DIFFERENT INTENSITY OF AEROBIC EXERCISE TRAINING IN MODULATING THE ANTHROPOMETRIC INDEXES OF OBESE COLLEGE STUDENTS**

S C. Huang¹, C C. Ho, S C. Chen, Y C. Liang, NB. Kan, Y F. Liou, S H. Yu

¹Department of Nutritional Science, Toko University, Chiayi County 61363, Taiwan (R.O.C.)

²Department of Health and Leisure Management, Yuanpei University, Hsinchu City 30015, Taiwan (R.O.C.)

³Department of Leisure Industry and Health Promotion, National Ilan University, Yilan County 26047, Taiwan (R.O.C.)

⁴Physical Education Center, Ta Hwa University of Science and Technology, Hsinchu County 30740, Taiwan (R.O.C.)

⁵Department of Health and Leisure Management, Yuanpei University, Hsinchu City 30015, Taiwan (R.O.C.)

⁶General Education Center, Taipei Physical Education College, Taipei City 11153, Taiwan (R.O.C.)

⁷Graduate Institute of Sports Training, Taipei Physical Education College, Taipei City 11153, Taiwan (R.O.C.)

Background and objectives: Anthropometric indices [body mass index (BMI), waist circumference (WC), waist-to-hip ratio (WHR), and waist-to-height ratio (WHtR)] have been reported to be related to the risk of chronic disease. Due to the limited data with controversial results on the role of different aerobic exercise intensity on anthropometric indexes. The purpose of this study was to determine whether progressive aerobic exercise intensity effects the changes in anthropometric indices and health-related physical fitness measurements in obese college students.

Methods: Forty-eight obese subjects [body mass index (BMI) ≥ 27 kg/m², aged 18-26 years old] were randomized into four equal groups (n = 12): light-intensity training group (LITG): 40-50% of their heart rate reserve (HRR); middle-intensity training group (MITG): 50-70% of their HRR; high-intensity training group (HITG): 70-80% of their HRR, and control group (CG). The aerobic exercise training program was performed 60 minutes per day on a treadmill three days/week in a training period of 12 weeks. All subjects' anthropometric data, blood biochemical parameters, and health-related physical fitness components were measured at baseline and after 12 weeks.

Results: At baseline, there were no significant differences in anthropometric indices among four groups. After 12 weeks

of exercise intervention with different intensities, HITG and MITG had significantly higher changes in body weight, WC, WHR and WHtR than LITG. The changes in BMI and percent body fat differ among four groups.

Conclusions: The twelve week high or middle intensity exercise training program effectively improved obese college students' body weight and WC might be to preventive the risk of abdominal obesity-related chronic disease.

Key words: Aerobic training, exercise intensity, body composition, health-related fitness.

PO1809**STUDENTS' PERCEPTION OF A CONDITIONAL CASH TRANSFER PROGRAM WHICH PROVIDES THEM WITH SUBSIDIZED SCHOOL LUNCHES IN JAMAICA**

C. Powell¹, E. Mundy-Parkes¹, D. Francis¹

¹University of The West Indies, Mona

Background and objectives: A conditional cash transfer to ensure that children in primary and secondary schools in Jamaica receive school lunches was evaluated to determine the children's experiences and opinions of the program and perceived benefits.

Methods: A cross-sectional study was conducted using a random selection of schools from clusters (primary, junior high and secondary) within each parish in the country and a systematic selection of children within schools. Children were interviewed to ascertain their experiences and any perceived benefits of the program.

Results: 1734 students from 75 schools were interviewed. 46% reported receiving lunch five days per week while 34% got lunch 3-4 days. 28% made a co-payment for lunch. When the subsidized lunch was not provided 37.6% of students bought snacks, 32% bought a cooked lunch, 8.2% reported not eating anything and 2.7% reported not attending school on those days. Students reported psychosocial effects such as being bothered (8.9%), embarrassed (7.2%), feeling inferior compared to other children (8.9%) and angry (7.0%) because other persons knew that they were on the program. Significantly more girls than boys reported feeling embarrassed (9.0% vs 5.2%). Younger students were more likely to be bothered and embarrassed than those in the higher grades. 10% of students reported being teased by other students and 9.7% said that adults at school treated them differently because they were on the program. More than 60% of students felt that their attendance and concentration on school work were better, 58% reported better attention in class, while 50% felt that their behaviour in class was better as a result of their program participation.

Conclusions: Students generally had positive views of the impact of the programme on their school performance. There was some evidence of negative psychosocial effects of program participation.

Key words: conditional cash transfer, school lunch.

PO1810

HEMOGLOBIN LEVELS OF 1 TO 5 YEAR OLD CHILDREN ADMINISTERED VITAMIN A SUPPLEMENTS IN SELECTED HIGH VAD AREAS IN LEYTE, PHILIPPINES

M A R M. Ramirez¹, J. Mason²

¹Food and Nutrition Research Institute, Department of Science and Technology, Taguig City, Philippines

²International Health and Development Department, Tulane University, School of Public Health and Tropical Medicine, New Orleans, Louisiana, U.S.A

Background and objectives: Micronutrient malnutrition often occurs as multi-nutrient deficiency. Studies show relationships between iron indices and vitamin A status however the mechanism remains unclear. In the Philippines vitamin A deficiency is addressed through vitamin A capsule (VAC) supplementation, food fortification and food-based approaches. The paper described the iron status of 1-5 year old children in areas with high vitamin A deficiency (VAD) and change in hemoglobin levels in children given high-dose vitamin A capsules.

Methods: This is part of a research undertaking conducted by the Food and Nutrition Research Institute in collaboration with Tulane University of New Orleans, Louisiana which examined effects of extra VAC supplementation on serum retinol levels of 1 to 5 year old underweight children using quasi-experimental research design. This analysis described the iron status of children given vitamin A capsules and change in hemoglobin levels thereof. Study groups were: children given regular VAC, extra VAC supplementation, and those exposed to vitamin A fortified oil (VAFO) promotion. Descriptive statistics were used to measure iron status of the children. Change in mean hemoglobin was compared across vitamin A exposure groups using t-test and analysis of variance.

Results: Prevalence of iron deficiency anemia (IDA) was significantly higher among children with VAD at baseline (51 percent) compared to children with acceptable to high levels of serum retinol. Mean change in hemoglobin was highest among those supplemented with three extra VAC (1.36 g/L) and exposed to VAFO promotion (1.32 g/L) among anemic children.

Conclusions: There was moderate VAD and IDA among children at baseline. Mean change in hemoglobin was not sig-

nificant across vitamin A exposure, however significant across iron status. Significant responses to supplementation were evident among anemic children who received three VAC. Combined effects of vitamin A and iron supplementation need to be examined.

Key words: hemoglobin, vitamin A supplementation.

PO1811

DIETARY RECOMMENDATIONS FOR ALCOHOL CONSUMPTION: A NARRATIVE REVIEW

R. Gopane¹, H. Vorster

¹North-West University, USA

Background and objectives: The purpose of this paper is to review food-based dietary guidelines (FBDGs) as a vehicle to guide populations towards responsible and sensible drinking of alcoholic beverages. The problems with alcohol policies are briefly discussed and the option to use FBDGs as a way to recommend about alcohol consumption stated.

Methods: A computer search on FBDGs of different countries was done

Results: Of the 75 countries for whom FBDGs could be found, 56 included a guideline on alcohol consumption. These guidelines varied from explicit advice not to drink, to warnings not to drink during pregnancy and breastfeeding, to drink sensibly, responsibly or moderately, with some countries advising on age restrictions for drinking or giving amounts (units) that are compatible with good health.

Conclusions: A discussion of drinking patterns in different countries indicated that present alcohol consumption in many do not reflect the advice given in the FBDGs. It is concluded that at least in South Africa, a guideline "not to drink" may be indicated.

Key words: Food-Based Dietary Guidelines, alcohol.

PO1812**MATERNAL NUTRITION KNOWLEDGE IS ASSOCIATED WITH MEETING THE MINIMUM ACCEPTABLE DIET AMONG CHILDREN 6-23 MONTHS IN GHANA**

S. Gyampoh¹, G. Otoo¹, R. Aryeetey²

¹Department of Nutrition and Food Science, University of Ghana, Legon, Accra, Ghana

²School of Public Health, University of Ghana, Legon, Accra, Ghana

Background and objectives: Starting and maintaining appropriate complementary feeding, is essential for growth of children; preventing irreversible growth insults. In Ghana, sub-optimal diets beyond age 6 months are common and associated with growth faltering. The study assessed feeding among children 6-23 months in Ghana.

Methods: Cross-sectional study of 110 mother-child pairs attending child welfare clinics in Accra, Ghana. Questionnaires were used to collect data on background and child feeding knowledge. Child dietary diversity (DDV), meal frequency, and minimum acceptable diet were determined using a 24-hour dietary recall. Chi-square analysis was used to determine the association between feeding and two age groups; 6-8 months and 9-23 months. Predictors of minimum acceptable diet were determined using logistic regression.

Results: Fifty-three percent of children were aged between 6-8 months while 57% were between 9-23 months. Majority (91%) were breastfed on day preceding the interview. Most children (64%) were fed as frequently as recommended for age; only 41.8% were fed meals with minimum DDV. Between groups, 71.7% children aged 6-8 months were fed the recommended number of times compared with 56.1% for children 9-23 months. In contrast, significantly more children aged 9-23 months received dietary diverse meals ($p=0.021$). Minimum acceptable diet was met by 31.8% of all children, but this did not differ significantly between the two groups (6-8 months, 28.3% vs. 9-23 months, 35.1%; $p=0.540$). A higher feeding knowledge score among mothers, was the only significant predictor of a child being fed a minimum acceptable diet after controlling for confounders ($OR=1.48$; $p=0.005$).

Conclusions: Nutrition knowledge of mothers is an important factor in determining the way infants and young children are fed.

Key words: Complementary feeding, nutrition knowledge, dietary diversity.

PO1813**NUTRITIONAL DIAGNOSIS AND PROMOTING HEALTHY LIFESTYLE IN TEENAGERS IN HIGH SCHOOL IN CELAYA, GUANAJUATO.**

N. Pescador¹, M. Vera¹, S. Delgado¹

¹Universidad de Guanajuato, Mexico

Background and objectives: Under increasing rates of chronic degenerative diseases, it is important to start from the early stages of development to assess adequate nutritional status, and if necessary implement appropriate measures to improve it.

Methods: This study took place in a high school in Celaya, Guanajuato, Mexico, and working with students between 12 and 15 years. The aim was to assess nutritional status and promote healthy lifestyles. We used the SPSS version 19. Statistical analyzes for quantitative variables were: mean and standard deviation for quantitative variables were frequencies. We assessed 157 students, of whom 50.3% were female and 49.7% male, mean BMI was 20.86, found that 30% of those tested had ideal state of nutrition, obesity 22.9%, 21.7% overweight, 14.6% moderate malnutrition and 8.3 % moderate. Workshops were implemented with students and mothers to provide guidance and promote healthy lifestyles.

Acknowledgments: We thank the Mexican Youth Institute for the scholarship provided for implementing the program.

Key words: nutritional status, high school students, healthy lifestyles.

PO1814**NUTRIMETRIA: A SCORE FOR WEIGHT AND HEIGHT IN SCHOOL CHILDREN**

J.E. Selem¹, L. López Velázquez¹, M. Richaud¹

¹Office of Public Health, Tenabo, Campeche, Mexico

Background and objectives: Mexico ranks number one in the world in incidence of overweight and obese children. We present clinical tools that help in the management of malnutrition.

Methods: anthropometric measures are taken and processed in the epidemiological software Epi-Info for Windows in order to generate a numerical nutritional score for each of the possible nine combinations of weight and height measurements (each based on the categories of low, medium or high) in school children. Numerical values assigned to these weight and height categories are added to obtain a numerical nutritional score where the number six corresponds to a child with normal (medium) height and weight. These nutritional scores can be summarized in a 3x3 table where the rows correspond to these

weight categories and the columns to these height categories. Low, medium and high categories for weight resulted dividing the whole range of body mass values using the cutoff values of one standard deviation above and below the mean body mass value, and those for height resulted from the cutoff values of two standard deviations above and below the mean value of a measure of height that adjusts for age.

Results: Among 637 school children ranging in age from 6 to 14 years, 320 (52.32%) obtained a score of 6; 28 (4.39%) obtained a score of 4 (0.62%); 4 obtained a score of 5; 279 (43.8%) obtained a score of 9; and 6 (0.94%) obtained a score of 11. The percentage of overweight or obese children was 44.74%, which is higher than the national value of 34.4% (Chi-squared = 17.59, $p < 0.0002$). The percentage of children with low height (adjusted for age) was 4.39% points lower than the national value of 13.4% (Chi-squared = 34.79, $p < 0.00002$).

Conclusions: This nutritional score is useful in the management of malnutrition.

Key words: Nutrimetria (nutritional score), height and weight measurements.

PO3327

A STUDY OF CHILEAN SCHOOL CHILDREN: RELATIONSHIP BETWEEN SUGARED NON-ALCOHOLIC BEVERAGES AND BODY MASS INDEX

J. Araneda¹, H. Amigo²

¹Facultad Ciencias de la Salud y de los Alimentos, Departamento de Nutrición y Salud Pública, Universidad del Bio-Bio, Chillán, Chile

²Facultad de Medicina, Departamento de Nutrición, Universidad de Chile, Santiago, Chile

Background and objectives: The changes in food consumption patterns in the last few years have been notable. A generalized increase in calorie consumption indicates that this intake is due to behaviors and habits acquired early in life. The objective was to evaluate the relationship between sugared non-alcoholic beverages and Body Mass Index (BMI) in Chilean school children.

Methods: The study used a population-based cross-sectional design. Multi-stage probability sampling was used to select 1074 school children between the ages of 6 and 18 residing in urban and rural areas of the country. A Quantitative Consumption Tendency Survey was applied, which analyzed the food habits and behaviors in the last 30 days. Linear multivariate models were adjusted to determine the increase in BMI per 250 ml daily serving.

Results: Of the total, 92.0% (CI = 89.9-94.2) consumed sugared beverages daily with a mean of 424.3 ml ($p_{25-75}=212.1-707.2$). For school children who consumed more

than one serving (250cc) daily, the increase in the BMI coefficient in school children aged 6 to 13 is $\hat{\alpha}=0.13$ ($p < 0.01$) and $\hat{\alpha}=-0.23$ ($p < 0.01$) in school children aged 14 to 18.

Conclusions: Chilean school children have a high daily consumption of high-energy beverages. Consumption of sugared non-alcoholic beverages is positively associated with BMI only in school children aged 6 to 13.

Key words: School children, diet, sugared beverages.

PO3328

ANTHROPOMETRIC ASSESSMENT AND BLOOD PRESSURE IN MEXICAN SCHOOL-AGED CHILDREN

A. Vergara-Castañeda¹, R. Ayala-Moreno¹, L. Martino-Roaro¹, L. Castillo-Martinez², A. Orea-Tejeda²

¹Facultad de Ciencias Químicas, Universidad La Salle, México

²Instituto Nacional de Ciencias Médicas y Nutrición "Salvador Zubirán", México

Background and objectives: Accurate indirect measurements of body fat are fundamental in order to detect as early as possible whether the population overall or a given child has high blood pressure (BP). Objective: To examine associations between anthropometric measures as body mass index [BMI], waist circumference [WC], waist-to-height ratio [WHtR] and BP among school-aged children.

Methods: 1239 children aged 9.4 years (range; 7.6 to 13.5) were assessed in 10 public schools of low socioeconomic status in México City. BP was assessed according to the American Pediatric Academy. Anthropometrics, including weight, height, waist circumference [WC] and body composition (BIA and Fat Mass) were taken in all children. BMI and WHtR were calculated. BMI was categorized in agreement with the International Obesity Task Force cut points. HtR was calculated by dividing the WC by the height.

Results: 49.5% were boys, mean systolic blood pressure (SBP) and diastolic blood pressure (DBP) were 107.7 and 75.0 mmHg, respectively. We observed that WC showed the highest correlations with SBP ($r=0.588$, $p < 0.001$) and DBP ($r=0.509$, $p < 0.001$), while BMI showed the highest correlations with total FM ($r=0.956$, $p < 0.001$). Linear regression was also performed to calculate the variation of BP explained by different anthropometric indices (R^2), the results confirmed our findings in the partial correlations analyses. Further analyses in boys and girls separately showed that BMI explained the greater variation of DBP ($R^2=29.6\%$) in boys and SBP ($R^2=35.8\%$) in girls compared with WC and WtHR, meanwhile WC explained in a higher proportion SBP in boys ($R^2=37.3\%$) and DBP in girls ($R^2=23.2\%$).

Conclusions: Among Mexican school children, BMI and WtHR do not differ in their associations with BP. However WC was a better indicator of BP, and may be preferred because of its simplicity, additional data are needed to examine its relation to another cardiovascular risk factors.

Key words: Anthropometrics, hypertension, children.

PO3329

ASSOCIATIONS OF DIABETES AND OBESITY GENOTYPES TO DIETARY PATTERNS IN PRE-SCHOOL AND SCHOOL AGED CHILDREN

C. Wall¹, T. John², A. Morgan¹, K. Waldie³, L. Ferguson¹, R. Murphy⁴, E. Mitchell²

¹Discipline of Nutrition, The University of Auckland, Auckland, New Zealand

²Department of Paediatrics: Child and Youth Health, The University of Auckland, Auckland, New Zealand

³School of Psychology, The University of Auckland, Auckland, New Zealand

⁴Department of Medicine, The University of Auckland, Auckland, New Zealand

Background and objectives: For the effective prevention and treatment of obesity and diabetes It is important to attempt to elucidate the genetic as well as the behavioural and environmental factors influencing dietary intake. The aim of this study was to determine whether obesity and diabetes genes were associated with dietary patterns in pre-school and school aged children.

Methods: The Auckland Birthweight Collaborative (ABC) Study is a longitudinal study in Auckland, New Zealand, approximately half the sample were born SGA. Dietary information has been collected by food frequency questionnaires at 3½ (n=550) and 7 (n=591) years of age. Dietary pattern scores were created from these questionnaires using factor analysis. DNA was collected at 11 and genotyped for 54 snps on 42 obesity and diabetes genes, including 7 snps on MC4R and FTO. The relationship between dietary patterns and genotype were assessed using generalised linear models.

Results: Three dietary patterns were determined: junk, traditional and healthy. There were 15 associations between dietary patterns and genotypes, including 5 on MC4R and FTO, however there was little consistency in the relationships between the two time points. Given the number of associations tested we would expect to detect 16 significant effects at the 5% level by chance.

Conclusions: The results suggest that there is no association of childhood dietary patterns with obesity and diabetic genotypes. Childhood dietary intake thus would appear to be

influenced almost entirely by socio-demographic and environmental factors and not influenced by genes.

Key words: Genotypes, birth weight, dietary patterns, diabetes, obesity.

PO3330

CHARACTERIZATION OF AREAS OF DEFICIENT KNOWLEDGE ABOUT DM AMONG TYPE 2 BANGLADESHI DIABETIC SUBJECTS ATTENDING A TERTIARY CARE HOSPITAL

F. Jasmine¹, A. Ferdous¹, F. Saleh¹, L. Ali¹

¹Bangladesh University of Health Sciences, Dhaka, Bangladesh

Background and objectives: Bangladesh has the highest number of diabetic population in the world and knowledge-based education is the most feasible strategy to prevent diabetes and its complications. The present study aimed to identify the deficient areas of diabetes related knowledge among type 2 DM subjects and to characterize patients with the lowest levels of knowledge.

Methods: Under an observational cross-sectional design 500 type 2 DM subjects (M 58%, F 42%; age 49.4±8.8 years, M±SD) were purposively selected from the OPD of BIRDEM Hospital (the central hospital of the Diabetic Association of Bangladesh). Data were collected by a pre-designed, pre-tested, interviewer-administered questionnaire.

Results: Although 81% subjects had fairly good idea about the basic definition of DM, 98% had no correct knowledge about its risk factors. About 34% subjects did not know the normal fasting blood glucose level. About 24% subjects had no idea about the principles of dietary management. Virtually all subjects (97%) did not know about the food exchange system. About 81% subjects had no knowledge about the basic rules of foot care. The male group (15%) had comparatively less knowledge about the principles of dietary management compared to female (9%). Occupation played a more consistent role in determining the area-wise knowledge level with housewives having very low level in all areas; 27% in basic definition of DM, 36% in its risk factors, 16% in the normal fasting blood glucose level, 8% in the principles of dietary management, 36% in food exchange system and 31% in the basic rules of foot care. Conclusion: Bangladeshi patients with diabetes have some knowledge of DM although the overall knowledge level is poor. The risk factors of diabetes, monitoring, principles of dietary management, food exchange system and basic rules of foot care are the commonest deficient areas.

Key words: Dietary management, type 2 diabetes mellitus.

PO3331**MONOUNSATURATED FAT INTAKE AND HYPERTENSION AMONG URBAN SCHOOL CHILDREN IN MEXICO CITY**

A. Vergara-Castañeda¹, R. Ayala-Moreno¹, L. Martino-Roaro¹, L. Castillo-Martínez², A. Orea-Tejeda²

¹Facultad de Ciencias Químicas, Universidad La Salle, México

²Instituto Nacional de Ciencias Médicas y Nutrición, México

Background and objectives: The quantity and quality of fats consumed in the diet influence the development of cardiovascular risk factor. Studies focusing on lipids and lipoproteins are well documented; less information exists on the role of fats on blood pressure (BP) during childhood. The objective was to examine the relation between fat intake and blood pressure among school children.

Methods: Cross-sectional data were examined. 1239 children were evaluated in 10 different public schools of low socioeconomic status in México City. BP was assessed according to the American Pediatric Academy. A 24-hour intake recall was obtained. High fat intake group (HFI) had a total fat intake >30% of the total energy intake and the recommended fat intake group (RFI) <30% of the total energy intake.

Results: Mean age was 9.4±0.7 years old, 49.5% were boys, the prevalence of overweight and obesity was 23.6 and 12.3%, respectively. 44.9% of the children presented systolic or diastolic hypertension. Mean systolic blood pressure (SBP) was 107.8 mmHg and 75mmHg for diastolic blood pressure (DBP). The 79.6% of the sample belonged to the HFI. DBP was significantly higher in the HFI group compared with the RFI group (77.1mmHg vs. 73.4 mmHg, p=0.039). The difference in SBP was not significant. A linear regression showed that total fat intake (p=0.045) and monounsaturated fat (p=0.003) were positively related to SBP, meanwhile DBP was only related to monounsaturated fat (p=0.05).

Conclusions: Prevalence of hypertension among school children is higher than reported in national surveys as well as a high fat diet intake. Among these children, BP was lower in those with lower intake of fat, suggesting that fat intake profile is related with BP. High monounsaturated fat intake may contribute to higher SBP and DBP levels in school children, putting them at risk for the development of hypertension.

Key words: Fat-intake, hypertension, school children.

PO3332**PREVENTION OF LINEAR GROWTH FALTERING AMONG LOW BIRTH WEIGHT INFANTS IN RURAL BANGLADESH: A COMMUNITY-BASED CLUSTER RANDOMIZED TRIAL**

S. Shafique^{1,7}, J. Chowdhury^{2,3}, S. Jolly², H. Shikder², D. Sellen^{1,4,5}, S. Zlotkin^{1,5,6,7}

¹Department of Nutritional Sciences, University of Toronto, Canada

²Research and Evaluation Division, BRAC, Bangladesh

³Micronutrient Initiative, Canada

⁴Department of Anthropology, University of Toronto, Canada

⁵Dalla Lana School of Public Health, University of Toronto, Canada

⁶Department of Paediatrics, University of Toronto, Canada

⁷Research Institute and Centre for Global Child Health, Hospital for Sick Children, Toronto, Canada

Background and objectives: Low birth weight (LBW) infants in low income countries are vulnerable to frequent infections resulting in postnatal linear growth faltering. The study estimated relative efficacy of directed use of water-based hand sanitizers (HS) containing benzalkonium chloride and a new expanded multiple micronutrient powder (MNP) along with nutrition, health and hygiene education (NHHE) to prevent infections and linear growth faltering among LBW infants in rural Bangladesh.

Methods: A prospective 2X2 factorial, cluster-randomized controlled trial was conducted among 467 full-term LBW infants from 0-12 months, using 48 clusters randomly assigned as follows: A. From 0 to 6 months, i) NHHE alone or ii) NHHE plus HS; B. From 6-12 months i) NHHE alone; ii) NHHE plus HS; iii) NHHE plus MNP (to be provided with complementary foods); and iv) NHHE plus both HS and MNP.

Results: Preliminary results suggest that infants in the 'NHHE plus both HS and MNP' group gained more in length by 12 mo than those with 'NHHE alone' [mean (95% CI) = 2 cm (0.5 cm); P<0.01] and had a greater increase in length-for-age z-score (LAZ) [0.33 (-0.25, -0.47); P<0.05]. Mean duration of diarrhea episodes during infancy (0-12 mo) was significantly lower in the 'HS plus NHHE' group compared to the 'NHHE alone' group (3.1±1.2 vs. 5.8±1.6 days, P<0.01). Upper respiratory tract infections (URTI) and cough were also significantly lower in the 'HS plus NHHE' group compared to the 'NHHE alone' group (22.5% vs. 27.1% and 8.1% vs. 11.2%, P<0.05, for both).

Conclusions: A novel approach of using hand sanitizer in combination with MNP may reduce infections and prevent li-

near growth faltering among term LBW infants in the first year of life.

Key words: Low birth weight, linear growth, stunting, infection, hand hygiene.

PO3333

TRENDS AND DETERMINANTS OF MATERNAL AND CHILD UNDER-NUTRITION IN NEPAL: FURTHER ANALYSIS OF THE NEPAL DEMOGRAPHIC HEALTH SURVEY, 1996-2011

S. Mebrahtu¹, J. Crum², P. Dahal¹, R. Pokharel³, J. Mason², P. Hutchinson²

¹UNICEF Nepal

²Tulane University, New Orleans, USA

³MoHP, Kathmandu, Nepal

Background and objectives: Nepal has made progress in reducing micronutrient deficiencies and under-nutrition. But 41 percent of children under five are stunted and almost 25 percent of women aged 15-49 are underweight in 2011. The Government of Nepal (GoN) has renewed efforts to further reduce under-nutrition, requiring understanding of trends and possible causes. This project aimed to explore trends and determinants of child and maternal nutrition in Nepal (1996-2011), for design and targeting of interventions; results will help inform implementation of the multi-sector nutrition plan (2013-2017), involving expansion of a package of nutrition specific and nutrition sensitive interventions for accelerated reduction of under-nutrition.

Methods: Analysis of Nepal Demographic and Health Survey data was performed using data of 12,515 children aged 0-35 months. Selected nutrition indicators were examined using bivariate and multivariate analyses.

Results: National improvement in stunting was substantial, but with wider inequities by ecology and wealth quintiles. Stunting improved within all wealth quintiles (greater among richest), with women's education contributing significantly. Water supply and sanitation had interactive effects on stunting. Maternal underweight has improved, mostly in recent years, in the Terai, with increased education and within every wealth quintile (greater among richest). Child and maternal under-nutrition differ among caste/ethnic groups. Tobacco use was associated with lower height-for-age of children and BMI of women. Adequately iodized salt use positively affected weight-for-age.

Conclusions: Improving women's education and strengthening tobacco control programs are important for reducing child and maternal under-nutrition. Increasing wealth, and improvement in both water supply and sanitation, drive enhancement of child nutrition. Targeting interventions by location and caste/ethnic group is indicated. Programs that target

children should include mothers. Future study of proximate determinants of maternal and child under-nutrition would be beneficial for further recommendations for nutrition-specific interventions.

Key words: Determinants, disparity, trends, stunting, under-nutrition.

PO3334

25-HYDROXYVITAMIN D, ITS GENETIC DETERMINANTS AND THE RISK OF CARDIOVASCULAR DISEASES IN THE GERMAN ARM OF THE EPIC-STUDY

T. Kühn¹, K. Rudolf¹, B. Teucher¹, V. Katzke¹, F. Hirche³, C. Weikert², H. Boeing², J. Dierkes⁴, G. I. Stang³, B. Buijsse²

¹Department of Cancer Epidemiology, German Cancer Research Center (DKFZ), Heidelberg, Germany

²Department of Epidemiology, German Institute of Human Nutrition (DIfE) Potsdam-Rehbrücke, Nuthetal, Germany

³Institute of Agricultural and Nutritional Sciences, Martin-Luther-University Halle-Wittenberg, Halle (Saale), Germany

⁴Department of Clinical Medicine, University of Bergen, Bergen, Norway

Background and objectives: Cohort studies have shown inverse associations between 25(OH)D and CVD risk. Also, genetic variants related to 25(OH)D have been identified. The use of these variants as instrumental variables enables analyses on 25(OH)D and CVD risk in cohort studies that are not affected by reverse causation and less prone to confounding. Instrumental variable analyses on 25(OH)D and the risks of myocardial infarction (MI) and stroke were carried out in a case-cohort study nested in the EPIC-Germany study.

Methods: A subcohort (n=2132, mean age: 50.6) was randomly selected and included into the analyses along with incident cases of MI (n=559) and stroke (n=471) that occurred during a 7.6 year-follow-up. Plasma 25(OH)D was measured in baseline samples by LC-MS/MS. Eight single nucleotide polymorphisms (SNPs) were selected as potential instrumental variables and genotyped. Associations between 25(OH)D, SNPs, and the risks of MI, stroke, and overall CVD were assessed by multivariable regression analyses.

Results: Subjects with 25(OH)D levels <25 nmol/L had a higher risk of MI and stroke than those with levels ≥50 nmol/L, the hazard ratio for overall CVD being 1.57 (95% CI: 1.15-2.15). Two SNPs in the GC and DHCR7 genes were strongly associated with 25(OH)D (p<0.01). A SNP score that explained 4.4% of the variance in 25(OH)D was not related to the risk of MI, stroke or overall CVD (HR: 1.0, 95% CI: 0.71-1.42).

Conclusions: Despite significant associations between 25(OH)D and CVD risk in the present study, the lack of association observed for the SNPs indicates no major role of 25(OH)D in the development of CVD. However, detection of modest associations between SNPs and CVD in larger consortia cannot be excluded. Together with upcoming results of RCTs, these studies will provide better insights into the potential of vitamin D in CVD prevention.

Key words: Vitamin D, CVD, SNPs, cohort.

PO3335

BUILDING NUTRITION CAPACITY FOR SCALING UP NUTRITION IN AFRICA

B. Ellahi¹, A. Paul², R. Annan³, S. Sarkar², A. Jackson⁴

¹Dept. of Clinical Science, University of Chester, UK

²School of Science, University of Greenwich, UK

³Faculty of Science, Kwame Nkrumah University of Science & Technology, Kumasi, Ghana

⁴IMTF University of Southampton Medical School, Southampton, UK

Background: Recent developments towards reducing the burden of nutrition-related disease in high burden countries highlight the importance of professional capacity in nutrition to ensure effective delivery and sustainability of nutrition interventions. Our focus is to highlight capacity needs vis-à-vis meeting the objectives for scaling up nutrition interventions in Africa.

Methods: The International Malnutrition Task Force (IMTF) in conjunction with the African Nutrition Society undertook a training workshop on developing competency-based curricula for training nutritionists in Africa. This was followed by in-depth study of current nutrition training in Africa Higher Education Institutions, the latter to ascertain types and levels of courses, staffing capacity and graduate destinations. Group discussions and plenary sessions allowed participants to express their thoughts in the former whilst self-reported questionnaires were administered to institutions as well as an online search to enable data gathering, collation and analysis in the latter.

Discussion: The workshop identified gaps in current training and the need for standardised knowledge, skills and competency-based curricula for training of nutritionists in Africa irrespective of country resource base. Determining competencies and coming to an agreement on what every nutritionist should know was the expected outcome for this workshop. The review of African HEI capacities and types of training revealed that less than 45% of institutions were adequately staffed, there was lack of uniformity in curricula and standards; content, emphasis and focus differed widely.

Conclusion: We conclude that there is a wide gap between current and future expectations for meeting the needs for scaling up nutrition and training levels and capacity in nutrition-related subjects in Africa. This requires serious efforts to help mitigate and thereby meet the needs for scaling up nutrition interventions in high burden countries.

Key words: Scaling up nutrition; capacity building; nutrition training; Africa.

PO3336

COST OF OBESITY FOR THE NATIONAL HEALTH SYSTEM IN BRAZIL: AN APPLICATION OF THE COST-OF-ILLNESS METHOD

M.L. Oliveira¹, E.N. Silva², L.M.P. Santo²

¹Ministry of Social Development, Brasilia, Brazil

²Universidade de Brasilia, Brazil

Background and objectives: Obesity is a global public health problem and a risk factor for several diseases that financially impact the healthcare systems. According to the National Survey conducted in 2008-2009, obesity affects 14.8% of the Brazilian population, including 12.5% of adult men and 16.9% of adult women. Obese individuals represent nearly 25% of all overweight men and nearly a third of all overweight women. The prevalence of overweight and obesity have sharply increased over the last four decades. This study aimed to estimate the costs attributable to obesity, measured by Body Mass Index ≥ 30 kg/m² (BMI) and morbid obesity, defined as BMI ≥ 40 kg/m², in adults aged 20 and over from the Brazilian public health system; perspective in 2011.

Methods: The cost-of-illness methodology was adopted with a top-down approach based on prevalence. The proportion of the cost of each obesity-associated comorbidity was calculated and obesity prevalence was used to calculate the attributable risk. Direct financial cost data (hospitalization, bariatric surgery, outpatient care, medications and diagnostic procedures) were extracted from the Ministry of Health information systems, available on the web.

Results: Costs attributable to obesity totaled US\$ 269.6 million (1.9% of expenditures on medium- and high-complexity health assistance). Morbid obesity costs amounted to 23.8% of all obesity costs (US\$ 64.2 million) despite having an 18 times lesser prevalence. Bariatric surgery costs in Brazil totaled US\$ 17.4 million in 2011. **Conclusion:** The financial cost of obesity to the Health System in Brazil in 2011 was estimated at nearly US\$ 269.6 million and morbid obesity cost was proportionally 4.3 times greater than that of obesity cost.

Conclusions: Studies of this nature need to be made in Brazil more frequently to allow monitoring of the economic impact of the obesity epidemic over the years.

Key words: Obesity, morbid obesity, costs and cost analysis, Brazil.

PO3337

DO ARABIC WEIGHT LOSS MOBILE APPLICATIONS COMPLY WITH EVIDENCE-BASED WEIGHT MANAGEMENT GUIDELINES?

A. Alnasser^{1,2}, A. Sathiaseelan³, A. Al-Khalifa², D. Marais¹

¹Division of Applied Health Sciences, University of Aberdeen, UK

²Food Science and Nutrition Department, King Saud University, Saudi Arabia

³The Computer laboratory, University of Cambridge; UK

Background and objectives: Saudi Arabia (SA) has a growing problem of obesity especially in women. Mobile phone technology has successfully been used for health promotion including obesity. Many smartphone users gather health information from their devices with 20% downloading health applications (Apps). SA is one of six countries that has the highest smartphone users in the world. However, it has been shown that 47% of SA App users prefer them to be in Arabic. In recent studies of health and weight loss Apps, it was found that most Apps did not cover all aspects of evidence-based weight management guidelines. The aim of this study was to identify and systematically review Arabic weight loss Apps for compliance to these guidelines as used by Breton et al (2011).

Methods: The six most relevant App stores were systematically searched using the Arabic words for weight and diet. Apps were downloaded if they met the inclusion and exclusion criteria. Data was extracted to identify whether Apps had features which adhered to the practices as well as user ratings and cost. Apps were scored out of 13 according to the practices.

Results: Sixty-five Arabic weight loss Apps were identified, mostly (58%) from Google Android. The average practices score was 2.2 out of 13 with no Apps scoring more than 6 and only nine scoring 4-6. Meal planning was the most common (38%) feature. Five Apps were rated 5-stars with a mean rating of 4.2 stars. Most Apps were free and the highest cost was £2.99. **Conclusion:** Current Arabic weight loss Apps have low levels of compliance with recommended weight management guidelines. It is suggested that existing Apps should include more features based on the evidence or that a new Arabic App be developed.

Key words: Mobile technology, weight loss management, Arabic

FOOD CONSUMPTION, NUTRITIONAL DIAGNOSIS AND BODY IMAGE PERCEPTION INTO THE SCHOOL-AGED CHILDREN AT TABASCO STATE. MEXICO

V. Rivas-Acuña¹, A. Anlehu-Tello¹, J A. Rodríguez-Hernández¹, O. Lutzow-Lezama¹, J. Laguna-Sánchez¹

¹Universidad Juarez Autonoma de Tabasco, División Académica de Ciencias de la Salud, Villahermosa Tabasco, Mexico

Background and objectives: During, the school-aged, to monitor the nutritional status by dietary indicators, anthropometric and body image perception is necessary, to obtain causative agents and detect potential deficiencies and excesses risks factors. To analyze food consumption, nutritional diagnosis and body image perception in school-age children at Tabasco State. Mexico.

Methods: A Descriptive study was conducted in six elementary schools. Between April 2011 and February 2012, Sample: 2084 children aged 5 to 13 years old. Some variables were measured: age, sex, grade level, weight, height, body mass index, waist circumference index, body image perception and frequency food consumption

Results: age of 8.6 (SD = 0.5, 5-13), 52% female and 48% male. Water was the most consumed liquid, next milk and soft drinks. Favorite foods by groups were corn tortillas, milk, tomatoes, edible oil, bananas and beans. 0.6% low-weight, 53.1% normal-weight, 18.3% overweight and 28% obesity. Overweight children perceived as normal, thin and very thin his/her body image. Meanwhile, obese children perceived as thin, normal and overweight his/her body image. The diet was high in carbohydrates, proteins and lipids, producing overfeeding. Inadequate and lacking water consumption compared to the consumption of soft drinks, thus leading a higher caloric intake of simple carbohydrates.

Conclusions: The diet was not balanced, with excessive carbohydrates, proteins and lipids. Children had a body image perception that lessens weight problem; obesogenic environment could be changing its perception and might trigger eating disorders. Through multidisciplinary interventions would improve the quality of life of children by providing them information to make them aware of their diet and their body image perception.

Acknowledgements: This Project was funded by Fondo Mixto de Fomento de la Investigación Científica y Tecnológica CONACYT-Gobierno del Estado de Tabasco Key: TAB-210-C19-144149.

Keywords: School-age children, food consumption, body image perception, obesity, overweight.

PO3339**NEW SODIUM REDUCTION TECHNOLOGY'S POTENTIAL FOR DECREASING DIETARY SODIUM INTAKE IN POPULATIONS AT RISK***L. Spence¹, P. Samuel¹, V. Fulgoni²*¹Tate & Lyle, Hoffman Estates, USA²Nutrition Impact, LLC, Battle Creek, USA

Background and objectives: Current US dietary data indicate that there has been little progress in reducing sodium intake. Multiple solutions are needed to help decrease sodium intake in order to meet population-wide recommendations of 2300 mg/d and 1500 mg/d for at risk groups, including African Americans and persons aged ≥ 51 years (y). Using NHANES 2007-2010 data, we modeled the potential impact on sodium intake via a new sodium reduction technology, SODA LO™ Salt Microspheres (Tate & Lyle, Hoffman Estates, IL, USA) based upon potential usage levels in 953 foods.

Methods: Suggested sodium reductions ranged from 20-30% and usual intakes were modeled by assuming market penetration of 50 and 100%. SAS 9.2, SUDAAN 11, and NHANES survey weights were used in all calculations with assessment across gender, age, and ethnic groups. The National Cancer Institute method was used for usual intake determination.

Results: Current sodium intakes as mean (SE) exceed recommendations across all ethnic groups for 2+ y and 51+ y at 3458 (21) and 3323 (21) mg/d and for African Americans at 3290 (33) and 3032 (56) mg/d. Sodium reduction, with 50 and 100% market penetration, was estimated for 2+ y and 51+ y at 137 (2) and 274 (3) mg/d and 122 (2) and 244 (4) mg/d, respectively. For African Americans, 2+ y and 51+ y, sodium reduction was estimated at 141 (3) and 282 (6) mg/d and 114 (3) and 229 (6) mg/d, respectively.

Conclusions: These reductions represent ~4-9% potential decreases in intake thus innovations like SODA LO™ could contribute to meaningful reductions in sodium intake. Using the maximal sodium reduction of 282 mg, there is potential for a reduction of 950,000 cases of uncontrolled hypertension with a direct medical cost savings of about \$1.5 billion dollars.

Key words: Sodium, Epidemiology

PO3340**THE COMBINED IMPACT OF FIVE LIFESTYLE FACTORS ON ALL-CAUSE, CANCER, AND CARDIOVASCULAR MORTALITY – A PROSPECTIVE COHORT STUDY AMONG DANES***K. Petersen¹, N. Johnsen¹, A. Olsen¹, V. Albieri¹, L. Olsen¹, L. Dragsted², K. Overvad^{3,4}, A. Tjønneland¹, R. Egeberg¹*¹Danish Cancer Society Research Center, Danish Cancer Society, Copenhagen, Denmark²Department of Nutrition, Exercise and Sports, Copenhagen University, Frederiksberg C, Denmark-³Department of Public Health, Aarhus University, Aarhus C, Denmark⁴Department of Cardiology, Aalborg University Hospital, Aalborg, Denmark

Background and objectives: An accumulating body of evidence has shown that individual lifestyle factors are associated with premature mortality. As lifestyle behaviours coexist several studies have investigated the impact of a combination of lifestyle factors on mortality, but few have used public guidelines and none have studied the association in a Scandinavian population. Our objective was to investigate the combined impact of five lifestyle factors on all-cause, cancer, and cardiovascular mortality based on international and national health recommendations.

Methods: The study population included 51 521 Danes aged 50-64 years, without any diagnosis of cancer, cardiovascular disease, or diabetes at baseline (1993-97). Lifestyle factors were chosen a priori and included smoking, alcohol consumption, physical activity, waist circumference, and diet. These factors were dichotomised according to adherence to international and national recommendations and combined in an index. Adherence to each recommendation yielded 1 point in the index.

Results: During a median follow-up time of 14 years, 6768 participants died. After adjustment for potential confounding factors, adherence to one additional recommendation was for men associated with mortality rate ratios (95% confidence interval (CI)) of 0.71 (0.68-0.73) for all-cause, 0.73 (0.70-0.77) for cancer, and 0.66 (0.62-0.71) for cardiovascular mortality. Among women, corresponding mortality rate ratios were 0.70 (0.68-0.73) for all-cause, 0.75 (0.71- 0.79) for cancer, and 0.59 (0.53-0.66) for cardiovascular mortality. If participants had adhered to at least four recommendations at baseline, 51% (95% CI: 48-55%) of all deaths among men and 48% (44-52%) of all deaths among women might have been prevented.

Conclusions: Adherence to a combination of modifiable lifestyle behaviours was associated with a markedly lower risk of all-cause, cancer, and cardiovascular mortality. Adherence to health recommendations could have prevented a substantial fraction of deaths, suggesting a huge preventive potential by improving healthy lifestyle behaviours of the population.

Key words: Lifestyle, mortality

PO3341

VIEWS OF PARENTS IN FOUR EUROPEAN COUNTRIES ABOUT THE EFFECT OF FOOD ON THE MENTAL PERFORMANCE OF PRIMARY SCHOOL CHILDREN

H. Gage¹, B. Egan¹, P. Williams², E. Györei³, B. Brands⁴, J-C. López-Robles⁵, K A. Brown¹, C. Campoy⁵, B. Koletzko⁴, T. Decsi³, M M. Raats¹

¹Food, Consumer Behaviour and Health Research Centre, University of Surrey, United Kingdom of Great Britain and Northern Ireland

²Department of Mathematics, University of Surrey, United Kingdom of Great Britain and Northern Ireland

³Department of Paediatrics, University of Pécs, Hungary

⁴Dr. von Hauner Children's Hospital, Ludwig-Maximilians University, Germany

⁵Department of Paediatrics, University of Granada, Spain

Background and objectives: Children's nutrition is largely determined by the home environment. The importance parents attribute to food as an influence on mental performance was investigated.

Methods: Parents of school children (aged 4-11yrs) were recruited through state primary schools in four European countries. Participants were asked to sort 18 cards representing possible determinants of four elements of mental performance (attention, learning, mood, behaviour) according to perceived strength of effect. Determinants were identified from the literature, and grouped in six categories: food-related, school environment, physical, social, psychological, biological. Effects were scored: 0 = none; 1 = moderate; 2 = strong. Views were compared between and within countries.

Results: 200 parents took part (England: 53; Germany: 45; Hungary: 52; Spain: 50). Differences existed between countries in the proportions reporting university education and being in employment. Taking all countries together, parent's ranking of categories of determinants for their impact on mental performance was: physical i.e. activity and sleep (mean 1.77), psychological i.e. mood and behaviour, for attention and learning elements only (1.69); school environment (1.57); food (1.33); social (1.11); biological (0.91). This ranking holds for each element of mental performance separately. Of determinants in the food category, parents thought regularity of meals had more influence on mental performance (mean 1.58) than what a child eats now (1.36), food at school (1.35), nutrition as a baby / infant (1.02).

Conclusion: Detailed understanding of parents' perceptions of what affects mental performance of children can help target and formulate communications for parents.

Acknowledgements: We are grateful to the schools that enabled us to undertake this study and to the parents who took part in the experiment. This study was supported by the European Communities 7th Framework Programme (NUTRIMENTHE Grant agreement number: 212652).

Key words: Mental performance; parents; child nutrition; Europe; card sorting.

PO 3342

DIET AND ACTIVITY RISK FACTORS FOR TYPE 2 DIABETES IN ALBERTA YOUTH: COMPARISON BETWEEN 2005 AND 2008

L. McCargar, L. Forbes, S. Fraser, S. Downs, K. Storey, R. Plotnikoff, K. Raine, J.C. Spence, R. Hanning
University of Alberta, Edmonton, Canada

Background and objectives: Unhealthy dietary and physical activity (PA) patterns of Canadian youth have been implicated in the increasing rates of early onset chronic diseases. To address this, many initiatives promoting healthy youth and healthy schools occurred in Alberta between 2005 and 2008. The purpose of this study was to examine differences in the prevalence of lifestyle risk factors for type 2 diabetes (T2D) between two province-wide samples of Alberta adolescents in grades 7 to 10, in 2005 and 2008.

Methods: The Web Survey of Physical Activity and Nutrition was used to assess dietary and PA patterns. Students completed the online survey during school time. Validated tools for dietary intake and PA were used. For each risk factor, dichotomous variables were constructed, designating participants as either at risk or not at risk, relative to cut-off values.

Results: In total, 4936 students participated in 2005 (mean age 13.6 yr) and 5091 students participated in 2008 (mean age 13.3 yr). Compared to 2005, mean BMI, energy intake, fat intake (% kcal), glycemic index (GI) and glycemic load (GL) were lower in 2008 ($P < 0.05$); and carbohydrate (% kcal), protein (% kcal), fibre and vegetable and fruit intakes were higher in 2008 ($P < 0.05$). When risk factor cut-offs were applied, in 2008, a lower proportion of students were: overweight, obese, consuming high GI, high GL, high fat, low fibre, low veg/fruit intake ($P < 0.05$). There were no differences in magnesium intakes or PA levels between the two timepoints.

Conclusions: Overall positive improvements were observed between 2005 and 2008 as the proportion of adolescents having specific risk factors for T2D was lower for most variables. This may be due, in part, to the significant awareness and health promotion programming for this target population that took place during this time.

Key words: Adolescents, diet, activity.

T4. Nutrition and Management of Diseases**PO1446****PROJECT TO FIGHT CHILDHOOD OVERWEIGHT WITH VIDEO GAMES. IN CHILD WITH SOCIAL DISADVANTAGE. ACTIVE ASSISTANCE TECHNOLOGY FOR HEALTH RELATED BEHAVIOR CHANGE***F. Fernandez Rosado*¹¹Andalusian Health Servicion , Cádiz, Spain

Background and objectives: Information technology can help individuals to change their health behaviors. This is due to its potential for dynamic and unbiased information processing enabling users to monitor their own progress and be informed about risks and opportunities specific to evolving contexts and motivations. However, in many behavior change interventions, information technology is underused by treating it as a passive medium focused on efficient transmission of information and a positive user experience. Gaming has in children and adolescent's lives, we should embrace the opportunity to influence health behaviour through this avenue and use an evidence-based approach to do this in a thoughtful way. Exergaming (video games that are a form of exercise) can be used to motivate direct physical activity in combating overweight and obesity among children. Similarly, interactive educational video gaming can aid in developing self-care abilities and healthy behavioral skill building.

Methods: The study is an unrandomized trial with before-after design. We selected 15 overweight children aged 7 to 13 years, of parents with more than 5 years of unemployment, and we provided the games: Design a healthy child (American Diabetes Association), Design a healthy plate (American Diabetes Association), and finally 60 minutes PlayStation Eye Toy USB camera maximum day. DXJ3QKZ8K With free access to the games. After three months the weigh. Paired t, Pearson's Correlation Coefficient, or Partial Correlation test was used to analyze the findings. F.J. FERNANDEZ ROSADO

Results: The children's average age was 10.5 ± 2.7 years, 58% male body mass index (BMI, 27.91 ± 2.55 kg/m² vs 25.84 ± 3.52 kg/m² P=0.04)

Conclusions: Interactive educational video gaming and exergaming was significantly associated with weight reduction in children of parents long-term unemployment. We know

that programs targeting individual or family households may have little impact without more comprehensive environmental changes that address social and economic disparities. A drop of water in the desert can be life.

Key words: Behavior change, health promotion, exergaming, interactive digital games, virtual environment. The author has no conflict of interest.

PO1815**ASSESSING THE EFFECTIVENESS OF INTUITIVE EATING TO PROMOTE WEIGHT LOSS (PILOT STUDY)***J. Anglin*¹¹College of Health and Human Services, California State University, Long Beach, USA

Background and objectives: Obesity is an excess of body weight as a result of an excessive accumulation of fat that can result in increase morbidity and mortality. It has been identified as the leading cause of preventable deaths. The intuitive eating (IE) approach uses an individual's response to internal cues of hunger, satiety, and appetite and replaces calorie restriction (CR). Objective: To assess the effectiveness of CR and IE to induce weight loss in obese adults.

Methods: The study was a randomized controlled trial. The subjects were California State University, Long Beach students. The subjects engaged in physical activity 3 times per week for 30 minutes (6 weeks) and recorded their daily food intake in a food diary. Instructions were given for the CR and IE at the start and midpoint (3 weeks) of the study. Independent t-test was used to assess the differences between the groups and paired t-test compared the differences within the groups.

Results: The CR group loss significantly more ($p=0.03$) weight than the IE group. No statistical significance was observed between the groups' body mass index ($p=0.60$) and body fat percentage ($p=0.51$).

Conclusions: The CR approach appears to be more effective in promoting weight loss.

Key words: Obesity, calorie restriction, intuitive eating, weight loss.

PO1817**PREVALENCE OF OVERWEIGHT AND OBESITY AMONG CHILDREN, ADOLESCENTS, AND YOUNG ADULTS, IN TONEKABONE, IRAN (2010-2012)***H. Nasiri Reineh¹, M. Jarrahi¹*¹The Islamic Azad University, Tonekabon Branch, Iran

Background and objectives: Obesity is associated with increased risks of chronic diseases. Obesity is now the most prevalent nutritional disease among children and adolescents in Iran. The purpose of this study was to describe the prevalence of overweight and obesity among girls in tonekabone a city in the north of Iran.

Methods: Participants in this cross-sectional study were 2971 girls (0-24 years old) and randomly selected in 4 clusters. weight and height at all samples and waist and hip circumference in subjects 14-24 years were measured by standard protocols. BMI (Body Mass Index) kg/m² and WHR (waist -hip ratio) were calculated. In children overweight and obesity were defined as at or above the 85th percentile but less than the 95th, and at or above 95th percentiles, respectively (AS BMI for age the growth charts for girls). In young adults, overweight and obesity were defined as follows: overweight BMI 25.0-29.9, obese BMI ≥ 30. WHR of 0.85 or greater in young adult subjects is indicative of android obesity. Statistical analyses were done by software SPSS version 15.

Results: The data indicates that prevalence percent of overweight and obesity in subjects have been follow, respectively: 1) in under 5 years: 2.9 ± 0.5 (n=1322) 2) in 7-11 years: 10.7 ± 12.4 (n=291) 3) in 12-14 years: 17.5 ± 4.5 (n=442) 4) in 16-24 years: 38.3 ± 4.56 (n=916) . At all the Prevalence of overweight and obesity in subjects was $69.4\% \pm 21.96\%$ in the other hand the Prevalence android obesity in young adult subjects have been 29.1%.

Conclusions: the large prevalence of overweight and obesity and Its association with other diseases and some forms of GI cancer make the picture of cancer in this region more in future. The knowledge on the prevalence of overweight and obesity and its determinants can help implement population-based preventive measures.

Key words: overweight-Obesity-Children-Adolescents-Iran

PO1818**DIABETES CAN REDUCE THE BENEFITS OF DIETARY POLYPHENOLS IN BLOOD***H. Cao¹, Y. Xie¹, X. Chen¹, J. Xiao²*¹Department of Chemistry, Central South University, Hunan, China²Department of Biology, Shanghai Normal University, Shanghai, China

Background and objectives: Studies show increased risk of common infections in diabetic patients. Diabetes is characterized by high levels of glucose in blood, which can react with plasma proteins through a non-enzymatic process. It is hypothesized that non-enzymatic modifications (glycation of plasma proteins) may be responsible for increased infection rates in diabetics. The objective of this study is to reveal the influence of glycation of plasma proteins in diabetics on the radical scavenging potential of polyphenols .

Methods: Blood was centrifuged to get plasma proteins from both diabetics type 2 (TPP) and healthy (HPP) volunteers. Using fluorescence spectroscopy we determined the binding affinity between plasma proteins and polyphenols. DPPH free radical, ABTS radical, and superoxide anion scavenging and ferric reducing antioxidant power (FRAP) assays were carried out to study the influence of plasma proteins on antioxidant potential of polyphenols.

Results: Glycation of plasma proteins in type II diabetes lowers the affinities for polyphenols. Both HPP and TPP masked DPPH free radical, ABTS radical, and superoxide anion scavenging potential of dietary polyphenols. However, plasma proteins hardly affected reducing power of polyphenols. Compared with HPP, TPP weakens the masking effect on DPPH free radical, ABTS radical, and superoxide anion scavenging potential of polyphenols.

Conclusions: TPP showed lower binding affinities for polyphenols in blood than that of HPP. There are more free polyphenols in diabetes. It will cause more polyphenols expose to free radicals in blood. Therefore, polyphenols in diabetics' blood tend to be oxidized and can not be efficiently delivered to other tissues, which reduces the benefits of polyphenols.

Key words: Diabetes, plasma proteins, dietary polyphenols, free radicals, antioxidant potential.

PO1819**DIETARY PATTERNS PREDICTING CHANGES IN OBESITY INDICES (BMI,WC,WHR) IN LONGITUDINAL TEHRAN LIPID AND GLUCOSE STUDY**

S. Eghtesadi¹, R. Sherafat-Kazemzadeh¹, P. Mirmiran², M. Gohari³, S. Jalali-Farahani², F. Hosseini-Esfahani², M. Vafa¹, M. Hedayati⁴, F. Azizi⁴

¹Department of Nutrition and Biochemistry, Tehran University of Medical Sciences, Tehran, Iran

²Obesity Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran

³Department of Biostatistics, Tehran University of Medical Sciences, Tehran, Iran

⁴Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran

Background and objectives: To study the association between dietary patterns and obesity indices (BMI,WC,WHR) among Tehranian adults in a 6-year follow-up study.

Methods: Over a duration of 6 years, 141 adults were examined before and after this period for obesity indices. Dietary intakes were recorded at baseline by two 24 hour dietary recalls, as well as obesity indices at the beginning and the end of the course of study. Dietary intakes were converted into grams of intakes of food items and categorized into 16 groups. Reduced rank regression analysis (RRR) derived five patterns with total fat, polyunsaturated to saturated fat ratio, cholesterol, fiber and calcium intakes as response variables. Factors (dietary patterns) were generated retaining a corresponding factor loading of 0.17 on the food groups. The calculated factor scores were categorized in quintiles and changes in obesity indices were scrutinized within quintiles of these factor scores.

Results: The first pattern (traditional) showed high loadings on refined carbohydrates, whole grain, vegetables, red and processed meat, saturated / trans fat and eggs, showing significant high positive correlation with fat, cholesterol and calcium intake ($r=0.478, 0.626, \text{ and } 0.486$, respectively; $P<0.001$). All obesity indices had increasing trend across quintiles of pattern score ($P<0.05$ for BMI and WHR, $P<0.001$ for WC). The fifth pattern (egg) had high loading for eggs, salty snacks, and fruits, and negative loadings for red and processed meat, saturated and trans fat, plant oil and dairy products, indicating increasing trends for WC ($P<0.001$) and WHR ($P<0.05$) after adjustment for potential confounders. Other patterns showed non-significant trends for obesity indices.

Conclusions: The results were indicative of two dominant dietary patterns correlated with increase in obesity indices in Tehran.

Key words: Dietary pattern, anthropometry, obesity, cohort.

PO1820**SCREENING FOR UNDERNUTRITION IN NEURO-REHABILITATION USING 2 SCALES: NUTRITIONAL RISK SCORE 2002, INNSBRUCKER NUTRITION SCORE AND CONSISTANT NUTRITIONAL MANAGEMENT**

C. Haider¹, H. Zauner¹, N. Geringer-Manakanatas¹, G. Wood², J. Altenberger¹

¹Rehabilitation Center Grossgmain PVA, Grossgmain, Austria

²University of Salzburg, Department for Psychology, Salzburg, Austria

Background and objectives: Poorer rehabilitation potential for stroke patients with neurogenic dysphagia and undernutrition was documented (FOOD Trial). In our setting with swallowing and nutritional management these patients exhibit remarkable improvement during neurorehabilitation (NR). We investigated the hypothesis that augmented nutritional strategy improves outcome and uncovers the underestimated rehabilitation potential of patients with neurogenic dysphagia.

Methods: 127 consecutive NR patients, therapy according to the principles of AHA, European NR Society. Assessment of nutritional status: Innsbruck Nutrition Score (INS): body mass index, loss of weight, creatinin quotient, oral food intake, clinical nutrition recommended if score 3-4, indispensable if score >5 . Nutritional risk screening (NRS 2002): BMI kg/m², unintentional loss of weight, decrease of food intake, severity of illness. If NRS 2002 scores 3-4 monitoring, ≥ 5 nutrition intervention indicated. Improvement in NR: Delta values: Barthel Index (BI), basic (BADL), extended activities of daily living (EADL). Rivermead motor assessment (RMA). Statistics: Chi-square-, T-test, Mann-Whitney-test, Spearman's-Rank.

Results: $n=47$: NRS 2002 score ≥ 5 , $n=80$: NRS 2002 3-4. $n=6$ remarkably undernourished. Comparing INS and NRS 2002: highly significant association ($r(126)=.688, p<.001$), high concurrent validity, perfect concordance between INS item "daily oral energy intake" and NRS 2002 cut off value ($x\geq 5$). Controlling for heterogeneity of diagnosis and nutritional status patients were divided in subgroups. Table 2+3. Cognitive deficits: whole sample 69%, patients with nutritional support 87.5%, without nutritional support 50.8%. 64/127 patients needed nutritional support (mealtime supervision, assistance, tube feeding, intravenous nutrition). Swallowing, nutritional, cognitive profile: same distribution in the diagnostic subgroups. Dysphagic patients improved significantly better under augmented nutritional strategies.

Conclusions: Nutritional and swallowing management facilitates better outcome in NR also in patients only at risk for undernutrition. INS and NRS 2002 show high concurrent validity in correlation analysis.

Key words: dysphagia, nutritional assessment and management.

PO1821**STROKE AND NUTRITION: A REVIEW OF STUDIES***M. Foroughi¹, M. Akhavan²*¹Isfahan University Medical Science, Isfahan, Iran²Food security research center, Isfahan, Iran

Background and objectives: Stroke is one of the leading causes of death and certainly the major cause of disability in the world. Diet and nutrient has an effect on the stroke. The aim of this study was to review studies on the relationship between nutrition and stroke.

Methods: In this study, the term fat, cholesterol, antioxidant and vitamins, salt, potassium, calcium, carbohydrate, vegetables and fruit, fish, meat, dairy, chocolate, tea, whole grain, sugar-sweetened beverages, mediterranean diet, DASH diet, western diet and stroke were searched in PubMed search engine. Studies included were observational studies, cohort studies, clinical trials, systematic reviews, and meta-analysis reviews.

Results: Our study revealed improvements in nutrition and diet. Nutrition and diet can reduce the incidence of stroke.

Conclusions: Nutrition and diet reduce the incidence of stroke, but more studies need to be done in this area.

Key Words:

PO1822**OBESITY AMONG EMPLOYEES OF MINYA UNIVERSITY, EGYPT***R. Nashed¹, N. Kamal¹, M. Khalifa¹, E. Mahfouz¹*¹Community Medicine Department, Faculty of Medicine, Minia University, Minia, Egypt

Background and objectives: Obesity is a complex, multifactorial condition in which excess body fat results from an imbalance of energy intake and expenditure, and may put people at health risks. This study aimed to determine the magnitude of obesity, its risk factors and hazards among employees of Minya University, and to study the impact of some interventional approaches for control of obesity among them.

Methods: Interventional study, included 480 employees from Minya University. Socio-demographic characteristics and data related to knowledge, attitude and practice of employee about obesity, its risk factors and hazards were collected. Anthropometric measurements, vital signs, blood sugar and lipid profile were examined. Three types of interventions were approached for obese: dietary regime, exercise, or both. After intervention, anthropometric measurements, vital signs and blood examination were retested for the interventional group. Health education was done for obese employee.

Results: Obesity among employees of Minya University was 33.8%. It was more common among females, and increased

with age. Central obesity among males and females were 32.8% and 38.4 % respectively. About 40.7% of clerical and administrative employee, 28.4% of faculty and 23.1% of the manual workers at Minya University were obese. Physical inactivity, eating snacks and eating more than three regular meals were significantly related to the development of obesity. Significant relation was also found between obesity and joint or back pain. Obese employees had higher systolic blood pressure. After our different interventional approaches cholesterol level decreased, HDL increased, and BMI decreased among obese. Diet plus exercise was better than diet alone, which in turn is better than exercise alone.

Conclusions: Obesity represented an increasing health problem among employees of Minya University. Intervention by dietary regime plus exercise was the best method to lose weight and to improve obesity complication.

Key words: Obesity, diet, exercise, health education.

PO1823**LOW-CARBOHYDRATE-SCORE AND THE RISK OF CORONARY HEART DISEASE***H. A. Boakye¹*¹Ghana Education Service, Accra, Ghana

Background and objectives: Low-carbohydrate diets have been advocated for weight loss and to prevent obesity, but the long-term safety of these diets has not been determined.

Methods: We evaluated data on 1500 women in the Nurses' Health Study who had completed a validated food-frequency questionnaire in Maamobi polyclinic in the Zongo settlement of Ghana. Data from the questionnaire were used to calculate a low-carbohydrate-diet score, which was based on the percentage of energy as carbohydrate, fat, and protein (a higher score reflects a higher intake of fat and protein and a lower intake of carbohydrate). The association between the low-carbohydrate-diet score and the risk of coronary heart disease was examined.

Results: During follow-up, we documented 1994 new cases of coronary heart disease. After multivariate adjustment, the relative risk of coronary heart disease comparing highest and lowest deciles of the low-carbohydrate-diet score was 0.94 (95% confidence interval [CI], 0.76 to 1.18; P for trend=0.19). The relative risk comparing highest and lowest deciles of a low-carbohydrate-diet score on the basis of the percentage of energy from carbohydrate, animal protein, and animal fat was 0.94 (95% CI, 0.74 to 1.19; P for trend=0.52), whereas the relative risk on the basis of the percentage of energy from intake of carbohydrates, vegetable protein, and vegetable fat was 0.70 (95% CI, 0.56 to 0.88; P for trend=0.002). A higher glycemic load was strongly associated with an increased risk of coronary heart disease (relative risk comparing highest and lowest deciles, 1.90; 95% CI, 1.15 to 3.15; P for trend=0.003).

Conclusions: Our findings suggest that diets lower in carbohydrate and higher in protein and fat are not associated with increased risk of coronary heart disease in women. When vegetable sources of fat and protein are chosen, these diets may moderately reduce the risk of coronary heart disease.

Key words: Coronary, multivariate adjustment, low-carbohydrate-diet.

PO1824

FIBER INTAKE AND STAGE OF CHANGE AMONG DIABETES TYPE 2 PATIENTS: A CROSS SECTIONAL STUDY

P. Keshani¹, MS. Farvid²

¹Department of Nutrition, Shiraz University of Medical Sciences, Shiraz, Iran

²Department of Community Nutrition, National Nutrition and Food Technology Research Institute, Faculty of Nutrition Sciences and Food Technology, Shahid Beheshti University of Medical Sciences, Tehran, Iran

Background and objectives: Increased consumption of fiber in the diet of diabetic patients is usually recommended to better control their blood glucose level. The transtheoretical model (TTM), which has positive results in diabetes consultations on healthy eating adherence, claims that people need different pieces of advice depending on their stages of readiness to change behavior. The aim of this study was to assess the stages of change for diabetes type 2 patients based on their dietary fiber intake.

Methods: This was a cross-sectional study among 126 individuals aged 30 to 65 years with type 2 diabetes by a randomly-selected sample of members of Iranian Diabetes Society in Tehran, Iran. First, three-day food record was used to assess fiber intake and stages of change were determined based on valid questionnaire and patient fiber consumption. Nutritional data were analyzed using Nutritionist IV software. Other data were analyzed using t-tests, chi square and ANOVA. P value less than 0.05 was considered significant.

Results: Mean daily fiber intake was 23.05 ± 7.76 grams (8 to 48.7 grams) in type 2 diabetic patients. Most patients were in the maintenance stage (52%) and lowest in action stage (5.6%). 8%, 12% and 22.4% of patients were in pre-contemplation, contemplation and preparation stages, respectively. There is no sex difference in fiber intake and stage distribution as well as no difference in age, diabetes duration, education, income and employment status. But fiber intake was higher in married patients than single or divorced ones (23.5 ± 7.66 vs 16.9 ± 6.86 , $P=0.014$).

Conclusions: The findings of this study indicate that most type 2 diabetic patients were in the maintenance stage of fiber intake; it was higher than the minimum recommendation and didn't vary significantly with social economic status.

Key words: Stages of change, dietary fiber, type 2 diabetes.

PO1825

LIVER DISEASE FINDINGS IN CHILDREN AND ADOLESCENTS WITH TYPE 1 DIABETES

N. Göbüt¹, B. Kirel¹, N. Deđirmenci¹

¹Osmangazi University, Eskişehir, Turkey

Background and objectives: Liver findings in patients with type 1 diabetes (DM) are defined as elevated liver transaminase, hepatic glycogenosis, non-alcoholic fatty liver disease (NAFLD) and hepatomegaly.

Methods: Hepatobiliary ultrasonography (USG) and blood biochemical analysis were done in 93 girls and 95 boys (aged 2-18 yr) with type 1 DM. Their clinical data also were recorded.

Results: In 10 patients (5%), ALT levels were high ($ALT \geq 40$). Hepatosteatosi was determined in 45 patients (24%) by USG. 7 patients with hepatosteatosi had elevated ALT levels and 7 patients with elevated ALT levels, hepatosteatosi were determined. Hepatic glycogenosis was observed in a patient with persistent elevated ALT level through biopsy. The frequencies of hepatosteatosi and elevated ALT levels were not different between patients with good-bad glycemic control. In obese patients, the frequencies of elevated ALT levels (%) and hepatosteatosi (%) were higher. While the daily insulin dosage was high in obese patients, a positive correlation was determined between body mass index (BMI) and daily insulin dosage. However, high BMI and ALT levels in patients with hepatosteatosi, triglyceride (TG), HDL-C, HbA1c levels showed no difference. On the other hand, body weight (BW), BMI, AST and TG levels in patients with elevated ALT levels were found to be higher and HDL-C levels were found to be lower.

Conclusions: Children with DM have higher frequency of hepatic disease findings, such as NAFLD and elevated ALT levels. Glycemic control is not directly effective on these findings. However, in obese diabetics, the high frequency of these findings and higher dosage of insulin usage suggest that nutrition and insulin, which are closely related with each other during the treatment of these patients, have an important role on these hepatic findings.

Key words: diabetes, NAFLD, hepatic glycogenosis, obesity, children.

PO1826**RELATIONSHIP BETWEEN NUTRITION INTAKE AND PERIODONTAL CONDITION IN FEMALE JAPANESE PERIODONTITIS PATIENTS**

S. Maruyama¹, E. Horinishi¹, I. Morita², K. Inagaki², T. Noguchi²

¹College of Human Life and Environment, Kinjo Gakuin University, Nagoya, Aichi, Japan

²School of Dentistry, Aichi-Gakuin University, Nagoya-city Aichi, Japan

Background and objectives: Periodontal diseases constitute a variety of inflammatory conditions affecting the health of the periodontium. It is the most common reason for adult tooth loss. We hypothesized that there was the relationship between dietary intake and periodontal condition.

Methods: Study design was a cross-sectional study. The subjects were 82 Japanese female periodontitis patients, aged 18 to 69 years (35% 14 years). A dietary survey was conducted three days using dietary records. Subjects were recruited and diagnosed through one periodontist. The periodontal conditions assessed were present teeth, percentages of teeth with periodontal pockets. The extent of periodontal disease was defined as percentages of teeth with probing depth (PD) of 4 mm or more (4PD%). Adjustment was made for cigarette smoking, race/ethnicity. For analyses, the study subjects were categorized into quintiles on the basis of the distribution of 4PD% subjects. The subjects were classified into three categories (4PD% < 16.5, the slight periodontitis group (SP group), n = 21; 31.6% 4PD% < 58.6, the moderate periodontitis group (MP group), n = 40; and 58.7% 4PD %, the progressed periodontitis group (PP group), n = 21). Analysis of differences of dietary energy adjusted intakes (g/1,000kcal) by periodontal status was assessed using one-way analysis of variance and Tukey's honestly significant difference test. Two-sided P values less than 0.05 were considered statistically significant. The protocol of the present study was approved by the Ethics Committee of Aichi Gakuin University.

Results: Protein intake were lower in PP group than those of the SP group.

Conclusions: There was a relationship between nutrition intake and periodontal condition in female Japanese periodontitis patients.

Key words: periodontal condition, nutrition intake, Japanese patients.

PO1827**ATTENUATED ORAL FATTY ACID SENSITIVITY IS ASSOCIATED WITH ACUTE EXCESS ENERGY INTAKE**

R. Keast¹, K. Azzopardi¹, L. Newman¹, R. Haryono¹

¹Deakin University, Melbourne, Australia

Background and objectives: Excessive consumption of dietary fat is implicated with development of obesity. Attenuated oral and gastrointestinal sensitivity to the breakdown products of dietary fat, fatty acids (FA) may be associated with increased energy consumption. The objective was to determine the association between oral FA sensitivity and energy intake following consumption of a high fat meal.

Methods: Subjects (n=24; 14 males, 10 females, age 28±11.3 yrs, BMI 23.2±7.3) attended six laboratory sessions. Oral FA sensitivity was determined and subjects identified as hypersensitive (<3.8mM) or hyposensitive (>3.8mM) to oleic acid (C18:1). Subjects participated in a crossover study and were randomly assigned to a high fat, high protein, high carbohydrate or balanced macronutrient breakfast. Following this, subjects were required to consume a buffet-style lunch until comfortably full. The amount consumed (kJ and g) was measured, as was perceived satiety before and following meals.

Results: Fifty eight percent of subjects were orally hypersensitive and 42% of subjects hyposensitive to oleic acid (C18:1). Following the high fat breakfast only, FA hyposensitive subjects consumed significantly more energy (+2,100 kJ) and grams (+138 g) of food at lunch compared to FA hypersensitive subjects (P<0.01). There were no significant differences in perceived satiety or between consumption of lunch food by hyper and hypo-sensitive subjects for the other breakfasts (P>0.05).

Conclusions: Attenuated oral FA sensitivity is associated with excess energy consumption following a high fat meal and may be a causal factor in development of obesity.

Key words: Obesity, taste, fat, diet.

PO1829**BLOOD LEVELS OF HOMOCYSTEINE, OXIDATIVE STRESS AND INFLAMMATORY BIOMARKERS IN CHILDREN WITH ACUTE GLOMERULONEPHRITIS**

S. Kajanachumpol¹, S. Sirisate², K. Tangnaratchakit², D. Viroonudomphol³, P. Tantibhedhyangkul²

¹Research Center, Ramathibodi Hospital, Faculty of Medicine, Mahidol University, Bangkok, Thailand

²Department of Pediatrics, Ramathibodi Hospital, Faculty of Medicine, Mahidol University, Bangkok, Thailand

³Department of Chemical Metrology and Biometry, National Institute of Metrology, Pathum Thani, Thailand

Background and objectives: Studies have documented a strong inverse association between plasma homocysteine (Hcy) and renal impairment. Hyperhomocysteinemia (HHcy) itself may further aggravate kidney dysfunction. One proposed mechanism of homocysteine-induced glomerular injury involves oxidative stress and inflammatory factors. The present study was, therefore, to determine blood Hcy, oxidative and inflammatory biomarkers during the cause of acute primary glomerular disease in children.

Methods: Twelve children (3 boys, 9 girls; aged 4 to 16 years) with abrupt onset of acute glomerulonephritis (AGN with increased ASO titers); while fifteen age- and sex-matched normal children (5 boys, 10 girls) served as controls. Blood samples were collected from patients after an overnight fast at 0, 3, 7, 28 and 60 days after admission and at day zero from each control, for determination of serum oxidant (malondialdehyde), plasma/serum antioxidants (ferric reducing ability of plasma, vitamin C, vitamin E, uric acid and total thiol), and inflammatory biomarkers (hs CRP and ferritin).

Results: Results show that patients with AGN had significant increase levels of plasma Hcy as compared to controls, it gradually declined to normal values by day 28. The concentrations of MDA, FRAP, uric acid, vitamin E, hs CRP and ferritin were significantly higher in the patients than in the controls but the levels of total thiol were significantly lower. The values of all parameters steadily decreased to normal with time of follow up.

Conclusions: The present study has shown HHcy in children with AGN. The concentrations of plasma Hcy paralleled those of serum BUN and creatinine. There were apparent associations among plasma Hcy, renal function, oxidative stress and inflammatory biomarkers. Whether these associations have any clinical implications remain to be elucidated.

Key words: Homocysteine, oxidative stress, acute glomerulonephritis, inflammatory biomarkers.

PO1830**GENETIC INFLUENCES ON FAT ACCUMULATION PATTERN IN YOUNG JAPANESE FEMALES**

M. Kagawa¹, H. Miyaki¹, M. Hiraoka², K. Uenishi³, Y. Kagawa⁴

¹Institute of Nutrition Sciences, Kagawa Nutrition University, Saitama, Japan

²Laboratory of Clinical Biochemistry, Kagawa Nutrition University, Saitama, Japan

³Laboratory of Physiological Nutrition, Kagawa Nutrition University, Saitama, Japan

⁴Laboratory of Medical Chemistry, Kagawa Nutrition University, Saitama, Japan

Background and objectives: Excessive fat accumulation is associated with a number of chronic health problems. Unlike Caucasians, a certain proportion of young Japanese females have a large proportion of body fat (%BF) even with low body mass index (BMI: kg/m²). The present study aimed to examine influence of genetic polymorphisms in fat accumulation pattern.

Methods: Seventy-four Japanese females (18 – 30 years old) completed anthropometry as well as body composition assessments using dual energy x-ray absorptiometry (DXA: Lunar Prodigy, GE Healthcare). Participants also provided their blood samples to analyze uncoupling protein 1 (UCP1) A-3826G and angiotensinogen 1 (AGT1) M235T gene polymorphisms. UCP1 polymorphism was split into G/G and non-G/G and AGT1 gene was categorized into T/T and non-T/T.

Results: Among the participants, 17.3% (n = 13) had G/G polymorphism whereas 64% (n = 48) possessed T/T polymorphism. Compared with the non-G/G group, the G/G showed a greater fat accumulation in the upper body (p<0.05). For AGT1, the T/T showed a greater fat accumulation in the abdominal region compared to their non-T/T counterparts (p<0.05). In addition, 92.3% of G/G groups had %BF greater than 30% and 45.8% of T/T group had abdominal %BF greater than 30%, which were significantly (p<0.05) greater than their counterparts. Furthermore, 90.9% of the G/G group and 42.5% of the T/T group with BMI below 23 kg/m² had total and abdominal %BF above 30% respectively (p<0.05).

Conclusions: The present study indicated that UCP1 and AGT1 polymorphisms may contribute in fat accumulation pattern in young Japanese females and a development of “masked obesity” risk in this particular population.

Key words: Gene polymorphism; fat accumulation pattern; Japanese females; masked obesity

PO1831

A HOLISTIC APPROACH IDENTIFIES PRIORITY TARGETS TO REDUCE CHRONIC DIET-RELATED DISEASE PREVALENCE: AN EXHAUSTIVE REVIEW OF POOLED AND META-ANALYSES

A. Fardet¹, Y. Boirie¹

¹Human Nutrition Unit (JRU 1019), Department of Human Nutrition, INRA & Auvergne University, Human Nutrition Research Centre of Auvergne, Clermont-Ferrand, France

Background and objectives: In nutritional researches, analyzing the relationships between food groups, diet-related chronic diseases (DRCs) and/or impaired metabolism is a common reductionist approach. However, to determine the sequential changes from deregulated metabolisms to diseases and to unravel solid associations between food group consumption and disease risks, there is a need for more holistic approaches. Our aim was to objectively assess the relationships between main food groups/beverages, DRCs and deregulated metabolisms.

Methods: Exhaustive data were extracted from articles collected between 1950 and 2011. 2950 articles have been selected, analyzed and classified according to the studied associations: 10 DRCs vs. 10 deregulated metabolisms, DRCs vs. DRCs, and DRCs vs. 17 food groups/beverages. For each association, the number of articles was counted and main tendencies were unraveled. Priority was given to quantitative reviews.

Results: Diabetes and obesity are key diseases that lead to all other DRC, while cancer, cardiovascular diseases, skeletal and muscle diseases are terminal ones. Liver diseases, kidney diseases, digestive diseases and mental illnesses are both consequences and causes of the others. All diseases have multi-factorial causes, and most result from impaired antioxidant/ inflammatory/acido-basic status, carbohydrate/lipid/one-carbon metabolism, neuron functioning, DNA transcription, blood pressure and/or digestive microflora. Grain products are promising foods for preventing DRC risks, more than fruits and vegetables. Plant-based food groups are more protective than animal-based one. Our work also emphasizes the directions for future targeted researches.

Conclusions: Nutritional strategies focusing on obesity and diabetes prevention should be prioritized to reduce other major chronic diseases prevalence, and grain-based foods consumption should be encouraged. These data demonstrate that translational and in biblio researches are now necessary to face the exponential amount of nutritional data published every year and to search for trajectory associations among the system complexity.

Key words: chronic diseases, deregulated metabolisms, food groups, associations, risk factors.

PO1832

HYPOCHOLESTEROLEMIC AND ANTIOXIDATIVE EFFECTS OF EXTRACTS FROM THE INTERNAL ORGANS OF SEA CUCUMBER

Y. Lu¹, Y. Liang¹

¹Department of Nutritional Science, Fu Jen Catholic University, New Taipei City, Taiwan

Background and objectives: Recent studies have shown that methanol extracts from fresh or dried sea cucumber body, especially those including internal organs exhibited radical scavenging properties against DPPH. The aims of the present study were to evaluate the antioxidative and hypocholesterolemic capacities of internal organs from sea cucumber in vitro and in vivo.

Methods: Firstly, several kinds of internal organ wastes from sea cucumber (*Holothuria atra*, *Bohadschia argus*, *Metriatyla scabra*) were finely cleaned, lyophilized, pulverized to powder and then extracted with cold water, hot water or methanol. Second, the internal organ powder was fed to hamsters for six weeks to study its antioxidative effect.

Results: Results showed that the extracts with cold water had better antioxidative activity in vitro. Animal studies showed that the diet containing 5% internal organs of sea cucumber significantly decreased serum LDL and hepatic TBARS (thiobarbituric acid-reactive substances) levels and increased the serum total antioxidant capacity (TAC). Diet containing 10% sea cucumber internal organs significantly decreased serum and LDL TBARS levels, total cholesterol, and increased the serum TAC.

Conclusions: The cold water extracts of internal organs from sea cucumber had better antioxidative activity in vitro, and might inhibit lipid peroxidation by improving antioxidant status in vivo. Moreover, diets containing 10% sea cucumber internal organs can significantly exhibit hypocholesterolemic effect in decrease serum total cholesterol.

Key words: antioxidative, hypocholesterolemic, sea cucumber.

PO1833**IS EARLIER START OF ENTERAL NUTRITION BETTER FOR POSTOPERATIVE COURSE IN ESOPHAGEAL CANCER PATIENTS?**

Y. Koyama¹, S. Kosugi¹, E. Sakata¹, K. Tastuda¹, M. Hasegawa¹, M. Ikarashi¹, N. Manba¹, C. Toshikawa¹, T. Wakai¹

¹Division of Digestive & General Surgery/Niigata University Graduate School of Medical & Dental Sciences, Niigata, Japan

Background and objectives: Early enteral nutrition, defined as starting enteral nutrition (EN) within 72hrs after admission/surgery, has become popular, and starting within 24hrs has been more recommended recently, because earlier EN has reported to have more benefits for reducing mortality and decreasing the length of hospital stay. However, during 72hr period, whether earlier EN start should be better for postoperative patients is still unclear. We retrospectively examined whether earlier EN start is better or not for postoperative course in esophageal cancer patients.

Materials & Methods: Among 115 patients with thoracic esophagectomy for esophageal cancer at Niigata University Hospital during 2005-2010, the patients in whom started EN within 3 days after operation were entered. The patients were divided into 3 groups; the patients with EN started at postoperative day 1, day 2, or day 3 was categorized as Group 1, Group 2, or Group 3, respectively. Clinical factors such as days for first gas passage, the dose of postoperative albumin-drug used (D-alb), difference of serum albumin value between day 7 and pre-operation (α -alb), incidence of postoperative infectious complication (IPIC), and use of total parenteral nutrition were compared among the 3 groups. The statistical analysis was performed by Kruskal-Wallis test, Bonferroni test and Chi square test. The statistical significance was defined as $p < 0.05$.

Results: There was no significant difference on days for first gas passage, α -alb or IPIC among the groups. D-Alb in Group 3 was significantly higher compared with Group 2 ($p = 0.0164$), however, comparable with Group 1. TPN use was more frequent in Group 3 compared with other groups ($p = 0.0004$).

Conclusions: Earlier EN start as possible does not have further advantage for postoperative course, therefore, early EN start should be scheduled by the condition of patient in the range of 72hrs.

Key words: early enteral nutrition, esophageal cancer, TPN

PO1834**THE EFFECT OF FUNCTIONAL FOOD WITH INULIN ON METABOLIC SYNDROME**

A. Kaminskas¹, A. Abaravicius¹, A. Liutkevicius²

¹Faculty of Medicine of Vilnius University, Department of Physiology, Biochemistry and Laboratory Medicine, Vilnius, Lithuania

²Kaunas University of Technology, Food Institute, Kaunas, Lithuania

Background and objectives: Lithuanian scientists and manufacturers has put together effort to develop food products in the functional food category, such as yogurt and sausages with probiotic cultures and fiber-rich bread and cakes, chicken eggs with omega-3 fatty acids, etc. Inulin is one of the most important ingredient of functional foods. It has been shown to reduce postprandial glycemia and insulinemia. Also inulin has been suggested to have beneficial effects on hypertriglyceridemia. The goal of this work was to determine whether the addition of a moderate dose of inulin to a moderately high-carbohydrate diet would normalize the concentration of plasma lipids and carbohydrates, as well as have a beneficial effect on total metabolism status in subjects with metabolic syndrome.

Methods: Twenty five patients diagnosed with metabolic syndrome (46 ± 8 yrs) were recruited for this study. Patients were recommended to modify their habitual diet by eating 125 ml of yogurt (included 5 grams of inulin) as a daily food supplement over a period of 28 days. The subjects were tested before and after 28 days of yogurt consumption.

Results: After the inulin supplementation, serum LDL-cholesterol decreased significantly ($p < 0.05$, baseline vs. follow-up). Yogurt consumption had no effect on total cholesterol and triglyceride concentration. Inulin supplementation resulted in a significant decrease in serum malondialdehyde concentration ($p < 0.01$) as well as a significant reduction in body weight ($p < 0.001$), body mass index ($p < 0.01$), and both systolic and diastolic blood pressure ($p < 0.001$ and $p < 0.01$ respectively).

Conclusions: According to the findings of the current study, these changes are likely to have a beneficial impact on individuals with metabolic syndrome and improve their health.

Key words: functional food, inulin, metabolic syndrome.

PO1835**TOBACCO SMOKE AND SIDE-STREAM CIGARETTE SMOKE INDUCE THE RISK OF CARDIOVASCULAR DISEASE**

*D. Viroonudomphol*¹, *T. Hanroongroj*², *S. Tribanyatkul*³, *U. Pinyosirikul*⁴

¹Dept. of Chemical Metrology and Biometry, National Institute of Metrology, Bangkok, Thailand

²Dept. of Tropical Nutrition and Food Science, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand

³Phramongklao Hospital and College of Medicine, Bangkok, Thailand

⁴Dept. of Clinical Chemistry, Faculty of Medical Technology, Mahidol University, Bangkok, Thailand

Background and objectives: Disease risk due to smoking is not limited to smokers only. Passive smoking exposure to environmental tobacco smoke is associated with adverse health effect. Side-stream cigarette smoke, a major component of secondhand smoke induces reactive oxygen species with promote oxidative stress. This paper summarizes the cardiovascular effects of tobacco smoke according to the results of the alternative level of biochemistry substance: Cholesterol (C), HDL-Cholesterol (HDL-C), LDL-Cholesterol (LDL-C), Triglyceride (TG), Malondialdehyde (MDA), Conjugate diene (CD) and Homocysteine (Hyc).

Methods: Studies were carried out on 150 smokers (50 industrial cigarette smokers, 50 passive smokers and 50 local tobacco smokers compared with 50 nonsmoking controls.

Results: Levels of C, LDL-C, TG and MDA were significantly lower in smokers than in controls. Whereas Hyc levels were significantly lower among smokers than controls. No significant differences of HDL-C and CD were found between both groups. For dietary intake assessment, smokers consumed significantly less energy from carbohydrate, fat compared to controls, while energy derived from protein did not differ between groups. Moreover, smokers consumed less dietary fiber and vitamins compared with controls. Increasing whole blood toxic trace elements in healthy smokers may be explained by low antioxidant trace elements and vitamins that lead to develop oxidative stress and cardiovascular disease.

Conclusions: Therefore public health should not only aim for smoking cessation, but also concern about diet in terms of vitamin and mineral content to protect the risk of cardiovascular disease.

Key words: tobacco smoke, side-stream smoke, cardiovascular disease.

PO1836**NUTRITION FOR THE BREAST CANCER PATIENT: THERAPEUTIC OPTIMIZATION BASED ON POPULATION-SPECIFIC FACTORS**

*A. Ronco*¹

¹Unit of Oncology and Radiotherapy, Pereira Rossell Women's Hospital, Montevideo, Uruguay

Background and objectives: Provided that the harmful actions of certain dietary and environmental elements during years on a human organism are partially responsible in the development of a cancer, it seems logic to think that those actions can go on working if patients do not modify their usual intakes. In the last years scientific studies are showing an improvement of disease-free and overall survival in breast cancer patients when certain nutritional guidelines involving diet and management of overweight are followed. Our purpose is to move in a tailored way the exposure of the putative risk and protective factors to the lowest possible risk level, in order to improve the prognosis.

Methods: We propose a risk profile, based on several items drawn from local case-control studies: intake of red and white meat, dairy foods, oils and fats, vegetables and fruits; fat-to-muscle ratio; serum vitamin D level and serum triglycerides/HDL ratio, among other items. The assignment of a low, medium or high risk value is done depending on the variable nature and its association to the risk of breast cancer. Unlike some laboratory results, cut-off points used for classification might represent population-specific features.

Results: The profile change attempts to modify the 2/16-alpha-OH estrogen metabolites and omega-6/ omega-3 fatty acids ratios, the body composition, and other relevant nutritional features in order to improve the patients hormonal, metabolic and immunity status.

Conclusions: Methodology seems to be feasible elsewhere from a practical viewpoint. Each country or region could construct its own reference values, since some items (diet, anthropometry) may be population-specific. Because no studies indicate that a prudent diet is pejorative for health, we are trying to change inadequate nutritional patterns into an adequate one, in order to make feasible a subsequent change of the prognosis.

Key words: breast cancer, nutrition, risk factors, survival

PO1837**CURRENT GLYCEMIC CONTROL AMONG THE MIDDLE CLASS INDONESIAN DIABETIC SUBJECTS***T.S. Yen¹, M.K. Htet²*

¹South East Asian Ministers of Education Organization, Regional Center For Food and Nutrition, University of Indonesia, Jakarta, Indonesia

²Research Institute Trisakti University, Jakarta, Indonesia

Background and objectives: Being the fourth most populous country in the world with diabetes, Indonesia is projected to have 21.3 millions of diabetic people in 2030. Better socioeconomic status, life style changes, particularly in dietary patterns have contributed a great deal to the incidence and risks of type 2 Diabetes in the country. Recently we have conducted a survey among the diabetic subjects to study their current glycemic control.

Methods: A cross sectional survey was conducted among the 121 office staff, known cases of diabetes, who were working at Telecommunication Company in Jakarta, Indonesia. This was a screening phase of an intervention study which will investigate the effectiveness of empowerment model to achieve glycemic control. Subjects were interviewed using a short structured questionnaire and anthropometry assessments such as weight, height and waist circumference were done. To assess their current glycemic control, HbA1C measurements was done.

Results: Among the subjects 86% (n=104) were men. The mean age was 49.2±4.2 year and 47.6±5.5 year for men and women respectively. 50.4% of them were diagnosed as diabetes within last 5 years. According to their BMI, 47.1 % and 40.5% of them were overweight and obese respectively. Waist circumference measurements showed 53.7% of them were above the cut off value. The mean value of HbA1C was 9.3%.

Conclusions: The finding showed that half of the cases were recently diagnosed in the last five years which suggests the increasing trend of diabetes among the middle class Indonesians. The poor glycemic control was reflected in their HbA1C values and timely actions are necessary to prevent further complications of diabetes.

Key words: Diabetes, HbA1C, Indonesia.

PO1838**NUTRITIONAL STATUS OF TUBERCULOSIS AND HIV CO-INFECTED PATIENTS ATTENDING ANTI-RETROVIRAL TREATMENT CENTER OF SCHOOL OF TROPICAL MEDICINE, KOLKATA, INDIA***A. Bhowmik¹, D. Chaudhuri², S. Kamal Guha³*

¹Centre of Excellence in HIV Care, School of Tropical Medicine, Kolkata, West Bengal, India

²Department of Biochemistry and Nutrition, All India Institute of Hygiene & Public Health, Kolkata, West Bengal, India

³Department of Tropical Medicine, School of Tropical Medicine, Kolkata, West Bengal, India

Background and objectives: Malnutrition is a common hallmark of HIV disease. It plays a synergistic role in immunosuppression initiated by HIV and is an independent risk factor for disease progression. Tuberculosis (TB) also weakens the nutritional status and increases morbidity and mortality. Thus, it is important to assess the nutritional status of HIV-infected and HIV-TB co-infected subjects. This cross-sectional study was aimed to compare the nutritional status of HIV-infected patients with or without active tuberculosis.

Methods: Antiretroviral Therapy (ART) naïve patients were randomly selected from ART centre of School of Tropical Medicine, Kolkata, India, following written, informed consent. The baseline Body Mass Index (BMI), Grip Strength (GS), Triceps Skin Fold (TSF), mid upper arm circumference (MUAC), serum albumin, hemoglobin, and CD4 count was documented. All subjects were evaluated for presence of Opportunistic Infections (OI). Active TB was diagnosed by the Revised National Tuberculosis Control Program (RNTCP) guideline of Government of India. Statistical analysis was done to compare the above baseline characteristics between HIV-TB co-infected and HIV mono-infected patients by using SPSS16.

Results: Active TB was diagnosed in 48 patients among 131 HIV positive patients and their median CD4 count, serum albumin, hemoglobin and BMI of active TB patients were 113 cell/μL, 3.25 gm/dl, 10 gm/dl and 16.14 Kg/m² respectively while those of non-TB patients were 205 cell/μL, 4gm/dl, 11.5 gm/dl and 18.13 Kg/m² respectively. All the TB infected patients were on TB treatment with RNTCP regimens. BMI (p=0.00), GS (p=0.04), TSF (p=0.00), MUAC (p=0.00), CD4 (p=0.01), hemoglobin (p=0.01) and serum albumin (p=0.00) were significantly higher in case of non-TB patients.

Conclusions: HIV-TB co-infected patients have a grossly compromised nutritional status and need immediate nutritional support in form of nutritional counselling and/or supplementation to improve their health status.

Key words: Nutritional status, tuberculosis, HIV.

PO1839

SATISFYING SUGAR CRAVINGS IN PEOPLE WHO ARE OBESE AND DIABETIC WITH SYNSEPALUM DULCIFICUM: UNDERUTILIZED AND NEGLECTED FRUIT SPECIE IN GHANA

*B. Asenso Barnieh*¹

¹Ghana Education Service (NSHTS), Kumasi, Ghana

Background and objectives: Managing the dietary intake of sugar has been found to be one of the most cost effective ways of coping with obesity and diabetes. However, this means of preventing and coping with diabetes and obesity has been found to be difficult for both adults and children since the need to satisfy their cravings for sugar is paramount. Synsepalum dulcificum, an underutilized and neglected indigenous Ghanaian fruit has been used for centuries in Ghana to satisfy sugar cravings. The fruit is unsweet with a mild taste. However, after eating this fruit, any sour food subsequently consumed, turns extremely sweet. The sweetening effect can last for about one hour. This research was conducted to find out if Synsepalum dulcificum can serve as an alternative means of managing sugar craving in people especially those with obesity and diabetes.

Methods: The research used literature review to determine the essential analysis of this fruit and the possibility of serving as a sugar substitute.

Results: The results indicated that the sugar content in the fruit has been found to be insignificant. The sweetening effect of the fruit is attributed to the presence of Miraculin, which is used as a sugar substitute. The fruit has been tried in obese and diabetic patients without side effects. Cancer patients with unpleasant metallic taste in their mouth had it masked after eating the fruit.

Conclusions: It can be concluded that the fruit can serve as a means of satisfying sugar cravings in many people whilst managing their dietary sugar intake due to the insignificant sugar content. It is recommended that the fruit must be cultivated on a large scale. Also the consumption of the fruit must be promoted among people who are obese and diabetic.

Key words: Synsepalum dulcificum, fruit, sugar, obese, diabetes

Background and objectives: In pulmonary tuberculosis impaired nutritional status including zinc status is common. Still, no previous studies have been performed in Bolivian patients in this regard.

Methods: We conducted an intervention study with twenty patients with pulmonary tuberculosis to evaluate the effects of zinc supplementation as an addition to conventional treatment. Changes in the clinical course, presence of tuberculosis bacilli in sputum, radiological improvements and nutritional status of patients were monitored. The patients were randomized into two groups given zinc (45 mg/day) or placebo for three months.

Results: During the supplementation period the concentration of zinc in plasma increased from 11(0.6) µmol/L to 14(1.5) µmol/L in the supplemented group and the mean increment was 22% compared with 6% in the placebo group. In the zinc-supplemented patients the frequency of thoracic pain decreased as early as in the second week and the cough, expectoration and night sweats decreased after of four weeks of therapy, but in the placebo group these symptoms remained for a longer time. Bacilli in sputum disappeared more rapidly in zinc-supplemented patients than in the placebo group. The concentrations of CRP, haptoglobin and orosomucoid in plasma were increased prior to the intervention and after 90 days they had diminished but the decrease was not significantly affected by zinc supplementation.

Conclusions: This pilot study indicates that addition of a daily supplement of 45 mg of zinc to conventional anti-tuberculosis therapy can accelerate the clinical recovery. It is necessary perform further studies with a larger sample size to confirm the findings.

Key words: zinc supplementation, pulmonary tuberculosis, symptom disappearance, sputum bacilli clearance.

PO1841**EFFECT OF VITAMIN E AND C SUPPLEMENTATION ON ELDERLY WITH MILD COGNITIVE IMPAIRMENT (MCI) IN ISFAHAN, IRAN**

⁴Isfahan Center of Health Research, Nationally Institute of Health Research, Tehran University of Medical Science, Iran

⁵Department of Biostatistics and Epidemiology, Isfahan University of Medical Sciences, Isfahan, Iran

Background and objectives: There are inconsistent results regarding the potential role of vitamin antioxidants in improving cognition function among elderly individuals. This study was carried out to investigate the effect of vitamins C and E on Mild Cognitive Impairment in Isfahan, Iran.

Methods: In a randomized, double-blind, placebo-controlled trial, 256 elderly with mild cognitive impairment received 300 mg of vitamin E plus 400 mg vitamin C per day (n=127) or placebo (n=129), for one year. Information on background characteristics and anthropometric measurements at baseline and food consumption through 3-Day Diet Recall every two months were collected. Some of the oxidative stress biomarkers were measured. Cognitive performance was evaluated by Mini Mental State Examination (MMSE) score. All measurements were performed at three time points on days 0, 180 and 360 post interventions.

Results: One year antioxidant supplementation resulted in reduced Malodialdehyde level ($P<0.001$) and elevation of Total Antioxidant Capacity ($P<0.001$) and red blood cell Glutathione ($P<0.01$) compared with control group. The serum 8-hydroxydeoxyguanosine levels did not show any difference between the two groups ($P<0.4$). After adjusting for the covariates effects, MMSE score showed, the difference within subject variable in both supplemented and control groups was significant ($P<0.001$). None of ($P=0.88$) the mean value of MMSE score in sixth and twelfth time points between supplemented and control groups (25.88 ± 0.17 vs. 25.86 ± 0.18 and 26.8 ± 0.17 vs. 26.59 ± 0.18) differed significantly.

Conclusions: Despite significant improvement in most of the oxidative stress biomarkers, long-term antioxidants supplementation was not observed to enhance cognitive performance in this study.

Key words: Supplementation, elderly, MCI, Vitamin E, Vitamin C.

PO1842**METABOLIC SYNDROME AND ITS DETERMINANTS IN A SAMPLE OF YOUNG IRANIAN CHILDREN WITH OBESITY**

F. Esfarjani¹, M. Khalafi¹, F. Mohammadi¹, N. Zamani-Nour¹, R. Kelishadi²

¹Department of Food and Nutrition Policy and Planning Research, National Nutrition and Food Technology Research Institute, Faculty of Nutrition Sciences and Food Technology, Shahid Beheshti University of Medical Sciences, Tehran, Iran

Introduction: Childhood obesity increases the risk of metabolic syndrome (MetS) both in childhood and adulthood. The present study was determined the prevalence of MetS and its potential determinants in a representative sample of obese children .

Material and Method: This cross-sectional study was conducted in 2011 among 150 obese children, i.e. body mass index ($BMI\geq 95$ th percentile) with seven years of age. They were randomly selected from 9 health centers in 3 districts of the north Tehran. Trained nutritionists completed a socio-demographic questionnaire by interviewing parents, and conducted the physical examination. Mets was defined based on modified ATP III criteria .

Results: The mean (SD) of weight, height, and BMI was 37.5 (6.3) kg, 127.2 (4.7) cm and 23.08 (2.9) kg/m^2 , respectively. The prevalence of MetS was 13.4%, without significant difference in terms of gender. The most common component of MetS was abdominal obesity (79%). While 21.3% of children did not have any component of MetS, 42% of them had at least one component. Most children with MetS had a history of breastfeeding for less than 6 months. Waist circumference, systolic and diastolic blood pressure, fasting blood glucose, and triglyceride levels were higher in Mets compared to controls.

Key words: Metabolic Syndrome, Children, obesity, prevention

PO1843**SOCIOECONOMIC POSITION AND BODY MASS INDEX AMONG ADULTS: THE ROLE OF TAKEAWAY FOOD***K. Miura¹, G. Turrell¹*¹School of Public Health and Social Work, Queensland University of Technology, Brisbane, Australia

Background and objectives: Lower socioeconomic groups have a higher prevalence of overweight and obesity. However, we have little knowledge about why these inequalities exist. The aim of this study was to examine whether takeaway food consumption mediated (explained) the association between socioeconomic position and body mass index (BMI).

Methods: A postal-survey was conducted among 1500 randomly selected adults aged between 25-64 years in Brisbane, Australia during 2009 (response rate 63.7%, N=903). BMI was calculated using self-reported weight and height. Participants reported usual takeaway food consumption, and these items were grouped into 'healthy' and 'less healthy' choices. Socioeconomic position was ascertained by education, household income, and occupation.

Results: The mean BMI was 26.5 kg/m² for men and 25.7 kg/m² for women. Among men, none of the socioeconomic measures were associated with BMI. Contrary, women with Diploma/Vocational education (B=2.12) and high school only (B=2.60), and those who were white-collar (B=1.55) and blue-collar employees (B=2.83) had higher BMI compared with their more advantaged counterparts (all p<0.05). However, household income was not associated with BMI. Lower socioeconomic men and women consumed high levels of 'less healthy' choices; however, there were no clear patterns for 'healthy' choices. Frequent consumption of 'healthy' choices was significantly associated with higher BMI among women only. In contrast, frequent 'less healthy' takeaway food consumption was significantly associated with higher BMI for both men and women. The consumption of 'less healthy' takeaway food, but not 'healthy' choices, partly mediated the observed education or occupation differences in BMI among women.

Conclusions: Decreasing the consumption of 'less healthy' takeaway options may reduce socioeconomic inequalities in overweight and obesity among women but not men. However, reducing the consumption of 'less healthy' takeaway food may have an important role in the growing epidemic of overweight and obesity among all adults.

Key words: socioeconomic, obesity, mediation.

PO1844**TRANS FAT ENHANCED DOXORUBICIN INDUCED CARDIOTOXICITY IN MICE***M.C. Yin¹, H.C. Wang¹, W.T. Chen¹, C.C. Ho¹*¹Department of Nutrition, China Medical University, Taichung City, Taiwan

Background and objectives: This study examined the combined effects of trans fatty acid (TFA) diet plus doxorubicin upon cardiac oxidative and inflammatory stress. The influence of TFA and/or doxorubicin on cardiac activity and expression of associated factors was also evaluated.

Methods: Five-week-old male C57BL/6 mice were divided into two groups, one consumed normal diet, and the other consumed a diet prepared by shortening, rich in TFAs. After 8 week, normal diet or TFA diet groups were further divided into two sub-groups, and doxorubicin (25 mg/kg) or saline was given via one single i.p. injection. After 48 h, mice were killed with carbon dioxide. Blood and cardiac tissue were collected for analyses.

Results: TFA diet increased cardiac content of TFAs, but did not affect activity of lactate dehydrogenase (LDH) and creatine phosphokinase (CPK) in blood (P>0.05). Normal diet with doxorubicin treatment increased LDH and CPK activities (P<0.05), however, TFA diet plus doxorubicin treatment further elevated the activity of these two enzymes (P<0.05). This combination also markedly raised cardiac xanthine oxidase activity, caused greater production of reactive oxygen species, malonyldialdehyde, interleukin (IL)-6, IL-10, tumor necrosis factor- α and monocyte chemoattractant protein-1 in heart than TFA diet alone or normal diet with doxorubicin treatment (P<0.05). TFA diet increased nuclear factor kappa B (NF- κ B) activity (P<0.05), but did not affect the expression of NF- κ B and mitogen-activated protein kinase (MAPK) (P>0.05). Normal diet with doxorubicin treatment augmented cardiac activity, mRNA expression and protein production of NF- κ B, and enhanced MAPK expression (P<0.05). However, TFA diet plus doxorubicin treatment further up-regulated cardiac expression of NF- κ B p65, p-p38 and p-ERK1/2 (P<0.05).

Conclusions: These findings suggest that TFA diet exacerbates doxorubicin-induced cardiac oxidative and inflammatory injury. TFAs should be eliminated for patients with doxorubicin therapy.

Key words: Trans fatty acid, doxorubicin, cardiac injury; NF- κ B, MAPK.

PO1845**A SCIENTIFIC VALIDATION OF ANTIHYPERGLYCEMIC AND ANTIHYPERLIPEMIC ATTRIBUTES OF TRICHOSANTHES DIOICA FRUITS**

P. Rai¹, S. Gupta², R. Jayasundar¹, G. Watal²

¹Department of NMR, All India Institute of Medical Sciences, New Dehli, India

²Medicinal Research Lab, Department of Chemistry, University of Allahabad, Allahabad, India

Background and objectives: *Trichosanthes dioica* had been considered as an effective and safe ethnotherapeutic in Indian traditional system of medicine. The objective of the study was to validate the glycemic potential of *T. dioica* fruits.

Methods: Effects of variable doses of lyophilized powder of its aqueous extract were studied on blood glucose level (BGL), hemoglobin (Hb), total protein (TP), and lipid profile of normal, mild and severely diabetic animals. Body weight (bw) and urine sugar (US) were additional parameters studied.

Results: Dose of 1000 mg/kg decreases BGL of normal and mild diabetic rats significantly ($P < 0.01$) during fasting blood glucose (FBG) and glucose tolerance test (GTT) studies respectively. Four weeks long term study of severely diabetic rats with the same dose showed significant fall ($P < 0.001$) in FBG, postprandial glucose (PPG), total cholesterol (TC) and triglyceride (TG) levels. A significant increase ($P < 0.01$) in high density lipoprotein (HDL) is of value addition. TP, Hb and bw also showed significant increase ($P < 0.05$). Moreover, a significant reduction in US was observed from +4 to +1.

Conclusions: The scientific validation of ethnotherapeutics efficacy of *T. dioica* as an antidiabetic agent could be used for developing an oral drug managing diabetes and hyperlipidemia associated with it.

Key words: *Trichosanthes dioica*, antidiabetic, hyperlipidemia, Wistar rats.

PO1846**BMSO ALTERS WHITE ADIPOSE TISSUE PROTEIN PROFILES IN C57BL/6J MICE DISPLAYING DELIPIDATIVE, INFLAMMATORY AND BROWNING CHARACTERISTICS**

P. M. Chao¹, C. H. Hsieh¹, G. C. Chen¹

¹Institute of Nutrition, China Medical University, Taichung, Taiwan

Background and objectives: We have previously shown the anti-adiposity effects of bitter melon seed oil (BMSO), which is rich in *cis*-9, *trans*-11, *trans*-13 conjugated linolenic acid

(*c9,t11,t13*-CLN), in C57BL/6J mice. In this study, a proteomic approach was carried out to compare the protein profiles differentially expressed in the white adipose tissue (WAT) of mice fed a soybean oil based high fat diet with or without BMSO. Methods and

Results: Two-dimensional difference gel electrophoresis (pH4-7) revealed 32 statistically significant spot changes (>2 -fold, $P < 0.05$). Among them, 15 up- and 8 down-regulated proteins by BMSO were identified. Combined with histological analysis which shows BMSO resulted in macrophage infiltration and brown adipocyte recruitment, the proteomic data depict a WAT, affected by chronic BMSO administration, featuring a reduced caveolae formation, increased ROS insult, tissue remodeling/repair, and mitochondria uncoupling activity, as well as stabilized actin cytoskeleton, putatively related with an increased inflammation response.

Conclusions: This study provides an opportunity to find out some novel genes participating in the delipidative, inflammatory and browning of the WAT, and these changes may account for the BMSO-mediated anti-adiposity effect.

Key words: Bitter melon seed oil, proteomic analysis, white adipose tissue.

PO1847**SERUM VITAMIN D AND RISK OF ALZHEIMER'S DISEASE**

P. Knekt¹, K. Sääksjärvi¹, T. Jääskeläinen¹, J. Marniemi¹, M. Heliövaara¹

¹National Institute for Health and Welfare, Helsinki, Finland

Background and objectives: Low vitamin D status has been suggested to be related to an increased Alzheimer's disease risk. The present study investigates whether serum vitamin D level predicts the occurrence of the disease.

Methods: The study was based on the Mini-Finland Health Survey. The study population consisted of 5010 men and women, aged 50-79 years of age and free from Alzheimer's disease. During a 17-year follow-up period, 151 incident Alzheimer's disease (ICD-10 code 290) cases occurred according to a population wide Hospital Discharge Register and death certificates. Serum 25(OH)D concentration was determined by radioimmunoassay from serum samples frozen at -20°C and stored at baseline of the study. Sociodemographic, lifestyle and metabolic factors were determined by questionnaires, interviews and measurements at baseline. The strength of association between serum 25(OH)D concentration and Alzheimer's disease incidence was estimated using Cox's model.

Results: Individuals with higher serum vitamin D concentrations showed a statistically significantly reduced risk of Alzheimer's disease in women. The relative risk between the highest and lowest quartiles of serum vitamin D was 0.38 (95%

CI 0.18-0.82) in women and 0.89 (95% CI 0.39-2.06) in men after adjustment for sex, age, marital status, education, alcohol consumption, leisure-time physical activity, smoking, body mass index, and month of blood drawn.

Conclusions: The results are in line with the hypothesis that low vitamin D predicts the development of Alzheimer's disease. Further studies are needed to confirm these findings.

Key words: Alzheimer's disease, cohort study, vitamin D.

PO1848

THE RISK OF METABOLIC SYNDROME IS ASSOCIATED WITH INCREASED OXIDATIVE STRESS IN SUBJECTS WITH COLORECTAL ADENOMAS

F.P. Chen¹, Y.C. Huang¹, F.C. Chiang², C.C. Lin³

¹School of Nutrition, Chung Shan Medical University, Taichung, Taiwan

²Division of Colorectal Surgery, Department of Surgery, Taichung Veterans General Hospital, Taichung, Taiwan

³Institute of Medicine, Chung Shan Medical University, Division of Gastroenterology, Chung Shan Medical University Hospital, Taichung, Taiwan

Background and objectives: Several studies have shown that the risk of metabolic syndrome and increased oxidative stress are associated with the development of colorectal adenomas. However, the link between metabolic syndrome and oxidative stress in subjects with colorectal adenomas is unclear. The aim of this study was to determine the association between metabolic syndrome and oxidative stress in subjects with colorectal adenomas.

Methods: Seventy subjects with adenomatous polyps and 137 colorectal polyps-free control subjects were recruited.

Results: The prevalence of metabolic syndrome in subjects with colorectal adenomas and colorectal polyps free was 57.1% and 26.3%, respectively. Metabolic syndrome (OR, 2.22, 95% CI, 1.13-4.37) was significantly associated with the development of colorectal adenomatous polyps after adjusting for age, gender and serum creatinine. Oxidative stress indicators [malondialdehyde (beta = 0.71, p < 0.05) and oxidized low density lipoprotein-cholesterol (beta = 0.01, p < 0.05)] are significantly associated with the risk of metabolic syndrome in subjects with colorectal adenomas.

Conclusions: Increased oxidative stress might be a significant factor to the risk of metabolic syndrome in subjects with colorectal adenomas.

Key words: metabolic syndrome, colorectal adenoma, oxidative stress, malondialdehyde, oxidized low density lipoprotein-cholesterol.

PO1849

ASSOCIATION BETWEEN MATERNAL DIETS EVALUATED BY THE HEALTHY EATING INDEX SCORE AND BLOOD LIPIDS, LIPOPROTEIN, AND HOMOCYSTEINE LEVELS AT BIRTH

F.J. Sanchez-Muniz¹, E. Gesteiro², B. Rodriguez Bernal¹, S. Bastida¹

¹Universidad Complutense de Madrid, Madrid, Spain

²Hospital de Mérida, Mérida, Spain

Background and objectives: The Healthy Eating Index (HEI) score is a valuable tool to evaluate diet quality during pregnancy. To determine the relationship between first trimester diet quality and serum lipoprotein profile, arylesterase (AE) and homocysteine values at birth.

Methods: Cord-blood of the offspring of 35 women whose diets were 'adequate' or 'inadequate' according to their HEI-score (>70 or <=70, respectively).

Results: Low HEI-score diets did not differ in atherogenic index and contain less (g/1000 kcal) CHO (P=0.027), fibre (P=0.011), Mg (P=0.010), K (P=0.011), vitamin C (P=0.024), retinol (P=0.040), beta-carotenes (P=0.047), vitamin K (P=0.017) and more fats (P<0.001), cholesterol (P<0.001), Na/K (P= 0.019), vitamin B12/folate (P=0.017) ratios and contributed (%En) fewer CHO (P=0.005), more fats (P=<0.001) and SFA (P=0.002) than their high HEI-score counterparts. Mothers at the low HEI-score delivered infants with high total cholesterol (TC) (P=0.049); HDL-c (P=0.002) but low TC/HDL-c ratio (P=0.014).

Conclusions: The HEI score defines diet quality during the first trimester of pregnancy considering several diet-prevention aspects for degenerative diseases and appears associated to CVD markers at birth. More studies are needed to understand the importance later in life of such findings.

Key words: Pregnancy, neonates, HEI-score, neonatal-CVD markers.

PO1850

ANTHOCYANIN-RICH MAIZE PURPLE PLANT PIGMENT STIMULATED THE PROLIFERATION AND DIFFERENTIATION OF OSTEOBLASTIC MC3T3-E1 CELLS

B. Zhou¹, Z. Zhang¹, X.H. Wang¹

¹Department of Nutrition and Food Hygiene, Shenyang Medical College, Shenyang, Liaoning, China

Background and objectives: Apoptosis of osteoblasts has been proposed as the common basis of osteoporosis, with oxi-

ductive stress as the major cause. Supplementation with antioxidants may be beneficial in the treatment of this condition. Anthocyanin is known to function as antioxidant. There is no study available that reported the effect of anthocyanin treatment on osteoporosis. The aim of this study is to investigate the effect of maize purple plant pigment (MPPP) that is an anthocyanins-rich pigment (approximately 70% based on weight) extracted from maize purple plant on the proliferation and differentiation in osteoblastic MC3T3-E1 cells.

Methods: MPPP was added into the medium in a parallel treatment at (0, 0.001, 0.01, 0.1, 1, 10, 100 and 1000) $\mu\text{mol}\cdot\text{L}^{-1}$ volume concentration, respectively. MTT assay was carried out to estimate the proliferation. Alkaline phosphatase (ALP) and collagen type I (CTX-I) concentration were measured in cells that were treated with MPPP at the concentration of (0.1, 1, 10) $\mu\text{mol}\cdot\text{L}^{-1}$ for 72h.

Results: After incubation for 48h and 72h, the cells proliferation increased at the concentration of (0.001,0.01,0.1,1,10) $\mu\text{mol}\cdot\text{L}^{-1}$. There were no significant proliferation at high concentration of MPPP (100, 1000 $\mu\text{mol}\cdot\text{L}^{-1}$). After incubation for 24h, proliferation was observed at only one concentration (1 $\mu\text{mol}\cdot\text{L}^{-1}$) of MPPP. MPPP increased significantly the ALP activity and CTX-I concentration of the cells in all levels of MPPP.

Conclusions: MPPP therefore stimulated the proliferation and osteoblastic differentiation of MC3T3-E1 cells and may have potential to prevent osteoporosis.

Key words: anthocyanin, MC3T3-E1, osteoblaste osteoporosis, antioxidant.

PO1851

EFFECTS OF CONSUMPTION OF A DRINK OF CASHEW (ANACARDIUM OCCIDENTALE) ABOUT GLUCOSE-INSULIN RESPONSE IN PATIENTS WITH TYPE 2 DIABETES MELLITUS

M. Romero¹, A. Bravo¹, E. Esteva¹, E. Maury²

¹Laboratorio de Investigaciones y Desarrollo en Nutrición (LIDN), Universidad del Zulia, Maracaibo, Venezuela

²Carrera de Nutrición y Dietética, Facultad de Salud y Ciencias de la Actividad Física, Universidad Internacional SEK, Santiago, Chile

Background and objectives: Numerous plants with possible hypoglycemic activity have been described. Some of them are being widely studied with very positive results. Among them is the cashew (*Anacardium occidentale*). The goal of this work was to evaluate the effect of the consumption of a cashew drink on postprandial glucose-insulin response in type 2 diabetics.

Methods: we developed a drink of pseudo cashew juice 60% (v/v), sucralose, annatto, citric acid and sodium benzoate. The study was conducted on a sample of 10 adults proof intake control with 50 g of carbohydrates (white bread) and 250 mL of water. A week later the test was repeated with white bread and drink 250 mL of cashew. Blood samples were taken at 0, 60 and 120 minutes. The postprandial response was assessed by the positive incremental area, determined the area under the curve by the trapezoidal rule.

Results: cashew drink consumption decreased glucose at 120 min post-ingestion of food, 209.81 ± 60.25 mg/dL (test control) vs. 181.61 ± 48.26 mg/dL (try cashew), with significant decrease in glucose AUC ($p < 0.05$). Cashew juice significantly increased the insulin response at 120 min, 25.45 ± 9.16 mUI/mL (test control) vs. 36.38 ± 12.80 mUI/mL (try cashew) ($p < 0.05$).

Conclusions: consumption of drinking cashew improved glucose-insulin response of patients studied.

Key words: *Anacardium occidentale*, hypoglycemic effect, type 2 diabetes mellitus, blood glucose, insulin.

PO1852

EFFECTS OF THE CONSUMPTION OF A CASHEW BEREVAGE (ANACARDIUM OCCIDENTALE) ON THE GLYCEMIC AND INSULIN RESPONSE IN HEALTHY YOUNG ADULTS

M. Romero¹, A. Bravo¹, R. Escalona¹, B. Vanessa¹, C. Alejandra¹

¹Laboratorio de Investigaciones y Desarrollo en Nutrición (LIDN), Universidad del Zulia, Maracaibo, Venezuela

Background and objectives: For years there has been a tendency to make proposals on the development of new food products, and to evaluate the properties and benefits of their consumption through clinical trials. The aim of this work was to evaluate the effect of the consumption of a cashew drink (*Anacardium occidentale*) on postprandial glucose-insulin response in healthy subjects.

Methods: A beverage was made with the pseudo clarified juice of cashew 60% (v/v), non-caloric sweetener (sucralose), natural dye (annatto), citric acid (0.05%) and sodium benzoate (0.005%). A sample of 11 healthy young adults (18-25 years) males took the test of oral glucose tolerance, with a load of 75 g glucose in aqueous solution (OGTT-control). A week later the test was repeated with additional consumption of 250 ml of the cashew drink (OGTT-cashew). Three venous blood samples were taken at 0, 60 and 120 minutes, to analyze the levels of glucose with the glucose oxidase method (Wiener Lab) and insulin (DRG Diagnostics). The postprandial glucose-insulin

response area was estimated with positive incremental glucose and insulin, determined the area under the curve (AUC) by the trapezoidal rule. We calculated rates of change of glucose (PVGx) and insulin (PVIx) during rehearsals.

Results: Under the conditions of the study, consumption of cashew drink significantly increased insulin response, 4140.82 ± 2306.63 ABC (OGTT-control) vs. 5788.36 ± 2028.21 (OGTT-cashew) ($p < 0.05$). Cashew juice induced a significant increase in serum insulin at 120 min, with a PVI of 110.99 ± 165.42 (OGTT-control) vs. 300.31 ± 248.87 (OGTT-cashew) ($p < 0.05$).

Conclusions: Consumption of the drink increases the insulin response with no apparent change in the glycemic response in healthy adults.

Key words: Anacardium occidentale, dietetic beverage, glycemic response, insulin response.

PO1853

ERYTHROCYTE LEVELS OF N-3 POLYUNSATURATED FATTY ACIDS AND BIOMARKERS OF INFLAMMATION AND OXIDATIVE STRESS IN PATIENTS WITH AND WITHOUT DEPRESSION

Y. Park¹, D. Baek¹

¹Department of Food and Nutrition, Hanyang University, Seoul, South Korea

Background and objectives: Associations between n-3 polyunsaturated fatty acids (PUFAs), inflammation, oxidative stress and the risk of depression have been suggested. We evaluated the hypothesis that erythrocyte n-3 PUFAs are inversely associated with biomarkers for inflammation and oxidative stress in Koreans with and without depression.

Methods: Study participants comprised 80 cases diagnosed with depression based on Center for Epidemiological Studies Depression Scale Korea version (CES-D-K) scores ≥ 25 and psychiatrist confirmation and 80 age- and sex-matched healthy controls without histories of depression.

Results: CES-D-K scores, the number of depressed patients, levels of inducible nitric oxide synthase (iNOS) and tumor necrosis factor (TNF)- α ; were negatively associated with Omega-3 Index (erythrocyte levels of eicosapentaenoic acid and docosahexaenoic acid) after adjusting for confounding factors. Levels of iNOS, superoxide dismutase, interferon- γ , and nitrotyrosine were significantly higher in depressed patients than in healthy controls. Concentrations of iNOS, TNF- α , thiobarbituric acid reactive substances, and nitrotyrosine were negatively associated with erythrocyte levels of n-3 PUFAs and saturated fatty acids, but positively associated with erythrocyte levels of n-6 PUFAs and trans fatty acids.

Conclusions: The erythrocyte omega-3 index and levels of n-3 PUFAs were inversely associated with biomarkers of inflammation and oxidative stress in Koreans with and without depression. (This work was supported by a grant from the Korea Research Foundation (2012R1A1A2040553) funded by the Korean government.)

Key words: Cytokine, depressed patients, erythrocyte, n-3 polyunsaturated fatty acids, oxidative biomarkers.

PO1854

HYPOCHOLESTEROLEMIC EFFECT OF MANGO GINGER (CURCUMA AMADA ROXB) ON HYPERCHOLESTEROLEMIC ADULT PATIENTS

A. Thomas¹, M. Manikuttan¹, N. Jose¹

¹Department of Home Science, C.M.S. College, Kottayam, Kerala, India

Background and objectives: Epidemiological studies strongly imply that hypercholesterolemia is a powerful risk factor for the development of cardiovascular diseases. Lowering lipids can be done through dietary or pharmacological therapy. From immemorial time, man depended on plants for all his medicinal needs. Plant based bioactive compounds are gaining popularity due to their multi-functional therapeutic property and is generally considered to be safe. Mango ginger (Curcuma amada Roxb.) is a perennial, rhizomatous, aromatic herb belonging to the family Zingiberaceae. Mango ginger rhizome is a unique spice abundantly used in Ayurveda and Unani system of medicine and also for culinary purposes in Asian Countries. Mango ginger powder exhibits anti-hypercholesterolemic property.

Methods: In this investigation, 70 subjects were screened, 16 adults of 20-55 years, suffering from hypercholesterolemia (200-240mg/dl) with no other medical complications, not on any medications, were selected by purposive sampling for supplementation and were categorized into two groups A (8 males) and B (8 females). The anthropometric measurements were assessed and blood samples were collected to evaluate lipid profile (CHOD-POD method). Ten grams of mango ginger powder was supplemented daily for 45 days. Data were analysed using t-test.

Results: Lipid profile of the selected samples before and after supplementation showed significance at one percent level.

Conclusions: The pilot study conducted confirms anti-hypercholesterolemic property of mango ginger powder. It can be considered as a part of dietary approach or as a functional food in lowering cholesterol in moderately hypercholesterolemic subjects, although, further studies have to be done in a larger population for a longer period. (Acknowledgement: University Grants Commission, New Delhi, India.)

Key words: Hypercholesterolemia, mango ginger, herb, supplement.

PO1855

A COHORT STUDY ON THE PREVALENCE OF OBESITY AND HYPERTENSION AMONG SHARPEVILLE ELDERLY IN SOUTH AFRICA (2005-2011)

O. Otitoola¹, W. Oldewage-Theron¹, A. Egal¹

¹Centre of Sustainable Livelihood, Vaal University of Technology, Vanderbijlpark, South Africa

Background and objectives: Obesity, a global epidemic and risk factor for many cardio vascular diseases has become a public health concern in South Africa especially among the elderly. This study investigated the prevalence of obesity and its association with high blood pressure with a view to document the effect of weekly aerobic activity conducted among the elderly.

Methods: Anthropometric variables and blood pressure of 355 elderly aged 50-98 years were measured biennially from 2005 to 2011 using standard techniques. Data collected were analysed with SPSS, version 20.

Results: The mean body mass index (BMI) ranged from 29.8-31.1 kg/m² and 28.5-24.2 kg/m². Prevalence of overweight and obesity (80.4-82.3% versus 73.5-42.8%) and central obesity (77.9-87% versus 42.8-28.6%) increased in women and reduced in men during the study period. Women had significantly higher (P=0.01) prevalence of obesity than men. The mean blood pressure reduced from 154/97 to 141/84 mmHg (p>0.05) in women and 169/113 to 154/86 mmHg (p>0.05) in men from 2005 to 2011. There was no significant difference in the mean systolic and diastolic blood pressure in men and women. Systolic blood pressure correlated strongly with weight (r²=0.730; p=0.001) and moderately with BMI (r²=0.386; p=0.001) and waist circumference (r²=0.465; p=0.001) Respondents with BMI >25 kg/m² had significantly higher (p<0.05) systolic and diastolic blood pressure and are four times more likely to be hypertensive (OR, 4.510, 95% CI 1.30-15.71; p<0.05) than those with BMI<25 kg/m². Prevalence of hypertension reduced in both men and women during the study period though the difference was not statistically significant (p>0.05).

Conclusions: Prevalence of obesity was found to be significant amongst the study population especially in women and was strongly associated with hypertension. Body weight reduction is important in lowering blood pressure.

Key words: Anthropometric indices, obesity, hypertension, elderly, South Africa.

PO1856

HIGHER HOMOCYSTEINE IS ASSOCIATED WITH THE INCREASED RISK OF COLORECTAL CANCER INDEPENDENTLY OF OXIDATIVE STRESS AND ANTIOXIDANT ENZYME ACTIVITY

Y C. Huang¹, M H. Yang¹, Y C. Lan¹, F F. Chiang², H M. Wang²

¹School of Nutrition, Chung Shan Medical University, Taichung, Taiwan

²Division of Colorectal Surgery, Department of Surgery, Taichung Veterans General Hospital, Taichung, Taiwan

Background and objectives: Increased homocysteine concentration and oxidative stress and decreased antioxidant enzyme activities are thought to affect carcinogenesis. However, the association of homocysteine with oxidative stress status and antioxidant enzyme activities in patients with colorectal cancer is unclear. The purpose of this study was to determine the association of homocysteine with oxidative stress indicators and antioxidant enzyme activities, and further analyze the relation with the risk for colorectal cancer.

Methods: One hundred and sixty-eight patients with colorectal cancer and 188 healthy controls were recruited.

Results: There was no significant association of plasma homocysteine with oxidative stress indicators and antioxidant enzyme activities in either colorectal cancer patients or healthy controls after adjusting for potential confounders. Higher homocysteine exhibited significantly increased risk of colorectal cancer (OR, 1.28; 95% CI, 1.17; V1.40) after adjusting for potential confounders. The association between homocysteine and the risk of colorectal cancer remained significant (OR, 1.32; 95% CI, 1.18-1.47) after oxidative stress indicators and antioxidant enzyme activities were simultaneously adjusted.

Conclusions: Higher homocysteine is strongly associated with the risk of colorectal cancer independently of oxidative stress indicators and antioxidant enzyme activities.

Key words: homocysteine, oxidative stress, antioxidant enzyme activities, colorectal cancer.

PO1857**PROTEOMIC ANALYSIS OF POTENT LIPOLYTIC ACTION OF LACTOFERRIN IN RAT MATURE ADIPOCYTES**

³Kyoto Prefectural University of Medicine, Kyoto, Japan

⁴Ritsumeikan University, Kyoto, Japan

Background and objectives: Lactoferrin (LF) is a multifunctional milk protein. In previous reports, we proved that enteric-coated LF decreased the visceral fat accumulation in a clinical trial. Animal studies revealed that ingested LF was delivered to mesenteric fat and in vitro experimentations showed that LF promoted the lipolysis of mature adipocytes. In this study, we analyzed protein expression profiles and their activation time using mature adipocytes to identify the underlying mechanism of lipolysis induced by LF.

Methods: Pre-adipocytes derived from mesenteric fat tissue of male rats were cultured and differentiated into mature form, and cells were collected at various time courses after addition of LF. Protein expression profiles were analyzed by proteomics.

Results: Proteomic analysis revealed that the expression levels of adenylate cyclase (cAMP synthase, AC) and hormone sensitive lipase (late-limiting enzyme of lipolysis, HSL) were significantly up-regulated by LF. Then we measured phosphorylation levels of key proteins, and found that HSL was phosphorylated by protein kinase A (PKA) within 5-15 minutes. The enzymatic activity of PKA was also activated in the same time-course. These results suggested that PKA activated by cAMP transduced phosphorylation signals in adipocytes, and activated HSL began the fat breakdown process. Proteins involved in Ras-Raf-ERK pathway also showed some distinct alterations. We detected the increased phosphorylation level of CREB, a downstream transcription factor of both cAMP and Ras-Raf-ERK pathway, which regulates the expression levels of AC and HSL. These results strongly explain increasing expression levels of AC and HSL.

Conclusions: In further finding of the crosstalk between Ras-Raf-ERK and cAMP pathway, LF may influence these networks both in phosphorylation and transcriptional regulation, and then these effects result in the promotion of lipolysis in mature adipocytes.

Key words: lactoferrin, lipolysis, adipocytes, proteomic analysis.

PO1858**EFFECT OF DIETARY AND PHYSICAL ACTIVITY INTERVENTION IN OVERWEIGHT AND OBESE THAI ADULTS**

P. Artitdit¹, O. Iamopas¹, D. Bhakta²

¹Department of Nutrition and Dietetics, Queen Sirikit National Institute of Child Health, Bangkok, Thailand

²Faculty of Life Science, London Metropolitan University, London, UK

Background and objectives: The healthy dietary pattern advice is beneficial to balance the energy and macronutrient intake while an increase of moderate-intensity physical activity is a strategy to improve lifestyle behavior.

Methods: A total of 60 overweight and obese Thai adults (BMI \geq 23.0 kg/m²), aged 20-60 years, employees at Queen Sirikit National Institution of Child Health, was invited into one hour in nutritional knowledge sessions which focused on calorie restriction and healthy dietary pattern, and one hour in moderate-intensity physical activity sessions every month through 4 months. The measurement of body weight, waist circumference, dietary intake, physical activity, blood pressure, and blood biomarkers were collected at baseline and the end of intervention.

Results: The mean (+SD) age of all participants was 41.6+9.1 years and their mean BMI was 28.0+3.6 kg/m² at baseline. After 4 months, the differences in body weight was -1.2+1.8 kg (P<0.01) and waist circumference was -4.2+4.6 cm (P=0.02). The change of their dietary pattern increased approximately 1 serving/day of vegetables intake and 0.6 serving/day of fruits intake, although it was non-significant (NS). Their consumption of rice and starchy foods decreased by 1 serving/day (NS), and by 2 servings/day of fat (P<0.01). These led to a reduction in energy intake by an average of 170 kcal/day (P=0.02) and 5% decrease energy from fat (P<0.01). The self-reported increase in moderate-intensity physical activity was 38.5+26.0 minutes/week (NS). Mean reduction in systolic and diastolic blood pressure was 9.6+8.1 mmHg (NS) and 4.6+6.4 mmHg (NS). Changes of total cholesterol, high and low density lipoprotein cholesterol, and fasting plasma glucose were -11.3 mg/dL (NS), 0.6 mg/dL (NS), -4.8 mg/dL (NS) and -7.0 mg/dL (P=0.03), respectively.

Conclusions: A healthy dietary pattern advice and moderate-intensity physical activity could achieve significant in weight management in overweight and obese Thai adults.

Key words: overweight, obese, dietary pattern.

PO1859**THE EFFECTS OF DIETARY POLYUNSATURATED FATTY ACIDS IN THE PREVENTION OF CORONARY HEART DISEASE**

S. Zeghichi-Hamri¹, M. de Lorgeril², P. Salen², J. de Leris²

¹Department of food sciences, Bejaia University, Bejaia, Algeria

²Laboratory Heart and Nutrition, Joseph Fourier University, Grenoble, France

Background and objectives: Dietary n-3 polyunsaturated fatty acids (PUFA) reduce coronary heart disease (CHD) complications, such as chronic arrhythmia and sudden cardiac death. Improved myocardial resistance to ischemia-reperfusion injury results in smaller myocardial infarction, which is a major factor in the occurrence of CHD complications.

Methods: We hypothesized that a specific dietary fatty acid profile (low in saturated and n-6 PUFA but high in plant and marine n-3 PUFA) may improve myocardial resistance to ischemia-reperfusion injury and reduce infarct size. To test this assumption, we used a well-defined rat model of myocardial infarction.

Results: In comparison to a diet that is high in either saturated or n-6 PUFA but poor in plant and marine n-3 PUFA, a diet that is low in saturated fats and n-6 PUFA but rich in plant and marine n-3 PUFA results in smaller myocardial infarct size ($P<0.01$). The effects of the 3 diets were also examined by analyzing the fatty acid composition of plasma, erythrocyte cell membranes, and the phospholipids of myocardial mitochondria. The results show a great accumulation of n-3 PUFA and a parallel decrease in arachidonic acid, the main n-6 PUFA, in plasma, cell membranes, and cardiac mitochondria ($P<0.0001$).

Conclusions: We conclude that improved myocardial resistance to ischemia-reperfusion may be one of the critical factors explaining the protective effects of dietary n-3 PUFA against CHD complications in humans. In addition to increasing n-3 PUFA intake, an optimal dietary pattern aimed at reducing cardiovascular mortality should include a reduction of the intake of both saturated and n-6 PUFA.

Key words: Coronary heart disease, ischemia-reperfusion injury, infarct size, n-3 fatty acids.

PO1860**TRENDS OF OBESITY, HYPERTENSION AND WEIGHT PERCEPTION OF SAHRAOUI ETHNIC GROUP IN SOUTHERN MOROCCO (2001-2011)**

M. Rguibi^{1,2}, H. Barouaca^{2,3}, R. Belahsen¹

¹Biology Department, Training and Research Unit on Nutrition & Food Sciences, Laboratory of Biotechnology, Biochemistry & Nutrition, Chouaib Doukkali University, School of Sciences, El Jadida, Morocco

²Moroccan Association of Health and Nutrition Education, Casablanca, Morocco

³Biology Department, Laboratory of Biochemistry Nutritional Biochemistry Unit, Faculty of Sciences Dhar El Mahraz, University of Sidi Mohamed Ben Abdellah, Fez, Morocco

Background and objectives: The prevalence of obesity is high among Sahraoui women and may contribute to elevated prevalence of cardiovascular diseases. We examined the trends in obesity prevalence, hypertension prevalence and weight perception among Sahraoui women.

Methods: Data were collected from regional surveys conducted in 2001 and 2011 in Southern Morocco. The sample was randomly selected among adult healthy urban women aged 15 years and older, non pregnant.

Results: The prevalence of obesity, overweight and hypertension increased from 2001 to 2011. The overall prevalence of obesity increased from 49% to 51,7%, abdominal obesity from 76% to 90.5% and overweight from 30,1% to 31,8%. The similar trend was observed for hypertension that is more prevalent among obese and overweight women compared to normal weight women. Body image perception and physical inactivity were key factors in this elevated prevalence. During the past 10 years, there was a significant increase in the percentage of women who want to lose body weight (4,9% to 33,7%) but the desire to gain weight remains very high even among normal weight women (69,7%). Obesity was negatively associated with time spent in walking and positively associated with time spent in some sedentary activities. Also, eating disorders seem to be an increasing problem among Moroccan Sahraoui women. In fact 22,9% of studied women reported having an eating disorder which is more common among overweight (21,9%) and obese (29,8%) compared to normal weight women (3%).

Conclusions: High prevalence of obesity and hypertension trends are for a raise, suggesting apparent needs for immediate attention in terms of prevention and health education among the studied population.

Key words: Obesity, hypertension, body image perception, Sahraoui population, Southern of Morocco.

PO1861

VEGETABLE AND FRUIT CONSUMPTION IS INVERSELY ASSOCIATED WITH COLORECTAL CANCER RISK IN CHINESE POPULATIONS

C. Zhang¹, X. Zhong¹, Y. Fang², Y. Chen¹, M. Lu¹

¹Department of Medical Statistics and Epidemiology, Sun Yat-Sen University, Guangzhou, People's Republic of China

²Department of Colorectal Surgery, Sun Yat-sen University Cancer Center, Guangzhou, People's Republic of China

Background and objectives: The associations between vegetable and fruit intakes and colorectal cancer risk have been examined in many epidemiological studies, but the results remained inconsistent. Few studies have been conducted in the Chinese population. This study aimed to examine the associations of vegetable and fruit intakes with colorectal cancer risk in Guangzhou, China.

Methods: A case-control study was conducted between July 2010 and October 2012 in Guangzhou, China. Six hundred and thirteen consecutively recruited colorectal cancer cases were frequency matched to 613 controls by age (5-year interval) and gender. A validated food frequency questionnaire was used to collect dietary information by face-to-face interviews. Multivariate logistic regression models were used to estimate the odds ratios (ORs) and 95% confidence intervals (CIs).

Results: Total vegetables and fruits intakes were found to be inversely associated with colorectal cancer risk. The adjusted ORs for the highest quartile comparing with the lowest quartile were 0.47 (95%CI 0.34-0.66, P for trend <0.01) for total vegetables and fruits, 0.58 (95%CI 0.41-0.80, P for trend <0.01) for total vegetables, and 0.57 (95%CI 0.41-0.79, P for trend <0.01) for total fruits. The inverse associations were observed in both men and women. When analyzed by cancer site, the adjusted ORs (95% CIs) comparing total fruit and vegetable intakes of the highest versus the lowest quartile were 0.48 (0.33 to 0.71, P trend <0.01) for colon cancer and 0.45 (0.29 to 0.70, P trend <0.01) for rectal cancer. Similar site-specific associations were observed for total vegetables and total fruits.

Conclusions: This study suggested that greater consumption of vegetables and fruits were associated with a decreased risk of colorectal cancer in Chinese populations.

Key words: vegetable, fruit, colorectal cancer, case-control study, China

PO1862

ALTERATION OF CARDIOVASCULAR DISEASE RISK BIOMARKERS IN PREPUBERTAL CHILDREN

J. Olza¹, C M. Aguilera¹, M. Gil-Campos², R. Leis³, G. Bueno⁴, R. Cañete², R. Tojo³, L A. Moreno⁵, A. Gil¹

¹Department of Biochemistry and Molecular Biology II, University of Granada, Granada Spain

²Paediatric Research and Metabolism Unit, Reina Sofia University Hospital, Córdoba, Spain

³Paediatric Department, Clinic University Hospital of Santiago de Compostela, Santiago de Compostela, Spain

⁴Paediatric Department, Lozano Blesa University Hospital, Zaragoza, Spain

⁵School of Health Sciences, University of Zaragoza, Zaragoza, Spain

Background and objectives: The worldwide epidemic of childhood obesity in the last years has accelerated the occurrence, in the paediatric population, of disorders usually observed in adults. One of these disorders is the metabolic syndrome, which is driven by obesity and involves insulin resistance, dyslipidaemia and hypertension. A metabolic cluster score has been developed in order to have a valid tool to diagnose the "at risk" children with a continuous parameter. The objective of the present study was to evaluate the use of a metabolic syndrome cluster score, and to assess its association with biomarkers of inflammation and CVD risk.

Methods: 677 prepubertal Caucasian Spanish children, 295 obese, 146 overweight and 236 normal-weight aged 4-12 years were recruited. Metabolic syndrome features as well as inflammation and CVD risk biomarkers were measured. A metabolic syndrome cluster score was calculated, consisting on the average/5 of the standardized scores from the components of the metabolic syndrome.

Results: The metabolic score was different among normal-weight, overweight and obese children (-0.44±0.04, 0.28±0.05, 1.32±0.06, p<0.001, respectively). The percentage of the metabolic syndrome in the obese group was 9.4%. Metabolic syndrome components as well as leptin, CRP and PAI-1 were significantly different among groups, being higher in the obese group, except in the case of HDL-c, which was lower. Resistin, TNF- α , IL-6, MPO and sE-selectin were higher in the obese compared with overweight and normal-weight groups.

Conclusions: The use of the metabolic syndrome cluster score reflects better the degree of affectation in each individual than the common classification of the metabolic syndrome; letting us identify the "at risk" children, which have not been diagnosed with metabolic syndrome, but present metabolic alterations. This score is a helpful tool that can be used in the clinical practice to make an early diagnosis.

Key words: metabolic syndrome, child, risk factors.

PO1863**INFLAMMATION MARKERS CORRELATE WITH INSULIN SENSITIVITY PARAMETERS IN OBESE ADOLESCENTS**

M. Aguilar-Cordero², E. Gonzalez-Jimenez², F. Rivas-Garcia³, J.S. Perona¹

¹Nutrition and Lipid Metabolism, Instituto de la Grasa - CSIC, Sevilla, Spain

²Hospital San Cecilio, Granada, Spain

³Ayuntamiento de Guadix, Granada, Spain

Background and objectives: There is a general consensus that obesity is an eminently inflammatory process, since impairments in the secretion of certain inflammation markers, such as ceruloplasmin, leptin, adiponectin, have been observed in these patients. There is evidence that these inflammation markers correlate with parameters related to insulin resistance in obese adults. This study was conducted to ascertain if these correlations can be observed also in adolescents.

Methods: The study was conducted in a group of 12 obese (BMI > 30 Kg/m² and percentile > 95) and 12 normal-weight (BMI = 20-25 Kg/m² and percentile in the range 5-85) adolescents. Serum levels of adiponectin, leptin, ceruloplasmin and insulin levels were determined by commercial ELISA kits. Insulin and glucose concentrations were determined by immunoassay and the homeostasis model assessment (HOMA2-IR) score was calculated using the HOMA Calculator software (Diabetes Trial Unit, Churchill Hospital, Oxford, UK).

Results: Ceruloplasmin and leptin concentrations were higher in the serum of obese adolescents while that of adiponectin was lower. Insulin concentrations and HOMA-2 values were higher in the obese group. Ceruloplasmin correlated with both parameters with a high level of significance. However, leptin levels did not correlate with either HOMA2-IR or insulin, and adiponectin correlated with HOMA2-IR but not insulin.

Conclusions: The inflammation parameters studied, as well as markers for insulin sensitivity were notably altered in obese adolescents. However, although we found a relationship between insulin resistance and some of these markers, only ceruloplasmin correlated with both HOMA-2-IR and insulin concentrations, revealing as a potential string marker of insulin resistance in obese adolescents. Acknowledgements: This work was supported by the City Hall of Guadix (Spain) and was funded by a grant from the Spanish Ministry of Science and Innovation (AGL2011-23810) and San Cecilio Hospital (Granada, Spain).

Key words: obesity, adolescence, inflammation, ceruloplasmin, insulin resistance.

PO1864**THE PREVALENCE OF OVERWEIGHT AND OBESITY AMONG 7-16-YEARS CHILDREN AND ADOLESCENTS AND ITS RISK FACTORS IN SOUTHERN CHINA**

H. Xue¹, Y. Liu¹, X. Zhou¹, R. Duan¹, G. Cheng¹

¹Department of Nutrition and Food Safety, West China School of Public Health, Sichuan University, Chengdu, China

Background and objectives: Several studies have suggested that the prevalence of overweight and obesity among children and adolescents in China has increased dramatically since 1990's. However, research focused on their risk factors is lacking. The aim of this work was to examine the prevalence of overweight and obesity among children and adolescents in Southern China, and to understand their risk factors.

Methods: A total of 2638 children and adolescents aged 7-16-years were selected randomly from cities and communities in Southern China. Parental information, as well as physical activity, diet (3-day 24h diet records) were questioned. The anthropometric measures were examined by ultrasonic height and weight instrument, skin-fold caliper and tape. Data were analyzed with logistic multivariate regression.

Results: The anthropometric parameters, i.e., height, weight, waist circumference, skin-fold thickness and hips were collected. The percentage body fatness was calculated according to Slaughter et al. Waist to hip ratio (WHR) was estimated. Their parents answered the family information and birth data. The primarily analysis suggested that the prevalence of overweight and obesity among children and adolescents in Southern China was in line with the reports of other studies from this country. Furthermore, the overweight in Chinese children was positively associated with gender, excessive total energy intake, less physical activity.

Conclusions: Our primary analysis provide that overweight and obesity among children and adolescents in Southern China is epidemic. The information about the risk factors, particularly in nutrients and food/food groups, will be examined in further analyses.

Key words: overweight, obesity, children, risk factor, China.

PO1865**HYPERTENSION, VITAMIN D STATUS AND BODY MASS INDEX IN AN URBAN SOUTH AFRICAN COMMUNITY***R. Lategan¹, V. Van den Berg¹, C. Walsh¹*¹Department of Nutrition and Dietetics, University of The Free State, Bloemfontein, South Africa

Background and objectives: Hypertension, a major health concern, is affecting morbidity and mortality worldwide. A relationship exists between body weight and hypertension. Low levels of vitamin-D are associated with higher blood pressure levels and obesity markers. This study aims to assess vitamin-D status in a low-income, urban South African community, to determine the association between vitamin-D status, body mass index (BMI) and prevalence of hypertension.

Methods: Blood pressure, weight and height were measured by trained professionals, using calibrated equipment and standardized techniques. Blood samples were obtained through venous puncture after overnight fast. Serum concentrations of 25-hydroxyvitamin D (25(OH)D) was determined with chemiluminescent immunoassays.

Results: 339 adults were included, with a mean age of 44.3 (± 10.6) years (range 25-63). 45% had a BMI reflecting normal/underweight, 23% overweight and 32% obese. 65.8% females and 18.4% males were overweight/obese. 63.4% of the study population either had blood pressure $>140/90$ mmHg or were currently using antihypertensive medication. Mean 25(OH)D concentration was 38.4 ng/ml (96 nmol/L), ranging from 8.7-82.2 ng/ml, indicating adequate status. Mean 25(OH)D concentrations were 37.0 ± 10.6 ng/ml and 43.5 ± 11.8 ng/ml for females and males, respectively. One participant had 25(OH)D concentration <12 ng/ml, indicating deficiency and 13 participants had 25(OH)D between 12-20 ng/ml, indicating inadequacy. Inverse relationships between BMI and vitamin-D status ($p=0.01$) and mean arterial blood pressure and vitamin-D ($p=0.05$) was found, but no correlation between vitamin-D and hypertension or mean arterial blood pressure when controlled for BMI.

Conclusions: More than half of this population was overweight/obese and hypertensive. Vitamin-D status was adequate, despite expected low vitamin-D intake. Latitude and sun exposure could have favored vitamin-D status. Results support an inverse relationship between vitamin-D and hypertension, but seem to depend on an accompanying increase in BMI.

Key words: hypertension, vitamin D, BMI, South Africa.

PO1866**BMI, WAIST TO HEIGHT RATIO, BODY ADIPOSITY INDEX AND WAIST CIRCUMFERENCE ARE ASSOCIATED WITH HYPERTENSION IN AN URBAN AFRICAN COMMUNITY***R. Lategan¹, V. Van den Berg¹, C. Walsh¹*¹Department of Nutrition and Dietetics, University of The Free State, Bloemfontein, South Africa

Background and objectives: Hypertension is becoming more prevalent in low-income countries, increasing global disease burden. A strong relationship between body weight and hypertension exists. This study determines the relationship of various body adiposity indices (body mass index (BMI, kg/m²), waist-to-height ratio (WHtR), body adiposity index (BAI) and waist circumference (WC)) with blood pressure.

Methods: 339 Adults aged between 25 and 63 years from the Assuring Health for All in the Free State (AHA-FS) study were included. Calibrated equipment and standardized techniques were used to measure blood pressure, human immunodeficiency virus (HIV) and anthropometric measurements. Weight and height were measured to calculate BMI; WC and height to calculate WHtR; and height and hip circumference to calculate BAI.

Results: More than a third (39.8%) of the sample was HIV-positive. 63.4% had blood pressure values $>140/90$ mmHg or were using antihypertensive medication. Based on BMI, 44.8% of the study population were normal/underweight, 23% overweight, and 32.1% obese. The majority (58.6%) had a WHtR representing increased cardiovascular risk. Mean BAI was 34.1%, and 76.3% had an overweight/obese body fat percentage. A WC representing increased cardiovascular risk was measured in 44.3% females and 3.9% males. Significant positive correlations between mean arterial blood pressure and BMI ($r=0.261$; $p<0.001$), WHtR ($r=0.357$; $p<0.001$) and BAI ($r=0.245$; $p<0.001$) were found. WHtR seemed a stronger predictor of mean arterial pressure than BMI or BAI. HIV status was inversely correlated with all adiposity indices ($p<0.001$).

Conclusions: Findings support weight loss as first line intervention to prevent and treat hypertension and suggest WHtR as practical screening tool for hypertension risk.

Key words: Hypertension, BMI, waist to height ratio, body adiposity index, waist circumference.

PO1867**DIETARY FATTY ACIDS IN RELATION TO INFLAMMATORY MARKERS IN PATIENTS WITH CORONARY ARTERY DISEASE***Z. Paknahad¹, M. Niknam¹, M.R. Maracy¹, M. Hashemi¹*¹Isfahan University of Medical Sciences, Isfahan, Iran

Background and objectives: Atherosclerosis, with its major manifestation, coronary artery disease (CAD) is a chronic inflammatory disease. Dietary fatty acids intakes favorably affect on inflammatory responses. This study was conducted to examine the association between dietary fatty acids and inflammatory markers, IL-6 (Interleukin 6) and hs-CRP (high sensitivity C-reactive protein), in CAD patients among Iranian population.

Methods: This hospital-based cross-sectional study was conducted in Chamran Heart Hospital, Isfahan, Iran in 2012. Patients aged ≥ 45 years with first ever symptomatic CAD confirmed by angiography were included. A semi-quantitative food frequency questionnaire was used to assess the usual intakes of dietary fatty acids.

Results: After adjustment for potential confounders, saturated fat was statistically significantly related to hs-CRP ($P=0.011$) and IL-6 ($P < 0.001$) concentrations. Intakes of Eicosapentaenoic acid (EPA) and decosahexaenoic acid (DHA) and monounsaturated fat (MUFA), were significantly related to plasma hs-CRP concentration ($P=0.002$ and $P=0.001$, respectively) but not IL-6, albeit MUFA was modestly inversely related to IL-6 ($P=0.08$). No significant relationships were observed for other fatty acids, α -linolenic acid and linoleic acid.

Conclusions: Our findings suggest that saturated fat, EPA+DHA and MUFA were significantly related to plasma inflammatory markers. The present results do not support the hypothesis that n-6 fatty acids antagonize the effects of n-3 fatty acids.

Key words: Fatty acids, coronary artery disease, high sensitivity C-reactive protein, interleukin-6.

PO1868**SESQUITERPENOIDS FROM INULA WISSMANNIANA HAND.-MAZZ. WITH THEIR INHIBITORY ACTIVITIES AGAINST LPS-INDUCED NO PRODUCTION IN RAW264.7 MACROPHAGES***X.R. Cheng^{1,2}, J. Sun¹, X. Tang¹, H.Z. Jin², W.D. Zhang²*¹State Key Laboratory of Food Science and Technology, School of Food Science and Technology, Jiangnan University, Wuxi, China²School of Pharmacy, Shanghai Jiao Tong University, Shanghai, China

Background and objectives: Metabolic syndrome is a chronic, low-grade, systemic, inflammatory condition, of which inflammation maybe play a pivotal role from cell signal transduction mechanism. Sesquiterpenoids, a group of structurally diversified secondary metabolites, are major constituents of plants belonged to Inula genus, and their remarkable anti-inflammatory activities have attracted much attention. As a part of our ongoing research program for anti-inflammatory sesquiterpenoids derived from Inula species, we examined Inula wissmanniana Hand.-Mazz., a plant endemic to Yunnan province, PR China, with no phytochemical studies reported previously.

Methods: The air-dried plants of *I. wissmanniana* were chopped and percolated with 95% EtOH to give crude extract. After removing the fatty components, the residual crude extract was further partitioned with methylene dichloride to give a methylene dichloride soluble fraction. This fraction was further subjected to silica gel, Sephadex LH-20, and preparative HPLC column chromatography to give single compounds. The structures of all isolates were elucidated by combinative analyses of MS, NMR, and X-ray crystallography data. Moreover, all isolates were tested their cytotoxicities against RAW264.7 macrophages and their inhibitory effects against lipopolysaccharide (LPS)-induced NO production in RAW264.7 macrophages.

Results: The structures of all isolates were elucidated to be eight germacrane (five new) and thirteen eudesmane (seven new) derivatives. All isolates showed no toxicity at the dose evaluated (20 μ M) on RAW264.7 macrophages, but most of them exhibited significant inhibitory effects against NO production in this cell line, with IC₅₀ values ranged from 0.65 to 10.68 μ M.

Conclusions: *I. wissmanniana* contained high content of sesquiterpenoids in germacrane and eudesmane frameworks. Most of the isolates exhibited their potential anti-inflammatory activities, which might be further applied to reverse metabolic syndrome.

PO1869**EFFECTS OF ORAL ADMINISTRATION OF QUERCETIN ON THE ANTICANCER EFFECT OF TRICHOSTATIN A IN A XENOGRFT TUMOR MODEL***S.T. Chan^{1,2}, Y.C. Lin¹, S.L. Yeh¹*

¹School of Nutrition, Chung Shan Medical University, Taichung, Taiwan

Background and objectives: Our previous study consistently showed that quercetin enhances the anticancer effect of trichostatin A (TSA), an anti-cancer drug, in vitro and in xenograft mice given intraperitoneal doses of quercetin. However, whether oral administration of quercetin in xenograft mice exerts such an effect is unclear. In this study we compared the effects of quercetin administered orally and intraperitoneally on the anti-tumor effect of TSA.

Methods: Nude mice were subcutaneously injected in the right flank with A549 cells at a dose of 5×10^6 cells. After three weeks, the animals were then randomly assigned to the following six groups (n=6/group) for 15 weeks: control, TSA, OL+TSA, OH+TSA, IL+TSA and IH+TSA for TSA alone or in combination with quercetin treatment. TSA was given twice a week (0.5 mg/kg) by intraperitoneal injection (IP), while quercetin was given 3 times a week by oral gavage (OL and OH, 20 and 100 mg/kg, respectively) or by IP (IL and IH, 2 and 10 mg/kg, respectively).

Results: We found that only IH+TSA rather than TSA alone significantly inhibited tumor growth in tumor-bearing nude mice. Consistently, only IH +TSA significantly increased the total concentration of quercetin in the tumor tissue of mice. Despite showing a slight anti-tumor effect, TSA alone increased lymphocyte DNA damage and plasma lipid peroxidation in nude mice compared with the control group. In contrast, quercetin administration both orally and intraperitoneally decreased the adverse effects of TSA.

Conclusions: These results indicate that compared with IP, the enhancing effect on the anti-tumor effect of TSA was lower when quercetin was administered orally. However, quercetin administered both orally and intraperitoneally similarly diminished TSA-induced adverse effects in nude mice. Further studies are warranted to investigate the effect of quercetin administered orally at higher doses.

Key words: quercetin, trichostatin A.

PO1870**PROTECTIVE EFFECTS OF AQUEOUS EXTRACT FROM HOULTUYNIA CORDATA ON ACETAMINOPHEN-INDUCED HEPATOTOXICITY IN C57BL/6J MICE***W.H. Liu^{1,2}, Z.H. Wang³, W.T. Chen², M.C. Yin²*

²Department of Nutrition, China Medical University, Taichung, Taiwan

³Medical Center of Aging Research, China Medical University Hospital, Taichung, Taiwan

Background and objectives: *Houttuynia cordata* is used in folk medicine for diuresis, detoxification, antiviral, antibacterial and antileukemic therapy. This study examined the protective effects of *H. cordata* aqueous extract (HAE) against acetaminophen (APAP)-induced hepatotoxicity in mice.

Methods: Five-week old male C57BL/6J mice were divided into three groups (ten mice per group): normal (N), control (C), and HAE+APAP groups. The HAE+APAP group were supplemented with 8% (w/w) HAE in drinking water for five weeks. Both C and HAE+APAP groups were followed by APAP (350 mg/kg body weight) intraperitoneal injection. After 24 hours, mice were sacrificed and oxidative stress and inflammation biomarkers in liver were measured. Acetaminophen treatment significantly elevated both alanine aminotransferase (ALT) and aspartate aminotransferase (AST) activities; however, the pre-intake of HAE significantly protected liver against the subsequent acetaminophen-induced elevation of ALT and AST activities. The pre-intake of HAE also significantly diminished acetaminophen-induced GSH (glutathione) depletion, and MDA (malondialdehyde) formation via restoring the SOD (superoxide dismutase), catalase and GPX (glutathione peroxidase) activities in liver. Moreover, the levels of IL-6 (interleukin-6), TNF- α (tumor necrosis factor- α), MCP-1 (monocyte chemotactic protein-1) and CYP2E1 (cytochrome P450 2E1) in liver from mice with HAE intake were significantly decreased.

Conclusions: These results support that *H. cordata* may be considered as a preventive agent for acute liver injury.

Key words: *Houttuynia cordata*, acetaminophen, hepatotoxicity, inflammation.

PO1871**SHORT TERM MICRONUTRIENT-ANTIOXIDANT SUPPLEMENTATION HAS NO IMPACT ON GASTRIC ATROPHY IN ZAMBIAN ADULTS: A RANDOMISED CONTROLLED TRIAL***V. Kayamba¹, M. Chomba², P. Kelly³*¹Department of Internal Medicine, University of Zambia, Lusaka, Zambia²Department of Internal medicine, University Teaching Hospital, Lusaka, Zambia³Department of Internal medicine, Barts and The London School of Medicine and Dentistry, London, UK

Background and objectives: We set out to investigate the possibility preventing gastric cancer by reversing atrophy, using micronutrient-antioxidant supplementation.

Methods: Archival samples from a randomised controlled trial, (Kelly et al, *Trans R Soc Trop Med Hyg.* 2008;102:194-9) were used in this study. In this trial, 500 healthy volunteers were randomly allocated to either a micronutrient-antioxidant supplementation or placebo. The supplements contained vitamins, A, B1, B2, B6, B12, C, D3, E, niacin, folic acid, iron, zinc, copper and selenium, in quantities 1.5-2 times the daily requirements. We analysed 215 archival samples, from subjects who had taken either supplementation or placebo for a median of 19 (range 14 to 27) months. Gastric atrophy was determined using pepsinogen 1 to 2 ratio of less than 3.0 and compared between the two groups. Also analysed were the effect of HIV infection, age, body mass index (BMI), smoking, alcohol intake and gastric pH.

Results: Gastric atrophy was found in 8 (7.8%) of 103 subjects on supplementation, and 7 (6.3%) of 112 on placebo (RR 1.24; 95%CI 0.47-3.3; P=0.22). HIV infection was diagnosed in 5 participants with atrophy and 61 without (RR 1.07; 95%CI 0.37-3.2; P=1.0). The lack of effect of supplementation on atrophy was not changed after stratification for HIV status (M-H OR 2.0; P= 0.920). Gastric atrophy was found to be more prevalent in those above the age of 40 years, P=0.02 (CI 0.09-0.84). BMI, smoking, alcohol intake showed no impact on gastric atrophy.

Conclusions: An average of 19 months of micronutrient-antioxidant supplementation has no impact on gastric atrophy in Zambian adults. The high gastric pH seen in HIV patients cannot be attributed to gastric atrophy.

Key words: Gastric cancer, atrophy, micronutrient-antioxidant.

PO1872**THE EFFECT OF DIETARY INTERVENTION ON FOOD INTAKE, WEIGHT AND BIOCHEMISTRY PROFILE AFTER KIDNEY TRANSPLANTATION***M.K. Hong¹, M.Y. Rha¹, Y.Y. Cho¹, W.S. Huh², H.Y. Oh²*¹Department of dietetics, Samsung Medical Center, Seoul, South Korea²Division of Nephrology, Samsung Medical Center, Seoul, South Korea

Background and objectives: In the chronic posttransplantation phase, nutritional goal is achievement of healthy weight and normal biochemistry profile. The purpose was to assess the impact of the follow-up of dietary intervention on food intake, biochemistry profile and weight after kidney transplantation.

Methods: We provided 55 kidney transplant recipients (27 men, 28 women, from 2009 to 2010 in a general hospital, Korea) with individualized nutritional counseling, at the 1-month after the kidney transplantation procedure. A follow-up 3-day food record was provided to subjects for return before the next visit, in approximately 5 to 6 months. Subjects who completed and returned follow-up food intake records were listed in Group A (n=21); whereas, those who did not were in Group B (n=34). Food records were analyzed using Computer Aided Nutritional analysis program (Version 3.0). The statistical analyses were performed using PASW (Version 20).

Results: The mean age was 44.98 ± 11.15 years. At the 6-month after KT, total calorie intake decreased significantly (1741.71 ± 358.71kcal vs 1514.43 ± 236.74kcal, p=0.022) in Group A. Although there was no significant effect, intakes of fat (51.99 ± 17.64g vs 38.25 ± 11.77g) and cholesterol (310.85±174.5mg vs 265.40±101.08mg) decreased in Group A. At the 12-month after KT, Triglyceridemia in the group A were significantly lower than that of group B (100.52±34.26 vs 128.70±61.12 mg/dl, p=0.025). Although there was no significant effect, Group A post-acute phase weight gain (1.62±2.16 vs 5.39±5.79kg), Creatinine (1.14±0.24mg/dl vs 1.21±0.29mg/dl), Total cholesterol (168.35±33.6l vs 173.43±26.05mg/dl), and LDL(98.97±26.06 vs 99.29±19.01mg/dl) were all lower than that of group B, at the 12-month after KT.

Conclusion: The follow-up of dietary intervention for kidney transplant recipients may be beneficial in controlling post-acute phase excessive weight gain and achieving normal biochemistry profiles.

Key words: dietary intervention, kidney transplantation

PO1873**BENEFICIAL EFFECT OF LOW INTAKE OF ALCOHOL ON HIGH-FAT DIET FED RATS AND SENESCENCE-ACCELERATED MICE(SAMP1)**

A. Osaki¹, A. Kimoto¹, N. Kato¹, H. Izu², K. Matsumaru²

¹Graduate School of Biosphere Science Hiroshima University, Higashihiroshima, Hiroshima, Japan

²National Research Institute of Brewing, Higashihiroshima, Hiroshima, Japan

Background and objectives: There is accumulating epidemiological evidence suggesting beneficial effect of low intake of alcohol on the development of diseases including cardiovascular disease, diabetes, etc. However, there are very limited animal studies on the effect of low intake of alcohol. This study was aimed to elucidate the effect of low intake of alcohol on the rats fed a high-fat diet and on the SAMP1 (senescence-accelerated prone-1) mice.

Methods: In experiment 1, growing male SD rats (5 week old) were fed a high-fat diet (30% beef tallow) for 12 weeks. Alcohol was given with drinking water containing 1% and 2% ethanol. In experiment 2, male SAMP1 mice (9 week old) were fed a commercial stock diet for 18 weeks. Alcohol was given with drinking water containing 1% or 2% ethanol.

Results: In experiment 1, the food intake and growth were unaffected by intake of ethanol. Serum levels of glucose and lipids were also unaffected. Compared with control, the intake of 1% and 2% ethanol caused a significant reduction in serum ALT activity, ammonia and urate. Serum LDH activity was lower in the 1% ethanol group ($P < 0.05$), but not in the 2% ethanol group. In experiment 2, to evaluate the degree of senescence, we scored the changes of aging, including behavior and appearance such as skin, hair and eyes. These score data in large part retarded the ageing process of the SAMP1 mice by ethanol, especially 1% ethanol intake ($P < 0.05$).

Conclusions: This animal study provides evidence for the beneficial influence of low intake of alcohol in rodents.

Key words: alcohol, high-fat diet, SAMP1 mice.

PO1874**THE ASSESSMENT OF OBJECTIVE SCORE OF NUTRITION ON DIALYSIS (OSND) IN TURKISH HEMODIALYSIS PATIENTS**

P. Turker¹, G. Kiziltan¹, M. Saka¹

¹Baskent University, Faculty of Health Science, Department of Nutrition and Dietetics, Ankara, Turkey

Background and objectives: The objective of this study was to determine the nutritional status of Turkish hemodialysis patients by objective score of nutrition on dialysis (OSND).

Methods: The study included 185 hemodialysis patients (72 women, 113 men) with a mean age of 52.8 ± 15.88 years. Anthropometric measurements and some biochemical parameters were analyzed. Body Mass Index (BMI) was calculated by using dry weight of the patients and evaluated by ERA/EDTA guidelines. Nutritional status was assessed by objective score of nutrition on dialysis (OSND). OSND results in a score from 5 (severely malnourished) to 32 (normal). The score results were categorized in three status. A score 28-32 indicates normal nutritional status of the patients, 23-27 indicates moderate nutritional risk and <22 indicates an unsatisfactory nutritional status of hemodialysis patients. All data was evaluated by SPSS 11.5 for Windows.

Results: In this study, the mean durations of chronic renal failure and going on dialysis were 83.5 ± 81.02 months and 8.9 ± 7.45 years, respectively. The mean BMI value of the patients was 23.9 ± 4.77 kg/m². The 36.2% of the patients were overweight and obese, 53.5 % of them were normal, 10.3% of them were underweight. The mean score of OSND was 22.02 ± 4.11 . The percentages of the patients with low, moderate and normal nutritional status were 49.7%, 44.3% and 11.0%, respectively. There was a significant positive correlation between BMI and OSND score ($r = 0.574$, $p = 0.000$). There was no significant relation between OSND score and gender ($\chi^2 = 2.674$, $p = 0.263$). But the patients over than 65 years have higher OSND score than the patients below than 65 years and it is statistically significant ($\chi^2 = 6.608$, $p = 0.037$).

Conclusions: As a conclusion, OSND, new tool for nutritional assessment, can be used to assess the nutritional status of the hemodialysis patients and correlate with BMI and age.

Key Words: Hemodialysis, nutrition, OSND, BMI.

PO1875**CHANGES IN GREEN BEANS POTASSIUM CONTENT BY SOAKING AND COOKING: IMPLICATIONS IN CHRONIC KIDNEY DISEASE MANAGEMENT**

M. Martinez-Pineda¹, C. Yagüe¹, A. Caverni², A. Vercet¹

¹Department of Animal Production and Food Science, University of Zaragoza, Zaragoza, Spain

²Department of Nutrition, NUTRICIA Laboratory, Zaragoza, Spain

Background and objectives: Diabetes Mellitus and Glomerulonephritis are the most common causes of chronic kidney disease (CKD). In order to prevent associate complications, like hyperkalemia and cardiovascular disease, dieticians should recommend a low potassium diet. So that vegetables with high potassium content, as green beans, are frequently limited in this type of diet. However vegetables are a good source of nutrients and fiber and should be included in a healthy diet.

The aim of this study is to quantify potassium content reduction from fresh and commercial frozen green beans by soaking and by different cooking methods normal cooking (NC) and double cooking (DC), in order to incorporate them in CKD patients' diet.

Methods: Green beans were soaked during 12 hours at refrigeration temperatures and cooked using natural mineral water. Potassium was extracted from the ash of dried samples and determined through flame photometry. The method was validated using a certified reference material and AOAC parameters.

Results: Both procedures: soaking and cooking reduced significantly potassium content. Soaking was effective in potassium leaching in both types of green beans, but percentage of loss was significantly higher in frozen ones, $86,97 \pm 11,16$ versus $14,89 \pm 4,97$. Soaking and cooking had an additive effect in potassium reduction, but the difference between NC and DC was no statistically significant in any case. Cooking after soaking in fresh green beans reduced approximately 50% of total potassium content while frozen ones gave the greatest losses, $97,22 \pm 0,39\%$. The best result obtained was $2,80 \pm 0,36$ mg K / 100g edible portion, in frozen green beans after soaking and NC.

Conclusions: These results can provide tools to dieticians to prevent hyperkalemia incorporating these vegetables in their diets, making them more attractive and varied and as consequence healthier.

Key words: Chronic kidney disease, potassium, green beans, cooking.

load. Outcome parameters were biomarkers of cardiovascular disease and glycemic control as well as anthropometric data. Random effects meta-analyses were performed to determine the weighted mean differences with 95% confidence intervals using the software package Review Manager 5.0.25 of the Cochrane Collaboration.

Results: A total of fourteen studies ($n = 2344$ participants) fulfilled the objectives and were included in the present meta-analyses. Weighted mean differences (WMD) in change of C-reactive protein [-0.43 mg/dl, (95% CI -0.78 to -0.09), $p = 0.01$], and fasting insulin [-5.16 pmol/L, (95% CI -8.45 to -1.88), $p = 0.002$] were significantly more pronounced following low glycemic index/load diets, respectively. In addition, low glycemic index/load diets were associated with a significantly more decreased fat-free mass when compared to their high glycemic index/load counterparts [WMD: -1.04 kg, (95% CI -1.73 to -0.35), $p = 0.003$]. Following a sensitivity analysis excluding subjects with type 2 diabetes, changes in C-reactive protein and fasting insulin remained significant more distinct in the low glycemic index/load groups.

Conclusions: The data of this systematic review provide evidence for a favorable effect of low glycemic index/load diets in the primary and secondary prevention of obesity-associated diseases.

Key words: cardiovascular risk factors, glycemic index, glycemic load, meta-analysis.

PO1876

SYSTEMATIC REVIEW OF EFFECTS OF DIETS WITH EITHER LOW OR HIGH GLYCEMIC INDEX ON CARDIOVASCULAR AND METABOLIC RISK FACTORS

G. Hoffmann¹, L. Schwingshackl¹

¹Department of Nutritional Sciences, University of Vienna, Vienna, Austria

Background and objectives: This systematic review and meta-analysis investigated long-term randomized controlled trials (RCTs) applying glycemic index-related diets in the management of obesity and type 2 diabetes mellitus emphasizing on the potential benefits of low glycemic index/load on risk factors of cardiovascular disorders.

Methods: Electronic searches for RCTs with a running time of at least six months were performed in MEDLINE, EMBASE and the Cochrane Library with no restrictions to language and calendar date. In all intervention studies, participants had to be subjected to a diet defined to be of low glycemic index/load in comparison to a control diet of high glycemic index/

PO1877

COMPARISON OF LONG-TERM LOW-FAT VS. HIGH-FAT DIETS ON GLYCEMIC CONTROL AND CARDIOVASCULAR RISK FACTORS IN SUBJECTS WITH ABNORMAL GLUCOSE METABOLISM: A SYSTEMATIC REVIEW AND META-ANALYSIS

L. Schwingshackl¹, G. Hoffmann¹

¹University of Vienna, Dept. of Nutritional Sciences, Vienna, Austria

Background and objectives: The long-term effects of dietary macronutrient composition on metabolic profiles in patients with abnormal glucose metabolism had to be established. This meta-analysis aimed to elucidate the effect of replacing dietary fat with carbohydrate on glycemic control and cardiovascular risk factors.

Methods: We searched systematically in MEDLINE, EMBASE and the Cochrane Trial Register for long-term randomized trials (≥ 12 months) that investigated the effects of two kinds of prescribed diets (a low-fat (LF) diet and a high-fat (HF) diet); in these studies, energy and protein intake did not differ significantly between the two dietary groups. Study specific weighted mean differences were pooled using a random

effect model by the Cochrane software package Review Manager 5.0.25.

Results: Fourteen studies that included 2003 patients met our inclusion criteria. The HF diet significantly decrease triacylglycerols weighted mean difference (WMD) [-17.50 mg/dl (95% CI -21.70 to -13.31), $p < 0.00001$], diastolic blood pressure [WMD: -1.30 mmHg (95% CI -1.82 to -0.95), $p < 0.00001$], respectively, increase HDL cholesterol [WMD: 1.88 mg/dl (95% CI 0.48 to 3.29), $p = 0.009$] and adiponectin [WMD: 1.10 μ g/ml (95% CI 0.87 to 1.33), $p < 0.00001$] compared with the LF diet. In addition fasting glucose [WMD: -7.31 mg/dl (95% CI -13.19 to -1.43), $p = 0.01$] were reduced significantly in T2D subjects following a HF diet. Meta-regression revealed that increases in TC and HbA1c were associated with higher amounts of carbohydrates, whereas increases in HDL-cholesterol were associated with higher intakes of MUFA and total fat content.

Conclusions: Our findings suggested that replacing carbohydrates with fat could influence positively cardiovascular risk factor and should therefore recommend by international Diabetes Associations.

Key words: low fat, high fat, glycemic control, meta-analysis, abnormal glucose metabolism.

face-to-face food frequency and multiple 24-hour diet recall questionnaires. Energy requirements were calculated using the Harris-Benedict equation.

Results: The prevalence of malnutrition measured by BMI was 12.8%. Ninety-two percent of participants consumed diets that were inadequate and met less than 70% of recommended energy intake. Average energy intake was 1315.7 \pm 302.1 kcal (requirements, 2490.6 \pm 335.8kcal) with mean dietary intakes of carbohydrates, proteins and fats each significantly half of the recommended intakes (p -values each < 0.001). The correlation between energy intake and BMI was significant ($p < 0.005$) and strongly negative ($r = -0.876$) for energy intakes less than 1000kcal. Half of patients with BMI less than 18.5kg/m² were indifferent about their current weight while 50% with BMI > 25 were conscious of being overweight/obese. None of the respondents was able to approximate his/her ideal weight.

Conclusions: Energy intake in HIV positive individuals on HAART is significantly lower than dietary requirements, an observation which compromises adequate energy and nutrient intake required for optimal HAART. Nutrition counselling is needed in this population to ensure nutrient dense foods are consumed.

Key words: Energy intake, energy requirements, HIV/AIDS, BMI.

PO1878

EVALUATION OF THE NUTRITIONAL STATUS AND DIETARY PATTERNS OF PERSONS LIVING WITH HIV/AIDS ON HAART IN NGAOUNDÉRÉ, CAMEROON

F E. Ngoinange¹, M. E. Ngole², M. Carl³

¹Regional Delegation of Health, Ngaoundere, Cameroon

²Ministry of Public Health, Yaounde, Cameroon

³National School of Agro-Industrial Sciences, University of Ngaoundere, Ngaoundere, Cameroon

Background and objectives: Nutritional priorities vary, and dietary recommendations may be less straightforward in HIV-infected individuals as HIV treatment and outcomes continue to evolve. This study sought to determine macronutrient intake in HIV-infected adults and investigate the relationships between duration of treatment, nutrient intake, and BMI of patients receiving Highly Active Antiretroviral Therapy (HAART), at the AIDS outpatient clinic of the Ngaoundéré Regional Hospital.

Methods: The study included 195 HIV patients on HAART (48 men, 147 women), aged 18-60 years and screened for malnutrition. Of these 51 had a 24-hour dietary recall (24HDR), 36 of who completed three 24HDR assessments, at one month intervals. Nutritional status was evaluated using body mass index (BMI), and dietary pattern evaluated using a structured

PO1879

SAFETY AND EFFICACY OF FORTIFICATION VERSUS FORTIFICATION PLUS SUPPLEMENTATION WITH IRON IN AFRICAN PREGNANT WOMEN: A RANDOMISED CONTROLLED TRIAL

M N. Mwangi^{1, 2}, P E A. Andang'o^{1, 3}, A M. Mwangi³, H. Verhoef^{2, 4}, H F J. Savelkoul²

¹Department of Nutrition and Health, Maseno University, Maseno, Kenya

²Cell Biology and Immunology Group, Wageningen University, Wageningen, The Netherlands

³Applied Nutrition Programme, Department of Food Technology and Nutrition, University of Nairobi, Nairobi, Kenya

⁴Nutrition and Public Health Intervention Research Unit, London School of Hygiene and Tropical Medicine, London, UK

Background and objectives: There are concerns that supplemental iron can lead to increased burden of malaria. More African governments are adopting mandatory flour fortification with iron in addition to universal iron supplementation in pregnancy. The safety of the high iron intake resulting from these policies is not established. The aims of this study were: to

compare the presence of malarial infection in parturient women who received a combination of iron-fortified foods with iron supplements versus iron-fortified foods only; to assess intervention effects on neonatal iron stores at 1-month of age; to assess intervention effects on the maternal prevalence of iron deficiency anaemia at 1-month after delivery; and to assess intervention effects on maternal intestinal pathogens at 1-month after delivery.

Methods: The study was a double-blind, randomised, placebo-controlled intervention trial with two parallel groups. It was conducted in Nyanza province, Kenya, from September 2011 and is projected to end in April 2013. Pregnant women with a gestational age of 16-23 weeks (n=470) received fortified flour and were randomly allocated to daily supplements with iron (60mg Ferrous fumarate) or placebo. Flour was fortified to a target level of 20 mg iron as NaFeEDTA per kg flour. Currently, the final 40 participants are presenting for their last assessments.

Results: The main outcome measure was maternal Plasmodium infection at parturition as assessed by dipstick tests and PCR. Secondary outcome measures were: maternal iron status at 1-month after delivery, neonatal iron stores at 1-month of age as assessed by plasma ferritin concentration; and maternal intestinal pathogens at 1-month after delivery. Data analysis and publication of results is in progress.

Conclusions: This is the first study to investigate the safety and efficacy of iron interventions in pregnant African women in malaria endemic region. The design implications, methods and ethical considerations will be presented at ICN.

Key words: Iron-supplementation, fortification, malaria, pregnancy.

PO1880

THE OVERVIEW OF PREVALENCE OF OVERWEIGHT/OBESITY AMONG CHILDREN AND ITS RISK FACTORS IN CHINA

H. Xue¹, Y. Liu¹, X. Zhou¹, R. Duan¹, G. Cheng¹

¹Department of Nutrition and Food Safety, West China School of Public Health, Sichuan University, Chengdu, China

Background and objectives: The aims of this study were to summarize the overweight/obesity prevalence among Chinese children and to review its potential risk factors.

Methods: Literature published in 2000-2012 and focused on overweight/obesity among Chinese children aged 7-18-years was assessed by systematic review.

Results: The prevalence of overweight/obesity among Chinese children increased dramatically. This increase grew rapidly over the course of time: the rates in 1985, 1995, 2000, 2005

and 2010 were 0.10%, 3.20%, 5.11%, 6.55%, and 8.03%. This trend was more relevant for boys. Furthermore, the prevalence in cities was higher than that in communities and was higher in younger group. The risk factors related to overweight/obesity among Chinese children were: parental overweight/obesity, male gender, birth weight and rapid weight gain during pregnancy. Physical inactivity (doing homework>2h/d, watching TV or playing computer>2-4h/d), diet (higher daily energy intake, higher percentage energy of protein and fat, and higher intakes of thiamine, niacin, and selenium, or lower percentage energy of carbohydrate, calcium per body weight), and unbeneficial eating and sleeping behaviors were important environmental factors. The related social factors included family residence, family economic status, family's knowledge about obesity and the feeding concept. However, the relevance of parental education, children's learn-segment and type of school, family type (single parent, parents or family-living-together), activity motivation, and nutrient intakes such as Zn, Fe, vitamins B2, C and E needed further studies.

Conclusions: The prevalence of overweight/obesity among Chinese children increased rapidly, characterized with time, gender, region and age group. Moreover, it's related to inheritance, environmental factors, and society status.

Key words: overview;,overweight/obesity, children, risk factor, China.

PO1881

IMPACT OF CARICA PAPAYA MEAL ON SERUM CHOLESTEROL AND SOME OXIDATIVE STRESS ENZYMES IN RATS

H. Iyawe¹

¹Ambrose Alli University Ekpoma, Ekpoma, Nigeria

Background and objectives: Health benefits of Carica papaya have been studied by different researchers, with most studies focusing on the use of extracts from different solvents. The objective of this study was to investigate the effect of consumption of whole unripe fruit on some serum parameters.

Methods: A five by three experiment was designed, consisting of Control (fed commercial diet), Group A (fed 80% commercial diet + 20% peeled papaya) and Group B (fed 80% commercial diet + 20% unpeeled papaya). The experimental animals were all handled in compliance with international guidelines as prescribed by the Canadian Council on the Care and Use of Laboratory Animals. Feeding period lasted twenty-eight days. At the end of the feeding experiment the animals observed overnight fast and were sacrificed. Blood and liver tissues were collected and processed for analysis. Standard procedures were used for parametric analysis.

Results: Body weight increased (29.82-38.81) % across groups. Groups A (0.95 ± 0.05) mg/dl and B (1.99 ± 0.05) mg/dl showed potentials to significantly ($P < 0.05$) reduce serum cholesterol compared to control (2.38 ± 0.05) mg/dl. Group B animals had their mean globulin (466.72 ± 76.01) mg/dl reduced ($P < 0.05$) compared to control (814.97 ± 56.41) mg/dl. Catalase activity in serum of Groups A (40.11 ± 0.75) Umin-1 and B (47.30 ± 3.37) Umin-1 animals increased significantly ($P < 0.05$) compared to control (28.08 ± 2.55) Umin-1. A reduction ($P < 0.05$) in liver catalase activity (64.40 ± 2.06) Umin-1 was observed in Group B compared to others. The triacylglycerides in the test groups were statistically same compared to control.

Conclusions: Consumption of peeled unripe papaya appears safe as it demonstrates potential to reduce the risk of vascular malady due to cholesterol lowering effect in addition to not containing the phyto-toxic principles that inhibit liver catalase activity.

Key words: Unripe papaya, lipids, catalase.

PO1882

OMEGA-3 FATTY ACIDS IMPROVE OXIDATIVE STRESS IN WOMEN WITH POLYCYSTIC OVARY SYNDROME

M. Rafrafi¹, E. Mohamadi¹

¹Department of Community Nutrition, Faculty of Nutrition, Tabriz University of Medical Sciences, Tabriz, Iran

Background and objectives: Fish oil has beneficial effects in a number of disease states. It was reported that levels of long chain polyunsaturated fatty acids [eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA)] were decreased in infertile women. Objectives of this study were to determine the effects of omega-3 fatty acids supplementation on some oxidative stress markers such as serum total antioxidant capacity (TAC), malondialdehyde (MDA) and paraoxonase 1 (PON1) activity in women with polycystic ovary syndrome (PCOS).

Methods: This double-blind randomized controlled clinical trial was conducted on 61 overweight or obese PCOS patients; aged 20-35 yr. Thirty of the subjects had taken 4 g/day omega-3 fatty acids and 31 were given placebo over 8 weeks. Fasting blood samples, anthropometric measurements and 3-day, 24-hour dietary recalls were collected at the baseline and at the end of the trial.

Results: Dietary intake of n-3 LC PUFA from usual diet was low in studied subjects (0.23 mg/day). Omega-3 fatty acids supplementation significantly decreased serum levels of MDA ($P = 0.01$) and increased serum PON1 activity ($P = 0.038$) compared with placebo. Changes in serum TAC levels and anthro-

pometric measurements were not statistically significant in any groups at the end of the study ($P > 0.05$).

Conclusions: Low dietary intake of n-3 LC PUFA is prevalent in women with PCOS. Supplementation with omega-3 fatty acids improved some indices of oxidative stress in PCOS patients and might contribute to the improvement of metabolic complications in these patients.

Key words: Omega-3 fatty acids, polycystic ovary syndrome.

PO1883

NUTRITIONAL PATTERN AND VISCERAL OBESITY ASSOCIATION IN MIDDLE AGE EGYPTIAN WOMEN

N.E. Hassan^{1,2}, S. El Shebini², N. Ahmed²

¹Biological Anthropology Department, National Research Centre, Cairo, Egypt

²Nutrition and Food Science Department, National Research Center, Cairo, Egypt

Background and objectives: Adipose tissue pathogenicity differs according to adipose tissue localization, visceral or subcutaneous. Visceral fat is highly active tissue from metabolic point of view. The aim of this study was to explore the association between nutritional patterns, eating behaviors and visceral obesity in middle age Egyptian women.

Methods: Study includes 549 volunteers, obese women (body mass index (BMI) > 30) with mean age 40.80 ± 10.47 years, and mean BMI 36.17 ± 7.23 Kg/m², they were enrolled in a program for losing weight in National Research Center. All were subjected to: full medical examination, blood pressure, 24 hour dietary recall, food frequency questionnaire and anthropometric measurements including weight, height and calculated BMI. Visceral obesity was determined by ultrasound. The sample was divided into 3 groups according to level of visceral adiposity.

Results: revealed that 6.2, 63.4 and 30.4 percent of the obese women have visceral adiposity < 3 mm, 3-7mm, ≥ 7 mm were classified as group (1), group (2) and group (3). Highly significant difference was recorded between group (3) and the other groups regarding BMI and systolic and diastolic pressure. Dietary results showed significant difference between group (1) and the other two groups in level of daily consumption of saturated fatty acids, and numerical difference in total energy, carbohydrate and cholesterol. Mean values of vitamins B did not reveal much difference, while vitamin D in group (3) showed the least value. Minerals content of diet revealed that group (3) consumed significant higher amount of sodium and significant lower level of potassium. Group (2&3) showed high percent in

frequent intake of bread, meat, chicken, fish and sweets, and less frequency of milk, legumes, fruits and vegetables.

Conclusions: Unhealthy eating behaviors is considered a factor inducing visceral obesity, may be crucial for obesity related comorbidities. Acknowledgements: All participants; for their help and National Research Centre for funding.

Key words: Visceral obesity, nutrients, eating behavior.

PO1884

OXIDATIVE DAMAGE, AGEING AND DEGENERATIVE DISEASES IN WNIN OBESE RATS

H. Nemani^{1,2}, U. Putchha², S. Pothan¹, G. Nappanveetil¹

¹National Centre for Laboratory Animal Science, National Institute of Nutrition, Hyderabad, India

²Department of Pathology, National Institute of Nutrition, Hyderabad, India

Background and objectives: Obesity is a debilitating nutritional disorder and has a direct bearing on health and longevity, as exemplified by both animals and humans. WNIN/Ob and WNIN/GR-Ob, obese mutants which were developed from WNIN rat colony have shown characteristic traits of obesity in terms of physical, physiological and clinical morbidity. These mutants survive 1-1½ years, where as normal rats life span is 3-3½ years. The present study summarizes the observations on the life expectancy of these animals along with incidence of diseases(s) noticed during the observed period. It was also ascertained, whether these animals suffer from oxidative damage.

Methods: Ageing markers like plasma protein carbonyls, and lipid peroxidation in both phenotypes at three different time points studied. Additionally, a selected set of rats from Ob/Ob and GR-Ob strains were observed from birth, till the end of their natural death, in terms of food intake, body weights and any deviations from normal health at the time of death.

Results: The plasma malanoldialdehyde and protein carbonyl levels in both the mutants were significantly higher at all the age levels tested compared to lean controls. There was a significant difference in the average life span of both the obese mutants compared to their lean littermates. In general, drop in food intake was noticed in obese rats, as they crossed 400-450 days and about 50% animals showed abdominal and mammary gland tumours, and few with testicular tumours. About 10-12% of animals showed cataract around 400 days of age.

Conclusions: These initial data indicate that both the mutants are ageing faster compared to lean controls, making them vulnerable to degenerative diseases much earlier in life and this could be due to oxidative damage that is occurring, on account of their obesity status.

Key words: Obesity, ageing, protein carbonyl, tumours, cataract.

PO1885

THE EFFECTIVENESS OF NUTRITION EDUCATION AMONG OUTPATIENTS WITH TYPE 2 DIABETES MELLITUS IN JUMPANG BARU MAKASSAR HEALTH CENTER, INDONESIA

S K. Hamid¹, N. Jafar²

¹Nutrition Departement, Departement of public health Hasanuddin of University, Makassar, Indonesia

Background and objectives: Diabetes Mellitus (DM) is a problem despite high prevalence of obesity in many parts of the world are increasing rapidly. One major factor is the lack of knowledge in conducting therapy in patients with diabetes mellitus diet that can lead to increased blood sugar levels. The aim of this study was to determine the influence of nutrition education on knowledge, dietary compliance, and glucose control among outpatients with type 2 DM in Jumpandang Baru Makassar Health Center.

Methods: This research was a pre-experimental study designed with one group pretest-posttest. Sampling was conducted using purposive sampling technique with samples 27 people. Data analysis was performed with the Mc Nemar test.

Results: Showed there were not influence ($P = 0.125$) but have been increasing their knowledge were 85,2% to 100%, there were influence in diet improved adherence ($P = 0.035$) and there were influence of control of blood sugar levels Outpatient Type 2 DM ($P = 0.000$).

Conclusions: Nutrition education can increase knowledge so as to improve dietary compliance and to maintain blood sugar levels. Outpatient Type 2 DM are suggested to the Outpatient DM Type 2 f or more set up their blood glucose. they should be assisted the physical activity (Sport) and the drug compliance. The researchers recommended further research with a nutrition education control group to find out more about the difference between people are given nutrition education and not given to nutrition education.

Key words: Diabetes mellitus, nutrition education.

PO1886**OXIDATIVE STRESS, PROBIOTICS AND CARDIOVASCULAR DISEASES**

M. Zilmer^{1,2}, E. Songisepp², T. Kullisaar¹

¹Department of Biochemistry, Tartu University, Tartu, Estonia

²Biocompetence Centre of Healthy Dairy Products, Tartu, Estonia

Background and objectives: Both health-supporting effects of possible probiotics and impact of high-grade oxidative stress (OxS) concerning pathogenesis of diseases have a large number of articles in the PubMed database. Interestingly, quite scarce data describe influence of probiotics on human body OxS status yet. However, an accumulation of data about physiologically relevant antioxidative lactic acid bacteria (LAB) is growing. Nowadays, limited clinical trials have been conducted on the effect of antioxidative LAB on OxS-driven cardiovascular disease (CVD)-related markers. Thus, it is important to analyze possibilities of antioxidative LAB to influence on OxS status in human body with a special focus on CVD. New approaches in global CVD risk reduction are needed. For the prevention of CVD risk the antiinflammatory agents and antioxidants are considered as a possible “third great wave” (Bhatt, 2008). Thus, it is necessary to find out possible candidates as adjuvant components of CVD prevention complexes.

Methods: It is rational that LAB with multivalent biopotency, including especially biovaluable antioxidative potency/properties may have a great impact to be possible candidates for applying in CVD prevention/al-levation complexes.

Results: Our presentation analyzes possible mechanisms of action of some LAB on both common and novel markers of CVD.

Conclusions: We will analyze results on clinical trials showing that antioxidative LAB with multivalent biopotency may have impact concerning strategy of prevention of pathogenesis of CVD.

Key words: Oxidative stress, lactobacilli, cardiovascular diseases.

PO1887**DOSAGE EFFECTS OF QUERCETIN ON HIPPOCAMPUS-DEPENDENT LEARNING AND MEMORY IN MICE FED WITH HIGH FAT DIETS**

L. Guowei^{1,2}, S. Xia¹, B. Wang¹, J. Sun^{1,2}, X. Tang^{1,2}, Y. Shi^{1,2}

²Institute of Food Nutrition and Functional Factor, School of Food Science and Technology, JiangNan University, Wuxi, China

Background and objectives: Effects of quercetin (Q) on cognition remains unclear because previous studies showed contradictory results under different conditions. This study was designed to investigate the dosage effects of quercetin on cognitive impairment induced by high-fat diets (HFD).

Methods: Male KM mice were randomly assigned to five groups fed respectively with basic diet (C), C added with 0.005% quercetin (CQ), HFD (20% fat), HFD with 0.005% quercetin (HFDQ1) and 0.01% quercetin (HFDQ2) for 12 weeks. Plasma and hippocampal malondialdehyde (MDA), total antioxidant capacity, activity of CAT, SOD, GSH/GSSG and hippocampal-dependent learning and memory related gene expression were examined. Morris water maze was used to evaluate the cognition.

Results: compared with C and HFDQ1-HFDQ2 group, the escape latency were increased and time percentage spent in the target quadrant were decreased ($P < 0.05$) during the morris water maze test in HFD and CQ group. Administration of high dose quercetin may contribute to improving antioxidant capacity and attenuate HFD-induced learning and memory defects. The expression of hippocampal cAMP-responsive element binding protein (CREB) and brain-derived neurotrophic factor (BDNF) were decreased significantly ($p < 0.05$) in HFD and CQ groups, accompanying with higher content of carbonyl compound and MDA in mice brain. The level of MDA was significantly negatively correlated with the expression of CREB and BDNF ($P < 0.05$). It should be noted that quercetin could induce significant cognitive impairment in mice under normal diet conditions.

Conclusions: appropriate dosage of quercetin supplement can improve cognition damaged by high-fat diets via prevention of oxidative stress and augment expression of hippocampal BDNF and CREB. Acknowledgments: This study was supported by the 12th 5-Year Plan for Science and Technology Development (No.2012BAD33B05), China.

Key words: Quercetin, hippocampal, high-fat diets, BDNF, CREB, learning, memory.

PO1888**ELEVATED PLASMA MALONDIALDEHYDE AND ADVANCED OXIDATION PROTEIN PRODUCTS IN ADULTS WITH DYSLIPIDEMIA**

L. Guowei^{1,2}, G. Wu¹, Y. Shi^{1,2}, J. Sun^{1,2}, X. Tang^{1,2}, M. Cheserek²

¹The State Key Laboratory of Food Science and Technology, JiangNan University, Wuxi, China

²Institute of Food Nutrition and Functional Factor, School of Food Science and Technology, JiangNan University, Wuxi, China

Background and objectives: Dyslipidemia has become a leading global health problem owing to its strong association with a cardiovascular disease. Malondialdehyde (MDA) and advanced oxidation protein products (AOPP) induced by oxidative stress are involved in the progression of dyslipidemia. The aim of this study was to estimate oxidation products in plasma of adults with abnormal blood lipid.

Methods: Recruitment of participants for this study was carried out at the Jiangnan University hospital. A total of 778 subjects aged 40-49 years old were divided into five groups according to the Chinese guidelines on prevention and treatment of dyslipidemia in adults. Group I (n=110): total cholesterol (TC) <5.18 mmol/L, triglycerides (TG) <1.70 mmol/L and high density lipoprotein cholesterol (HDL-c) <1.04 mmol/L; Group II (n=261): TC >5.18 mmol/L and TG<1.70 mmol/L; Group III (n=204): TG>1.70mmol/L and TC<5.18 mmol/L; Group IV (n=139): TC>5.18 mmol/L and TG>1.70mmol/L; Group V(n= 64): high density lipoprotein cholesterol (HDL-c) <1.04 mmol/L. Plasma lipid profiles, reduced glutathione (GSH), MDA, AOPP and dityrosine (DTyr) were assayed.

Results: No significant difference was observed in plasma GSH level across the five groups. However, a marked increase in the plasma MDA content was found in the dyslipidemia groups (Group II, III, IV and V). When the dyslipidemia groups were compared, Group II had a significantly lower MDA content. Similarly, this tendency toward increased AOPP and DTyr level was also indicated for dyslipidemia groups. Plasma MDA values showed a positive correlation (adjusted for age and sex) with TG, TC, AOPP and DTyr.

Conclusions: These findings are consistent with an increased level of MDA and oxidation protein products in subjects with dyslipidemia. **Acknowledgements:** The present study was supported by the 12th Five-Year Plan for Science and Technology Development (No. 2012BAD33B05).

Key words: Dyslipidemia, malondialdehyde, advanced oxidation protein products, human.

PO1889**INTER-RELATIONSHIP OF OXIDATIVE STRESS MARKERS AND THYROID HORMONES IN PREDICTING METABOLIC SYNDROME IN ADULT MEN**

L. Guowei^{1,2}, Cheserek M.J. MJ², Y. Shi^{1,2}, G. Wu², L. Shen², J. Sun^{1,2}, Tang. X²

¹The State Key Laboratory of Food Science and Technology, JiangNan University, Wuxi, China

²Institute of Food Nutrition and Functional Factor, School of Food Science and Technology, JiangNan University, Wuxi, China

Background and objectives: Oxidative stress and thyroid dysfunction are associated with metabolic syndrome, a known risk factor for cardiovascular diseases and type II diabetes. The aim of this study was to examine the inter-relationship of oxidative stress markers and thyroid hormones in Chinese men with metabolic syndrome and its components.

Methods: Men aged 30 to 60 years with hypertension (n=411), dyslipidemia (n=325), hyperglycemia (n=238) and metabolic syndrome (n=100) were compared with healthy controls (n=154). Anthropometric measurements, blood pressure, fasting plasma lipids, thyroid stimulating hormone (TSH), free triiodothyronine (FT3), free thyroxine (FT4), total antioxidants (T-AOC), oxidized low density lipoprotein cholesterol (oxLDL), malonyldehyde (MDA), dityrosine, advanced oxidation protein products (AOPP) were measured. Metabolic syndrome (MS) was defined according to NCEP-ATP III criteria.

Results: Significantly (p<0.05) higher plasma levels of oxLDL, MDA, dityrosine and AOPP were found in men with metabolic syndrome and its components than controls. TSH was high in hypertension, dyslipidemia, hyperglycemia and MS; FT3 in dyslipidemia and MS while FT4 was elevated in hypertension and dyslipidemia. Subclinical hypothyroid men with MS showed a significant (p<0.05) increase in all the oxidative stress markers and lower T-AOC (9.23 ± 2.53 U/ml) compared to euthyroids (10.61 ± 2.02 U/ml). Oxidative stress markers and thyroid hormones concomitantly associated with metabolic syndrome and its components with MDA and TSH appearing as strongest predictors.

Conclusions: Lipid peroxidation and elevated thyroid stimulating hormone levels are strong biomarkers of metabolic syndrome in Chinese adult men. **Acknowledgments:** The study was supported by the 12th 5-Year Plan for Science and Technology Development (No.2012BAD33B05), China.

Key words: Metabolic syndrome, oxidative stress markers, thyroid hormones.

PO1890**THE ALLEVIATING EFFECT OF FERMENTED WHEY PRODUCT TO THE MALE PATIENTS WITH LOWER URINARY TRACT SYMPTOMS**

T. Kullisaar^{1,2}, K. Ausmees², A. Veskioja³, A. Rehema¹, K. Erlich¹, K. Zilmer¹, E. Songisepp³, M. Zilmer¹

¹Department of Biochemistry, University of Tartu, Tartu, Estonia

²Medita clinic, Tartu, Estonia

³Bio-Competence Centre of Healthy Dairy Products, Tartu, Estonia

Background and objectives: After the age of 50, the prostate begins to increase in size. This is known as benign prostatic hypertrophy (BPH). Consequently, when the prostate enlarges the urethra is compressed and this causes difficulty in urinating including hesitancy, dribbling, reduced force of the urinary stream, and occasional bleeding or infection. The aim of our study was to evaluate the efficiency of consuming fermented whey product (FWP) to several biochemical parameters as well as to the lower urinary tract symptoms (LUTS).

Methods: The tested product was fermented whey based drink, pasteurized after fermentation. Patients (30) were selected from outpatient department of MediTa clinic. Inclusion/exclusion criteria were: moderate LUTS (IPSS score range 8-19) on the basis of International Prostate Symptom Score and clinical investigations: PSA <10 ng/ml; urinary flow 5-15 ml/sec; prostate volume <80 mL; post-voided urine (<300 mL).

Results: During consumption of the FWP IPSS score decreased in average 41%, whereas irritative and obstructive symptoms changed in parallel. LUTS symptoms changed in correlation of uCRV, Hb1c, oxLDL, IL-10 and 8-isoprostanes in urine. Statistically significant changes in biochemical parameters were seen only in study group.

Conclusions: LUTS may have several causes. Compression of urethra by enlarged prostate explains LUTS in BPH patients. During the OxS the peroxidation of cell membrane phospholipids and generation of 8-isoprostanes, the prostaglandin-like compounds, that can cause LUTS. We can conclude that consuming FWP may improve LUTS as well as OxS and inflammatory markers in patients with IPSS (8-19).

Key words: LUTS, OxS, fermented whey.

PO1891**THE EFFECT OF NUTRITIONAL THERAPY ON QUALITY OF LIFE IN STABLE CHRONIC OBSTRUCTIVE PULMONARY DISEASE (COPD)**

S. Metin^{1,2}, G. Kiziltan¹, N. Ucar²

¹Baskent University, Faculty of Health Sciences, Department of Nutrition and Dietetics, Ankara, Turkey

²Ataturk Chest Diseases and Thoracic Surgery Education and Research Hospital, Ankara, Turkey

Background and objectives: COPD (Chronic Obstructive Pulmonary Disease) patients should be considered at high risk for reduced quality of life because of systemic inflammation. The aim of this study was to determine the effect of nutritional therapy on quality of life in COPD.

Methods: Participants of the study were 21 male, stable COPD patients, ages between 40-65 years (mean 58.8±4.75) without any systemic disease. Nutritional status was assessed by food-frequency questionnaire and Subjective Global Assessment. Daily nutrition intakes were calculated by nutrition information system (BEBIS) computer program for Turkey. Healthy nutrition and omega-3 supplemented (1g/day) dietary therapy of COPD patients provided by dietitians. Quality of life (QOL) evaluated by Short Form-36 (SF-36) questionnaire, a general measure of quality of life in chronic diseases. Before and after dietary education, results of SF-36 subgroup scores compared with nutritional intakes and nutritional status (SGA) of the patients. Data evaluated by SPSS 13.0 for Windows.

Results: Patients' daily energy intake was lower before the intervention. Daily mean dietary carbohydrate intake was 263.1±58.18 g (52.8% of total energy) before intervention and 230.8±70.26 g (48.6% of total energy) after intervention (p<0.05). The percentage of dietary fat from total energy was 32.9±5.30% before the intervention, this ratio increased to 36.7±6.79% after the intervention (p<0.05). Omega-3 and omega-6 consumptions of the patients were increased after the dietary management (p<0.05). According to SF-36 questionnaire, after dietary management physical and mental component scores were increased (p<0.05). Before and after dietary intervention, the percentages of well-nourished patients were 90.5%, moderately-malnourished patients was 9.5% by SGA classification. Moderately-malnourished patients had low physical health score (p<0.05).

Conclusions: According to these results, the effect of nutritional therapy education is very important for COPD patients either on survival or quality of life.

Key words: COPD, quality of life, diet, SF-36.

PO1892**NUTRITIONAL SUPPORT WITH OMEGA-3 RICH DIETS IMPROVE INFLAMMATION, RESPIRATORY FUNCTIONS AND EXERCISE CAPACITY IN STABLE COPD**

S. Metin^{1,2}, G. Kiziltan¹, N. Ucar², M. Saka¹

¹Baskent University, Faculty of Health Sciences, Department of Nutrition and Dietetics, Ankara, Turkey

²Ataturk Chest Diseases and Thoracic Surgery Education and Research Hospital, Ankara, Turkey

Background and objectives: COPD (Chronic Obstructive Pulmonary Disease) is a major cause of chronic morbidity and mortality. However, none of the currently available agents are capable of slowing the relentless progression of disease. Therefore, this study was planned to determine the nutritional status of COPD patients and to investigate the effects of nutritional support with low carbohydrate, omega-3 rich diet on inflammation and respiratory functions.

Methods: The study was conducted on 21 male patients ages between 40-65 years old without any systemic disease at Ataturk Chest Diseases and Thoracic Surgery Education and Research Hospital. Nutritional status of the patients was assessed by food-frequency questionnaire, three-d 24-h dietary record and Subjective Global Assessment. BMIs calculated and graded as position papers on COPD published by the American Thoracic Society (ATS) and the European Respiratory Society (ERS). Six Minute Walking Test, BORG scale and respiratory functions were assessed. Biochemical parameters, anthropometric measurements of the patients were also determined. Omega-3 rich diets were personalized.

Results: The mean age and mean duration of COPD of the patients were 58.8±4.75 and 4.7±4.46 years, respectively. Before and after dietary management, anthropometric measurements and biochemical parameters of patients were similar. According to SGA results, before and after management, the percentages of well-nourished and moderately-malnourished patients were also similar. After dietary intervention, patients' mean BORG dyspnea scale results were decreased ($p < 0.05$). The mean walking distance of the patients before and after dietary intervention were 395.9±53.65 m and 420.8±48.07 m respectively ($p < 0.05$). Before and after dietary management, FEV1/FVC were 64.1±11.61% and 67.8±9.37% respectively ($p > 0.05$). There was a significant negative correlation between dietary omega-3 and BORG dyspnea scale ($r = -0.623$, $p = 0.003$).

Conclusions: COPD patients should be considered at high risk because of systemic inflammation. For these reasons, accurate and efficient medical nutrition therapy is important.

Key words: COPD, omega-3 fatty acids, inflammation, dyspnea.

PO1893**LIVER ENZYMES AND CARDIOMETABOLIC RISK FACTORS IN EUROPEAN ADOLESCENTS; THE HELENA STUDY**

¹³University School of Health Sciences, University of Zaragoza, Zaragoza, Spain

Background and objectives: High levels of alanine aminotransferase (ALT) and gamma glutamyltransferase (GGT), as well as low aspartate aminotransferase to ALT ratio (AST/ALT) are considered useful noninvasive early surrogate markers of non-alcoholic fatty liver disease and are associated with the risk of all-cause mortality. The aim of this work was to explore the associations of liver biomarkers with cardiometabolic risks and their clustering.

Methods: ALT, GGT and AST/ALT were measured in 1084 adolescents (52.8% females) aged from 12.5 to 17.5 years from nine European countries. We also measured waist circumference, blood pressure, triglycerides, high density lipoprotein-cholesterol and insulin. A continuous cardiometabolic risk (MetS) score was computed as the mean of the standardized outcomes scores (MetS Z-score). High MetS was defined as the coexistence of at least three of four adverse ($>1SD$) cardiometabolic risk factors.

Results: High ALT and GGT levels and low AST/ALT ratio were associated with adiposity and with the number of adverse cardiometabolic risk factors in both males (all $P < 0.001$) and females (all $P < 0.05$). High GGT levels and low AST/ALT ratio were associated with high MetS Z-score in males and females (all $P < 0.001$). Higher ALT was associated to higher MetS Z-score in males ($P < 0.001$), but not in females. Additionally, ROC analyses showed a significant discriminatory accuracy of AST/ALT ratio in identifying the low/high MetS in male and female adolescents (both $P < 0.01$). The AST/ALT ratio thresholds were: 1.00 for males 12.5-14.9y, 0.74 for males 15-17.5y, 0.86 for females 12.5-14.9y and 0.87 for females 15.17.5y.

Conclusions: Higher GGT and lower AST/ALT ratio are associated with higher cardiometabolic risk factors and their clustering in male and female European adolescents, while the associations of ALT were gender-dependent. Our results suggest the usefulness of evaluating AST/ALT ratio as a screening test in the assessment of adolescents with high cardiometabolic risk.

Key words: Liver enzymes, cardiometabolic risk, adiposity.

PO1894

INFLUENCE OF WEIGHT STATUS ON CARDIOVASCULAR AND LIPID PROFILE IN MOROCCAN OLDER ADULT WOMEN

V A. Aparicio¹, A. Carbonell-Baeza², M. Senhaji³, M del M. Fernandez¹, D. Camiletti-Moiron¹, P. Ruiz-Cabello¹, M. Delgado-Fernandez⁴, P. Aranda¹

¹Department of Physiology and Institute of Nutrition and Food Technology, Faculty of Pharmacy and School of Sport Sciences, University of Granada, Granada, Spain

²Department of Physical Education, Faculty of Education Science, University of Cádiz, Cádiz, Spain

³Department of Physiology and Pathophysiology, University Abdelmalek Essaadi, Tetouan, Morocco

⁴Department of Physical Education and Sport, Faculty of Sport Sciences., University of Granada, Granada, Spain

Background and objectives: Overweight and obesity, which are highly related to cardiovascular disease (CVD), has become one of the main public health problems in Morocco. We aimed to analyze the association of weight status with cardiovascular and lipid profile in Moroccan older adult women.

Methods: The study comprised 151 women from the North of Morocco with an age ranged 45-65 years (52.5 ± 0.6). Fatness was assessed by bioelectric impedanciometry and anthropometry. We measured resting heart rate, blood pressure, and

plasma fasting glucose, total cholesterol, LDL-cholesterol, HDL-cholesterol and triglycerides. The association between weight status and the study outcomes was examined by one-way analysis of covariance after adjusting for age. Pairwise comparisons with Bonferroni's adjustment were performed to identify between which groups the differences were significant. Chi Squared test was used to analyze differences on metabolic syndrome (MS) prevalence.

Results: Women presented a BMI equal to 30.2 and an 81% of the sample was overweight or obese. Resting heart rate was 75.9 beats per min. Systolic blood pressure was 132 mmHg and diastolic 72.1 mmHg. Plasma biochemical analysis showed a fasting glucose concentration of 110.6 mg/dL. Total cholesterol was equal to 191.8 mg/dL, composed by 48.8 mg/dL of HDL-cholesterol and 120 mg/dL of LDL-cholesterol. Plasma triglycerides were 115 mg/dL. A 57% of the sample presented MS. Systolic as well as diastolic blood pressure increased across weight status categories (both, $P < 0.01$). Plasma triglycerides and the prevalence of MS also increased as weight status increased ($P < 0.05$ and $P < 0.001$, respectively). Pairwise comparisons showed differences mainly between the normal-weight vs. obese group.

Conclusions: The prevalence of MS risk factors increased as weight status increased. Nutritional and exercise programs focus on a better cardiovascular and lipid profile are mandatory in this population.

Key words: Weight status, metabolic syndrome, obesity, Moroccan.

PO1895

PREVALENCE OF OVERWEIGHT/OBESITY IN RELATION TO HEIGHT FOR AGE IN CAMEROONIAN CHILDREN.

L. Navti¹, K. Parhofer², E. Tange³, F. Uta⁴, S. Bechtold-Dalla Pozza⁵

¹Department of Biological Sciences, Catholic University of Cameroon, Bamenda, Cameroon

²Department of Internal Medicine II, Ludwig-Maximilians University, Munich, Germany

³Department of Nutrition and Food Sciences, Catholic University of Cameroon, Bamenda, Cameroon

⁴Department of Pneumology, Ludwig-Maximilians University, Munich, Germany

⁵Department of Endocrinology and Diabetology, Children's Hospital, Ludwig-Maximilians University, Munich, Germany

Background and objectives: In developed nations, taller children exhibit a greater propensity to overweight/obe-

sity. This study tests the hypothesis that the prevalence of overweight/obesity is greater in taller children. Specifically, it explores the relationship between childhood height for age and two measures of body fatness – body mass index (BMI) and waist circumference (WC).

Methods: A cross sectional study of 557 children (287 boys and 270 girls, mean age of 9.0 ± 1.8 years) from the North West Region of Cameroon. Height, weight and WC were measured and BMI calculated. Variables were converted to standard deviation scores (SDS) using the WHO 2007 references for height, weight and BMI and UK 1990 references for WC. Cases were divided into quartiles of height SDS, then BMI and WC SDSs compared across quartiles using 1-way Anova with post-hoc Bonferroni test. Prevalence of overweight/obesity (BMI for age $> +1$ SDS) and abdominal overweight/obesity (WC for age > 91 st percentile) within each quartile determined. Odds ratios (OR) used to assess association between overweight and non-overweight after logistic regression analysis.

Results: Significant increase in mean BMI (-0.08 to 0.65) and WC (-0.11 to 0.87) SDSs with increasing quartiles of height SDS. Prevalence of overweight/obesity and abdominal overweight/obesity increased from the first quartile (0.7 – 5.0%) to the fourth quartile (30.2 – 33.1%) of height SDS. Children with a higher height SDS had a more than three times higher OR for overweight/obesity than their shorter peers ($p < 0.001$).

Conclusions: This study confirms that a higher height for age was associated to a higher frequency of overweight/obesity measured by BMI SDS. This is replicated when WC SDS is used as a measure of adiposity. However, more objective monitoring of height through longitudinal studies is needed to substantiate this suggestion.

Key words: Height, waist circumference, BMI, children.

PO1896

OXIDANT AND ANTIOXIDANT STATUS IN CHRONIC RENAL FAILURE PATIENTS

H.F. Tbahrit¹, D. Meknassi², A. Messaoudi³, A. Kaddous², M. Bouchenak¹, K. Mekki¹

¹Laboratoire de Nutrition Clinique et Métabolique, Faculté des Sciences, Université D'Oran, Oran, Algérie

²Service de Néphrologie, Etablissement Hospitalier Universitaire d'Oran, Oran, Algérie

³Service de Biochimie, Etablissement Hospitalier Universitaire d'Oran, Oran, Algérie

Background and objectives: Oxidative stress (OS) has been identified as a risk factor for cardiovascular diseases (CVD). In chronic renal failure (CRF) patients, OS is a disturbance of ba-

lance between pro-oxidant and antioxidant systems, leading to CVD. The aim of this cross sectional study was to evaluate the redox status in patients with different stages of CRF.

Methods: 154 patients were divided into 6 groups according to the classification of the National Kidney Foundation (2003). CRF stage 1 (n=28), CRF stage 2 (n=28), CRF stage 3 (n=28), CRF stage 4 (n=18), Hemodialysis (HD; n=40) and peritoneal dialysis (PD, n = 12). Oxidant state was evaluated by analysis of thiobarbituric acid reactive substances (TBARS; Quintanilha et al., 1982), lipid hydroperoxide (LPO) and carbonyls (Cayman Chemical's EIA kit). Antioxidant defense was evaluated by analysis of enzymes activities: superoxyde dismutase (SOD), glutathione peroxidase (GPx), glutathione reductase (Gred) (Colorimetric photometric method; Fluka, Suisse) and Catalase (Cayman Chemical kit).

Results: TBARS and LPO were elevated in HD and decreased in PD and CRF groups ($p < 0.001$). Carbonyls were increased in PD (1.30 ± 0.16 mmol/mg; $p < 0.001$) compared to HD and to CRF groups. SOD (49.01 ± 3.03 U/g Hb) and GSH-Px (3.99 ± 1.39 U/g Hb) activities were decreased in HD compared to CRF groups and PD ($p < 0.001$). Moreover, Gred was decreased in HD (0.98 ± 0.20 U/g Hb) compared to CRF groups and PD ($p < 0.001$). Decrease in Catalase activity was noted only in HD (47.99 ± 5.89 U/g Hb) compared to CRF groups and PD ($p < 0.001$).

Conclusions: HD and PD aggravate oxidative stress generated by uremia. HD accentuates lipid and protein oxidation, while PD aggravates protein oxidation. However, the activity of antioxidant enzymes was altered by both dialysis treatments.

Key words: Oxidative stress, antioxidants enzymes, CRF, hemodialysis, peritoneal dialysis.

PO1897

RESVERATROL INHIBITED FAT INDUCED DYSBACTERIA IN SYSTEM MIMICKING COLON FERMENTATION

J. Sun^{1,2}, G. Le^{1,2}, Y. Shi^{1,2}, C. Qi³, H. Jiang (le falta el número), X. Tang. X^{1,2}

¹The State Key Laboratory of Food Science and Technology, JiangNan University, Wuxi, China

²Institute of Food Nutrition and Functional Factor, School of Food Science and Technology, JiangNan University, Wuxi, China

³COFCO Eastocean Oils and Grains Industries Co., Ltd., Zhangjiagang, China

Background and objectives: The growth of both Gram-positive and, to a lesser extent, Gram-negative bacteria is inhibited by fatty acids by hindrance of nutrient transportation and

accumulation of hydrogen peroxide in the cell. This might be a reason for high fat diet to change colon bacteria composition. This study was aimed to explore the influence of triglyceride and resveratrol, a typical antioxidant, on colon bacteria composition in a fermentation model *in vitro*.

Methods: Fresh feces were sampled from a 30-year old healthy man, bacteria were immobilized polysaccharide gel beads and were inoculated in colon mimicking culture medium (CMCM) for 48 h. Gel beads harvested and were then incubated in following medium: i) CMCM, ii) CMCM containing monoglyceride (8g/L) or medium containing 0.06% of resveratrol. Lactobacilli, *Escherichia coli* and enterococcus were detected by plate count on selective medium, total-AOC, hydrogen dioxide and hydroxy radical scavenging ability (HRSA) were also analyzed.

Results: Lactobacilli showed decreasing trend after monoglyceride treatment. *Escherichia coli* and enterococcus showed increasing trend. Ratio of G+/G- bacteria decreased significantly while HRSA decreased significantly also. Resveratrol addition significantly increased ratio of G+/G- bacteria. It led to significant decrease of hydrogen dioxide and increase of HRSA and T-AOC in fermenting system. T-AOC showed significant positive and negative correlation with lactobacilli ($R=0.77$, $P=0.04$) and enterococcus ($R=-0.91$, $P=0.04$), respectively. hydrogen dioxide was significantly positive related with *Escherichia coli* ($R=0.93$, $P=0.02$). HRSA showed significant negative correlation with enterococcus ($R=-0.60$, $P=0.03$).

Conclusions: Resveratrol can prevent monoglyceride induced decrease of G+/G- bacteria ratio and production of oxygen free radical.

Key words: colon, fermentation, resveratrol, lactobacilli, hydrogen dioxide.

PO1898

SERUM URIC ACID LEVELS OF SECONDARY SCHOOL-AGE STUDENTS IN NORTHERN AND SOUTHERN REGIONS OF THAILAND

W. Suttikomin¹, P. Leelahagul¹, K. Klawisait², G. Janthranant², W. Ponchai², P. Wongnatgul²

¹Graduate Program In Nutrition, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Nakhon Pathom, Thailand

²Princess Chulabhorn's College Chiangrai, Chiang Rai, Thailand

Background and objectives: Hyperuricemia is commonly associated with hypertension, metabolic syndrome, and other risk factors of cardiovascular disease. In our study we found that the secondary school-age students in Northern and Southern regions of Thailand had high prevalences of obesity,

hypertriglyceridemia, and hypercholesterolemia. The aim of this study was to investigate the serum uric acid levels and its relationship with cardiovascular risk factors in those secondary school-age students.

Methods: The cross-sectional study by Waisaihealth Program, involved 816 Thai northern, and 873 Thai southern secondary school-age students aged 11-19 years. Their nutritional and uric acid status were assessed by Tanita BC-418 MA body composition analyzer, serum uric acid, serum triglyceride and serum LDL cholesterol levels.

Results: Serum uric acid levels ranged from 2.8-11.9 mg/dL and 2.7-10.9 mg/dL in northern students and southern students, respectively, no significant difference between two regions. Mean±SD of serum uric acid level in northern female adolescents (4.9 ± 1.0 mg/dL) was significantly lower than those in southern female adolescents (5.1 ± 0.9 mg/dL). In obese and hypertriglyceridemic adolescents from northern and southern regions had significantly higher mean serum uric acid levels than those in normal weight adolescents.

Conclusions: Our data indicated that obese and hypertriglyceridemic adolescents are prone to hyperuricemia. Thus these abnormalities can result in cardiovascular disease in their older age. Different dietary habits and life style among regions had effects on serum uric levels.

Key words: Serum uric acid, hyperuricemia, adolescent, obesity.

PO1899

GLUTAMINE ADMINISTRATION MODULATES LUNG $\gamma\delta$ T CELL EXPRESSION IN SEPTIC MICE

Y.M. Hu¹, C.L. Yeh², M.H. Pai³, S.L. Yeh¹

¹School of Nutrition and Health Sciences, Taipei Medical University, Taipei, Taiwan

²Department of Food and Nutrition, Chinese Culture University, Taipei, Taiwan

³Department of Anatomy, Taipei Medical University, Taipei, Taiwan

Background and objectives: Sepsis is a common clinical syndrome with high mortality rates. Acute lung injury is the most frequent complication of sepsis. Previous study reported that $\gamma\delta$ T cells play a major role in linking innate and adaptive immune systems and are instrumental in reducing lung damage associated with inflammation. Glutamine (GLN) has been considered as an essential amino acid during catabolic conditions due to its immunomodulating properties. This study investigated the effects of GLN administration on regulating lung $\gamma\delta$ T cells in polymicrobial sepsis.

Methods: Mice were randomly assigned to normal group (NC), septic saline group (SS), and septic GLN group (SG). All

mice were fed with chow diet. Sepsis was induced by cecal ligation and puncture (CLP). The SS and SG groups were respectively injected with saline and 0.75 g GLN/kg body weight once via tail vein 1 h after CLP. Mice were sacrificed 6, 12, and 24 h after CLP. Their lungs were collected for further analysis.

Results: Compared to normal mice, sepsis resulted in higher lung $\gamma\delta$ T cell and neutrophil percentages and higher cytokine expressed by $\gamma\delta$ T cells. The SG group had higher lung $\gamma\delta$ T cell percentage and lower neutrophil numbers. Apoptotic rates of lung $\gamma\delta$ T cells were lower, whereas neutrophils were higher than those of the SS group. Moreover, interleukin (IL)-17A, interferon- γ , and IL-10 expressed by $\gamma\delta$ T cells, and CXCR2 expressed by neutrophils decreased in the SG group. Also, GLN reduced IL-17A, IL-1 β , and IL-23 concentrations and myeloperoxidase activity in lung tissues.

Conclusions: Our results suggest that GLN administration after initiation of sepsis affects lung $\gamma\delta$ T cell percentage and cytokine secretion, and prevented apoptosis of $\gamma\delta$ T cells and neutrophil infiltration to the lungs.

Key words: sepsis; acute lung injury; $\gamma\delta$ T cell; glutamine; Interleukin 17

PO1900

DISCOVERY OF A LOW GLYCEMIC INDEX POTATO AND RELATION BETWEEN IN VITRO STARCH DIGESTION AND GLYCEMIC RESPONSE

K. Ek², S. Wang¹, L. Copeland¹, J. Brand-Miller²

¹Department of Plant and Food Science, Faculty of Agriculture and Environment, The University of Sydney, Sydney, Australia

²Boden Institute of Obesity, Nutrition & Exercise and the School of Molecular Bioscience, The University of Sydney, Sydney, Australia

Background and objectives: Potatoes are the world's third largest food crop and most extensively consumed root vegetable. Nutritional studies on potatoes using in vivo and in vitro approaches to classify digestibility and availability of carbohydrates indicate that cooked potatoes contain mostly rapidly digested starch and have a high glycemic index (GI). Finding a low GI potato and developing a screening method for finding low GI cultivars is both a health and agricultural priority. Our aims were to screen commonly used and newly introduced cultivars of potatoes, in a bid to discover a low GI potato and to describe the relationship between in vitro starch digestibility of cooked potatoes and their in vivo glycemic response.

Methods: Seven commercial potato cultivars sourced from growers in Tasmania and South Australia, were tested for their GI according to International Standard Organisation (ISO) guidelines. In vitro enzymatic starch hydrolysis and chemical

analyses, including amylose content were performed for each potato cultivar and correlations sought with the respective GI values.

Results: The potato cultivars showed a wide range of GI values (53 - 103). The cultivar Carisma was classified as low GI, Nicola (GI = 69) as medium GI and the other five cultivars were classified as high GI according to ISO classification. The GI values were strongly and positively correlated with the percentage in vitro enzymatic hydrolysis of starch from the cooked potatoes. Content of total starch, amylose, and dietary fibre were not correlated to in vitro starch digestibility or GI of the cooked potatoes.

Conclusions: A low GI potato cultivar (Carisma, GI = 53) was identified. Under the conditions of our experiments, in vitro methods were a reliable predictor of GI classification for potatoes.

Key words: glycemic index, potatoes, in vitro digestion, amylose.

PO1901

ANDROGRAPHOLIDE SUPPRESSES TNF- α -INDUCED OXIDATIVE STRESS BY MODULATING CELLULAR ANTIOXIDATION IN HUMAN ENDOTHELIAL CELLS

L. Chia-Yang¹, L. Kai-Li², C. Haw-Wen *et al* *events pro no se indica donde trabaja/estudia*

¹School of Nutrition, Chung Shan Medical University, Taichung, Taiwan

²Department of Nutrition, China Medical University, Taichung, Taiwan

Background and objectives: Andrographolide, the major bioactive component of *Andrographis paniculata*, has been demonstrated to have various biological properties including anti-inflammation, anti-oxidation, and anti-hepatotoxicity. Oxidative stress is considered to be a major health risk in aging, inflammation, cancer, atherosclerosis, and diabetes mellitus. Previous studies have shown that NADPH oxidase is a major source of reactive oxygen species. Many phytochemicals were shown to up-regulate the expression of antioxidant genes associated with endothelial cells.

Methods: In this study we used EA.hy926 endothelial-like cells as cell model, and used Western blotting, real-time PCR, spectrophotometer, shRNA, and peroxide formation to explore the antioxidative activity of andrographolide.

Results: The results showed that andrographolide induces heme oxygenase-1 (HO-1) and glutamate cysteine ligase modifier subunit (GCLM) gene expression, and superoxide dismutases (SOD-1), and glutathione reductase (GSR) gene expression as well as enzyme activity in a time-dependent manner.

The mechanism underlying up-regulation of HO-1 and GCLM by andrographolide is associated with ERK or PI3K/Akt pathways. Nrf2 and AP-1 were demonstrated to play a crucial role in modulating HO-1, GCLM, SOD-1, and GSR gene expression by using shNrf2 and shJUN. Cellular GSH level is increased by andrographolide, and andrographolide-induced increase in GSH level is blocked by shGCLM. TNF- α induces the activation of NADPH oxidase subunits, p47 and p67. In addition, TNF- α -induced oxidative stress is attenuated by andrographolide. Further, shp47 abolished TNF- α -induced p65 nuclear translocation and ICAM-1 gene expression.

Conclusions: Taken together, andrographolide attenuates TNF- α -induced oxidative stress is at least in part through enhancement of cellular antioxidative capacity. These results implicate that andrographolide is an antioxidant candidate based on its antioxidant status-enhancing effect.

Key words: andrographolide, antioxidation, TNF- α , NADPH oxidase, human endothelial cells.

PO1902

DIETARY QUERCETIN ATTENUATES OXIDANT-INDUCED ENDOTHELIAL DYSFUNCTION AND ATHEROSCLEROSIS IN APOE KO MICE FED A HIGH-FAT DIET

N. Ward¹, Y. Shen¹, I. Puddey¹, Y. Wang², R. Stocker³, K. Croft¹

¹School of Medicine & Pharmacology, University of Western Australia, Perth, Australia

²School of Medical Sciences, University of Sydney, Sydney, Australia

³Victor Chang Cardiac Research Institute, Sydney, Australia

Background and objectives: There are several lines of evidence to suggest that quercetin, a polyphenol derived in the diet from fruits and vegetables, contributes to cardiovascular health. Endothelial dysfunction is an early risk factor in the development of atherosclerosis. The aim of this study was to investigate the effects of quercetin supplementation on endothelial function and the development of atherosclerosis in mice fed a Western high fat diet (HFD)

Methods: Wild-type (WT) C57BL6 and ApoE KO mice were randomly assigned to receive either (i) high fat diet (HFD), or (iii) HFD supplemented with 0.5% w/w quercetin (Q) for 14 weeks.

Results: Compared with animals fed the HFD, the HFD supplemented with quercetin attenuated the development of atherosclerosis in the ApoE KO mice. The HFD+Q diet significantly improved endothelium-dependent relaxation of aor-

tic rings isolated from WT, but not ApoE KO mice, while the HFD+Q attenuated hypochlorous acid-induced endothelial dysfunction in aortic rings from both the WT and ApoE mice. Mechanistic studies revealed that the HFD+Q significantly improved oxidative stress, urinary nitrite levels, endothelial NO synthase activity and increased heme oxygenase-1 (HO-1) protein expression in aorta. Separate experiments demonstrated that quercetin did not protect against oxidant-induced endothelial dysfunction in arteries obtained from heterozygous HO-1 KO mice.

Conclusions: Quercetin protects mice fed a high fat diet against oxidant-induced endothelial dysfunction and ApoE KO mice against atherosclerosis. These effects are associated with improvements in NO bioavailability and critically related to arterial induction of HO-1.

Key words: quercetin, endothelial function, atherosclerosis, HO-1.

PO1903

EFFECTS OF DIFFERENT AMOUNTS AND TYPES OF DIETARY FATTY ACIDS ON BODY WEIGHT, FAT ACCUMULATION AND LIPID METABOLISM IN DIET-INDUCED OBESE HAMSTERS

Y.W. Chien¹, J.H. Yang¹, C.H. Hsia¹, C.Y. Chen¹, S.Y. Lim¹

¹Taipei Medical University, Taipei City, Taiwan

Background and objectives: The aim of this study was to assess the effect of different amounts of a special mix oil on body weight, fat accumulation and lipid metabolism of hamsters with diet-induced obesity (DIO).

Methods: This special mix oil contains 60% monounsaturated fatty acids (MUFAs) and the polyunsaturated-to-saturated fatty acid ratio is adjusted to 5 (P/S ratio = 5). Male Golden Syrian hamsters were randomly assigned to the control group (n=12) and obesity group (n=30) which were given low-fat diet (5% w/w soybean oil) and high-fat (35% w/w) respectively during DIO period for 9 weeks. After DIO period, the obesity hamsters were randomly subdivided into three subgroups (n=10/group) switched to a low-fat, moderate-fat and high-fat diet: the 5% (w/w) experimental mix oil (OB-M5) group, 15% experimental mix oil (OB-M15) group and 20% experimental mix oil (OB-M20) group for 8 weeks. The control hamsters continued on a low-fat diet. Consumption of food was measured daily, and body weight was measured weekly. Serum insulin and leptin concentrations were assessed. Hepatic and adipose tissue fatty acid metabolic enzymes were determined using enzyme activities analysis.

Results: After the DIO period, the obesity group significantly increased in weight and weight gain compared with the control group. No differences were observed in weight, weight

gain, epididymal and retroperitoneal fat weights in all groups after 8 weeks dietary intervention. **Conclusions:** Experimental mix oil (MUFAs 60%, P/S ratio = 5) seemed to be beneficial in preventing moderate and high fat intake caused weight and adipose tissue weight gain by preventing insulin concentration, fatty acid synthase(FAS) and lipoprotein lipase(LPL) enzymes activity increased in DIO hamsters.

Key words: monounsaturated fatty acids, polyunsaturated to saturated fatty acid ratio, diet-induced obesity.

PO1904

ESTIMATE OF A MINERAL COMPOSITION FOR AN ORAL FOOD COMPLEMENT TO HOSPITALIZED ONCOLOGIC PATIENTS

K. Diego Quintaes¹, J.S. Manzoli de Sá¹, K.A. Louvera Silva¹, D.C. Faria Moreira¹, M.A. Morgano²

¹Ouro Preto Federal University, Nutrition School, Ouro Preto, Brazil

²Quality and Control Center of Foods, Food Technology Institute, São Paulo, Brazil

Background and objectives: Sometimes hospitalized patients have insufficient alimentary ingestion. This study analyzed the mineral composition of an artisanal oral food complement (OFC) through the data of food consumption of oncologic patients who received oral diet, separately or associated to the OFC.

Methods: The mineral composition, determined by ICP OES, and the food consumption of patients under regular, blend and soft diets were evaluated in six non-consecutive weekdays, without repetition of the menu, being that patient with increased nutritional necessities also received OFC. The levels of Ca, P, Na, K, Mg, Mn, Zn, Cu and Se consumed by the patients were calculated deducting the weight from the leftover of the sent weight, using an electronic scale. Results were compared to the nutritional recommendations (RDA), with statistical analysis by ANOVA and Tukey tests ($P < 0.05$).

Results: A total of 163 patients participated: 77.3, 16.6 and 6,1% under regular, blend and soft diet, respectively, being that 23.0, 30.7 and 40.0% received OFC with their diet. The average acceptances of the diets was of 70.0% and OFC 89,7%. There were fewer acceptance for the meal following the OFC, lunch (49.7 versus 56.8%) and dinner (64.9 versus 57.6%). The adequacy of the consumption was similar among patients with or without OFC, except for the Ca which recommendation was reached by the patients with OFC ($p < 0.001$). The mineral content to achieve RDA using OFC was estimated to be 700 mg Ca; 0.1 mg Cu; 0.2 mg Fe; 2600 mg K; 200 mg Mg; 0.4 mg Mn; 2.9 mg Zn; 0.02 mg Se, without P and Na.

Conclusions: Mineral supplementation to patients beco-

mes necessary to comply with RDA. The administration of mineral supplements is recommended in these patients given the fact that there is no interference with the patient's meals acceptance.

Key words: dietotherapy, food analysis, food consumption, nutritional supplement.

PO1905

NUTRITIONAL EVALUATION OF DAILY INTAKE IN ALZHEIMER'S PATIENTS

J.M. Rubio-Perez¹, P. Zafrilla¹, P. Palacio-Vales¹, J.M. Morillas-Ruiz¹

¹Department of Food Technology & Nutrition, Catholic University of San Antonio, Murcia, Spain

Background and objectives: Changes in nutritional status, primarily characterized by meaningful weight reduction, are reported during the course of Alzheimer's disease (AD). The aim of the present study was to evaluate the daily intake of a group of elderly subjects with Alzheimer's dementia and a control group.

Methods: 100 subjects were included in this study. 24 patients (17 females and 7 males), aged 76 ± 4 years (mean \pm SEM), with AD at initial phase (ADI) and 24 patients (18 females and 6 males), aged 77 ± 3 years with AD at moderate phase (ADM). All patients were selected from Alzheimer's associations of the Region of Murcia, Spain. Furthermore, 52 control subjects (C) (40 females and 12 males), aged 79 ± 4 years, without dementia were included. It was performed a nutritional evaluation of daily intake by means of a 24 h questionnaire and it was done for three not consecutive days, including a holiday. The nutritional survey data were processed with Dietsource 3.0 software. Anthropometric variables, including weight, height and body mass index, were measured. Statistical analysis was performed with SPSS 17.0 software.

Results: The weight of ADM (64.84 ± 1.90 kg) was significantly lower ($p = 0.002$) than the weight of C (74.87 ± 2.46 kg), as well as the caloric intake (1776 kcal/24h vs. 2106 kcal/24h) ($p = 0.006$). It was observed that, with advance of the disease, this caloric intake was lower (ADI= 2020 kcal/24h; ADM= 1776 Kcal/24h) ($p = 0.04$). In ADM, daily intake of folic acid (268 ± 22.79 μ g), selenium (44.02 ± 7.03 μ g) and zinc (7.20 ± 0.53 mg) was lower than the intake of these micronutrients in C ($p < 0.05$).

Conclusions: It is necessary to perform a nutritional education to the family or caregivers of Alzheimer's patients to improve their nutritional status, especially in the moderate stage of the disease, to avoid associated complications.

Key words: Alzheimer's disease, daily intake, nutritional evaluation.

PO1906**AN UNDIGESTED GLIADIN PEPTIDE ACTIVATES INNATE IMMUNITY AND PROLIFERATIVE SIGNALING IN ENTEROCYTES: ROLE IN CELIAC DISEASE**

M. Nanayakkara¹, G. Lania¹, M. Maglio¹, V. Discepolo¹, R. Auricchio¹, M. Sarno¹, R. Troncone¹, S. Auricchio¹, M. V. Barone¹

¹Department of Pediatrics and ELFID, University of Naples Federico II, Naples, Italy

Background and objectives: Upon ingestion of gliadin, the major protein component of wheat and other cereals, the celiac intestine is characterized by the proliferation of crypt enterocytes with an inversion of the differentiation/proliferation program. Gliadins, and A-gliadin peptide P31-43 in particular, act as growth factors for Celiac Disease (CD) crypt enterocytes. The effects of gliadin on proliferation and activation of innate immunity are mediated by growth factors (EGF) and innate immunity mediators (IL15). We studied the molecular bases of the proliferative and innate immune response to gliadin peptides in enterocytes.

Methods: CaCo-2 cells have been used to study EGF, IL15 and P31-43 induced proliferation. Silencing mRNAs and blocking EGFR- IL 15-antibodies have been used to study proliferation in CaCo-2 cells and intestinal biopsies from CD patients and controls.

Results: In CaCo-2 cells IL15 and EGF cooperate to induce proliferation in intestinal epithelial cells at both the transcriptional and post transcriptional levels and the relative receptors can interact to activate each other signalling. We have also found that P31-43 effects on CaCo-2 cell proliferation and downstream signalling are mediated by cooperation between EGF and IL15. Only when used in combination, blocking EGFR and IL15 antibodies, can reduce the increased crypts enterocytes proliferation in intestinal biopsies from CD patients.

Conclusions: EGFR/IL15R-alpha cooperation regulates intestinal epithelial proliferation induced by EGF, IL15 and gliadin peptide P31-43. Increased proliferation of crypt enterocytes in the CD intestine is mediated by EGF/IL15 cooperation.

Key words: Celiac Disease, EGF, IL15, intestinal proliferation.

PO1907**ADHERENCE TO THE MEDITERRANEAN DIET AND RISK OF BLADDER CANCER IN THE EUROPEAN PROSPECTIVE INVESTIGATION INTO CANCER AND NUTRITION**

G. Buckland^{1,2}, N. Roswall², M. M. Ros³, H. B. Bueno-de-Mesquita³, A. Tjonneland², N. Travier¹, C. A. Gonzalez¹

¹Unit of Nutrition, Environment and Cancer, Cancer Epidemiology Research Programme, Catalan Institute of Oncology (ICO-IDIBELL), Barcelona, Spain

²Institute of Cancer Epidemiology, Danish Cancer Society, Copenhagen, Denmark

³The National Institute for Public Health and the Environment (RIVM), Bilthoven, The Netherlands

Background and objectives: There is growing evidence on the protective effect of the Mediterranean dietary on cancer. To our knowledge though, no epidemiological study to date has investigated the influence of the Mediterranean diet on bladder cancer. Therefore, we evaluated the association between adherence to the Mediterranean diet and risk of urothelial cell bladder cancer (UCC) in the European Prospective Investigation into Cancer and Nutrition (EPIC).

Methods: 477,312 participants (29.8% male), mostly aged 25-70 years, were recruited from 10 European countries between 1991-2000 and included in this analysis. Information from validated dietary questionnaires was used to develop a relative Mediterranean diet score (rMED) which represented each participant's level of adherence to a Mediterranean dietary pattern, including 9 key components. Multivariable Cox regression models were used to assess the effect of the rMED on UCC risk. The models were stratified by sex, center and age at recruitment and adjusted for energy and tobacco smoking (status, intensity, duration and time since quitting).

Results: After an average follow-up of 11 years, 1,425 participants (70.9% male) were diagnosed with a first incident UCC (430 classified as aggressive/ high risk tumours and 413 as non-aggressive/low risk tumours). There was no evidence of a statistically significant association between the rMED and risk of UCC overall (HR: 0.84 (95% CI 0.69, 1.03)) or in aggressive (HR: 0.88 (95% CI 0.61, 1.28)) and non-aggressive tumours (HR: 0.78 (0.54, 1.14)) for a high versus low rMED score. There was also no evidence of interaction by smoking, body mass index, European region or age at diagnosis.

Conclusions: In EPIC, there is no evidence that adherence to the Mediterranean diet is associated with risk of UCC. These findings reflect the weak evidence for associations between questionnaire-derived dietary factors and bladder cancer risk.

Key words: Mediterranean diet, bladder cancer, cohort.

PO1908**DIABETES KNOWLEDGE EVALUATION IN TYPE 2 DIABETIC PATIENTS**

M. Dominguez-Lopez¹, I. Gonzalez-Molero¹, M. Gonzalez-Marín¹, M. Garcia¹, M.S. Ruiz de Adana¹

¹Endocrinology and Nutrition Service, Carlos Haya Hospital, Málaga, Spain

Background and objectives: Knowledge about medications, diet, exercise, home glucose monitoring, foot care, and treatment modifications is necessary to effectively self-manage diabetes. The aim of this study was to assess the knowledge among our type 2 diabetic patients and to identify knowledge deficits and features that are associated with this knowledge.

Methods: A cross-sectional sample survey of patients' knowledge of diabetes was carried out by administering a 23-item diabetes knowledge questionnaire adapted to Spanish language to collect information.

Results: 90 patients were evaluated, mean age 6.1+/-11.7 years, 57.1% men. Mean duration of diabetes was 12+/-8.66 years, mean time of attendance in our endocrinology department 3.45+/-3.47 years. 35.7 % presented chronic complications disease-related; 70% HTA, 73% obesity and 83.3% dyslipemia. 30 % were treated with oral hypoglycemic agents (OHA), 10% insulin treated and 60% with combined treatment. Mean BMI was 33.8 +/-4.8, and mean HbA1c 7.55+/-1.05%. 51.9% of the patients answer correctly more than 75% of the questions and 48.1% more than 50 %. None of the patients answered correctly less than 50%. The number of right answers was statistically significant regarding age (mean 58.8±12.9 years in more than 75% of right answers vs 65.1±10.1 years in 50-75% of right answers, PO,05), but there were no significant differences depending on years of evolution (12.7± 10.2 vs 10.3±6.3), BMI (33.5±5.5 vs 33.7± 4.9), HbA1c (7.4±1.2 vs 7.8±0.7%) or time of endocrinology clinic attendance (4±4.1vs2.7±2,5 years). There were also no statistically significant differences depending on sex, chronic complications or previous educational programmes. Insulin treated patients answered correctly more than 75% in 100% of cases vs patients treated with OHA (41,2%, PO,026).

Conclusions: In our group of DM2 patients, most of them had appropriate diabetes related knowledge. Patients with better scores had less mean age, and are insulin-treated.

Key words: Diabetes, knowlegde, nutrition.

PO1909**ASSOCIATIONS BETWEEN FTO GENE POLYMORPHISM, DIET, PHYSICAL ACTIVITY, AND BODY MASS INDEX IN LITHUANIAN ADULT POPULATION**

J. Petkeviciene¹, V. Kriaucioniene¹, A. Smalinskiene², A. Raskiliene¹

¹Department of Preventive Medicine, Lithuanian University of Health Sciences, Kaunas, Lithuania

²Institute of Cardiology, Lithuanian University of Health Sciences, Kaunas, Lithuania

Background and objectives: Single-nucleotide polymorphism rs9939609 in FTO gene is significantly associated with body mass index (BMI). Moreover, lifestyle factors, including diet and physical inactivity, are important contributors to weight gain. The aim of this study was to assess the effect of FTO gene polymorphism, energy and nutrient intake, physical activity, and gene-environmental interactions on BMI in Lithuanian adult population.

Methods: A cross-sectional health survey was carried out in random sample of Lithuanian population aged 25–64 years. The data from 1026 subjects (424 men and 602 women) were analysed. Single-nucleotide polymorphism rs9939609 was assessed using a real-time polymerase chain reaction. 24-hour recall and food frequency questionnaire were used for evaluation of dietary habits. BMI was calculated using measured height and weight. Multiple linear regression models were fitted to test the effects of FTO genotype, diet, physical activity as well as gene-environmental interactions on BMI.

Results: Men and women with TT genotype had the lowest mean values of BMI, while individuals carrying AA genotype had the highest BMI. Compared to the carriers of TT genotype, the likelihood of obesity was significantly higher for the carriers of AA genotype (odds ratio was 1.69, 95% confidence interval 1.29-2.21). No significant association was found between rs9939609 and dietary intake or physical activity. Multivariate linear regression analysis showed that FTO genotype, percentage of energy from fat, and physical activity were significant determinants of BMI. Our data did not reveal any statistically significant interactions between FTO genotype and energy intake as well as nutrient intake on BMI. However, high level of physical activity attenuated the effect of the FTO polymorphism on BMI (p for interaction 0.02).

Conclusions: No interaction of rs9939609 with energy and nutrient intake on BMI was found. Physical activity can modulate the effect of FTO on BMI.

Key words: obesity, gene-environmental interactions.

PO1910**USE OF WAIST TO HEIGHT RATIO IN ASSESSING METABOLIC DERANGEMENTS AMONG NORMAL AND OVERWEIGHT/OBESE INDIVIDUALS**

V P. Wickramasinghe¹, C. Arambepola², P. Bandara¹, M. Abeysekera¹, S. Kuruppu¹, P. Dilashan¹, B S. Dissanayake¹

¹Department of Paediatrics, University of Colombo, Colombo, Sri Lanka

²Department of Community Medicine, University of Colombo, Colombo, Sri Lanka

Background and objectives: Although BMI is used to assess obesity it does not always relate to central obesity, the main metabolic risk factor. Waist circumference(WC) to height ratio(WHtR) is a simple index of central obesity. This study looks at its usefulness in detecting metabolic derangements in 5-15 year old Sri Lankan children.

Methods: A cross sectional descriptive study conducted in Colombo district. Height, weight and WC were measured. FM assessed using InBody-230 BIA machine (Boispace Co Ltd, South Korea) and validated against Sri Lanka body composition equations. BMI and WHtR were calculated. BMI was classified based on IOTF cutoffs. After a 12hour fast, blood was drawn for fasting blood glucose(FBS) and lipid profile. Standard OGTT was performed with random blood sugar(RBS) at 2hours. Metabolic derangements(MetD) were defined as; WC for age >90th centile (UK standards); FBS>100mg/dl or RBS>140 mg/dl; HDL-C<40mg/dl; triglyceride>150mg/dl; and SBP/DBP >+2SD for age (UK standards). Metabolic syndrome(MetS) was diagnosed by a high WC with >2 MetD. ROC were drawn to determine best WHtR that predicts MetS as well as >2 MetD.

Results: 920 children (547boys) were studied. 13.3% were obese/overweight and 38.5% had a normal BMI. 13.6% had central obesity. Those with normal BMI, but central obesity had higher total and LDL cholesterol and triglyceride levels(p>0.05). WHtR detected more cases with abnormal, cholesterol and HDL than BMI, but triglyceride, LDL and ALT cases detected were similar by both. WHtR to detected MetS was 0.51(sensitivity-1.00; specificity-0.83) in boys and 0.49(sensitivity-0.83; specificity-0.83) in girls. To detect >2 MetD was 0.42(sensitivity-0.6; specificity-0.62) in boys and 0.45(sensitivity-0.62; specificity-0.62) in girls.

Conclusions: Internationally accepted BMI and WHtR have similar efficacy in detecting MetD. Cutoffs developed for MetS is similar to international cutoffs, but to detect >2 MetD is quite low.

Key words: Waist height ratio, Sri Lankan children, central obesity.

PO1911**SELENIUM DEFICIENCY IN ASYMPTOMATIC HIV-INFECTED ADULTS**

M. Stambullian^{1,2}, S. Feliu¹, A. Piñeiro³, E. Villaamil³, L I. Cassetti², N. Slobodianik¹

¹Department of Nutrition, School of Pharmacy and Biochemistry, University of Buenos Aires, Buenos Aires, Argentina

²Helios Salud, Buenos Aires, Argentina

³Department of Toxicology, School of Pharmacy and Biochemistry, University of Buenos Aires, Buenos Aires, Argentina

Background and objectives: Selenium is particular relevant in HIV infection because it might modulate immune cells. The aim of this study was to evaluate selenium status in asymptomatic HIV-infected outpatients.

Methods: Descriptive, cross-sectional study which included 106 HIV-infected adults. Samples of whole blood were collected from fasting patients. Clinical data were obtained from medical records. Plasma selenium was determined in hemolysis-free plasma by flame atomic absorption spectrometry. A calibration curve was performed, using commercial standards. Reference values were taken from international bibliography (60–160 µg/L). The Ethics Committee of the University of Buenos Aires approved the study. All participants gave informed consent before recruitment. Student's t-test, ANOVA or Wilcoxon Rank Sum analysis were applied to analyze differences between means. Pearson's correlation coefficient was used to measure the relationship between selenium and other parameters. Values were considered statistically significant for p<0.05. Software used was SPSS17.0.

Results: 69.8% males, mean (SD), age 38,6 (8,5) years old. 80% under antiretroviral treatment. Media (SD) CD4 count of 461.7 (235.0) cells/mm³, median (IQR) viral load <50 (<50-433000) copies/mL. Although nutritional status evaluated by BMI seemed to be well [24.3 (4.1) kg/m²], 63.3% of the patients presented selenium under reference value. Selenium median (IQR) was 49.3(31.9-68.75) µg/L. It is interesting to point out that patients with less than 200 CD4/mm³ had a significantly lower selenium mean (SD) than patients with more than 200 CD4/mm³ [32.3 (15.0) µ/L vs. 57.0 (26.1) µ/L with 200-500 CD4/mm³, p<0.001; vs. 51.6 (27.2) µ/L with >500 CD4/mm³, p=0.034]. On the other hand, viral load and selenium had a statistical direct correlation (Pearson coefficient 0.248; p=0.018).

Conclusions: The results show a great number of patients with selenium deficiency, which seems to have a relation with HIV parameters. Nutritional counseling to improve nutrient adequacy should be performed from the diagnosis of HIV. Partially supported by UBA (Grant 20020100100044).

Key words: HIV, selenium, deficiency, adult, CD4.

PO1913**BODY FAT AND INFLAMMATION IN CUBAN SCHOOL CHILDREN**

M. Hernandez-Triana¹, V. Ruiz-Alvarez¹, M E. Diaz-Sanchez¹, C. Viera-Cosiñol¹, H. Hernandez-Hernandez¹, G. Pita-Rodriguez¹, A. Cabrera¹, I. Puentes¹

¹Department of Biochemistry and Physiology, Institute of Nutrition, La Habana, Cuba

Background and objectives: Body fat excess is associated with insulin resistance and inflammation. The aim of this study was to identify this association in school children.

Methods: Case-control study in 2012 with 51 overweight (OW) (mean age 107 months) and 51 normal children, paired by age, sex, and socioeconomic status, and submitted to measurements of body fat by deuterium dilution, inflammatory cytokines, insulin, ferritin, transferrin receptors, glucose, serum lipids, haemoglobin, energy expenditure, blood pressure, and dietary intake. Comparisons were carried out means Odd ratios, Mann Whitney tests, main component and multivariate analysis and logistic binary regression.

Results: OW children with 1.7 times more body fat showed higher levels of C-Reactive Protein (CRP), insulin, triglycerides, blood pressure, physical activity, and higher intake of refined cereals, canned fruits, soft drinks, fast foods, dietary energy, carbohydrate, polysaccharides, animal fat, methionine, and sodium; the essential fatty acids intake was lower and the sugar intake double as recommended and not different between groups. Most OW children had both parents OW (OR=7.955, P=0.0000) and mothers with higher BMI at pregnancy. Children born by caesarea showed a 2.4 higher risk to be OW at school age (p=0.0031, IC: 1.04–5.56). Four factors explained 72% of the sample variance: the association between adiposity, higher fast foods and fat intake and higher levels of CPR and insulin.

Conclusions: Fat accretion in school children was strongly associated to inflammation, hyperinsulinemia, and high intake of fast foods, refined cereals, total energy, carbohydrates, sodium, and animal fat. Overweight was more related with food intake, BMI at pregnancy and parents' overweight, than with a sedentary life style.

Key words: body fat, school children, inflammation, cytokines.

PO1914**THE MEDITERRANEAN DIET IMPROVES THE LOW-DENSITY LIPOPROTEIN PARTICLE SIZE PHENOTYPE IN MEN WITH METABOLIC SYNDROME**

C. Richard¹, P. Couture¹, S. Desroches¹, B. Lamarche¹

¹Institute of Nutrition and Functional Foods, Laval University, Quebec, Canada

Background and objectives: Studies have indicated that individuals with small, dense low density lipoprotein (LDL) particles are at increased risk of cardiovascular disease. The impact of the Mediterranean diet (MedDiet) on various electrophoretic characteristics of LDL particles has not been extensively studied to date. The objective of the study was to investigate the effect of the MedDiet without weight loss (-WL) and with weight loss (+WL) on various features of the LDL particle size phenotype in men with metabolic syndrome (MetS).

Methods: The diet of 19 men with MetS (NCEP-ATP III, age 24-62 years) was first standardized to a typical North American control diet that they consumed for 5 weeks under isoenergetic feeding conditions (all foods and beverages provided). Subjects were then fed a MedDiet for 5 weeks also under isoenergetic conditions (MedDiet-WL), after which they underwent a 20-week weight loss period in free-living conditions (average weight loss $-10.2 \pm 2.9\%$ body weight, $P < 0.01$). This was followed by consumption of the MedDiet (5 weeks) under isoenergetic conditions (MedDiet+WL). Features of the LDL size phenotype were determined at the end of each isoenergetic feeding period by polyacrylamide gradient gel electrophoresis.

Results: MedDiet-WL led to a significant increase in LDL-peak particle diameter (LDL-PPD, +0.7%) and in the proportion of medium size LDL (LDL₂₅₅₋₂₆₀ Å, +11.1%) and reduced the proportion of small dense LDL (LDL_{<255} Å, -11.7%) vs. the control diet (all $P < 0.05$). MedDiet+WL was associated with a further increase in LDL-PPD (0.2%, $P < 0.05$) but had no further impact on the proportion of small dense LDL compared with MedDiet-WL.

Conclusions: Data from this controlled feeding study suggest that consumption of MedDiet, even in the absence of weight loss, beneficially alters the atherogenic properties of LDL particles in high risk men with MetS.

Key words: Mediterranean diet, metabolic syndrome, weight loss, LDL particle size.

PO1915**ARTHROSPIRA PLATENSIS AS NUTRITION SUPPLEMENT FOR ADULTS INFECTED BY THE HUMAN IMMUNODEFICIENCY VIRUS**

F. Winter¹, F. Emakam¹, J. Kfutwah², M. Azabji³, M. Krawinkel¹

¹Institute of International Nutrition, University of Giessen, Giessen, Germany

²Laboratory of Virology, Centre Pasteur Cameroun, Yaoundé, Cameroon

³Faculty of Biomedical Sciences, University of Yaoundé I, Yaoundé, Cameroon

Background and objectives: Supplements are often used to improve the nutritional status of HIV patients. *Arthrospira platensis* (Asp), also known as *Spirulina*, is a cyanobacteria rich in proteins and micronutrients. There is a paucity of data describing the immune modulating activity and nutritional properties of Asp. This gender-oriented study describes the influence on a sensitive pre-High Active Anti-Retroviral therapy (pre-HAART) population.

Methods: A three month pilot-Randomized Controlled Trial (RCT) compared the supplementation between five gram/day of Asp with a placebo containing the same amount of protein and calorie in HIV infected women. The study was conducted in Yaoundé, Cameroon. The disease predictors were CD4 T-cells and viral load. Common nutritional markers were also assessed. Statistical analyses carried out non-parametric tests and the size effect of each interaction was calculated.

Results: There were no differences observed on the immune and virological markers during the pilot-RCT. Nutritional markers were improved. Both groups registered a weight increase of 0.65 Kg, $p < 0.05$ for the placebo and 0.5 Kg, $p > 0.05$ for Asp. The cholesterol decrease was significant for the Asp group -0.14 g/l, $p < 0.05$. The hemoglobin and erythrocyte count did not significantly improve. The antioxidant serum status differ significantly $p < .001$ with a large size effect $r = .51$ between the groups, $+56$ μ M for Asp and -22 μ M for the placebo.

Conclusions: The observed stabilization of the immune markers under Asp supplementation can be considered encouraging. The increase of antioxidant capacity and the lower cholesterol levels should be a focus in future research. Moreover, we would recommend further research on natural nutritional interventions in larger doses and on a larger population. Nutritional intervention with a natural local product can improve the pre-HAART phase as prevention against complications in the chronic HIV infection.

Key words: HIV, pre-HAART, supplement, spirulina, natural product, antioxidant.

PO1916**EFFECTS OF MESEMBRYRYBRYANTHEMUM FORSSKALEI HOCHST SEEDS IN STREPTOZOTOCIN-INDUCED DIABETIC RATS**

N. Alfaris¹, D. Ahmad², N. AlqohaiZ¹, Z. Al Othman³

¹Department of Nutrition and Food Science, Princess Nora University, Riyadh, Saudi Arabia

²Department of Chemistry, King Saud University, Riyadh, Saudi Arabia

Background and objectives: The aim of present investigation was to study the effects of *Mesembryanthemum forsskalei* Hochst (Samh) seeds in streptozotocin-induced diabetic rats.

Methods: Thirty rats were administrated streptozotocin to induce diabetes and 6 rats were used as untreated diabetic control. Diabetic rats were fed with 5, 10 and 15% Samh seed alone or in combination with fatty diet i.e. 2% cholesterol for 6 weeks. Effects of Samh seed on blood glucose levels, lipid profiles and enzyme activities of diabetic rats were examined. In addition, total cholesterol (TC), triglyceride (TG) and high density lipoprotein-cholesterol (HDL-C) were determined. In addition, liver lipid profile, lipid peroxide production malondialdehyde (MDA) and reduced glutathione (GSH) were measured in diabetic rats' liver, and levels of superoxide dismutase (SOD), catalase (CAT) and glutathione peroxidase (GPX) were also determined.

Results: Diabetic rats treated with 15% Samh seed diet had significantly decreased levels of TC (40%), TG (46%) and HDL-C (31%) respectively. There was no significant effect in glucose levels in 15% Samh seeds treated rats for 6 weeks. A decrease in enzymes levels, AST (58.2%), LDH (1.6%), ALT (24.3%) and ALP (5.38%) in 5% Samh seeds diet treated rats were observed and were found near to untreated control. The samh seed diet supplemented with cholesterol significantly increased ($P < 0.05$) levels of liver peroxide production MDA, TC and TG in diabetic rats compared to the samh diet not supplemented with cholesterol. However, the samh seeds significantly decreased ($P < 0.05$) GSH levels.

Conclusions: Findings from the present study demonstrated that non fatty Samh seeds diet could have hypoglycemic and antihyperlipidemic effects in diabetic rats and could be useful means for the treatment of diabetic patients.

Key words: Samh seeds, streptozotocin, diabetes, hypoglycemic, antihyperlipidemic.

PO1917**ADVANCED GLYCATION END-PRODUCTS IN THE DIET AND RELATION WITH GLYCATED HAEMOGLOBIN LEVELS IN DM2 INDIVIDUALS**

D. Godoy^{1,2}, N. Silva¹, C. Vega¹

¹Carrera Nutrición y Dietética, Universidad de Valparaíso, Valparaíso, Chile

²Departamento Nutrición y Alimentos, Universidad de Valparaíso, Valparaíso, Chile

Background and objectives: Nutritional Intervention is recognized as a key component controlling type 2 Diabetes (DM2). Intake of food with high content of Advanced glycation end-products (PGA) has been related with a poor metabolic control in DM2 individuals. to the aim of this work was to determine the correlation between PGA intake and Glycated haemoglobin (HbA1c) in DM2 individuals.

Methods: Modified Intake frequency surveys were conducted to 41 individuals in 18 to 60-year-old age group, within all the categories of nutritional status, HbA1c between 6% and 10% no more than 3 months old. The variables studied covered the PGA and HbA1c dietetic intake. Data was tabulated in SPSS software Version 17, applying descriptive statistics for characterizing the sample and the diet. Quantitative variables were analyzed with Pearson correlation test, considering significant a $p < 0,05$.

Results: 59% of the individuals studied were female, 83% revealed overnutrition; the average of HbA1c was $7,5 \pm 1,6\%$. A positive relation, weak but significant between PGA intake of the diet and HbA1c ($r=0,368$ $p=0,01$) was obtained.

Conclusions: According to the current research, the nutritional recommendations in DM2 individuals should include food counseling intended for decreasing PGA intake in the diet.

Key words: Type 2 Diabetes Mellitus, diet, end-products of advanced glycation, glycated haemoglobin.

PO1918**ANTI-HYPERGLYCEMIC EFFECT OF VANILLIC ACID IN HIGH-FAT DIET INDUCED PREDIABETIC RATS**

S C. Shen¹, W C. Chang², J W. Chen², P L. Kuo¹, J S B. Wu²

¹Department of Human Development and Family Studies, National Taiwan Normal University, Taipei, Taiwan

²Graduate Institute of Food Science and Technology, National Taiwan University, Taipei, Taiwan

Background and objectives: High fat diet (HFD) fed rats, as one of the insulin resistant animal models, was widely used for understanding the mechanisms of diabetes. Phenolic compounds are widely present in considerable amounts in fruits, vegetables, and beverages in the human diet. Although studies indicated the anti-hyperglycemia effect of phenolic acid, however, there was no report for vanillic acid regarding to anti-diabetes. In this study, animal model was performed to investigate the effect of vanillic acid on anti-hyperglycemia and lipid metabolism in HFD-induced prediabetic rats.

Methods: The male Sprague-Dawley rats fed with HFD (60% fat) for 12 weeks were orally administered with vanillic acid (30mg/kg b.w.) during the last 4 weeks. The fasting blood glucose, insulin and triglyceride levels were determined. The protein expressions of lipid metabolism related enzymes, insulin signal transduction and inflammation factors were analyzed by western blotting.

Results: The fasting blood glucose of HFD rats (111.7 ± 9.2 mg/dl) significantly reduced after treated with vanillic acid (94.5 ± 1.9 mg/dl) during the last 4 weeks. The treatment of vanillic acid also reduced triglyceride levels in HFD rats. The protein expressions of adipose triglyceride lipase (ATGL) is increased, whereas the fatty acid synthase (FAS), acetyl CoA carboxylase (ACC) is decreased, suggesting the increase of lipolysis and decrease of lipogenesis, respectively, in HFD rats administered with vanillic acid. The increasing levels on IR, IRS-1, Akt, PI3K, Glut4 revealed improvement of adipose insulin signaling in HFD rats administered with vanillic acid. The expressions of NF-kB, COX-2, MCP-1 and ICAM-1 are decreased, indicating the alleviation on inflammation in HFD rats administered with vanillic acid.

Conclusions: The above observations suggest the potential of vanillic acid for developing into health food on preventing prediabetic syndromes.

Key words: vanillic acid, anti-diabetes, western blotting, insulin signaling.

PO1919**RELATIONSHIP BETWEEN MRNA LEVELS OF LEUCOCYTE ZINC TRANSPORTERS AND INFLAMMATORY MARKERS IN THE OBESE KOREAN WOMEN**

J. Kim^{1,2}, H. Noh², H. Paik², J. Chung³

¹Graduate School of East-West Medical Science, Kyung Hee University, Yongin, South Korea

²Department of Food & Nutrition, Seoul National University, Seoul, South Korea

³Department of Food & Nutrition, Kyung Hee University, Seoul, South Korea

Background and objectives: Obesity, a chronic inflammation state, has been associated with altered zinc metabolism. Two families of zinc transporters, the ZnT (SLC30) and the Zip (SLC29) family, are known to be involved in the regulation of zinc metabolism. In the current study, we examined the gene expression levels of leukocyte zinc transporters between obese (BMI=28.3±3.0, n=35) and non-obese (BMI=20.7±1.0, n=20) young women aged 18-28 yr, using quantitative real-time PCR.

Methods: Inflammatory markers such as high sensitivity C-reactive protein (hs CRP), tumor necrosis factor-alpha (TNF-α), and interleukin-6 were measured in serum.

Results: Zinc intake and serum zinc concentration did not differ between two groups, but inflammatory markers were significantly higher in the obese than in the non-obese (P<0.05). Among all zinc transporters examined, the Zip1 mRNA was most abundantly expressed in the leukocytes. The mRNA levels of many zinc transporters (ZnT4, ZnT5, ZnT9, Zip1, Zip4, and Zip6) were significantly lower in the obese than in the non-obese (P<0.01). The mRNA levels of ZnT4 and ZnT5 were negatively correlated with serum hs CRP concentrations (r=-0.35, P=0.008; r=-0.35, P=0.009) in the young women. The mRNA levels of two transporters were negatively correlated with serum TNF-α (r=-0.44, P=0.0009; r=-0.40, P=0.002). In addition, the Zip1 mRNA level was significantly correlated with serum hs CRP (r=-0.28, P<0.05) and TNF-α (r=-0.35, P=0.009) in young women.

Conclusions: Our study results suggest that inflammation state in obesity may be related with zinc metabolism through changes in the gene expressions of various zinc transporters.

Key words: obesity, zinc transporter, inflammatory marker

PO1920**VITAMIN B6 ELEVATES EXPRESSION OF IGFBP1, AN ANTI-TUMOR FACTOR, IN HEPG2 HEPATOMA CELLS**

S. Suidasari¹, P. Zhang¹, T. Hasegawa¹, N. Yanaka¹, N. Kato¹

¹Graduate School of Biosphere Science, Hiroshima University, Higashi-hiroshima, Hiroshima, Japan

Background and objectives: There is growing epidemiological evidence suggesting that vitamin B6 (B6) is a protective factor for several cancers. Our studies have also shown the protective effect of dietary B6 on colon carcinogenesis in rodents. Recent studies have suggested that the anti-tumor effect of B6 is ascribed to lowering cell proliferation, inflammation and angiogenesis. However, the detailed mechanisms remain yet unknown. Recently, our DNA microarray study has shown that B6 (pyridoxal: PL) treatment markedly elevated gene expression of IGFBP1 (IGF binding protein-1) in HT29 colon cancer cells. IGFBP1 is mainly produced in the liver, and has been thought to be a protective factor against cancer and cardiovascular disease (CVD). Thus, we hypothesized that the anti-tumor and anti-CVD effect of B6 is at least in part ascribed to higher expression of IGFBP1. This study was conducted to investigate the effect of B6 on the expression of IGFBP1 in HepG2 hepatoma cells.

Methods and results: This study demonstrated that 500 μM PL markedly induced IGFBP1 gene expression in HepG2 cells. Remarkable elevation of IGFBP1 protein by PL addition was not only observed in cell lysates, but also in medium of HepG2 cells. Treatment with ERK inhibitor suppressed the induction of IGFBP1 by PL. PL treatment elevated phosphorylated c-Jun protein, being a down-stream factor of ERK and involved in the promoter activity of IGFBP1.

Conclusions: This study provided evidence that B6 can induce expression of IGFBP1, anti-tumor and anti-CVD factor, by mechanisms involving ERK and c-Jun in hepatoma cells.

Key words: vitamin B6, cancer, cardiovascular disease, IGFBP1, hepatoma cells.

PO1921**EFFECTS OF RICE PROTEIN ON GLUCOSE HOMEOSTASIS AND DIABETIC NEPHROPATHY IN OBESE DIABETIC ZDF RATS**

M. Kubota¹, M. Yamaguchi², R. Watanabe³, A. Saito⁴, M. Fujii⁵, S. Fujimura^{1,2}, M. Kadowaki^{1,2}

³Department of Health and Nutrition, University of Niigata Prefecture, Niigata, Japan

⁴Department of Applied Molecular Medicine, Niigata University, Niigata, Japan

⁵Kameda Seika CO., LTD., Niigata, Japan

Background and objectives: Obesity is a risk factor of various diseases, e.g., diabetes, hypertension, and cardiovascular diseases. Especially, diabetes causes diabetic nephropathy and remarkably impairs the quality of life of the patients. It was reported that soy protein had beneficial effects on glucose homeostasis and diabetic nephropathy in diabetic animals. However, we have limited reports that dietary proteins have some beneficial effects on them. Therefore, we attempted to clarify whether rice protein (RP), a new vegetable protein material, has beneficial effects on glucose homeostasis and diabetic nephropathy in obese diabetic Zucker Diabetic Fatty (ZDF) rats.

Methods: Six week old male ZDF rats were fed 20% RP or casein (C) diets for 8 wk. Fasting blood glucose (every week), insulin, adiponectin, and other blood parameters were measured. Urinary albumin excretion, one of the standards for the diagnosis of kidney disease, was measured at 0, 2, 4, 6, 8 wk. In addition, renal glomeruli was morphologically observed to assess the damages of renal glomerular tissues.

Results: There was no significant difference in the fasting blood glucose levels between two groups. However, hemoglobin A1c was significantly suppressed in the RP group, compared with the C group. From these results, it is suggested that RP may improve glucose homeostasis. Urinary albumin excretion was significantly suppressed by RP at 8 wk. In addition, the mesangial matrix score, an index of glomerular tissue damage, was significantly suppressed by RP. From these results, it is suggested that RP has renoprotective effects in ZDF rats.

Conclusions: RP improves glucose homeostasis and delays the progression of diabetic nephropathy in obese diabetic rats.

Key words: Rice protein, ZDF rat, diabetes, obesity.

PO1922**EFFECTS OF SEVEN SELECTED COMPOUNDS IN TRADITIONAL ANTI-DIABETIC CHINESE HERB MEDICINE ON TH1/TH2 CYTOKINE SECRETIONS USING MOUSE PRIMARY SPLENOCYTES**

P.C. Chou¹, J.Y. Lin¹

¹Department of Food Science and Biotechnology, National Chung Hsing University, Taichung, Taiwan

Background and objectives: Type 1 diabetes (T1D) is a Th1-skewed autoimmune disease with chronic inflammation. To find potential compounds for anti-T1D, seven compounds in traditional anti-diabetic Chinese herb medicine, including baicalein, baicalin, berberine, emodin, geniposide, palmatine and wogonin, were selected to assay their effects on Th1/Th2 cytokine secretions in vitro.

Methods: The selected compounds were purchased at the highest available purity. Cell viabilities of mouse primary splenocytes treated with selected compounds at different concentrations for 72 h were determined using 3-(4,5-dimethylthiazol-2-diphenyl)-2,5-tetrazolium bromide assay. Non-cytotoxic optimal concentrations were further adopted to treat mouse primary splenocytes for 48 h. Cell culture supernatants were collected to determine Th1 (IFN- γ , IL-1 β , IL-2, and TNF- α) and Th2 (IL-4, IL-5, IL-6, and IL-10) cytokines using sandwich ELISA.

Results: The results showed that seven selected compounds exhibited differential cytotoxicities on the splenocytes. The IC50 of baicalein, baicalin, berberine, emodin, geniposide, palmatine, and wogonin were 98.6, 68.7, 28.9, 22.8, 54.5, 50.5, and 27.2 μ M, respectively, indicating that emodin has the strongest cytotoxicity, but baicalein shows the weakest toxicity on splenocytes. Based on the IC50, non-cytotoxic optimal doses of individual selected compounds were determined. Moreover, baicalein and baicalin treatments at 0 to 25 μ M significantly ($P < 0.05$) increased IL-6 and IL-10 secretions by the splenocytes. Berberine and emodin treatments at 0 to 6.25 μ M significantly inhibited IFN- γ secretions dose-dependently, but increased IL-10 productions. Baicalein, baicalin, berberine and emodin significantly increased Th2/Th1 cytokine secretion ratios, suggesting that these selected compounds have a Th2-inclination property.

Conclusions: Among seven selected compounds, baicalein, baicalin, berberine and emodin exhibited a Th2-inclination property. However, berberine and emodin treatments at appropriate concentrations may have the strongest potential for anti-inflammation and anti-T1D, via inhibiting Th1 cytokine secretions, but increasing Th2 cytokine productions.

Key words: anti-inflammatory effects; berberine; emodin; primary splenocytes; Th1/Th2 cytokines

PO1923**RICE PROTEIN AMELIORATES PROGRESSION OF DIABETIC NEPHROPATHY IN NON-OBESE DIABETIC GK RATS**

R. Watanabe¹, M. Kubota², A. Saito³, T. Kumagai⁴, M. Fujii⁴, S. Fujimura⁵, M. Kadowaki⁵

¹Department of Health and Nutrition, University of Niigata Prefecture, Niigata, Japan

²Center for Transdisciplinary Research, Niigata University, Niigata, Japan

³Department of Applied Molecular Medicine, Niigata University, Niigata, Japan

⁴Kameda Seika, CO., LTD. Niigata, Japan

⁵Department of Applied Biological Chemistry, Niigata University, Niigata, Japan

Background and objectives: The increase of type 2 diabetes mellitus (T2DM) patients is becoming a serious problem all over the world. T2DM is associated with various complications such as diabetic nephropathy. Diet therapy is an important treatment to delay the progression of diabetic nephropathy. Rice is a staple food as a major source of not only energy but also protein in Asian countries. Therefore, to evaluate the quality of protein on diabetes and diabetic nephropathy, we focused on the effect of rice protein (RP), a new vegetable protein material, in non-obese diabetic Goto-Kakizaki (GK) rats.

Methods: Seven week old male GK rats were fed 20% RP or casein (C) in high-sucrose (30% sucrose) diets for 6 or 15 wk. Diabetes-related parameters in the blood, urinary albumin and phosphorus excretion, and gene expressions in the kidneys of inflammatory cytokines and heme oxygenase 1 (Hmox1), the enzyme related to the antioxidative potency, were measured, and renal histology was evaluated.

Results: RP did not show to improve fasting blood glucose, plasma insulin, and plasma adiponectin levels at 15 wk. However, RP significantly suppressed urinary albumin and phosphorus excretions compared with C. In morphological observation of kidney tissues, the expansion of mesangial matrix in renal glomeruli was significantly suppressed by RP. In addition, at as early as 6 wk, the gene expression of MCP-1 was not significantly increased in the RP group, but increased by C. The gene expression of Hmox1 in the RP group was higher than that of the C group at 6 wk.

Conclusions: These results strongly suggest that RP could delay the progression of diabetic nephropathy through suppression of inflammation and an increasing antioxidative potency.

Key words: Rice protein, Goto-Kakizaki rat, diabetic nephropathy.

PO1924**ANTIOXIDANT CAPACITY AND MINERAL CONTENTS OF FIVE SPECIES OF CUCURBITACEAE SEEDS FROM CAMEROON**

M.B. Achu Loh¹, J. Madah Silatsa¹, E. Fokou¹

¹Department of Biochemistry, Faculty of Science, University of Yaounde I, Yaounde, Cameroon

Background and objectives: Phytochemical compounds and minerals of Cucurbit seeds have antioxidant and antiradical activities that could help fight cancer. This work analyses some secondary metabolites, the total antioxidant capacity and antiradical ability of oils, the levels of phenols and minerals in the seeds of *Lagenaria siceraria*, *Cucumeropsis mannii*, *Cucurbita maxima*, *Cucurbita moschata* and *Cucumis sativus*, collected from different agro-ecological zones in Cameroon.

Methods: The phenol content was assayed using the Folin-Ciocalteu reagent, the total antioxidant capacity by the Ferric reducing antioxidant power method, the antiradical ability with respect to 1,1-Diphenyl-2-Picrylhydrazyl radical and the mineral composition by atomic absorption spectrophotometry.

Results: The results showed that saponins, tannins, flavonoids, alkaloids, phenols and triterpenes were present in all the seeds, except *C. mannii* which did not contain saponins. The total phenol content varied from 299 (*C. mannii*) to 735 mgEAG/100g dw (*C. maxima*). The total antioxidant capacity was high, ranging from 50 (*C. moschata*) to 97.78 mgEq catechin/g dw (*C. sativus*). *L. siceraria* seed oil had the highest antiradical activity (0.083 ml/mg), while *C. moschata* (0.034 ml/mg) and *C. maxima* (0.030 ml/mg) oils had the least. These seeds were rich in macro minerals, especially *C. moschata* with highest levels of phosphorus (810.26), potassium (681.38) and magnesium (586.21 mg/100g dw). *C. sativus* and *C. mannii* seeds had the highest calcium levels (90.06 and 87.80 mg/100g dw respectively). For trace elements, iron and zinc were predominant, with highest levels in *C. moschata* seeds (5.06 and 5.46 mg/100g dw respectively). These seeds also contained copper (0.11-0.59 mg/100g dw) and manganese (1.69-2.81 mg/100g dw).

Conclusions: These seeds have potential as anticancer agents and could also be added in diets to reduce mineral deficiencies (especially *C. moschata* seeds).

Key words: Antioxidant, antiradical activities, minerals, Cucurbitaceae.

PO1925**THE WEIGHT OF ALGERIAN CHILDREN IS MOVING TOWARDS OBESITY**

C. C. Mekhancha-Dahel¹, W. Adjali-Hassani², R. Karoune¹, N. Bouzenada²

¹Université Constantine 1, ALNUTS, INATAA, Constantine, Algeria

²SEMEP, EPSP Ben M'Hidi, Constantine, Algérie

Background and objectives: The nutritional transition in Algeria develops like most southern countries. The presence of thinness and obesity is a real problem for care in these countries unprepared for this change. Overweight has been reported since 2002 among Algerian school children since the data fluctuate significantly. Our aim is to understand the evolution of the situation in a large city in Algeria.

Methods: Cross-sectional surveys of school children aged 6-18 years from Constantine (Algeria) were carried out in 2004 (4018), 2006 (2481), 2007 (1388) and 2011 (2048). Anthropometric measurements of weight (kg), height (cm) were collected in a standardized way. BMI is calculated and percentage of obesity, overweight and thinness are presented according frequently used classification (IOTF, 2000, 2007).

Results: Data show that all children are exposed to overweight and obesity and it appears a increase : 5.6% in 2004; 4.8% in 2006, 5.6% in 2007 and 11.1% in 2011. The high percentage of overweight occurred in girls ($p < 0.05$). Instead thinness seems stable: 5.2% in 2004, 6.7% in 2006, 7.4% in 2007 and 5.6% in 2011. According to the IOTF references, overweight (including obesity) school children living in disadvantaged areas are all affected by overweight than others. The observed rates are at levels similar to those reported in other parts of the country and at intermediate levels to those reported in Europe.

Conclusions: These data make it possible to think that Algerian school children weight status confirm a process of transition. An unbalanced diet rich in sugar and fat must be the predisposing factor, particularly due to snacking. Adoption of preventive measures targeting young people in schools is urgent.

Key words: obesity, schoolchildren, Constantine, Algeria.

PO1926**DIETARY PATTERNS AND LIPID LEVELS IN A LITHUANIAN ADULT POPULATION**

V. Kriaucioniene¹, J. Petkeviciene¹, J. Klumbiene¹

¹Department of Preventive Medicine, Lithuanian University of Health Sciences, Kaunas, Lithuania

Background and objectives: Nutrition plays an important role in the development of dyslipidemias. Dietary patterns might have a greater effect on dyslipidemias than any single food item. The aim of the study was to evaluate relationship between dietary patterns and lipid levels in Lithuanian adult population.

Methods: A cross-sectional health survey was carried out in randomly selected sample (N=1739) of Lithuanian population aged 25-64. Food frequency questionnaire was used for evaluation of dietary habits. Factor analysis was employed in order to reduce the number of food items. Serum lipids were determined using enzymatic methods. Multiple linear regression models were fitted to test the effect of dietary patterns on lipid levels controlling for age and body mass index.

Results: Mean value of serum total cholesterol was 5.60 (1.16) mmol/l in men and 5.51 (1.14) mmol/l in women. The factor analysis extracted four main factors, which accounted for 49% of the total variance in food intake in both genders. In men, 'Vegetables and fruits' factor (i.e. fresh vegetables, fruits, and boiled vegetables) was inversely associated with total cholesterol level ($r = 0.192$; $p = 0.017$). 'Light food' factor (i.e. poultry, fish, porridges, and cereals) contributed negatively to total cholesterol and low-density lipoprotein cholesterol level. Higher score of 'Heavy food' factor (i.e. meat and meat products, and potatoes) was related to a higher level of triglyceride ($r = 0.147$; $p = 0.046$). The negative association was found between 'Snacks' factor (i.e. cheese and confectionery) and the level of high-density lipoprotein cholesterol ($r = 0.092$; $p = 0.003$). In women, 'Light food' factor was inversely related to the level of low-density lipoprotein cholesterol ($r = 0.129$; $p = 0.042$).

Conclusions: The present study identified four main diet patterns that were associated with lipid levels in a Lithuanian adult population. The interventions aimed at reducing the prevalence of dyslipidemias should focus on identified dietary patterns.

Key words: dietary patterns, lipids.

PO1927**GLYCEMIC INDEX, GLYCEMIC LOAD, AND FIBER INTAKE AND RISK OF ADENOCARCINOMAS AND SQUAMOUS CELL CARCINOMAS OF THE ESOPHAGUS**

P H. Lahmann¹, T. Ibiebele², P M. Webb², C M. Nagle², D C. Whiteman²

¹School of Population Health, University of Queensland, Herston Road, Herston, Australia

²Population Health Department, Queensland Institute of Medical Research, Herston/Brisbane, Australia

Background and objectives: Glycemic index (GI) and glycemic load (GL) have been investigated as etiologic factors for some cancers, but epidemiological data on possible associations between dietary carbohydrate intake and esophageal cancer are scant. We examined the association between GI, GL, and other dietary carbohydrate components and risk of esophageal cancer accounting for established risk factors.

Methods: We analysed data from a population-based Australian case-control study (2002-05) comprising 299 adenocarcinoma (EAC), 245 squamous cell carcinoma (ESCC), 337 gastro-oesophageal junction adenocarcinoma (EGJAC) and 1507 controls sampled from a population registry. Dietary information was obtained using a 135-item FFQ; GI and GL were derived from an Australian GI database. Multivariable logistic regression models, including adjustment for sex, were used to derive Odds Ratios (ORs).

Results: All three case groups tended to have a lower intake of fiber and protein, and higher intake of fat, total energy, and alcohol (ESCC only) compared to controls. GI was unrelated to all histological types. GL was not associated with risk of EAC and EGJAC, but was inversely associated with risk of ESCC (adjusted model, p trend=0.0006). We observed a 48% reduced risk of ESCC in the highest versus the lowest (reference) quartile. Further, mean intake of total carbohydrate and starch was related to similarly large risk reductions of ESCC. Mean fiber intake was strongly and inversely associated with risk of EAC, EGJAC and ESCC (all p trend <0.001). Risk reductions for all subtypes were of similar magnitude (28%-37% per 10g/day increment of fiber intake).

Conclusions: This study suggests a reduced risk of esophageal SCC with higher GL level, but provides no evidence for the role of GI in the development of any of the esophageal cancer types. Increased fiber intake appears to be comparably protective for all histological types.

Key words: esophageal cancer, glycemic index/load.

PO1928**CALCIUM INTAKE IN PATIENTS WITH MUSCULOSKELETAL DISEASES**

T. Nestares^{1,2}, A. Ramos^{1,2}, M. Gomez^{1,2}, M. Salinas², M. Lopez-Frias^{1,2}

¹Departament of Physiology, University of Granada, Granada, Spain

²Institute of Nutrition and Food Technology, University of Granada, Spain

Background and objectives: Calcium intake deficiency is associated with bone diseases. Musculoskeletal diseases (MD) are one of the main public health problems and the third leading cause of work disability (Tornero et al, 2002). The aim of the study was to establish the correlation between intake and serum levels for calcium in patients diagnosed of MD.

Methods: We recruited 77 outpatients (aged = 37.7 ± 9.6) with bone-muscular pathology diagnosed by functional and clinical variables in a rehabilitation clinic from Granada (Spain). They were divided in 3 groups according to their pain: cervical ($n = 29$), low back ($n = 24$) and knee ($n = 24$). Blood was drawn to determine serum calcium levels by colorimetric method using a commercial kit (SPINREAC). Dietary intake was assessed by a personal interview, using a food-frequency and 3-d diet record questionnaires. Data were analyzed using Nutriber software (Mataix and García, 2005). Student's T test for independent samples was used to determine significant differences between groups, using the SPSS software version 19.0.

Results: We found that 28.2% of the patients do not reach 2/3 of recommended Ca intake (DRIs 2011). Regarding the type of MD, there was greater number of subjects with insufficient Ca intake in low back pain group (45.5%) vs. 28% and 9 % in cervical and knee pain groups, respectively. The lower Ca intake is correlated with a lower dairy products intake ($P < 0.05$). However, serum calcium levels are within normal limits (8.5 -10.5 mg /day).

Conclusions: Lack of correlation between intake and serum levels reflect the homeostatic control of calcium (Mataix et al, 2006). Obtained results support the idea that an insufficient calcium intake must be a factor involved in the development of MD.

Key words: Musculoskeletal diseases, calcium, bone diseases.

PO1929**EFFECT OF A CARDIAC REHABILITATION PROGRAM ON THE EVOKED INFLAMMATORY SIGNALING AS A RISK FACTOR IN PATIENTS WITH CARDIOVASCULAR DISEASE**

M. Lopez Frias^{1,2}, M. Gomez^{1,2}, A. Ramos^{1,2}, E. Sanchez², C. de Teresa³, J. Diaz Castro^{1,2}, J. Ochoa^{1,2}, T. Nestares^{1,2}

¹Departament of Physiology, University of Granada, Granada, Spain

²Institute of Nutrition and Food Technology, University of Granada, Spain

³Departament of Medicine, Andalusian Centre of Sports Medicine from the Hospital "San Juan de Dios", Granada, Spain

Background and objectives: Cardiac rehabilitation programs (CRP) improve quality of life and psycho-social functions and allows for the more efficient management of risk factors. The aim of the study was to evaluate the evoked inflammatory signaling as a risk factor in patients with Cardiovascular Disease (CVD) attending a CRP in comparison with those not attending the mentioned CRP.

Methods: We recruited 160 subjects suffering CVD and members of Cardiac Patients Association from Granada (Spain). They were divided into two groups: CRP (n=88, attending a CRP) and no-CRP (n=72, who refuse to attend the CRP). CRP was carried out during 12 months and consisted of combined dietary and exercise prescriptions. TNF- α , IL-6, IFN- γ , sICAM-1, sVCAM-1, MCP-1 and VEGF levels were determined in plasma using Milliplex based on the Luminex xMAP human CVD (Millipore Corporation, Missouri, USA). A two-tailed non-paired Student's t-test was used due to the normal distribution of results, and correlations were determined by Pearson's coefficient, using SPSS software version 19.0.

Results: Patients not attending CRP featured a remarkable over-expression of the proinflammatory cytokine IL-6 ($P = 0.012$), whereas no changes were observed in the other cytokines studied, according to Baum et al. (1999). Obesity and lack of physical activity are also determinants of impaired endothelial function (Steinberg et al., 1996) and tends to cluster with other risk factors including a pro-inflammatory state (Kapiotis et al., 2006), which might explain our findings.

Conclusions: These data suggest that CRP in CVD patients reduces one of the most noteworthy inflammatory biomarkers, improving the evolution of the disease.

Key words: Cardiac rehabilitation programs, inflammatory signaling, cardiovascular disease.

PO1930**ANTI-HYPERGLYCEMIC AND ANTI-OBESITY EFFECT OF ICHNOCARPUS FRUTESCENS, LINN. ON STREPTOZOTOCIN INDUCED DIABETIC RATS**

²National Centre for Laboratory Animal Science, National Institute of Nutrition, Hyderabad, India

Background and objectives: *Ichnocarpus frutescens* is commonly known as Indian Sarsaparilla, highly regarded in Ayurvedic medicine for the treatment of diabetes, and considered as a substitute for *Hemidesmus indicus*. This plant is also used by native tribes in atrophy, convulsions, cough, dysentery, measles, tuberculosis and glandular tumors. The present study summarizes the observations on the administration of Hexane, Ethyl acetate and Methanol extracts of *I. frutescens* for its anti-diabetic and anti-obesity activity on the streptozotocin induced diabetic rats.

Methods: Shade dried powdered leaves was extracted with Hexane, ethyl acetate and methanol by percolation method. These extracts were concentrated under reduced pressure to yield a dry extracts and were subjected to phytochemical investigations to identify the phytoconstituents. 36 adult male WNIN rats taken for the study and were divided into six groups. Group I normal control rats and Group II diabetic control rats received standard diet. Group III, IV and V diabetes induced rats received extracts mixed diets. Group-VI rats treated with Gliberclamide. Biochemical parameters for anti-diabetic activity, body composition by total body electrical conductivity (TOBEC) for anti-obesity activity and bone mineral contents by dual X-ray absorptiometry were studied.

Results: Blood glucose, serum hepatic marker enzymes and lipid levels were significantly reduced in diabetic rats treated with extracts and this was more pronounced with the ethyl acetate extract. A significant increase in the lean body mass, bone mineralization seen in the rats treated with extracts. Histology revealed a reduction in liver steosis and an increase in the architecture of islets of the pancreas.

Conclusions: The present study suggests that, the hexane, ethyl acetate and methanol extracts derived from the aerial parts of *I. frutescens* have beneficial effects in curing diabetes mellitus, and new antidiabetogenic drugs can be developed from aerial parts of *I. frutescens*.

Key words: Diabetes, anti-obesity, bone mineralization, steosis.

PO1931**CATALASE POLYMORPHISMS IN CHILDHOOD OBESITY**

A I. Ruperez¹, J. Olza¹, M. Gil-Campos², R. Leis³, R. Tojo³, R. Cañete², A. Gil¹, C M. Aguilera¹

¹Department of Biochemistry and Molecular Biology II, University of Granada, Granada, Spain

²Unit of Pediatric Endocrinology, Reina Sofia University Hospital, Córdoba, Spain

³Unit of Investigation in Nutrition, Growth and Human Development of Galicia, University of Santiago de Compostela, Santiago de Compostela, Spain

Background and objectives: Catalase (CAT) is one of the major enzymes of the antioxidant systems. Previous studies have proven that genetic variations in the CAT gene are putative risk factors for metabolic disease. Single nucleotide polymorphisms (SNPs) in the promoter region have been associated with hypertension and impaired glucose tolerance. In the present study we analyzed the association of candidate CAT SNPs with childhood obesity and its related phenotypes.

Methods: This is a case-control study in which we recruited 194 obese children (105 male, 89 female) and 191 normal-weight children (110 male, 81 female) aged 3-13. A total of 14 SNPs in the CAT gene were selected from the HapMap and NCBI databases based on their location, function and minor allele frequency. Genotyping was performed with the Illumina GoldenGate assay. Statistical analysis was performed with PLINK and SPSS 15.0. Erythrocyte catalase activity was determined spectrophotometrically.

Results: SNPs located in the promoter region showed a significant association with obesity: rs769214 [OR=1.42; CI 95%:1.03,1.96; P=0.035] and rs1049982 [OR=1.41; CI 95%:1.02,1.95; P=0.039]. Serum catalase values were significantly decreased in obese children (90±2 KHb) compared to normal weight children (104±3 KHb) (P<0.001). Both SNPs were associated with higher BMI, BMI Z-Score, weight, plasma fatty acid-binding protein 4 and apolipoprotein B and lower plasma cortisol levels. However, none of the studied SNPs was associated with catalase activity.

Conclusions: SNPs rs769214 and rs1049982 seem to play a role in childhood obesity. The nature of this relation remains unknown, however, the association of these promoter SNPs with obesity biomarkers may indicate a role of CAT in the early onset obesity that needs to be elucidated in further experiments. Acknowledgements: This study was funded by: ISCIII-FIS [PI 020826, PI051968], Junta de Andalucía [PO6-CTS 2203, 0098/2005], and ISCII-FIS-RETIC [Red SAMID RD08/0072/0028].

Key words: catalase, single nucleotide polymorphism, childhood obesity.

PO1932**NUTRITIONAL STATUS AND INTERVENTIONS IN CHILDREN HOSPITALIZED FOR PLEURAL EMPYEMA**

K. Huysentruyt¹, J. Willekens¹, I. de Schutter², E. de Wachter², A. Malfroot², T. Devreker³, Y. Vandenplas³, J. de Schepper⁴

¹Department of Pediatrics, UZ Brussel, Brussels, Belgium

²Department of Pediatrics - Pulmonology, UZ Brussel, Brussels, Belgium

³Department of Pediatrics - Gastro enterology, UZ Brussel, Brussels, Belgium

⁴Department of Pediatrics - Endocrinology, UZ Brussel, Brussels, Belgium

Background and objectives: Prolonged fever, pain and surgical interventions put otherwise healthy children with pleural empyema at risk for prolonged hospitalization and weight loss. Our aims were to investigate the change in body weight during hospitalization and two weeks after discharge, and to determine clinical risk factors for weight loss during hospitalization.

Methods: Retrospective review of the medical records of 18 boys and 18 girls hospitalized with pleural empyema in UZ Brussel (2007-2011) for data regarding age, length of stay (LoS), stay in pediatric intensive care unit (PICU), nutritional interventions, body weight and height during hospitalization and at outpatient follow-up (n=28) 2 weeks after discharge.

Results: Median (range) age and LoS were 3.45 (1.0-14.8) years and 19.25 (10-37) days. Body weight and height was reported at admission for 36 and 28 children, and at follow up for 28 and 27 patients. Minimal body weight during hospitalization was retrieved for 26 children. 7 (19.4%) patients received a nutritional intervention: 6 parenteral nutrition and 1 oral supplements. Children receiving a nutritional intervention had a significantly longer LoS (p=0.01) and stay on intensive care (p=0.03). 21/26 (80.8%) patients lost weight during hospitalization, with 38.0% and 9.5% losing respectively >5% and >10% of their initial body weight. Two weeks after discharge, 15/27 (55.6%) patients did not yet reach their initial weight for height (WFH) z-score. Maximal percentage weight change during hospitalization did not correlate with age, LoS or days on PICU.

Conclusions: Although children with pleural empyema were infrequently weighed during hospitalization, >10% weight loss was documented in 7.7%. Nutritional intervention was started in one fifth of the children, especially in children with a stay on intensive care and a longer LoS. We recommend weight surveillance and more frequent nutritional interventions in severe infections such as empyema.

Key words: child; empyema; nutritional status; under-nutrition.

¹⁰Institute of Preventive Medicine, Copenhagen University Hospitals, Copenhagen, Denmark

Background and objectives: The effect of dietary protein and/or glycemic index (GI) on metabolic syndrome (MetSyn) status has not been investigated in large-scale intervention trials. This study aimed to investigate the effect of weight loss and weight maintenance with diets varying in protein and GI on MetSyn status within the DiOGenes study, a randomized, controlled dietary intervention.

Methods: 938 overweight/obese adults from eight European countries entered an 8-week low-calorie diet (LCD) period. 773 adults who lost $\geq 8\%$ of body weight were randomized to one of five ad libitum diets for 6 months: low-protein (LP)/low-GI (LGI); LP/high-GI (HGI); high-protein (HP)/LGI; HP/HGI; and control diet. MetSyn was defined using the National Cho-

lesterol Education Program criteria (2001). MetSyn status was assessed at baseline, post-LCD and post-intervention, by using a standardized, continuous MetSyn score. A greater absolute decrease in MetSyn score indicates a favourable outcome.

Results: Completers data was available for 661 (weight loss phase, i.e. baseline and post-LCD) and 434 (weight maintenance phase, i.e. post-LCD and post-intervention) participants. Weight loss during the LCD significantly reduced total MetSyn score (-1.48 vs. -4.45, $P < 0.001$). During weight maintenance, changes in MetSyn score differed significantly between the dietary groups, with the highest increase observed in the LP/HGI group ($P = 0.039$, partial $\eta^2 = 0.023$), supporting earlier evidence that a diet with an increased ratio of protein to carbohydrate that includes low GI foods has beneficial effects on MetSyn in obese individuals. Protein, GI or their interaction did not independently affect MetSyn score.

Conclusions: In this sample of European overweight/obese adults, a moderately-high protein diet, which incorporates low, as opposed to high-GI foods, was beneficial in MetSyn management following weight loss. Acknowledgements: The Diogenes project is funded by the European Union (Contract no FOOD-CT-2005-513946).

Key words: Diogenes, obesity, protein, glycemic index, metabolic syndrome.

PO1934**SPECIFIC PLASMA PROTEINS IN PATIENTS SUFFERING FROM HEAD AND NECK CANCER WITH OR WITHOUT NUTRITIONAL SUPPORT. PRELIMINARY STUDY**

O. Casbarien¹, C. Silva², M.S. Feliu², A. Badía¹, N. López Delgado¹, M. Perman³, A. Navigante¹, N. Slobodianik²

¹Angel Roffo Institute, Buenos Aires, Argentina

²Department of Nutrition School of Pharmacy and Biochemistry University of Buenos Aires, Buenos Aires, Argentina

³Italian Hospital, Buenos Aires, Argentina

Background and objectives: Previous results demonstrated that a group of patients suffering from head and neck cancer showed an impairment of nutritional status and inflammation. The objective of this work was the comparison of the levels of specific plasma proteins, in patients who received oral intake of a nutritional supplement versus a group that couldn't take it.

Methods: Fourteen adult patients, were attended in the A. Roffo Institute, with local advanced head and neck cancer, underwent therapy with chemoradiotherapy; seven of them completed the oral intake of nutritional support (S) and the other couldn't tolerate it (NS). The Ethics Committee of the School of Pharmacy and Biochemistry (University of Buenos Aires)

approved the study and participants gave informed consent before recruitment. The nutritional supplement joined to the habitual diet, was administered during 60 days (Supportan®, Fresenius-Kabi) and provides 500 Kcal/day, P% 27, F% 40 (2 g EPA provided by fish oil, MCT and vegetal oils) and 33% of carbohydrates. Blood samples were collected from fasten patients. Specific plasma protein fractions: TTR, transferrin, Apo A-I, Apo B and PCR were measured by single radial immunodiffusion technique (Biocientífica SA, Argentina and Binding Site, UK).

Results: Results were expressed as mg/dL, $X \pm SD$ (S vs NS): TTR: 21.2 ± 8.9 vs 17.7 ± 7.4 ; Transferrin: 188.9 ± 36.1 vs 157.9 ± 49.0 ; ApoA: 124.6 ± 30.6 vs. 106.2 ± 27.1 ; ApoB: 136.1 ± 44.7 vs 103.8 ± 35.8 ; PCR: 1.4 ± 1.8 vs 2.8 ± 2.3 .

Conclusions: Group S showed higher values of TTR, transferrin, Apo AI and Apo B with lower levels of PCR than NS, although no statistical differences were observed between groups. Taking into account preliminary data, the results suggest that the administration of this oral supplement was useful to maintain the initial values of these plasma proteins. This effect was not observed in NS.

Acknowledgements: Supported by UBA (20020100100044).

Key words: head and neck cancer-plasma proteins-nutritional support

PO1935

HYPOGONADISM IS AN EARLY EVENT IN THE DEVELOPMENT OF METABOLIC SYNDROME IN FRUCTOSE-FED RAT

S. Anil¹, P. Uday kumar¹, V. Sai santosh¹, J. Sugeedha¹, V. Venu babu¹, T. Anupama¹, S. Ahamed Ibrahim¹

¹National Institute of Nutrition, Andhra Pradesh, Hyderabad, India

Background and objectives: High fructose consumption induces metabolic syndrome (MS), which predisposes to type II diabetes and cardiovascular diseases. MS is a complex pathophysiological entity associated with multiple risk factors including insulin resistance (IR), dyslipidemia, visceral obesity, and hepatic steatosis. In the present study we investigated the time dependent changes in MS parameters in fructose induced model of metabolic syndrome in Sprague-Dawley (SD) rats.

Methods: Weanling male SD rats (n=48) were divided into two groups: Control group (n=24) fed with starch based synthetic diet (AIN-93) and experimental group (n=24) fed with fructose based diet (54.5%) to induce MS. After 4, 8 and 12 weeks of feeding, OGTT and body composition by TOBEC were measured. At the end of each time point animals were euthanized and plasma and tissue samples were collected. Plasma insulin, total testosterone, glucose, triglycerides (TG), total

cholesterol were estimated. Hepatic steatosis was evaluated biochemically by TG estimation and further confirmed by H&E and Oil red staining. Testicular morphology was assessed by H&E staining. Student's t-test was used for statistical analysis.

Results: Food intake and visceral obesity was comparable between the groups at all time points. As early as 4th week plasma total testosterone levels were decreased (48%, $p < 0.05$) in fructose fed rats but normalized at later time points Insulin resistance developed in fructose fed rats at 8th week and it heightened at 12th week ($p < 0.05$). Plasma triglyceride levels were increased ($p < 0.05$) in fructose fed rats at 8th and 12th weeks. Liver triglycerides were increased ($p < 0.05$) in fructose rats at all time points.

Conclusions: Hypogonadism and hepatic steatosis were the early changes in fructose induced model of MS. Further, in this model Insulin resistance was developed in the absence of visceral obesity.

Key words: High fructose, metabolic syndrome, hypogonadism.

PO1936

UNYDIET: A GLOBAL COMPUTER PROGRAM DEVELOPED TO PERSONALIZE NUTRITIONAL ASSESSMENT WITH UPDATED FUNCTIONS

L. Garcia de Diego¹, M. Cuervo¹, J.A. Martinez¹

¹Department of Food Sciences and Physiology, University of Navarra, Pamplona, Spain

Background and objectives: Different nutritional assessment instruments can evaluate the health status of an individual calculating nutritional needs and intake as well as specific nutritional features and predict the possible development of chronic diseases. Currently, there are several criteria and questionnaires that allow us to make a prognosis of health status and to assess the quality of life, as related to nutrition of an individual in a quick and easy way. The aim of this project was to design a new program in which all these approaches are included.

Methods: In order to achieve this goal, a search was carried out in different databases such as PUBMED or MEDLINE, as well as in virtual libraries related to clinical nutrition, pharmacology, quality of life or physical education and in scientific societies websites related to medicine, nutrition and dietetic; using different keywords depending on the module that was being worked: Anthropometry, Medical History, Diet History, Diagnosis, Quality of life, Fitness, Energy Expenditure and Diet.

Results: The result is a computer program that can be used on any operating system as it has been performed under Java Swing, using SQLite database and some external libraries such

as JfreeChart for plotting graphs. This application includes different screening tools through which you can: assess nutritional status by anthropometrics, biochemical measurements, clinical data, psychosocial traits including genetic risk of developing a disease by an individual as well as to evaluate his/her quality of life. Also, the program included several diagnostic criteria for diseases such as the metabolic syndrome and other eating disorders.

Conclusions: UNYDIET is a prototype of software useful for educators, scientists, clinicians and nutritionists because of the great number of tools included. It also offers the possibility of creating new and individualized utilities.

Key words: Software, nutrition, screening, questionnaire, diagnostic criteria.

PO1937

DETERMINING ENERGY AND PROTEIN REQUIREMENTS BY INDIRECT CALORIMETRY AND 24-HOUR URINARY UREA NITROGEN IN ADULT PATIENTS WITH SKELETAL FRACTURES

M. Ruiz¹, S. Gonzalez¹

¹Universidad del Bio-Bio, Chillán, Chile

Background and objectives: Pathological skeletal trauma states are associated with hypermetabolic and hypercatabolic states. The objective was to determine energy requirements by indirect calorimetry and protein requirements by urinary urea nitrogen.

Methods: This was a descriptive transversal study of 10 patients (6 leg fractures and 4 arm fractures). Weight, height, and BMI were measured. Resting metabolic rate was evaluated by the indirect calorimetry method (RMR IC) after overnight fasting (10-12 h) and for 30 min at physical and mental rest. The exclusion criteria were: fever, respiratory disease, anaerobic metabolism, and use of hypo- and hypermetabolic medication. Assessment included protein catabolism evaluation by 24-h urinary urea nitrogen (UUN), trauma factor (RMR CI/BMR Harris-Benedict equation), and energy metabolism [(RMR IC x 100)/BMR FAO/WHO/UNU 2001]. The statistical analysis included central tendency and dispersion measurements and descriptive statistics.

Results: The sample consisted of 10 patients (8 men and 2 women) aged between 26 and 63 years with a mean of 4.5 d post fracture. The nutritional state of the subjects was 20% normal, 70% overweight, and 10% obese. Mean RMR CI was 1525 kcal/d (1110-1730 kcal/d) and mean UUN was 8.23g/24/h, which was classified as minor. The trauma factor was 0.97; 60% were classified as hypometabolic, 30% normometabolic, and 10% hypermetabolic.

Conclusions: A total calorie intake of 22.80 kcal/kg/d and 1.05g/kg/d protein intake could be sufficient for the patients under study.

Key words: Resting metabolic rate, protein requirements, skeletal trauma, adult.

PO1938

HYPOCALORIC DIET WITH CARBOHYDRATE EATEN MOSTLY AT LUNCH AND PROTEIN MOSTLY AT DINNER INCREASES FASTING SERUM GLUCOSE

R D M. Alves¹, F C E. Oliveira¹, K. Pfrimer², E. Ferriolli³, J. Bressan¹

¹Department of Nutrition and Health, Federal University of Viçosa, Viçosa, Brazil

²Department of Nutrition and Metabolism, São Paulo University, Ribeirão Preto, Brazil

³Department of Clinical Medicine, São Paulo University, Ribeirão Preto, Brazil

Background and objectives: Obesity is known to be a risk factor for many chronic diseases. Recent evidences suggested that a diet with carbohydrates eaten mostly at dinner have additional metabolic benefits compared to a conventional hypocaloric diet in obese individuals. Little is known about the effects of a diet with carbohydrate eaten mostly at lunch. This study aimed at evaluating the metabolic effects of a hypocaloric diet with carbohydrate eaten mostly at lunch and protein mostly at dinner.

Methods: Twenty-one healthy men aged between 20-43 years with BMI ranged from 26.5 to 35.2 kg/m² were included in this 8-week randomized clinical trial. The hypocaloric diet prescribed to control group included a balanced lunch and dinner. To the experimental group a hypocaloric diet with a high-carbohydrate/low-protein lunch and a high-protein/low-carbohydrate dinner was prescribed. Weight, body composition using deuterium isotope and fasting serum glucose, insulin and lipid profile were evaluated at baseline and at end of the study. The t test, for groups comparison, and paired t test, for within group comparison, were performed by using the SAS software.

Results: Despite no difference between groups (P>0.05), both groups significantly reduced body weight, yet, a significant reduction in the body fatness was observed only in the experimental group (P<0.05). Serum glucose increased in the experimental group (P=0.0049) while in control group serum insulin decreased (P=0.0314) and HDL-cholesterol increased (P=0.0293).

Conclusions: Thus, a hypocaloric diet with carbohydrate eaten mostly at lunch and protein mostly at dinner does

not seem to have better metabolic effects than a conventional weight loss diet, mainly considering glucose homeostasis and HDL-cholesterol. Acknowledgements: Coordenação de Aperfeiçoamento de Pessoal de Nível Superior-CAPES, Conselho Nacional de Desenvolvimento Científico e Tecnológico-CNPq, and Fundação de Amparo à Pesquisa no Estado de Minas Gerais-FAPEMIG.

Key words: Carbohydrate, protein, body composition, obesity, glucose homeostasis.

PO1939

THE RELATIONSHIP BETWEEN BREASTFEEDING AND POSTPARTUM WEIGHT LOSS - A SYSTEMATIC REVIEW AND CRITICAL EVALUATION

C. Neville¹, M. McKinley¹, V. Holmes¹, D. Spence², J. Woodside¹

¹Centre for Public Health, Queen's University Belfast, Belfast, United Kingdom

²School of Nursing and Midwifery, Queen's University Belfast, Belfast, United Kingdom

Background and objectives: Pregnancy and the postpartum period is a time of increased vulnerability for weight gain or retaining excess body fat in women. Breastfeeding (BF) has been shown to have many health benefits for both mother and baby, however its role in postpartum weight management is unclear. Our aim was to systematically review the literature published to date examining the relationship between BF and postpartum weight loss and maternal body composition.

Methods: Electronic literature searches were carried out using MEDLINE, EMBASE, PubMed, Web of Science, BIOSIS, CINAHL and British Nursing Index. Searches covered publications up to 12/06/2012. This systematic review included observational studies (prospective and retrospective) carried out in BF mothers (exclusively or as a sub-group), who were less than or equal to 2 years postpartum and with a BMI >18.5kg/m², with an outcome measure of change in weight and/or body composition.

Results: Thirty-seven prospective studies and 8 retrospective studies met the selection criteria; studies were stratified according to study design and outcome measure. Studies were heterogeneous, particularly in relation to sample size, measurement time-points and in the classification of BF and postpartum weight loss. The majority of studies reported little or no association between BF and weight loss (n=27, 63%) or change in body composition (n=16, 89%), although this depended on the measurement time-points and BF intensity. Any associations observed tended to be relatively small and were often confounded by other factors, particularly gestational weight gain.

Conclusions: This review highlights the difficulties of examining the association between BF and weight management in observational research and challenges the widely held belief that BF promotes weight loss. More robust studies are needed to reliably assess the impact of BF on postpartum weight management.

Key words: breastfeeding, postpartum, weight.

PO1940

EFFECT OF LOW-CARBOHYDRATE RESTRICTED DIET AND MODERATE CALORIC RESTRICTION ON HYPERGLYCEMIA, DYSLIPIDEMIA AND REVERSE CHOLESTEROL TRANSPORT IN OBESE RAT

S. Louala¹, A. Benyahia-Mostefaoui¹, M Y. Lamri-Senhadj¹

¹Département de Biologie, Laboratoire de Nutrition Clinique et Métabolique (LNCM), Université d'Oran, Oran, Algérie

Background and objectives: The low-calorie-diets were developed as a strategy for initiating or accelerating weight reduction including improved glucose metabolism and lipid profile. The aim of the study was to investigate whether 40% of caloric restriction compared to a low-carbohydrate restricted diet can improve the dyslipidemia, hyperglycemia and reverse cholesterol transport in obese rat.

Methods: Male Wistar rats (n = 18) consumed at weaning an obesogenic diet. At 405 ± 14g, obese rats were randomly divided into three groups (n = 6) consumed each for 4 weeks a low-carbohydrate restricted diet (LCR) (1.16MJ) or a calorie restricted diet (40% of energy of the standard diet (0.96MJ) (CR) or normocaloric diet (NC) (1,60MJ). At day 28, glycemia and serum total cholesterol (TC) and triacylglycerols (TG) concentrations were estimated. High density lipoproteins (HDL2 and HDL3) were separated and their contents and composition in lipids and apolipoproteins (apo's) were analyzed. Lecithin:cholesterol acyltransferase (LCAT) activity was determined.

Results: The two low calorie diets reduced serum TC values (-68% and -66%), TG contents (-62% and -52%) and glycemia (-62% and -46%), respectively compared to NC diet. However, LCR diet increased HDL-cholesterol (1.2- and 2- fold) and apo A-1 (1.16- and 1.26- fold) compared to CR and NC diets, respectively. In LCR and CR groups versus NC group, respectively, HDL3-phospholipids and HDL3-unesterified cholesterol were decreased (-52% and -38%) and (-86%) whereas, LCAT activity and HDL3-apo's were increased (+80% and +77%) and (+16% and +10%), respectively. The LCR diet elevated the content of HDL2-cholesteryl esters (+24% and +55%), respectively compared to both groups.

Conclusions: In obese rats, low carbohydrate restriction diet may have a more protective effect against cardiovascular risk by improving the anti-atherogenic metabolic pathway of cholesterol and triacylglycerols.

Key words: Rat, obesity, low calorie diets, LCAT.

PO1941

THE EFFECT OF POMEGRANATE EXTRACT AND JUICE INTAKE ON SATIETY PARAMETERS IN HUMAN VOLUNTEERS: A PILOT STUDY

A. Stockton¹, E. Al-Dujaili¹, I. Davidson¹, S. Drummond¹

¹Dietetics, Nutrition & Biological Sciences, Queen Margaret University, Edinburgh, UK

Background and objectives: The health benefits of antioxidant rich pomegranate have been recognized throughout history and shown to neutralise free radicals better than other juices (Basu, Penugonda, 2009). Appetite control has been implicated as an important factor in the dietary treatment of obesity (Drapeau et al. 2007), and research shows that dietary antioxidants may modify appetite by inducing satiety (Josic et al. 2010). This study aimed to investigate the effect of pomegranate extract and juice (PomeGreat, UK) intake on satiety parameters in human volunteers.

Methods: Ethical approval was granted by the Ethics Committee (Queen Margaret University). Volunteers (7 males and 22 females) participated in a randomised, double-blind, placebo-controlled parallel study [Mean BMI was 25.05±3.91kg/m² (18.57-32.46), age 34.5±13.7years (19-62)]. After randomisation, participants consumed either one pomegranate extract (n=15) or placebo capsule daily (n=14) for 3 weeks and then ate a lunch where they drank pomegranate or placebo juice (energy-matched low polyphenol drink) beforehand. Participants recorded their feelings of hunger, desire to eat, fullness and satisfaction on Visual Analogue Scales at 15 minute intervals for 120 minutes. Dietary history and habits were also recorded.

Results: The pomegranate extract group drinking pomegranate juice tended to report feeling less hungry (12%), had less desire to eat (21%), felt fuller (16%) and more satisfied (15%) than those who consumed the placebo. They also ate less (22%) on average (446.97g vs.574.25g; p=0.05) than the placebo group. Moreover, they rated their food as being significantly more palatable (p=0.05) than the placebo group.

Conclusions: This research indicates that pomegranate extract and juice can promote satiety by reducing hunger and desire to eat and enhancing fullness and satisfaction, while simultaneously increasing enjoyment of the food. It also suggests that pomegranate extract intake may have the potential to assist in reducing risk factors for overweight and obesity.

Key words: pomegranate, satiety, appetite, antioxidants, obesity.

PO1942

ANALYSIS OF DETECTION AND NUTRITIONAL APPROACH IN INTESTINAL HIGH-OUTPUT STOMAS

J J. Arenas Villafranca¹, J. Abiles¹, R. Romero Dominguez¹, A A. Fontalva Pico², G. Moreno Carretero², N. Gandara Adan², V. Faus Felipe¹

¹Pharmacy and Nutrition Department, Hospital Costa del Sol, Marbella, Spain

²General Surgery Department, Hospital Costa del Sol, Marbella, Spain

Background and objectives: Surgical approach of digestive cancer is one of the main causes of discharge stoma construction. These stomas are related to complications that have been widely described, but little is known about the development of high-output stomas.

Methods: A retrospective observational study was conducted, from January to June of 2011, on patients who underwent an output stoma. Universal variables, causes and type of surgery, nutritional and pharmacological treatment were collected. Presence and severity of complications, morbidity and mortality related to stomas were examined.

Results: Of 39 new stoma formations, 28.2% were ileostomies and 71.8% colostomies. Colorectal cancer was in 64% of cases the main cause of surgery. Complications associated with the stoma were present in 48.7% of the patients, the most frequent being stenosis. Six patients were identified with high-output stoma. Those stomas were located in colon in all patients, preserving the ileocecal valve in every case. Causes of high-output stoma were not identified in any case and the resected length of intestine did not statistically differ from those patients without high-output. All patients were wrongly advised to increase their oral fluid intake and in any case plasmatic magnesium was measured, no losses were treated with oral rehydration salts solutions and only two patients were referred to nutrition department. At discharge, no patient weights were controlled and no patient received nutritional recommendations for the management of the debit. 33% re-entered because of stoma complications.

Conclusions: High-output stomas are a common but little identified complication. They are not usually taken into account by clinicians, resulting in a lack of information about pathophysiology, parameters that define them and their related complications. An adequate nutritional support in these patients could reduce hospital re-entry and metabolic complications related to stoma losses.

Key words: Colostomy, high-output, hypomagnesemia, ileostomy, ostomies.

PO1943**EARLY PREDICTION OF DIETARY WEIGHT LOSS THERAPY EFFECTIVENESS**

B. Jablonowska-Lietz¹, M. Wrzosek², D. Wolanska³, G. Nowicka²

¹Promotion Centre of Healthy Nutrition and Physical Activity, National Food and Nutrition Institute, Warsaw, Poland

²Department of Pharmacogenomics, Medical University of Warsaw, Warsaw, Poland

³Department of Prevention of Diet-related Diseases, National Food and Nutrition Institute, Warsaw, Poland

Background and objectives: It is suggested that new strategies are needed for successful obesity prevention and treatment. To personalize weight-loss therapy and to predict its effectiveness, we assessed individuals' health locus of control, emotion regulation, and self-efficacy which can make them determined to eat well and exercise regularly.

Methods: The study group consisted of 48 individuals with BMI=32.15±2.02, mean age 39.70 ± 5.33 years. Recruited subjects participate in a 3-month dietary intervention program. Weight loss was assessed at each visit. Dietary compliance regarding energy and nutrient intake were monitored by 3-day food records. Before the dietary intervention all patients filled in the Multidimensional Health Locus of Control (MHLC) scale to assess the beliefs by which person determines his or her health status; the Courtauld Emotional Control Scale (CECS) for the assessment of emotion regulation; and the General Self-Efficacy Scale (GSE) to assess a general sense of perceived self-efficacy.

Results: The mean score in the dimension of internal control on the MHLC Scale was M = 26.33; SD = 4.98 and was related to successful weight loss (r = -0.61, p < 0.05). The mean score in the CECS total was M = 49.77; SD = 10.34 and was associated with frequency of sweets intake (r = 0.42, p < 0.05). Patients with low GSES statistically less frequently consult dieticians or try to lose weight on their own than the other GSES groups (s² = 9.65, df = 4, p = 0.047). There were no statistically significant differences between men and women in the scores of the Scales.

Conclusions: Introducing psychological perspective is infrequent in obesity treatment but it is a challenge, and also an opportunity to concentrate on patients' resources and may contribute to evaluation of the comprehensive treatment program.

Key words: obesity, weight-loss, psychological scales.

PO1944**ADIPONECTIN AND PREDICTION OF THE EFFECTIVENESS OF WEIGHT LOSS THERAPY**

B. Jablonowska-Lietz¹, M. Włodarczyk², D. Wolanska³, M. Wrzosek⁴, G. Nowicka⁴

¹Promotion Centre of Healthy Nutrition and Physical Activity, National Food and Nutrition Institute, Warsaw, Poland

²Department of Nutrigenomics, National Food and Nutrition Institute, Warsaw, Poland

³Department of Prevention of Diet-related Diseases, National Food and Nutrition Institute, Warsaw, Poland

⁴Department of Pharmacogenomics, Medical University of Warsaw, Warsaw, Poland

Background and objectives: There is a strong evidence suggesting that adiponectin plays an important role in modulation of lipid profile and insulin resistance, while its metabolic actions as an adipose-specific protein decreases proportionally to the rise in BMI. The relationship between adiponectin levels and BMI, % of total fat mass (%FM), VAT adipose tissue, HOMA-IR, and serum lipid profile during 3-months period (four visits) of weight-loss therapy was studied.

Methods: The recruited group consisted of 60 subjects of both sexes, 30-50 years old, with excess body weight: 30 ≤ BMI < 35, non-smokers, not under any pharmacological therapy. Plasma lipids, glucose, and insulin concentrations were determined by routine laboratory methods. Adiponectin levels were measured by ELISA assay. Insulin resistance index (IR-HOMA) was calculated using the following formula: insulin(μU/ml) × fasting blood glucose (mg/dl) / 405. Weight loss was controlled at each (of the four) visit by anthropometric and body composition measurements (BMI, %FM and VAT level assessed by bioimpedance, using TANITA MC 180 MA camera).

Results: There was a statistically significant correlations between adiponectin and serum lipids: HDL-cholesterol, total cholesterol/HDL-cholesterol ratio, LDL-cholesterol, serum triglycerides (p<0,05). All "obesity measures" (weight-loss, BMI, %FM, VAT) and HOMA-IR were negatively correlated with adiponectin level (p<0,05). It was also found that the strength of the relationship between adiponectin and VAT (assessed by linear regression) increases during a weight loss therapy (from r:-0,045 before therapy to r:-0,64 at the end of weight loss therapy, all p<0,05).

Conclusions: Adiponectin seems to be the one of the major factors, predicting the effectiveness of applied dietary program, obesity reduction and associated metabolic disorders. Acknowledgements: This study was supported by The Polish National Science Centre (N151923).

Key words: Adiponectin, weight loose, lipid profile, VAT, HOMA-IR.

PO1945**MA-PI MACROBIOTIC DIET AND TYPE 2 DIABETES. MULTICENTRIC STUDY**

C. Porrata-Maury¹, M. Hernandez-Triana², V. Ruiz-Alvarez², M E. Diaz-Sanchez², F. Fallucca³, W. Bin⁴, B. Baba-Abubakari⁵, M. Pianesi⁶

¹Macrobiotic Diet Service, Finlay Institute, La Habana, Cuba

²Department of Biochemistry and Physiology, Institute of Nutrition, La Habana, Cuba

³Centro Internazionale Studi Diabete, Roma, Italy

⁴Traditional Tibetan Medicine Hospital, Xining, China

⁵Tamale Teaching Hospital, Tamale, Ghana

⁶UPM Un Punto Macrobiotico, Roma, Italy

Background and objectives: Satisfactory results have been observed in long term interventions with macrobiotic vegetarian Ma-Pi diet (70% carbohydrate as whole cereals, 12% vegetable protein, 18% fat) in diabetic patients. The aim of this study was to evaluate the short term effect of this diet in type 2 diabetes.

Methods: A 21- day multicenter intervention was carried out in adults from Cuba (n=61), China (n=16), Ghana (n=23) and Italy (n=24), supported by Un Punto Macrobiotico, Italy. Biochemical indicators, body composition and blood pressure were measured at onset and intervention end. Changes were analyzed by univariate and multivariate statistical methods.

Results: Significantly (p=0,000) decreased: glycemia, 24,1%; cholesterol, 18,6%; LDL cholesterol, 21,5%; LDL/HDL ratio, 20,0%; cholesterol/HDL ratio, 18,2%; triglyceride, 23,4%; urea, 32,5%; capillary blood glucose (33,6%, in fasting; 37,9%, two hours after breakfast; 32,5%, two hours after lunch); blood pressure (systolic,7,5%; diastolic,6,1%); urine pH increased (13,6%). No adverse events were observed. Four components were extracted by Principal Component Analysis (PC), which accounted for 69,3% of the total variance: PC1 was characterized by lipid indicators, PC2 by glycemia and glycem profile, PC3 by blood pressure, PC4 by urea and urine pH. Similar behavior was evidenced for glycemia and glycem profile in all countries, according to One-Way ANOVA of the extracted PC2 scores, (p=0,237).

Conclusions: The 21 day intervention with Ma-Pi macrobiotic diet in type 2 diabetic adults improved carbohydrate, lipid and protein metabolism and blood pressure. The improvement of the carbohydrate metabolism showed a similar pattern in all countries.

Key words: Ma-Pi macrobiotic diet, type 2 diabetes, adults.

PO1946**SUGAR INTAKE IN CUBAN CHILDREN AND ADOLESCENTS**

I. Puentes¹, A. Cabrera-Martinez¹, M. Miranda-Diaz¹, M. Caridad-Romero¹, D. Matos¹, M. Hernandez-Lozano¹, C. Viera-Casiñol², V. Ruiz-Alvarez², M. Hernandez-Triana²

¹Department of Communitarian Nutrition, Institute of Nutrition and Food Hygiene, La Habana, Cuba

²Department of Biochemistry and Physiology, Institute of Nutrition, La Habana, Cuba

Background and objectives: High sugar consumption is associated with overweight, glucose intolerance, serum lipids modifications and predisposition to diabetes mellitus. Nutritional recommendations set the sugar upper level intake around 10% of the total energy intake. The objective of this study was to assess its dimension in the Cuban young population.

Methods: 873 children and adolescents (56 preschoolers, 768 school children and 49 adolescents, 4-16 y of age) included in studies of body composition, physical activity and daily energy expenditure by isotopic methods were submitted to semi-quantitative dietary recalls, 24 hours dietary recalls or 3 day weighed dietary records for the assessment of the sugar contribution to the total energy intake. Data were evaluated with the FAO CERES Software.

Results: High energy intake, fast foods and soft drinks; low consumption of fruits, vegetables, and micronutrients. Sugar intake doubled the nutritional recommendation. In some studied groups, one of each three children consumed more than three times the recommended daily portion.

Conclusions: The observed high sugar intake in all children and adolescents favours fat accretion and the high prevalence of NCDs in adulthood. Those results shall be urgently considered in the nutrition policy.

Key words: Adolescents, children, Sugar intake.

PO1947**THYROID HORMONE PRODUCTION IS ASSOCIATED WITH THE DIFFERENCE IN METABOLIC MARKERS BETWEEN OBESE AND OBESITY RESISTANT MICE**

J. Zhen^{1,2}, X. Tang^{1,2}, G W. Le^{1,2}, Y H. Shi^{1,2}, J. Sun^{1,2}, X R. Chen^{1,2}

¹State Key Laboratory of Food Science and Technology, Jiangnan University, Wuxi, Jiangsu, China

²Institution of Food Nutrition and Functional Factor, School of Food Science and Technology, Jiangnan University, Wuxi, Jiangsu, China

Background and objectives: Diet-induced obesity (DIO) and obesity resistance (DIO-R) are two different models characterized by different metabolic states. The aim of this study was to explore the association between thyroid hormones and different metabolic markers in DIO and DIO-R mice.

Methods: Sixty female C57B/L mice (4week old) were randomly divided into two groups: Group I (n=15, Control) received normal diet containing 5.34%fat; Group II (n=45) received high-fat diet (HFD) containing 19.57%fat. After 20 weeks, Group II subjects were selected and divided into two groups according to their body weight: DIO group (n=15) and DIO-R group (n=15). All animals were weighed and slaughtered after a 12-hour fasting. Concentration of blood glucose (FPG), plasma insulin (FINS), lipid parameters (TCH, TG, HDL-C and LDL-C) and thyroid hormones (T3, T4, FT3 and FT4) were measured. T3/T4 ratio and insulin resistance index (IRI) were calculated. Deiodinase-1(Dio1) which is the major source of circulating thyroid hormone was also determined in the liver by RT-PCR.

Results: Feeding the HFD for 26 weeks significantly increased body weight, FPG, FINS, and IRI, but significantly decreased the level of thyroid hormones in the DIO group, resulting in the development of hyperlipidemia and hyperglycemia. In contrast, the DIO-R group exhibited significantly higher level of thyroid hormones as compared to the DIO group and presented partial restoration in hyperlipidemia and hyperglycemia. Moreover, Dio1 mRNA expression in the DIO-R group was significantly higher than in the DIO-R group.

Conclusions: The present study indicates that thyroid hormones level is related to different metabolic markers between DIO and DIO-R mice, which may be attributed to the abnormal mRNA expression of Dio1 in the liver. Acknowledgements: Supported by the 12th Five-Year Plan for Science and Technology Development (No. 2012BAD33B05).

Key words: High-fat diet, obesity, obesity resistance, hyperlipidemia, hyperglycemia, thyroid hormones.

PO1948**BODY FAT MASS DETERMINATION OF ARGENTINEAN CHILDREN BY DEUTERIUM DILUTION TECHNIQUE AND ITS RELATIONSHIP TO LIPID PROFILE**

I. Fernandez¹, S M. Vidueiros¹, C. Napoli¹, A. Paganini², D. Bustamante², G. Tarducci^{2,3}, A. Pallaro¹

¹Department of Nutrition, Faculty of Pharmacy and Biochemistry, University of Buenos Aires, Argentina

²PROPIA, School of Medical Sciences, University of La Plata (UNLP), Buenos Aires, Argentina

³Physical Education Department, Faculty of Humanities (UNLP), Buenos Aires, Argentina

Background and objectives: Body composition, particularly body fat, is associated to non-transmissible chronic diseases. The aims of this study were to determine body fat mass (FM) in argentinean children using the Deuterium Dilution Technique (DDT) and to analyze its association with the lipid profile.

Methods: 98 children (51 boys, 47 girls), aged 6-12 years old, were recruited for the study. Weight (kg), height (cm), waist circumference (WC; cm) and triceps, biceps, subscapular and suprailiac skinfolds were measured. Body mass index (BMI; weight/height²) and sum of skinfolds (SK; mm) were calculated. Total Body Water was determined by DDT. Children received a weighed oral dose of deuterium oxide (0.5 g/Kg; 99%) and two samples of saliva (basal and post-equilibration period of 3 hours) were obtained. Deuterium concentration was determined by FTIR and FM% was calculated. Blood samples were collected. Total plasma cholesterol (CT; mg%) and triglycerides (TG; mg%) were determined by enzymatic-colorimetric technique. LDL cholesterol (LDL-C; mg%) was calculated using Friedewald equation.

Results: The FM% was 28.6 ± 7.4 (Boys: 25.5 ± 6.7 vs Girls: 32.0 ± 2.4; p<0.001). FM% was significantly correlated (0.05>p<0.0001) to BMI (r=0.74), WC (r=0.69), SK (r=0.88), CT (r=0.22), TG (r=0.45), and LDL-C (r=0.20).

Conclusions: As expected, girls showed higher FM% than boys. It was observed an association between fat mass and anthropometric measures and between fat mass and lipid profile, mainly with the triglycerides plasma levels. This study supports the importance of the determination of FM in the nutritional assessment of programs for the prevention and control of overweight and obesity in children. Acknowledgements: Supported by UBACyT 20020100100255, OIEA/RLA6064.

Key words: Body fat, children, deuterium dilution, lipid profile.

PO1949**GLUTAMINE MODULATES CHANGES TO SMALL INTESTINAL INTRAEPITHELIAL $\gamma\delta$ T LYMPHOCYTE EXPRESSION IN MICE WITH ACUTE DSS-INDUCED COLITIS***M.H. Pai¹, J.J. Liu², W.J. Chen³, C.L. Yeh⁴*¹Department of Anatomy, Taipei Medical University, Taipei, Taiwan²School of Medical Laboratory Science and Biotechnology, Taipei Medical University, Taipei, Taiwan³Department of Surgery, College of Medicine, National Taiwan University, Taipei, Taiwan⁴Department of Food and Nutrition, Chinese Culture University, Taipei, Taiwan

Background and objectives: This study investigated the effect of glutamine (GLN) on small intestinal intraepithelial lymphocyte (IEL) $\gamma\delta$ T-cell cytokines and immune regulatory factor gene expressions in a mouse model of dextran sulfate sodium (DSS)-induced colitis.

Methods: Mice were randomly assigned to a normal control group, or 2 DSS-treated groups. The control group (C) and one of the DSS group (DC) were fed with a common semipurified diet, while the other DSS-treated group (DG) were provided an identical diet except that part of the casein was replaced by GLN, which provided 25% of total amino acid nitrogen. The diets were fed for 10 days, then mice in the control group received distilled water and DSS groups were treated with distilled water containing 2.5% DSS for 5 d. At the end of the experiment, mice were sacrificed and small intestines were collected for histological examination. Intestinal IEL $\gamma\delta$ T-cell subset was isolated for the analysis of proinflammatory mediator gene expressions.

Results: Compared to normal mice, DSS-colitis resulted in lower IEL $\gamma\delta$ T-cells percentage and higher messenger (m) RNA expressions of interferon γ ; tumor necrosis factor α ; interleukin (IL)-17, complement 5a receptor, and keratinocyte growth factor by IEL $\gamma\delta$ T-cells. GLN administration enhanced the proportion of IEL $\gamma\delta$ T-cells, and the immunomodulatory mediator genes expressed by IEL $\gamma\delta$ T-cells exhibited decreases in colitis mice. The histological findings showed that the immunoreactive intensity of ZO-1 expression in intestinal mucosa was higher in DG than the DS group.

Conclusions: These results indicated that pretreatment with GLN promoted the proportion of small intestinal IEL $\gamma\delta$ T-cells, and downregulated $\gamma\delta$ T-cell-expressed inflammatory mediators that may consequently ameliorate the severity of DSS-induced intestinal epithelial injury.

Key words: glutamine, dextran sulfate sodium-induced colitis, intraepithelial lymphocyte, $\gamma\delta$ T-cell, inflammatory mediator.

PO1950**EFFICACY OF A LIFESTYLE INTERVENTION PROGRAM USING HEALTHY PLATE FOR TREATING DIABETIC SUBJECTS WITH OBESITY: A RANDOMIZED CONTROLLED TRIAL***T. Yamauchi^{1,4}, K. Yamauchi², T. Katayama³, N. Sakane¹*¹Division of Preventive Medicine, Kyoto Medical Center, Kyoto, Japan²Department of Nutritional Science, Nagoya University of Arts and Sciences, Aichi, Japan³Takarazuka University School of Nursing, Osaka, Japan⁴Nursing Department, Gamagori City Hospital, Aichi, Japan

Background and objectives: Portion size is an important determinant of energy intake. Then, we developed the Japanese-version portion size control plate. The aim of the study is to assess the efficacy and safety of a lifestyle intervention program using the portion control plate (Healthy plate®) to reduce the body weight and achieve the good glycemic control in diabetic subjects with overweight and obesity.

Methods: We randomized 19 diabetic subjects with overweight and obesity (body mass index (BMI) \geq 24, aged 20-70) to an intervention group including group-based lecture and counseling by a dietician incorporating a healthy plate (n=10) or waiting list control group (n=9). Exclusion criteria included insulin therapy, dementia, and chronic renal failure. Following initial lecture on diabetes and diet, subjects in the intervention group were contacted at 1, 2, and 3 months by the dietician for 2-hour group-based session. Subjects in the control received instructional handouts on diabetes knowledge, diet, and exercise. The primary endpoint was improvement of glycemic control as measured by glycosylated hemoglobin (A1C). The secondary endpoint was change in body weight, serum lipids, and diet-related quality of life. Analysis was done by intention to treat.

Results: Drop-out rate was 5.3 %. Subjects in the intervention group had a greater change (\pm SD) in weight from baseline at 3 month (-3.6 \pm 2.6 kg vs. -0.3 \pm 1.6 kg; p=0.04) and a trend in A1C from baseline at 3 month. The majority of subjects assigned to the intervention group reported the overall intervention was helpful and would recommend it to others. Adverse events were not reported.

Conclusions: The findings suggest that the healthy plate also enabled diabetic subjects to decrease body weight with safety.

Acknowledgements: This work was supported by JSPS KAKENHI Grant Numbers 23500825, 24501029.

Key words: Portion control plate, weight loss, diabetes, obesity.

PO1951**EFFECT OF ANDROGRAPHOLIDE ON STREPTOZOTOCIN-INDUCED DIABETIC CATARACT IN SPRAGUE-DAWLEY RATS.**

R.N. Ramavat¹, H. Nemani¹, S. Pothani¹, N. Turlapati², B. R. Geereddy¹

¹National Centre For Laboratory Animal Science, National Institute of Nutrition, Hyderabad, India

²Department of Zoology, Osmania University, Hyderabad, India

Background and objectives: Cataract, characterized by cloudiness or opacification of the crystalline eye lens, dramatically affects the quality of life. Duration of diabetes and the associated chronic hyperglycaemia increase the risk of development of cataract. Andrographolide, an active principle in the leaves of *A. paniculata* has shown significant anti-hyperglycaemic action in streptozotocin-induced diabetic rats. The present study was carried out to investigate the anticataractous potential of Andrographolide through its capacity to prevent streptozotocin-induced hyperglycaemic osmotic and oxidative stress.

Methods: 48 SD rats were taken for the study and divided into four groups of twelve animals each. Group I (control) rats received vehicle and hyperglycaemia was induced in experimental rats (Group-II, III and IV). Diabetic rats (Group II) (positive control) and Group III, IV diabetic rats treated with Andrographolide at two different doses. Eyes examined, using slit lamp bio microscope for incidence of cataract and expressed as percentage of total lenses in each group. Biochemical parameters were measured in the lens of control and experimental rats.

Results: Treatment with Andrographolide decreased the blood glucose levels in a dose-dependent manner. Significant decrease in both total and soluble protein was observed in group II compared to group I. Supplementation of Andrographolide improved both total and soluble protein levels in group III and IV compared to group II. The percentage of mature cataract lenses decreased to 52% and 28% in group III and IV respectively. The levels of antioxidant enzymes were also increased in group II.

Conclusions: In conclusion, a combination of glycemic control, antioxidant potential could be the mechanism in delaying the cataract formation by Andrographolide. Therefore, delaying of cataract associated with diabetes by treatment with Andrographolide merits further attention and can be explored for their potential antihyperglycemic and anticataractous properties.

Key words: Diabetic cataract, hyperglycemia, streptozotocin, andrographolide.

PO1952**POSTPRANDIAL EFFECTS OF POTASSIUM SUPPLEMENTATION ON VASCULAR FUNCTION AND BLOOD PRESSURE**

N. Blanch¹, P.M. Clifton², J.B. Keogh¹

¹School of Pharmacy and Medical Science, University of South Australia, Adelaide, Australia

²Baker IDI Heart and Diabetes Institute, Adelaide, Australia

Background and objectives: Increased potassium intake has been related to reduced blood pressure (BP) and improved vascular function. The effect of potassium supplementation on endothelial function and BP in the postprandial state is not known. The aim was to determine the effect of potassium supplementation on post prandial endothelial function, as assessed by flow mediated dilatation (FMD).

Methods: Thirty-two healthy, normotensive volunteers received a meal with 1300 mg (33mmol) potassium (HighK) and a control low potassium (LowK) 130 mg (3.3mmol) meal on 2 separate occasions in a randomized order. FMD and BP were measured while participants were fasting and at 30, 60, 90 and 120 minutes after the meal.

Results: There was a postprandial decrease in FMD in both groups. FMD decreased less after the HighK meal compared to the LowK meal ($p < 0.05$). Both meals produced a postprandial decrease in BP at 30 minutes which returned to baseline levels by 120 minutes. No significant differences in BP were observed between meals. There were no correlations between FMD and BP prior to randomization. FMD and BP were negatively correlated at 90 (SBP: HighK $r = -.55$, $p < .01$; LowK $r = -.54$, $p < .01$) and 120 minutes (SBP: HighK $r = -.56$, $p < .01$; LowK $r = -.42$, $p < .01$) after both meals, and at 30 (SBP: $r = -.39$, $p < 0.05$) and 60 minutes (DBP $r = -.36$, $p < 0.05$) following the HighK meal. There was a negative correlation between the change in SBP and FMD ($r = -.435$, $p < .05$) at 90 minutes after LowK treatment.

Conclusions: A high potassium meal, which represents similar amounts of potassium in 2-3 serves of fruit, can lessen the postprandial reduction in brachial artery FMD when compared to a low potassium meal. This suggests potassium intake may have protective effects on vascular dilatation in the postprandial state.

Key words: potassium, endothelial function, blood pressure.

PO1953**PREVALENCE OF INSULIN RESISTANCE IN AN OBESE EGYPTIAN YOUNG POPULATION**

M. Zaki¹, S. Kholoussi², S. Kamal³, H. El-Bassyouni⁴

¹National Research Centre, Biological Anthropology Department, Medical Research Division, Cairo, Egypt

²National Research Centre, Immunogenetics Department, Human Genetics and Genome Research Division, Cairo, Egypt

³National Research Centre, Biological Anthropology Department, Medical Research Division, Cairo, Egypt

⁴National Research Centre, Clinical Genetics Department, Human Genetics and Genome Research Division, Cairo, Egypt

Background and objectives: Insulin resistance (IR) and glucose intolerance are frequent in obese children and adolescents and lead to a significant risk for hypertension and cardiovascular diseases, as well as for type 2 diabetes. This study aimed to investigate the prevalence of IR in a sample of Egyptian obese young population and assess factors associated with IR. In addition, the study attempted to determine the cut-off values of homeostatic model assessment of insulin resistance HOMA-IR for the diagnosis of metabolic syndrome (MS).

Methods: A descriptive, cross-sectional study was conducted on 300 obese young individuals (150 males and 150 females) and 200 with normal weight as controls. All subjects participated in the project entitled "Obesity among Youth: Lifestyle and Genetic Factors" funded by the Science and Technology Development Fund, Egypt. They gave their informed consent which approved by the Ethical Research Committee of National Research Centre. Variables examined included body mass index (BMI), waist circumference (WC), waist to hip ratio (WHR), systolic and diastolic blood pressure (SBP and DBP), fasting blood glucose, cholesterol, triglycerides (Tg), high density lipoprotein (HDL), low density lipoproteins (LDL), insulin and insulin resistance (IR) measured HOMA-IR. Cut-off values of HOMA-IR for diagnosis of MS were calculated by receiver operating characteristic (ROC) analysis.

Results: The overall prevalence of IR was 20.5% among obese young subjects. Patients with IR had a significant higher levels of WHR, BP, Tg, glucose, total cholesterol, insulin, HOMA-IR and low HDL level as compared to obese patients without IR and controls. The area under the curve (AUC) (95%CI) was 0.770 (0.681-0.771) for MS.

Conclusions: Abdominal obesity, dyslipidemia and hypertension are risk factors for IR. The study determined the optimal HOMA-IR cut-off points for the diagnosis of MS in subjects with and without IR.

Key words: Youth, IR, obesity, cut-off points.

PO1954**THE EFFECT OF SPARC ON INSULIN-SENSITIVE GLUCOSE METABOLISM IN SKELETAL MUSCLE**

N. Hirano¹, W. Aoi¹, M. Takami¹, A. Nakayama¹, Y. Oga-ya¹, S. Wada¹, A. Higashi¹

¹Laboratory of Health Science, Graduate School of Life and Environmental Sciences, Kyoto Prefectural University, Kyoto, Japan

Background and objectives: Secreted protein acidic and rich in cysteine (SPARC) is a muscle-secretory protein which elevated in response to exercise. SPARC is shown to inhibit fat accumulation and involved in regulation of energy metabolism. In this study, we investigated the effect of SPARC on glucose metabolism in skeletal muscle.

Methods: Young male wild type (WT) and SPARC-KO (SPKO) mice were used. Oxygen consumption and carbon dioxide exhaustion were measured in the dark phase and carbohydrate oxidation was calculated. After measuring body weight and epididymal fat weight, blood and gastrocnemius muscle were collected. Blood glucose and plasma insulin were measured. Protein was extracted from the muscle and used for measuring Akt phosphorylation by western-blot analysis. Statistical analysis used Mann-Whitney's U test and, in all analyses, $p < 0.05$ indicated statistical significance. The data is shown as mean \pm standard error.

Results: Blood glucose level was significantly higher in SPKO mice (171.1 ± 6.2 mg / dL) than in WT mice (146.5 ± 8.6 mg / dL) ($p = 0.036$). Epididymal fat weight and blood insulin were identical between mice. The amount of carbohydrate oxidation was significantly lower in SPKO mice (56.9 ± 1.9 μ g/g B.W./min) than in WT mice ($64. \pm 2.4$ μ g/g B.W./min) ($p = 0.025$). Phosphorylation level of Akt, a rate-limiting enzyme of insulin-dependent signaling pathway, was significantly reduced 42.9% in SPKO mice compared to WT mice ($p < 0.001$).

Conclusions: SPARC improves glucose metabolism associated with enhancement of insulin sensitivity in skeletal muscle. **Acknowledgements:** This study was partly supported by Grants-in-Aid from the Japan Society of Promotion of Science (23700776WA).

Key words: SPARC, skeletal muscle, glucose metabolism.

PO1955**GENETIC LINKAGE BETWEEN FATTY ACID DESATURASE POLYMORPHISM AND OBESITY IN A SOUTHERN ITALY POPULATION**

B. Varriale¹, T. Esposito², P. Tammaro³, C. Dalia⁴, D. Scarpa⁵

⁴Ospedale Riuniti S. Maria della Pietà, Medicine Division, Nola, Naples, Italy

⁵Department Experimental Medicine, Laboratory Molecular Genetics, Second University of Naples, Naples, Italy

Background and objectives: The fatty acid composition of serum lipids and adipose tissue triacylglycerols reflects the dietary fat intake over the previous weeks/years. The fatty acid composition is also influenced by desaturating enzymes. Serum fatty acids and desaturase indices have been related to obesity, insulin resistance, type-2-diabetes and the metabolic syndrome. However, little data exist among fatty acids-CoA desaturase (FADS-1/FADS-2) polymorphisms and obesity in humans, although studies in knock-out mice indicate a clear linkage between the obesity status and desaturation of fatty acids.

Results: In the present study we demonstrate a clear link between particular polymorphisms of FADS-1 and FADS-2 and obesity in a southern Italy population (n=92). The exon one of FADS-1 gene showed a mutation in the GCG/AGG codon (Ala/Thr). The exon two showed a mutation in the AAT/GAT codon (Ile-Asp). The exon 3 showed a mutation in the GCC/GGC codon ((Ala-Gly). The exon 5 showed a mutation in the GCC/GGC codon (Ala-Gly). The exon two of FADS-2 gene showed a mutation in the GGC/AGC codon (Gly/Ser). All mutations determined were missense mutations. The changes in amino acid sequences observed may determine a variation in enzyme efficiency and as a consequence a low levels of desaturated fatty acids. Interestingly our patients showed high levels of saturated fatty acids that may play a role in the tendency to obesity. All obese subject showed one of the above mutation at least.

Conclusions: The introduction of desaturated fatty acids in diet help to improve the fatty acid composition of obese patients in terms of saturated/desaturated ratio. On the other hand the group of normal subjects, used as controls, did not show such polymorphisms and had a normal content of desaturated fatty acids.

We conclude that these polymorphisms may be a useful tool to early diagnosis of obesity.

Key words: Desaturation, mutation, fatty acid composition, genetics, obesity.

PO1956**CARBOHYDRATE DEPRIVATION AND BODY WEIGHT IN THYROID AUTOIMMUNITY**

T. Esposito¹, J M. Lobaccaro², M G. Esposito³, M. Mondà¹, B. Varriale⁴

³Complex Operating Unit of General Surgery, Evangelical Hospital Villa Bethany, Naples, Italy

⁴Department Experimental Medicine, Lab. Molecular Genetics, Faculty of Medicine, Second University of Naples, Naples, Italy

Background and objectives: The thyroid is one of metabolism regulating gland. Its function is to determine the amount of calories that the body has to burn to maintain normal weight. Thyroiditis are inflammatory processes that result mainly in autoimmune processes. We have conducted the present study in order to have a clear picture on both autoimmune status and the control of the body weight.

Methods: We have evaluated the amount of either anti-thyroid, or anti-microsomal, or anti-peroxidase antibodies in patient with high antibodies.

Results: A balanced diet devoid of carbohydrates (bread, pasta, fruit and rice) and free of goitrogen food and based on the BMI, the distribution of body mass and intra- and extracellular water led to three weeks give the following results 1. Patients treated as above show a significant reduction of anti-thyroid (-40%, p <0.013), anti-microsomal (-57%, p <0.003) and anti-peroxidase (-44%, p <0,029). 2. Untreated patients have a significant increase in anti-thyroid (+9%, p <0.017) and anti-microsomal (+30%, p <0.028). Even the anti-peroxidase rise without reaching statistical significance (+16%, p > 0064). 3. With regard to body parameters measured in patients undergoing to this diet significant changes are seen in the reduction of body weight (-5%, p <0.000) and in body mass index BMI (-4%, p <0.000). Lastly 83% of patient with high auto-antibodies are Bread test positive to lactase with a lactase deficit higher than 50%.

Conclusions: This let us to hypothesize a correlation with ChREBP (carbohydrate responsive element protein) and therefore a possible role of carbohydrate metabolism in the development and maintenance of autoimmune thyroiditis associated to body weight increase and slower basic metabolism.

Key words: Thyroiditis, antibodies, carbohydrate, body weight reduction, BMI.

PO1957

PREVALENCE AND RELATED KNOWLEDGE OF HYPERTENSION AMONG ADULTS OF SHIJIAZHUANG

F. Chen¹, C. Zhao¹, J. Zhou¹, D. Feng¹, W. Zhao¹, Z. Guo¹, P. Bai¹, W. Fan¹

¹Shijiazhuang Center For Disease Prevention and Control , Shijiazhuang, Hebei, China

Background and objectives: Studies on hypertension usually focus on the treatments, whereas the healing effect is usually overlooked. Our objective was to study the prevalence rate, the awareness rate, the treatment and control rate of hypertension among adults in Shijiazhuang urban area, to appraise the present situation of hypertension prevention and control, and improve the preventive and treat effect.

Methods: We used a confidential National Health and Nutrition Examination Survey data set (2010-2012) that included 946 adult inhabitants of 450 families randomly selected from six residents' committees in Shijiazhuang in 2010. We analysed the data in SPSS and compared the prevalence rate, the awareness rate, the treatment and control rate of hypertension between men and women.

Results: The overall hypertension prevalence rate of Shijiazhuang urban adults was 35.62%, 43.29% for males and 30.13% for females. The standardized hypertension prevalence rate was 28.41%. The overall hypertension awareness rate was 52.52%, 51.46% for males and 53.61% for females; the differences in hypertension awareness in different ages were statistically significant ($p < 0.05$). The overall hypertension treatment rate was 45.99%, 43.86% for males and 48.19% for females; the differences of hypertension treatment in different ages were statistically significant ($p < 0.05$). The overall hypertension control rate was 12.46%, 9.94% for males and 15.06% for females; the differences of hypertension treatment in different ages were statistically significant ($p < 0.05$). Ageing was accompanied by a treatment rate raise.

Conclusions: These results show that besides the high rates of hypertension awareness and treatment, the healing effect still needs further improvement. We should strengthen comprehensive prevention and treatment of hypertension and pay more attention to healing effect.

Key words: Hypertension, prevalence rate, treatment rate, Healing effect.

PO1958

CONVERSION OF GASTRIC BYPASS TO SLEEVE AS A TREATMENT OF SEVERE AND PERSISTENT HYPOGLYCEMIA

M. Gonzalo-Marin¹, I. Gonzalez-Molero¹, M. Dominguez-Lopez¹, J.A. Garcia-Arnes¹, J.L. Gallego²

¹Endocrinology and Nutrition Service, Carlos Haya Hospital, Málaga, Spain

²General and Digestive Surgery Service

Background and objectives: In recent years, positive results have been published about an emerging technique for bariatric surgery, gastric sleeve, with a reduction of excess weight about 50% after 4 years and with few complications. Also, after gastric bypass certain complications may arise that require the conversion to another technique: if the patient develops hyperphagia, he/she may require placement of a gastric band or ring; if the patient develops polyphagia, he/she may need a conversion to malabsorptive technique; and if the patient develops severe hypoglycemia after eating, he/she may need a gastric sleeve. After performing this, food pass again through the pylorus and duodenum with less changes in the gastrointestinal peptide secretion and glucose homeostasis than those occurring after performing the bypass, so this could contribute to the disappearance of hypoglycemia after performing the conversion.

Methods: We report a patient with persistent hypoglycemia after bariatric surgery due to hyperinsulinism generated by islet cells hyperplasia that was treated by converting the bypass into sleeve.

Results: A 45 year old woman with morbid obesity (BMI:48) underwent bariatric surgery (gastrojejunal bypass). One year after surgery and after successful weight loss (BMI:25.9) she began with postprandial hypoglycemia that did not improve with dietary treatment, acarbose or diazoxid. Oral glucose tolerance test showed hyperinsulinism and hypoglycemia. Mesenteric arteriography imaging was normal but hypersecretion was found in splenic and superior mesenteric area. We conducted a body and tail pancreatectomy and splenectomy. The pathology confirmed the presence of islets cells diffuse hyperplasia supporting diagnosis of nesidioblastosis. A few months later hypoglycemia recurred. We decided to place a gastrostomy and feeding in this manner checking whether hypoglycemia improved. She only ate by mouth proteins and hypoglycaemia disappeared. A few months later, when the patient tolerated a sufficient volume, she underwent a conversion from bypass to gastric sleeve. Now the patient continues without hypoglycemia and maintains weight.

Conclusions: Rather than total pancreatectomy (which can generate chronic malabsorption syndrome and diabetes), there is a new therapeutic option for severe cases of persistent hypoglycemia resistant to medical treatment, much less aggressive: the conversion of gastric bypass to sleeve.

Key words: morbid obesity, hypoglycemia.

PO1959**PROCESSED FOOD CONSUMPTION AND ESOPHAGEAL SQUAMOUS CELL CARCINOMA IN CHINESE***S. Lin¹, X. Wang¹, C. Huang², X. Liu¹, I. Yu¹*¹The Chinese University of Hong Kong, Hong Kong, China²Sichuan University, Chengdu, China

Background and objectives: Esophageal squamous cell carcinoma (ESCC) is one of the most prevalent cancers in China. Some studies reported its positive association with processed food consumption, but others did not. This study aimed to further examine the association between ESCC and consumption of processed food.

Methods: A population-based case-control study was conducted in a high ESCC risk area of China, in which 722 incident ESCC cases with histological confirmation and 722 controls matched with age and sex were included. Demographic characteristics and lifestyles including smoking and alcohol consumption were collected; detailed information on daily food consumption during the past 5 years prior to onset of the disease for cases and the past 5 years for controls were obtained with validated food frequency questionnaire (FFQ). Average intake per week on salted meat, preserved and pickled vegetables were categorized into four levels based on quartiles. Conditional logistic regression models were applied to estimate odd ratios (OR) for ESCC associated with processed food intake. Consumers that never had processed food were the reference group, and smoking, alcohol, drinking and family cancer history were adjusted.

Results: Salted meat intake was significantly associated with an increased risk of ESCC (OR=1.93, 95% CI 1.27, 2.94), showing a clear exposure-response trend. A higher level of preserved vegetable consumption was related to a higher risk, though only the highest level reached a statistical significance (OR=2.24, 95% CI 1.52, 3.29). Pickled vegetable intake was also associated with a higher risk (OR=1.94, 95% CI 1.33, 2.85), but no clear exposure-response trend was detected.

Conclusions: The data support that consumption of traditionally processed food increases a risk of ESCC. Effective interventions on individuals' dietary habit are needed to reduce the cancer risk, particularly in high risk areas of China.

Key words: esophageal cancer, diet, salted meat, processed vegetables.

PO1960**PLASMA RETINOL BINDING PROTEIN STATUS IN RELATION TO OCULAR CHANGES IN CYSTIC FIBROSIS PATIENTS TREATED WITH VITAMIN A SUPPLEMENTS***M. Mrugacz¹*¹Department of Pediatric Ophthalmology, Medical University of Białystok, Białystok, Poland

Background and objectives: Cystic fibrosis (CF) is an autosomal recessive disease characterised by increased viscosity of mucus secretions. The patients suffer from chronic pulmonary changes, pancreatic deficiency, and an obstruction of the gastrointestinal tract. The disease affects all secretory epithelia including the eye. The influence of nutritional status on long-term survival and quality of life of cystic fibrosis patients is well documented. Steatorrhea and absorption may be associated with vitamin deficiencies, including vitamin A. The aim of this study was to assess plasma retinol binding protein status and ocular surface changes in children and adolescents with cystic fibrosis.

Methods: The study was conducted and the patients were recruited at the regional Chest Diseases Unit. All the patients are regularly seen by a CF specialist dietitian. Twenty five patients had the investigations of plasma retinol binding protein, visual acuity, external examination, tear film break-up time, fluorescein staining and Schirmer's tear test. Twenty five age and sex matched controls without CF or ocular pathology were also recruited.

Results: Plasma RBP concentration is significantly lower in patients with CF than in control group. Seven of our patients with CF had clinical evidence of dry eye.

Conclusions: Low plasma RBP levels occur frequently in clinically stable and retinol supplemented CF patients. We recommend monitoring of plasma RBP levels in CF patients and evaluation of ocular surface changes.

Key words: Vitamin A, retinol binding protein, eye, cystic fibrosis.

PO1961**FRIED FOODS CONSUMPTION AND THE INCIDENCE OF HYPERTENSION IN A SPANISH COHORT: THE SUN STUDY**

C. Sayon-Orea¹, A. Gea¹, I. Zazpe^{1,2}, E. Toledo¹, M A. Martinez-Gonzalez¹, M. Bes-Rastrollo¹

¹Dept. of Preventive Medicine and Public Health, University of Navarra, Pamplona, Spain, CIBER Fisiopatología de la Obesidad y Nutrición (CIBERObn), Instituto de Salud Carlos III, Madrid, Spain

²Dept. of Food Sciences, Physiology, University of Navarra, Pamplona, Spain

Background and objectives: The consumption of fried foods might be linked to the development of hypertension. However, evidence from long-term prospective studies is scarce. Therefore, the aim of our study was to evaluate the association between fried foods consumption and the incidence of hypertension in a Mediterranean cohort.

Methods: The SUN project is a prospective Spanish cohort study. For the present analyses we included 13,680 participants (5,059 men and 8,621 women), free of hypertension at baseline with a mean age of 36.5 y (SD: 10.8) who were followed-up for a median of 6.3 years, to assess the incidence of hypertension and the average change of systolic and diastolic blood pressure.

Results: During the follow-up, 1,232 incident cases of hypertension were identified in participants without baseline hypertension. After adjusting for potential confounders, the hazard ratio for developing hypertension among participants with higher consumption of fried foods (>4 times/week) was 1.22 (95% CI: 1.04-1.42) in comparison with those who consumed these food items <2 times/week (p for trend 0.02). The consumption of fried foods was associated with a 6-year increase of systolic blood pressure among participants with the highest consumption of fried foods compared to those in the lowest category of consumption (r coef. = 1.05 mm; Hg 95% CI: 0.12 to 1.99 mmHg).

Conclusions: In this Mediterranean cohort study, a more frequent consumption of fried foods at baseline was associated with a higher risk of developing hypertension during follow-up. **Acknowledgements:** The SUN Study has received funding from the Spanish Government (Grants PI01/0619, PI030678, PI040233, PI042241, PI050976, PI070240, PI070312, PI081943, PI080819, PI1002658, PI1002293, RD06/0045, G03/140 and 87/2010), and the Navarra Regional Government (36/2001, 43/2002, 41/2005, 36/2008, 45/2011).

Key words: Hypertension, fried foods, cohort study.

PO1962**DIETARY INTAKE OF ACRYLAMIDE AND OESOPHAGEAL CANCER (OC) RISK IN THE EUROPEAN PROSPECTIVE INVESTIGATION INTO CANCER AND NUTRITION (EPIC) COHORT**

L. Lujan-Barroso¹, E J. Duell¹, M. Obon-Santacana¹, N. Slimani², H. Boeing³, C A. Gonzalez¹

¹Unit of Nutrition, Environment and Cancer, Catalan Institute of Oncology (ICO-IDIBELL), Barcelona, Spain

²Dietary Exposure Assessment Group, International Agency for Research on Cancer, Lyon, France

³Department of Epidemiology, German Institute of Human Nutrition, Potsdam, Germany

Background and objectives: Acrylamide (AA) is a water soluble chemical compound, reactive in air and polymerizable. Based on animal and in vitro studies, the International Agency for Research on Cancer (IARC) classified AA as 'probably carcinogenic' to humans in 1994. Three previous studies have evaluated the association between dietary AA intake and OC risk, but only one observed an association. The aim of the study was to assess whether dietary AA intake increases the risk of developing OC, including oesophageal squamous cell carcinoma (OSCC) and oesophageal adenocarcinoma (OAC) in the EPIC cohort.

Methods: EPIC was designed to investigate the relationships between diet, lifestyle, and environmental factors and the incidence of cancer and includes participants from 23 centers in 10 European countries. The hazard ratios (HRs) and their corresponding 95% confidence intervals (CIs) for the development of OC were estimated using Cox proportional hazards regression models. HRs are presented as risk per 10 µg of AA per 2000 kcal. All models are adjusted for sex, total energy intake, fruit, smoking intensity, processed meat, alcohol (OSCC) and BMI (OSCC and OAC).

Results: After a mean of 11 years of follow-up, 341 OC were identified; 142 of which were OAC, 176 OSCC and the remaining 23 were not specified or other types. At baseline, the mean AA intake was 26.22 µg/d. No association between AA intake and OC was found (HR: 1.01 (95% CI 0.92-1.12)), even when OC was evaluated by histological subtypes (OSCC: HR: 0.96, 95% CI 0.83-1.11; and OAC: HR 1.04, 95% CI 0.90-1.21).

Conclusions: In agreement with previous studies, we did not observe a statistically significant association between AA intake and OC risk.

Key words: Acrylamide, oesophageal cancer, cohort, nutrition.

PO1963**DIETARY INTAKE OF ACRYLAMIDE AND PANCREATIC CANCER RISK IN THE EUROPEAN PROSPECTIVE INVESTIGATION INTO CANCER AND NUTRITION (EPIC) COHORT**

M. Obon-Santacana¹, L. Lujan-Barroso¹, N. Slimani², H. B. Bueno-de-Mesquita^{3,4}, E.J. Duell¹

¹Unit of Nutrition, Environment and Cancer, Cancer Epidemiology Research Program, Catalan Institute of Oncology (ICO-IDIBELL), Barcelona, Spain

²Dietary Exposure Assessment Group, International Agency for Research on Cancer, Lyon, France

³National Institute for Public Health and the Environment (RIVM), Bilthoven, The Netherlands

⁴Department of Gastroenterology and Hepatology, University Medical Centre, Utrecht, The Netherlands

Background and objectives: Based on animal and in vitro studies, the International Agency for Research on Cancer classified acrylamide (AA) as 'probably carcinogenic' to humans. To date, three epidemiologic studies, with <349 pancreatic cancer (PC) cases and with different design and range of intakes, have evaluated the association between dietary intake of AA and PC risk, and overall they have found no association. The aim was to assess the association between dietary intake of AA and the risk of PC in the EPIC cohort.

Methods: The EPIC cohort included men and women mostly aged 35 to 75 at enrolment from 10 European countries. Food consumption data were matched to a harmonized AA database that is largely based on the EU monitoring database of AA levels in foods maintained by the European Community Institute for Reference Materials and Measurements.

Results: After a mean follow up of 11 years, 865 PC cases were observed and included in the present analysis. At baseline, the mean dietary intake of AA was 26.22µg/d. No overall association was found between dietary intake of AA and PC risk in EPIC (HR: 0.95, 95% CI: 0.88-1.01 per 10µg/day). There was no effect measure modification by smoking status, sex, diabetes, alcohol intake and geographic region. However, there was an inverse association (HR: 0.73, 95% CI: 0.61-0.88 per 10µg/day) between AA intake and PC risk in obese persons as defined using body mass index (BMI ≥30kg/m²), but not when body fatness was defined using waist and hip circumference or their ratio.

Conclusions: Dietary intake of acrylamide was not associated with an increased risk of PC in the EPIC cohort.

Key words: acrylamide, pancreatic cancer, cohort, nutrition, obesity.

PO1964**CHANGES IN MICROBIOTA AND EPIGENETIC METHYLATION OF INFLAMMATION RELEVANT GENES IN TYPE 2 DIABETES AND OBESITY**

M. Remely¹, C. Merold¹, Y. Chen¹, E. Aumueller¹, D. Jahn¹, S. Doworzak¹, B. Hippe¹, H. Brath², A.G. Haslberger¹

¹Dep. Nutritional Sciences, Univ. of Vienna, Vienna, Austria

²Gebietskrankenkasse, Vienna, Austria

Background and objectives: Metabolic diseases are believed to involve changes in the structure of microbiota causing low grade inflammation.

Methods: We studied obese and type 2 diabetes patients in a four month intervention period in comparison to a lean control group. Intervention involved Victoza for type 2 diabetics and nutritional counselling for both intervention groups. Microbiota were analysed for abundance and diversity by PCR-DGGE, qPCR and 454 Pyrosequencing. Epigenetic methylation of 3-7 CpG sites in promoter regions of TLR2, TLR4, FFAR3, TNF-α; and Line1, as a marker for global methylation, were analysed.

Results: In type 2 diabetes and obesity the diversity of band patterns was decreased compared to healthy controls. Firmicutes/Bacteroidetes ratio, abundance of lactic acid subgroups and Enterobacteria increased during the intervention period in type 2 diabetes. In contrast, the ratio of Firmicutes/Bacteroidetes was decreasing in obese patients with weight loss. We generally found a significant decreased methylation in TLR2, TLR4 and FFAR3 in obesity but also decreased methylation in diabetics, (TLR2: obese: 2,96%, TLR4: obese: 4,30%, FFAR3: diabetics: 31,75%; obese: 32,51%). CpG methylation of TNF-α; and Line1 did not show significant changes between the groups. In general we found a significant correlation between an increased BMI/WHR and decreased methylation of TLR2, TLR4 and FFAR3 but increased methylation of Line1.

Conclusions: Our results suggest that a different composition in microbiota in obesity and type 2 diabetes effect the epigenetic regulation of inflammatory molecules, possibly also underlying a progression of the metabolic disease. Interactions between microbiota and epigenetic regulation may involve NF-kB signalling from bacterial cell wall components or DNA as well as SCFA binding to SCFA-receptors or TLRs. Significant correlations of anthropometric measurements and TLR2, TLR4, FFAR3 or in contrast to global methylation assessed by Line1 could develop into useful markers.

Key words: obesity, diabetes, microbiota, epigenetic.

PO1965**IS THE ONE-ANASTOMOSIS GASTRIC BYPASS (OAGB) USEFUL IN NORMALIZING WEIGHT, BMI AND LIPID PROFILE IN THE SHORT AND THE MEDIUM TERMS?**

M.J. Castro^{1,2}, J.M. Jimenez², M.A. Carbajo², M.J. Cao¹, E. Quinto¹, M.A. Barba³, A. Mayo⁴

¹Institute Endocrinology Nutrition (IENVA), University of Valladolid, Valladolid, Spain

²Center Excellence Treatment Obesity, Valladolid, Spain

³Department Infirmary, University of Valladolid, Valladolid, Spain

⁴Department of Statistics, University of Valladolid, Valladolid, Spain

Background and objectives: The aim of this study was to describe the variation of weight, BMI and lipid profile in obese patients after a postoperative period of 3 and 12 months.

Methods: Sample: 418 obese patients, two groups: 183 with BMI < 40, and 235 with BMI ≥ 40. Variables: sex, age, weight, BMI, total cholesterol (Col-t), cholesterol HDL (HDL-c), cholesterol LDL (LDL-c), and triglycerids (TG). Results are expressed as the Mean ± Standard Deviation. ANOVA and P-Pearson ($p < 0.05$) were applied.

Results: Non-morbid group: (i) Mean weight: 98.57 ± 12.46 preoperative (preQ), 71.57 ± 9.38 (3 months), and 62.14 ± 10.15 (12 months). (ii) Lipid profile: Col-t: 209.82 ± 42.70 preQ and 168.73 ± 28.09 (12 months); HDL-c: 54.28 ± 16.06 preQ and 59.94 ± 13.85 (12 m); LDL-c: 130.47 ± 37.91 preQ and 92.25 ± 24.29 (12 m); TG: 121.31 ± 67.45 preQ and 78.63 ± 30.99 (12 m). Morbid group. (i) Mean weight: 126.55 ± 20.13 preQ, 86.76 ± 12.97 (3 m) and 73.57 ± 13.50 (12 m). (ii) Lipid profile: Col-t: 189.56 ± 38.14 preQ and 161.30 ± 27.21 (12 m); HDL-c: 46.19 ± 12.31 preQ and 56.68 ± 12.10 (12 m); LDL-c: 118.99 ± 33.77 preQ and 86.66 ± 24.19 (12 m); TG: 128.93 ± 74.01 preQ and 80.30 ± 38.85 (12 m). P-value $p < 0.001$.

Conclusions: The weighted reduction per year was higher in morbid patients. All non-morbid patients normalize the BMI the 3rd month, and morbid patients after 12 months. Col-t and LDL-c decrease in both groups (the higher decrease in non-morbid and morbid patients, respectively). TG decrease equally in both groups. HDL-C increased in both groups (the higher increase in morbid patients). The OAGB is an effective technique in reducing weight and improving lipid profiles.

Key words: Gastric Bypass, BMI, lipid profile.

PO1966**EFFECTS OF LIFESTYLE INTERVENTION AND MEAL REPLACEMENT ON GLYCEMIC AND BODY WEIGHT CONTROL IN CHINESE SUBJECTS WITH IMPAIRED GLUCOSE REGULATION**

D. Xu¹, J. Sun¹, M. Chen¹, Y. Chen¹, H. Xie¹, W. Sun¹, Y. Lin¹, J. Jiang¹, W. Sun², A. Chen², Q. Tang³

¹Clinical Nutrition Center, Huadong Hospital, Fudan University, Shanghai, China

²Caojiadu Community Health Center, Jing'an District, Shanghai, China

³Jing'an Temple Community Health Center, Jing'an District, Shanghai, China

Background and objectives: Impaired glucose regulation (IGR) refers to a metabolic status between normal glucose homeostasis and diabetes. It is necessary to initiate effective interventions for IGR patients to promote the restoration of normal glucose regulation (NGR) and prevent diabetes. The present study aimed to evaluate the impact of a lifestyle intervention program, combined with a daily low-glycemic index meal replacement, on body weight and glycemic control in IGR patients.

Methods: Subjects with IGR were recruited from two community and randomly assigned to an intervention group ($n = 46$) and control group ($n = 42$). Both groups received health counseling at baseline. The intervention group also received a daily meal replacement and intensive lifestyle intervention to promote healthy eating habits during the first 3 months of the study, and follow-up visits performed monthly until the end of the one-year study.

Results: Results showed that body weight loss after one year was significant in the intervention group compared to the control group ($-1.8 \text{ } \ddagger \text{ } 2.2$ vs. $-0.6 \text{ } \ddagger \text{ } 2.5$ kg, $P < 0.05$). The 2-h plasma glucose concentration decreased 1.24 mmol/L in the intervention group and increased 0.85 mmol/L in the control group ($P < 0.05$) compared to their baseline respectively. A 5-kg body weight loss at one year was associated with a decrease of 1.49 mmol/L in 2-h plasma glucose ($P < 0.01$). The incidence of NGR in the two groups was significantly different (39.0 vs. 7.5%, intervention vs. control; $P = 0.001$).

Conclusions: The present study has illustrated that treatment with regular contact, lifestyle advice and low-glycaemic index meal replacements was an effective means of improving weight loss and glycaemic control, and promoting the conversion from IGR to NGR in IGR patients over a 1-year period.

Key words: E° Impaired glucose regulation, meal replacement, glycaemic control, weight loss.

PO1967**IMPROVEMENT OF THE PLASMA AND ERYTHROCYTES LIPID PROFILE IN OVERWEIGHT/OBESE AND DYSLIPIDEMIC PATIENTS AFTER CONSUMPTION OF A NATURALLY PUFA-ENRICHED CHEESE**

³Lactalis Iberia, Villarrobledo, Albacete, Spain

⁴Lodyn S.L., Ciudad Real, Spain

Background and objectives: Obesity is considered a key factor in a vast array of diseases. There are evidences associating the PUFA-enriched diets with a lower incidence of cardiovascular diseases (CVD). In this sense, there is much interest in adding value to dairy products by naturally increasing the PUFA levels. Within the context, a PUFA-enriched low fat cheese was elaborated (Lactalis Iberia) from ruminant milks whose diet included a commercial linseed supplement (Lodyn S.L.). A balanced hypocaloric diet including the consumption of this functional cheese for its potential benefits by overweight/obese and dyslipidemic patients, was analyzed. Our aim was to assess the effect of the functional cheese intake, through the changes in the lipid composition of plasma and erythrocytes from volunteers and identify potential health biomarkers.

Methods: A prospective, randomized, double-blind, placebo-controlled clinical trial was performed. Sixty two overweight/obese and dyslipidemic volunteers were randomly assigned to receive during 12-wk a 60 g/day intake of Light Cheese (LC) or Light Functional Cheese (LFC). Lipids from plasma and erythrocytes were derivatized by a direct transmethylation procedure. Lipid profile was thoroughly monitored by GLC-MS.

Results: The dietary-induced changes in the FA composition of plasma and erythrocyte were similar. In volunteers consuming LFC, the levels of myristic (C14:0), palmitic (C16:0) and stearic (C18:0) acids significantly decreased. This is interesting since C14:0 and C16:0 are considered to be cholesterol-raising and are associated with the increased incidence of CVD. A major increase in the PUFA content, correlated with the higher amount of linoleic acid (C18: 2), was also detected. An enhancement in oleic acid (C18:1c9) level, occurred in erythrocytes but not in plasma.

Conclusions: The LFC intake improves the FA composition of plasma and erythrocytes from overweight/obese and dyslipidemic patients. Acknowledgements: This work has been supported by CENIT-PRONOS Project (2008-2011).

Key words: Obesity, lipid profile, PUFA-enriched cheese.

PO1968**AN EVALUATION OF SATIETY, AND WEIGHT CHANGES FOR THE TREATMENT OF PRIMARY OBESITY WITH THE P.O.S.E PROCEDURE.**

M. Sanchez Bohorques¹, J C. Espinos¹, R. Turro¹, A. Mata¹, M. Cruz¹, M. Prat¹, S. Oliva¹, J. Turro¹

¹Unidad de Endoscopia y Pruebas Funcionales Digestivas, Centro Médico Teknon, Barcelona, Spain

Background and objectives: Obesity is a complex, metabolic disease. Diet and exercise, medications, and bariatric surgery have been used as tools to affect satiety and treat obesity. A less invasive surgical tool, the Incisionless Operating Platform® (USGI Medical, San Clemente, CA, USA) utilizes the g-Cath EZ® suture anchor, to plicate gastric tissue endoscopically, inducing physiologic and mechanical changes in gastric function, prolonging the sensation of satiety and assisting compliance with a reduced calorie diet.

Methods: A prospective, single site study was initiated with institutional Ethics Board approval. Enrolled patients were ages 21-60 with BMIs of ≥ 30 and ≥ 40 and no prior bariatric procedure. Suture anchors were placed in the fundus and antral inlet to inhibit fundal accommodation and slow emptying. Diet was advanced post -op to full solids over 4-6 weeks to allow for tissue healing. A standardized liquid satiety test (Ensure) was done pre-procedure and at 2/6 months. Also, subjective feelings of fullness and hunger were recorded at 2-4, and 6 months post-procedure.

Results: 18 patients were enrolled (78%F/22%M). Mean age =39.1. Mean baseline weight was 101.7Kg; mean BMI (kg/m²)=36.3. Six month mean AW loss was 16.9 kg (N=18). Satiety test demonstrated reduced capacity and earlier satiety in all patients tested at 2/6 months. Mean volume change and time to satiety significantly changed compared to pre-procedure at 2/6 months (p <.05). Reduction in capacity at 2 months correlated with weight loss at same time-point. This mirrored subjective perceptions of satiety. The majority of patients (n=16) reported less hunger and earlier satiety post-procedure.

Conclusions: At early follow-up, satiety markers and patient perceptions of satiety may be related to successful weight loss. The patient's feeling of earlier fullness and longer satiety may also contribute to dietary compliance.

Key words: Satiety, obesity, weight Loss.

Background and objectives: Few studies have investigated the association between whole-grain intake and colorectal cancer. Whole-grain products are one of the dietary items prone to measurement errors, making the use of objective measures, such as biomarkers, highly relevant. The objective of the study was to investigate the association between biomarkers of whole-grain intake, alkylresorcinols, and colorectal cancer in a nested case-control study within the European Prospective Investigation into Cancer and Nutrition (EPIC).

Methods: We included 1372 first incident colorectal cancer cases and 1372 individually matched controls and calculated the incidence rate ratios (IRR) for overall and sub-sites of colorectal cancer using conditional logistic regression adjusted for potential confounders.

Results: Plasma total alkylresorcinol concentrations were not associated with risk of overall colorectal cancer, proximal colon cancer or rectal cancer. However, high plasma total alkylresorcinol concentrations were statistically significantly associated with lower incidence of cancer located in the distal (left or descending) part of the colon. Adjusted IRR of distal colon cancer for highest versus lowest quartile of plasma alkylresorcinol was 0.48 (95% confidence interval = 0.28 to 0.83). Furthermore, we observed an inverse association with colon cancer for the Scandinavian part of the participants. Alkylresorcinols may be more appropriate as biomarkers in Middle Europe and Scandinavia i.e. in areas where whole grains are regularly consumed.

Conclusions: Whole-grain intake, assessed by alkylresorcinols, was associated with a lower incidence of distal colon cancer. Alkylresorcinols seem useful as objective biomarkers of whole-grain intake in populations where whole-grains are a staple part of the diet. Acknowledgements: This work was supported by World Cancer Research Fund International (WCRF) and WCRF Netherlands (WCRF NL) (2011/436), and Nor- dForsk (Centre of Excellence programme HELGA (070015)).

PO1970

ASSOCIATION BETWEEN PROTEIN INTAKE AND OBESITY AMONG CHILDREN

J. Armstrong¹, R. Alzaheb¹, J. Godwin¹, J. Jackson¹

¹Glasgow Caledonian University, Scotland, UK

Background and objectives: Dietary intakes of macronutrients, particularly protein, have been examined as part of attempts to understand the dietary aspects of obesity. This study examines the relationship between protein intake and obesity in children in Scotland.

Methods: The data were from the Survey of Sugar Intake among Children in Scotland. The survey was carried out in children aged 3-17 in 2006. Diet was assessed by semi-quantitative food frequency questionnaire and height and weight were measured. Of the 1390 subjects with complete dietary and anthropometric data, 889 were used in the analyses following the exclusion of mis-reporters. Children were classified as obese or non-obese, BMI z-score ≥ 1.64 and < 1.64 respectively. Analyses of covariance were performed to determine the mean differences in protein intake (g/day) between obese and non-obese children. Logistic regression tested the association

between protein intake and obesity, while controlling for age, gender, physical activity, social class and energy intake/basal metabolic rate ratio.

Results: The mean \pm SD protein intake of obese children was significantly higher compared with the non-obese children in all three age groups: 3-5 years (62.3 ± 15.6 vs 54.7 ± 11.8 g/day); 6-10 years (67.1 ± 20.5 vs 61.5 ± 14.7 g/day); and 11-17 years (78.0 ± 22.6 vs 66.8 ± 18.5 g/day). There was a significant association between the protein intake and obesity after controlling for confounders: 3-5yrs Adjusted Odds Ratio (AOR) 1.12; 95% Confidence Interval (CI) 1.04-1.20; 6-10yrs AOR 1.10; 95% CI 1.06-1.13 and 11-17yrs AOR 1.07; 95% CI 1.04-1.09.

Conclusions: Obese children had higher protein intakes than their non-obese counterparts at all ages. High protein intake in childhood may contribute to childhood obesity. Acknowledgements: UK Data Archive, Food Standard Agency UK funded the Survey.

Key words: Protein intake, obesity, children.

PO1971

EXCESS WEIGHT AND BREAST DENSITY AT PUBERTY, AN UNKNOWN ASSOCIATION: EVIDENCE FROM THE GROWTH AND OBESITY CHILEAN COHORT

A. Pereira¹, M.L. Garmendia¹, R. Uauy¹, C. Corvalan¹

¹Institute of Nutrition and Food Technology, University of Chile, Santiago, Chile

Background and objectives: Mammographic breast density (BD) is the strongest predictor of Breast Cancer (BC) risk and it is negatively associated with Body Mass Index (BMI), which is a risk factor for postmenopausal BC. However little is known in relation to BD and adiposity during puberty; the former is highest at the end of puberty and declines with age; thus understanding the association between BD and adiposity at the end of puberty would be critical for determining BC predisposition during adulthood.

Methods: We recruited 61 girls from an ongoing cohort of 400 low-income Chilean girls born in 2002-2003, who reached Tanner Breast Stage 4 or 5 in 2012. At the same visit, we assessed i) anthropometric measures (weight and height) and ii) breast composition (% fibroglandular volume (FGV), absolute FGV (AFGV, i.e. dense tissue) and breast volume) by DXA, a validated method to measure breast composition at young ages (low dose radiation). Crude and adjusted Odds Ratio (OR) and 95% Confidence intervals (95% CI) were estimated to assess the relation between excess weight (BMI z-score > 1) and %FGV, AFGV or breast volume.

Results: The mean age and height z-score of the study group were 122 months (sd=4.8) and 0.8 (sd=0.9) respectively

and 61% of the girls had excess weight. After adjusting by age and height, excess weight was positively associated with breast volume (r adj=88.9, 95%CI:50.6-127.3), and inversely associated with %FGV (r adj=-15.1, 95%CI:-19.9;-10.2). Excess weight had a positive relation with AFGV, but it did not reach statistical significance (p -value=0.1).

Conclusions: Our results supports that excess weight is inversely associated with %FGV since puberty. Further studies are needed to assess the possible association between adiposity and absolute dense tissue. Studying adiposity and breast composition during puberty is of paramount; it is known that puberty is a time of great susceptibility to breast carcinogens, thus preventive strategies must be addressed at early stages.

Key words: Breast, puberty, body weight

PO1972

WAIST CIRCUMFERENCE AS PREDICTOR FACTOR FOR LOW-GRADE INFLAMMATION IN MIDDLE-AGED BRAZILIAN MEN

A. Oliveira^{1,2}, P G. Cocate², H H M. Hermsdorff², J. Bressan², A J. Natali³

¹Department of Sciences of Physical Education and Health, Federal University of São João del Rei, São João del Rei, Minas Gerais, Brazil

²Department of Nutrition and Health, Viçosa Federal University, Viçosa, Minas Gerais, Brazil

³Department of Physical Education, Viçosa Federal University, Viçosa, Minas Gerais, Brazil

Background and objectives: Anthropometrical variables could predict a low-grade inflammation, since the relationship between inflammatory markers and adiposity indicators has been thoroughly reported. The aim of this cross-sectional study was to identify the best anthropometric predictor for high-sensitivity C-reactive protein (hs-CRP) concentrations as well as a potential cut-off for this adiposity indicator.

Methods: Two-hundred and twenty-eight men (age: 52±5y; BMI: 25.9±3.7kg/m²), employees at the Federal University of Viçosa – Viçosa (Brazil), were enrolled. Body mass index (BMI), body adiposity index (BAI), waist (WC), abdominal (ABD), hip (HC) and arm (MUAC) circumferences were measured. Plasma hs-CRP concentrations as well as lipid (total cholesterol, triglycerides and HDL-c) and glucose (glucose and HOMA-IR) profiles were assessed. The ROC curve was used to identify the best predictor among adiposity indicators in relation to the high hs-CRP (\geq ; 1.0 mg/dL). The anthropometric and metabolic variables were compared between low and high hs-CRP groups by the Mann-Whitney tests.

Results: Subjects with high hs-CRP had greater prevalence for hyperglycemia, hypertriglyceridemia, and insulin re-

sistance as well as lower HDL-c concentrations, as expected. By the ROC curve analysis, WC [(AUC=0.662) and ABD (AUC=0.659)] were the best predictors for the occurrence of high hs-CRP, with the cut-offs of 87.7 cm (sensitivity: 63.9%; specificity: 63.2%) and 90.95 cm (sensitivity: 62.4%; specificity: 60.6%), respectively.

Conclusions: The central adiposity indicators, WC and ABD, showed the strongest relations to hs-CRP higher than 1.0 mg/dL in this cross-sectional study. In addition, the cut-offs of 87.7 and 90.95 cm for WC and ABD, respectively, may be suggested as predictors of low-grade inflammation in middle-aged Brazilian men, though further studies with larger populations are necessary.

Acknowledgements: We thank the Foundation for Research Support of the State of Minas Gerais – FAPEMIG (Brazil) for financial support.

Key words: Anthropometry, biomarkers, inflammation, cardiovascular diseases.

PO1973

THE CONSUMPTION OF LEGUMES AND WHITE MEATS IS RELATED WITH ADIPOSITY AND LIPID BIOMARKERS: CROSS-SECTIONAL STUDY IN MIDDLE-AGED BRAZILIAN MEN

P G. Cocate¹, A. Oliveira^{1,2}, H H M. Hermsdorff¹, R C G. Alfenas¹, G Z. Longo¹, M C G. Peluzio¹, J. Buthers¹, A J. Natali³

¹Department of Nutrition and Health, Federal University of Viçosa, Viçosa, Minas Gerais, Brazil

²Department of Sciences of Physical Education and Health, Federal University of São João del Rei, São João del Rei, Minas Gerais, Brazil

³Department of Physical Education, Federal University of Viçosa, Viçosa, Minas Gerais, Brazil

Background and objectives: The consumption of legumes and white meat (L&WM) has been considered as a good choice within healthy dietary pattern. Thus, this cross-sectional study aimed to investigate the potential association of the consumption of L&WM with total body fat (TBF) and circulating lipid profile in middle-aged Brazilian men.

Methods: Two-hundred and ninety-four men (age: 51±5y; BMI: 25.8±3.5kg/m²), employees at Federal University of Viçosa – Viçosa (Brazil), were enrolled. TBF was assessed by DXA (Lunar 13.31, GE®). Circulating lipid profile (total cholesterol, LDL-cholesterol, and triglycerides), occurrence of metabolic syndrome as well as lifestyle variables (smoking, alcohol consumption, and physical activity) were assessed by standardized protocols. Food intake was estimated by a validated quantita-

tive food-frequency questionnaire. Multiple linear regression models were performed.

Results: Comparing the highest with the lowest tertile of energy-adjusted- L&WM consumption (<119.0 vs. >163.7 g/d), subjects included in the highest tertile presented lower TBF values (21.97±7.7 vs. 24.3±7.4%, P=0.040), independently of age, smoking status, alcohol consumption, physical activity level, energy intake, and metabolic syndrome occurrence. In addition, those subjects with the highest tertile of energy-adjusted-L&WM consumption had lower plasma concentrations of total cholesterol (206.3±42.5 vs. 218.9±37.7 mg/dL P=0.030) and LDL-cholesterol (142.8±35.3 vs. 132.6±35.3 mg/dL, P=0.040), independently of age, smoking status, alcohol consumption, physical activity level, energy intake, and obesity prevalence (TBF > 20%).

Conclusions: L&WM consumption was inversely associated with TBF and lipid biomarkers, indicating its beneficial effect on adiposity and lipid profile control in middle-aged men. Acknowledgements: We thank the Foundation for Research Support of the State of Minas Gerais - FAPEMIG (Brazil) for financial support.

Key words: white meat, legumes, body fat, cholesterol.

¹Department of Biochemistry and Physiology, Institute of Nutrition and Food Hygiene, La Habana, Cuba

²Department of Communitarian Nutrition, Institute of Nutrition and Food Hygiene, La Habana, Cuba

³Department of Microbiology, Institute of Nutrition and Food Hygiene, Havana, Cuba

Background and objectives: Body fat excess is associated with insulin resistance, hyperlipemia, inflammation and gut microbiota changes. The aim of this study was to identify these associations in adolescents.

Methods: From 420 subjects in study (12-15 years), 26 with overweight, randomly selected, and paired by age and sex with

26 normal adolescents were submitted to records of body fat by deuterium dilution and anthropometry, epidemiologic and life style recall, clinical history, arterial blood pressure (following the recommendations of the 2004 IV Report on Diagnosis, Evaluation, and Treatment of High Blood Pressure in Children and Adolescents), 24 h dietary recall, physical activity by Actiheart monitors (2 week days, 1 week end day), glycaemia, serum lipids, serum citoquines (CPR, TNF-α and IL-6 by ELISA), and composition of the gut microbiota.

Results: Our results in overweight adolescents were as follows: hyperglycemia (17% of cases and no controls), low HDL Cholesterol (40% vs.13%), low physical activity, high levels of inflammatory citoquines, and 50% higher values of *E. coli*, *Bifidobacteria* and *Enterobacteria*.

Conclusions: Overweight classification only by size and not by body composition not favoured the comprehension of the associations between body fat, glucose intolerance, and serum affections. In all subjects, a mean 18 kg overweight was registered, but 12 kg were fat. Those differences shall be considered.

Key words: Body fat, adolescents, inflammation, gut microbiota.

PO1975

B-VITAMINS AND BONE HEALTH AMONG COELIAC DISEASE PATIENTS

M. Clarke¹, M. Ward¹, W. Dickey², L. Hoey¹, H. McNulty¹

¹Northern Ireland Centre for Food and Health, University of Ulster, Coleraine, Northern Ireland

²Department of Gastroenterology, Altnagelvin Hospital, Londonderry, Northern Ireland

Background and objectives: Osteoporosis, a condition characterised by decreased bone mass, incurs healthcare costs in excess of €30 billion per year in Europe alone. Emerging evidence indicates that compromised B-vitamin status and/or elevated homocysteine (Hcy) may have a negative effect on bone health [1]. Patients with coeliac disease, a common inflammatory condition induced by gluten consumption, are at increased risk of B-vitamin deficiency and osteoporosis. The aim of this investigation is to explore the relationship between B-vitamin status and bone mineral density (BMD) among coeliac patients.

Methods: Baseline data from coeliac patients (n= 115), recruited from specialist coeliac clinics in Northern Ireland and enrolled at this centre in an ongoing 2 year randomised controlled trial with folic acid and vitamin B12, were examined. Blood samples were collected and analysed for plasma Hcy, red cell folate, serum folate and vitamin B12 at Trinity College Dublin. BMD at the total hip, femoral neck and spine were measured using dual energy X-ray absorptiometry scans (Lunar Prodigy, GE Healthcare, UK).

Results: Serum B12 concentrations were significantly correlated with BMD at the femoral neck ($r = 0.644$; $P < 0.001$) and total hip ($r = 0.487$; $P = 0.012$) after adjustment for age and BMI in male coeliac patients ($n = 31$).

Conclusions: These preliminary findings add to the current body of evidence suggesting a potential protective role for B-vitamins in bone health. Results of the 2 year randomised, placebo controlled intervention trial are expected in 2014. Acknowledgements: We would like to acknowledge funding from the Department for Employment and Learning, Northern Ireland. Key words: B-vitamins, bone Health, coeliac disease.

PO1976

PREVALENCE OF METABOLIC SYNDROME IN INDIAN ADULTS FROM MUMBAI CITY AND ITS CORRELATION TO THEIR DIETARY PATTERN

J. Madan¹, R. Battalwar¹, A. Narsaria¹, A. Malandkar¹, V. Nadkarni¹

¹Department of Food and Nutrition, SVT College of HomeScience, SNDT Women's University, Mumbai, India

Background and objectives: Metabolic syndrome is a pre requisite to diabetes and heart disease. There is a lacunae of Indian studies on prevalence of metabolic syndrome. The present study aimed to find out the prevalence of metabolic syndrome in Mumbai city and its correlation to the dietary pattern.

Methods: The present study was an observational cross sectional study of 500 adults from middle and-upper income group of Mumbai city. Data collected included anthropometric and biochemical parameters using standardized techniques. The dietary pattern was detailed using qualitative and quantitative pretested and standardized dietary questionnaire.

Results: The prevalence of metabolic syndrome was 39% as per the modified ATP III criteria with high prevalence of overweight (80%), high waist circumference, high body fat, high LDL and Low HDL levels. There was a positive correlation between BMI, waist circumference, total body fat ($p=0.000$), fasting blood sugars ($p=0.005$), and a negative correlation with HDL levels ($p=0.01$). The total energy and fat intake were positively correlated to incidence of metabolic syndrome ($p=0.01$) and negatively correlated with fruit and vegetables intake ($p=0.002$). High refined carbohydrate intake was associated with high HbA1c ($p=0.04$), elevated systolic blood pressure ($p=0.01$) and high uric acid levels ($p=0.008$).

Conclusions: There is a felt need to identify Indian adult population with metabolic syndrome so that with early intervention the onset of non communicable diseases can be pre-

vented. A concerted input towards quality of diet with desired macronutrient modulation coupled with increase in physical activity is the suggested way out.

Key words: Metabolic Syndrome, prevalence, dietary pattern, Indian adults.

PO1977

EFFECT OF DIET ON LIPIDS BLOOD LEVELS

M. Lara¹, H. Amigo², P. Bustos²

¹School of Public Health, Faculty of Medicine, University of Chile, Santiago, Chile

²Department of Nutrition, Faculty of Medicine, University of Chile, Santiago, Chile

Background and objectives: Globally there has been an explosive increase in cardiovascular risk factors, such as dyslipidemia. Studies have reported that diet modifies blood lipid levels, however the magnitude of this effect at the population is unclear. The objective of this study was to quantify the effect of energy, carbohydrate and fat intake on blood levels of triglycerides (TG) and total cholesterol (TC) in adults.

Methods: 518 subjects aged 32 to 38 years were randomly selected from a registry of individuals born between 1974 and 1978 at the Hospital of Limache, Region of Valparaiso, Chile. We measured blood levels of TG and TC. A food frequency questionnaire was carried out to quantify energy and macronutrient intake during the last month (Software FP2). Multiple linear regression models adjusted for BMI, physical activity, alcohol consumption and education was performed.

Results: Sex interaction was found ($p < 0.015$) therefore the analysis was stratified. Only in women there was association between diet and blood lipid levels. TG levels increased 1.2 mg/dL (95% CI: 0.3 to 2.1) per 100 kcal and 5.9 mg/dL (95% CI 0.8 to 10.9) per 100 grams of carbohydrates consumed. While TC increased 0.5 mg/dL (95% CI 0.1 to 1.0) per 100 kilocalories and 16.6 mg/dl (95% CI 4.0 to 29.3) per 100 grams of fat consumed.

Conclusions: In adult women, higher energy and carbohydrate intake increases blood levels of TG and higher energy and fat intake increases the TC. This study provides information to guide food interventions to improve blood lipid level at the population. Funded by Fondecyt Proyect #1100414.

Key words: Diet, energy, blood lipids, triglycerides, cholesterol.

PO1978**THE ASSOCIATION BETWEEN URINARY SODIUM AND POTASSIUM EXCRETION AND CAROTID INTIMA MEDIA THICKNESS IN PEOPLE WITH DIABETES***K.S. Petersen¹, P.M. Clifton², J.B. Keogh¹*¹School of Pharmacy and Medical Sciences, University of South Australia, Adelaide, Australia²Baker IDI Heart and Diabetes Institute, Adelaide, Australia

Background and objectives: There is significant evidence that sodium intake is positively associated with cardiovascular disease. Carotid intima media thickness (CIMT) is a strong and independent predictor of vascular events. Few studies have investigated the association between CIMT and sodium and potassium intake in people with type 1 and type 2 diabetes. The objective was to investigate the correlation between predicted 24 hour urinary sodium and potassium excretion and CIMT in people with type 1 and type 2 diabetes.

Methods: Participants (age 53+18years) were 41 adults with type 1 (n= 13) or type 2 (n= 28) diabetes recruited from the community. Common CIMT was measured using B mode ultrasound. Carotid pulsatility index and resistive index were measured using Doppler evaluation. A random spot urine sample was collected and predicted 24 hour urinary sodium and potassium excretion was calculated using the following formula: spot urine sodium or potassium concentration/spot urine creatinine concentration x predicted 24 hour creatinine (- 2.04 x age + 14.89 x weight + 16.14 x height (cm) -2244.45).

Results: Mean predicted 24 hour urinary sodium and potassium excretion were 191+133mmol and 139+74mmol, respectively. Twenty four hour sodium excretion was positively correlated with mean and maximum left CIMT (r= 0.372 and 0.357; both p<0.05), independent of age, in the whole cohort. Potassium and the sodium to potassium ratio were not correlated with CIMT. There was no correlation between urinary sodium or potassium excretion and carotid resistive index or pulsatility index in this cohort.

Conclusions: Urinary sodium excretion is positively associated with CIMT in people with type 1 and type 2 diabetes.

Key words: Diabetes, carotid intima media thickness, sodium, potassium.

PO1979**PERCENTILES OF FRUIT AND VEGETABLE INTAKE ACCORDING TO AGE AND NUTRITIONAL STATUS IN ADULTS AND ELDERLY IN SÃO PAULO, BRAZIL***J. Pereira¹, A. Carvalho¹, A. Mendes¹, A. Previdelli¹, D. Vieira¹, D. Marchioni¹, R. Fisberg¹*¹Departamento de Nutrição, Faculdade de Saúde Pública, Universidade de São Paulo, São Paulo, Brazil

Background and objectives: Evidence suggests that fruit and vegetable intake (FVI) plays a protective role against chronic diseases, as obesity, diabetes, cardiovascular diseases and cancer. The World Health Organization (WHO) recommends the intake of a minimum of 400 g of fruit and vegetables per person/day, in order to prevent these health problems. The aim of this study is to identify differences in fruit and vegetable intake, according to age and nutritional status.

Methods: Data from a cross-sectional population-based survey among a representative sample (n=529) of adults and elderly people living in Sao Paulo, Brazil (ISA-Capital Survey, 2008). Dietary intake was assessed using two 24-hour dietary recalls and a Food Frequency Questionnaire. Habitual intake was estimated by the Multiple Source Method. Confidence Intervals (95%) for the percentiles (25, 50, 75) were used to assess the differences in FVI (g), according to the aging group (20-59 years and 60 years or more) and nutritional status (normal weight and overweight/obese).

Results: The overall mean consumption of fruit and vegetables was 179.9 g, which is 55% less than the recommended and only 4.35% of the population achieved the intake of 400 g. About 53% of the population is overweight, and this proportion is similar among adults and elderly (p=0.676), however there were no significant differences in percentiles of FVI according to nutritional status: normal weight - p25=85.8 g (CI:71.5-96.7 g); p50=144.0 g (CI:126.8-166.8 g); p75=226.4 g (CI:209.6-249.4 g) and overweight - p25=105.3 g (CI:87.8-121.8 g); p50=171.6 g (CI:156.2-189.2 g); p75=253.6 g (CI:238.3-275.7 g). Percentiles of FVI were significantly higher in all percentiles among elderly - p25=129.8 g (CI:113.5-145.5 g); p50=213.7 g (CI:191.6-230.4 g); p75=309.5 g (CI:273.8-328.7 g) than among adults - p25=71.3 g (CI:59.0-82.4 g); p50=129.9 g (CI:119.3-141.3 g); p75=196.5 g (CI:178.8-207.9 g), in both nutritional status. It was nevertheless below the recommendation.

Conclusions: FVI among adults and elderly of São Paulo was below the WHO recommendation. The percentiles were higher among the elderly and did not differ between nutritional status.

Key words: Food consumption, portion size, fruit, vegetables, obesity.

PO1980**RISK FACTOR OF IRON INTAKE, CALCIUM INHIBITOR AND BIRTH SPACE TO INCIDENT OSTEOPOROSIS FOR PREGNANT WOMEN**

S. Ardiansyah¹, T. Siswati², E. Ismail², N. Dwi Handayani³

¹Nutrition Departement, Health Polytechnic of Malang, Malang, Indonesia

²Nutrition Departement, Health Polytechnic of Yogyakarta, Yogyakarta, Indonesia

³Dietitien of Sardjito Hospital, Yogyakarta, Indonesia

Background and objectives: Osteoporosis happened when a woman is pregnant or lactating. Pregnant women must have more iron intake, more calcium intake for development babies inside. A factor that inhibitors calcium absorption is the presence of organic substances that can be compound with calcium to form insoluble salts, such as the consumption of oxalic acid, sodium and fiber. Birth space of near can also being the risk of osteoporosis, the mother which no time to recover health after child birth.

Methods: Observasional research with design of case-control study. Research conducted at Klinik Nurani Godean. There are 90 sample pregnant women such as 30 pregnant women as osteoporosis and 60 pregnant women as non osteoporosis. As data research iron intake, calcium inhibitor, birth space, and Bone Mineral Density.

Results: Most pregnant women with osteoporosis happen in the third trimester (60%), iron consumption risk (93,3%), oxalic acid consumption risk (53,3%), sodium consumption risk (56,7%), fiber consumption risk (56,7%) and birth space risk (3,3%). After that, the majority of pregnant women on non-osteoporosis happen in the second trimester (35%) and the third trimester (33,3%), iron consumption risk (91,7%), oxalic acid consumption risk (30%), sodium consumption risk (45%), fiber consumption risk (48,3%) and birth space risk (1,7%).

Key words: Iron intake, calcium inhibitor, birth space, osteoporosis.

PO1981**EFFECT OF CALCIUM SUPPLEMENTATION ON BONE MASS AND CALCIUM METABOLISM IN ADOLESCENTS, LACTATING AND POSTMENOPAUSAL WOMEN: A 2-YEAR RANDOMIZED TRIAL**

Y. Chen¹, Z. Zhang², X. Ma², R. Wang², J. Li¹, W. Zhong¹, C. Zhang¹, Z. Huang³, X. Yang³, Y. Su²

¹Department of Medical Statistics & Epidemiology, Sun Yat-sen University, Guangzhou, China

²Department of Nutrition, Sun Yat-sen University, Guangzhou, China

³National Institute of Nutrition and Food Safety, Chinese Center for Disease Control and Prevention, Beijing, China

Background and objectives: The aim of this study was to examine effect of calcium supplementation on bone changes and calcium metabolism.

Methods: 210 adolescents (11-14y), 150 lactating women and 320 postmenopausal women (57 ± 4 y) were recruited for this double-blind, randomized trial. Participants were randomly assigned into 3 or 4 groups with daily doses of 40 g milk powder and 0, 300 and 600 mg calcium in the Low, Middle, and High dose groups for two years; and an additional Blank group for postmenopausal women. Bone mineral density (BMD) and content (BMC) at the whole body, spine and hip were determined using DXA at 0, 1 and 2 year. 10 participants in each age-intervention group further completed a 7-day calcium balance study using a double stable-isotope technique.

Results: 184 adolescents, 101 lactating and 287 postmenopausal women completed the study. During the 2-year intervention, mean calcium intake (mg/d) in the Low, Middle and High dose groups were: 685, 962, 1184 (girls); 761, 1008 and 1264 (boys); 777, 1069 and 231 (lactating women); and 730, 940, and 1205 and 720 (blank group) in postmenopausal women; BMD and BMC increased substantially in adolescents and decreased in lactating and postmenopausal women, but no significant difference in the 2-year changes in BMD and BMC among the three intervention groups in each study population. Calcium metabolism study showed enough calcium retention (342 mg/d) was found in adolescents (mean intake 1000 mg/d); positive balance (53 mg/d) was obtained in lactating women (mean intake: 893 mg/d), and net balance reached in postmenopausal women (mean intake: 1024 mg/d).

Conclusions: Our findings suggest mean calcium intakes of 700-800 mg/d could produce the plateau effect on bone changes, but higher values of calcium balance are obtained in the metabolism study in the three populations.

Key words: Calcium intake, bone mass, calcium metabolism, randomized trial, Chinese.

⁶Tan Tock Seng Hospital, Singapore

Background and objectives: Ethnicity has been shown to influence inter-individual variability in postprandial glycemic responses. However, no studies to date have examined glycemic variability among the ethnic groups in a multi-ethnic Asian population. We hypothesized that ethnic differences in glycemic responses following a mixed meal tolerance test (MMTT) is a function of body composition and fat distribution.

Methods: Blood samples, anthropometric measurements and body composition (DEXA) were obtained from 83 male subjects [32 Chinese (C), 25 Malay (M), 26 Asian-Indians (I)] who had no history of glucose intolerance. They underwent a liquid MMTT, consisting of 400 ml of Ensure PlusTM (300 kcal, 40.4 g carbohydrate, 12.5 g protein, 9.8 g fat). Postprandial glycemic responses (incremental area under the curve, iAUC) over 240min of MMTT were calculated using the trapezoidal rule. **Results:** The mean \pm SE age and body mass index (BMI) were 25.2 ± 4.2 years and 21.3 ± 1.4 kg/m² respectively. Despite similar BMI, the inter-ethnic fat adiposity was different, with the Indians having a greater waist circumference (cm) (I: 78.3 ± 4.8 vs. C: 75.2 ± 3.5 vs. M: 73.9 ± 4.1 , $p=0.001$) and a trend towards higher percent body fat (I: 19.8 ± 5.1 vs. C: 18.2 ± 4.5 vs. M: 16.4 ± 4.8 , $p=0.051$). The postprandial glycemic response (iAUC), adjusted for age, waist circumference and percent body fat was highest in Malays, followed by Indians and Chinese (M: 275.1 ± 155.7 vs. I: 197.1 ± 137.3 vs. C: 99.5 ± 196.3 , $p=0.002$) over 240min.

Conclusions: Although Indians have greater abdominal adiposity reflecting higher insulin resistance, their glycemic response was lower than Malays. Other physiological and me-

tabolic factors should be evaluated to provide further insights into the inter-ethnic variability in glycemic responses.

Key words: Postprandial glycemia, ethnicity, adiposity.

PO1983**GLUTAMINE ADMINISTRATION MODULATES T LYMPHOCYTE POLARIZATION IN DEXTRAN SULFATE SODIUM-INDUCED COLITIS**

C. Hsiung¹, M H. Pai², C C. Li¹, Y C. Hou³, S L. Yeh¹

¹School of Nutrition and Health Sciences, Taipei Medical University, Taipei, Taiwan

²Department of Anatomy, Taipei Medical University, Taipei, Taiwan

³Department of Surgery, National Taiwan University, Taipei, Taiwan

Background and objectives: Inflammatory bowel disease (IBD) is a multifactorial disorder of unknown etiology. Dys-regulated immune response between T regulatory (Treg) and T-helper (Th) cells may be responsible for the pathogenic mechanism. Glutamine (Gln) is a nutrient with immune-modulatory properties. This study investigated the effects of Gln on Th/Treg cell homeostasis and colonic inflammatory mediator expression in mice with dextran sulfate sodium (DSS)-induced colitis.

Methods: Mice were randomly assigned to a normal control group, and 2 DSS-treated groups. The control group (C) and one of the DSS group (DC) were fed with a common semipurified diet, while the other DSS-treated group (DG) were provided an identical diet except that part of the casein was replaced by Gln, which provided 25% of total amino acid nitrogen. The diets were fed for 10 days. At day 6, mice in the control group received distilled water and DSS groups were treated with distilled water containing 1.5% DSS for 5 d. At the end of the experiment, mice were sacrificed for further examination.

Results: DG group had lower plasma haptoglobin, colon weight/length ratio, immunoglobulin G, monocyte chemoattractant protein-1, tumor necrosis factor- α levels than the DC group. Also, the percentages of interleukin-17F, interferon- γ in blood and gene expression of transcription factors T-bet, RAR-related orphan receptor- α expressions in mesenteric lymphatic node were lower while blood Foxp3 was higher in the DG group than the DC group and had no differences from the C group.

Conclusions: The results showed that Gln administration suppressed Th1/Th17 and Th-associated cytokine expressions. Also, the expression of Treg was upregulated. These findings suggest that Gln modulates the balance of Th/Treg that may consequently reduce inflammatory reaction in DSS-induced colitis.

Key words: DSS-induced colitis, IBD, T-lymphocytes.

PO1984**EFFECTS OF EICOSAPENTAENOIC ACID AND DO-COSAHEXAENOIC ACID ON PROSTATE CANCER CELL MIGRATION INDUCED BY TUMOR-ASSOCIATED MACROPHAGE**

C.C. Li¹, Y.C. Hou², M.H. Pai³, S.L. Yeh¹

¹School of Nutrition and Health Sciences, Taipei Medical University, Taipei, Taiwan

²Department of Surgery, National Taiwan University, Taipei, Taiwan

³Department of Anatomy Taipei Medical University, Taipei, Taiwan

Background and objectives: Dietary n-3 polyunsaturated fatty acids (PUFAs) are associated with reduced risk of prostate cancer (PCa). Tumor-associated macrophages (TAMs) are the main intratumoral infiltrating leukocytes, and increased TAMs numbers correlates with poor prognosis in PCa. The aim of this study was to investigate the effect of n-3 PUFAs on PCa cell migration induced by TAMs.

Methods: PCa epithelial cell line, PC-3, were pretreated with 50 μ M eicosapentaenoic acid (EPA), 50 μ M docosahexaenoic acid (DHA) or 10 μ M peroxisome proliferators-activated receptor (PPAR)- γ antagonist GW9662 before exposure to the conditioned medium (CM). CM was derived from M2-polarized THP-1 macrophages treated with phorbol-12-myristate 13-acetate (PMA), interleukin (IL)-4 and IL-13. We analyzed the DNA binding activity of PPAR- γ by transcriptional assay kit. The nuclear factor (NF)- κ B p65 and I κ B α were assayed by Western blot. The mRNA expressions of matrix metalloproteinase (MMP)-9, urokinase-type plasminogen activator receptor (uPAR), colony stimulating factor (CSF)-1 and transforming growth factor (TGF)- β were measured by real-time RT-PCR in PC-3. Also, migration ability of PC-3 was evaluated by using a co-culture system of M2 macrophages and PC-3.

Results: PPAR- γ DNA binding activity significantly increased in PC-3 incubated with CM in the presence of EPA or DHA. EPA/DHA administration upregulated cytosolic I κ B α expression and decreased protein levels of nuclear NF- κ B p65 in PC-3. Furthermore, EPA/DHA downregulated the mRNA expressions of MMP-9, uPAR, CSF-1 and TGF- β . Also, PC-3 migration ability was inhibited. Pre-treatment with GW9662 abolished the favorable effect of EPA/DHA on PC-3.

Conclusions: These results indicate that EPA or DHA administration reduce PC-3 cell migration and decrease chemotactic ability of macrophages. The impact of EPA/DHA may partly be explained by upregulating PPAR- γ and decreasing NF- κ B p65 transcriptional activities in PC-3.

Key words: Prostate cancer, TAM, n-3 PUFAs, PPAR- γ , migration.

PO1985**GABA TEA ON CARDIAC FIBROSIS AND FAS DEATH RECEPTOR DEPENDENT APOPTOTIC PATHWAY IN STREPTOZOTOCIN-INDUCED DIABETIC RATS**

⁴Graduate Institute of Chinese Medical Science, China Medical University, Taichung, Taiwan

Background and objectives: GABA tea is a tea product that contains a high level of gamma-aminobutyric acid (GABA). Thus, this study aimed to investigate the effect of GABA tea on diabetic myocardial fibrosis, and further to clarify the potential mechanisms.

Methods: In this study, to investigate the roles of GABA tea in the heart of diabetic rats, male Wistar rats as diabetic animal models were injected with 55 mg/kg streptozotocin (STZ) to induce diabetes for 2 weeks, and subsequently administrated with the dosages of 4.55 and 45.5 mg/kg/day GABA tea extract for 6 weeks.

Results: Our data showed that the fasting blood glucose levels were reversed back to normal levels in GABA tea-treated diabetic rats as compared with untreated diabetic rats. Additionally, we observed GABA tea as potent inhibitors of cardiac fibrosis induced by STZ. We further found that GABA tea exposure reduced the elevated expression of tumor necrosis factor-alpha (TNF-alpha), Fas and Fas ligand (FasL) in the excised hearts of diabetic rats. Moreover, our results demonstrated that the STZ-induced protein level of activated caspase-8 and caspase-3 were significantly inhibited after GABA tea treatment. Taken together, we propose that the inhibitory effect of GABA tea on STZ-induced cardiac fibrosis could be mediated by reducing blood glucose and further attenuating TNF- α expression and/or the Fas/FasL system-mediated apoptosis in rats.

Conclusions: These findings will provide implications for the potential of GABA tea in anti-diabetic property, which may involve polyphenol and GABA and the consequent antioxidant action.

Key words: GABA tea, diabetes, heart, Fas, TNF-alpha.

PO1988**TEN-YEAR CARDIOVASCULAR RISK PREDICTION AMONG 194 THAI MIDDLE-AGED ADULTS**

S. Putadechakum¹, V. Leelahaku³, T. Klangjareonchai², C. Roongpisuthipong²

¹Research Center, Ramathibodi Hospital, Mahidol University, Bangkok, Thailand

²Department of Medicine, Ramathibodi Hospital, Mahidol University, Bangkok, Thailand

³Department of Fundamental Nursing, Mahidol University, Bangkok, Thailand

Background and objectives: Cardiovascular diseases (CVD) cause an estimated 17 million deaths each year, accounting for one-third of all deaths worldwide. More than one-third of these deaths occur in middle-aged adults. This study estimated 10-year CVD risk trends in Thai middle-aged adults living at Bangkoknoi district where the subjects have migrated from various parts of Thailand.

Methods: Total number of 194 subjects (51 M, 143 F) aged 35-59 were enrolled into this study via multistage sampling method from the people living in Bangkoknoi district and volunteered for the study. Information on the marital status, education, occupation, living condition, physical activities, smoking, consumption and drinking habits, stress as well as their history of diseases were obtained through a questionnaire. Anthropometric and biochemical assessment were also determined. We estimated 10-yr risk of CVD by using Framingham heart study risk factor categories point scores, the risk functions by gender, age group in account of level of blood pressure, total serum cholesterol, HDL-C, LDL-C, diabetes and smoking status.

Results: Mean±SD of age, BMI, WHR, %BF, systolic and diastolic BP were 45.6±6.7 yr, 23.2±3.3 kg/m², 0.88±0.06, 29.9±6.0 %, 126.1±17.1 mmHg, 83.9±13.1 mmHg in males, and 46.5±7.8 yr, 25.2±4.3 kg/m², 0.82±0.11, 40.4±4.5%, 121.4±19.2 mmHg, 80.4±11.8 mmHg in females. Male subjects: 49% had a 10-year risk for CVD of < 10%, 31.4% had a risk of 10-20%, and 20% had a risk of > 20% when compared to female subjects, 71.3% had a 10-year risk for CVD of < 10%, 21% had a risk of 10-20%, and 7.7% had a risk of > 20%.

Conclusions: 10-year CVD risk were highly prevalent in males who had the common combination of risk factors. Therefore, the current epidemic rise of CVD in middle aged adult needs attention.

Key words: CVD, Framingham heart study, 10-yr CVD risk.

PO1990**DIABETES: A RISING PROBLEM IN TANZANIA. WHAT CAN WE DO?**

C. Ludwig¹, S.D. Habicht¹, M.E. Swai², M.B. Krawinkel¹

¹Institute of International Nutrition, Justus-Liebig-University Giessen, Giessen, Germany

²Kilimanjaro Christian Medical Centre, Moshi, Kilimanjaro Region, Tanzania

Background and objectives: Tanzania is faced with high rates of pre-diabetes (9.4%) and diabetes (2.3%). To identify possibilities for improvement, two cross-sectional studies on underlying factors, such as lifestyle, were conducted in the Kilimanjaro Region, Tanzania. The first study assessed knowledge on and management of diabetes among diabetic patients. The second study assessed rate of overweight, pre-diabetes, and related risk factors among adults without any diagnosed disease.

Methods: The 2011 study included 155 adult diabetic patients of the Kilimanjaro Christian Medical Centre, interviewed with standardized questionnaires. The 2012 study assessed following health indicators among 105 participants around Moshi: body mass index, fasting blood glucose, and blood pressure, among others. Two 24-hour dietary and physical activity recalls and a food frequency questionnaire were conducted.

Results: Almost all patients were on medication. Only one patient was on diet treatment alone. Farmers were significantly older at diagnosis than non-farmers, which demonstrates the role of physical activity in diabetes prevention. Although almost 50% could name four to six different symptoms, complications, or causes, this knowledge was presumably gained after diagnosis. More than 2/3 of patients were diagnosed at least 6 months after symptoms started. The 2012 study revealed high intakes of refined carbohydrates and fats and a median physical activity level of 1.5 (IR: 0.4). Forty percent of participants were overweight or obese. According to WHO criteria, 17% were classified as pre-diabetic.

Conclusions: The results demonstrate the need to increase awareness, management, and prevention of diabetes. Information leaflets could be placed in markets, churches/mosques, and bars. Access to glucose tests should be increased. Nutrition counseling, support groups, and sporting facilities should be instituted at community and clinical level. Additionally, preventive strategies are required. A dietary intervention study with bitter melon among pre-diabetics is planned in Tanzania for 2013.

Key words: Diabetes, knowledge, management, prevention.

PO1991

FOOD AND ALCOHOL INTAKE IN JAPANESE TYPE 2 DIABETES

Y. Takano¹, H. Minami¹, H. Fukushima¹

¹Prefectural University of Kumamoto, Kumamoto, Japan

Background and objectives: The number of type 2 diabetic patients is increasing in Japan. It is necessary for patients to continue diet therapy, exercise therapy and pharmacotherapy. Usually we suggest that patients stop drinking alcohol. However, there are many people who continue drinking. We investigated food and alcohol intake in Japanese type 2 diabetic patients.

Methods: A total number of 45 Japanese type 2 diabetic patients were surveyed as the subjects of this study. We measured the body height, weight, fasting blood glucose, HbA1c, TG, LDL-cho, HDL-cho. We also examined food and alcohol intake and physical activity. For the food and alcohol intake we used the BDHQ (brief-type self-administered diet history questionnaire) and drinking behavior questionnaire. And to measure physical activity we used the IPAQ (International Physical Activity Questionnaire). The statistical difference was determined by Student's t-test. A P value of less than 0.05 was considered statistically significant.

Results: There was no significant difference in blood measurements among people who drank often, people who drank a high volume and people who neither drank often nor in large quantities. Drinking frequency and volume of males was significantly higher than females ($p < 0.001$). In subjects who drank while eating dinner, 30% of males and females said they ate less when they drank and 70% of people said their food intake did not change. In people who drank often and people who drank a lot there were many males and people with high energy intake. People who drank often and people who drank a lot showed significantly lower protein and carbohydrate intake than people who neither drank often nor a large amount.

Conclusions: The results of this study suggest that people who drink often and people who drink a lot usually reduce their amount of food intake.

Key words: Alcohol, type 2 diabetes, Japanese.

PO1992

THE DEVELOPMENT OF A PORTABLE MEAL CARD TO COMPLEMENT NUTRITION EDUCATION FOR PERSONS WITH DIABETES

K. Fujisawa¹

¹Department of Food and Nutrition, Okayama Gakuin University, Kurashiki, Japan

Background and objectives: The number of people with diabetes has been increasing around the world, including Japan, where the rate of nutrition education of diabetics is high, but compliance with the principles taught in nutrition education is not verified. Thus, the creation of a portable meal card for persons with diabetes receiving nutrition education will be a useful measure to improve compliance. This paper presents such a card.

Methods: The portable meal card was developed and six university seniors majoring in nutrition were asked to use the card. After that, a questionnaire was administered to them. The questionnaire assessed the card's ease of use in terms of size, layout, the items mentioned on it, and so on.

Results: The data assessed included the questionnaire results the contents of a meal card, the students' photographs of their meals and the quantity of energy, protein, liquids, carbohydrates, and salt in them. An additional subjective component of values was indicated individually by participants. Recipes and cooking advice are printed on the back of the card. A postcard size was deemed the most suitable in terms of its convenience for printing.

Conclusions: Although this experiment was conducted among students, there are differences between them and diabetic patients, many of whom have little knowledge of nutrition and are elderly. A future follow-up study among diabetic patients will be conducted to examine the ecological validity of the card.

Key words: Diabetes, Portable meal card, nutrition education.

PO1994

KNOWLEDGE AND PRACTICES ON HOME MANAGEMENT OF DIARRHEA (HMD) AMONG CAREGIVERS OF CHILDREN 6-24 MONTHS IN URBAN AREA JAKARTA

Y. Novrianto¹

¹Seameo Recfon, Faculty Medicine University of Indonesia, Jakarta, Indonesia

Background and objectives: Diarrhea is a leading cause of morbidity and mortality across all age groups and regions of

the world. Among children 0-59 months of age, it is responsible for 1.236 million deaths. The HMD is challenging for community in the urban setting area. This study was conducted to assess knowledge, and practice of caregivers on HMD in children aged 6-24 months.

Methods: The study design was cross sectional. It was conducted on May 7 to 21, 2012 in Paseban village, Central Jakarta. Both quantitative and qualitative methods were carried out.

Results: As many as 42% of children aged 6-24 months suffered of diarrhea within the past two weeks; 57% of them were children aged 12-24 months. Diarrhea duration was less than three days (69%). A half of the caregivers had good knowledge (50%) on home management of diarrhea. Most of caregivers had poor practice (55%) on home management of diarrhea. There was no significant association between diarrhea within the past two weeks and the child's nutritional status, child's characteristics, caregiver's characteristics, and caregiver's knowledge and practice on home management of diarrhea. There was a significant association between caregiver's characteristics (age and education background) and caregiver's knowledge on home management of diarrhea.

Conclusions: Further research is needed to investigate the quality and quantity of child's intake during diarrhea. The socialization amongst the caregivers on diarrhea home management guidelines practices needs to be improved. Further effort need to be done to synchronize the guidelines and health staff opinion based on updated knowledge on diarrhea disease, including on child's intake during illness. Primary health center services need to be improved to increase community's referral to the primary health center.

Key words: Home management of diarrhea, children aged 6-24 months old, urban area.

This study investigated the follow-up visit rates after surgery on weight loss and body composition changes in patients with sleeve gastrectomy (SG), Roux-en-Y gastric bypass (GB) and adjusted gastric banding (AGB).

Methods: This was a retrospective clinical study of obese patients after bariatric surgery during 2011 to 2012 in Taipei Medical University Hospital, Taiwan. There were 26 patients with GB, 51 with AGB and 315 performed SG in this study. The calorie and protein recommendations to the patients were based on NIH and ASMBS guidelines. The postoperative follow-up visits were scheduled at 1 week, 1, 3, 6, 9, and 12 months. Body compositions [weight, muscle mass, fat mass, and waist-hip ratio (WHR)] were measured before and after surgery using BIA method.

Results: All patients took multi-vitamin/mineral on the first month (AGB 70-80% vs. SG and GB 80-90%) after surgery. All patients had significant weight loss, lower body fat mass and WHR after follow up for 1 year. However, SG or GB had greater extend of body fat loss and lower WHR than AGB. Compare to the patients with lower follow-up visit rates, patients with higher visit rates resulted in higher body weight and fat mass loss, and WHR decrement. Also, the frequency of multi-vitamin/mineral consumption was higher.

Conclusions: Our results suggest that patients with SG or GB had better outcomes than AGB after follow up for 1 year. Independent of the surgical procedure performed, patients with higher follow-up visit rates had greater extend of body weight and fat mass loss than low visit rates.

Key words: Body composition, diet management, bariatric surgery, morbid obesity.

PO1995

EFFECTS OF DIETARY MANAGEMENT AFTER BARIATRIC SURGERY ON BODY COMPOSITION CHANGES IN TAIWAN

I C. Cheng^{1,2}, W. Wang¹, S C. Wei¹, P H. Hsueh¹, T W. Chung³, S L. Yeh²

¹Comprehensive Weight Management Center, Taipei Medical University, Taipei, Taiwan

²School of Nutrition and Health Sciences, Taipei Medical University, Taipei, Taiwan

³Department of Dietetics, Taipei Medical University Hospital, Taipei, Taiwan

Background and objectives: Bariatric surgery is now regarded as the most effective method to control morbid obesity. Dietary management after the surgery is very important in long-term weight loss and maintenance for the patients.

PO1996

NUTRITIONAL STATUS OF HOSPITALIZED CANCER PATIENTS IN TAIWAN

I C. Cheng^{1,3}, T W. Chung², C H. Liu², C J. Lee², Y J. Lin², H Y. Su², M Y. Chin²

¹Comprehensive Weight Management Center, Taipei Medical University, Taipei, Taiwan

²Department of Dietetics, Taipei Medical University Hospital, Taipei, Taiwan

³School of Nutrition and Health Sciences, Taipei Medical University, Taipei, Taiwan

Background and objectives: The clinical care discussed malnutrition screening form nurse before in our hospital. This show that the third cancer patients who had moderate and height malnutrition were oral cancer, hepatic, and rectal colon cancer. In this study was to find whose the first severe malnutrition of cancer hospitalized, and the distribution of the nutritional status in Taipei medical university hospital, in Taiwan.

Methods: This was a retrospective clinical study. For all patients, the dietitians visited and recorded their nutritional status, laboratory tests [albumin (Alb), hemoglobin, C-reactive protein (CRP), and total lymphocyte count (TLC)], and nutritional problems [Alb <3, Body mass index < 18.5, NPO > 5 days, weight loss >10 % during 6 month, and poor intake].

Results: There were almost 1500 cancer patients who received the dietitian assessment and counseling on the first time during 2012. The results showed that there were significant differences in body mass index, dietary calorie intake, and protein intake among the high, moderate, mild and none malnutrition status. The biomarkers Alb, Hg, and TLC were mild different among nutrition status. Moreover, the percentage of different cancer disease discussed. This data indicated that the cancer patients who had higher malnutrition.

Conclusions: This study revealed the cancer patients to widespread malnutrition, nutritional intervention could increase their intake instead the nutritional status when hospitalized. We will as soon as possible to give nutritional support to prevention of cancer patients into severe malnutrition.

Key words: Nutritional therapy, nutritional status, cancer.

EATING RATE IS ASSOCIATED WITH EATING BEHAVIORS ACCORDING TO GENDER AND OBESITY

S. Park¹, W S. Shin²

¹Department of Oriental Medical Food and Nutrition, Semyung University, Chungcheongbuk-do, Republic of Korea

²Department of Food and Nutrition, Hanyang University, Republic of Korea

Background and objectives: The aim of this study was to compare the differences in eating behaviors and masticatory performances between genders or obesity status, and to determine the associations between eating behaviors and masticatory performances in both genders according to obesity status.

Methods: Twenty four (50% M and 50% F) adults were matched on age, gender, obesity status and dental health. Eating behaviors were assessed by the Three Factor Eating Questionnaire (TFEQ) and chewing performances were measured using electromyography (EMG) while eating a boiled-rice (150 g). Compared with lean participants, obese participants had significantly higher level of disinhibition ($p < 0.05$ for M; $p < 0.01$ for F). Chewing performances were not significantly different by obesity status. Males had greater bite size ($p < 0.05$ for lean; $p < 0.01$ for obese) and chewing power ($p < 0.001$) and faster eating rate ($p < 0.01$ for lean; $p < 0.05$ for obese) than females. Females habitually chewed more ($p < 0.01$ for lean; $p < 0.05$ for obese) and had longer meal duration ($p < 0.05$) than males.

In lean males, the eating rate was negatively ($r = -.812$, $p < 0.05$) associated with disinhibition and total number of chew (TNC) was positively ($r = .902$, $p < 0.05$) associated with the hunger sensitivity on the TFEQ. In obese males, the eating rate was negatively ($r = -.860$, $p < 0.05$) associated with cognitive restraint and positively ($r = .871$, $p < 0.05$) associated with the hunger sensitivity. No significant associations between eating behaviors and chewing performances were observed in females.

Conclusions: Disinhibited eating was differentiated in obese adults. Eating behaviors were related to the rate of ingestion or TNC in males but not in females. Therefore, gender specific intervention and counseling aimed to improve the eating rate could be promising for the eating behavioral treatment in the obese. Acknowledgements: This research was supported by grants from the Globalization of Korean Foods R&D program, funded by the Ministry of Food, Agriculture, Forestry and Fisheries, Republic of Korea.

Key words: Obesity, gender, eating behavior, TFEQ, eating rate.

PO1998

PERCEPTIONS AND SATISFACTION ON HOSPITAL FOODSERVICE AND DIETARY INTAKE AMONG HOSPITALIZED DIABETIC DIET RECEIVERS

R. Jamaluddin¹, N A. Abd Manan¹, H. Abu Saad¹, M S. Ab Karim¹

¹Universiti Putra Malaysia, Selangor Darul Ehsan, Malaysia

Background and objectives: During hospitalization, patients with diabetes or its related symptoms are prescribed with diabetic diet, where the total calorie has been modified according to individual's requirement and stages of illness. Nevertheless, there are reports on low dietary intake among diabetic patients. In fact, patients' perception on hospital foodservice is reported to influence their dietary intake. Therefore, this study aimed to study the relationship between dietary intake and patients' perceptions and satisfaction on hospital foodservice among diabetic diet receivers.

Methods: Seventy-seven hospitalized patients who received diabetic diet in a local government hospital were recruited. A validated questionnaire consisting of four dimensions of foodservice, namely food quality, timeliness and reliability, staff issue and physical environment was used to investigate patients' perceptions and satisfaction on hospital foodservice. Weighed food intake (hospital food) and one day food record (non-hospital food) were used to measure patients' dietary intake.

Results: The total score of four dimensions of foodservice (Mean \pm SD = 59.9 \pm 6.05, Max score = 120) and patients' satisfaction (Mean \pm SD = 6.10 \pm 1.61, Max score = 10) showed

a moderate satisfaction on hospital foodservice. The means of energy and protein intake from hospital foods were higher than non-hospital foods. About 55% (n=42) of the patients met the individual requirement for energy and protein intake from the hospital foods. Of four foodservice dimensions, only food quality (r=0.588), timeliness and reliability (r=0.450) and staff issue (r=0.376) had significant (p<0.001) and positive correlations with patients' satisfaction on hospital foodservice. These three dimensions also showed significantly positive association between the energy intakes from hospital food.

Conclusions: The presence of associations between dietary intake and the foodservice dimensions indicated that satisfaction with the foodservices may influence diabetic patients' dietary intake during hospitalization.

Key words: Perceptions, satisfaction, hospital foodservice, Malaysia.

PO1999

OVERWEIGHT AND OBESITY TRENDS AMONG ELDERLY MEN LIVING IN UMLAZI -DURBAN SOUTH AFRICA

X. Mkhize¹, W. Oldewage-Theron², C. Napier³

¹Mangosuthu University of Technology, Umlazi, South Africa

²Vaal University of Technology, Vanderbijlpark, South Africa

³Durban University of Technology, Durban, South Africa

Background and objectives: Overweight and obesity trends are more prevalent in women than men; however they must be investigated in elderly men. Although anorexia of ageing is also a reality in older men, overweight and obesity trends have been detected in this population group. The objective of the study was to determine the nutritional status of free living elderly men (>60yrs) living on state pension, in Umlazi, KwaZulu-Natal (Durban) South Africa. The mean age for elderly men was 73.

Methods: The nutritional status included anthropometrics to determine BMI, waist circumference and WTHR scores, dietary intake and blood pressure correlations of the elderly.

Results: 34.2% men were overweight (BMI> 25-29.9) and 18.8% were obese (BMI> 30), 43.0% were within normal weight (BMI > 18.5- 24.9) and only 4.0% were underweight (BMI <18.5), the mean BMI score was 26. Waist circumference scores indicated 74.0% (\bar{x} 102 cm) were within the cut of points and 26.0% (>102 cm) exceeded cut off points. Waist to hip ratio-WTHR scores indicated that 48.0% were at risk for metabolic syndrome exceeding > 0.5 and 52.0% were not at risk. Hypertension was also prevalent in 83.0% of the men

and there was a correlation between systolic pressure and BMI significant at 0.01. The carbohydrate intake was 65.0% of the WHO nutrient intake goals and fibre consumption was 33.3% of the RDA.

Conclusions: Central obesity, overweight and obesity trends were detected within the elderly men in this community. Interventions to reduce weight are detrimental in reducing health risks particularly for older people; since they can also improve the quality of life and fewer medical complications.

Key words: Elderly men, obesity, nutritional status.

PO2000

BETAINE IMPROVES GENOMIC HYPOMETHYLATION AND ALLEVIATES THE HEPATIC STEATOSIS INDUCED BY HIGH FAT DIET IN MICE

H. Zhu¹, L. Wang¹, J. Zhou¹

¹Department of Nutrition, Sun Yat-Sen University, Guangzhou, Guangdong, China

Background and objectives: Betaine is a natural compound in common foods and serves as a methyl donor. The hepatoprotective effects of betaine supplement on fatty liver has been reported in experimental and clinical studies, with mixed results. The present study aims to determine the effect of betaine supplement in NAFLD mice through methyl group metabolism.

Methods: Thirty-two male C57BL / 6 mice were divided into four groups and fed with control diet (CD); high fat diet (HFD); HFD +1% betaine (HFD + 1% B) and HFD +2%betaine(HFD + 2% B), respectively, for 12 weeks.

Results: Betaine supplement significantly reduced visceral fat ratio, serum ALT, AST, TG (all P < 0.05) and dose-dependently alleviated hepatic TG deposite (P < 0.01) of NAFLD mice. HFD greatly increased serum homocysteine levels (P < 0.05), decreased serum choline (P < 0.01) and hepatic S-adenosine methionine level (P > 0.05), treatment of betaine significantly reversed the abnormal metabolism of hepatic methyl group. Genomic DNA hypomethylation was found in HFD, and betaine supplement significantly improved it (P < 0.01) to the CD level. HFD markedly increased FAS-UCP2-ACOX mRNA expression and decreased the PPAR α mRNA expression-all P<0.05-, betaine supplement reversed the dysregulated gene expression.

Conclusions: Disordered methyl group metabolism likely contributes to the genomic hypomethylation during high fat diet induced NAFLD, betaine supplement can correct methyl group metabolism, elevate global DNA methylation level in the liver, regulate the expression of genes involving in triglyceride metabolism, and ultimately alleviate liver injury induced by high fat diet. Acknowledgements: This study was supported by grants from National Natural Science Foundation of China

(81072302 and 81273050) and Natural Science Foundation of Guangdong Province of China (10151008901000207).

BODY ADIPOSITY INDEX IS A GOOD PREDICTOR FOR INCIDENT HYPERTENSION IN ADULTS

D. Moliner-Urdiales¹, E. G Artero², X. Sui³, V. España-Romero⁴, D.C. Lee⁵, S.N. Blair³

¹Department of Education, University Jaume I, Castellón, Spain

²Area of Physical Education and Sport, University of Almería, Almería, Spain

³Department of Exercise Science, University of South Carolina, Columbia, South Carolina, USA

⁴MRC Epidemiology Unit, Institute of Metabolic Science, Addenbrooke's Hospital, Hills Road, Cambridge, United Kingdom

⁵Department of Kinesiology, Iowa State University, Ames, Iowa, USA

Background and objectives: In recent years, there have been an increased number of studies showing the strong association between obesity and the risk of hypertension, which is well recognized as a major cause of morbidity and mortality. The body adiposity index has been recently proposed as a new method to estimate the percentage of body fat (%BF). The aim of our study was to compare BAI, body mass index (BMI), and waist circumference with respect to their ability to predict hypertension risk in a sample of middle-aged men and women.

Methods: The present follow-up analysis comprised 10309 individuals (2259 females) free of hypertension from the Aerobics Center Longitudinal Study (ACLS), who completed a baseline examination during 1988-2003. Incident hypertension was ascertained from responses to mail-back surveys between 1990 and 2004.

Results: During an average follow-up of 9.1 years, 872 subjects (107 females) became hypertensive. Cox proportional hazards regression analysis was used to calculate hazard ratios (HRs) for incidence of hypertension according to 3 different sets of confounders. In the fully-adjusted model, males in the middle and upper categories of all body adiposity measures showed a higher risk of incident hypertension (HRs ranged from 1.49 to 2.09). Females showed a higher risk of incident hypertension in the upper categories of BAI and BMI (HRs 1.84 and 3.36, respectively) but not waist circumference (HR 1.72).

Conclusions: In our best knowledge, no previous studies have analyzed the ability of BAI to predict the risk of incident

hypertension. The middle tertile of BAI only identified higher risk of hypertension in males, thus showing lower discrimination accuracy in females. In order to predict incident hypertension, BAI could be considered an alternative to traditional body adiposity measures, being as good predictor as BMI or waist circumference.

Key words: Obesity, body fat, BAI, blood pressure, adults.

PO2002

ASSOCIATION BETWEEN BODY ADIPOSITY INDEX AND CARDIOVASCULAR DISEASE RISK FACTORS IN ADULTS: THE AEROBICS CENTER LONGITUDINAL STUDY

D. Moliner-Urdiales¹, E. G Artero¹, X. Sui¹, V. España-Romero¹, D.C. Lee¹, S.N Blair¹

¹University Jaume I, Castellón, Spain

Background and objectives: The body adiposity index (BAI) has been recently proposed as a new method intended to substitute BMI as an easy estimate of percentage body fat (%BF). Validation studies showed contradictory results, and the association between BAI and cardiovascular disease (CVD) risk factors is not well established. The aim of the study was to analyze the association between BAI and CVD risk factor compared with BMI and %BF in adult men and women.

Methods: The present analysis comprised 10309 individuals (2259 females) enrolled in the Aerobics Center Longitudinal Study (ACLS) between 1988 and 2003, with valid data for BAI, BMI, %BF and CVD risk factors (e.g. total cholesterol, fasting blood glucose, systolic and diastolic blood pressure, and cardiorespiratory fitness).

Results: All body adiposity measures were positively correlated with each other ($P \leq 0.001$). BAI showed lower correlation values with %BF than BMI in both males and females. Significant associations were shown between all body adiposity measures and CVD risk factors (all $P \leq 0.001$). The highest correlation values for fasting blood glucose, systolic and diastolic blood pressure were found with BMI, and for total cholesterol and cardiorespiratory fitness with %BF. Except for systolic and diastolic blood pressure, BAI showed slightly stronger association with CVD risk factors in males than in females.

Conclusions: BAI showed lower correlation values with %BF than BMI indicating that calculation of BAI could result in inaccurate estimation of %BF. Our results reported significant associations between all adiposity measures and CVD risk factors. However, in general BAI showed slightly weaker associations than BMI or %BF, indicating that in our sample BAI did not provide a meaningful alternative to BMI or %BF as a CVD risk indicator.

Key words: Obesity, body fat, BAI, cardiovascular disease, adults.

PO2003**THE IMPACT OF OBESITY ON SPIROMETRIC LUNG FUNCTION OF THAI SCHOOL AGED CHILDREN**

U. Udomsubpayakul¹, C. Boonlarptaveechoke², S. Suwanpromma², A. Pruetthipan³

¹Section for Clinical Epidemiology & Biostatistics, Ramathibodi Hospital, Mahidol University, Bangkok, Thailand

²Division of Pediatric, Lerdsin Hospital, Bangkok, Thailand

³Division of Pediatric Pulmonology, Ramathibodi Hospital, Mahidol University, Bangkok, Thailand

Background and objectives: The prevalence of obesity among children and adolescent has increased greatly in all parts of the world. Obese children are at increased risk of a wide range of health conditions including respiratory diseases. The aim of this study was to investigate the impact of obesity on spirometric lung function in school aged children in Bangkok, Thailand.

Methods: Cross sectional data were collected from 1,038 children, aged 6-18 years, from 7 schools in Bangkok, Thailand. By using WHO 2007 plus, body mass index (BMI)-for-age Z-score (growth reference for 5-19 year), children were classified as obesity if their BMI were $>+2$ SD and normal if their BMI were >-2 SD to 0.99 SD. All children underwent physical examination, anthropometric assessment and spirometric lung function measured with Jaeger spirometer (Jaeger, model: 97342 Hoechberg, Germany). Spirometric parameters were compared between the two groups using unpaired t-test.

Results: There were 124 in the obesity group and 406 children in the normal group. Obesity had statistically significant lower spirometric values than normal including forced vital capacity (FVC) $2.95 + 0.75$ VS $2.74 + 1.04$, $p=0.034$, forced expiratory volume in the first second (FEV1) $2.68 + 0.70$ VS $2.40 + 0.92$, $p=0.002$, Forced expiratory flow at 25% point to the 75% point of Forced Vital Capacity $3.39 + 1.09$ VS $2.95 + 1.25$, $p<0.001$, FEV1/FVC $90.81 + 6.28$ VS $87.84 + 6.51$, $p<0.001$. There were no statistical difference in age and height between obesity and normal groups ($p>0.05$).

Conclusions: We confirm the impact of obesity on lung function in our Thai children. These findings emphasize the importance of preventive intervention on obesity in children as early as possible in order to avoid possible future respiratory complications.

Key words: BMI, obesity, spirometric lung function, children, adolescent.

PO2004**DIETARY RESTRAINT AND COMPLIANCE TO EXERCISE REGIMEN ARE KEY PREDICTORS OF WEIGHT LOSS**

S Q. Chen¹, M F F. Chong², Y S. Lee³, E S. Tai⁴, K. Venkataraman¹, K W. Tham⁵, S L. Teo⁶, M. Meaney², Y S. Chong⁷, P D. Gluckman², E Y H. Khoo⁴

¹Department of Obstetrics & Gynaecology, National University of Singapore (NUS), Singapore

²Singapore Institute for Clinical Sciences, Agency for Science, Technology and Research (A*STAR), Singapore

³Department of Pediatrics, National University Hospital (NUH), Singapore

⁴Division of Endocrinology, Department of Medicine, National University Hospital (NUH), Singapore

⁵Department of Endocrinology, Singapore General Hospital (SGH), Singapore

⁶Department of Dietetics, Singapore General Hospital (SGH), Singapore

⁷Department of Obstetrics & Gynaecology, National University Hospital (NUH), Singapore

Background and objectives: Measures of eating behaviors have been shown to predict weight loss outcomes but results are inconsistent. We aim to investigate if dietary restraint, disinhibition and hunger scores from the Stunkard Three-Factor Eating Questionnaire (TFEQ) or other measures are key factors to weight loss in individuals who have undergone an intervention program.

Methods: Healthy overweight Chinese adult men aged 21-45 years with $>25\%$ body fat and BMI of ≥ 23 to 35kg/m^2 were recruited into the Singapore Adult Metabolism Study for a 16-week weight loss intervention program using behavioral therapy, meal replacements and supervised exercise regimen. TFEQ, three 24 hr recalls and a nutritional knowledge questionnaire were administered and anthropometric measurements taken, pre- and post- intervention.

Results: Analysis from the first 38 subjects, who lost a mean of 7.84kg (9.52% of their original weight), showed significant decrease in energy intake ($p<0.001$), disinhibition ($p<0.001$) and hunger ($p=0.004$) scores, while protein intake, nutritional knowledge and restraint scores increased (all $p<0.001$) significantly after intervention. The average number of meal replacements consumed per day and exercise sessions attended per week was 1.3 ± 0.08 and 2.3 ± 0.11 respectively. Post-intervention restraint scores and number of exercise sessions attended were significantly associated with weight loss ($r=0.409$, $p=0.009$; $r=2.88$, $p<0.001$) and percentage body fat loss ($r=0.439$, $p=0.028$; $r=1.79$, $p=0.045$) in models which adjusted for age, change in energy and macronutrient intake, amount of meal

replacements consumed and improvement in nutritional knowledge (adjusted R-square=0.533 for weight loss; 0.232 for percentage body fat loss).

Conclusions: Our results are consistent with extant evidence, suggesting that dietary restraint and close adherence to exercise regimen are important factors of weight loss. This emphasizes the importance of targeting dietary restraint and exercise as the key goals in behavioral therapy for successful weight loss.

Key words: weight loss, TFEQ, restraint, disinhibition, exercise

PO2005

ENVIRONMENTAL FACTORS ASSOCIATED WITH OVERWEIGHT AND OBESITY IN UNIVERSITY STUDENTS OF THE BASQUE COUNTRY

I. Donis¹, A.M. Rocandio¹, M.J. Muñoz-Cachón², E. Rebató², M. Arroyo-Izaga¹

¹Department of Pharmacy and Food Sciences, Faculty of Pharmacy, University of the Basque Country UPV/EHU, Vitoria-Gasteiz, Spain

²Department of Genetics, Physical Anthropology and Animal Physiology, Faculty of Sciences and Technology, University of the Basque Country UPV/EHU, Bilbao, Spain

Background and objectives: The development of excess weight is usually attributed to environmental risk factors, some of them modifiable. The aim of this study was to assess the environmental factors associated with overweight and obesity (OV/OB) in a population of university students.

Methods: A cross-sectional nutritional survey was carried out in the University of the Basque Country. A sample (n=857, 70.9% females) of the adult population (18 to 25 years old) was studied. Indices and body composition were estimated by anthropometry, and body fat was used as criteria of diagnosis of OV/OB. Dietary questionnaires and a global questionnaire including questions related to sociodemographic, economic and lifestyle variables were used. Data were analyzed using SPSS version 20.0.

Results: The prevalence of OV/OB was 25.1%, being higher in males than in females (P<0.001). Protective factor against excess weight were considered: eating four or more times a day in both sexes; and being male whose mothers work in services sectors, technical job, are businesswomen or manager, that is, professional categories with an intermediate salary, in comparison with male whose mothers do other activities like housework. The predictor of OV/OB in females was being a higher score in the crowding index, an indication of the social class.

Other factors like physical activity, smoking habit, alcohol consumption, or adherence to the dietary guidelines were considered neither protective nor predictive of excess weight.

Conclusions: This study uncovered some modifiable risk factor for excess weight in this population and identifies some risk groups according to socioeconomic status. These outcomes could be translated into the development of lifestyle intervention to prevent and treat excess weight. Acknowledgements: This survey was supported by following projects: EHU12/24, UPV 00154.310-E-13972/01, UPV 00101.125-15283/03; and a pre-doctoral scholarship from the UPV/EHU.

³Department of Zoology and Cellular Biology, Faculty of Pharmacy, University of the Basque Country UPV/EHU, Vitoria-Gasteiz, Spain

⁴Department of Digestive, Alto Deba Hospital, Osakidetza, Arrasate/Mondragón, Spain

Background and objectives: The relationship between diet and colorectal cancer (CRC) has been extensively studied, sometimes with controversial results. However dietary data from CRC patients post-surgery has been examined in only few studies. We evaluated dietary intake and lifestyle characteristics of patients with CRC from the Basque Country.

Methods: This study included 51 patients who had undergone surgical resection of CRC (66.7% males). Mean age was 60.8 (SD 5.5) years. Various socio-demographic, economic, clinical, lifestyle and dietary characteristics were measured. A food frequency questionnaire was used to collect information on the dietary intake. Adherence to the dietary guidelines was evaluated using the Healthy Eating Index for Spanish Diet (HEISD) (theoretical range 0-100). Data were analyzed using SPSS version 20.0.

Results: The score for HEISD was 76.3 (SD 8.0), that is to say, their diet “needs changes”; the majority of participants (76.5%) was included in this category. The components of HEISD who obtained the worst scores were: legumes, processed meats and sweets. We found no significant statistical differences for HEISD by sexes, nor between the categories according to the socio-demographic, economic and lifestyle characteristics; except by smoking status. Current smokers obtained lower scores for HEISD (69.5) than past smokers (78.2) and who never smoked (77.8) ($P < 0.05$).

Conclusions: The results show that a significant proportion of the participants did not meet the dietary guidelines for legumes, processed meats and sweets. Moreover, smoker patients reported significantly lower adherence to the HEISD than no smokers. These outcomes could be translated into the development of effective recommendations for maintaining or improving health and quality of life of these patients. Acknowledgements: The present study was supported by two projects (Department of Health and Consumer Affairs, Basque Government, 2011111153; Saiotek, S-PE12UN058).

Key words: Diet quality, food habits, colorectal cancer, post-surgery, adults.

METABOLIC AND MORPHOLOGIC COMPLICATIONS ASSOCIATED WITH HIV INFECTION AND ANTIRETROVIRAL MEDICATION: A SURVEY IN MALAYSIA

N. Hejazi¹, M.S.L. Huang¹, L.K. Geok², C.L. Kwok Choong³

¹Department Nutrition and Dietetics, Faculty of Medicine and Health Sciences, Universiti Putra Malaysia, Serdang, Selangor Darul Ehsan, Malaysia

²Department of Nutrition and Dietetics, School of Pharmacy and Health Sciences, International Medical University, Kuala Lumpur, Malaysia

³Department of Medicine, Hospital Sungai Buloh, Sungai Buloh, Selangor, Darul Ehsan, Malaysia

Background and objectives: Metabolic disturbances including blood lipid and glucose abnormalities with the changes in distribution of body fat mass such as abdominal obesity are known as the hallmark adverse consequences of antiretroviral therapy (ART) among HIV subjects. This study aimed to determine the prevalence and associated risk factors with the metabolic and morphologic disorders among people living with HIV/AIDS (PLHIV).

Methods: A cross-sectional study was conducted among 340 Malaysian adult PLHIV on ART with a two-stage proportional stratified sampling based on the ethnicity and gender.

Sociodemographics, medical history, dietary intake, biochemical tests and anthropometrics were collected.

Results: Most of the responders were male (79.8%), Chinese (63.8%), aged between 30-49 (76.1%) and employed (62.7%). Mean age and CD4 count was 42 years, and 403 cells/mm³ while 86% presented undetectable HIV-1 viral load. The mean duration of ART was 43 months and combination of one NRTI + two NNRTI was the most frequent (>80%) antiretroviral regimen. Dyslipidemia was prevalent among two-third of the responders. While 78% and 11% of subjects had normal blood glucose and impaired fasting glucose, remained 11% of responders had diabetes. Incidence of abdominal obesity and metabolic syndrome among responders was 4.5% and 27.9%. Increase in waist circumference was a significant risk factor for low HDL-C and elevated TG while BMI > 25.00 (Kg/m²), higher energy intake, higher percentage energy from carbohydrate and higher percentage energy from fat were the potential risk elements for metabolic syndrome. ART was not contributed in metabolic abnormalities.

Conclusions: The prevalence of dyslipidemia and metabolic syndrome were common. The medical and dietary interventions should be proposed in multidisciplinary therapeutic approach for a proper management of these health problems and improvement of patients' quality of life.

Key words: Metabolic and morphologic complications, HIV antiretroviral medication, Malaysia.

PO2008

INVESTIGATION OF LYCOPENE INTAKE IN THE DIFFERENT LITHUANIAN ETHNOLINGUISTIC GROUPS

A. Mazeikiene¹, A. Jakaitiene¹, Z.A. Kucinskiene¹, V. Kucinskas¹

¹Faculty of Medicine, Vilnius University, Vilnius, Lithuania

Background and objectives: Lycopene is a potent antioxidant, and it has been suggested that intake of lycopene-rich food is associated with a decreased risk of cardiovascular diseases (CVD). The goal of this study was to evaluate the median intake of lycopene in the Lithuanian population and the association of lycopene intake with biochemical blood risk factors of CVD in different Lithuanian ethnolinguistic groups.

Methods: 1140 randomly selected subjects (2–85 y) from 6 Lithuanian ethnolinguistic regions provided three 24-hour recalls to evaluate the consumption of lycopene. Subjects were interviewed using validated questionnaire consisting of lifestyle and clinical data. Serum concentrations of total cholesterol, HDL-Ch, LDL-Ch, triglyceride, Apo A-1, Apo B, Lp(a), glucose and hsCRP were measured using standardized proce-

dures. Due to the non-normal distribution of variables, nonparametric tests were applied using IBM/SPSS v20.0.

Results: The median dietary lycopene intake in study population was 2.2 (SD 7.48) mg/day or 0.07 (SD 0.11) mg/kg body weight per day. Major food sources of lycopene were tomatoes and tomato products (79%). Lycopene intake from natural dietary sources varied significantly between the Lithuanian ethnolinguistic groups (the lowest 1.54 (SD 5.64) mg/day, highest 3.07 (SD 7.66) mg/day, $p=0.01$) and gender (women 2.8 (SD 7.78) mg/day and men 1.83 (SD 7.22) mg/day, $p=0.01$). Median lycopene intake was significantly higher ($p=0.00$) in summer compared to winter period: 3.01 (SD 8.30) and 1.37 (SD 6.03) mg/day respectively. The lowest consumption of lycopene was in a study group of subjects older than 65 years (1.16 (SD 3.25) mg/day). Higher lycopene intake significantly correlated with higher HDL-Ch concentration ($r=0.079$; $p<0.001$).

Conclusions: In the study population and different Lithuanian ethnolinguistic groups the median lycopene intake was one of the lowest compared to intakes reported in other European countries and below the acceptable daily intake. Higher dietary lycopene intake was associated with higher HDL-Ch concentration. Acknowledgements: The study was supported by LITGEN Project (VP1-3.1-SMM-07-K-01-013).

Key words: Lycopene, Lithuanian ethnolinguistic groups.

PO2009

NUTRITIONAL STATUS OF PATIENTS WITH CARDIOVASCULAR DISEASES IN HOSPITALS

M. Jarosz¹, E. Rychlik¹, J. Dzieniszewski¹

¹National Food and Nutrition Institute, Warsaw, Poland

Background and objectives: Incorrect nutritional status of patients may prolong hospital stay and increase the cost of treatment. The objective of the study was to assess the nutritional status, including the prevalence of underweight, overweight and obesity among patients hospitalized due to cardiovascular diseases.

Methods: The study was performed in 16 Polish hospitals. It comprised 454 patients with cardiovascular diseases. The nutritional status was evaluated with the use of anthropometric measurements: height, weight, BMI and arm circumference and biochemical methods red blood cells count, haemoglobin concentration, white cells count, lymphocyte count in peripheral blood and serum albumin concentration.

Results: Among studied patients overweight occurred in 42.5% of males and 35.2% of females, whilst obesity in 24.9% and 41.2% respectively. Underweight was noted in 2.3% of males and 1.7% of females. Biochemical abnormalities, indicating the possibility of malnutrition have been reported frequently. A

decrease of lymphocyte count was recorded in 18.1% of males and 19.7% of females, and a deficient serum albumin concentration was noted in 20.1% and 17.5% respectively. Some indicators of nutritional status deteriorated during hospital stay. Haemoglobin concentration and count of red blood cells, white cells and lymphocyte decreased in males. Changes in these indicators in females were not statistically significant. Weight and BMI decreased in both genders, however these changes do not significantly affect the increase of underweight occurrence, or a reduction of overweight and obesity prevalence.

Conclusions: Overweight or obesity are frequent in patients hospitalized due to cardiovascular diseases. Rarely this group appears to be underweight, however the results of blood chemistry, such as lymphocytes count and serum albumin indicates the possibility of malnutrition. Hospital stay could pose a risk of deterioration in the nutritional status of patients.

Key words: Cardiovascular diseases, hospital stay, nutritional status.

PO2010

PROSTATE CANCER MORBIDITY AND CHANGES IN THE DIET IN POLAND IN THE YEARS 1970-2010

M. Jarosz¹, E. Rychlik¹, W. Sekula¹

¹National Food and Nutrition Institute, Warsaw, Poland

Background and objectives: Prostate cancer morbidity in Polish males is very high. Its standardised incidence rate in 2010 amounted to 32.3/100 thousand resulting from growing trend during the period of 1970-2010. Diet is probably one of the factors that played a significant role in prostate cancer pathogenesis. The objective of the study was to investigate the relation between selected dietary factors and prostate cancer morbidity in Poland in 1970-2010.

Methods: Standardised prostate cancer incidence rates were derived from the National Cancer Registry administered by the Institute of Oncology. The information source on the dietary pattern was the database established by the National Food and Nutrition Institute. This database covers data derived from the national food balance sheets showing food quantities available for consumption per capita/year and original calculations on the amounts of the energy and nutrients from food. The Spearman rank correlation coefficient (r_s) was used as a measure of the relationship between examined variables.

Results: Positive correlation was found for prostate cancer incidence rates in 1970-2010 and vitamin D intake ($r_s=0.74$) and edible fats ($r_s=0.89$) and meat ($r_s=0.60$) consumption. Edible fats consumption significantly increased during that period from 20.8 to 32.2 kg/person/year, whilst meat consumption from 53.0 to 74.3 kg/person/year, also the share of processed

meat increased. Negative correlation was noted with respect to food containing selenium such as cereals ($rs=-0.74$) and fish ($rs=-0.51$).

Conclusions: Dietary habits have probably contributed to the increase of prostate cancer morbidity rates between 1970 and 2010. That unfavourable trend could be affected predominantly by the growing edible fat and meat consumption, especially processed meat and the decrease of selenium content in the diet related to lower consumption of cereals and fish. Also the increase of vitamin D intake could influence the morbidity.

Key words: Prostate cancer, food consumption, nutrient intake.

PO2011

EFFECT OF KALE JUICE SUPPLEMENTATION ON THE LYMPHOCYTE DNA DAMAGE OF KOREAN SUBCLINICAL HYPERTENSIVE PATIENTS

M.H. Kang¹, J.H. Han¹, H.J. Lee¹, T.S. Kim²

¹Dept. of Food and Nutrition, Hannam University, Daejeon, South Korea

²Pulmuone Health & Living Co., Ltd., Seoul, South Korea

Background and objectives: Kale (*Brassica oleracea*) is claimed to have beneficial properties for human health, such as anti-mutagenic, immune-regulatory and antioxidant activities. In this study, we examined whether daily supplementation of kale juice for 6 weeks could modulate the levels of plasma total radical-scavenging antioxidant potential (TRAP), plasma conjugated diene (CD) and lymphocyte DNA damage in Korean subclinical hypertensive patients.

Methods: Eighty four subclinical hypertensive patients exhibiting a systolic blood pressure (BP) over 130 mmHg or a diastolic BP over 85 mmHg received 300 ml/day of kale juice for 6 weeks, and blood samples were drawn before and after 6 weeks. Plasma levels of TRAP and CD were analyzed using spectrophotometer. Lymphocyte DNA damage was determined using the COMET assay and damage was quantified by measuring % DNA in the tail (TD), tail length (TL), and tail moment (TM).

Results: Plasma levels of TRAP and CD were not significantly changed after the supplementation of kale juice. However, levels of lymphocyte DNA damage representing TD, TL and TM at baseline (0 week) decreased significantly from 12.1% to 8.4%, 201.9 μ m to 146.3 μ m, and 27.4 to 14.4, respectively, after 6 weeks of kale juice supplementation ($p<0.001$).

Conclusions: These results suggest that consuming moderate amounts of daily kale juice may favorably restore lymphocyte DNA damage in subclinical hypertensive patients. Acknowledgements: This research was supported by the Basic

Science Research Program of the National Research Foundation of Korea (NRF) under the sponsorship of the Ministry of Education, Science and Technology (2012-0001682).

Key words: Kale juice, hypertensive patients, COMET assay, DNA damage.

PO2012

DARK CHOCOLATE RICH IN POLYPHENOLS AND ITS INFLUENCE ON BLOOD PRESSURE AND BMI IN NORMOTENSIVE ADULTS: A PRELIMINARY STUDY

G. Farhat¹, E. Al-Dujaili¹

¹Department of Dietetics, Nutrition and Biological Sciences, Queen Margaret University, Musselburgh, United Kingdom

Background and objectives: Dark chocolate (DC) is believed to be rich in polyphenols with favourable effects on health. Several studies investigated the relationship between DC and blood pressure and whether it influences body weight. The aim of this study was to investigate the effect of polyphenol-rich DC on blood pressure and BMI in the normotensive apparently healthy population.

Methods: Ethical approval was granted by the Divisional Ethics Committee at Queen Margaret University. Thirty nine healthy men and women with BMI<25 kg/m² (18-41 years old) were recruited to participate in a parallel randomized single-blinded study. Participants randomly received 20 g daily of either a placebo DC with negligible amount of polyphenols (19), or a DC containing 500 mg of polyphenols (20) for a period of 4 weeks. Anthropometry, blood pressure and other parameters were assessed before and at the end of intervention. Urine and blood samples were also collected.

Results: Results showed no significant effect of on systolic ($p=0.636$) or diastolic ($p=0.771$) blood pressure following the consumption of DC rich in polyphenols in a similar manner to placebo DC. In addition, no significant change in BMI was observed in the group administered DC rich in polyphenols ($p=0.443$) or placebo DC ($p=0.08$). This neutral effect on blood pressure was in agreement with the results of a large meta-analysis which showed that DC is only effective in decreasing blood pressure in pre-hypertensive and hypertensive subjects. The effect on body weight did not match that obtained with animal studies which showed that DC may reduce weight.

Conclusions: This pilot study suggests that DC intake did not reduce blood pressure or body weight in normotensive participants. A long-term larger study is required to test whether DC can influence body weight and blood pressure in healthy people.

Key words: Polyphenol, dark chocolate, blood pressure, BMI.

PO2013**NUTRITIONAL STATUS OF PATIENTS WITH OBSTRUCTIVE SLEEP APNEA SYNDROME (OSAS) TREATED BY POSITIVE AIRWAY PRESSURE (PAP)**

P. Jesus^{1,2}, V. Arnold³, P. Fayemendy⁴, P. Samptiaux³, B. Melloni^{3,5}, J.C. Desport^{1,2,4}

¹Regional Care Centre for Severe Obesity, University Hospital, Limoges, France

²INSERM UMR1094, Neuroepidemiology, School of Medicine, Limoges, France

³ALAIR & AVD, Limoges, France

⁴Nutrition Unit, University Hospital, Limoges, France

⁵Department of Respiratory Pathology, University Hospital, Limoges, France

Background and objectives: OSAS, diagnosed by polysomnography Apnea Hypopnea Index (AHI) $\leq 5/h$ of sleep, is common (5-10% of adults). It is often treated with PAP. The aims of this study were i) to assess the nutritional status of patients with OSAS treated by PAP and supported by a care giver at home ii) to look for a link between nutritional status and OSAS after a long PAP treatment.

Methods: AHI was recorded when PAP was established. After a 66.4 ± 4.59 months, one collected AHI, Epworth's sleepiness scale (up to 15, normal <8), compliance (h), weight, body mass index (BMI).

Results: PAP at home was set in 435 patients with initial AHI at 52.8 ± 25.9 . At the final assessment, they were aged 63.8 ± 10.4 years, with a sex ratio M/F at 3.7 and a BMI at 33.5 ± 6.1 . Nutritional status was normal in 5.7% of cases, 23.0% of patients were overweighted, 71.3% were obese (massive obesity: 12.9%). AHI decreased to 4.0 ± 4.0 ($p < 0.0001$), Epworth's scale was at 4.3 ± 3.0 and observance at 7.1 ± 1.8 hours. For sleep, alertness, memory and headache, respectively 45.5%, 52.6%, 58.6% and 86.6% of patients were improved or had no more disorder. There was no link between the duration of PAP treatment and the final BMI nor between nutritional status and final AHI.

Conclusions: PAP used for more than 5 years in patients with OSAS normalizes AHI, improves symptoms and sleepiness scale. At the end of the follow-up, younger patients and those with normal BMI have a lower need of PAP. Overweight or obesity remains highly prevalent. It could be interesting to consider whether a nutritional care associated with the coverage of excess weight could reduce the need of PAP.

Key words: Nutritional status, obstructive sleep apnea syndrome, positive airway pressure.

PO2014**BODY MASS INDEX, GLYCEMIC CONTROL AND MACRO-ALBUMINURIA IN TYPE 2 DIABETIC PATIENTS IN IBADAN, NIGERIA**

G. Fadupin¹, I. Nganya¹

¹Department of Human Nutrition, University of Ibadan, Ibadan, Oyo State, Nigeria

Background and objectives: The presence of overweight and obesity with poor glycemic control in type 2 diabetic patients are predicting factors for decline in renal function. This study assessed the body mass index (BMI), glycemic control and macro albuminuria in patients with type 2 diabetes mellitus (DM) in Ibadan, Nigeria.

Methods: The cross sectional study involved 240 male and female type 2 diabetic patients. A semi-structured, interviewer administered questionnaire was used to obtain the socio-demographic information and medical history of the patients. Their body mass index (weight (kg) /height (m)²) were determined and categorized into underweight (<18.0 kg/m²), normal weight 18 – 24.9 kg/m²), overweight 25 – 29.9 kg/m²) and obese (>30 kg/m²). The last four fasting blood sugar level was obtained from the patient's record and the mean was determined. The presence of macro albuminuria was tested on the patients using Medi-test strips. The data was analyzed as range, means with their standard deviations and percentages. Chi-square test was employed to determine the association between the BMI, glycemic control and presence of albuminuria among the patients.

Results: The age of the patients ranged from 35 – 76 years. Majority (67.2%) of the patients were diagnosed with DM <10 years. Most (59.2% and 31.7%) of the patients were treated with diet + hypoglycemic drugs and diet + insulin respectively. Only 37.8% had normal weight while 72.2% were either overweight or obese. Hyperglycemia was present in 69.8% of the patients out of which 20.2% and 34.6% were either overweight and obese respectively. Macro-albuminuria was more prominent in 4.2% and 6.7% Overweight and obese than in 1.8% patients with normal weight.

Conclusions: Poor glycemic control and micro-albuminuria were more prevalent among obese type 2 diabetic patients.

Key words: Body mass index, glycemic control, macro-albuminuria, type 2 diabetic patients, Nigeria.

PO2015**SALT INTAKE AND SALT REDUCTION IN SECONDARY SCHOOL-AGE STUDENTS OF PRINCESS CHULABHORN'S COLLEGE CHIANGRAI (REGIONAL SCIENCE SCHOOL)**

W. Puengputtho¹, P. Leelahagul¹, K. Klawisait², N. Thongsuk², G. Janthranant², K. Hoiyeephoo²

¹Graduate Program In Nutrition, Ramathibodi Hospital, Bangkok, Thailand

²Princess Chulabhorn's College Chiangrai (Regional Science School), Chiang Rai, Thailand

Background and objectives: High sodium consumption has been identified as an important risk factor for cardiovascular disease, together with obesity and hypercholesterolemia. From Waisaihealth Program by Leelahagul P since 2009-2012, in students of Princess Chulabhorn's college Chiangrai (PCC-CR), aged 12-18 years it was found that prevalence of obesity and hypercholesterolemia is high, 6.7 - 29.0% and 20.8 - 21.0%, respectively. The aim of this study was to investigate the relationships among sodium intake, obesity, and hypercholesterolemia in those students.

Methods: Prospective study. PCCCR students, aged 12-18 years, who had obesity or hypercholesterolemia participated in this study for 12 months. We used Tanita BC-420 for body composition analysis at weeks 0, 16, 24, and 32; dietary assessment by 24-hour dietary records 3 days/week throughout the study; serum LDL-cholesterol measurement at weeks 0, 16, and 32; and 24-hour urinary sodium excretion measurement at weeks 8 and 32.

Results: The means of sodium intake in obese, hypercholesterolemic, obese and hypercholesterolemic students were 3,123, 2,999, and 2,687 mg/day, respectively. The means of urinary sodium excretion in obese, hypercholesterolemic, obese and hypercholesterolemic students were 121, 90, and 150 mmol/day, respectively. Students with over body fat had significantly higher average of urinary sodium excretion than normal body fat and low body fat students ($P=0.013$). Hypercholesterolemic students had significantly lower average of urinary sodium excretion than normocholesterolemic students ($P=0.015$).

Conclusions: The results of this study found that students who were obese had high sodium intake, whereas hypercholesterolemic students had lower sodium intake than normocholesterolemic students. Therefore, a campaign to reduce sodium intake in student is necessary, in addition to reducing weight and serum cholesterol because the obesity, hypercholesterolemia, and high sodium intake are risk factors that contribute to cardiovascular disease.

Key words: Sodium, urinary, hypercholesterolemia, obesity, adolescent.

PO2016**BIOACTIVE COMPOUNDS OF ROSMARINUS OFFICINALIS AGAINST COLON CANCER CELLS LINES**

Ma I. Borrás Linares^{1,2}, A. Pérez Sánchez³, V. Micol Molina³, D. Arráz Román^{1,2}, E. Barrajón Catalán³, J.A. Ferragut Rodríguez³, A. Segura Carretero^{1,2}, A V. Fernández Gutiérrez^{1,2}

¹Department of Analytical Chemistry, University of Granada, Granada, Spain

²Research and Development of Functional Food Centre (CIDAF), Granada, Spain

³Institute of Molecular & Cell Biology (IMCB), Miguel Hernández University, Elche, Spain

Background and objectives: Rosmarinus officinalis L., commonly called rosemary, is one of the most widely used and commercialized plant extracts not only as a culinary herb for flavoring but also as an antioxidant in processed foods and cosmetics. This plant has been traditionally used as an herbal medicine for a large variety of disorders. Its beneficial effects have been attributed to the high content in bioactive compounds, such as phenolic diterpenes, flavonoids and other phenolic compounds. The aim of this work has been to carry out a characterization of the bioactive compounds present in a rosemary extract obtained using Supercritical Fluid Extraction. This extract has shown the capacity to inhibit cell proliferation in colon cancer human cell models, HT-29 and SW480. In order to elucidate which compound or compounds are responsible for such effect, the bioactive extract has been fractionated by using semi-preparative chromatography, and their antiproliferative activity against these cell lines have been studied.

Methods: The extract and the fractions have been analyzed using ultra-performance liquid chromatography (UPLC), coupled with a quadrupole-time of flight mass spectrometry (QTOF-MS) detector. The bioactivity of the extract and fractions has been determined using MTT cell proliferation assay.

Results: The fractions containing the highest concentration in diterpenes correlated with the highest inhibition of proliferation in both colon cancer cell models. Nevertheless, none of purified fractions improved the antiproliferative activity of the whole extract. HT-29 colon cancer cells were more resistant compared to SW480 cells to the most bioactive fractions and whole extract.

Conclusions: We hypothesised that carnolic acid is the compound that contribute the most to the observed antiproliferative activity. Nonetheless, other compounds, probably flavonoids also contribute significantly to the antiproliferative of the whole extract.

Key words: Rosmarinus officinalis, diterpenes, phenolic compounds, colon cancer.

PO2017**INTAKE OF LONG-CHAIN OMEGA-3 FATTY ACIDS AND RISK OF CORONARY HEART DISEASE IN THE SPANISH EPIC COHORT STUDY**

⁸Public Health Division of Gipuzkoa, BioDonostia Research Institute, San Sebastián; CIBER de Epidemiología y Salud Pública (CIBERESP), Madrid, Spain

Background and objectives: Evidence about the benefits of omega-3 fatty acids intake on coronary heart disease (CHD) is varied and discordant. The objective of this study is to assess the relation between dietary intake of total omega-3 fatty acids, eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) on the risk of CHD in the Spanish cohort of the European Prospective Investigation into Cancer and Nutrition (EPIC).

Methods: Study of cohorts, where the analysis included 41,091 men and women aged 20-69 years, recruited from 1992 to 1996 in Asturias, Gipuzkoa, Granada, Murcia and Navarra. The cohort had a mean follow-up of 10.4 years. Omega-3 fatty acids intake was estimated from a validated dietary questionnaire. Anthropometry and other characteristics were collected also. Case are participants with definite incident CHD. Cox proportional hazards regression were used to assess the association between the intake of omega-3 fatty acids, EPA or DHA and CHD. Models were run separately for men and women and included covariates showing different levels of adjustment.

Results: A total of 609 participants (79% men) had a defini-

te CHD event. Mean intake of EPA+DHA was 0.8 g/d (SD: 0.4) in men and 0.5 g/d (SD: 0.2) in women. After stratification by age and adjustment for several risk factors, no significant associations were found between total omega-3 fatty acids, EPA or DHA intake and the risk of CHD in men or women

Conclusions: We have found no evidence of association between the intake of total omega-3 fatty acids, EPA or DHA and the risk of CHD in either men or women from the Spanish EPIC study. The overall null results obtained in the present study together with the varied and not entirely consistent results found in previous studies highlight the need of further research to analyse the cardio protective effect of omega-3 fatty acids intake.

Key words: Long-chain omega-3 fatty acids, coronary heart disease.

PO2018**DISTRIBUTION OF FAECALIBACTERIUM PRAUSNITZII PHYLOTYPES IN OBESE, DIABETIC PATIENTS AND CONTROLS COMPARED WITH HRMA AND ARISA.**

B. Hippe¹, M. Remely¹, S. Dworzak¹, A G. Haslberger¹

¹Department of Nutritional Sciences, University of Vienna, Vienna, Austria

Background and objectives: Faecalibacterium prausnitzii is one of the most abundant commensal bacteria in the healthy human large intestine. Information on their genetic diversity and role in the inflammatory genesis is limited. Two phylogroups have been described We analyzed the different phylogenotypes of F. prausnitzii and their occurrence as well as butyrate production in obese, diabetics, and lean controls under nutrition intervention. We compared strain specificity and function. We examined F. prausnitzii as a diversity marker. Method comparison for fast routine analysis is under consideration.

Methods: We compared fecal samples of groups of obese, diabetics and lean controls at three time points with two primer pairs detecting F. prausnitzii and analyzed with qPCR and melt curve analysis, high resolution melt curve analysis (HRMA) and automated ribosomal intergenic spacer analysis (ARISA). F. prausnitzii depending butyrate gene levels are detected by qPCR. Phylogenetic differences of all detected F. prausnitzii strains were statistically analyzed and a phylogenetic tree was constructed.

Results: Obese- and diabetic groups differed significantly at all three time points compared to lean controls with fewer F. prausnitzii copies. All groups show significant stability over the measured period. F. prausnitzii butyryl CoA:acetate CoA-transferase genes (butyrate levels) did not correlate to the total F. prausnitzii amount, due to variations in F. prausnitzii phylogenotypes.

Conclusions: Different phylotypes of *F. prausnitzii* and their various functions may lead to differences in the inflammatory genesis in the host. SCFA producers may have an influence in developing obesity.

Key words: Faecalibacterium prausnitzii, high resolution melt curve analysis (HRMA), butyrate, automated ribosomal intergenic spacer analysis (ARISA).

PO2019

EFFECT OF HIV INFECTION ON WEIGHT GAIN DURING TREATMENT OF MALNUTRITION IN MARASMIC CHILDREN BETWEEN 6 AND 59 MONTHS OF AGE

M. Sanchez¹, I. Zuza¹, L. Calvo¹

¹Accion Contra El Hambre, Madrid, Spain

Background and objectives: The effects of HIV on nutritional status are well known. Children affected by HIV infection have increased their nutrient requirements, which could make nutritional recovery more difficult. The objective of this study was to have more evidence about the influence of the HIV on the weight gain in children during treatment of severe acute malnutrition.

Methods: This study analysed the databases from nutritional centres working with ACH support in Swaziland. The study focused on 206 children affected by marasmo admitted in nutritional centres. Main variables studied were weight gain (cut off 8 g/Kg/day) and results of HIV test. Data were analyzed and results were compared with chi-square test.

Results: 206 children suffering of marasmo between 6-59 month old were cured or transferred to OTP. HIV test was done in 76,2% (157/206) giving the result HIV(+) in 45,8% (72/157) and HIV(-) in 54,2% (85/157). In HIV (-) children, weight gain > 8 g/Kg/day was present in 65,8% (56/85), whereas in HIV (+) was present only in 47,2%(34/72). When weight gain >8 g/Kg/day was compared considering HIV status, chi-square test showed significant differences.

Conclusions: The results show that weight gain was higher in HIV (-) children, which confirms that HIV (+) malnourished children need more time to recover and reach appropriate weight for height index. Probably the treatment of severe acute malnutrition should be readjusted in HIV (+) children to adapt it to their increased nutritional requirement.

Key words: Weight gain, HIV status.

PO2020

ORAL HYGIENE STATUS AND PREVALENCE OF GUM DISEASE IN OBESE CHILDREN

T. Ndanu¹, A. Lartey², R. Ayeetey³, J. Sackeyfio¹, G. Otoo²

¹University of Ghana Dental School, Korle Bu, Ghana

²Nutrition and Food Science Department, University of Ghana, Legon, Ghana

³School of Public Health, University of Ghana, Legon, Ghana

Background and objectives: Consistent association between adult obesity and gum diseases has been shown. This association is not clear in obese children. Determining such possible links may help initiate remedial measures to reduce the prevalence among obese children. Poor oral hygiene and dietary habits are major causes of gum disease. This study compared oral hygiene status and gum disease in obese and non-obese children.

Methods: School children (n=510) ages 9-15 yrs were recruited from 8 selected private schools in Accra, Ghana. Oral examination was carried out among 219 obese and 291 non-obese children. Oral plaque, calculus, and gingival indices and Silnes and LÖe Plaque score were used to determine oral hygiene status. Community Periodontal Index of Treatment Need (CPITN) was used to assess gum disease status. Questionnaire was used to measure oral hygiene practice e.g., tooth cleaning materials and frequency, mouth wash and toothpick use.

Results: Mean age was 11.5 years. About half, 49.8% (n=254) of children had barely visible plaques while 46.1% (n=235) had abundant plaques at the gingival margin. Supragingival calculus was 70.6% (n=360) and subgingival calculus was just 4.0% (n=8). Majority 88.0% (n=449) had healthy gums but 10% (n=51) had swollen gum and 2% (n=10) had enlarged and bleeding gum on probing. Only 10% of the obese and 13.4% of the non-obese had various degrees of gum conditions. Silnes and Loe Plaque index estimating oral hygiene status was 1.38±0.34 in obese and 1.43±0.36 in non-obese. Prevalence of gum disease was 4.7% for all children but 3.7% and 5.5% for obese and non-obese respectively. None of the oral hygiene indices was significantly different for the two groups.

Conclusions: No significant differences in the oral hygiene indices and gum disease between obese and non-obese but lower Plaque index in the obese suggest better oral hygiene.

Key words: child obesity, gum disease, plaque, calculus.

PO2021**DAIRY PRODUCTS INTAKE AND CARDIOMETABOLIC RISK FACTORS: IS THERE A RELATIONSHIP?**

R. Fisberg¹, M. Castro¹, D. Marchioni¹, M. Alves², G. Pos-
sa³, M. Fisberg³

¹Department of Nutrition, School of Public Health,
University of São Paulo, São Paulo, Brazil

²Health Institute, São Paulo State Department of
Health, São Paulo, Brazil

³Department of Pediatrics, Federal University of São
Paulo, São Paulo, Brazil

Background and objectives: Previous studies have shown inverse relationship of dairy products with blood pressure. However, it remains unclear whether dairy products are also inversely related to other cardiometabolic risk factors like dyslipidemia and obesity. The aim of this study was to investigate the relationship of dairy products intake with cardiometabolic risk factors through a structural equation model.

Methods: A total of 482 adults participating in a population-based survey "Health Survey of São Paulo (HS-SP)", Brazil, between 2009-2011 were evaluated. Dairy products intake (whole milk and yogurt; skimmed and low-fat milk and yogurt; cheeses) were assessed by two non-consecutive 24h-recalls. Adjustment for the within-person variation of intake of dairy products was performed through the Multiple Source Method. A Structural Equation Model was used to test a theoretic model for the relationship of each dairy product with obesity indicators (BMI and waist circumference), as well as with the following latent variables: blood pressure (systolic, diastolic and mean arterial pressure) and dyslipidemia (total cholesterol/HDL-cholesterol ratio, triglyceride/HDL-cholesterol ratio). The model was adjusted for potential confounding factors (age, sex, ethnicity, energy intake, antihypertensive and hypocholesterolemic drugs). Goodness-of-fit indexes (Comparative Fit Index (CFI); Tucker-Lewis Index (TLI); Standardized Root Mean Square Residual (SRMSR) were used to assess model fit.

Results: Whole milk and yogurts were inversely related to waist circumference ($r = -0.042$; $p = 0.011$), blood pressure ($r = -0.143$; $p = 0.001$) and dyslipidemia ($r = -0.152$; $p = 0.002$). Skimmed and low-fat milk and yogurt as well as cheeses were not related to any variable under investigation. The goodness-of-fit indexes indicated an acceptable model fit (CFI = 0.973; TLI = 0.954; SRMR = 0.035).

Conclusions: Whole milk and yogurt intakes may contribute to reduce the cardiometabolic risk by their protective effects against central obesity, high blood pressure and dyslipidemia.

Key words: Dairy products, cardiometabolic risk, structural equation model.

PO2022**RELATIONSHIP BETWEEN INDICATORS OF LIPID, GLUCOSE, AND OXIDATIVE METABOLISM AND BODY WEIGHT IN AUSTRIAN ADULTS**

A. Meyer¹, V. Hasenegger¹, I. Elmadfa^{1,2}

¹Institute of Nutritional Sciences, University of Vienna,
Vienna, Austria

²International Union of Nutritional Sciences, Vienna,
Austria

Background and objectives: The contribution of overweight to oxidative stress-related chronic diseases is well known. The Austrian Nutrition Report 2012 is part of a regularly conducted representative survey about nutritional status of the Austrian population and encompasses detailed anthropometric measures and biochemical measurements including metabolic health indicators revealing the influence of bodyweight on these parameters.

Methods: Body weight and height were measured in 417 adult men and women (18-64 years). Total, LDL, HDL cholesterol, and triglycerides, levels of uric acid, bilirubin, and whole blood fasting glucose, as well as the total radical-trapping antioxidant parameter (TRAP) were determined photometrically in plasma, HbA1c in whole blood by HPLC. Results were analyzed statistically with PASW (Predictive Analyses Software for Windows, 18.0, 2009, SPSS Inc., Chicago, IL).

Results: On average, levels of health indicators did not markedly deviate from reference ranges. Overweight subjects (BMI > 25 kg/m²) showed higher levels of total (n.s.) and LDL cholesterol ($p < 0.05$), triglycerides ($p < 0.01$), fasting glucose ($p < 0.001$), HbA1c ($p < 0.01$), uric acid ($p < 0.001$), and TRAP ($p < 0.005$) than participants with normal weight. Likewise, the coefficient of total to HDL cholesterol was higher in overweight. Among those with fasting glucose above the reference level of 6 mmol/L, 70 % were overweight. Obese (BMI > 30 kg/m²) had higher glucose and uric acid levels than overweight persons ($p < 0.05$). BMI correlated HDL cholesterol ($r = -0.403$, $p < 0.001$), triglycerides ($r = 0.208$, $p < 0.001$), glucose- ($r = 0.264$, $p < 0.001$), uric acid level ($r = 0.383$, $p < 0.001$), HbA1c ($r = 0.118$, $p < 0.05$), and TRAP ($r = 0.171$, $p < 0.01$), as well as with bilirubin level ($r = 0.138$, $p < 0.05$).

Conclusions: Our data confirm the negative impact of overweight on lipid and glucose metabolism and uric acid excretion, the latter being a risk factor for gout despite its antioxidative properties. Acknowledgements: This project was funded by the Austrian Ministry of Health.

Key words: Overweight, blood lipids, oxidative stress, glucose metabolism, Austrian Nutrition Report 2012.

PO2023**IMMUNOMODULATORY EFFECTS OF DHA AND ARA IN THE TREATMENT OF COW'S MILK ALLERGY IN ALLERGIC INFANTS**

E. Matencio¹, M D. Mesa², M C. Rico², M V. Martín², J F. Haro¹, F. Romero¹, G. Ros³, P. Abellán¹, A. Gil²

¹Hero Global Technology Center, Hero Spain, S.A., Alcantarilla, Spain

²Institute of Nutrition & Food Technology "José Mataix", Biomedical Research Center, University of Granada, Granada, Spain

³Department of Food Science and Nutrition, Faculty of Veterinary Sciences, University of Murcia, Murcia, Spain

Background and objectives: Prevalence of cow's milk protein allergy (CMPA) has increased for the last decades in infants during the first years of life. Atopic march starts early in life and go on up to adulthood. There is a little knowledge about the role of docosahexaenoic acid (DHA) in the treatment of allergy. We aimed to investigate whether the consumption of DHA and arachidonic acid (AA) added to an extensively hydrolyzed infant formula was able to increase the levels of DHA and AA in red blood cells and decrease allergic response in infants with CMPA.

Methods: An open, multicenter, national clinical trial was performed in 22 infants with CPMA were fed with hypoallergenic formula for three months and blood samples were taken before and after nutritional treatment. Quantitative analysis of DHA and AA in phospholipid of red blood cells was performed by chromatographic gas coupled with flame ionization detector. Plasma levels of IL-8, IFN- α , IL-4, IL-10, IL-13, TGF- β and IL-17A were measured by immunoassay, with a MILLIplex™ kit using the Luminex 200 system based in the xMap technology. Differences between before and after treatment were assessed by U Mann Whitney test.

Results: DHA and AA in red blood cells after the consumption of hypoallergenic formula tended to increase. In plasma IL-8 significantly decreased (1764.12 \pm 1542.84 vs 8.88 \pm 3.52 pg/ml, $p < 0.05$) and IL-10 tended to increase. IL-4 and IL-13 were not detected in plasma and IL-17A, IFN- α tended to decrease.

Conclusions: IL-8, an intestinal inflammatory cytokine, significantly decreased after treatment indicating that inflammatory response is being modulated at the gut by means of feeding with the new therapeutic formula fortified with DHA and AA. Cytokine profile in plasma in allergic infants can be modified by the consumption of DHA and AA.

Key words: Cytokines, DHA, infant, allergy.

PO2024**GREATER BODY MASS INDEX IS ASSOCIATED WITH LOWER PERCENTAGE OF IRON ABSORPTION, BUT NOT WITH IRON STATUS IN CHILEAN WOMEN**

M F. Mujica¹, A. Brito^{1,2}, D. Lopez de Romaña^{1,3}, F. Pizarro¹, M. Olivares¹

¹Micronutrients Laboratory, Institute of Nutrition and Food Technology (INTA), Universidad of Chile, Santiago, Chile

²USDA, ARS, Western Human Nutrition Research Center (WHNRC), University of California, Davis, USA

³The Micronutrient Initiative, Ottawa, Ontario, Canada

Background and objectives: The prevalence of overweight and obesity has increased at an alarming rate worldwide and is now a common health concern in Chile. Some studies have noted a possible association between iron (Fe) deficiency and obesity, but scarce evidence is available in Chile. To assess whether body mass index (BMI) is associated with both Fe status and bioavailability.

Methods: A retrospective study was conducted using data from 318 Chilean childbearing age women who had previously participated in absorption studies conducted at our laboratory. BMI, Fe nutritional status and bioavailability were measured. Fe absorption was determined with double radioiron erythrocyte incorporation. Women received either 0.5 mg of Fe (group 1; $n = 137$) or 3 mg of Fe plus ascorbic acid (1:2 molar ratio) (group 2; $n = 181$), both as ferrous sulfate, labeled with either ⁵⁵Fe or ⁵⁹Fe radioisotopes.

Results: 29%, 47% and 24% of women were classified as, normal, overweight or obese, respectively according to WHO criteria. Fe absorption was statistically significant lower in obese women. The geometric mean and range ± 1 SD of percentage of Fe absorption in normal women of group 1 was 32.9% (15.9-68.2) v/s 19.7% (8.4-46.3) in obese. In group 2, this percentage was 36% (15.5-83.3) v/s 30.1% (14.5-62.5), respectively (2-way ANOVA: nutrition status and Fe dose $p < 0.05$; interaction N.S.). Of all women, 7% had Fe deficiency anemia, 10% Fe deficiency without anemia and 18% depleted Fe stores. No significant differences were found in Fe nutritional status comparing by nutritional classification. Although Fe absorption was lower in obese, they had significantly higher values of serum ferritin ($p < 0.01$) and hemoglobin ($p < 0.05$).

Conclusions: Higher BMI is associated with a lower percentage of Fe absorption in Chilean childbearing age women, but not with Fe deficiency.

Key words: Iron, micronutrients, body mass index, overweight, obesity.

PO2025**NUTRITION RISK FACTORS ASSOCIATED WITH HIV IN RURAL AND URBAN COMMUNITIES IN SOUTH AFRICA***C M. Walsh¹, M. Pienaar¹, G. Joubert²*¹Department of Nutrition and Dietetics, University of The Free State, Bloemfontein, South Africa²Department of Biostatistics, University of The Free State, Bloemfontein, South Africa

Background and objectives: Nutritional risk factors can be described as those directly related to food and nutrition (e.g. reduced food intake) and those indirectly related to food and nutrition (e.g. poverty and food insecurity). The objective of this study was to determine significant independent nutritional risk factors associated with HIV in rural and urban communities in the Assuring Health for All (AHA) study.

Methods: 547 rural and 419 urban adults between 25-64 years participated. 16.8% of rural and 40.8% of urban participants were HIV-infected. Logistic regression with forward selection ($p < 0.05$) was used to select significant independent factors (anthropometry, socio-demography, household food security, dietary diversity, physical activity and reported health) associated with HIV. Variables with a p -value of < 0.15 were considered for inclusion in the model.

Results: In this sample, the odds of having HIV decreased as age increased. In rural areas, odds of having HIV were decreased for microwave oven ownership (odds ratio 0.20) and being married (odds ratio 0.17). Odds were increased in participants who spent less than R50 (€4.2) per week on food (odds ratio 3.15); had a body fat percentage of $< 5\%$ versus $25\%+$ (odds ratio 4.41) or had been diagnosed with tuberculosis (odds ratio 3.81). In the urban sample, the odds of having HIV were decreased if a person was male (odds ratio 0.29), and increased if a person experienced periods of food shortage (odds ratio 2.34) and had a body fat percentage of $< 15\%$ versus $25\%+$ (odds ratio 8.62).

Conclusions: Indicators related to wasting, previous tuberculosis and a lower socio-economic status (indicated by being female [urban] and unmarried [rural]; spending very little on food [rural]; and food shortage [urban]), increase the odds of having HIV. A vicious cycle develops, with poverty increasing the likelihood of contracting HIV/AIDS, and HIV/AIDS contributing to poverty.

Key words: nutritional risk, HIV.

PO2026**EFFECTS OF CONJUGATED LINOLEIC ACID ISOMERS ON PPAR-GAMMA AND ADIPOCYTE-SPECIFIC GENES IN ADIPOCYTES TREATED WITH ANTI-RETROVIRAL DRUGS***C. Loonam¹, S. O'Dell¹, A. Mullen¹*¹Diabetes & Nutritional Sciences Division, King's College London, London, United Kingdom

Background and objectives: HIV-associated lipodystrophy, a side-effect of antiretroviral drugs (ARV), has been suggested to occur as a result of down-regulation of peroxisomal proliferator-activated receptor-gamma (PPAR- γ), leading to reduced expression of anti-inflammatory adiponectin and increased leptin, resistin and pro-inflammatory interleukin (IL)-6. Conjugated linoleic acid (CLA) isomers, c9,t11-CLA in particular, are activating ligands for PPAR- γ . We hypothesised that CLA isomers mitigated ARV-induced down-regulation of PPAR- γ and adipocyte-specific genes, as well as inflammation. This study investigated the effect of CLA isomers on PPAR- γ , adipocyte-specific genes and inflammation in adipocytes pre-treated with ARV.

Methods: 3T3-L1 pre-adipocytes were differentiated in the presence of tenofovir (TDF; 1 μ M), ritonavir (RTV; 20 μ M) or indinavir (IDV; 10 μ M) and 100 μ M of either c9,t11-CLA or t10,c12-CLA. Gene expression was investigated using real-time RT-PCR and protein secretion using ELISA. Statistical analysis was performed using ANOVA (SPSS, v20).

Results: The addition of c9,t11-CLA significantly increased PPAR- γ gene expression in the presence of RTV, and adiponectin gene expression in IDV-treated cells compared with vehicle (DMSO) control ($p = 0.001$, $p = 0.003$, respectively). c9,t11-CLA significantly increased adiponectin secretion in RTV-treated cells ($p = 0.021$). t10,c12-CLA significantly decreased PPAR- γ expression in IDV- and TDF-treated cells ($p < 0.001$, $p = 0.015$, respectively), adiponectin gene expression in RTV- and TDF-treated cells ($p = 0.031$, $p < 0.001$, respectively) and adiponectin protein secretion for all ARV ($p < 0.001$). t10,c12-CLA significantly increased IL-6 gene expression in IDV- and TDF-treated cells ($p = 0.001$, $p < 0.001$, respectively).

Conclusions: Here, for the first time, we have shown that CLA isomers have differential effects on adipocytes treated with ARV. c9 has shown potential beneficial effects by increasing PPAR- γ and anti-inflammatory adiponectin, while t10 CLA seems to have a detrimental effect by decreasing PPAR- γ and adiponectin, and increasing pro-inflammatory IL-6 expression.

Key words: HIV-associated lipodystrophy syndrome, conjugated linoleic acid isomers; PPAR- γ , adiponectin.

PO2027**THE SPANISH FOOD PYRAMID SCORE AND ITS ASSOCIATION WITH OVERWEIGHT/OBESITY IN THE GRANADA-EPIC STUDY (EUROPEAN PROSPECTIVE INVESTIGATION INTO CANCER AND NUTRITION)**

E. Molina-Montes^{1,2}, I. Uzhova³, E. Molina-Portillo¹, J.M. Huertas^{4,5}, G. Buckland⁵, P. Amiano^{6,2}, V. Menéndez⁷, A. Barricarte^{8,2}, C.A. González⁵, M.J. Sánchez^{1,2}

²CIBER Epidemiología y Salud Pública, CIBERESP, Madrid, Spain

³Department of Bioscience and Nutrition, Karolinska Institute, Stockholm, Sweden

⁴Department of Epidemiology, Murcia Regional Health Council, Murcia, Spain

⁵Unit of Nutrition, Environment and Cancer, Cancer Epidemiology Research Programme, Catalan Institute of Oncology (ICO-IDIBELL), Barcelona, Spain

⁶Public Health Division of Gipuzkoa, BioDonostia Research Institute, San Sebastian, Spain

⁷Public Health Directorate, Asturias, Spain

⁸Public Health Institute of Navarra, Pamplona, Spain

Background and objectives: Adherence to dietary guidelines has been related to prevention of chronic diseases and obesity. Due to the steady increase of the obesity prevalence in Spain there is a need to evaluate whether the national guidelines may be efficient to tackle this problem. The aim was to develop the Spanish Food Pyramid Score (SFP) and to investigate its association with overweight and obesity in the EPIC-Granada study.

Methods: Cross-sectional study within EPIC-Granada, including 7,575 participants. The SFP was developed to assess adherence to the dietary guidelines. Overweight and obesity were defined as BMI ≤ 25 - <30 kg/m² and ≥ 30 kg/m², respectively, and abdominal obesity as waist circumference ≥ 102 cm (men) and 88 cm (women). Logistic regression was conducted to estimate odds ratios of overweight & obesity vs. normal weight, and obesity vs. over & normal weight, by quintiles of the SFP and by 10 points increment in the adherence to this score, controlling for potential confounders.

Results: No statistically significant association between adherence to the SFP and risk of overweight was observed. A 10 point increase in the adherence to the SFP was associated with a 13% (95% CI:0.76-0.99) lower risk of obesity only in men (p interaction by sex=0.03). Abdominal obesity risk decreased globally by 12% (95% CI:0.82-0.94) per 10 points increase in the adherence to the SFP. The effect of the SFP on obesity risk was stronger in physically active subjects.

Conclusions: A higher adherence to the SFP may lead to a lower risk of obesity in men and a lower risk of abdominal obesity in both sexes. Thus, the Spanish dietary guidelines might be an effective tool for the prevention of obesity among the general population. However, prospective studies investigating this relationship are warranted.

Key words: Nutrition policy, dietary guidelines, diet quality, obesity.

PO2028**POMEGRANATE AND ITS DERIVATIVES CAN IMPROVE BONE HEALTH THROUGH DECREASED INFLAMMATION AND OXIDATIVE STRESS IN AN ANIMAL MODEL OF POSTMENOPAUSAL OSTEOPOROSIS**

Background and objectives: Recently, nutritional and pharmaceutical benefits of pomegranate (PG) have raised a growing scientific interest. Since PG is endowed with anti-inflammatory and antioxidant activities, we hypothesized that it may have beneficial effects on osteoporosis.

Methods: We used ovariectomized mice as a well described model of postmenopausal osteoporosis to study the influence of pomegranate consumption on bone health. Mice were divided into five groups as following: sham-operated (SH CT) and ovariectomized (OVX CT) control mice fed a standard diet versus OVX treated mice given a modified diet from the AIN-93G diet, containing 5.7% of pomegranate lyophilized mashed totum (OVX PGt), or 9.6% of pomegranate fresh juice (OVX PGj) or 2.9% of pomegranate lyophilized mashed peel (OVX PGp).

Results: As expected, ovariectomy was associated with a decreased femoral bone mineral density (BMD) and impaired bone microarchitecture parameters. Consumption of PGj, PGp or PGt induced bone sparing effects in those OVX mice, both on femoral BMD and bone microarchitecture parameters. In

addition, PG (whatever the part) up-regulated osteoblast activity and decreased the expression of osteoclast markers, when compared to what was observed in OVX CT littermates. Consistent with the data related to bone parameters, PG consumption elicited a lower expression of pro-inflammatory makers and of enzymes involved in ROS generation, whereas the expression of anti-inflammatory markers and anti-oxidant actors was enhanced.

Conclusions: These results indicate that all pomegranate parts are effective in preventing the development of bone loss induced by ovariectomy in mice. Such an effect could be partially explained by an improved inflammatory and oxidative status.

Key words: Pomegranate, nutritional prevention, osteoporosis, animal model, inflammation, oxidative stress.

⁶Institut National de la Santé et de la Recherche Médicale (Inserm), Paris, France

Background and objectives: In the current context of longer life expectancy, the prevalence of osteoporosis is increasingly important. This is why development of new strategies of prevention is highly suitable. Some dietary fats and particularly conjugated linoleic acid have a positive impact on bone formation leading to improved bone mineral density (BMD). Pomegranate seed oil (PSO) and its major component: punicic acid, a conjugated linolenic acid specific to this fruit, have potent anti-inflammatory and anti-oxidative properties both in-vitro and in-vivo, two process strongly involved in osteoporosis establishment.

Methods and results: In this study, we demonstrated that PSO consumption (5% of the diet) improved significantly bone BMD and prevented trabecular microarchitecture impairment

in ovariectomized (OVX) mice C57bl6j, compared to OVX controls animals. Those findings are associated with transcriptional changes in bone tissue, suggesting involvement of both osteoclastogenesis inhibition and osteoblastogenesis improvement. In addition, thanks to an ex-vivo experiment, we provided evidence that serum from mice fed pomegranate seed oil (5% by gavage) had the ability to significantly down-regulate the expression of specific osteoclast differentiation markers and RANK-RANKL downstream signaling targets in osteoclast like cells (Raw264.7). Moreover, in osteoblast like cells (MC3T3-E1) it elicited significant increase in ALP activity, matrix mineralization and transcriptional levels of major osteoblast lineage markers involving the Wnt/ α -catenin signaling pathways may. Our data also reveal that PSO inhibited pro-inflammatory factors expression, while stimulating anti-inflammatory ones.

Conclusions: These results demonstrate that PSO is highly relevant regarding osteoporosis. Indeed, it offers promising alternatives in the design of new strategies in nutritional management of age-related bone complications.

Key words: Pomegranate seed oil, nutritional prevention, osteoporosis, cell lines, animal model.

⁵Clermont Université, Université d'Auvergne, Imagerie Moléculaire et Thérapie Vectorisée, Clermont-Ferrand, France

⁶Institut National de la Santé et de la Recherche Médicale (Inserm), Paris, France

Background and objectives: Aging is associated with impairment of bone remodeling process, characterized by an increase in the resorption/formation ratio and leading to a progressive loss of bone. This process is amplified by inflammatory and oxidative stress on bone microenvironment associated with age-related bone loss. Pomegranate (PG), especially pomegranate peel, has been used worldwide for many years as medical products. Recently, nutritional and pharmaceutical benefits of pomegranate raised a great scientific interest.

Methods: In this study, we investigated whether pomegranate peel extract (PGPE) consumption could effectively inhibit osteoporosis establishment through bone cells differentiation modulation.

Results: In ovariectomized control mice (OVX CT) compared to sham control mice (SH), the bone mineral density (BMD) decreased and bone microarchitecture were significantly impaired. However, PGPE metabolites substantially inhibited the decreased BMD and bone microarchitecture impairment induced by ovariectomy. Moreover, PGPE consumption reduced the osteoclast differentiation and bone resorption by inhibiting major osteoclasts markers, on RAW264.7 cells and in-vivo. In addition PGPE appeared to increase activity and differentiation of osteoblastic cells MC3T3-E1 and in-vivo. Furthermore, PGPE significantly improved inflammation and oxidative parameters on osteoporotic bone microenvironment.

Conclusions: Taken together, PGPE may be a good candidate to nutritional supplement in order to prevent osteoporosis progression and particularly for the management of postmenopausal osteoporosis.

Key words: Pomegranate peel extract, nutritional prevention, osteoporosis, cell lines, animal model.

we hypothesized that GPR40 may play a role in mediating the effects of fatty acids on bone remodeling.

Methods: GPR40/FFAR(1) -knockout (GPR40^{-/-}) and wild-type (WT) mouse bone phenotypes were compared using both in vitro primary cultures of bone marrow and in vivo CT analyses under administration of a GPR40 agonist (GW9508).

Results: We showed that GPR40^{-/-} mice exhibit osteoporotic features suggesting a positive role of GPR40 on bone density. In bone marrow cultures, we showed that GW9508 abolished bone resorbing cell differentiation. Alteration of the Receptor Activator of NF- κ B Ligand (RANKL)-induced osteoclast differentiation occurred via the inhibition of the Nuclear Factor κ B (NF- κ B) signalling pathway as demonstrated by decrease in gene reporter activity, inhibitor of κ B kinase (IKK β / β) activation, inhibitor of κ B (IkB) phosphorylation and Nuclear Factor of Activated T cells 1 (NFATc1) expression. The GPR40-dependent effect of GW9508 was confirmed using shRNA interference in osteoclast precursors and GPR40^{-/-} primary cell cultures. In addition, in vivo administration of GW9508 counteracted ovariectomy-induced bone loss in wild-type but not GPR40^{-/-} mice enlightening the obligatory role of the GPR40 receptor. We are now looking forward to proving that natural GPR40 agonists, long chain fatty acids, parallel GW9508 effects in a fatty acid class-depending way.

Conclusions: In a context of growing prevalence of metabolic and age-related bone disorders, our results demonstrate for the first time in translational approaches that GPR40 is a relevant target for the design of new nutritional and therapeutic strategies targeting fatty acids to counter bone complications.

Key words: free fatty acids, GPR40, osteoclast, osteoporosis.

⁴Postgraduation Program in Medicine – Medical Sciences, Universidade Federal do Rio Grande do Sul, Brazil

⁵Department of Genetics, Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil

Background and objectives: Gaucher Disease (GD) is characterized by multisystem manifestations, such as hepatosplenomegaly and hematological abnormalities. Studies have reported hyperferritinemia in patients with GD before enzyme replacement therapy (ERT), however some patients continue to present it while undergoing treatment. The aim of this study was to assess the nutritional status and ferritin levels in a sample of patients with Gaucher Disease at the Reference Center in Rio Grande do Sul, Brazil.

Methods: A retrospective study, data were obtained from medical records. Nutritional status were assessed for BMI; ferritin levels were considered elevated when above 291 ng/mL for women and 322 ng/mL for men.

Results: Thirty-five patients were followed at CRDG (male=17, mean age 35 ±16 years old). The majority of patients assessed in this study present with normal weight; however, approximately 40% of them (14 patients adults) were overweight. Twenty-two patients (63%) had hyperferritinemia (male=15; 68%), from which 18 were on ERT and 12 had some alteration in liver enzymes. Data on the percentage of transferrin saturation were available for 21 patients with hyperferritinemia and revealed that none of them was above the reference value. The subgroup who initiated treatment with age >18 years (n=16) had a significant increase in BMI after ERT (p <0.0001) and BMI presented correlation with serum ferritin level (r=0.725, p=0.001).

Conclusions: ERT seems to contribute to the weight gain of GD patients. BMI presented correlation with ferritin levels. Hyperferritinemia is common in GD patients without ERT, though the causes of their persistence even under treatment are unclear. Since it does not seem to be associated with hemochromatosis, further studies are warranted in order to see possible association with inflammatory processes related with the disease and with metabolic syndrome and/or overweight.

⁶Laboratory BRAIN Idem

Background and objectives: Gaucher disease (GD) is a rare genetic disease characterized by multisystemic manifestations such as hepatosplenomegaly, hematologic abnormalities, and bone pain. There are reports of low levels of HDL-cholesterol (HDL) in patients with GD, regardless of treatment. The aim of this study was to assess the levels of HDL in a sample of patients with GD at the Reference Center of Rio Grande do Sul, Brazil.

Methods: A retrospective study; data were obtained through review of medical records. Nutritional status was assessed by BMI and HDL levels were considered high risk when <40 mg/dL. Clinical and laboratorial parameters of importance were evaluated in order to relate them to the levels of HDL.

Results: Data on HDL levels were available for 33 patients (male = 17, mean age 35 ± 15 years): 6 were overweight and 5 obese. The BMI of the patients showed no significant correlation with HDL levels, LDL-cholesterol (LDL), total cholesterol (COL-T) and triglycerides (TRIGL). HDL levels were considered high risk for 21 patients (64% male = 11), being 5 overweight and 3 obese. COL level was moderately high for one patient, and LDL for another; levels of TRIGL were borderline for 5 and high for 3. Significant correlations were found (r=0.596, p = 0.004) between the levels of HDL and COL-T, but not with LDL and TRIGL.

Conclusions: Low levels of HDL-COL observed in two thirds of patients are consistent with data reported in the literature and do not seem to be associated with higher cardiovascu-

lar risk as lower levels of HDL-COL also correlated with lower levels of COL-T. Additional studies are needed to understand the mechanisms involved in the lipid profile of these patients.

Key words: Gaucher Disease, nutritional status, HDL-Cholesterol, lipid profile.

Background and objectives: Gestational diabetes mellitus (GDM) leads to poor health outcomes for the mother and her child. Previous studies have examined the risk of GDM with either elevated body iron stores or dietary iron intake. This study relates indicators of iron status to the risk of GDM.

Methods: At 26-28 weeks of gestation, women in the birth cohort "Growing Up in Singapore Towards healthy Outcomes (GUSTO)" were tested for GDM using oral glucose tolerance

testing. Blood samples were obtained for serum ferritin and iron measurements (n=472). Dietary iron intake and data on iron supplementation were also ascertained using 24-hr food recalls and interviewer-administered questionnaires. Logistic regression analyses were performed to determine risk factors for GDM.

Results: Based on WHO criteria, 17.4% of participants were diagnosed as having GDM. GDM was more prevalent among women in the highest quintiles of serum ferritin (Q1: 13.5%, Q2: 12.2%, Q3: 19.1%, Q4: 13.5%, Q5: 28.3%; p for trend=0.014) and total iron intake (Q1: 13.6%, Q2: 13.5%, Q3: 11.8%, Q4: 16.3%, Q5: 31.5%; p for trend=0.002). No associations were observed between serum iron concentrations or iron intakes from supplements and GDM. In models adjusted for BMI, ethnicity, maternal age, total energy intake and other covariates, the highest quintiles (compared to lowest four quintiles) of serum ferritin and total iron intake remained significant risk factors for GDM, with adjusted odds ratio (AOR) of 2.23 (95% CI: 1.15-4.30, p=0.017) and 3.30 (95% CI: 1.73-6.31, p<0.001), respectively. However, when the two variables were simultaneously included in the multivariate model, only elevated total iron intake remained significantly associated with GDM (AOR= 2.92 [95% CI: 1.50-5.67], p=0.002).

Conclusions: Our findings suggest that elevated dietary iron intake during pregnancy is linked to an increased risk of GDM in our Asian population.

Key words: Gestational diabetes mellitus, serum ferritin, dietary iron intake.

²Institute of Nutrition of Central America and Panama (INCAP) Comprehensive Centre for the Prevention of Chronic Diseases, Guatemala City, Guatemala

³Nutrition Area, World Food Programme, United Nations, Dominican Republic Country Office.

⁴RAND Corporation, Santa Monica, USA

Background and objectives: Excess weight and body fat are important risk factors for cardiovascular disease. How much

these factors affect people with HIV and on antiretroviral therapy (ART) is of increasing concern. The aim of this study was to determine the prevalence of overweight, central obesity and excess body fat among HIV-infected adults in the Dominican Republic (DR).

Methods: A cross-sectional study of 160 HIV-infected adults of mean±SD age of 40±11 years old (31% male; 72% on ART) was conducted from March-December 2012 in four geographically-dispersed health centres (Santo Domingo, Puerto Plata, San Juan and Higüey). We measured anthropometric and socioeconomic data and ran descriptive analysis (ttest/Chi2) and multivariate logistic regression analysis.

Results: Mean±SD of energy intake among men and women was 1779±530 and 1711±593kcal (p=0.491), respectively. Overall, 38% (32% of men and 41% of women, p=0.282) were overweight using BMI (>24.9kg/m²); 28% (27% of men and 29% of women, p=0.727) had excess body fat (>25% in men and >33% in women) using bio-impedance analysis; and 37.5% (8% of men and 51% of women, p=0.001) had central obesity using waist circumference (>102cm in men and >88cm in women). After adjusting for age, sex, energy intake and health centre, we found no association between nutritional status and being on ART; women were much more likely to have central obesity than men (OR=20.4; IC95%=5.9;70.4); and increasing age was associated with excess of body fat (OR=1.05; IC95%=1.01;1.09).

Conclusions: Overweight is a substantial public health problem among HIV-infected adults in DR. Over a third of HIV patients were overweight according to BMI, central obesity and body fat; ART was not associated with nutritional status in this sample. Updated nutrition guidelines and policies are needed to address overweight among HIV-infected adults. Implementation of physical activity programs and nutritional and other behavioural change counselling could be viable solutions.

Key words: HIV, nutrition, overweight, obesity, anthropometry.

PO2036

DIETARY INTAKE OF PHYLLOQUINONE IS ASSOCIATED TO LOWER CONCENTRATIONS OF METABOLIC MARKERS IN ELDERLY SUBJECTS AT HIGH CARDIOVASCULAR RISK

M. Juanola-Falgarona^{1,2,3}, J. Salas-Salvadó^{1,2,3}, R. Estruch^{1,2,3,4}, M. Portillo^{3,5}, R. Casas^{2,3,4}, J. Miranda^{3,5}, M. Martínez-González^{3,6}, M. Bulló^{1,2,3}

⁵Department of Nutrition and Food Science, University of Pais Vasco, Vitoria, Spain

⁶Department of Preventive Medicine and Public Health, University of Navarra, Pamplona, Spain

Background and objectives: Vitamin K has been related to glucose metabolism, insulin sensitivity and diabetes. Because inflammation underlies all these metabolic conditions, it is plausible that the potential role of vitamin K in glucose metabolism occurs through the modulation of cytokines and related molecules. The purpose of the study was to assess the associations between dietary intake of vitamin K and peripheral adipokines and other metabolic risk markers related to insulin resistance and type 2 diabetes mellitus.

Methods: Cross-sectional and longitudinal assessments of these associations in 510 elderly participants recruited in the PREDIMED centers of Reus and Barcelona (Spain). We determined 1-year changes in dietary phylloquinone intake estimated by food frequency questionnaires, serum inflammatory cytokines and other metabolic risk markers.

Results: In the cross-sectional analysis at baseline no significant associations were found between dietary phylloquinone intake and the rest of metabolic risk markers evaluated, with exception of a negative association with plasminogen activator inhibitor-1. After 1-year of follow-up, subjects in the upper tertile of changes in dietary phylloquinone intake showed a greater reduction in ghrelin (-15.0%), glucose-dependent insulinotropic peptide (-12.9%), glucagon-like peptide-1 (-17.6%), IL-6 (-27.9%), leptin (-10.3%), TNF (-26.9%) and visfatin (-24.9%) plasma concentrations than those in the lowest tertile (all p<0.05).

Conclusions: These results show that dietary phylloquinone intake is associated with an improvement of cytokines and

other markers related to insulin resistance and diabetes, thus extending the potential protection by dietary phyloquinone on chronic inflammatory diseases.

Key words: Vitamin K, inflammation, insulin resistance, diabetes.

PO2037

SERUM FERRITIN IS ASSOCIATED TO OSTEOCALCIN: A POTENTIAL MECHANISM OF IRON-INDUCED INSULIN RESISTANCE

M. Juanola-Falgarona^{1,2}, J. Fernández-Cándido¹, J. Salas-Salvadó^{1,2}, M. A. Martínez-González^{2,3}, R. Estruch^{2,4}, M. Fiol^{2,5}, V. Arija-Val¹, M. Bulló^{1,2}

⁴Department of Internal Medicine, Institut d'Investigacions Biomèdiques August Pi Sunyer (IDIBAPS), Barcelona, Spain

⁵University Institute for Health Sciences Investigation, Palma de Mallorca, Spain

Background and objectives: Increased iron stores are associated with increased risk of type 2 diabetes; however, the mechanisms underlying these associations are poorly understood. Recent studies have demonstrated a direct and causal effect of iron stores in the modulation of circulating levels of adiponectin. Because a reduction of circulating osteocalcin levels after iron overload has been demonstrated in cell cultures, and osteocalcin is related to glucose and insulin metabolism we analysed the associations between serum osteocalcin or adiponectin concentrations with serum ferritin, soluble transferrin receptor (sTfR) and insulin resistance in elderly subjects.

Methods: We evaluated a total of 423 subjects from the PREDIMED cohort in a population-based cross-sectional analysis. Extensive clinical, nutritional and laboratory measurements, including osteocalcin, adiponectin, ferritin and sTfR, were recorded.

Results: Age- sex and BMI-adjusted serum ferritin was positively correlated with increased glucose and insulin circulating levels but also with HOMA-IR, and was inversely associated with total osteocalcin and adiponectin. A regression analysis revealed that the serum ferritin and transferrin receptor levels were significantly associated with a decrease in total

OC and in ucOC. These associations were apparent both in normoglycemic and in subjects with impaired glucose metabolism. Serum sTfR levels were associated with lower ucOC levels in the whole-study subjects and remained significant only in the IGM individuals.

Conclusions: These findings describe for the first time an inverse association between serum ferritin and sTfR with osteocalcin and also with adiponectin, thus supporting that iron metabolism could contribute to the origin of type 2 diabetes mellitus and osteoporosis.

Key words: Ferritin, osteocalcin, insulin Resistance, type 2 diabetes mellitus.

PO2038

URTICACEAE FAMILY HERBAL TEAS AS ANTI-INFLAMMATORY AGENTS

M. Franciscovic¹, D. Orčić¹, F. Šibul¹, Svirčev, M. Lesjak¹, I. Beara¹, N. Mimica-Dukić¹

¹Department of Chemistry, Biochemistry and Environmental Protection, Faculty of Sciences, University of Novi Sad, Serbia

Background and objectives: Species from Urticaceae family, particularly from genus *Urtica* and *Parietaria*, have been used in traditional medicine since ancient times, primarily, as a diuretic to treat urinary, bladder and kidney problems. They are also edible, and have been used as a leaf vegetable and for tea preparations. However, their traditional use have not been examined by modern research. Therefore, in this work the attempt was made to assess the anti-inflammatory potential of teas made from herbs of following species: *Urtica dioica*, *Parietaria judaica*, *Parietaria vulgaris* and *Parietaria officinalis*.

Methods: The extracts used for analysis were prepared by the standard tea preparation - plant material was mixed with boiling water during 10 minutes, followed by filtration. The anti-inflammatory activity, of obtained extracts, was examined by means of cyclooxygenase-1 (COX-1) and 12-lipoxygenase (12-LOX) inhibition. Formed products were detected using LC-MS/MS. Inhibition curves of PGE₂, 12-HHT and TXB₂ production were used to investigate inhibition of COX pathway, while 12-HETE was used as indicator of 12-LOX pathway.

Results: Investigated extracts exhibited significant activity (IC₅₀ in range 1.61-5.36 mg/ml for 12-HHT production, 2.76-5.40 mg/ml for 12-HETE, 0.842-4.17 mg/ml for PGE₂ and 1.94-3.15 mg/ml for TXB₂). The highest potential in inhibiting COX-1 and 12-LOX pathway had the extract of *U. dioica* herb. For the extract *P. judaica* herb it was not possible to determine IC₅₀ value for 12-HETE, indicating that there was no inhibition of 12-LOX pathway.

Conclusions: All extracts have demonstrated the ability to inhibit the COX-1 enzyme, while the inhibition of 12-LOX enzyme was not successful only by *P. judaica* herb extract. The most potent extract was *U. dioica* herb, thus justifying its long term usage. Acknowledgements: This research is funded by Serbian Ministry of Education, Science and Technological Development research grant Nr. 172058.

Key words: Urticaceae, anti-inflammatory potential.

PO2039

EFFECTIVENESS OF DIET BASED ON SIGE TESTS USED AS SOLE METHOD OR IN COMBINATION WITH CLA IN IBS PATIENTS

M. Jarosz¹, I. Traczyk¹, W. Respondek¹, M. Mekus¹, R. Tomasiuk²

¹Department of Dietetics and Nutrition in Hospitals with Clinic of Metabolic Diseases and Gastroenterology, National Food and Nutrition Institute, Warsaw, Poland

²Department of Laboratory Diagnostics, Regional Brodnowski Hospital, Warsaw, Poland

Background and objectives: Irritable bowel syndrome (IBS) is a chronic disease, burdensome for patients. Therapy has often small influence on their well-being improvement. The main objective of the present work was the evaluation of the effectiveness of diet modification based on the presence of sIgE antibodies supplemented or not with CLA.

Methods: Concentrations of sIgE antibodies against eight food allergens were determined among 150 adult patients with IBS. 60 patients were randomly selected for the 12 week intervention study. Based on serological results, an individual diet was recommended to each patient. Apart from the diet, 30 patients (randomly selected) additionally received conjugated linolenic acid (CLA) (3,000 mg/day).

Results: Both therapy methods were effective, especially in patients with the diarrheal IBS. Diarrhea retreated in half of the patients ($p>0.05$) who had suffered from that symptom before diet modification and in 63% of people who were on the diet supplemented with CLA ($p<0.05$). All other outcomes showed trends in favour of the diet supplemented with CLA. Such treatment caused receding stomach pain in nearly half of the patients (15 of 29, $p=0.050$) in comparison to five people treated by sole diet (22%). The number of patients complaining on bloating at level 3rd (severe: symptoms prevent normal functioning) decreased particularly. This change was found in 10 patients who were treated with diet ($p>0.05$) and 15 whose diet was enriched in CLA ($p<0.05$).

Conclusions: Diet modification based on IgE antibodies may be effective in terms of decreasing IBS symptoms. CLA can enhance this effect particularly in the diarrheal IBS form.

Further research is needed. Acknowledgements: Research supported by the Polish Ministry of Science and Higher Education (project: N40405231/2712).

Key words: IBS, IgE antibodies, dietary therapy.

PO2040

DIET MODIFICATION BASED ON THE RESULTS OF SIGE CONCENTRATION AGAINST FOOD ANTIGENS AND QUALITY OF LIFE IN IBS PATIENTS

M. Jarosz¹, I. Traczyk¹, W. Respondek¹, M. Mekus¹, R. Tomasiuk²

¹Department of Dietetics and Nutrition in Hospitals with Clinic of Metabolic Diseases and Gastroenterology, National Food and Nutrition Institute, Warsaw, Poland

²Department of Laboratory Diagnostics, Regional Brodnowski Hospital, Warsaw, Poland

Background and objectives: Irritable bowel syndrome (IBS) is a prevalent and expensive condition that significantly impairs quality of life (QOL). The aim of this study was the assessment of QOL in IBS patients before and after diet modification based on the results of sIgE concentration against food antigens.

Methods: The study included 28 IBS patients. Every patient was recommended to limit, for 12 weeks, the intake of allergens sources (from among egg white, egg yolk, wheat, rye, strawberry, apple, lemon, nut antigens) for which the elevated concentration of sIgE were detected. Depending on the results, patients limited the consumption of one, two or three sources of allergens. The QOL was assessed on the basis of the SF-36 questionnaire before and after intervention and was compared to QOL of the control group ($n=50$).

Results: We found that IBS patients scored lower on all eight scales of the SF-36 QOL questionnaire compared to healthy subjects. This applied especially to general health (GH domain) and emotional relationships (RE domain). After the dietary intervention the significant improvement in general health as well as in physical health in IBS patients was noted. Other QOL parameters improved, but without statistical significance. The improvement in the QOL of IBS patients found in this study after dietary intervention was not enough to compensate the statistically significant difference between QOL of IBS and healthy subjects.

Conclusions: Irritable bowel syndrome significantly affects the patients quality of life. The dietary treatment can be the important tool to achieve it's improvement. Acknowledgements: Research supported by the Polish Ministry of Science and Higher Education; research project No. N404 052 31/2712.

Key words: IBS, diet modification, life quality.

PO2041**MARGINAL ZINC DEFICIENCY MAY WORSEN DIABETES IN ZUCKER DIABETIC FATTY RATS***L. Rech¹, C. Taylor¹*

¹Department of Human Nutritional Sciences, University of Manitoba; Canadian Centre for Agri-Food Research in Health and Medicine, St. Boniface Research Centre, Winnipeg, Manitoba, Canada

Background and objectives: Zinc deficiency may be present in diabetes and contributes to hyperglycemia, leading to hypozincemia and hyperzincuria. Many of the symptoms of zinc deficiency and diabetes are the same, and are related to increased inflammation. Zinc supplementation may improve immunity, insulin sensitivity and signalling, and reduce inflammation, which may improve diabetes. The purpose of this study was to determine if marginal zinc deficiency (MZD) worsens and zinc supplementation (ZS) improves the parameters of diabetes and immune cell proportions in Zucker diabetic fatty (ZDF) rats.

Methods: The study used 30 male ZDF rats fed MZD (3 ppm), zinc control ([ZC], 30 ppm), or ZS (300 ppm), and 10 male lean ZDF rats fed ZC diet, for 8 weeks. Assessment of diabetes included obesity, hyperlipidemia, hepatic steatosis, oral glucose tolerance testing, glycemic control, pancreatic islet insulin immunostaining, serum markers of kidney function, and inflammation (serum haptoglobin and monocyte chemoattractant protein-1 [MCP-1]). Immune cell proportions (B-cells, T-cells, monocytes/macrophages, and natural killer cells) were determined by flow cytometry.

Results: ZDF rats fed MZD had significantly reduced peri-renal fat pad mass, improved blood lipid levels (increased high-density lipoprotein cholesterol and decreased triglycerides), and an improvement in the blood urea to creatinine ratio; however, they had pancreatic islet cell hypertrophy, reduced glucose tolerance, and β -cell function. ZS did not change pancreatic islet cell size or number. Obesity and diabetes elevated serum concentrations of haptoglobin and MCP-1. ZC and ZS increased proportions of cytotoxic (CD8) T cells and there was a trend ($P=0.09$) for ZC and ZS to reduce proportions of helper (CD4) T-cells compared to lean rats. ZDF rats had a lower CD4 to CD8 ratio compared to lean rats. There was a trend for ZS to reduce proportions of recent thymic emigrants compared to ZC and lean ZDF rats ($P<0.06$).

Conclusions: MZD may exacerbate diabetes, while ZS had no effect on diabetes in ZDF rats.

Key words: zinc, diabetes

PO2042**OBESITY IS ASSOCIATED WITH REDUCED IRON STATUS AND INCREASED HEPcidIN CONCENTRATIONS IN WOMEN IN SOUTHERN INDIA***I. Aeberli¹, P. Thankachan², A V. Kurpad²*

¹Human Nutrition Laboratory, ETH Zurich, Zurich, Switzerland

²St. John's Research Institute, National Academy of Health Sciences, Bangalore, Karnataka, India

Background and objectives: Rapid urbanization in India has brought about changes in eating habits and lifestyle leading to obesity, but micronutrient (MN) deficiencies still persist. The aim of this study was therefore to assess direct associations between obesity and NM status in middle class women living in an urban area in South India, with a special focus on iron metabolism.

Methods: In a cross-sectional study design, fasting blood samples and anthropometric measures of 18-35 year old middle class women in Bangalore, India were collected. Weight, height, waist circumference and % body fat (using BodPod) were assessed. From the blood samples, inflammatory markers (CRP and AGP), serum ferritin (SF), transferrin receptor (TfR), hemoglobin (Hb), hepcidin, zinc, retinol, folate and vitamin B12 were assessed.

Results: Of the 146 subjects included, 51 were normal weight (NW, BMI<23 kg/m²), 72 were overweight (OW, BMI 23-29.9 kg/m²) and 23 obese (OB, BMI \geq 30 kg/m²); 19 were diagnosed with the metabolic syndrome. OW and OB subjects had a lower iron status (TfR) compared to NW but showed increased inflammation and hepcidin ($p<0.05$). None of the other MN (zinc, retinol, folate, B12) or Hb differed significantly between the groups. BMI and body fat were associated with TfR and hepcidin ($p<0.05$) in univariate correlations. In a multivariate linear regression controlling for CRP and hepcidin only BMI remained a significant predictor of TfR ($p=0.032$, $r=0.220$). Hepcidin was not significantly correlated with TfR ($r=0.019$, $p=0.825$).

Conclusions: OW and OB Indian women are at an increased risk to develop iron deficiency while other MN do not seem to be affected. Increased hepcidin points towards an involvement of this protein in the etiology of iron deficiency in obesity, although direct associations are likely to be confounded by inflammation.

Key words: Iron deficiency, hepcidin, obesity, India, micronutrients.

PO2043**EFFECTIVENESS OF THE GLUTEN REDUCTION INTAKE, WITH AND WITHOUT PROBIOTIC, IN IBS PATIENTS WITH POSITIVE SEROLOGICAL TEST FOR COELIAC DISEASE**

W. Respondek¹, I. Traczyk¹, M. Jarosz¹, M. Mekus¹, R. Tomasiuk²

¹Department of Dietetics and Nutrition in Hospitals with Clinic of Metabolic Diseases and Gastroenterology, National Food and Nutrition Institute, Warsaw, Poland

²Department of Laboratory Diagnostics, Regional Brodnowski Hospital, Warsaw, Poland

Background and objectives: Irritable bowel syndrome (IBS) treatment is difficult and often ineffective. The objective of this study was to evaluate the effectiveness of a diet with gluten reduction combined or not with probiotic in IBS patients with positive serological tests for celiac disease.

Methods: In 27 IBS patients with elevated antibodies against tissue transglutaminase (anti-tTG) and / or anti - gliadin (AGAs) a 12-week dietary intervention was applied. In 13 subjects the diet with gluten reduction was recommended (intervention RG) and 14 patients were advised to use the same diet, but with probiotic [capsules *Lactobacillus rhamnosus* GG, 6x10⁹ cfu twice a day] (intervention RGP). The effectiveness of these interventions was evaluated by the changes in the IBS symptoms severity and in the antibodies concentration.

Results: Both the RG and RGP interventions were effective in the vast majority of the subjects. The average severity of pain and bloating decreased significantly after both types of intervention. In the case of diarrhea and constipation, their severity decreased significantly after RGP intervention. In comparison to the RG the RGP intervention was successful in a greater portion of persons suffering from diarrhea (90% vs 67%) and flatulence (71.4% vs 54.5%). In the most patients the normalization of anti-tTG and AGAs concentration was detected (81,8% and 75% subjects respectively).

Conclusions: Gluten intake reduction in IBS patients with positive serological test for celiac disease is justified. It results in clinical and biochemical improvement. Adding probiotics to such diet increases its effectiveness, particularly in IBS patients with diarrhea and flatulence. Acknowledgements: Research supported by the Polish Ministry of Science and Higher Education; research project No. N404 052 31/2712.

Key words: IBS, gluten intolerance, diet modification.

PO2044**PROCYANIDINS EXTRACTED FROM THE LITCHI PERICARP ATTENUATE ATHEROSCLEROSIS AND REGULATE GENES CONTROLLING LIPID METABOLISM IN APOLIPOPROTEIN-E KNOCKOUT MICE**

S. Rong¹, Y. Yang¹, Z. Wang¹, X. Xiang¹

¹Department of Food Nutrition Assessment, Institute of Nutrition and Food Safety, Chinese Center For Disease Control and Prevention, China

Background and objectives: Epidemiological studies strongly supported the role for procyanidins-rich beverages and fruits in the prevention of cardiovascular diseases. Procyanidins extracted from the litchi pericarp (LPPC) is a new source of procyanidins isolated and identified in our laboratory which has been proven to possess strong antioxidant activities. The aim of the present study was to investigate the effect of LPPC on atherosclerosis and hyperlipidemia.

Methods: Apolipoprotein-E knockout (ApoE KO) mice fed on a high fat diet (21% fat, 0.15% cholesterol) with or without LPPC intervention for 24 weeks.

Results: The results showed that LPPC intervention alleviated atherosclerosis, fat accumulation and hyperlipidemia in ApoE KO mice. Moreover, LPPC could significantly increase hepatic mRNA expressions of farnesoid X receptor (FXR) and small heterodimer partner (SHP) which emerge as key regulators of lipid homeostasis at the transcriptional level, decrease mRNA expressions of 3-hydroxy-3-Methylglutaryl (HMG)-CoA reductase which mediates cholesterol biosynthesis, and increase mRNA expressions of ATP-binding cassette transporter-1 (ABCA1) which modulates cholesterol efflux.

Conclusions: These findings indicated that LPPC ameliorated atherosclerosis and hyperlipidemia via regulating gene expression involved in hepatic lipid homeostasis in ApoE KO mice fed a HFD. The direct modulation effect of LPPC on signaling pathway may be relevant to explain the health effects ascribed to the regular consumption of dietary flavonoids.

Key words: Procyanidins, atherosclerosis, hyperlipidemia, liver, FXR.

PO2045**ASSOCIATION BETWEEN EATING BEHAVIOR AND NIGHTTIME SLEEP AMOUNT IN OBESE CHILDREN**

M. Gutierrez¹, G. Weisstaub¹, J.L. Santos², P. Peirano¹

¹University of Chile, Santiago, Chile

²Catholic University of Chile, Santiago, Chile

Background and objectives: Many studies have shown the relationship among sleep patterns and appetite regulation and increased risk for obesity. The objective of this study was to assess the association between eating behavior dimensions and nighttime sleep amount in obese and normal weight schoolers.

Methods: In a set of 129 schoolers (64 normal weight and 65 obese), ages 9.9 ±1.79 years normal weight and 9.59±1.49 years obese, 57% normal weight and 47% obese boys, we assessed the eating behavior dimensions (Child Eating Behavior Questionnaire) and nighttime sleep amount (Actiwatch*64) in the non-dominant wrist continuously for four days. Sleep restriction was considered for sleep amount less than 570 minutes. Obesity was defined as BMI>95 (CDC). Eating behavior patterns, nighttime sleep amount and frequency of awakenings were compared using ANOVA and chi square. The study was approved by INTA ethics committee and parents signed an informed consent.

Results: Relative to normal weight children, obese children showed a higher score in the pro-ingestion dimension and a lower score in two anti-ingestion dimensions (satiety response and slowness in eating). No differences in sleep amount were found between groups. Obese children that slept less than 570 minutes obtained even less score in the anti-ingestion dimensions compared with obese children who slept more (p<0.05).

Conclusions: Obese children present different score in both pro- and anti-ingestion dimensions of the eating behavior compared with normal weight children within the obese group, those who sleep less than recommended for their age show even more marked differences in the anti-ingestion dimensions. We suggest that the relationship between nighttime sleep amount and eating behavior patterns might contribute to the understanding of altered nutrition status in childhood. Acknowledgements: DI 2005 MULT 05/06-2.

Key words: Eating behavior, obesity, nighttime sleep restriction.

PO2046**IS FOOD ALLERGY A CAUSE OF SYMPTOMS WHICH IN IBS PATIENTS OPINION ARE INDUCED BY CONSUMPTION OF CERTAIN FOOD PRODUCTS?**

I. Traczyk¹, W. Respondek¹, M. Jarosz¹, M. Mekus¹, R. Tomasiuk²

¹Department of Dietetics and Nutrition in Hospitals with Clinic of Metabolic Diseases and Gastroenterology, National Food and Nutrition Institute, Warsaw, Poland

²Department of Laboratory Diagnostics, Regional Brodnowski Hospital, Warsaw, Poland

Background and objectives: It is not clear why some food products are often suspected to cause IBS symptoms. According to one hypothesis it may be due to food allergy. The main objective of the study was to estimate the association between IgE-dependent food allergy and gastrointestinal adverse reactions referred by IBS patients due to the ingestion of certain foods.

Methods: The study included 150 IBS patients and 50 control subjects. Questionnaire survey data on food products which in patients' opinion cause IBS symptoms were collected. In the IBS and control groups the sIgE concentration against selected food antigens (egg white, egg yolk, wheat, rye, strawberry, apple, lemon, nut) was determined.

Results: Patients most often connected their IBS symptoms with milk and milk products (50%) and eggs (30%). The fish, cruciferous vegetables, broccoli, legumes, and peppers, citrus fruits, strawberries, nuts were also quite often reported as the cause of gastrointestinal complaints. Most of the subjects from both IBS and control groups had a little elevated concentration of specific IgE against all tested allergens. Moreover, positive results for some allergens (apple, egg yolk, nuts) were even more frequent in the control group.

Conclusions: Our results did not confirm that adverse reactions after ingestion of certain foods in IBS patients are connected with food allergy. It can be assumed, however, that IBS typical visceral hypersensitivity may cause that even a slight increase of sIgE concentrations, that does not result in any complaints in healthy people, may lead to an exacerbation of IBS symptoms in people with this syndrome.

Acknowledgements: Research supported by the Polish Ministry of Science and Higher Education; research project No. N404 052 31/2712.

Key words: IBS symptoms, food products, sIgE.

PO2047**HINOKITIOL SUPPRESSES METASTASIS OF HUMAN HEPATOMA SK-HEP1 CELLS BY INHIBITING MATRIX METALLOPROTEINASE-2/9 AND UROKINASE-PLASMINOGEN ACTIVATOR**

W. Yu-Ling¹, L. Te-Chung¹, L. Kai-Li¹

¹School of Nutrition, Chung Shan Medical University, Taichung City, Taiwan

Background and objectives: Hinokitiol is a natural component isolated from *Chamaecyparis taiwanensis*. Hinokitiol possesses a wide range of biochemical and pharmacological activities, including anti-bacterial, anti-proliferative, and antioxidant capacities, as well as induction of cellular differentiation and apoptosis. Although hinokitiol has been shown to inhibit tumor cell proliferation, the antimetastatic effect of hinokitiol on human hepatoma is unknown.

Results: Without a notable cytotoxic effect on SK-Hep1 cells, hinokitiol dose-dependently decreased cell migration measured by the Boyden chamber assay. Moreover, hinokitiol significantly decreased enzyme activities and protein expressions of matrix metalloproteinase-9 (MMP-9), matrix metalloproteinase-2 (MMP-2), and urokinase-plasminogen activator (uPA). Additionally, hinokitiol reduced phosphorylation of p38 mitogen-activated protein kinases (p38), phosphatidylinositol-3-kinase/serine/threonine protein kinase (PI3K/Akt), and focal adhesion kinase (FAK). Data from the electrophoretic mobility shift assay showed that hinokitiol significantly repressed nuclear factor kappa B (NF- κ B) DNA-binding activity.

Conclusions: hinokitiol inhibited the metastasis of SK-Hep1 cells by reducing expression of MMP-2, MMP-9, and uPA which may be related to its inhibitory effect on activation of p38, PI3K/Akt and FAK as well as transcriptional activity of NF- κ B. These findings suggest that hinokitiol could be considered as antimetastatic agent of hepatoma.

Key words: SK-Hep1, hinokitiol, metastasis, MMP-2/9, uPA.

PO2048**ASSESSMENT OF THE RELATIONSHIP BETWEEN IBS OCCURRENCE AND SELECTED FACTORS SUSPECTED TO BE RELATED TO THIS DISEASE**

W. Respondek¹, I. Traczyk¹, M. Jarosz¹, M. Mekus¹

¹Department of Dietetics and Nutrition in Hospitals with Clinic of Metabolic Diseases and Gastroenterology, National Food and Nutrition Institute, Warsaw, Poland

Background and objectives: Irritable bowel syndrome (IBS) is one of the most common functional gastrointestinal disorders. Its pathogenesis is very complex and not fully understood. The objective of this study was to assess the relationship between the factors in the field of nutritional status and medical history and the IBS development.

Methods: The study involved 150 IBS patients and 50 control subjects. In all of them anthropometric measurements (weight, height and waist circumference) were recorded. Based on their results the BMI was calculated and abdominal obesity prevalence was assessed. Using questionnaire survey data on the prevalence of allergies in the past, allergy in the first-degree relatives, allergy, asthma and skin diseases present today were collected.

Results: We found that abdominal obesity, defined according to NCEP-ATP III criteria, significantly increased the IBS risk development [OR=3.01, 95% CI= [1.0; 9.1], p=0.05]. From another analyzed factors only skin diseases were significantly more common in IBS patients compared to those without the disease (p = 0.005). There was no significant relationship between nutritional status measured with BMI and the IBS prevalence.

Conclusions: Abdominal obesity defined according to the NCEP-ATP III criteria enhances the risk of IBS development. Increased incidence of skin diseases in IBS patients compared to the control group indicates that the autoimmune reactions can play role in the IBS pathogenesis.

Acknowledgements: Research supported by the Polish Ministry of Science and Higher Education; research project No. N404 052 31/2712.

Key words: IBS, risk factors, abdominal obesity.

PO2049**ASSOCIATION BETWEEN GRAIN CONSUMPTION AND SEVERITY OF NON-ALCOHOLIC FATTY LIVER DISEASE (NAFLD)**

M. Georgoulis¹, M. Kontogianni¹, N. Tileli¹, A. Margari^{ti}², M. Deutsch², D. Tiniakos³, E. Fragopoulou¹, R. Zafiro^{poulou}², Y. Manios¹, G. Papatheodoridis²

¹Department of Nutrition & Dietetics, Harokopio University, Athens, Greece

²Department of Internal Medicine, Medical School, National Kapodistrian University of Athens, Athens, Greece

³Laboratory of Histology & Embryology, Medical School, National Kapodistrian University of Athens, Athens, Greece

Background and objectives: There is evidence that long term dietary habits contribute to the presence and severity of NAFLD. The aim of the present study was to investigate the association between consumption of grains and the clinical and histological characteristics of patients with NAFLD.

Methods: Seventy-three NAFLD patients (inclusion criteria: steatosis on liver ultrasound and/or biopsy, elevated ALT and/or GGT, exclusion of other causes of liver injury) participated in the study. Consumption of grains (total, refined and whole grains) was estimated through a semi-quantitative food frequency questionnaire, while daily energy intake of the participants was estimated through three non-consecutive 24hour dietary recalls. Medical history, anthropometric indices, body composition analysis, physical activity data, biochemical parameters and inflammatory markers were available for all patients. Liver stiffness measurements by transient elastography was performed in 58 and liver biopsy in 34 patients.

Results: Consumption of refined grains was positively correlated to HOMA-IR index ($r=0.291$, $p=0.014$) and interleukin-6 levels ($r=0.254$, $p=0.033$), while it was negatively correlated to adiponectin levels ($r=-0.342$, $p=0.004$). In contrast, consumption of whole grains was negatively correlated to interleukin-6 levels ($r=-0.235$, $p=0.048$), while it was also associated with lower levels of HOMA-IR index (standardized beta coefficient= -0.294 , $p=0.006$) after adjusting for several potential confounders. No significant correlations were observed between consumption of grains and liver stiffness measurements or histological parameters. However, consumption of whole grains was associated with lower likelihood of non-alcoholic steatohepatitis (OR=0.858, 95%CI=0.739-0.996, $p=0.045$), after adjusting for sex and daily energy intake.

Conclusions: Our results support the detrimental effect of refined grain intake and the beneficial effect of whole grain intake on clinical characteristics of patients with NAFLD. Further research is required to clarify the role of grain intake in the development and progression of the disease.

Key words: Non-alcoholic fatty liver disease, dietary habits, refined grains, whole grains.

PO2050**EFFECT OF ORAL ADMINISTRATION OF DRY PURSLANE LEAVES ON ACUTE INTESTINAL INFLAMMATION INDUCED IN MICE**

H. Oduro-Obeng¹, B. Schwartz²

¹Nutrition and Socio-Economic Division, CSIR-Food Research Institute, Accra, Ghana

²Department of Nutritional Science, Hebrew University of Jerusalem, Rehovot, Israel

Background and objectives: Omega-3 polyunsaturated fatty acids have anti-inflammatory properties and can be beneficial in the treatment of inflammatory diseases, such as ulcerative colitis. The purpose of the current study was to investigate the ameliorative effect of purslane, an omega-3 rich vegetable in the preventive treatment therapy of experimental ulcerative colitis.

Methods: twenty-five C57BL/6J mice were randomly assigned to DSS-control group, high-dose purslane group (24%), medium-dose purslane group (8%), or low-dose purslane group (0.8%) receiving 3.5% dextran sulfate sodium (DSS) in their drinking water for eight days after ten days of receiving the intervention treatment as described above. A negative control group was also employed to received drinking water plus standard diet for the whole duration of the experiment.

Results: animals fed the different concentrations of purslane did not exhibit a statistically significant trend towards histopathological and clinical improvement after day 8 of DSS administration. There was no statistically significant difference observed between groups 8 days post-DSS. Also, no statistically significant decrease in neutrophil infiltration was observed, as depicted by myeloperoxidase activity. However, plasma fatty acid profile revealed a high concentration of DHA in the high dose group (24%) which was significantly different ($p<0.05$) from the two control groups but not from the other two intervention groups. ALA concentrations were not significantly different between all intervention groups.

Conclusions: our findings do not support a positive role of purslane leaves rich in the omega-3 fatty acids (ALA) supplementation in an experimental model of ulcerative colitis. Further studies are needed in order to investigate the combined role or effect of other compounds in purslane on the ulcerative colitis when given as a dietary supplement. Acknowledgements: The authors are grateful to the Pears Foundation of England for financial support.

Key words: Dextran sodium sulphate, colitis, mice, nutrition, fatty acid.

PO2051**THE PREVALENCE OF OBESITY AMONG FEMALE TEACHERS OF CHILD-BEARING AGE IN GHANA**

R. Pobe¹, W. Plahar¹, W. Owusu²

¹CSIR-Food Research Institute, Accra, Ghana

²Department of Nutrition and Food Science, University of Ghana, Accra, Ghana

Background and objectives: Obesity has become a public health problem in both developed and developing countries. In Ghana, the prevalence of obesity is high particularly among women. This rising trend of obesity is worrying as studies have shown an increased risk of morbidity, disability and mortality associated with it. This study examined the prevalence of obesity among Ghanaian teachers of child-bearing age.

Methods: A cross-sectional survey was conducted on 400 female teachers between the ages of 18-49 years from two sub-metropolitan areas in Accra District, Ghana. A questionnaire was used to gather information on the socioeconomic status, body mass index (BMI), waist-to-hip ratio (WHR), alcohol intake, physical activity and food intake. Correlations and chi-square test were used to determine association between the various variables and anthropometric indices while ANOVA was used for statistical differences between means.

Results: The mean age, BMI and WHR were 35.9 ± 8.2 years, 27.2 ± 5.3 kgm⁻² and 0.79 ± 0.07 respectively. About 34% of the women were overweight while 27% were obese with 17.8% centrally-obese. There was a strong positive correlation between BMI and WHR with age. The prevalence of obesity for a woman above 35 years was about four times higher than the prevalence among the younger age group (<25 years) and two times higher than that of the middle age group (26-35 years). This study found that at any age group underweight, overweight and obesity co-existed. Socioeconomic variables such as marital status, income and parity showed a positive association with BMI and waist circumference. Consumption of fruits and vegetables was low among respondents.

Conclusions: The prevalence of obesity was high among teachers of child bearing age. This study recommends healthy eating guidelines supported with vigorous physical activities established in schools to help teachers maintain healthy body weights and prevent its associated risk.

Key words: Obesity, prevalence, women, teachers, Ghana.

PO2052**EFFECTS OF SOY BAR OR OAT BRAN, ALONE OR ASSOCIATED, ON CHOLESTEROLEMIA AND OXIDATIVE STRESS IN DYSLIPIDEMIC SUBJECTS.**

C. Carreira¹, A. Pereira¹, C. Bortolasci¹, D. Barbosa¹, L. Lobato¹, T. Peixe¹, J. Mandarino¹, E. Lavado¹, R. Rodrigues¹, M. Grossmann¹

¹Universidade Estadual de Londrina, Londrina, Brazil

Background and objectives: Soy isoflavones have proven antioxidant activity as scavenger free radicals. Ingestion of 25 g/day soy protein can be considered an adjuvant treatment of dyslipidemia. Considering the lack of consensus regarding the consumption of soy as cereal bar, oat bran, or their combination in humans, the aim of this study was to evaluate the oxidative stress and lipid profile in dyslipidemic subjects after 45 days treatment with soy snack bar and oat bran.

Methods: Eighty-eight dyslipidemic individuals were assigned to 4 groups. Oat bran group ingested oat bran, soy snack bar group ingested 3 bars per day of soy, soy snack bar/oat bran group ingested 30 g of oat bran plus 3 bars, and control group ingested a hypocholesterolemic diet. Body mass index (BMI), lipid profile, antioxidant parameter (TRAP) and oxidative stress parameters were evaluated. The caloric values and chemical composition of oat bran and soy snack bar.

Results: Individuals of soy snack bar/oat bran showed a significant decrease in total cholesterol (CT) (-3.41%) and LDL cholesterol (LDL-C) (-6.66%) after 45 d. There was a significant increase in HDL cholesterol (10.0%) and a significant decrease in the levels of triglycerides (TG) (-8.68%) in the group that consumed the soy snack bars. CT showed a significant reduction between the groups soy snack bar/oat bran and soy snack bar after 45 d. Association group showed an improvement in antioxidant defenses in relation to all other groups. A significant decrease compared to the remaining nitric oxide (NOx) in the soy snack bar/oat bran after 45 d. And a significant decrease occurred in the group of soy snack bar/oat bran indices TRAP/FOX, TRAP/MDA and TRAP/NOx.

Key words: Soy, oxidative stress, lipid profile.

PO2053**NUTRITIONAL ASSESSMENT IN ONCOLOGICAL AND NON-ONCOLOGICAL HOSPITALIZED PATIENTS**

D V. Popova¹, B. Strahilova¹, V. Kamenova¹, D. Vundeva¹, N. Hadjipetrov¹, E. Dimitrova¹

¹Clinic of Metabolic Diseases and Dietetics, University Hospital Queen Giovanna-ISUL, Medical University of Sofia, Sofia, Bulgaria

Background and objectives: Hospitalized patients due to inadequate feeding are often at nutrition risk, causing increase of disease duration, complications, mortality rate and hospital expenses. The aim of this study was to perform a nutritional assessment in hospitalized patients.

Methods: A random group of 52 hospitalized patients was studied: 28 oncological (group A) and 24 non-oncological (group B) patients. The nutritional assessment by a special Nutrition Day Questionnaire and anthropometric measurements was performed.

Results: Our research established a normal body weight of 35.71% in group A and 8.33% in group B, underweight in 14.29% in group A and 8.33% in group B, overweight in 17.86% in group A and 33.34% in group B, obesity in 32.14% in group A and 50.0% in group B. Nutritional risk and need of nutritional support was found in 57.14% in group A and 16.67% in group B. There was a body weight reduction for the last three months in 53.57% in group A and in 20.83% in group B, and a decreased food intake for the last week in 50.0% in group A and in 33.34% in group B. Reduced appetite was reported in 35.7% in group A and in 33.34% in group B. At the end of the survey all patients were on a standard hospital diet and only 32.14% of group A and 8.33% of group B received nutritional support.

Conclusions: Nutritional risk in 38.5% and underweight in 11.54% of the hospitalized patients were found. The current hospital feeding is not corresponding to the nutritional needs in half of the hospitalized patients, and nutritional support was provided only in half of the risk patients. A nutritional assessment and therapy have to be made for all hospitalized patients.

Key words: Nutritional assessment, hospitalized patients, nutritional support.

PO2054**BLOOD LIPID PROFILES OF GHANAIAN SCHOOL-CHILDREN**

H. Nti¹, A. Lartey¹, G. Marquis²

¹Department of Nutrition and Food Science, University of Ghana, Legon, Accra, Ghana

²School of Dietetics and Human Nutrition, McGill University, Montréal, Canada

Background and objectives: Blood lipid profiles have been associated with cardiovascular risk factors and diseases. Data on lipid profiles of Ghanaian children are lacking. This study reports on the lipid profiles of Ghanaian schoolchildren between the ages of 9-15 years.

Methods: Fasting blood lipid profiles were determined in 802 children who participated in the nutritional assessment survey among schoolchildren. Finger-prick blood sample was used to determine total cholesterol, triglyceride, high density lipoprotein (HDL) and low density lipoprotein (LDL) cholesterol levels using the cardio-chek PA system analyzer.

Results: Mean blood lipid profiles for schoolchildren were 146.1±3.6 mg/dl for total cholesterol, 69.4±2.3 mg/dl for triglycerides, 52.8±1.5 mg/dl for HDL, 79.4±2.4 mg/dl for LDL and 3.0±0.1 for total cholesterol/HDL ratio. Using cut-offs for normal values of <200 mg/dl for total cholesterol, <150 mg/dl for triglycerides, >40 mg/dl for HDL cholesterol, <130 mg/dl for LDL cholesterol and <5 for total cholesterol/HDL ratio, the prevalence of children with abnormal values were 14% for high total cholesterol, 4% for high triglycerides, 28% for low HDL, 9% for high LDL and 4% for low total cholesterol/HDL ratio.

Conclusions: The majority of Ghanaian schoolchildren had normal lipid profiles. However, the substantial proportion with low HDL levels requires that interventions be put in place to improve physical activity and dietary habits of these children to reduce the risk of cardiovascular diseases in adult life.

Key words: lipid profiles, cholesterol, schoolchildren, Ghana.

PO2055**TOMATOES AS FUNCTIONAL FOOD: ANTI-INFLAMMATORY EFFECTS OF TOMATO KETCHUP AND IT'S MAIN MICRONUTRIENTS.**

M. Hazewindus¹, G R M M. Haenen¹, A R. Weseler¹, A. Bast¹

¹Department of Toxicology, Maastricht University, Maastricht, The Netherlands

Background and objectives: Persistent low grade inflammation is a common characteristic in the cardiometabolic syndrome. Fruit and vegetable consumption in general, but also tomato consumption in particular, have been found to mitigate this inflammatory process. We examined: firstly, if lycopene, vitamins C and E - in quantities as present in tomato and ketchup - reduce the formation of inflammatory biomarkers; secondly, if a combination of these compounds had synergistic effects; and thirdly, the effect of a single consumption of tomato ketchup on cytokine production in healthy volunteers.

Methods: In the first two studies, the anti-inflammatory properties of lycopene, vitamins C and E were studied in vitro using cultured human endothelial cells. In the third, placebo-controlled, study, six healthy male volunteers (aged 33 yrs-old, BMI 26 kg/m²) consumed a single serving of 200 grams of tomato ketchup, naturally containing ca. 30 mg lycopene, 190 mg vitamin C and 3 mg vitamin E. Six hours later, blood was collected from these volunteers. On a separate day, this procedure was repeated using a tomato-free test meal. The ability to adapt to an external inflammatory challenge (i.e. LPS) in these subjects was assessed with a functional bioassay for chemotaxis.

Results: In cultured endothelial cells, vitamins C and E significantly complemented the anti-inflammatory effect of lycopene to an increasing degree. In the ex vivo study, tomato ketchup reduced TNF- α production and a trend was observed for IL-8 inhibition, while tomato ketchup did not alter IL-10 release in blood from healthy volunteers upon addition of LPS ex vivo.

Conclusions: Tomato ketchup consists of a combination of components that have the potential to reduce chronic inflammation. These results strengthen the evidence of the potential protective role of tomatoes and tomato ketchup against cardiovascular diseases.

Key words: anti-inflammatory, tomato ketchup, lycopene.

PO2056**EFFECT OF TOMATO JUICE CONSUMPTION ON LIVER FATTY ACID PROFILE OF RATS WITH HIGH FAT DIET-INDUCED HEPATIC STEATOSIS**

G. Martin-Pozuelo¹, M. Santaella¹, V P. Gomez-Gomez¹, I. Navarro-Gonzalez¹, R. Gonzalez-Barrio¹, C. Peñafiel², F J. Garcia-Alonso¹, M J. Periago¹

¹Department of Food Science and Nutrition, Faculty of Veterinary, University of Murcia, Murcia, Spain

²Department of Pathological Anatomy, Faculty of Veterinary, University of Murcia, Murcia, Spain

Background and objectives: Nonalcoholic fatty liver disease (NAFLD) encompasses from simple steatosis (reversible and benign) to nonalcoholic steatohepatitis (NASH), cirrhosis and even liver failure or hepatocellular carcinoma. NAFLD is the most common liver disorder worldwide and it is associated with insulin resistance, dyslipidemia and metabolic syndrome. Several studies have shown that tomato could ameliorate the hepatic lipid metabolism dysfunction. Moreover, a recent study pointed out changes in fatty acid composition in mice with or without NAFLD. Taking into account all these data, we aimed to investigate whether tomato juice intake could modify the liver fatty acid profile in hepatic steatosis induced rats.

Methods: sixteen male Sprague Dawley rats were randomly divided into four groups according to the diet and beverage they received: standard diet and water (NA) or tomato juice (NL); and high fat diet and water (HA) or tomato juice (HL). After seven weeks, rats were sacrificed and liver samples were collected in order to carry out a histological examination and analyse the fatty acid profile by gas chromatography.

Results: In rats fed a high fat diet, histopathological examination revealed grade 2 hepatic steatosis, characterized by swelling of hepatocytes and fat accumulation. With regard to the liver lipid profile, the monounsaturated fatty acid content was 3-fold higher in HL and HA groups, compared to NA and NL. The amount of polyunsaturated fatty acid was 6-fold lower in HL and HA groups, while no differences were found for saturated fatty acids. Statistical analyses showed differences upon high fat diet intake but not upon tomato juice consumption.

Conclusions: The differences observed in the fatty acid profile are attributable to fat intake and not due to tomato juice consumption.

Key words: Tomato, fatty acid, liver, NAFLD, gas chromatography.

PO2057**ELEVATED LEVELS OF FERRITIN, TBARS AND EXPRESSION OF HEPCIDIN ARE RISK FACTOR FOR TYPE 2 DIABETES DEVELOPMENT***M. Andrews¹, M. Arredondo¹*

¹Micronutrients Laboratory, Institute of Nutrition and Food Technology, University of Chile, Santiago, Chile

Background and objectives: Obesity and type 2 diabetes mellitus share a strong pro-inflammatory profile. It has been observed that iron is a risk factor in the development of type 2 diabetes. The aim of this study was to evaluate the relationship between iron nutritional status and inflammation with the risk of type 2 diabetes development.

Methods: We studied 30 obese men with type 2 diabetes (OBDM); 30 obese subjects without diabetes (OB), and 30 healthy subjects (Cn). We isolated peripheral mononuclear cells (PMCs) and challenged them with high Fe concentrations. Total mRNA was isolated and relative abundance of TNF- α , IL-6 and hepcidin were determined by qPCR. Iron status, biochemical, inflammatory and oxidative stress parameters were also characterized.

Results: OBDM and OB patients showed increased hsCRP levels compared to Cn group (in mg/L, 4.1 vs 3.0 and 1.1, respectively, $p < 0.01$). OBDM subjects showed higher ferritin levels than Cn group (in $\mu\text{g/L}$, 95.5 vs 42.8, $p < 0.01$). TNF- α and IL-6 mRNA relative abundances increased in OBDM treated with high/Fe ($p < 0.0001$). Hpcidin mRNA increased in OB and OBDM with basal and high iron concentration ($p < 0.0001$). We found that the highest quartile of ferritin was associated with an increased risk of type 2 diabetes when it was adjusted to BMI (OR=2.04 CI=5.37-9.17; $p < 0.001$) and HOMA-IR (OR=1.19 CI 1.02-1.22; $p < 0.014$). This association was independent of the inflammatory status. The highest level of hepcidin gene expression also showed a trend of increased risk of diabetes (OR=4.54 CI 1.95-21.66; $p < 0.05$). Levels of hsCRP over 2 mg/L showed a significant trend of increasing the risk of diabetes.

Conclusions: Iron may stimulate the expression of pro-inflammatory genes (TNF- α and IL-6), and both hepcidin gene expression and ferritin levels could be a risk factor for the development of type 2 diabetes.

Key words: Hpcidin, ferritin, diabetes risk, inflammation.

PO2058**SUBJECTIVE PATIENTS' ASSESSMENT OF QUALITY OF FEEDING PRACTICE IN SELECTED POLISH HOSPITALS***W. Lysiak-Szydłowska¹, M. Janczuk²*

¹Faculty of Health Sciences, Powianski College, Kwidzyn, Poland

²St. Adalbert Hospital, Gdansk, Poland

Background and objectives: Hospital diet and feeding practice deeply effects patients well-being. The aim of the project was to study patients' opinion on quality of nutritional service in hospitals.

Methods: Meals were provided as a catering or in-house cooking. 448 patients in various hospitals of the Pomerania Voievodship (Poland) were engaged. Research was done on the basis of the anonymous questionnaire, which included questions on demographic data, the quantity and quality of the hospital nutrition, dietetic supplements of hospital meals; also specificity of the hospital ward were taken into account.

Results: Data pointed out that patients preferred meals prepared by in-house kitchen as opposed to catering. The taste, temperature and consistency as well as quantity of catering meals were assessed negatively; only 34% positive versus 69% positive for in-house cooking. It was not possible to take into account patients' food preferences in any of the hospital under investigations. Regardless of the specificity of the ward, the patients received enrichment by hospital diet to a small extent (6% of patients). The most common supplementation was the supply of physiological fluid infusion. The study also pointed out to insufficient drinking fluids (mineral water, tea, juice) supplied at treatment wards. The study revealed that in the surveyed hospitals, patients were not receiving meals, as recommended, before and after therapeutic procedure (diagnostic or surgery), and nutritional supplementation was rarely provided. The role of nutrition in prevention of hospital malnutrition is still underestimated.

Key words: Quality, hospital nutrition, subjective assessment.

PO2059**ASSOCIATION OF FOOD GROUPS CONSUMPTION WITH CENTRAL OBESITY AMONG IRANIAN WOMEN***A. Rezazadeh^{1,2}, N. Omidvar¹, B. Rashidkhani¹*

¹Community Nutrition Department, Faculty of Nutrition and Food Technology, Shahid Beheshti University of Medical Sciences and Health Services, Tehran, Iran

²Students Research Committee, Shahid Beheshti University of Medical Sciences and Health Services, Tehran, Iran

Background and objectives: Central obesity (enlarged waist circumference) is one of the metabolic syndrome's risk factors. The prevalence of central adiposity has increased precipitously in Iran, especially in women. Evidences suggest a prominent role of dietary intake habits in increasing or decreasing the risk of central obesity. The aim of this study was to define association of food group consumption with central obesity among Iranian women.

Methods: In this cross-sectional study, 460 women aged 20-50 years were selected by stratified random sampling in Tehran. Dietary intakes were characterized using validated 168 items semi-quantitative food frequency questionnaires. Food items were categorized in to 25 food groups based on similarity of nutrient profiles. Weight, height and waist circumference (WC) were measured with standard methods. Central obesity was defined as WC \geq 88 cm. Multivariate logistic regression was used to estimate odds ratio (OR) and 95% confidence intervals (CI).

Results: The mean of participants' WC was 84.7 \pm 8.5 cm and 171 (38.8%) subjects were centrally obese. After adjusting for confounders (age, smoking, physical activity and energy intake), being in the highest quartile category of consumption of poultries (OR: 0.29, 95% CI: 0.15-0.56), low fat dairies (OR: 0.32, 95% CI: 0.16-0.63), fruit and vegetables (OR: 0.52, 95% CI: 0.29-0.94), nuts (OR: 0.83, 95% CI: 0.49-0.93), and olive (OR: 0.54, 95% CI: 0.30-0.96) was significantly associated with reduced risk of being centrally obese. In contrast, being in the highest quartile of consumption of processed meat (OR: 2.04, 95% CI: 1.10-3.76), visceral meat (OR: 1.89, 95% CI: 1.3-3.48), high fat dairies (OR: 2.14, 95% CI 1.19-3.86), solid oil (OR: 2.58, 95% CI: 1.36-4.87), beverages (OR: 2.20, 95% CI: 1.20-4.08), refined grains (OR: 3.31, 95% CI: 1.76-6.24) was significantly associated with reduced risk, compared to the lowest quartile (p-trend: p<0.01). Other food groups (red meat, fish, eggs, artificial juices, legumes, garlic, potato, whole grains, snacks, sweets, pickles, liquid oil, tea and coffee) were not significantly related with central obesity.

Conclusions: Our findings suggest higher consumption of healthier food groups (fruit, vegetables, poultries, low fat

dairies, nuts, olive) may have a protective effect against central obesity in the studied women. However, unhealthy groups (processed meat, visceral meat, high fat dairies, solid oil, beverages and refined grains) may increase the risk.

Key words: Food group, central obesity, women, Iran.

PO2060**THE ASSOCIATION OF DIETARY LIPID PROFILE WITH HAVING HISTORY OF HYPERLIPIDEMIA IN IRANIAN WOMEN***A. Rezazadeh^{1,2}, N. Omidvar¹, B. Rashidkhani¹, A. Rezazadeh³*

¹Department of Community Nutrition, Faculty of Nutrition and Food Technology, Shahid Beheshti University of Medical Sciences, Tehran, Iran

²Students Research Committee, Shahid Beheshti University of Medical Sciences and Health Services, Tehran, Iran

³Agriculture Department, Chalous Azad University, Chalous, Iran

Background and objectives: Recent researches suggest that saturated fatty acid (SFA) intake increases hyperlipidemia and hypercholesterolemia risk; however, diets high in unsaturated fatty acids (UFAs) and reduced SFAs can prevent the risk of them. The aim of this study was to investigate the associations between intake of SFAs, monounsaturated fatty acids (MUFAs), polyunsaturated fatty acids (PUFAs) and hyperlipidemia in women living in Tehran.

Methods: In a cross-sectional study 460 women aged 20-50 y, living in Tehran, were selected by stratified random sampling method. Dietary intake was collected by a semi-quantitative questionnaire. Participants were asked about having history of hyperlipidemia that was defined by a doctor. Nutrient profiles were determined by N4 software. The association between having history of hyperlipidemia with dietary intake of SFAs, MUFAs and PUFAs was assessed by multivariate adjusted logistic regression.

Results: The mean \pm SD age of participants was 33.5 \pm 9.7 y, 24.2% of subjects had history of hyperlipidemia. The mean daily intake of total fat, SFA, MUFA and PUFA and cholesterol was 88.5 \pm 45.1 g/day, 35.4 \pm 16.9 g/day, 37.9 \pm 22.6 g/day, 27.5 \pm 23.3 g/day and 246.7 \pm 116.9 mg/day, respectively. After adjusting for confounders (age, energy intake, physical activity, body mass index and waist circumference), the odds of hyperlipidemia increased in individuals in the highest quartile of dietary total fat (OR: 6.4, 95% CI: 1.8-21.6), SFA (OR: 8.3, 95% CI: 2.2-30.4) and cholesterol (OR: 1.4, 95% CI: 1.1-3.4) consumption. Inversely, being in the highest quartile of dietary PUFA

was significantly associated with reduced hyperlipidemia risk (OR: 0.63, 95% CI: 0.43-0.65); also, being in the highest quartile of dietary PUFAs/SFAs ratio reduced the hyperlipidemia risk (OR: 0.42, 95% CI: 0.19-0.91) [p-trend<0.05]. Dietary MUFA, MUFAs/SFAs ratio, UFAs (PUFAs+MUFAs)/SFAs ratio were not associated with having history of hyperlipidemia.

Conclusions: Our findings suggest that having history of hyperlipidemia was associated with greater consumption of dietary total fat, SFAs and cholesterol in studied women. However, higher consumption of dietary PUFAs and higher PUFAs/SFAs ratio decreased the hyperlipidemia risk.

Key words: Dietary profile, history of hyperlipidemia, women, Iran.

PO2061

ROLE OF ANTIOXIDANTS IN THE TREATMENT OF MULTIPLE SCLEROSIS

P. Nieto¹, J. Serrano-Diaz^{2,3}, M.A. Murcia³, M. Carmona², G. Alonso², M. Martinez-Tome³

¹Department of Pharmacy, Torrecardenas Hospital, Almeria, Spain

²Cátedra de Química Agrícola, UCLM, Albacete, Spain

³Department of Food Science, Murcia University, Murcia, Spain

Background and objectives: Multiple sclerosis (MS) is an inflammatory demyelinating disease of the central nervous system (CNS). T lymphocytes and macrophages attack cells of the CNS, releasing large amounts of reactive oxygen and reactive nitrogen species. This stress contributes to neuroinflammation, demyelination and disease progression.

Methods: A literature review of antioxidant role in the MS treatment was conducted.

Results: Endogenous antioxidants: In patients with MS, there is a loss of reduced glutathione, leading to a reduction in the activity of glutathione peroxidase. Superoxide dismutase (SOD) converted superoxide into hydrogen peroxide, a less damaging free radical. Reduction of the SOD activity was found in erythrocytes of patients with MS. The quinone oxidoreductase-1 was strongly upregulated in astrocytes of active MS lesions, trying to counteract the adverse effects. Lipoic acid. Its antioxidant action is exerted through several mechanisms. Effective in MS in animal models has been proven. Exogenous antioxidants: Supplementation with 6 g of omega-3/day for 6 months in MS patients and healthy controls decreased the secretion of proinflammatory cytokines, IL-1b, TNF-alpha, IL-2, IFN-gamma, which are elevated in patients with EM. Antioxidant vitamins (α -tocopherol, β -carotene, retinol, and ascorbic acid) were reduced in the serum of MS patients during an out-

break. It may be by the increased oxidative stress due to products of lipid peroxidation. Regarding vitamin D, the prevalence of MS is lower when the consumption of oily fish is higher. Sudden decreases in serum levels of 25 (OH) D were associated with the occurrence of new outbreaks. Saffron reduced the symptoms of autoimmune encephalomyelitis, by preventing oxidative stress and leukocyte migration to the CNS.

Conclusions: Clinical trials which determine radiological and immunological parameters are necessary to confirm the benefit of antioxidants in the development and progression of MS. Acknowledgements: Funded by JCCM-FEDER (POIC10-0195-984).

Key words: Multiple sclerosis, antioxidants, saffron.

PO2062

ARGININE, GLUTAMIN AND β -HIDROXY- β -METHYLBUTIRATE ADDED TO BROCHOPLEURO-CUTANEOUS FISTULA TREATMENT

R. Guida¹, L. Otero Vidal¹

¹Intensive Respiratory Care Unit, Hospital del Tórax 'Dr. Antonio A. Cetrángolo', Vicente Lopez, Buenos Aires, Argentina

Background and objectives: The addition of arginine, glutamin and β -hidroxy- β -methylbutirate has demonstrated benefit in eschars, burns and diabetic foot treatment; a great deal of research is reported in medical literature. The aim of this study was to investigate whether this product might be useful in the treatment of brochopleurocutaneous fistula.

Methods: Male patient, 16 years old, diagnosed with polytrauma, closed chest trauma and hemopneumothorax. During outcome subject had septic shock, respiratory distress and high output right brochopleurocutaneous fistula with lung abscess and empiema. After 40 days, patient was referred to Hospital Cetrángolo. He was admitted with severe protein-caloric malnutrition and 23% of normal weight loss (Body Mass Index: 14.6 kg/m²) at lean body mass and fat body mass expense (Percentile 3 for both assessments). The thoracic wall wound measured 21 cm length, 8.5 cm width and 5.5 cm depth. Continuous enteral feeding was administered with specialized formulation for metabolic stress according to patient requirements (2300 ml/2900 kcal) during 15 days, transition was done to a high protein - fiber fortified formulation (2400 ml/2900 kcal) during 35 days until optimal oral intake was reached. From seventh day of enteral feeding, 48 g of specialized formulation were added containing 14 g of arginine, 14 g of glutamin and 2.4 g of β -hidroxy- β -methylbutirate administered by mouth during 6 months.

Results: Subject had good outcome with 27% weight gain (Body Mass Index: 18.6 kg/m²), fat body mass and lean body

mass recovery (Percentile 10 for both assessments), biochemical parameters normalization, septic focus resolution, thoracic wall wound measure significant decreased (7.4 cm length, 2.8 cm width and 1.5 cm depth) with wound edges granulation.

Conclusions: The supplemental arginine, glutamine and β -hydroxy- β -methylbutyrate shown effectiveness in the bronchopleurocutaneous fistula treatment also contributing to nutritional status recovery.

Key words: Bronchopleurocutaneous fistula, arginine, glutamine.

PO2063

BODY COMPOSITION, CENTRAL ADIPOSITY, BIOCHEMICAL INDICATORS AND BLOOD PRESSURE IN CUBAN ADOLESCENTS

ME. Diaz-Sanchez¹, V. Ruiz-Alvarez¹, L. Rodriguez-Dominguez², M. Montero-Diaz³, M. Hernandez-Triana¹, H. Hernandez-Hernandez¹, V. Moreno-Lopez¹, C. Arocha-Oriol¹, M. Diaz-Dominguez¹, D. Santana-Jardon¹, Y. Diaz-Fuentes¹

¹Instituto de Nutrición e Higiene de Los Alimentos, La Habana, Cuba

²Ministerio de Salud Pública, La Habana, Cuba

³Instituto de Cibernética, Matemática y Física, La Habana, Cuba

Background and objectives: Nutritional status is a physical condition related to a broad spectrum of chronic diseases. Total body fat and central adiposity are determinants for identifying metabolic complications of obesity; BMI probably is not the best alternative. The aim of this study was to explore associations between body size and composition, biochemical indicators and blood pressure in adolescents according to biological maturation.

Methods: In 690 adolescents (12-15 years old), weight, height, skinfolds, and circumferences were recorded; BMI, body fat content and distribution according to sexual maturation stage were calculated. Blood pressure, serum triglycerides, total cholesterol, HDL-C, LDL-C, VLDL-C and glucose were measured. Univariate and multivariate analysis were used to describe and compare the nutritional status categories with different anthropometric and biochemical indicators.

Results: Body dimension and composition by sex and maturation stage were different. Underweight prevalence was low and 23,3% of global overweight (overweight-obesity) was recorded. Biochemical indicators were not different between boys and girls; only triglycerides and VLDL were different by maturation stages within sex. Anthropometric measures, body fat and blood pressure increased parallel to BMI increase; nevertheless, more than 30% of adolescents showed excessive

body fat and 7% central adiposity at risk levels, in spite of normal BMI. Stepwise Discriminant Analysis evidenced that total body fat and waist circumference in boys, and total body fat, waist and abdominal circumferences in girls, were the main indicators which described their nutritional status.

Conclusions: Total body fat and trunk circumferences are helpful indicators of the adolescent nutritional status, including maturation stages. Metabolic risk was not identified in this group.

Key words: Body composition, central adiposity.

PO2064

COMPARATIVE STUDY OF CHILDHOOD OBESITY IN CHILDREN (6-12YEARS) LIVING IN THE RURAL AND URBAN COMMUNITIES OF ENUGU STATE, NIGERIA

¹Department of Nutrition and Dietetics, Imo State University Owerri, Imo State, Nigeria

²Department of Home Science, Nutrition and Dietetics, University of Nigeria Nsukka, Enugu State, Nigeria

Background and objectives: Childhood obesity is currently an escalating epidemic that affects many countries in the world. In Nigeria, obesity is not only negatively affecting adults, it affects the younger generation as well. Children are becoming obese at an alarming rate. This study aims at assessing the prevalence of childhood obesity in children (6-12years) living in rural and urban communities of Enugu state, Nigeria.

Methods: A multistage random sampling technique was used in selecting 2000 children used in this study, (1000 each from the rural and urban areas). A structured questionnaire was used to collect information on parents socio demographic status, physical activity pattern of the family, and anthropometric indices of the respondents (using standard methods). Physical exercise was carried out on a sub sample of the obese children. Data was analyzed using anthropometric z scores and categorized using WHO anthro software (2007). Comparison was done using chi square test for categorized variables.

Results: The z scores of all the anthropometric indicators were significantly higher ($p < 0.05$) for children in the urban than in the rural. More of the male children in the urban location were obese (70.9%) and overweight (50.4%) while only one female child in the rural area was found obese. Possible risk of getting obese were highest(46.2%) with children whose mothers monthly income was above N46,000 while those whose mothers monthly income was below N7,500 had the least prevalence (12.8%). The total time spent on exercise contributed positively to 6% ($R = 0.06$) of the variation in weight loss.

Conclusions: Maternal monthly income of less than N7,500, physical exercise and healthy eating habit were negatively related to childhood obesity while location, sedentary lifestyle, higher consumption of macronutrient rich foods were contributory factors in determining childhood obesity.

Key words: Childhood obesity, urban and rural, epidemic, overweight.

PO2065

LOWER ASPARTATE AMINOTRANSFERASE TO ALANINE AMINOTRANSFERASE RATIO IS ASSOCIATED WITH CARDIOMETABOLIC RISK MARKERS IN OVERWEIGHT AND OBESE CHILDREN

I. Labayen¹, N K. Pollock², J D. Allison³, B A. Gower⁴, H. Zhu², R. Bassali², C. Davis²

²Pediatrics, Medical College of Georgia, Augusta, GA, USA

³Radiology, Medical College of Georgia, Augusta, GA, USA

⁴University of Alabama, Birmingham, AL, USA

Background and objectives: More children are obese, exposing them to higher cardiometabolic risk. The study examined the relationships between liver biomarkers and cardiometabolic risk in overweight children.

Methods: Cross-sectional study in 222 overweight children (aged 7-11 years, 56% female, 58% black, 86% obese). Liver biomarkers included serum C-reactive protein (CRP), aspartate aminotransferase (AST) and alanine aminotransferase (ALT) levels, and the AST/ALT ratio was computed. Cardiometabolic risk markers included total body fat percentage (dual X-ray absorptiometry), visceral and subcutaneous abdominal adipose tissue (magnetic resonance imaging), fasting glucose and insulin, Matsuda index and insulinogenic index (2-hour oral glucose tolerance test), triglycerides (TG), high-density lipoprotein (HDL) and systolic blood pressure (SBP).

Results: Regardless of race or sex, AST/ALT decreased with the number of metabolic abnormalities and with higher adiposity, visceral and subcutaneous fat, Matsuda index, TG, TG/HDL ratio, SBP, and with lower HDL. The associations between lower AST/ALT and higher insulin, insulinogenic index and SBP were independent of total, subcutaneous and visceral adiposity ($r=-.16$ to $-.22$). ALT and CRP increased with the number of metabolic abnormalities. Higher ALT was significantly associated with greater body fat in boys ($r=.22$) and, independently of body fat, with higher insulin in whites and boys

($r=.22$ to $.26$), and with higher TG in blacks ($r = .18$ to $.20$). CRP was not associated with any marker of cardiometabolic risk after controlling for adiposity.

Conclusions: Lower AST/ALT was strongly and consistently associated with markers of cardiometabolic risk in overweight children, independent of sex, race, and adiposity. These findings suggest that the AST/ALT ratio should be evaluated further as a potential screening tool in children at risk for diabetes and cardiovascular disease. ⁵Departamento de Medicina Familiar, Universidad de la Republica, Montivideo, Uruguay

⁶Secretaria de Salud de Marcos Paz, Marcos Paz, Argentina

Background and objectives: Metabolic syndrome (MS) is characterized by a clustering of metabolic risk factors, including central obesity, glucose intolerance, hypertension, and atherogenic dyslipidemia, contributing to type 2 diabetes (DM2) and cardiovascular disease (CVD). Since the Southern Cone of Latin America (SCLA), a region completing nutritional transition, is undergoing large changes in lifestyle, epidemiological studies are needed. We aimed to estimate the prevalence and distribution of MS in a general adult population of the SCLA.

Methods: We conducted a population-based cross-sectional study on a multistage-probabilistic sample of 8,000 subjects aged 35-74 years old from four cities of Argentina (Bariloche and Marcos Paz (MP)), Chile (Temuco), and Uruguay (Canelones). MS was defined following NCEPATP III criteria that specifies ≥ 3 of: waist circumference ≥ 102 cm (men) or ≥ 88 cm (women); elevated triglyceride (≥ 150 mg/dl) or specific

treatment for dyslipidemia; reduced HDL-cholesterol of <40 mg/dl (men) or <50 mg/dl (women) or specific treatment, and elevated systolic BP (\geq 130 mm Hg) or diastolic BP (\geq 85 mm Hg) or antihypertensive treatment; and fasting plasma glucose \geq 100 mg/dl or self-reported diabetes.

Results: Of the adult population aged 35-74 yrs, 40.6 % (39.6% in men and 41.9% in women) had MS (MP: 42,7%; Bariloche: 38,3%; Temuco: 44,3%; and Canelones: 38,6). Age-specific prevalence of MS was 28.2 %, 40.9%, 50.6 %, and 55.3% among persons of 35-44, 45-54, 55-64 and 65-74 years of age, respectively.

Conclusions: We found a high prevalence of MS across the SCLA that showed little variation among sites, increased directly with age and inversely with level of education. These findings emphasize the urgent need to develop public health strategies for prevention and treatment of MS, to reduce the burden of CVD and DM2 in the SCLA.

Key words: Metabolic syndrome, prevalence, Latin America.

PO2067

EFFECTS OF RICE BRAN OIL AND PERILLA OIL ON DMH/DSS-INDUCED COLON CARCINOGENESIS IN RATS

P.C. Chen¹, S.C. Li¹, C.K. Shih¹

¹School of Nutrition and Health Sciences, Taipei Medical University, Taipei, Taiwan

Background and objectives: Colon cancer is the third most common cause of cancer death in Taiwan. Dietary n-3 and n-6 fatty acids play important roles in inflammation-associated colon carcinogenesis. Perilla oil is a good source of n-3 fatty acids and rice bran oil has an anti-tumor activity. The purpose of this study was to investigate the effect of varying ratios of dietary n-6 and n-3 fatty acids on colon carcinogenesis using a chemically induced animal model.

Methods: Male Sprague-Dawley rats were fed a modified AIN-93G 14% high-fat diet: groups HF and DHF, 14% soybean oil; group D10, 14% perilla oil and rice bran oil with modified n-6 and n-3 ratio of 10; group D2.5, 14% perilla oil and rice bran oil with modified n-6 and n-3 ratio of 2.5. All rats except for group HF were induced colitis-associated colon carcinogenesis by 1,2-dimethylhydrazine (DMH)/dextran sodium sulfate (DSS). The severity of colitis was assessed using disease activity index (DAI). After 87 days, rats were sacrificed and colon tissues were removed to examine for preneoplastic aberrant crypt foci (ACF) and aberrant crypts (AC). Glutathione (GSH) levels were measured in colon and liver tissues.

Results: The DAI score of groups D10 and D2.5 were significantly lower than that of group DHF. Group D2.5 and D10 had significantly lower numbers of colonic ACF and AC than

did group DHF. For antioxidant capacity, groups D2.5 and D10 had significantly higher colonic GSH levels than did group DHF. Moreover, group D2.5 had significantly higher hepatic GSH level than did groups DHF and D10.

Conclusions: These findings suggest that the combination of perilla oil and rice bran oil in diet with modified n-6 and n-3 ratio of 2.5 may delay colon carcinogenesis via anti-inflammatory and anti-oxidative mechanisms.

Key words: Colon cancer, rice bran oil, perilla oil.

⁴Institut Català pel Tractament i Recerca de l'Obesitat, Barcelona, Spain

Background and objectives: Currently, it is observed that young population has a high prevalence of metabolic conditions. One of these is the cardiometabolic syndrome (CMS), which has become the prelude to type 2 diabetes, coronary artery disease and stroke, by arteriosclerosis, being the leading cause of death in our country, and increasing the disease burden for health sector in forthcoming years. We aimed to determine the prevalence of cardiometabolic syndrome in young adults.

Methods: The following procedures were performed: Anthropometric measures, presence of Acanthosis Nigricans (AN), blood pressure, biochemical markers, and lifestyle assessment. CMS was diagnosed according to the FID.

Results: Study included 200 subjects (75.5% female and 24.5% male) average age 30.47 ± 10.92 years old. 25% of the population had SCM, 80.9% abdominal obesity, 35.5% AN; there were increases in systolic blood pressure 4.0%, diastolic blood pressure 6.1%, Total cholesterol 35.7%, triglycerides 52.8%; low HDL cholesterol 43.7%, mild physical activity 58.5% and 21.4% consume soft drinks in a daily basis.

Conclusions: Interventions are needed in lifestyle to stop the increasing incidence of SCM in young people, to prevent impairment of life quality and life expectancy.

Key words: Risk Factors, cardiometabolic syndrome, obesity.

ORAL TREATMENT WITH GABA IMPROVES THE SPLEEN AND PBMC IMMUNE DISTURBANCE IN OBESE MICE

Y. Shi^{1,2}, Y. Ma², B. Wang², G. Le^{1,2}, X. Tang^{1,2}, J. Sun^{1,2}

¹The State Key Laboratory of Food Science and Technology, JiangNan University, Wuxi, China

²Institute of Food Nutrition and Functional Factor, School of Food Science and Technology, JiangNan University, Wuxi, China

Background and objectives: Tregs are potent inhibitors of insulin resistance and chronic inflammation in long-term HFD-induced obesity and T2DM model. Four weeks of oral treatment with GABA gave rise to significant increase of Tregs in spleen, but just short-term of intervention could not compensate the self-defence of the immune system throughly. The aim of our research was to determine whether there was any disturbance in T regulatory cell number and function when we employed the long-term HFD-induced obesity and T2DM model and treated orally with GABA.

Methods: All C57BL/6 male mice were divided into four groups: control group was fed with normal diet, high fat group was fed with high fat diet (containing 20% lard oil) (HFD), two GABA groups were fed with HFD and water containing 2 mg/mL and 0.6 mg/mL GABA, respectively. The percentage of Treg cells and CD4+/CD8+ ratio in spleen and PBMC were evaluated. Each type of cell was separated for real-time RT-PCR analysis.

Results: After 20 weeks of HFD treatment, mice gained significant body weight ($P < 0.01$). Tregs in spleen and PBMC were significantly decreased in HFD mice ($P < 0.05$), while GABA significantly increased it in both spleen and PBMC ($P < 0.05$). HFD significantly decreased CD4+/CD8+ ratio ($P < 0.05$) which was reversed by GABA to controls level. Mice weight negatively correlated to the frequency of Tregs both in spleen and PBMC. Several genes that were crucial for Treg structure, function and survival including OX-40, 4-1BB, SOCS2, fas were abnormally expressed in high fat food fed mice ($P < 0.05$). GABA significantly inhibited disorder of these gene expression ($P < 0.05$).

Conclusions: GABA improved the long-term HFD-induced immune disturbance.

Key words: Treg, GABA, CD4+/CD8+, immune disturbance.

RESVERATROL REVERSED THYROID HORMONES AND LIPID METABOLISM DISORDER INDUCED BY HIGH-FAT DIET: POSSIBLE ROLES FOR GSK-3 β AND NRF2

Y. Shi^{1,2}, L. Li², G. Le^{1,2}, Zheng. J², X. Cheng^{1,2}

¹The State Key Laboratory of Food Science and Technology, JiangNan University, Wuxi, China

²Institute of Food Nutrition and Functional Factor, School of Food Science and Technology, JiangNan University, Wuxi, China

Background and objectives: The mechanisms by which resveratrol exerts its antioxidative effects on thyroid hormones (TH) and lipid metabolism are not completely understood. Oxidant injury and TH can both activate the PI3K and Akt. GSK3 β , a downstream of PI3K/Akt pathway, is a negative regulator of Nrf2 activity. The research tries to clarify the effect of high-fat diet (HFD) with or without resveratrol on TH and lipid metabolism at different periods, and the potential mechanisms related with GSK3 β -Nrf2 pathway.

Methods: C57BL/6 female mice were fed control, HFD and HFD plus 0.06% resveratrol, and then they were sacrificed and studied at the end of 1st, 3rd, 6th, 13th and 26th week respectively.

Results: HFD induced TH disorder in plasma, which characterized by significant elevation of plasma T3 and T4 from the 3rd to 13th week and decline at the 26th week, plasma TSH was significantly increased from 1st to 26th week together with type 1 deiodinase activity in liver decreased at 26th week in HFD group. Furthermore, the expression of GSK3 β was significantly reduced by HFD at the 6th week, but up-regulated at the 26th week. The mRNA expression of Nrf2 and its target genes were significantly higher in HFD group than those in control group. The balance of redox state in liver was disrupted by HFD at the end of 3rd week, lipid profiles were significantly elevated at the 26th week in HFD-fed mice. Resveratrol significantly relieved TH disorder and oxidative stress, down-regulated GSK3 β and Nrf2 and recovered dyslipidemia.

Conclusions: Resveratrol significantly reversed TH level, which could induce GSK3 β -Nrf2 pathway by activating PI3K, and this might be one mechanism of recovering dyslipidemia.

Key words: High-fat diet resveratrol thyroid hormone GSK3 β , Nrf2.

PO2071**GAMMA-LINOLENIC ACID IMPROVES PALMITATE-INDUCED INSULIN RESISTANCE IN C2C12 SKELETAL MUSCLE CELLS VIA AMPK/AS160 PATHWAY***P.Y. Chen¹, T.C. Liu¹, K.L. Liu¹*¹School of Nutrition, Chung Shan Medical University, Taichung, Taiwan

Background and objectives: It is well documented that lipid oversupply to skeletal muscle is related to the development of insulin resistance. In this study, we explored the effect of gamma-linolenic acid (GLA), an n-6 polyunsaturated fatty acid, on palmitate (PA) induced insulin resistance in C2C12 skeletal muscle cells.

Results: In presence of insulin, 750 μ M PA could decrease glucose uptake via down-regulation of phosphorylation of AMP-activated protein kinase (AMPK), AKT, AS160, and glucose transporter 4 (GLUT4) translocation in C2C12 skeletal muscle cells. Addition of 100 μ M GLA improved the PA-induced decrease of phosphorylation of AMPK, AKT and AS160 as well as GLUT4 translocation and glucose uptake stimulated by insulin. In skeletal muscle, AMPK plays a critical role in glucose metabolism. Reduction of AMPK expression using lentiviruses infection significantly decreased the ameliorative effects of GLA against PA-induced insulin resistance in C2C12 skeletal muscle cells.

Conclusions: In summary, our data suggested that GLA through AMPK/AS160 pathway diminished PA-induced insulin resistance in C2C12 skeletal muscle cell.

Key words: Gamma-linolenic acid, insulin resistance, AMPK, AS160.

PO2072**DIETARY GERANYLGERANIOL ALLEVIATES ATOPIC DERMATITIS IN NC/NGA MICE***N. Watanabe¹, M. Nagao¹, Y. Aoki²*¹Showa Women's University, Tokyo, Japan²Eisai Food, Chemical Co., Ltd, Tokyo, Japan

Background and objectives: Geranylgeraniol (GGOH) is the alcohol form of the side chain of Vitamin K1. GGOH has been shown to decrease NF κ B expression and suppress inflammation. NF κ B expression is one of the most important factors associated with the onset of atopic dermatitis. Therefore, dietary GGOH is expected to alleviate atopic dermatitis. In this study, our objective was to validate the effect of GGOH on atopic dermatitis.

Methods: Five week-old male NC/Nga mice were assigned to one of 4 dietary groups as follows: (1) Control diet, (2)

Control diet with picryl chloride swabbing on the dorsal skin, (3) 0.05% GGOH diet with picryl chloride swabbing, and (4) 0.5% GGOH diet with picryl chloride swabbing. The diets were designed according to the AIN-93G compositions and were provided to the mice ad libitum. The condition of the dorsal skin was monitored throughout the experimental period. The animals were dissected after 6 weeks, and then the livers, white adipose tissue, and spleens were weighed. The plasma levels of IgE, INF- γ , and IL-4 were also determined. Cross sections of the dorsal skin were stained with HE and then observed under a light microscope.

Results: Inflammation in the dorsal skin was significantly reduced in the 0.5% GGOH group than in the other 2 swabbed groups. Dietary GGOH suppressed atopic dermatitis-induced hyperplasia of the epidermis. Moreover, plasma levels of IgE as well as spleen weight were lower in the 0.5% GGOH group than in the other 2 swabbed groups.

Conclusions: Dietary GGOH appears to alleviate atopic dermatitis, and this beneficial effect might be exerted via the suppression of NF κ B.

Key words: atopic dermatitis, geranylgeraniol, IgE.

PO2073**INVOLVEMENT OF THE ESTROGEN RECEPTOR AND PI3K/AKT SIGNALING PATHWAYS IN S(-)-EQUOL-INDUCED ACTIVATION OF NRF2/ARE IN ENDOTHELIAL CELLS***T. Zhang¹, Q.Y. Zhang¹, J.D. Zhu¹, M.T. Mi¹*¹Research Center for Nutrition and Food Safety, The Third Military Medical University, Chongqing City, China

Background and objectives: S(-)-Equol is a natural product of daidzein produced by human gut, which has potential benefits in cardiovascular diseases. We determined whether S(-)-Equol activates Nrf2 during oxidative stress and explored the role of Nrf2 in attenuating the damage of endothelial cells caused by oxidative stress.

Methods: Primary endothelial cells were pretreated with S(-)-Equol (10nM-250nM), dual luciferase reporter gene assay was used to determine the Nrf2-ARE-Luc activity. Nrf2, HO-1 and NQO1 were analyzed using western blot assay and their mRNA levels were analyzed by real-time PCR assay. Cells were pretreated with specific inhibitors for estrogen receptor (ER) (ICI182,780), PI3K/Akt (LY294002), and ERK1/2 (PD98059) followed by treatment with S(-)-Equol, Nrf2, HO-1 and NQO1 levels were analyzed using western blot assay. Cells were preincubated with H₂O₂ or tBHP followed by S(-)-Equol, cell viability was determined using CCK-8 assay and cell apoptosis was analyzed using flow cytometry and TUNEL assay. CCK-8

analysis was conducted after Nrf2 gene interfered with siRNA followed by pretreatment with S(-)-Equol and H₂O₂.

Results: S(-)-Equol treatment resulted in the induction of an ARE-luciferase reporter gene and this upregulation was both dose and time dependent. S(-)-Equol increased Nrf2, HO-1 and NQO1 levels. S(-)-Equol treatment affected Nrf2 mRNA levels only slightly but caused a significant increase in HO-1 and NQO1 mRNA levels. Preincubation followed by co-treatment with S(-)-Equol significantly improved cell survival in response to H₂O₂ or tBHP. Such treatment also reduced number of apoptotic cells and TUNEL-positive-stained cells. S(-)-Equol-mediated protection of cells against H₂O₂-induced cell apoptosis was attenuated in cells transfected with an siRNA against Nrf2.

Conclusions: S(-)-Equol attenuated cell oxidative stress-induced injury through Nrf2/ARE antioxidant mechanism involving ER or PIK3/Akt signaling pathway.

Key words: S(-)-Equol, Endothelial cell, Nrf2.

PO2074

INITIATION OF AUTOPHAGY THROUGH UNFOLDED PROTEIN RESPONSE DURING CANCER-PREVENTIVE GERANYLGERANOIC ACID-INDUCED CELL DEATH OF HUMAN HEPATOMA CELLS

Y. Shidoji¹, C. Iwao¹, K. Okamoto¹

¹Molecular and Cellular Biology, Graduate School of Human Health Science, University of Nagasaki, Nagayo, Nagasaki, Japan

Background and objectives: Precision of anthropometric measurements is affected by human error and instrument quality, which influence the magnitude of detectable changes over time and in response to intervention. However, measurement error is rarely reported or even assessed in child growth studies.

Methods: As part of a longitudinal trial to evaluate the impact of zinc supplementation among Burkinabe children 6-30 mo old, 4 teams of 2 anthropometrists were trained to measure height, weight and mid-upper arm circumference (MUAC) according to WHO recommendations. Throughout the 15 mo of study, regular retraining and 13 standardization sessions were completed by recruiting 10-12 children measured twice by each team. The square root of the measurement error variance defined the technical error of measurement (TEM).

Results: TEM for child length across all standardizations (n=132 children) was 0.43 cm; this fluctuated between 0.27

and 0.67 cm throughout the study and permitted detection of a true change of 1.2 cm (range: 0.8-1.9) with 95% confidence (95%DC). The TEM for weight was 45 g (range: 30-105; 95%DC range: 86-297) and for MUAC was 2 mm (range: 1-4; 95%DC range: 2-10). During the intervention, 10,333 16-wk growth intervals and 2,547 48-wk intervals were assessed. TEM accounted for 38%, 19% and 213% of the mean 16-wk changes in length, weight and MUAC, respectively; and 12%, 6% and 69% of the respective mean 48-wk changes.

Conclusions: Regular training, supervision and standardization throughout a 48-wk trial increased the precision of anthropometric measures used for impact evaluation. Despite this, MUAC was inappropriate to measure 16-wk changes. TEM results can be used to select proper outcome indicators, evaluate staff/instrument performance and compare efficiencies of using longer time intervals versus larger sample sizes in planning trials with growth outcomes.

Acknowledgements: Supported by Thrasher Research Fund and Canadian International Development Agency.

Key words: Anthropometry, child, measurement error.

PO2075

LYCOPENE CONTENT OF THE EGYPTIAN FOODSTUFFS, DAILY INTAKE ESTIMATION AND COMPLICATIONS DEVELOPMENT OF TYPE II DIABETES MELLITUS, RATS MODEL

A. Ezz El-Arab¹, T. Hassan¹, S. Zaky², G. Ibrahim²

¹Department of Food Science and Nutrition, National Research Center, Egypt

²Department of Food Technology, Faculty of Agriculture, Cairo University, Egypt

Background and objectives: In spite of the interest in the role of potent antioxidant properties of lycopene in the prevention of chronic diseases, little is known about the lycopene content of the Egyptian foodstuffs and the contribution of these products to the intake of lycopene. This work aimed to determine lycopene content of Egyptian foodstuffs, estimate daily lycopene intake and investigate the possible role of lycopene in development of type II diabetes mellitus complications, regarding the effects of angiotensin-converting enzyme (ACE) activity.

Methods: The lycopene content was estimated by HPLC method, and provided to Egyptian representative sample population based on national survey to estimate the daily intake. We investigated HbA1C and the expression of ACE in a rat model of type 2 diabetes (D), diabetes + lycopene (DL, 45 mg/kg single-dose streptozotocin, and 10 mg lycopene/kg/day), lycopene (L) and healthy (H) groups for 28 days.

Results: The average intake levels of lycopene in Egypt are higher than the levels required for its beneficial biological effects, with different variations between different populations

(socio-economic- rural-urban). The main sources of lycopene were fresh tomatoes with highly percentage contribution of the total amount of this carotenoid in the diet. Blood glucose levels and HbA1c% in (D) and (DL) groups increased significantly compared to (H) and (L) groups. ACE activity in the (H & DL) groups was significantly lower than in the (L & D) groups, respectively.

Conclusions: These results have implications for the evaluation of the daily intake of lycopene in Egypt and raise important questions for establishing a recommendation for optimal daily lycopene intake. Lycopene intake inhibits the plasma ACE activity, a potential marker of development of diabetic complications particularly diabetic renal disease and hypertension.

Key words: lycopene content,egypt,daily intake,type II diabetes,ACE activity

PO2076

EFFECT OF PAPAYA YOGHURT (CARICA PAPAYA) TO SERUM LIPID PROFILE LEVEL OF HYPERLIPIDEMIC SPRAGUE DAWLEY RAT MODEL

N. Oktoviani¹, N. Fatmawati¹, N. Muthmainna¹, I. Kusumaningtyas¹, R. Aulia¹

¹Undergraduate Medical Student, Faculty of Medicine, Semester VI, Gadjah Mada University, Indonesia

Background and objectives: Hyperlipidemia increases risk of cardiovascular disease. Antihyperlipidemia drugs are quite expensive and have side effects in long term usage; therefore the result of therapy is still not satisfied. An alternative food expected to be an antihyperlipidemia is papaya yoghurt. The objective of the experiment is to understand the effect of papaya yoghurt (*Carica papaya*) to the lipid profile of hyperlipidemic rats.

Methods: Adult male Sprague-Dawley rats aged 2 mo and weighed 200-250 g were used for this experiment. All 5 groups were received 30days high-fat diet. Per treatment-group 5 rats were tested. Treatment with distilled water to group I, cholestyramine 0.072 mg to group II, papaya yoghurt 4.5 mL/kgBW to group III, papaya yoghurt 9 mL/kgBW to group IV, and papaya yoghurt 18 mL/kgBW to group V, was given for 28 days, three times a day. The observation of lipid profile (total cholesterol, HDL, LDL, and triglyceride) was performed at day 0, 14, and 28, and then was compared between groups.

Results: Papaya yoghurt could optimally decrease serum total cholesterol up to 53,14%, triglyceride up to 37,41%, and LDL level up to 44,20%, and could increase serum HDL level up to 66,12% in all samples for 14 and 28 days treatment (p < 0,05). It is known that the mechanisms for improving the lipid profile level are via inhibition of cholesterol absorption and

conversion of cholesterol into coprostanol that is excreted with feces.

Conclusions: Our data show that papaya yoghurt could significantly improve level of the lipid profile in hyperlipidemic rat ($p < 0,05$), but papaya yoghurt could improve level of the lipid profile more efficiently compared to cholestyramine in 14 days treatment, whereas, cholestyramine was still the most effective in 28 days treatment.

Key words: hyperlipidemia, lipid profile, papaya yoghurt.

PO2077

VEGETABLES AND PLANT OIL IMPROVE RISK FACTOR FOR SECONDARY COMPLICATIONS IN SUBJECTS WITH TYPE 2 DIABETES

E. Müllner¹, H. Brath², E. Forster², K-H. Wagner¹

¹Department of Nutritional Sciences, University of Vienna, Austria

²Diabetes Outpatient Clinic, Health Centre South, Vienna, Austria

Background and objectives: Diabetes is a growing health care problem worldwide. Epidemiological studies emphasize the role of glycemic control in T2DM subjects to prevent later complications. The diet has major impact on the onset and progress of diabetes related complications. Therefore a human intervention study was performed to investigate the ability of a nutritional therapy to modify risk factors associated with diabetes.

Methods: Seventy six diabetic and 21 non-diabetic individuals participated in this parallel, randomized, intervention-study. All participants received information about the importance of a healthy diet, while participant randomly assigned to the intervention group received additionally 300 g of vegetables and 25 ml of plant oil rich in polyunsaturated fatty acids per day for 8 weeks. Glycated hemoglobin (HbA1c) and parameters of lipid metabolism were measured at baseline, after 4 and 8 weeks.

Results: Glycemic control improved significantly after four and eight weeks of intervention in diabetic subjects. Surprisingly HbA1c was also significantly reduced after 8 weeks in diabetic individuals, receiving information about the benefits of a healthy diet. Levels of HbA1c remained constant in healthy subjects. Total cholesterol and LDL were significantly reduced after 8 weeks of intervention in diabetic and healthy subjects. Triglycerides and HDL were not changed during the intervention. There were no significant effects on parameters of lipid metabolism in subjects of the information group.

Conclusions: A nutritional intervention with vegetables in combination with a plant oil rich in polyunsaturated fatty acids has beneficial effects on glycemic control and lipid metabolism

of diabetic subjects. Even information about health benefits of a balanced diet has impact on glycemic control.

Key words: diabetes mellitus, glucose metabolism, lipid metabolism

PO2078

DIETARY LIPID DYNAMICS IN THE THORACIC LYMPH REGULATED BY FOOD COMPONENTS AND DRUG IN THE INTESTINAL LUMEN

B. Shirouchi¹, Y. Nakamura¹, Y. Furukawa¹, A. Kawachi¹, K. Imaizumi¹, M. Sato¹

¹Department of Bioscience and Biotechnology, Faculty of Agriculture, Graduate School of Kyushu University, Fukuoka, Japan

Background and objectives: Metabolic syndrome (MetS) is a cluster of metabolic disorders and contributes to the increase in cardiovascular morbidity and mortality. Dietary lipids have been recognized as contributing factors to the development or prevention of MetS. Absorbed dietary lipids in the intestine are secreted into the lymph and then transported to the bloodstream via the thoracic lymph duct. It is unclear how dietary lipid dynamics in the thoracic lymph are associated with the development of MetS. Therefore, we evaluated dietary lipid dynamics in the lymph regulated by a pancreatic lipase inhibitor (kakrol, a cucurbitaceous vegetable native to Bangladesh), an inhibitor of cholesterol absorption via NPC1L1 (ezetimibe, a hypocholesterolemic drug), and a water retention substance (guar gum, a water-soluble dietary fiber), which act in the intestinal lumen using thoracic lymph duct cannulation method.

Methods: Sprague-Dawley rats were trained to consume a control diet twice daily and then operated on to cannulate the thoracic lymph duct. The rats were fed each control diet or experimental diet, and their lymph was collected after feeding to quantify lipid levels. In each experiment, there were no significant differences in body weight and food intake between the control and experimental groups.

Results: Lymphatic triacylglycerol transports in the kakrol- and guar gum-fed rats were significantly decreased. Lymphatic total cholesterol transports in the kakrol, ezetimibe, and guar gum-fed rats were significantly decreased. The pancreatic lipase inhibitor significantly decreased lymphatic lipid transport without changing lymph flow. In contrast, the water retention substance significantly decreased lymphatic lipid transport via the reduction of lymph flow.

Conclusions: As comprehending the differences of dietary lipid transport in the lymph depending on food components and drugs, we may gain new insight into the prevention of MetS via the regulation of lymphatic dietary lipid dynamics.

Key words: lymphatic dietary lipid transport, metabolic syndrome

PO2079**MASTICATION EFFECTS ON GLYCAEMIA: PRACTICAL IMPLICATIONS FOR DIET ADVOCACY***V. Ranawana¹, M. Leow^{1,2}, J. Henry¹*¹Clinical Nutrition Research Centre, Singapore Institute for Clinical Sciences, Singapore²Department of Endocrinology, Tan Tock Seng Hospital, Singapore

Background and objectives: The glycemic index (GI) is a well-established dietary tool that enables people to make healthier food choices. However, glycemic variability is a persistent observation that challenges the accuracy and use of the GI. We were interested in seeing if mastication contributed to these variations. The objective of the current study was to determine the role of mastication on glycemic response (GR) and GI. Rice was used as the test food as it is the most common staple eaten in the world and has been implicated in the diabetes epidemic.

Methods: The study adopted a randomized, controlled, cross-over, non-blind design and used 15 healthy subjects (8 males and 7 females, mean (\pm SD) age 26 \pm 6) who returned on five separate days for three glucose and two test rice sessions. At the rice sessions, subjects chewed each mouthful 15 and 30 times. Mastication frequency was measured with real-time electromyograms recorded using bipolar surface electrodes attached to the masseter muscles. Subjective feelings of satiety were measured with visual analogue scales.

Results: Rice chewed to a lesser extent produced a total GR (155 mmol.min/L), peak GR (2.4 mmol/L) and GI (68) significantly lower than when chewed for longer (184 mmol.min/L, 2.8 mmol/L and 88 respectively). There was no effect of mastication on satiety.

Conclusions: The study shows that mastication influences GI and contributes to variations. This is the first record to show that the GI can be affected by an intrinsic human factor although it is by definition a food property independent of such variables. It also shows that rice GR can be reduced by a simple alteration in mastication. This has significant public health implications especially in rice eating societies where it contributes a large glycemic load and increases disease risk.

Key words: glycemic response, Glycemic Index, rice, mastication, diabetes.

PO2081**EFFECT OF A DIET-INDUCED WEIGHT LOSS PROGRAM ON CARDIOMETABOLIC RISK IN OVERWEIGHT AND OBESE ADULTS***L. Grandisoli^{1,2}, I. Santos², E. Aguchiku¹, C. Sperandio², N. Damasceno^{1,2}*¹Department of Nutrition and Dietetics, University Hospital, Sao Paulo University, Brazil²Department of Nutrition, School of Public Health, São Paulo University, Brazil

Background and objectives: Obesity is a risk factor for diabetes and cardiovascular disease. However, small weight losses of 5-7% are associated with significant improvements in health. The goal of this study was to assess the effect of a diet-induced weight loss program on cardiometabolic risk in overweight and obese adults.

Methods: Anthropometric and clinical parameters and body composition (bioelectric impedance) were analyzed before and after a 4 mo diet-induced weight loss program at University of São Paulo's Hospital, Brazil. Patients that modified their lipid, glucose or blood pressure drugs during the study were excluded. According weight and body fat percentage changes, patients were stratified in three groups. Results were analyzed using Wilcoxon test (SPSS 17.0).

Results: Thirty-five patients participated of the study (80% females). The mean age was 41 y and mean BMI was 33.7 kg/m². Twenty patients lost weight, with median percent of weight loss (%WL) of 1.83%. Patients with %WL between 0 and 1.83% (%WL median = 0.6%) presented reductions in BMI ($p = 0.017$) and diastolic blood pressure (DBP) ($p = 0.017$). Patients with %WL > 1.83% (%WL median = 3.11%) presented reductions in BMI ($p = 0.005$), waist circumference (CC) ($p = 0.005$), DBP ($p = 0.028$), LDL ($p = 0.017$), glucose ($p = 0.036$), insulin ($p = 0.032$) and HOMA-IR ($p = 0.013$). Regarding body fat percentage variations (%BF), 25 patients showed reduction (median %BF = -0.51%). Patients with %BF between 0 and -0.51% (median %BF = -0.36%) presented reductions in LDL ($p = p = 0.019$) and DBP ($p = p = 0.045$). Patients with %BF < -0.51% (median %BF = -0.74%) presented reductions in BMI ($p = 0.028$), DBP ($p = 0.022$), LDL ($p = 0.002$), total cholesterol ($p = 0.009$), insulin ($p = 0.010$) and HOMA-IR ($p = 0.006$). Patients who gained weight or body fat showed no improvements in anthropometric or clinical parameters.

Conclusions: A 3.1% weight loss and a 0.75% body fat reduction due to the weight-loss program were already sufficient to improve cardiometabolic risk in these patients.

Key words: obesity, diet, cardiovascular disease.

PO2082**EFFECTS OF COFFEE INTAKE ON INSULIN SIGNALING PATHWAY IN SKELETAL MUSCLE OF HIGH FAT DIET INDUCED OBESE MICE**

W. Aw^{1,2,3}, K. Egashira^{2,3}, S. Takahashi^{2,3}, H. Jia², Y. Kishimoto², H. Tanaka¹, H. Kato²

¹Graduate School of Biomedical Science, Tokyo Medical and Dental University

²Corporate Sponsored Research Program "Food for Life", Organization for Interdisciplinary Research Projects, The University of Tokyo

³Graduate School of Agricultural and Life Sciences, The University of Tokyo

Background and objectives: Emerging epidemiological studies have reported that coffee consumption may reduce the risk of Type 2 Diabetes (T2D). Our previous experiments in vivo showed that coffee intake suppressed elevated body weight gain and tended to alleviate insulin resistance induced by high fat diet. The objective of this study was to identify potential mechanisms underlying the influences of coffee intake on insulin signal in skeletal muscle.

Methods: 8-week old male C57BL6/J mice were raised for 9 weeks ad libitum on either a normal diet (ND), a high fat diet (HF), or high fat diet containing 2% freeze-dried caffeinated coffee (HFCC), or 2% freeze-dried decaffeinated coffee (HFDC), or 2% freeze-dried green unroasted coffee (HFGC). Protein and total RNA were extracted from skeletal muscle and subjected to Western blotting and microarray analysis (Mouse Genome 230 2.0, Affymetrix), respectively.

Results: Western blotting analysis revealed suppression of insulin-dependent tyrosine phosphorylation of IRS-1 and the levels of IRS-1 bound p85 by high fat diet was ameliorated in HFCC and HFGC. Ser473 phosphorylation of Akt/Pkb was also improved in HFCC. Microarray and qPCR results showed that the expression level of the gene for activating transcription factor 3 (ATF3), which is known to be induced by high glucose and high fatty acids, was down-regulated in HFCC. In addition, the expression level of suppressor of cytokine signalling 3 (SOCS3) which is related to insulin resistance in obese subjects was also decreased in HFCC and HFGC.

Conclusions: Western blotting analyses and gene expression profiles have elucidated that coffee modulates the insulin signaling pathway in skeletal muscle, thereby improving insulin resistance. These findings provide the insight that coffee intake may contribute to better management of T2D.

Key words: coffee intake, insulin signaling pathway, ATF3, SOCS3.

PO2083**SELF-REPORTED RATE OF EATING IS ASSOCIATED WITH ACCUMULATED VISCERAL FAT AND CIRCULATING ALT ACTIVITY IN MIDDLE-AGED APPARENTLY HEALTHY JAPANESE MEN**

M. Yamada¹, K. Mochizuki², N. Hariya³, N. Kasezawa⁴, K. Tohyama⁴, T. Goda¹

²Faculty of Life and Environmental Sciences, University of Yamanashi, Kofu, Japan

³Interdisciplinary Graduate School of Medicine and Engineering, University of Yamanashi, Kofu, Japan

⁴SBS Shizuoka Health Promotion Center, Shizuoka, Japan

Background and objectives: Elevated circulating alanine aminotransferase (ALT) and the accumulation of fat, particularly visceral fat, in healthy and preclinical subjects are reportedly associated with increased risk for metabolic diseases such as diabetes. In this study, we examined whether self-reported rate of eating is associated with accumulated visceral fat and elevated circulating ALT activity in middle-aged men.

Methods: We conducted a cross-sectional study of apparently healthy Japanese men aged 30-64 years who participated in health checkups. Associations between self-reported rate of eating and ALT, other clinical parameters or lifestyle factors were determined in 3,929 men by multivariate logistic regression analyses (MLRA). CT-scan of visceral and subcutaneous fat area was conducted for 320 subjects, and these data were subjected to analysis of covariance (ANCOVA), followed by MLRA with independent variables that included self-reported rate of eating.

Results: ANCOVA showed that self-reported rate of eating was significantly associated with BMI, diastolic blood pressure, LDL-cholesterol, as well as visceral and subcutaneous fat areas after adjustment for age, energy intake, alcohol intake, physical activity and smoking status. MLRA showed that among the lifestyle factors, higher self-reported rate of eating was the only variable that was significantly associated with visceral fat area, while alcohol intake was another major variable associated with subcutaneous fat area. Circulating ALT activity also showed an association with higher self-reported rate of eating, but the association between ALT activity and self-reported rate of eating disappeared after adjustment for BMI.

Conclusions: These results suggest that self-reported rate of eating is positively associated with accumulation of visceral fat, and as a consequence, with circulating ALT activity in middle-aged apparently healthy Japanese men.

Key words: self-reported rate of eating, visceral fat, subcutaneous fat, ALT, health checkups.

PO2084**RUTIN HAS BENEFICIAL EFFECTS IN THE CD4+CD62L+ T CELL TRANSFER INDUCED MODEL OF COLITIS IN THE MOUSE.**

C. Mascaraque², R. Gonzalez¹, A. Zarzuelo¹, M D. Suarez¹, O. Martinez-Augustin¹, F. Sanchez de Medina¹

¹University of Granada / CIBERehd, Granada, Spain

²University of Granada, Granada, Spain

Background and objectives: The flavonoid rutin has colonic antiinflammatory activity in chemically induced models of colitis. However these have been claimed to have important mechanistic differences with the human disease. The CD4+CD62L+ T cell transfer model shares many pathological features with human inflammatory bowel disease and has the advantage of being a strictly chronic and T lymphocyte driven model of colitis. Hence we have investigated the effects of rutin in this model.

Methods: CD4+CD62L+ T cells were isolated from wild type C57B6 mice splenocytes by magnetic separation (Miltenyi Biotec). 106 cells were injected intraperitoneally to RAG1 mice to induce colitis. For comparison, a PBS control was also employed. This colitis model produces a disruption of T cell homeostasis, resulting in large and small bowel inflammation at 5-8 weeks after T cell transfer. Treatment was started in animals with diarrhea and significant body weight loss. Experimental groups: wild type (WT), transference control (injected with PBS), colitis and rutin (28.5 mg/kg). Rutin (or vehicle) were administered by gavage.

Results: the colitis group showed significant changes in all the parameters examined compared with the WT and transference control groups. Rutin was effective in dampening the inflammatory response in the intestine, as evidenced by lower body weight loss (-20.2±2.5 vs -4.4±1.2), significantly decreased mesenteric cytokine expression, especially TNF- α and IFN- γ , (123.4±64.7 vs 94.9±31.5 pg/ml and 401.4±119.7 vs 143.8±8.3 pg/ml) and microscopic parameters. Alkaline phosphatase and myeloperoxidase activities in colon were not significantly reduced.

Conclusions: rutin has beneficial effects in the T cell transfer colitis model in mice, indicating that it has colonic antiinflammatory activity in lymphocyte driven colitis.

Key words: rutin, T cell transfer colitis model, flavonoid, inflammatory bowel disease.

PO2085**EFFECT OF THE INTAKE OF A HIGH-FAT SUCROSE DIET ON GUT MICROBIOTA COMPOSITION IN RATS**

U. Etxeberria¹, F. Milagro^{1,3}, N. Arias², M T. Macarulla^{2,3}, M P. Portillo^{2,3}, J.A. Martinez^{1,3}

²Department of Nutrition and Food Science, Faculty of Pharmacy, University of País Vasco, Spain

³CIBER Fisiopatología, Obesidad y Nutrición (CIBEROBn), Instituto de Salud Carlos III, Spain

Background and objectives: Intestinal microbiota has been recently considered as an important factor related to obesity. Gut microbiota is altered as a consequence of a long-term dietary manipulation, which could have a metabolic impact and affect host health. In this sense, the understanding of the diet-responsive groups of bacteria could give valuable information to treat diet-induced obesity and accompanying inflammatory complications. Therefore, the aim of this study was to investigate the effect produced by the intake of a high-fat sucrose diet on gut microbiota composition in rats.

Methods: Male Wistar rats were fed on a high-fat sucrose (HFS) diet during 6 weeks. Feces were freshly collected at baseline and at the end of the treatment. DNA was extracted and analyzed by RT-qPCR. Specific primers for the following groups of bacteria were used: Bacteroidetes, Bacteroides-Prevotella, Clostridium coccoides- Eubacterium rectale, Bifidobacterium spp., Lactobacillus group, Enterobacteriaceae and Actinobacteria.

Results: High-fat sucrose diet treatment significantly ($p < 0.05$) reduced the levels of Bacteroidetes and Clostridium coccoides-Eubacterium rectale. However, no statistical differences were found in Lactobacillus spp., Bifidobacterium spp., Bacteroides- Prevotella, Actinobacteria and Enterobacteriaceae levels at the end of the study when compared to the baseline.

Conclusions: This study showed that the intake of an obesogenic diet rich in fat and sucrose induces changes in the populations of gut microorganisms, confirming that diet is shaping the composition of gut microbiota. HFS diet-induced obesity is accompanied by lower levels of one of the major bacterial phyla in mammalian gut microbiota.

Key words: microbiota, diet-induced obesity, gastrointestinal tract, RT-qPCR.

PO2086**EFFECT OF AHCC ON CD4+CD62L+ T CELL-TRANSFER INDUCED COLITIS IN RAG MICE**

C. Mascaraque², R. Gonzalez¹, A. Zarzuelo¹, M D. Suarez¹, F. Sanchez de Medina¹, O. Martinez-Augustin¹

¹University of Granada / CIBERehd, Granada, Spain

²University of Granada, Granada, Spain

Background and objectives: a major advancement in our understanding of the pathogenesis of inflammatory bowel diseases (IBD) has been the development of mouse models of chronic gut inflammation. The CD4+CD62L+ T cell transfer model shares many pathological features with human IBD and has the advantage of being a strictly chronic and T lymphocyte driven model of colitis. We tested the antiinflammatory effects of active hexose correlated compound (AHCC), a nutritional supplement prepared from the mycelium of edible *Basidiomyces* fungi that contains a 74% of oligosaccharides, specially β -glucans.

Methods: CD4+CD62L+ T cells were isolated from wild type C57B6 mice splenocytes by magnetic separation (Miltenyi Biotec). 106 cells were injected intraperitoneally to RAG1 mice to induce colitis. For comparison, a PBS control was also employed. This colitis model produces a disruption of T cell homeostasis, resulting in large and small bowel inflammation at 5-8 weeks after T cell transfer. Treatment was started in animals with diarrhea and significant body weight loss. Experimental groups: wild type (WT), transference control (injected with PBS), colitis and AHCC (714 mg/kg). AHCC (or vehicle) were administered by gavage.

Results: the colitis group showed significant changes in all the parameters examined compared with the WT and transference control groups. AHCC treated mice displayed a lower body weight loss (-20.2 \pm 2.5 vs -6.6 \pm 2.2) and intestinal weight/length ratio. A macroscopic evaluation of the intestinal segments also revealed an improved damage score (1.9 \pm 0.3 vs 1.7 \pm 0.3). Ex vivo production of proinflammatory cytokines by mesenteric lymph node cells was also significantly decreased (TNF- α 123.4 \pm 64.7 vs 92.1 \pm 30.2 pg/ml; IFN- γ 401.4 \pm 119.7 vs 344.9 \pm 135.2 pg/ml; IL-17 129.2 \pm 14.9 vs 23.3 \pm 10.7 pg/ml).

Conclusions: AHCC has beneficial effects in the CD4+CD62L+ T cell transfer model of colitis.

Key words: T cell transfer colitis model, AHCC, inflammatory bowel disease.

PO2087**THE ASSOCIATION BETWEEN BODY MASS INDEX AND BLOOD PRESSURE AMONG SCHOOL CHILDREN IN MALAYSIA**

S. Shohaimi¹, Y W. Wong¹, M. Ahmad¹

¹Universiti Putra Malaysia

Background and objectives: Childhood overweight and obesity have become a common nutrition-related health problem and have been associated with a higher risk of hypertension. A cross-sectional study was conducted to determine the prevalence of obesity and hypertension and to evaluate the association between obesity and blood pressure in school children in Malaysia.

Methods: 315 boys and 357 girls aged 9-10 y (mean age, 9.6 \pm 0.5 years) in the states of Selangor and Kuala Lumpur participated in this study. Multi-stage stratified random sampling was used to select the participants. The children were classified on the basis of age and sex-specific BMI percentile as normal weight (< 85th percentile), overweight (\geq 85th and < 95th percentile) or obese (\geq 95th percentile) while hypertension was defined using National High Blood Pressure Education Program (NHBPEP) cut-off percentiles.

Results: The mean BMI for boys and girls were 21.4 \pm 5.7 and 19.1 \pm 4.6 kg/m² respectively. The mean systolic blood pressure (SBP) for boys and girls were 103 \pm 13 and 99 \pm 12mmHg respectively while the mean diastolic blood pressure (DBP) for boys and girls were 63 \pm 11 and 60 \pm 9mmHg respectively. The results revealed a high prevalence of overweight (22.6%) and obese (18.1%) children. The prevalence of hypertension among the children was 10.9%. Obese children were more likely to have hypertension (OR=15.6, $p < 0.001$). Logistic regression analyses showed child's BMI was significantly associated with increased odds of hypertension across gender (all $p < 0.005$) except for SBP in girls.

Conclusions: There is an urgent need of having health intervention programs to address the problem of obesity in children in order to reduce the risk of developing hypertension.

Key words: BMI, childhood obesity, hypertension, children, dietary intake

PO2088**WEIGHT LOSS AND DIET CHANGE AS RESULT OF A 12-WEEK DIET AND PHYSICAL ACTIVITY INTERVENTION IN BREAST CANCER SURVIVORS**

L. Hurtós^{1,2}, N. Travier², G. Buckland², L. Arribas¹, I. Peiró¹, A. Fonseca², A. Agudo²

¹Clinical Nutrition Unit, Catalan Institute of Oncology (ICO-IDIBELL), L'Hospitalet de Llobregat (Barcelona), Spain

²Unit of Nutrition, Environment and Cancer, Catalan Institute of Oncology (ICO-IDIBELL), L'Hospitalet de Llobregat (Barcelona), Spain

Background and objectives: Observational and experimental evidence suggests that energy restriction from a low-calorie diet and increased energy expenditure induced by physical activity (PA) could promote weight loss/maintenance that might be an important determinant of breast cancer (BC) prognosis. The aim of the present study was to assess the feasibility and effects of a diet and PA intervention designed to induce weight loss in BC survivors.

Methods: The intervention of this 12-week single-arm pre-post pilot study involved group-based sessions: one-hour weekly diet sessions delivered by a nutritionist and 75-minute bi-weekly PA sessions of moderate-to-high intensity led by experienced PA monitors. This intervention, conducted at the Catalan Institute of Oncology (Barcelona, Spain), in spring 2012, was targeted at overweight and obese women, aged 18 to 75 y, who had recently (up to 6 months previously) completed chemotherapy and/or radiotherapy for a non-metastatic BC. Before and after the intervention, anthropometry was measured and three 24-hour recalls were obtained.

Results: A total of 113 BC survivors were identified through hospital records and invited to participate and 42 of them, aged 33 to 70 y, signed the informed consent form and started the intervention. Among the 37 women who completed the intervention, we observed a significant average weight loss of 5.62 kg (sd = 2.04), as well as significant decreases in body mass index, fat mass and waist and hip circumferences. Significant decreases in total energy (-27%), fat (-39%), saturated fat (-44%) and carbohydrates (-24%) were also observed, while no differences were found for protein or fiber.

Conclusions: This pilot study demonstrated the success of a short-term lifestyle intervention based on diet and PA to induce weight loss and promote healthful changes in dietary habits in BC survivors. Further study is needed to determine the possible impact of this lifestyle change on BC prognosis.

Key words: BC, weight loss, diet.

PO2089**EFFECTS OF ALPERUJO EXTRACT ON β -CELL FUNCTION UNDER STRESS WITH GLUCOSE AND HYDROGEN PEROXIDE.**

C. Gonzalez¹, M. Andrews², E. Leiva¹, M. Arredondo²

¹Faculty of Sciences of Health, University of Talca, Talca, Chile

²Micronutrients Laboratory, INTA, University of Chile, Santiago, Chile

Background and objectives: Alperujo, an olive mill waste is a by-product rich in polyphenols, with a role as antioxidants, that could protect the organism against oxidative damage as occurs in Type 2 diabetes. The aim of the study was to investigate the antioxidant properties of alperujo extract (AE) on β -cells challenged with glucose and hydrogen peroxide (H₂O₂).

Methods: MIN6 cells were cultivated with DMEM as follows: 1) Pre-incubation with 20 μ M of total phenol from AE for 3 days and then challenge with glucose (100 mM) or H₂O₂ (0.15 mM) for 24 hours; 2) Pre-incubation with glucose (100 mM) or H₂O₂ (0.15 mM) for 5 days with and without AE. After that, we determine insulin and reactive oxygen species (ROS) production, intracellular iron and mRNA expression of BAX, BCL-2, Thioredoxin and UCP-2 genes by qRT-PCR.

Results: Insulin production increased in pre-incubated cells with AE and in those challenged with glucose and H₂O₂ for 5 days. ROS generation was increased in the cells pre-incubated with AE and with the stressors. Compared with control, the intracellular iron was increased in cells pre-incubated with glucose, H₂O₂ and in cells pre-incubated with AE ($p < 0.001$). The mRNA relative abundance of Bax only increased ($p < 0.001$) in cells pre-incubated with glucose, however the Bax/Bcl-2 ratio increased in cells pre-incubated with stressors and with AE. Thioredoxin decreased ($p < 0.001$) in the cells pre-incubated with glucose, H₂O₂ and with AE. UCP-2 mRNA increased in cells pre-incubated with glucose ($p < 0.05$) and H₂O₂ ($p < 0.001$) and decreased in the cells pre-incubated with AE.

Conclusions: In this research we found that alperujo extract could be an inductor of apoptosis of β -cell together with a stressor.

Key words: Diabetes mellitus, oxidative stress, iron, Bax/Bcl2 ratio, insulin.

PO2090**PREDICTIVE FACTORS OF ARTERIAL BLOOD PRESSURE IN YOUNG UNIVERSITY STUDENTS, CÓRDOBA, ARGENTINA**

M. Defagó¹, R. Bocco², A. Moreno², N. Perovic¹

¹Escuela de Nutrición, Facultad de Ciencias Médicas, Universidad Nacional de Córdoba

²Dirección de Salud, Secretaría de Asuntos Estudiantiles, Universidad Nacional de Córdoba, Argentina

Background and objectives: The university stage could be the first moment to take decisions about health. An increased risk of cardiovascular diseases (CV) has been detected in youth and adolescents, and this risk is different to adults. The purpose of this study was to examine risk and protective CV factors related to arterial blood pressure (BP) among university students in Córdoba, Argentina.

Methods: A random sample based on the clinical records from university students attendees to Health Direction (Student Department, Universidad Nacional de Córdoba) was developed during 2012. Data about Body Mass Index (BMI), BP, alcohol and tobacco consumption, age, sex, school and college, family history of CV diseases, and physical activity were analyzed. BMI was classified according to OMS and BP by ESC. Chi2 test was employed to analyze differences between variables, and a multivariate logistic regression analyses was performed. Stata version 11.0 was used for all analyses.

Results: about nutritional status of 401 students (38% male, 62% female), 65.66% were normal, 5.26% low weight, 22.31% overweight, 5.51% grade-1 obesity and 1.21% were grade-2 obese. About BP values, the population under study showed the distribution: 61.85% optima, 23.69% normal, 8.48% high-normal, 4.24% grade-1 hypertension, 0.25% grade-2 hypertension, and 1.25%, isolated systolic hypertension. A higher proportion of women had normal BMI in relationship to men ($p < 0.05$). Also, women had higher proportion on normal BP compared to men ($p < 0.001$). Logistic regression showed a strong correlation between normal BP and normal BMI (OR 3.07, IC 95% 1.55-6.08, $p < 0.001$), adjusted by sex, age, family history of CV diseases, tobacco, alcohol, and physical activity. Female sex had a strong association with normal BP (OR 2.4, IC 95% 1.02-4.07, $p < 0.05$).

Conclusions: normal BMI and female sex can predict normal BP in young university students.

Key words: blood pressure; protective factors; youth.

PO2091**MAPPING OF CIVIL SOCIETY ORGANIZATIONS IN LATIN AMERICA AND THE CARIBBEAN**

M.V. Tiscornia¹, L. Allemandi¹, V. Schoj¹

¹Fundación InterAmericana del Corazón Argentina, Buenos Aires

Background and objectives: Cardiovascular disease (CVD) is highly prevalent across Latin America and the Caribbean with heart disease and stroke constituting the number one cause of death. Hypertension is the main risk factor for CVD. The reduction of dietary salt strongly correlates with lower blood pressure and reduced risk of heart disease and stroke. Joint efforts from different sectors should be undertaken to guarantee effective salt reduction initiatives. The objective of this study is to identify and describe civil society organizations in the region whose work relates to dietary salt reduction.

Methods: This is a cross-sectional descriptive study that includes the mapping of civil organizations in Latin America and the Caribbean to identify those who are working on dietary salt reduction. We developed a structured questionnaire to be sent to the organizations identified during the mapping phase. Data collection and analysis is based on the grounded approach.

Results: We identified 62 organizations from 16 countries. We received 26 completed questionnaires from 14 countries. From the total number of organizations: 76.9% work on issues related to high blood pressure: 53.8% on research, 53.8% on the promotion of public policies, 65.4% on education campaigns targeted to consumers, patients and health professionals, and 46.1% conduct community-based activities. We found that 88.4% of the organizations specifically work on issues related to salt intake: 50% on research, 23% on advocacy, 57.7% on education, 19.2% on national, regional or local media campaigns linked to salt intake, and 23% on salt-related community-based activities.

Conclusions: This study represents a first step to identify regional civil society organizations involved in dietary salt reduction. As a result of this mapping, the ALASS (Acción Latinoamericana Sal o Salud) network will be strengthened and future collaborations and strategies will be developed.

Key words: civil society organizations, salt, cardiovascular disease, hypertension.

PO2092**EFFICACY OF A NUTRITION EDUCATION PROGRAM FOR RURAL THAI PREDIABETICS**

S. Songchitsomboon¹, N. Pimsingh², S. Ongroongruang³

¹Faculty of Medicine, Ramathibodi Hospital, Mahidol University, Thailand

²Phetchabun Provincial Health Office, Ministry of Public Health, Thailand

³Former Head of Department of Community and Family Medicine, Faculty of Medicine, Thammasat University, Pathum-thani, Thailand

Background and objectives: Thai National Health Examination Survey IV, 2009 reported the prevalence of impaired fasting glucose (IFG) is 10.7%, in males 11.8%, in females 9.5%. This study was conducted to examine the efficacy of a nutrition education program, involving group intervention among Thai prediabetics living in rural community settings in order to prevent progression to type 2 diabetes.

Methods: A two-group quasi-experimental design was carried out with one-hundred and two pre-diabetic subjects (almost are farmers). They were recruited from rural district in Phetchabun province, in the lower northern region of Thailand. There were 49 subjects in the intervention group and 53 in the control group. Nutrition education program consisted of six sessions with group based learning in a one year follow up. The process covered active learning in nutrition knowledge and skill practice in dietary self-management. Assessments for evaluation included biochemical characteristics, anthropometry and nutrient intakes.

Results: During one year follow-up, prevalence of new type 2 diabetic case in the intervention group was 10.2% (5/49), compared with 13.2% (7/53) in the control group. Data analysis in subjects who do not turn to diabetics showed that subjects in the intervention group (n = 44) increase their self-efficacy in meal plan and in decision of food choice. This resulted in proper total energy and carbohydrate intake. After one year, percentage of prediabetic subjects with BMI >23 kg/m² (56.8%), FBG >100 mg/dL (63.6%), HbA1c >5.9% (29.5%), triglycerides >150 mg/dL (25.0%), total cholesterol >200 mg/dL (13.6%) in the intervention group were significantly lower than the control group [80.4, 89.1, 52.2, 45.7, 30.4% (total number = 46), respectively].

Conclusions: Results from this study suggested that nutrition education in community based on group intervention is effective at improving diabetes risk factors among rural Thais.

Key words: prediabetes, self-dietary management, rural community.

PO2093**PREDICTORS OF CARDIOVASCULAR DISEASE IN MULTI-ETHNIC ASIAN PATIENTS WITH TYPE 2 DIABETES MELLITUS**

⁶Medical Department, Hospital Serdang, Selangor Darul Ehsan, Malaysia

⁷Department of Community Health, Faculty of Medicine and Health Sciences, Universiti Putra Malaysia, Selangor Darul Ehsan, Malaysia

Background and objectives: Cardiovascular disease (CVD) is the leading cause of mortality and morbidity in patients with type 2 diabetes mellitus (T2DM). Although patients with T2DM and CVD share common risk factors, the link between these diseases remains largely unexplained. Thus, this study intends to identify the predictors of CVD in Asian T2DM patients.

Methods: We conducted an analytical cross-sectional study on 313 patients aged 30 to 78 diagnosed with T2DM at selected tertiary hospitals upon prior ethical approvals. Systematic random sampling method was applied in patient selection. Socio-demographic data was assessed using a pre-tested interviewer-administered structured questionnaire. Diet (by 24-hour dietary recall), physical activity level [via International Physical Activity Questionnaire (IPAQ)], smoking and alcohol consumption status were ascertained. Anthropometric measurements were performed according to standard procedures. Clinical and laboratory characteristics on cardiovascular risk factors (medical history, treatments, blood pressure, glycemic control, and lipid profile) were collected from medical records, clinical examination and face-to-face interview. All statistical analyses were performed by using SPSS Statistics Version 21.0.

Results: The mean age of study subjects was 55.7±9.2 years, with a mean diabetes duration of 10.1±8.1 years; 52.1% subjects were females; and majority were Malays (47.0%). Approximately one third (36.1%) of the subjects were suffering from CVD. Logistic regression using forward stepwise method showed age

($B = 0.056$, adjusted OR95%CI = 1.058, $p = 0.004$), lower HDL-C level ($B = -1.466$, adjusted OR95%CI = 0.231, $p = 0.003$), working status of self-employed ($B = 1.381$, adjusted OR95%CI = 3.978, $p = 0.002$), low ($B = 1.164$, adjusted OR95%CI = 3.203, $p < 0.001$) and moderate physical activity levels ($B = 1.172$, adjusted OR95%CI = 3.227, $p < 0.001$) compared to high physical activity level were significantly associated with higher CVD risk, upon adjustment for potential covariates.

Conclusions: Increased age, lower HDL-C, low and moderate physical activity levels, and working status appeared to be significant predictive factors of CVD among the T2DM patients studied.

Key words: cardiovascular disease, type 2 diabetes mellitus, predictors.

DIETARY COMPLIANCE, DIETARY SUPPLEMENTATION AND TRADITIONAL REMEDY USAGE AMONG TYPE 2 DIABETIC PATIENTS WITH AND WITHOUT CARDIOVASCULAR DISEASE: AN UPDATE

M C. Tan¹, Y M. Chan^{1,2}, O C. Ng^{3,6,7}, A R. Hejar⁴, T W. Wong⁵, A. Joseph^{3,6,7}

¹Department of Nutrition and Dietetics, Faculty of Medicine and Health Sciences, University Putra Malaysia, Selangor Darul Ehsan, Malaysia

²Institute of Gerontology, Universiti Putra Malaysia, Selangor Darul Ehsan, Malaysia

³Department of Medicine, Faculty of Medicine and Health Sciences, Universiti Putra Malaysia, Selangor Darul Ehsan, Malaysia

⁶Medical Department, Kuala Lumpur General Hospital, Kuala Lumpur, Malaysia

⁷Medical Department, Hospital Serdang, Selangor Darul Ehsan, Malaysia

Background and objectives: Cardiovascular disease (CVD) is the principal cause of death in patients with type 2 diabetes mellitus (T2DM). A growing body of evidence revealed that diet is a key modifiable factor in preventing and reducing CVD risks. However, there is scant data addressed on dietary intake and complementary medicine usage of type 2 diabetic patients among multi-racial groups of Malaysia. This analytical cross-

sectional study aimed to intensively examine and compare the dietary compliance, dietary supplementation and traditional remedy usage of type 2 diabetic patients with and without CVD from selected tertiary hospitals in Malaysia.

Methods: Socio-demographics, dietary intakes, dietary supplementation, traditional remedy use, health history, anthropometric measurements and clinical characteristics were collected during the face-to-face interview.

Results: 313 patients treated for T2DM participated in this study, in which 36.1% of them had CVD. The mean age of study subjects was 55.7 ± 9.2 years (mean diabetes duration 10.1 ± 8.1 years) and 52.1% were females. On the whole, mean total energy intake of patients was 1674 ± 694 Kcal/day. Patients with CVD consumed higher total calories ($p = 0.001$). Likewise, mean carbohydrate, protein and total fat intake of CVD patients were significantly higher than non-CVD patients ($p < 0.05$), while mean intakes of cholesterol, fiber, minerals and vitamins were comparable between CVD and non-CVD groups. Regardless of CVD status, a notably high proportion of the patients did not meet the recommendations of the Medical Nutrition Therapy Guidelines for T2DM for total energy, carbohydrate, protein, total fat, and fiber intakes. Meanwhile, 52.4% used at least one dietary supplement and 12.1% took single traditional remedy or in various combinations.

Conclusions: Despite the dietary compliance, traditional remedies and supplement intakes did not differ between CVD and non-CVD patients, our dietary investigations warrant a better insight of the current dietary status of diabetics.

Key words: cardiovascular disease, type 2 diabetes mellitus, dietary status.

ASSOCIATIONS BETWEEN DISORDERED EATING AND BODY WEIGHT STATUS AMONG ADOLESCENTS IN KUALA LUMPUR, MALAYSIA

K. Sanker¹, C. Yit Siew¹, F W. Rezali¹, W. Fui Chee¹, Z. Mohd Shariff¹, M N. Mohd Taib¹

¹Department of Nutrition & Dietetics, Faculty of Medicine & Health Sciences, University Putra Malaysia

Background and objectives: Disordered eating and overweight are major public health problems among adolescents. The aim of this study is to determine the relationship between disordered eating, eating behaviors and body weight status among adolescents in Kuala Lumpur, Malaysia.

Methods: A cross-sectional multistage study was carried out in four selected schools in the Federal Territory of Kuala Lumpur. A total of 569 Malaysian students (male:42%; female: 52%) between the ages of 13-17 years completed the Eating Attitude Test-26 (EAT-26) that measures the symptoms and characteristics of disordered eating and Three Factor Eating

Questionnaire (TFEQ-R) which was used to measure restrained eating, uncontrolled eating, and emotional eating. Body weight and height of students were measured and BMI-for-age by sex was used to determine the body weight status.

Results: The prevalence of overweight and obesity (26.0%) was almost four times higher than the prevalence of thinness (7.0%) although 67.0% adolescents were normal weight. About one in five (24.4%) adolescents was engaged in disordered eating. It was found that the highest prevalence of disordered eating (39.3%) was found among obese adolescent followed by overweight (29.8%), normal weight (21.8%) and underweight (20.0%) adolescents ($X=12.4$, $p < 0.05$). Adolescents reported a mean score of 12.16 ± 3.29 , 19.56 ± 5.07 , 5.08 ± 2.24 in the cognitive restraint, uncontrolled eating and emotional eating respectively. All four predictor variables were significant in explaining the BMI-for-age among adolescents ($F(4, 564) = 27.55$, $p < 0.05$). Restrained eating ($t = 6.91$, $p < 0.05$), disordered eating ($t = 4.65$, $p < 0.05$), uncontrolled eating ($t = 2.59$, $p < 0.05$), and emotional eating ($t = 2.51$, $p < 0.05$) contributed significantly towards BMI-for-age among adolescents.

Conclusions: This study suggests that future intervention programs should implement healthful eating behaviors as it is needed to prevent obesity and eating disorders in adolescents.

Key words: Disordered eating, eating behavior, body weight status, adolescent.

NUTRITION KNOWLEDGE AND DIETARY LIFESTYLE AS CANCER RISK FACTORS AMONG UNIVERSITY OF IBADAN UNDERGRADUATES, NIGERIA

K. Ajayi¹, O. Adepoju¹

¹Department of Human Nutrition, University of Ibadan, Ibadan, Oyo State, Nigeria

Background and objectives: Nutrition knowledge and attitudes have effect on eating habits. Many healthy lifelong practices begin in adolescent. The aim was to determine the undergraduate students of University of Ibadan's knowledge of nutrition, lifestyle and dietary pattern as risk factors to cancer.
