IMPACT OF VARIOUS DIETARY OILS ON FADS1 AND FADS2 GENE EXPRESSION IN WHOLE BLOOD: A RANDOMIZED CROSSOVER CONTROLLED NUTRITIONAL INTERVENTION

M E. Labonté¹, P. Couture¹, D J A. Jenkins², P. Connelly², S. West³, P. Kris-Etherton³, P. Jones⁴, B. Lamarche¹

¹Institute of Nutrition and Functional Foods, Laval University, Québec, QC, Canada

²St-Michael's Hospital, University of Toronto, Toronto, ON, Canada

³Pennsylvania State University, University Park, PA, USA

⁴Richardson Centre for Functional Foods and Nutraceuticals, University of Manitoba, Winnipeg, MB, Canada

Background and objectives: Fatty acid desaturase (FADS)-1 and FADS2 genes play a major role in tissue polyunsaturated fatty acids (PUFA) homeostasis. Little is known regarding the impact of different dietary fatty acids on the expression of FADS1 and FADS2 in human. Our objective was to investigate

the impact of dietary oils containing various amounts of alpha-linolenic acid (ALA), linoleic acid (LA), oleic acid (OA) and docosahexaenoic acid (DHA) on the expression of FADS1 and FADS2 in adults.

Methods: In a randomized, crossover controlled full feeding trial, 118 men and women with abdominal obesity and at least one other component of the metabolic syndrome were fed with 4 experimental isoenergetic diets (15.5% protein; 35.7% fat; 50.6% carbohydrate) of 4 weeks each. Diets were formulated to provide 60 g/3000 kcal of different oils: 1-CONTROL (10.6g OA; 0.2g ALA; 41.6g LA), 2-FLAX (10.7g OA; 19.2g ALA; 22.5g LA), 3-High oleic canola (HO-CAN, 42.8g OA; 1.4g ALA; 8.8g LA), 4-High DHA canola (DHA-CAN, 37.9g OA; 1.2g ALA; 7.6g LA; 3.5g DHA). FADS1 and FADS2 gene expression in whole blood cells was assessed in a random sample of 10 subjects (6 men, 4 women) by real-time polymerase chain reaction from samples collected at the end of each diet.

Results: Consumption of DHA-CAN down-regulated whole blood FADS1 and FADS2 mRNA expression versus CONTROL (-20.7% and -12.4%, respectively), versus HO-CAN (-25.5% and -14.2%, respectively) and versus FLAX (-24.5% and -23.7%, respectively, all P<0.03). No other difference in FADS1 and FADS2 gene expression was observed between the various diets.

Conclusions: Data from this controlled feeding study suggest that consumption of a DHA-enriched canola oil down-regulates the PUFA desaturation pathway compared with n-6 PUFA, monounsaturated fat as well as plant source n-3 PUFA.

Key words: docosahexaenoic acid, fatty acid desaturase, gene expression, nutritional intervention

SCALING-UP HIGH IMPACT NUTRITION INTERVENTIONS: EXPERIENCES WITH THE ESSENTIAL NUTRITION ACTIONS FRAMEWORK

J. Nielsen¹, A. Guyon², V. Quinn¹

¹Helen Keller International, New York, USA

²John Snow, Inc. Research and Training Institute, Arlington, VA, USA

Background and objectives: Inadequate nutrition practices during the critical 1,000-day period from conception to the child's second birthday harm both women and children. Modifying such practices requires advocacy, training, systems strengthening, and behavior change communication strategies that address pertinent barriers and support doable actions. The Essential Nutrition Actions (ENA) framework provides universal, science-based guidance (Lancet 2008) for all these areas, utilizing key contact points across the life cycle and seven priority areas shown to improve nutrition and survival.

ENA has potential to support the Scaling Up Nutrition (SUN) movement.

Methods: This review summarizes the adaptation of the ENA framework over a period of fifteen years that guided broad scale implementation across numerous countries in Africa and Asia.

Results: In Ethiopia, Liberia, Niger, Madagascar and Uganda, ministries of health applied the framework in partnership with multiple non-governmental, bilateral and international partners. Benin, Ethiopia, Madagascar and Senegal carried out large-scale programs and documented impressive results. Burkina Faso, Liberia, Mali and Niger deliver this preventive strategy together with the Integrated Management of Acute Malnutrition, while in Nepal and Bangladesh, ENA has encouraged cooperation between the health and agricultural sectors to address nutrition and food security together at broad scale. In Côte d'Ivoire, ENA promotes the appropriate use of a fortified complementary food while protecting optimal breastfeeding. In some countries, careful, structured formative research has been conducted to tailor ENA messages to each local context; in others the generic messages have required only modest adjustments to be used effectively.

Conclusions: The ENA framework promotes key nutrition actions to be taken at key contact points in the life cycle. Maximizing contacts through multiple program opportunities within existing systems and community structures can achieve large-scale coverage to achieve a public health impact in reducing under-five mortality and morbidity.

Key words: high impact nutrition interventions, ENA framework

PO340

NATIONAL AND SUB-NATIONAL ESTIMATES OF CHILD AND ADULT NUTRITIONAL STATUS RELATED TO LATER LIFE NUTRITION-RELATED NON-COMMUNICABLE DISEASE (N-RNCD)

A. Pomeroy¹, A. D'Agostino¹

¹SPRING Project, John Snow, Inc., Arlington, USA

Background and objectives: Recent studies have demonstrated that many common manifestations of under-nutrition have significant associations with development of hypertension, insulin resistance, and obesity, particularly in an environment of growing calorie availability. These are pre-conditions related to the development of N-RNCDs. Addressing maternal and child under-nutrition is therefore important not only to prevent immediate threats of child morbidity/mortality, but also to reducing risk of N-RNCDs later in life. To gain insight into where future risk of N-RNCDs may lie in low-income countries, SPRING analyzed a set of Demographic and Health

Surveys for sub-national patterns, using supplementary national-level data to provide context.

Methods: Nationally, data were analyzed for trends in prevalence of pre-conditions, diabetes, calorie availability, and anthropometrics. Sub-nationally, data on low birthweight at term, stunting, overweight, stunted and overweight, stunted with an overweight mother, and overweight women were weighted and stratified by: education, wealth, location and region. Estimates were mapped and compared for co-existing conditions.

Results: In Southeast Asia, prevalence of overweight women is low but growing in several countries, as is calorie availability and projected diabetes prevalence. In Africa, prevalence of hypertension and female and child overweight is high and growing quickly in many countries. Particularly within Sub-Saharan African countries, there are surprising overlaps in low birthweight, stunting, and overweight, irrespective of household wealth, education, or region. Southeast Asian sub-national estimates followed more traditional patterns of status, with under-nutrition primarily among the poor and less educated and overweight among the wealthier and better educated.

Conclusions: This descriptive analysis explores where future risks may lie for N-RNCDs in low-income countries, identifying where under-nutrition programs may be tailored to avoid later life conditions. SPRING is building additional evidence on why certain sub-populations are more at risk and how this can be used to advise nutrition programs.

Key words: Stunting, Overweight, NCDs

PO341

PLASMA FATTY ACIDS INFLUENCE LIPID PROFILE AND BLOOD PRESSURE IN INDIVIDUALS WITH DIFFERENT CARDIOVASCULAR RISK

D. Estevez¹, M. Nuñez¹, S. Miyamoto², N. Damasceno^{1,3}

¹Nutrition Department, FSP, USP, Sao Paulo, Brazil

²Biochemistry Department, IQ, USP, Sao Paulo, Brazil

³Nutrition Service, Hospital Universitario, USP, Sao Paulo, Brazil

Background and objectives: Heart diseases are the main death cause all over the world. Therefore interventions in the risk factors, and specially, in diet, have been focal points in many public health interventions. Objective: Evaluate the influence of fatty acids (FA) percentage in plasma over lipid profile and blood pressure in different cardiovascular risk level individuals.

Methods: Adults and elders (n=374), from a clinical, prospective, randomized and double blind study based in nutritional intervention, were included in this clinical trial. After 12h

fasting, blood samples were collected. Lipid profile was analyzed from plasma (Total Cholesterol–TC; Low Density Lipoprotein–LDL; High Density Lipoprotein–HDL; Triglycerides–TG). Content of FA was determined through HPLC analysis and the areas were presented as percentage. All analyses were controlled by internal and external standards and two replicates. The blood pressure was measured based on the IV Brazilian Heart Society Guidelines. The statistical analysis evaluated the linear trend of TC, LDL, HDL, TG, Systolic Blood Pressure (SBP) and Diastolic Blood Pressure (DBP) stratified in low, medium, and high levels, and these related to age, BMI, Linoleic Acid (AL), Alfa Linolenic Acid (ALA), EPA, DHA and the sum of EPA and DHA percentage in plasma. The Statistical Package for the Social Sciences® (SPSS Incorporation, 2006), 16.0 version was used and the significance level was $p < 0.05$.

Results: The patients from the highest tertile of HDL had higher DHA content. Patients in the lowest tertile of DHA content were associated to higher levels of TG. When analyzing DBP, the individuals in the highest range presented lower levels of EPA and EPA+DHA plasma content.

Conclusions: Individuals with higher plasma fatty acid content of ω -3 metabolites (DHA and EPA), present better lipid profile (lower TG and higher HDL) and lower DBP.

Key words: Blood Pressure, omega 3, fatty acids, lipid profile, cardiovascular risk.

were collected after overnight water restriction. Following ingestion of D₂O, the 7-day deuterium elimination rate was estimated at baseline, and during weeks 5 and 6.

Results: At baseline, hydration status defined relative to SaOsm > 100 mmol/kg (3 out of 5 participants) did not agree with status defined relative to serum osmolality > 285 mmol/kg (5 out of 5 participants) or urine osmolality > 800 mmol/kg (5 out of 5 participants). Over the weeks of higher water intake, the participants who were initially classified as hydrated based on SaOsm < 100 mmol/kg responded differently from the other participants. They responded with a significantly greater increase in deuterium elimination (Mean SE: +51(0.3)% vs. +8(3)%), no change in RBC K:Na content, and no increase in serum sodium. In contrast, participants who were initially classified as dehydrated based on SaOsm > 100 mmol/kg significantly decreased RBC K:Na content (Mean SE: -1.7(0.5), and increased serum sodium (Mean SE: +2(0.6) mmol/l) and body weight (Mean SE: +1.2(0.3) kg).

Conclusions: Baseline SaOsm measured at a single point in time discriminated between participants' responses to 4 weeks of higher water intake. Further work is needed to pursue if and how saliva osmolality can be used to distinguish usual hydration status.

Key words: Saliva, osmolality, water intake, hydration, healthy men

PO342

SALIVA OSMOLALITY PREDICTS RESPONSE TO 4 WEEKS OF HIGHER WATER INTAKE IN HEALTHY FREE-LIVING MEN

J. Stookey¹, J. Hamer¹, D. Killilea¹, C. Chi¹, A. Higa², V. Ng², F. Peronnet³, E. Perrier⁴, A. Klein⁴

¹Children's Hospital Oakland Research Institute, Oakland, CA, USA

²Children's Hospital & Research Center Oakland, CA, USA

³University of Montreal, Canada

⁴Danone Research, Palaiseau, France

Background and objectives: No one gold standard index of hydration is sensitive to all aspects of optimal hydration. This study considered saliva osmolality (SaOsm) as an index of longer-term, usual status.

Methods: This secondary analysis used 6 weeks of longitudinal data from a clinical study where 5 healthy men (20–25y), with baseline 7d-mean total water intake below 2L/d, increased intake of drinking water by +0.8(0.3)L/d over weeks 3 and 4, and then +1.5(0.3)L/d over weeks 5 and 6, and significantly altered usual hydration status, based on serial 24-hr urine measures. Each week, fasting saliva, blood, urine, and body weight

PO343

THE ALTERATION IN THE PALATABILITY OF SWEET SUBSTANCES IN MICE BEFORE AND AFTER ONSET OF DIABETES

H. Yamazaki¹, M. Takata¹, T. Fushiki¹

¹Graduate School of Agriculture, Kyoto University, Japan

Background and objectives: Sucrose causes the higher level of satisfaction in comparison with the other sweet substances. Therefore, it seems difficult to find the perfect sweetener to alternative to sugar. It is supposed that such feeling of contentment is arisen from both signals of sweet stimuli and calories. It is also well-known that the alteration in energy metabolism affect the preference and the sensitivity of sweet taste. The purpose of this study was to investigate the contribution of caloric content to the palatability of sucrose and other sweet taste substances by using diabetic animals.

Methods: We investigated the effect of various concentrations of a sucrose or saccharin on fluid intake as well as mice's preferences in a licking test. As the most common animal model of human diabetes, streptozotocin (STZ)-induced diabetic mice (C57/BL6) were used in this experiment. The licking test were conducted before (BD) and after (AD) the onset of diabetes.

Results: The licking rates for the serial concentration of sucrose and saccharin were increased in a concentration-dependent manner in BD and AD mice. In the initial licking for 1 min, the number of lickings of AD mice were significantly higher than BD mice in lower concentration of sucrose. It is suggested that the sensitivity for the sweet stimuli were increased after the onset of diabetes. On the other hand, the results in licking rate in saccharin solution were not similar to sucrose.

Conclusions: It is suggested that the caloric stimuli generates the feeling of satisfaction not only by post-ingestion but also within the oral cavity.

Key words: Diabetes, Sucrose, Sweet, Oral Sensitivity

IS THE RELATIONSHIP BETWEEN THE BLOOD-GROUPS AND FOOD ALLERGY IN CHILDREN AND YOUNG PERSONS?

G. Maciejewska¹, M. Rokitka², M. Schlegel-Zawadzka³

¹Institute of Physiotherapy, Faculty of Health Sciences, Jagiellonian University Medical College, Krakow, Poland

²The Regional Outpatient Department of Paediatric Infection Disease, Hepatology Center of John Paul II Hospital, Krakow, Poland

³Institute of Public Health, Faculty of Health Sciences, Jagiellonian University Medical College, Krakow, Poland

Background and objectives: The aim of the study was to exam the relation between select food allergens and blood-groups (A,B,AB,0) in children and young persons living in Poland.

Methods: The study comprised 973 questionnaire fulfilled by parents of Polish children aged 0.12-23.3years (mean age: 7.7+/-3.9 years) treated because of allergy disease in the period 1999-2008. The examinations were done at the consulting rooms of physicians cooperating with the Polish Help Society for Children with Asthma and Allergic Diseases in the whole Poland. The parents of the allergic and the asthmatic children with disease symptoms after food intake were chosen. Several data were collected. The study was approved by two independent Ethical Committees (2002).

Results: The allergenic symptoms after food intake had 467 children (48%; 275 boys and 192 girls comprised the selection criterion). There was no differences between blood types of boys and girls (A:41%, O:27%, B:18%, AB:14%). However, taking into account food allergic symptoms (FA) the significant differences were found (FA: A:55%, AB:47%, B:38%, O:44%; NFA: A:45%, AB:53%, B:62%, O:56%; p<0.01). Three common food allergens

were recognized – milk (351 children), egg (286 children) and citrus fruit (277 children). The boys with A blood-group had more often allergic symptoms (FA: A:54%, AB:49%, O:44%, B:35%;, p<0.01). More girls had egg allergy than boys (G:67%, B:53%; p<0.01). The allergy for milk and milk products was related with blood groups (FA: AB:79%, A:76%, O:68%, B:54%; p<0.01) and respectively to gender groups: AB and A groups of girls (AB:72%, O:70%; p<0.01). Also citrus fruit allergy was more often in girls with AB blood group (78%, p<0.01).

Conclusions: The blood-group maybe an independent predictor for the possibility of the food allergy occurrence. However, more epidemiological study in different population is needed.

Key words: food allergy, blood-groups, children

PO345

EFFECTS OF LYCOPENE AND RED PALM OIL ON OXIDATIVE STRESS IN STREPTOZOTOCIN-INDUCED DIABETIC RATS

A. Rahmat¹, H. Jafari¹, S. Ebadi¹, N. Ramli¹, H. Khazaai¹

¹Universiti Putra, Malaysia

Background and objectives: Red palm oil and lycopene are potent anti-oxidant, known to assist to defend against oxidative damage and free radicals. This study was conducted to investigate the effects of red palm oil and lycopene on oxidative stress in streptozotocin- induced diabetic rats.

Methods: Diabetes was induced by injection with 55 mg/kg body weight of STZ (Streptozotocin) dissolved in 0.05 M citrate buffer (pH4.5). Lycopene (10 and 20 mg/kg bw) and red palm oil (10 and 20 mg/kg bw) were given to the diabetic rats by force feeding for six weeks supplementation. Parameters studied included fasting blood glucose level, oxidative stress biomarkers (superoxide dismutase and glutathion peroxidase), lipid profiles (low-density lipoprotein cholesterol, triglycerides, total cholesterol and high-density lipoprotein cholesterol) and body weight.

Results: Supplementation with red palm oil and lycopene significantly (p < 0.05) increased the level of HDL-C and reduced the plasma low-density lipoprotein cholesterol, triglycerides and total cholesterol of diabetic rats as compared to control diabetic (un-treated and super olein oil) animals. Superoxide dismutase and glutathione peroxidase activities were enhanced in diabetic treated groups with lycopene and red palm oil compared to that in control diabetic rats. The supplementation of lycopene and red palm oil (significantly prevented body weight loss starting from 3rd week of lycopene and red palm oil administration in treated animals. Level of oxidative stress markers were also reduced with administration of red palm oil.

Conclusions: Lycopene may have considerable therapeutic potential as an antioxidant but there was no lipid lowering effect in Type 2 diabetes mellitus. These findings also indicate antidiabetic capability of red palm oil.

Key words: Red palm oil, lycopene, antioxidant, oxidative stress

PO346

RESULTS OF THE "BACTEREMIA ZERO" PROTOCOL IN CRITICAL CARE PATIENTS WITH A NUTRITIONAL SUPPORT BY (PARENTERAL WAY INTRAVENOUS) AFTER A YEAR OF IMPLEMENTATION

C. Morente Marcos¹, M J. Machado Ramirez¹, G. Lobo Támer¹, V. Sáez Chica¹, S. Silvente Fernández¹

¹Hospital Universitario Virgen de las Nieves, Granada, Spain

Background and objectives: The bacteremia associated with the central intravenous catheters is the second most acquired medical complication in the ICU. Its prevalence can be modified with the incorporation of special insertion measures and through the exhaustive compliance of the Bacteremia Zero protocol through manipulation of the catheters. Objectives: To study the prevalence of bacteremia in critical care patients that received nutritional support via Parenteral Nutrition (PN) through a central intravenous catheter. Test the results after a year of implementation of the nursing care protocol, both in canalization of the central intravenous catheter as with subsequent care.

Methods: From the report made by the Microbiology Service with all records of the cultivated central intravenous catheters from 01/01/12 until 30/11/12, those that were contaminated and that belonged to patients that received Parenteral Nutrition were selected.

Subsequently, the microbial development in blood culture samples was studied, confirming the presence of the bacteremia when the culture was positive and with the same germ-polluting agent of the catheter.

Results: The culture was made in 126 central catheter tips from which 33 (26,1%) resulted positive. The 18,18% presented polymicrobial pollution before the implementation of the protocol. From January 1st until November 30th in 2012, 92 patients received Parenteral Nutrition (PN). of those, 10 displayed bacterial pollution (10,86%), confirming the presence of bacteremia. From these 10 patients, 30% displayed polymicrobial pollution; being the most common: *St. Coagulasa* (30%),

Candida Albicans (20%), *Enterobacter Cloacae* (20%), *Klebsiella Pneumoniae* (20%), *Enterococcus Faecalis* (10%).

Conclusions: Comparing with the results of 13,4% catheter pollution from the previous year, this year a decline was observed, bringing the number of pollutions down to 10,86% since the implementation of the "Bacteremia Zero" protocol.

Key words: bacteriemia, protocol, catheter infection, prevention, UCI patients, parenteral nutrition

PO347

DO OUR PATIENTS WITH CYSTIC FIBROSIS IMPROVE THEIR HABITS AND DIETARY INTERVENTION NUTRITIONAL STATUS AFTER PLANNED?

G. Lobo Tamer¹, A. Pérez Aragón¹, A. Pérez de la Cruz¹, M A. López Casado¹, F. Casas¹, J. Romero González¹, J. Maldonado¹

¹Hospital Universitario Virgen de las Nieves, Granada, Spain

Background and objectives: Malnutrition is common clinical findings in patients with cystic fibrosis (CF), as their energy and nutrient requirements are high, indicating an increase of 120% of the RDA for their age and sex. Nutritional intervention is compensated with obvious benefits both in growth and development as a respiratory function. To assess if CF patients improve their eating habits after following a nutritional intervention plan.

Methods: The study included patients with CF diagnostic criteria for conducting regular checks at our Hospital. Dietary intake was measured using the 'reminder 48 hours', supported by a photo book of food and further analysis with the software Food and Health. In order to access eating habits a frequency questionnaire was applied to validate the food consumption of the Spanish population. We also conducted a nutritional assessment, including weight and height measurements, arm circumference and skin folds (triceps, biceps, abdominal and subscapular), comparing our values with the graphs (under 14) and tables (over 14 years) with reference to the Spanish population.

Results: We included 27 patients, 59.3% male, 40.7% were under 14. From the dietary and nutritional intervention, we improved nutritional habits, especially the consumption of fruit and fish, reducing industrial bakery and carbonated drinks. With respect to energy and nutrient intake, we obtained an increase of 526.7 kcal / day, which impacted positively on nutritional status and the same improvement was observed in subsequent assessments. Regarding nutritional assessment, malnutrition was found in 25.9% of patients, the most affected parameters arm circumference and triceps skin fold.

PO350**EFFECT OF CARBOHYDRATES DIETS ON EATING BEHAVIOR AND OXIDATIVE STRESS IN RATS**

C. García¹, A. Martínez¹, M. Navarro¹

¹Behavioral Feeding and Nutrition Research Center, CUSur-University of Guadalajara, Guadalajara, México

Background and objectives: The high consumption of carbohydrates increases the presence of chronic noncommunicable diseases (NCDs) and additionally modifies eating behavior. NCDs are characterized by increased production of oxidative stress markers. However it is not clear how simple carbohydrates consumption affects eating behavior and oxidative stress. The objective of this project was to evaluate the effect of simple carbohydrates consumption on eating behavior and oxidative stress markers.

Methods: Nine adult rats of Wistar strain, divided into three groups, were exposed to diets with different simple carbohydrates diets: Control group (standard diet), Group 1 (diet high in simple carbohydrates), Group 2 (diet low in simple carbohydrates). Subsequently lipid peroxidation products MDA (oxidative stress markers) and production of advanced composite glycation (AGE) were measured at the beginning and end of the experiment. It is expected to identify the effects of the different models of diets on eating behavior and assess oxidative stress markers present in adult rats.

Results: Results showed that experimental diets increased eating behavior in comparison of control diet.

Conclusions: However, it was not clear the relation between experimental diets with oxidative stress markers. These findings suggest that high carbohydrate diets can modify eating behavior patterns.

Key words: carbohydrate, feeding behavior, markers of oxidation

PO351**PROCESSING METHODS AND NUTRIENT COMPOSITION OF FLOURS MADE FROM FERMENTED SOYABEANS(GLYCINEMAX), FERMENTED MAIZE(ZEAMAYS) AND UNFERMENTED GROUNDNUT(ARACHISHYPOGEA) USE IN COMPLEMENTARY FEEDING**

N M. Oly-Alawuba¹

¹Department of Nutrition and Dietetics, Imo State University Owerri, IMO State, Nigeria

Background and objectives: In Nigeria, the commonly accepted complementary food for babies are porridges prepa-

red with unsupplemented starchy foods like Maize(zeamays) Sorghum(sorghum bicolor) and tubers. Animal protein is rarely given due to its high cost. This study aims at assessing the processing methods and nutrient content of fermented Soyabean, fermented maize and unfermented groundnut flours for use in complementary feeding.

Methods: Soyabean grains were fermented for 24h, maize 24h. The Soyabean was dehulled by rubbing between palms and sundried, roasted until it turned light brown and drymilled into fine flour, (70mm meshscreen). The maize was wet milled, sieved and sundried. The groundnut sample was soaked in water for 10 minutes, drained, roasted until it turned light brown, then milled into groundnut paste. The proximate, mineral, vitamin and antinutrient composition of the flours were determined using official methods of analysis of AOAC.

Results: Fermented Soyabean flour and Groundnut flour had higher levels of protein (40.9g and 48.6g respectively) against the corn flour that had(0.53 g). Phytate, oxalate and tannins were highest in Soyabean (0.8 mg, 0.6 mg and 0.5 mg/100 g portion) while corn flour recorded least (0.2 mg, 0.1 mg and 0.1 mg/100 g portion). Calcium, Potassium, Sodium, Zinc, Iron and phosphorus were highest in Soyabean (220.16 mg, 214.39 mg, 275.62 mg, 8.3 mg, 7.14 mg and 585 mg) while corn flour recorded the least (78.15 mg, 178.31 mg, 168.53 mg, 5.53 mg and 3.62 mg).

Conclusions: Soyabean and groundnut flours are highly nutritious, they are good sources of protein, calcium, potassium, iron and zinc in formulating high nutrient dense complementary foods.

Key words: processing, fermentation, nutrient, complementary food.

PO352**EFFECTS OF SJAMP ON DEVELOPMENT AND IMMUNE FUNCTION OF EXPERIMENTAL HEPATOCARCINOMA IN RATS**

S. Yang¹, J. Shoujie¹, C. Lianhua¹, J. Xiaojun²

¹Nutrition, Qingdao University Medical College, Qingdao City, Shandong Province, China

²The Affiliated Hospital of Medical College Qingdao University, Qingdao city, Shandong Province, China

Background and objectives: Whether the Stichopus japonicus acid mucopolysaccharide(SJAMP) has an effect on inhibiting tumor development is uncertain. We utilized hepatocarcinoma-induced rats; model to determinate the effects of Stichopus japonicus acid mucopolysaccharide(SJAMP) on tumor growth and immune function.

Methods: Rats in blank model group and SJAMP intervention groups (A, B, C) were treated by gavage with DEN saline

solution (10 mg/kg) for 80 days to induce liver tumor. Meanwhile, the SJAMP intervention groups were treated by gavage with different SJAMP doses. Rats were killed at the 16th week. The number of the nodules and the size of the largest nodule among groups were noted to calculate the inhibition rate of the antitumor. The phagocytosis function of macrophages was detected by neutral red method. The tumoricidal function of spleen macrophage and natural killer cell activity were assayed by methyl thiazolyl tetrazolium (MTT). T lymphocyte subsets in peripheral blood of rats were examined by flow cytometry method.

Results: Compared with blank model group, in SJAMP intervention groups, the number of the nodules and the mean volume of the largest nodule significantly lessened ($P < 0.05$), the indices of the spleen and thymus increased ($P < 0.05$) and the capability of macrophage's phagocytosis and killing improved ($P < 0.05$). Compared with normal control group, natural killer cell activity and the levels of CD3+, CD4+T lymphocyte and ratio of CD4+ and CD8+ in blank model group were significantly lower, while with the gradual increase in SJAMP doses, natural killer cell activity, the levels of CD3+, CD4+T lymphocyte and ratio of CD4+ and CD8+ in three SJAMP intervention groups increased gradually.

Conclusions: In this study, SJAMP can inhibit the growth of tumor obviously, perhaps by stimulating the proliferation of immune organs and tissues to enhance the body cell immunity.

Key words: Diethylnitrosamine; *Stichopus japonicus* acid mucopolysaccharide; Macrophage; Natural killer cell; T lymphocyte subsets

PO354

DNA METHYLATION CHANGES INDUCED BY ZINC DEFICIENCY IN 0-2M-OLD RATS

Y. Jiang¹, Y. Hu^{1,2}, W. Pang¹, H. Lu^{1,2}, J. Li¹, C. Huang²

¹Institute of Health & Environmental Medicine, China

²Sichuan University, China

Background and objectives: Zinc is a component of the activity site of enzymes that epigenetically modify DNA. There is little information on the effects of zinc on DNA methylation in the hippocampus. The effects of zinc deficiency on the DNA methyltransferases (DNMT) expression and the methylation patterns of brain-derived neurotrophic factor (BDNF) gene were examined in this study.

Methods: Nine mother wistar rats were randomly divided into zinc-adequate group (ZA), pair-fed group (PF) and zinc-deficient group (ZD) and fed a diet containing 30, 30 and 1 mg/kg diet of zinc, respectively. Ten neonatal rats in each group were randomly selected according to their body weight at the

time of weaning and fed the same diet as their mothers and then sacrificed at the age of 60 day. The mRNA levels of DNMT1, DNMT3A, DNMT3B were measured by RT-PCR. qMS-PCR was used to screen methylation of BDNF exon IX DNA in the hippocampus of rats. Another independent assessment of altered methylation, Bisulfite sequencing PCR was used to examine site-specific methylation of 11 CpG dinucleotides within the same region of BDNF exon IX screened by qMS-PCR.

Results: Gene expression analysis showed increased DNMT1 and decreased BDNF mRNA levels in the hippocampus of ZD rats compared with ZA and PF rats ($P < 0.05$). Furthermore, zinc deficiency during 0-2 months produced a prominent increase in DNA methylation level in BDNF exon IX ($P < 0.05$) as compared with ZA and PF rats. Bisulfite sequencing PCR demonstrated that CpG sites of BDNF exon IX were mostly absolutely methylated in the hippocampus of zinc deficient rats compared with ZA and PF rats.

Conclusions: These results suggest that zinc deficiency in rats aged 0-2 months old influences the modification of DNA methylation.

Key words: Zinc deficiency, DNA methylation, hippocampus, BDNF, DNMT

PO355

FOOD INTAKE ASSESSMENT OF THE 'BOM PRATO' PROJECT USERS

A. Murakami Y Cruces¹, J. Almeida dos Santos¹, M. de Camargo¹, T. Sandoval¹, C. Freiberg¹

¹Centro Universitário São Camilo, Ipiranga - São Paulo, Brazil

Background and objectives: To face the hunger and malnutrition problem in the low income population in Brazil, the Government of the State of São Paulo, aligned with the actions of the "Fome Zero" (Zero Hunger) Program, has created initiatives such as "Bom Prato" (Good Meal) Project, to offer complete, balanced and high-quality meals to low income families (elderly, unemployed, underemployed, homeless and itinerant). In spite of having a low cost (about US\$0,50), the meals have a high caloric value (400 kcal for breakfast and 1200kcal for lunch). Objectives: Assess the nutritional status by food intake analyses, of the 'Bom Prato' Project users and its suitability according to FAO/WHO/2003 and the project itself.

Methods: There have been evaluated 315 people between 19 and 59 years old, who has reported going to the restaurant at least three times a week. The assessment of dietary intake was done with 24 hours dietary recall and following the food intake in the restaurant.

Results: The energy intake in the restaurant was above than the recommended by FAO/OMS/03, being the average of

948.55 kcal (SD=108.75), lower than proposed by the project. Macronutrients of the menu were adequately covered in 25.0% of carbohydrate, in 37.5% of protein and in 75.0% of lipids. In the daily food intake analysis 79.0% were below the energy needs. 78.7% had a diet normoglycemic, 59.9%, hyperproteic and 64.4% normolipidic. The saturated fat and cholesterol intake were above the recommended levels, respectively, 22.9% and 41.0%. The fiber intake was above average of 62.9%. The lunch was the most important meal of the day.

Conclusions: Most of the population does not have all the daily meals. The food intake at the popular restaurant represents a significant part of the daily intake. Therefore, this type of project is very important to offer a nutritionally balanced meal adequate for the population.

Key words: nutritional assessment, food intake

PO356

BLOOD PRESSURE CHANGES DURING PREGNANCY ACCORDING TO PRE-PREGNANCY BODY MASS INDEX: A PROSPECTIVE COHORT FROM RIO DE JANEIRO, BRAZIL

F. Rebelo¹, F Dayana Rodrigues², H. Roberta Mendes², S. Cláudio José¹, K. Gilberto²

¹National School of Public Health, Oswaldo Cruz Foundation, Rio de Janeiro, Brazil

²Institute of Nutrition, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil

Background and objectives: Systolic (SBP) and diastolic (DBP) blood pressure undergoes physiological changes during pregnancy. The weight status might be an important factor involved in abnormal pressure variations that can be associated with later hypertensive disorders. Objectives: To describe SBP and DBP levels during pregnancy according to pre-pregnancy BMI and compare it with post-partum blood pressure levels.

Methods: Prospective cohort of 227 women between 20-40 years of age, with singleton pregnancy and free of chronic and infectious diseases. SBP and DBP were obtained with automatic sphygmomanometer at 8-13th, 22-26th and 30-34th gestational weeks and 30 days after delivery. Pre-pregnancy BMI (kg/m²) was classified as: underweight/normal (<25.0); overweight (≥25.0 and <30.0); and obese (≥30.0). Statistical analysis comprised ANOVA (one-way and for repeated measures) and multiple linear regressions.

Results: Mean SBP and DBP were significantly lower in early pregnancy, compared to post-partum, for all strata of BMI, except in the obese group for SBP. SBP and DBP did not change throughout pregnancy for obese women, differently from other BMI groups. Although SBP and DBP were lower in underweight/normal group, comparing with obese, in all

trimesters of pregnancy (p<0.001), the DBP showed no differences between groups in postpartum (p=0.3906). Regression models were adjusted for age, ethnicity, marital status, parity, smoking status, physical activity, education and weather at blood pressure measurement and showed that a variation of 1.0 kg/m² in BMI increased on average 0.96, 0.71 and 0.87 mmHg in SBP and 0.45, 0.42 and 0.61 mmHg in DBP of the first, second and third trimester, respectively (p<0.001).

Conclusions: BMI was directly associated with blood pressure during pregnancy. Obese women presented a different pattern of blood pressure variation, showed no decrease in SBP in early pregnancy, and did not present the characteristic decrease up to the second trimester.

Key words: Blood pressure; BMI; Pregnancy; Cohort.

PO357

RECOMMENDATIONS FOR IODINE CONTENT MEASUREMENT METHODS IN SALT IODIZATION PROGRAMS

R. Yusufali¹, G. Garrett¹, L. Locatelli-Rossi¹

¹Global Alliance For Improved Nutrition (GAIN), Geneva, Switzerland

Background and objectives: Salt iodisation is the most effective intervention for the elimination of iodine deficiency. It is vital to monitor salt iodine content at various points in the supply chain for programs to be effective. Several methods of measurement have been developed, motivated by an attempt to make tests more precise, field- and user-friendly and cheaper. The objective of this paper is to review methods for iodine measurement available in order to develop recommendations for selecting the most appropriate method for salt iodisation programs.

Methods: Four validated methods for iodine measurement (Titration, WYD Iodine Checker[®], Bioanalyt iCheck[®] and Rapid Test Kit/RTK) were reviewed against cost, precision, user-friendliness and infrastructure requirements. These methods were then ranked considering the purpose of the different stages of a typical monitoring framework within a salt iodisation program.

Results: Titration is highly precise, requires technical user know-how and moderate infrastructure. Costs per analysis are low when a higher number of samples need analysed regularly. The WYD device is comparable to titration in most areas and is slightly more user friendly however has lower precision. The Bioanalyt iCheck[®] is the most user - friendly and has good precision however more costly in applications where a large number of samples have to be analysed on a regular basis. The RTK is the simplest and cheapest method. However its application is limited to qualitative results only.

Conclusions: On salt iodisation programs, the main objective of the monitoring exercise and use of the results should be considered when selecting the appropriate method for measuring iodine content in salt. Precision is not always the most important consideration. Cost and field- and user-friendliness must also be considered in order to ensure effective monitoring of iodization along the supply chain.

Key words: Salt Iodisation, Iodine, Micronutrients, Monitoring

PO358

SYSTEMATIC REVIEW AND META-ANALYSIS OF DIETARY PATTERNS AND DEPRESSION: OBSERVATIONAL STUDIES

J.S. Lai¹, S. Hiles^{1,2}, A.J. Hure¹, M. McEvoy¹, J. Attia¹

¹School of Medicine and Public Health, University of Newcastle, NSW, Australia

²Priority Research Centre for Translational Neuroscience and Mental Health, University of Newcastle, NSW, Australia

Background and objectives: Recent years have seen an increasing interest in the study of dietary patterns on the risk of depression. Study of whole diet rather than individual dietary components is of practical importance as nutrients are rarely eaten in isolation. This study aims to conduct a systematic review and meta-analysis of observational studies addressing the association between dietary patterns defined a priori (using diet quality scores or indices) and the risk of depression.

Methods: Six electronic databases were searched for studies published up to May 2012. Two reviewers evaluated the citations to determine eligibility. Studies assessing diet quality and depression among adults were included. Relevant studies were evaluated for methodological quality using the American Dietetic Association Quality Criteria Checklist for primary research and the European micronutrient Recommendations Aligned Network of Excellence scoring system. Only studies considered methodologically rigorous were included. Data were extracted by two reviewers to ensure accuracy. Effect sizes of eligible studies were pooled using a random effects model.

Results: One cohort and nine cross-sectional studies were included in this review. Due to the variety in diet quality scores used, meta-analysis could only be conducted for studies with similar definition of good diet quality (n=1 cohort; n=8 cross-sectional). Good diet quality is characterised by high intakes of fruit and vegetables, fish, whole-grain products, lean meat, and low-fat dairy. Results indicated that good diet quality was significantly associated with a reduced risk of depression (OR = 0.89; 95% CI: 0.85, 0.94; p<0.001).

Conclusions: This finding is clinically relevant for public

health, in particular for encouraging the consumption of good quality diet for primary prevention of depression. This review also highlights the need for better designed cohort and case-control studies to clarify the role of dietary patterns and depression risk.

Key words: dietary patterns, diet quality, depression, review

PO359

BODY IMAGE PERCEPTION IN BRASILIAN ELDERLY

R. Machado¹, M.A. Coelho¹

¹Ufrj/Federal University of Rio de Janeiro, Brazil

Background and objectives: Body image involves perception, affect, and cognitive components. Body image is not only changed due to age but to problems experienced, such as diseases, limitations of movement and especially the influence of stereotypes. Aim: To evaluate and compare the current body image and would like to take elderly residents in a poor area of Rio de Janeiro - Brazil.

Methods: It was used an evaluation model of body image with 81 seniors conducted by trained nutrition students. This assessment contains a series of nine silhouettes for men and nine for women in a progressive scale, where each senior must observe the pictures according to their sex and to answer how many of the figure corresponds to their body image. The silhouettes are classified as underweight, normal weight, overweight and obesity. Individuals reported body image corresponding to the current physical appearance and the appearance that they would like to have. Measures of frequency and reason prevailed (RP) with confidence interval (CI) of 95% were calculated.

Results: Body image had PR of 1.37 (CI 95%1.24 to 1.63) for thinness and PR 3.69 CI 95% (2.32 to 5.87) for overweight/obesity. In relation to physical appearance, the highest percentage was observed for the eutrophic with 40.7% followed by the silhouette of overweight/obesity with 43.2% and 16.0% of thinness. The results for the appearance that the elderly would like to have had the highest percentage for the silhouette of normal weight (59.3%), but 14.8% would like overweight / obesity and 25.9% had thinness.

Conclusions: The elderly identified themselves as having a much higher prevalence of overweight/obesity. Although many older people find to be a figure equivalent to an appropriate weight, they still want to be thinner.

Key words: elderly, body image, nutritional status

PO360**PREVALENCE OF OVERWEIGHT AND OBESITY AND ASSOCIATED FACTORS AMONG SCHOOL GOING CHILDREN IN KENYA: THE CASE OF NAKURU MUNICIPALITY**

D. Koros¹, E. Mbuthia², P. Tuitoek²

¹Hospitality and Tourism Studies Department, Rift Valley Institute of Science and Technology, Nakuru, Kenya

²department of Human Nutrition, Egerton University, Nakuru, Kenya

Background and objectives: Overweight and obesity are important determinants of diseases of lifestyle and other morbidity on the rise in developing countries. The aim of this study was to determine the prevalence of overweight and obesity and associated factors among school going children in Nakuru municipality. The study investigated the prevalence of overweight and obesity and associated factors including dietary patterns, types of physical activities, socio-economic factors, advertisements and home/physical environment.

Methods: A cross sectional survey design was adapted and a randomly selected sample of 200 school going children aged 10-14 years in 10 schools was used. A structured questionnaire was used to collect data and anthropometric measurements (height and weight) were taken using Seca calibrated scales. Data was analysed using Statistical Package for Social Sciences (SPSS) version 11.5. Descriptive statistics was done. Chi-square and binary logistic regression were used to determine association between variables. ANOVA and t-test were used to compare means between variables. Tests of significance were computed at $\alpha = 0.05$. The children whose percentile values were 85th to < 95th were classified as overweight and ≥ 95 th percentile obese.

Results: The study found that 20.5% of the children were overweight and 15.5%, obese. Prevalence of overweight and obesity was high among children from high socioeconomic status ($p = 0.000$) and in private schools ($p = 0.000$) irrespective of their gender and age.

Conclusions: Dietary patterns, types of physical activities, socioeconomic factors and home/physical environment influenced the prevalence of overweight and obesity among the children. Prevention and management may be achieved through a variety of interventions targeting home/physical environment, physical activity, and diet; by stakeholders' including parents, children, policy makers and programme planners.

Key words: Overweight and obesity, School going children, Dietary patterns, Socio-economic status and physical activities.

PO361**FACTORS ASSOCIATED TO THE UNDERREPORT OF ENERGY INTAKE IN FOOD RECORDS AMONG ADULTS FROM THE RIO DE JANEIRO AREA, BRAZIL**

T. Lopes¹, R. Luiz², D. Hoffman³, E. Ferrioli⁴, R. Sichieri⁵, R. Pereira¹

¹Departamento de Nutrição Social e Aplicada, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil

²Instituto de Estudos em Saúde Coletiva, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil

³Department of Nutritional Sciences, Rutgers, the State University of New Jersey, New Brunswick, NJ, USA

⁴Departamento de Clínica Médica, Faculdade de Medicina de Ribeirão Preto-Universidade de São Paulo, São Paulo, Brazil

⁵Departamento de Epidemiologia, Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil

Background and objectives: The main consequence of misreport in dietary surveys is the attenuation of association measures of the diet-disease relationship. In order of planning and carrying out studies evaluating dietary intake, it is important to identify characteristics related to the misreporting of food consumption. This study aimed to evaluate the individual characteristics associated with underreport of energy intake (EI) in food records (FR) of adults.

Methods: The studied group included 84 individuals between 20 - 60 years old who were recruited from a sample investigated in a population-based cross-sectional study in Duque de Caxias, state of Rio de Janeiro, Brazil. Energy intake was estimated from two non-consecutive FR, and the means were deattenuated for intraindividual variability. Energy expenditure (EE) was estimated using the Doubly Labeled Water (DLW) method. Misreport in EI was estimated by calculating the 95% limits of agreement of the EI/EE ratio, and underreport of EI was defined by $EI/EE < 0.62$. Multivariate logistic regression models were developed to estimate the association (odds ratio - OR; 95 confidence interval - 95%CI) between individual characteristics and EI underreport.

Results: Underreport of EI was observed in 36% of subjects, ranging between 24 and 43%, with a mean of 29%, being more frequent among women. The characteristics associated with underreport of EI were: irregular habits of meals consumption (OR=8.3; 95%CI:1.3; 53.9), regularly replacing lunch or dinner by snacks (OR=11.1; 95%CI: 2.2; 54.6), and the consumption of light products (OR=4.9; 95%CI: 1.3; 18.9), independently of gender and total energy expenditure.

Conclusions: Individuals that did not maintain regular habits of meals - and those that were trying to reduce sugar/fat intake had more difficulty in reporting accurately the food consumption.

Key words: energy intake, energy expenditure, food consumption, food records, dietary surveys

PO362

THE EFFECTS OF VITAMIN A, E ON PROLIFERATION OF HUMAN ESOPHAGEAL CANCER CELL LINE ECA-109 CULTURED WITH HUMAN SERUM

Y. Xiong^{1,2}, M. Li², C. Huang², C. Kou³

¹Institute of Public Health, Chongqing Center For Disease Control and Prevention, China

²West China School of Public Health, Sichuan University, China

³Yantin Tumor Institute, Yantin, China

Background and objectives: Studies on the effects of vitamins A and E on esophageal cancer are inconsistent. This study is to assess the effects of different concentrations of vitamins A and E on proliferation of human esophageal cancer cell line Eca-109, and explore the possible mechanisms.

Methods: By means of MTT assay, 3H-thymidine incorporation, cell toxicity experiment and flow cytometric analysis were used to observe the effects of vitamins A and E on cell proliferation with adding different concentrations of vitamins A and E in the medium with 5% human serum.

Results: Vitamin A could inhibit the proliferation of human esophageal cancer cell line Eca-109 in dose effect manner, affect the DNA synthesis, and block cell mitosis. The inhibitive effect of vitamin A at the level of 50mg/L was significant ($p < 0.01$), but the coordinated effect of Vitamins A and E on the proliferation of human esophageal cancer cell line Eca-109 was not observed. Vitamin A may make the cell gather in S phase and destroy DNA synthesis. Therefore, the cell could not pass the regulation point of G2/M and the mitosis was blocked.

Conclusions: Vitamin A may inhibit proliferation of the human esophageal cancer cell line Eca-109 cell.

Key words: vitamin A, vitamin E, Eca-109, human serum

PO363

CHANGES IN THE ULTRASTRUCTURE OF RAT'S SURAL NERVE SUBJECTED TO BRAZIL REGIONAL BASIC DIET

M.F. Larcher de Almeida¹, F. Vitorino Freitas², A.M. Blanco Martinez³

¹Department of Nutrition, Federal University of Rio de Janeiro, Macaé - RJ, Brazil

²Department of Pharmacy and Nutrition, Federal University of Espirito Santo, Alegre -ES, Brazil

³Department of Histology, Federal University of Rio de Janeiro, Rio de Janeiro - RJ, Brazil

Background and objectives: Malnutrition is a disease with worldwide prevalence. Their deleterious effects lead to complications in both the central and peripheral nervous system of mammals, especially if it occurs during development. For this reason the research aims to analyze the effects of a multideficient diet, used by the population in the forest zone of Pernambuco - Brazil, in the ultrastructure of the rat's sural nerve.

Methods: We used animals of different ages (p13, p21, p30 and p60) from litters whose mothers underwent multideficient diet during breastfeeding. We proceeded to ultrastructural analysis of qualitative, quantitative and statistical sural nerve, by analysis of the area of the myelin sheath and percentage of myelinated and unmyelinated fibers by electron microscopy transmission in control and experimental group.

Results: the multideficient diet caused malnutrition in animals of the experimental group while maintaining the ultrastructure of the nerve, but, leading to a significant reduction in the area of the myelin sheath in the animals at 21 and 60 days respectively: 3.5 μm^2 and 4.0 μm^2 in the malnourished group and 5.0 μm^2 and 7.5 μm^2 in the control group ($p < 0.001$). The undernourished group remained the same proportion of myelinated / unmyelinated with 21 days (43/52) and 60 days (46/50) differed from the control group that received gradual increase in myelinated fibers of the 21 (49/51) for p60 days (60/30) ($p < 0.05$).

Conclusions: the research revealed that regional basic diet of Pernambuco - Brazil causes changes in the ultrastructure of the sural nerve of mammals. The changes remained present until adulthood animals may cause permanent deficits in nerve impulse transmission.

Key words: sural nerve, myelin, basic regional diet, malnutrition

PO364**INSTAPA WP6: THE EFFECTS OF MICRONUTRIENT SUPPLEMENTATION WITH REDUCED IRON CONTENT ON MOTOR DEVELOPMENT IN INFANTS IN A MALARIAL AREA**

J. Kvalsvig¹, P. Holding², M. Taylor³, M. Chhagan⁴, P. Kitsao-Wekulo², S. Zulu¹, F. Mwangome², T. Jaeggi⁵, S. Kauchali⁶, I. Brouwer⁷

¹Department of Psychology, University of KwaZulu-Natal, Durban, KwaZulu-Natal, South Africa

²International Centre for Behavioural Studies, Mombasa, Coastal Province, Kenya

³Department of Public Health Medicine, University of KwaZulu-Natal, Durban, KwaZulu-Natal, South Africa

⁴Department of Paediatrics, University of KwaZulu-Natal, Durban, KwaZulu-Natal, South Africa

⁵Department of Health Sciences and Technology, Institute of Food, Nutrition and Health, ETH Zurich, Zurich, Switzerland

⁶Grey's Hospital, Department of Health, Pietermaritzburg, KwaZulu-Natal, South Africa

⁷Department of Human Nutrition, Wageningen University, The Netherlands.

Background and objectives: While iron deficiency anaemia is prevalent in malarial areas, iron supplementation may increase health risks in these areas. This presentation describes the impact of supplementation with micronutrient powders containing either a low iron dosage or no iron, on the motor development of infants in a double blind efficacy trial. The objectives are: (1) to compare the psychomotor performance of the INSTAPA cohort with unsupplemented infants (PNE cohort) from the same community; (2) to identify the aspects of psychomotor development most responsive to micronutrient supplementation.

Methods: The study site is a rural area on the Kenyan coast. Infants received daily micronutrient supplementation from 6 Å 18 months of age, and were assessed at six-monthly intervals to determine gross motor skill development, eye-hand co-ordination and level of motor activity. The scores of 238 supplemented infants on the Kilifi Developmental Inventory (KDI) were compared with the scores of 217 unsupplemented infants in the same area. We examined the association between KDI scores and the amount and type of motor activity observed, as well as the correlation between these measures and baseline haemoglobin.

Results: INSTAPA infants had improved eye-hand coordination relative to PNE children by 12 months of age (INSTAPA 17,2 PNE 16,1; $f=16.346$, $p<.001$). In the INSTAPA cohort at baseline only eye-hand co-ordination scores correlated signifi-

cantly with haemoglobin levels. The locomotor scores correlated with the amount of time spent mobile, but were independent of haemoglobin.

Conclusions: These analyses suggest that the development of eye-hand co-ordination is more specifically related to iron status at this age than general energy levels and exploration in infants.

Key words: Malaria, micronutrients, motor development

Acknowledgments: The project was realized in the framework of INSTAPA Project, funded by the European Union Seventh Framework Programme [FP7/2007-2013] under grant agreement nr 211484

PO365**VITAMIN D INSUFFICIENCY IN PRIMARY CARE POPULATION: A STUDY IN URBAN BHUBANESWAR, ODISHA, INDIA**

S. Pati¹, S. Pati²

¹Indian Institute of Public Health Bhubaneswar, PHFI, India

²Medical Officer in charge, Unit IX dispensary, Bhubaneswar, India

Background and objectives: Vitamin D deficiency is emerging as a major public health challenge globally. A number of studies have highlighted the presence of Vitamin D insufficiency among general populations. Present study aimed to assess the prevalence of vitamin D deficiency among primary care patients attending urban health dispensary of the Bhubaneswar city, Odisha and to examine the feasibility and efficacy of vitamin D replacement as a routine component of primary care.

Methods: Review of dispensary outpatient register of two month was undertaken to identify patients aged 18 years and more with at least one 25-hydroxyvitamin D level. When patients were found to be deficient (vitamin D <20) they were administered 50 000 units ergocalciferol monthly or over-the-counter calcium supplements with vitamin D. Descriptive statistics were used to calculate the prevalence rate, and paired t tests were used to compare the vitamin D levels pre and post treatment.

Results: Out of total 1790 patients 787 (44%) were found to have vitamin D deficiency, and 525 were treated with ergocalciferol or vitamin D supplements. Majority (81%) were either elderly or women. For patients deficient at baseline and treated with vitamin D supplementation, significant differences were found between baseline and follow-up vitamin D levels ($p < .001$). Among 525 patients deficient at baseline and treated, 357 were corrected with oral vitamin D (68%), leaving 168 patients (32%) deficient after vitamin D supplementation.

Conclusions: Study results indicate vitamin D deficiency to be highly prevalent in an urban, primary care population being more pronounced among elderly and women. This can be improved readily through oral vitamin D supplementation. The study also suggests that routine screening for vitamin D insufficiency may be useful for timely detection and treatment of vitamin D deficiency, especially in urban elderly populations.

Key words: vitamin D insufficiency, primary care, urban elderly

P366

SOCIO-CULTURAL, ORGANIZATIONAL, AND COMMUNITY LEVEL INFLUENCES ON PHYSICAL ACTIVITY LEVELS OF LATINO PRESCHOOL-AGED CHILDREN: A QUALITATIVE STUDY

A. Lindsay¹, M. Greaney², K. Sussner³, M. Wang⁴, E. Pheiffer⁵, K. Peterson⁶

¹Department of Exercise and Health Sciences, College of Nursing and Health Sciences, University of Massachusetts, Boston, USA

²Center for Community-Based Research, Dana-Farber Cancer Institute, Boston, Massachusetts, USA

³Department of Oncological Sciences, Division of Cancer Prevention and Control, Mount Sinai School of Medicine, New York, New York, USA

⁴Division of Preventive & Behavioral Medicine, University of Massachusetts Medical School, Worcester, Massachusetts, USA

⁵Curamericas Global, Inc., Raleigh, North Carolina, USA

⁶Human Nutrition, Department of Environmental Health Sciences, University of Michigan School of Public Health, Ann Arbor, Michigan, USA

Background and objectives: As more children grow up in families with immigrant parents of Latino origin, there is need to understand key influences on physical activity behaviors of young Latino children to prevent obesity in this high risk group.

Methods: We conducted six focus groups with low-income Latina mothers (N = 33) whose preschool-aged children (2-5 years) were enrolled in the Supplemental Nutrition Program for Women, Infants and Children (WIC) program in Rhode Island.

Results: Despite understanding the importance of physical activity for overall health, physical activity was not a top priority for the Latino mothers participating in the focus groups who face numerous barriers to establishing and maintaining

healthful physical activity habits for their preschool-aged children and themselves, particularly financial and socio-cultural barriers. Analyses revealed that Latina mothers perceive the WIC as a program focused on the development and maintenance of healthy eating habits and nutritional status of children and not physical activity.

Conclusions: Recognizing the importance of socioeconomic position and the influence of cultural factors on physical activity is essential if effective prevention and intervention programs for Latino families and their children are to be designed. Study findings emphasize the importance of the family as a central unit of change and suggest that successful interventions to promote physical activity among low-income Latino preschool children must take into account the needs and constraints of the family unit as a whole. The WIC program has the potential to be a venue for promoting awareness of and educating low-income Latino parents about the importance of helping their children develop and maintain early healthful physical activity habits.

Key words: Physical Activity, Latino, Obesity, Children, WIC Program.

PO367

A NUTRITION EDUCATION INTERVENTION TO COMBAT UNDERNUTRITION: EXPERIENCE FROM A DEVELOPING COUNTRY

A. Zahid Khan¹, G. Rafique¹, H. Qureshi¹, S.H. Badruddin²

¹Human Development Programme-Aga Khan University, Karachi, Pakistan

²Mahar Medical Center, Karachi, Pakistan

Background and objectives: Undernutrition in children is a major public health concern in Pakistan. The country has one of the highest rates of infant mortality in South Asia. A number of interventions focused only on providing nutrient supplementation have failed to change child undernutrition status in the country during the last 2 decades. The present study aimed to assess the impact of nutrition education on the nutritional status of children living in resource limited environments. The hypothesis was that nutrition education can improve nutritional status of children. This study reports the results of a three month intervention (Oct – Dec 2010) on the change in nutritional status of undernourished children.

Methods: Subjects were 586 children from Tando Jam and Quetta, Pakistan aged 6 months to 8 years. Children were characterized as mild, moderate or severely wasted on Z-Scores. Anthropometry and 24 hour dietary recall was used for nutritional assessment. The intervention strategy focused on nutrition education based on individual counseling targeting the mothers. The majority of these women could not read and write

te and so the sessions comprised of verbal discussions. Direct counseling sessions were also conducted with undernourished children 5 years and older. Primary outcome was decrease in severity of wasting as well as changes in feeding practices.

Results: Nearly 36% children in Tando Jam and 32% children at Quetta progressed to a normal nutritional status. There was a significant increase in the number of meals taken per day (Tando Jam- $p < 0.000$ /Quetta- $p < 0.025$). At Tando Jam significant increase was reported in the intake of high starch food items, vegetables and fruits ($p < 0.000$). In Quetta significant increase was noted in the intake of plant protein ($p < 0.005$), dairy foods ($p < 0.041$) and vegetables ($p < 0.026$).

Conclusions: Nutrition education was successful in reducing undernutrition in food insecure households.

Key words: community-based intervention, nutrition education, Pakistan, undernutrition.

PO368

HEALTH BENEFICIAL CONSTITUENTS OF FOUR UNDERUTILIZED TROPICAL FRUITS

F. Wireko-Manu¹, A. Boaky¹, I. Oduro¹

¹Department of Food Science and Technology, Kwame Nkrumah University of Science and Technology (KNUST), Kumasi, Ghana

Background and objectives: Tropical fruits are postulated to have health benefits but many lack literature to support such claims and remain underutilised. This research was to document relevant data on the health potential of selected underutilised Ghanaian fruits; *Irvingia gabonensis* (African mango; pulp and seeds), *Artocarpus altilis* (breadfruit; pulp), *Annona muricata* (soursop; pulp) and *Annona squamosa* (sweetsop; pulp).

Methods: Commercially-mature fruits were obtained when in season and edible portions freeze-dried and stored at -20°C prior to analysis. Samples were screened for selected phytochemicals using standard methods and their total phenolics spectrometrically determined using the Folin-Ciocalteu procedure and calculated as gallic acid equivalent (GAE). The ascorbic acid contents (AAC) were determined titrimetrically using N-bromosuccinimide and the total antioxidant activity (AOA), determined spectrometrically by 2,2-diphenyl-1-picrylhydrazyl radical scavenging.

Results: Detected phytochemicals included tannins, triterpenoids, saponins, sterols, cardiac glycosides, flavanoids and coumarins. There was varying AOA ($P < 0.05$) for the samples with values ranging from 78% (African mango pulp) to 63% for breadfruit although the total phenolic contents were low with African mango seeds (hull included) having the highest (20.96 mg/100g GAE). However, positive correlations (+1.0000;

$P < 0.05$) existed between the phenolics and AOA of all the samples except for soursop and sweetsop which recorded negative correlations (-1.0000 ; $P < 0.05$). High AAC were obtained with values ranging from 20.32 mg/100g (sweetsop) to 62.52 mg/100g (soursop) except for African mango seeds with the least value of 1.04 mg/100g. Similar positive correlations existed between the AAC and AOA of soursop and African mango (pulp and seeds) while breadfruit and sweetsop recorded negative correlations.

Conclusions: The study provides evidence that the consumption of these fruits may significantly boost the health of consumers due to their free radical scavenging potential, appreciable ascorbic acid contents and inherent essential phytochemicals.

Key words: health potential, phytochemicals, underutilised fruits

PO369

EFFECT OF TRANS FATTY ACIDS ON BLOOD GLUCOSE LEVEL AND NECROSIS IN RATS

R. Sartika¹

¹Department of Public Health Nutrition, University of Indonesia, Indonesia

Background and objectives: Trans fatty acids are a type of polyunsaturated fatty acid. High intake of trans fatty acids can cause inflammation and lipid peroxidation of cell membranes, which in turn damage cells and tissues by destructing cell membrane and core components of the cell. The purpose of the study was to investigate the effect of dietary trans fatty acids on blood glucose level and necrosis in the pancreatic β cell.

Methods: An experimental laboratory, with a Randomized Pre-Post test control group design was conducted on 12 male Wistar rats were fed for 14 days with diets containing 43% energy as fat and 2% trans fatty acid.

Results: After intervention, feeding trans fatty acid was significantly increase the blood glucose level in the treatment group than in the control group ($p < 0.05$). The destruction in the pancreatic β cell is not obvious, however the number of normal cells in the treatment group (transfat diet) are found less than in the control group ($p > 0.05$).

Conclusions: There are metabolic implications due to the ingestion of trans fatty acid.

Key words: trans fatty acid, blood glucose, necrosis, pancreatic β cell

PO370**RISK FACTORS FOR PRELACTEAL FEEDING IN THE FIRST THREE DAYS OF LIFE IN SEVEN LATIN AMERICA AND CARIBBEAN COUNTRIES.***C. Boccolini¹, R. Pérez-Escamilla²*

¹Departament of Social Nutrition, Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil

²Department of Chronic Disease Epidemiology, Yale School of Public Health, Yale University, USA

Background and objectives: WHO recommends exclusive breastfeed for six months of life. We aim to identify the risk factors related to give other foods or liquids than breast milk (prelacteal feeding) in the first three days of life.

Methods: The present study used secondary data from seven countries (Colombia/2010, Bolivia/2008, Guiana/2009, Haiti/2005, Honduras/2005, Peru/2007 and Dominican Republic/2007), obtained from the Demographic and Health Surveys. A binomial regression (having “gave only breast milk” as reference category for the outcome) was adjusted, having country of residence, wealth index, place of residence (urban/rural), educational level, birth weight, cesarean delivery, place of delivery (home/hospital), and sex of child as confounders. All variables without statistical significance ($p < 0.001$) were excluded from the model.

Results: The final sample was 58,056 children: 51.3% were male and 51.6% were living in urban areas. In the first three days of life, 67.0% of the mothers gave only breast milk to their baby, 17.9% gave infant formula, 6.4% gave tea or infusions, 5.0% gave milk (other than breast milk), 2.0% gave plain water, and 4.5% gave other foods or liquids. Considering the binomial model, the adjusted Odds Ratio (OR) of giving other food or liquids (than breast milk) in the first three days of life was higher in Haiti (OR=6.65), Dominican Republic (OR=3.57), Guiana (OR=2.76), Peru (OR=2.39), Bolivia (OR=2.35) and Honduras (OR=2.21), having Colombia as reference. The OR were also higher among the richest (OR=1.46) mothers, with higher educational level (OR=1.33), cesarean delivery (OR=2.51), and delivery at home (OR=1.29). All variables had statistical significance ($p < 0.001$).

Conclusions: The high frequency of mothers that gave pre-lacteal feeding to their babies early in live support the investment in policies targeted to the most vulnerable countries and individuals, in order to promote, support and protect breastfeeding.

Key words: breastfeeding, pre-lacteal feeding, child health, nutrition, epidemiology

PO371**DEVELOPMENT OF A PREDICTION EQUATION FOR ESTIMATING FAT-FREE MASS AMONG CHILDREN WITH ACUTE LEUKAEMIA UNDERGOING IN-PATIENT CHEMOTHERAPY***S Y. Tan², B. Poh¹, M N. Ismail³, R. Jamal⁴, S. Chaudhary⁵, A. Kurpad⁵*

¹Physical Activity and Energy Metabolism Research Group, School of Healthcare Sciences, Faculty of Health Sciences, Universiti Kebangsaan Malaysia, Kuala Lumpur, Malaysia

²Division of Nutrition and Dietetics, School of Health Sciences, International Medical University, Bukit Jalil, Kuala Lumpur, Malaysia

³Department of Nutrition and Dietetics, Faculty of Health Sciences, MARA University of Technology, Puncak Alam, Selangor, Malaysia

⁴Department of Paediatrics, Faculty of Medicine, Universiti Kebangsaan Malaysia

⁵Division of Nutrition, Department of Physiology, St. John's Medical College, Bangalore, India

Background and objectives: Fat-free mass (FFM) is an important index for energy and fluid requirements; hence, its assessment is crucial for optimal clinical care and clinical outcomes among hospitalized patients. Objective: To validate the assessment of FFM using bioelectrical impedance analysis (BIA) Maltron BioScan 916 against deuterium dilution technique among paediatric patients diagnosed with acute leukaemia and to develop a prediction equation for estimating FFM among these patients.

Methods: Forty-seven paediatric patients aged 3-12 years, diagnosed with either acute lymphoblastic leukemia (ALL) or acute myelogenous leukemia (AML) and undergoing chemotherapy treatments participated in the study. FFM was measured using BIA and deuterium dilution technique was the criterion method. For the development of prediction equation, patients were randomly divided into developmental group ($n = 32$) and validation group ($n = 15$). Prediction equation was generated from the developmental group using stepwise multiple regression analysis, which was then applied to the validation group.

Results: There was no significant difference between predicted FFM (17.4 ± 4.6 kg) and measured FFM (17.3 ± 4.8 kg) in the validation group ($p > 0.05$), with a pure error of 2.0 kg, relatively close to the standard error of estimate (SEE) of 1.6 kg in the developmental group. Therefore, the total sample ($n = 47$) was used to develop a final prediction equation as $FFM = (0.418 \times \text{impedance index}) + (0.152 \times \text{height}) + (0.088 \times \text{waist circumference}) - 12.2$, ($R^2 = 0.935$, pure error = 1.6 kg and $SEE = 1.7$ kg).

Conclusions: Impedance index was the strongest predictor of FFM and its usage improved the accuracy and validity of BIA in predicting FFM. The prediction equation developed for estimating FFM among paediatric patients with acute leukaemia may be useful for a more effective prescription and monitoring of treatment among this patient cohort.

Key words: children, acute leukaemia, fat-free mass, stable isotope

PO372

INAPPROPRIATE NUTRITION PRACTICES AMONG CHILDREN IN NORTHEAST BRAZIL

S S. Neves², H A M. Silva³, P C. Almeida², H S. Oliveira¹, P H M. Sousa²

¹Instituto Federal de Educação, Ciência e Tecnologia do Ceará - Campus Crato, Brazil

²Universidade Estadual do Ceará, Brazil

³Universidade da Integração Internacional da Lusofonia Afro-Brasileira, Brazil

Background and objectives: Feeding in the first years of life has vital importance for the full development of children. Both exclusive breastfeeding until six months old and the proper introduction of complementary feeding contribute to prevent diseases and nutritional deficiencies. This study investigated dietary patterns among children under two years of age.

Methods: This cross-sectional study included 360 children, randomly selected residents in Redenção, Brazil. Mothers answered a closed questionnaire concerning breastfeeding and introduction of complementary feeding and a 24-hour dietary recall.

Results: It was found 24.7% of children under 6, 25.0% of 6-11,9 and 50.3% of 12-23.9 months of age. Some mothers were adolescents (13%) and only 32.2% finished high school. The prevalence of exclusive breastfeeding under six months was 34.8%. The average and median duration of it was 73.9 (SD = ±67.9) and 60 days, respectively. Regarding the introduction of complementary feeding, 69.1% of children received it in addition to breast milk, regular amount considered by WHO. Early introduction was common, occurring in 78.6%. The feeding consistency was: liquid (91%), for under 6; solid or semi-solid (72.2%), for 6-11,9 months; the family meal (67.4%) for children older than one year of age. The most mentioned foods were milk and dairy products (83.6%), cereals (82.5%) and fruits (52.8%). Meat and eggs were present in the diet of only 43.4%. The minimum frequency of meals, the WHO indicator, was observed in 98.2% of the children. The evaluation of diet quality through Diversity Food Minimum indicator showed that only 56.5% of them had a diversified diet. Only maternal education was associated with the early introduction of foods (p = 0.017).

Conclusions: The exclusive breastfeeding and complementary feeding are far from that recommended by the WHO, mainly due to fluid delivery. The feeding of children was not very diverse.

Key words: breastfeeding; complementary feeding.

PO373

DEVELOPMENT OF CEREAL ENRICHED WITH ACITAN

I. García¹, D. Hernández¹, E. Fonte², A. Campo²

¹LABIOFAM Entrepreneurial Group, Cuba

² Research Institute of Foodstuff Industry, Cuba

Background and objectives: During several stages of life the organism requires certain components as vitamins, minerals, dietary fiber and antioxidant substances, which play an important role in the health benefit. The present work had as an objective to rehearse some technological variants comparatively to obtain a cereal enriched with Acitán (powder of banana pseudostem), which is achieved as a sub product, during the culture of banana tree. -

Methods: Observational tests firstly with different concentrations of rice flour, sugar, maltodextrine, vanilla and cocoa as scents were performed. The presence of Acitán was among 5-10% in the studied formulation. Tests were designed to laboratory scale with the purpose of obtaining a product of long life whose quality indexes resembled each other to a traditional cereal. The selected product was elaborated in pilot lots and its main indexes of general quality were characterized. The nutritional information was designed according to the requirements of the Registration Office of the Nutrition and Hygiene of the Foods Institute, of the Cuban Public Health Ministry.

Results: organoleptic Characteristics: fine powder, homogeneous, appearance; brown color and smell to a fresh product. Nutritional composition, humidity % 4,67 ;protein % 10,06 ;ashes % 1,65 caloric value Kcal 375,42 ;carbohydrate % 83,48.

Conclusions: It is concluded that the cereal enriched with Acitán to 10% ,constitutes an option for the healthy feeding of children and adults.

Key words: Acitán, functional foods, cereal

PO374**IMPACT OF HOMESTEAD FOOD PRODUCTION ON THE NUTRITIONAL STATUS OF CHILDREN 12-48 MONTHS AND THEIR MOTHERS IN BAITADI DISTRICT, NEPAL**

A. Pries¹, A. Osei¹, P. Pandey², D. Adhikari³, N. Sharma², D. Davis², J. Nielsen⁴, V. Quinn⁵, N. Haselow¹

¹Helen Keller International, Asia Pacific Regional Office, Phnom Penh, Cambodia

²Helen Keller International, Kathmandu, Nepal

³US Agency for International Development, Kathmandu, Nepal

⁴Helen Keller International, New York, USA

⁵Helen Keller International, Washington DC, USA

Background and objectives: In Nepal, stunting, wasting, underweight and anemia affects 41%, 11%, 29% and 46% of preschool children, respectively. The impact of nutrition-sensitive agriculture interventions on child growth and anemia has not been clearly elucidated. We assessed the effect of a 3-year homestead food production (HFP) project on anthropometrics and anemia among children 12–48 months and their mothers in Baitadi district, Nepal.

Methods: This study utilized a multi-stage cluster randomized, controlled design. Cross-sectional data were collected from 2,106 and 2,614 mother-child pairs at baseline and post-intervention, respectively, in villages assigned to receive HFP activities (treatment) or not (control). Bivariate results are presented; multivariate results will be ready later.

Results: Between baseline and post-intervention, food secure households improved by 26 percentage points in treatment compared to 9 percentage points in control communities. The proportion of treatment children fed the WHO-recommended minimum acceptable diet improved by 44 percentage points compared to 6 percentage points among control. Stunting and wasting were similar for baseline and post-intervention in either group. Underweight was significantly lower post-intervention (40.6%) compared to baseline (48.0%) in control, but remained the same among treatment children (43.4% vs. 41.0%). Anemia was significantly higher post-intervention than at baseline among control (42.5% vs. 31.6%), but remained similar among treatment children (30.8% vs. 28.2%). While underweight did not change among treatment mothers (28.2% vs. 26.6%), post-intervention underweight (23.0%) was significantly higher than baseline (17.5%) among control mothers. Anemia was higher post-intervention than at baseline in both treatment (24.6% vs. 19.6%) and control (35.8% vs. 21.1%) mothers, but increased less in the treatment group.

Conclusions: This study indicates HFP improved household food security and child feeding practices, and had a potentially positive impact on childhood and maternal anemia and maternal underweight. However, there was no demonstrated impact on childhood stunting, underweight and wasting.

Key words: children, homestead food production, anemia

PO375**EFFECTS OF A FERMENTED MILK PRODUCT ENRICHED WITH PROTEIN AND FIBRE TO SATIATION AND WEIGHT REDUCTION**

H. Stritecka¹, P. Hlúbik¹

¹University of Defence, Faculty of Military Health Sciences, Hradec Kralove, Czech Republic

Background and objectives: Weight management is aided by limiting calorie intake, which in turn is achieved by controlling meal/portion size and appetite and reducing hunger pangs. The desire to eat (appetite) is influenced by the contrasting feelings of hunger and fullness. Aim of the study: To investigate the effect of consumption of a milk product enriched with protein and fibre on self-reported measures of appetite in subjects managed their weight. Study group: 200 healthy, female volunteers, aged 20 to 45 years, were divided into 2 groups of 150 subjects in the test group and 50 subjects in the control group. All of volunteers were non-smokers. Subjects with known allergy to milk proteins or intolerance to lactose were excluded.

Methods: Subjects were provided with sufficient product to eat up to 1 pot/day for 14(+1) days. They had to eat at least 1 pot per day. The total duration of the study was approximately 3 weeks for each subject, 1 week lead-in phase followed by 2 week test phase, with 2 assessments of appetite measures using a self-reported questionnaire (SRQ) at 2 and 4 weeks.

Results: Evaluation of the time of satiation after eating of investigated product was found out relationship between consumption of this product and time of satiation. Group consumed this product reported satiation longer than 2,5 hour (31,6 %) and longer than 3 hour (7,5 %) vs. group consumed normal yogurt longer than 2,5 hour (20 %) and longer than 3 hour (4%).

Conclusions: The results showed higher satiation at group with consumed fermented milk product enriched with protein and fiber than group consumed only “normal” yogurt. It is better for obese people to eat this type of milk product for decrease of meal portion.

Key words: satiation, weight reduction, obesity, fibre

PO378

POLISH CONSUMER ATTITUDES TO REDUCE FAT CONTENT IN MEAT

M. Kosicka-Gębska¹, J. Gębski¹

¹Warsaw University of Life Science, Warsaw, Poland

Background and objectives: Due to the presence of many diet-related diseases, which one of the causes may be eating meat, many countries take action to reduce the amount of fat in it. In Poland, in order to get to the level of consumer acceptance of innovative activities involving the lower the fat content of the meat in order to improve the nutritional value of quantitative national survey was conducted.

Methods: The survey was conducted on a sample of 1000 people. To assess the benefits and risks of using the process of lowering the fat content of the meat used 6-point scale (where 1 - high, 2 - rather large, 3 - neither big nor small, 4 - rather small, 5 - small, 6 - none).

Results: The analysis of empirical data led to the conclusion that Polish consumers are positive about the removal of fats, including meat fat to improve the health and nutritional values. Over 70% of respondents accept such an effect. More than three fifths of respondents perceived the 'big' or 'fairly large' benefits of this process, with two fifths of respondents indicated the 'small' or 'rather small' risk. The benefits of reducing the fat content in meat saw significantly more consumers coming from rural areas (64.1%), those with medium (64.4%) and higher (61.7%), education, evaluating their knowledge of nutrition as well as the financial position of the 'very bad' and 'bad' level (respectively 73.9% and 66.3% and 61.0% and 70.6%). The lack of consumer benefits from a reduction in the fat content of the meat frequently pointed out the inhabitants of large cities, evaluators and nutritional knowledge to perceive the financial position of the 'very good' level, as well as possess a basic and higher education.

Conclusions: Respondents who took part in the study empirical accept the removal of fat from the meat, but other studies have shown that consumers are generally so much they do not accept the changes used in food products because of the fear of new foods appearing on the market (Jeżewska-Zychowicz and Babicz-Zielinska, 2011; Siro et al., 2008) and adverse modification used in traditional foods (Gutkowska et al., 2009). However, interest in products with less calories found in consumers of other nationalities (McNeil et al., 2012, International Food ..., 2009, O'Dea et al., 1996).

Key words: meat, lower fat content, the level of acceptance

PO379

BAMBARA GROUNDNUT, VIGNA SUBTERRANEA AS A PANACEA FOR MALNUTRITION IN DEVELOPING COUNTRIES LIKE NIGERIA

J. Atoyebi¹, B. Esan², S E. Aladele¹

¹National Centre for Genetic Resources and Biotechnology, Moor-Plantation, Ibadan, Nigeria

²Babcock University, Ilishan – Remo, Ogun – State, Nigeria

Background and objectives: In low- and middle-income countries, statistics revealed that approximately 925 million people are hungry, with 125 million and 195 million children underweight and stunted, respectively. Developing countries like Nigeria, though still trying to fulfil the Millennium development goal (MDG 1) in eradicating poverty and hunger are the worst hit by food insufficiency crisis in the world. However, neglected and under-utilised (NUS) plants like Bambara nut (*vigna subterranea*), even though beneficial, are not given adequate priority by both government and farmers in the value chain system, whereas if well tapped could solve the problems of malnutrition and food sufficiency, especially using novel biotechnology tools. This review paper accesses how this could be done.

Methods: The review addressed the utilization potential of bambara nut among the 36 states of Nigeria. Addressing the global challenge of micronutrient malnutrition requires the need for many strategies including short, intermediate and long-term sustainable approaches. Hence in addition to the conventional approaches of micronutrient supplementation and fortification, promoting sustainable food-based approaches to enable adequate intakes of micronutrients in bambara nut is researched into, to proffer a way out for developing nations to solve malnutrition problems.

Results: There needs to be improved awareness among the Nigerian populace and other developing nations of the benefits inherent in the consumption of NUS plant like bambara nut, as a way of getting adequate dietary micronutrients into the body system and thus solving the problem of food insufficiency in the country.

Conclusions: This review suggests that accelerating progress toward the achievements of the MDG1 targets is about the development of novel approaches and technologies towards increased focus in utilizing the NUS, like bambara nut to solving the problems of malnutrition and food insufficiency among developing nations.

Key words: Biotechnology, malnutrition, NUS plants, developing countries

PO380**FTO GENE EXPRESSION UNDER LOW OR HIGH GLYCEMIC INDEX (GI) DIET IN PREGNANT MICE AND PUPS**

T. Sideratou¹, K. Bell-Anderson¹, J. Brand Miller¹

¹Human Nutrition Unit, School of Molecular Biosciences, The University of Sydney, Sydney, NSW, Australia

Background and objectives: Fetal tissues and organs experience critical periods of rapid development and cell division. Fetal nutrition via the placenta will program the distribution of cell types, hormonal feedback and activity. The mother's diet therefore shapes the metabolic programming of her fetus. The fat mass and obesity associated gene (FTO) is related to leptin levels and obesity-related traits. Our hypothesis is that expression of FTO gene in tissues of pups of the low glycemic index (GI) diet-fed mothers will be lower than those of high GI diet-fed mothers. We aim to examine whether different GI isocaloric diets influence FTO gene expression.

Methods: Before mating and throughout pregnancy, female mice (n=30) were fed either a high or low GI diet. Placentas from half of each group were recovered at mid-gestation. Male pups (n=40) of both groups were weaned at aged 4 weeks and were further divided into 2 subgroups, one following their mothers' diet and one following a standard diet. The pups' weight and glucose and insulin tolerance were tested regularly until aged 5 months. Pups were then sacrificed and tissues collected for gene analysis and other investigations.

Results: Preliminary results indicate that mice exposed to a low GI diet show lower glucose responses. Liver histology indicates only high GI fed mice show signs of a loss of normal architecture and signs of inflammatory cells. From all tissues, Hypothalamic FTO gene expression was significantly increased in the high GI fed mice.

Conclusions: This study allows the investigation of the effects of nutritionally different regimes on FTO gene expression in specific tissues. We show that a low GI diet can differentially regulate the FTO gene expression, therefore, the risk of obesity. Targeted interventions during pregnancy may reduce the risk of childhood and adult obesity.

Key words: Fto gene, Glycemic index, metabolic programming

PO382**MATERNAL SELF-EFFICACY AND LIFE STYLE BEHAVIORAL PROBLEMS OF THE CHILD RELATED TO WEIGHT IN DYADS RESIDING IN NORTHEASTERN MEXICO**

Y. Flores-Peña¹, L L. Rocha-Aguirre², V M. Cárdenas-Villarreal¹, C M. Alba-Alba¹, R G. Hernández-Carranco¹, R M. Cerda-Flores¹

¹Universidad Autónoma de Nuevo León, Facultad de Enfermería, México

²Universidad Autónoma de Zacatecas, Departamento de Ciencias de la Salud, México

Background and objectives: All mothers, particularly mothers of overweight (OW) and OB children; face the child's lifestyle behaviors related to eating, physical activity, and weight issues. Objectives were: 1) Assess differences in maternal perception of their child's lifestyle – problem behavior (PB) and self-efficacy (SE) in managing these problems in two groups of mothers, and 2) Assess the relationship between PB and SE.

Methods: Participated 367 dyads (mother – child). Mothers answered the Lifestyle Behavior Checklist (LBC). Weight and height of mothers and children were measured. One group of mothers was mothers with normal weight children (NW) and b) mothers with OW-OB children. The reliability of the LBC scale was calculated, and were apply descriptive statistics, Test F, and Pearson's correlation coefficient.

Results: Cronbach alpha for the problems scale was $\alpha = .86$, and $\alpha = .96$ for the confidence scale. In both groups of mothers, PB with the highest mean was "watches too much television"; no significant difference was identified ($F = .232$, $p = .630$). The lowest SE mean in mothers of OW – OB children was "watches too much television" (Mean 7.83, SD = 1.81), and for de mothers with NW children was "refuses to eat certain foods" (Mean 8.32, SD = 1.78), with significant difference. Significant negative correlation between PB and SE was identified in both groups; mothers of NW children ($r = -.527$, $p = .001$) and mothers of OW – OB children ($r = -.461$, $p = .001$).

Conclusions: The LBC in Spanish was reliable. When the mothers perceived more problems, they had lower self-efficacy in managing PB. It is necessary to work with mothers in order to increase their SE; evidence supports the conclusion that SE affects the quality of care provided to children.

Key words: Self efficacy, Life style, Behavior, Body Weight

PO383**EFFECT OF WATER EXTRACT PHYSALIS AN-
GULATA L ON LIPID PROFILE AND ANTIATHEROS-
CLEROSIS OF SPRAGUE DAWLEY MALE RATS
INJECTED BY STREPTOZOTOCIN-LIPOPOLYSA-
CHARIDE**

⁴Departement of Patology Anatomy, Faculty of
Medicine, Gadjah Mada University, Yogyakarta,
Indonesia

Background and objectives: Prevalence of Diabetes Mellitus among adult in Indonesia reached 4,1% in 1995 and projected to 6,5 % in 2025. Hyperglycemia in patients with diabetes mellitus increases oxidative stress and endothelial dysfunction which plays role in atherosclerosis development and is an early sign of vascular disease in diabetes. Treatment of Diabetes Mellitus has done in a long period and numerous drugs mechanism action. Ciplukan herb (*Physalis angulata* L) is one of plants that have been used as anti-diabetic. The purpose of the research was to determine the effects of herbs water Ciplukan (*Physalis angulata* L) on lipid profile and antiaterosklerosis in insulin resistant rats.

Methods: This is true experiment designs with post-test only control group design, using randomized control trial. Twenty four rats, divided into 4 groups. STZ and LPS injections were given to make T2DM rats and complications. Assay of cholesterol, triglycerides, LDL and HDL using a reagent kit. Observation of atherosclerosis in the aorta preparations rats using histopathologic techniques with haematoxylin-eosin staining.

Results: Providing a wide variety of herbal extracts dose Ciplukan can decrease blood cholesterol levels, blood triglyceride levels, blood LDL levels and increase HDL blood levels of DM rats. The results of the analysis in the treatment group, showed that almost in all groups were significantly different for cholesterol, while LDL only in the K1 and K4 and significantly reduced atherosclerosis frequency in aorta.

Conclusions: Provision of varies water extracts Ciplukan herbs dose can reduce cholesterol, triglycerides, LDL, and raise HDL levels. Dose of 20 mg/kg body weight can reduce cholesterol and LDL levels and regenerates atherosclerosis injury in diabetic blood vessel.

Key words: Ciplukan herbs (*Physalis angulata* L), lipid profile, antihyperkolesterolemia, antiatherosclerosis.

PO384**POTENCY OF CIPLUKAN HERBS (PHYSALIS AN-
GULATA L) AS AN ANTIHIPERGLYCEMIA AND AN-
TIHYPERLIPIDEMIA IN SPRAGUE DAWLEY MALE

Background and objectives: Diabetes Mellitus type 2 (DMT2) is a disorder that has characteristic hyperglycemic conditions, impaired metabolism of carbohydrates, fats, and proteins are characterized by insulin resistance and or insulin deficiency. Hyperglycemia in patients with diabetes mellitus increases oxidative stress and endothelial dysfunction. *Physalis angulata* L is one of plants that have been used as antidiabetic. This study was conducted to find out potency of *Physalis angulata* L on serum glucose and lipid profile of DMT2 rats.

Methods: This research was true-experimental using pre and post test control group design. Samples were male Sprague Dawley rats, 3 months old, induced hyperglycemia and complication, given extract water of *Physalis angulata* L using 20 mg/kg BW dose for 21 days. The content of blood glucose, total cholesterol, HDL, LDL, and triglyceride were measured using enzymatic method. Normality of the data were tested by Shapiro Wilks test. Data were analyzed by paired t test and Anova continued by LSD test using computer program.

Results: The water extracts of *Physalis angulata* L can decrease blood glucose levels, blood cholesterol levels, blood triglyceride levels, blood LDL levels and increase HDL blood levels of DM rats. The results of the analysis in the treatment group, showed that almost in all groups were significantly different for glucose levels, cholesterol levels, blood triglyceride levels, blood LDL levels and increase HDL blood levels.

Conclusions: From the above results concluded that the water extracts of *Physalis angulata* L herbs dose of 20 mg/kg body weight can increase the potency of antihyperglycemic and antihyperlipidemic in single use.

Key words: Ciplukan herbs (*Physalis angulata* L), antihyperglycemia, antihyperlipidemia, blood sugar level, lipid profile.

PO385**IN VITRO DETERMINATION OF GLYCEMIC RESPONSE**

K. Argyri¹, A. Athanasatou¹, M. Bouga¹, M. Kapsokefalou¹

¹Department of Food Science and Technology, Agricultural University of Athens, Athens, Greece

Background and objectives: In vitro models that predict the bioavailability of dietary components have been extensively used as screening tools in nutrition. High blood glucose concentration is a risk factor for a number of diseases; therefore, blood glucose response to foods remains a very relevant biomarker on which to base values to guide selection of foods. Our objective was to develop an in vitro method that predicts the glycemic response.

Methods: An in vitro digestion procedure that predicts the bioavailability of mineral was adapted to mimic carbohydrate digestion. Index for glycemic response was the concentration of glucose in the soluble low molecular weight fraction of the digests. To evaluate our method, we compared a) published values on glycemic index (GI) or glycemic load (GL) for 13 food items and b) determined GL values for 15 meals with predicted glycemic response, obtained after subjecting these meals to our in vitro procedure.

Results: The correlations were significant when comparing predicted glycemic response, using the in vitro procedure, with published GL (Spearman's rho=0.953, p=0.000), or GI (Spearman's rho=0.883, p=0.002) for 13 foods and with glucose response in humans to 15 meals (Spearman's rho=0.736, p=0.003 at 120 min after consumption).

Conclusions: These results demonstrate a useful method to predict glycemic response in humans. Further exploitation of this approach may open up the way to the development of novel products with low postprandial glycemic responses.

Key words: glycemic response, glucose, glycemic load, in vitro, glycemic index

PO386**LIPIDOMIC PROFILING OF CHYLOMICRON TRIACYLGLYCEROLS IN RESPONSE TO HIGH FAT MEALS**

K. Linderborg¹, M. Bonham², P. Meikle³, A. Sinclair⁴, H. Kallio¹

¹Department of Biochemistry and Food Chemistry, University of Turku, Finland

²Department of Nutrition and Dietetics, Monash University, Australia

³Baker IDI Heart and Diabetes Institute, Australia

⁴Metabolic Research Unit, Deakin University, Australia

Background and objectives: Postprandial chylomicronaemia is a non-steady state condition with rapid remodelling of lipoproteins. The chylomicron triacylglycerol (TAG) composition is a function of several mechanisms including TAG hydrolysis in the gut, transfer of hydrolysis products to mucosal cells, TAG reassembly, TAG clearance from blood, and remnant uptake by the liver. These steps may be affected by differences in the molecular species of TAG ingested. Novel lipidomics, i.e. the molecular level tandem mass spectrometric analysis methods can reveal the selective formation and/or clearance of individual TAG in humans.

Methods: Several different tandem mass spectrometric methods were applied to human chylomicron TAG samples obtained from postprandial cross over trials. The meals served to healthy volunteers included dairy fat, vegetable oil, olive oil and olive oil enriched with polyunsaturated fatty acids of the omega-3 series.

Results: The fatty acid of the sn-2 position was conserved from the meal to chylomicron TAGs. Remodelling changes were seen between the meal and chylomicron TAGs. For example, in dairy and vegetable oil-based chylomicrons, there was a loss of trisaturated- and disaturated-TAG species and an increase in some mono- and di-unsaturated TAG species compared with the food TAG. Significant differences were found in the chylomicron TAG composition during the postprandial period, especially between the first and following hours.

Conclusions: In the frequently applied analytical procedures for characterization of fats, such as in the fatty acid composition analysis, the individual TAG molecular species are overlooked. Lipidomic Methods reveal the dynamic or non-steady state of postprandial TAGs in chylomicrons. This dynamic state is likely to be a reflection of differential rates of CM secretion and clearance which is regarded as a determinant of postprandial chylomicron accumulation and a risk factor for cardiovascular diseases.

Key words: Triacylglycerol, tandem mass spectrometry, lipidomics, postprandial lipemia

PO387

FATTY ACIDS PROFILE OF CAMEL MEAT

S. Naima¹, D. Olivier², B E. Mohamed¹, B. Saliha³, B. ba-baïssav³, G. Djamel¹, H. Jean-Luc²

¹Blida University, Algeria

²Liege University, Liège, Belgique

³Ouargla university, Algeria

Background and objectives: The camel is an animal often found in the Sahara. Camel meat is one of the main food resources for the autochthon population. Consumption of this meat is preferred for its organoleptic perception. This species is related to an environment with limited and random resources. In arid and semi-arid areas, this species is known for its resistance to thirst, heat and protein and mineral undernutrition. It's used for the meat production essentially. The quality of the meat depends on the content of fatty acids. The objective of this study was to determine the fatty acid composition of camel meat produced in Algeria.

Methods: The content of fat camel meat was determined from 61 samples of 61 camels in Ouargla slaughterhouse (Algeria). For these analyzes, we considered three factors in fatty acid content (age, sex and breed).

Results: Our results showed that the average content of ether extract of meat samples is equal to $16.3 \pm 1.6\%$, and the meat has the highest levels of saturated fatty acids which represent 54.6% of total acids, predominantly of C16: 0 and C18: 0 up to 48.8% and 39.3% respectively. The meat is rich also in monounsaturated fatty acids (35.0%), with a predominance of C18: 1cis9 up to 79.7%. Camel meat represented 10.4% of polyunsaturated fatty acids of total fatty acids which 8.0% are ω 6 and 1.9% is ω 3. We also note that the PUFA/SFA equal to 0.25 and ω 6/ ω 3 = 4.1. The statistical model used is covariance analysis followed by Student's test or ANOVA. No effect of age or breed could not be demonstrated for the various parameters (AGS, MUFA, PUFA, ω 6, ω 3, P / S and ω 6/ ω 3). Analysis by Student's t test showed that only the percentage of SFA (saturated fatty acids) of the total fatty acids was significantly higher in males (57.8% against 48.1%, $p=0.003$). Thus, the percentage of ω 6 was significantly higher in females (14.6% against 4.7%, $p=0.004$). The same observation was made for the percentage of ω 3, which is higher in females (2.95% against 1.44%, $p=0.016$). Overall, the percentage of PUFA (polyunsaturated fatty acids) (ω 6+ ω 3+cis9trans11CLA) is significantly higher in females (18.0% against 6.7%, $p=0.005$). The P/S and ω 6/ ω 3 are significantly higher in females 0.499 against 0.123 ($p=0.006$) and 5.35 against 3.51 ($p=0.006$) respectively. These results show that females have interesting nutritional characteristics. This maybe related with fatness of the carcass where it appears that the leaner animals, i.e., females have often a percentage of unsaturated fatty acids higher than males.

Conclusions: Nothing is opposed, in our opinion, the establishment of channels production and marketing of camel meat for its particular nutritional characteristics.

Key words: camel meat, saturated fatty acids, polyunsaturated fatty acids.

PO388

PREVALENCE OF STUNTING AND WASTING AMONG SCHOOL CHILDREN IN A RURAL AREA OF MOROCCO

M. EL Hioui¹, F Z Azzaoui¹, A. Ahami¹, Y. Aboussaleh¹

¹Equip of Clinic and Cognitive Neurosciences and Health, Laboratory of Biology and Health, Department of Biology, Faculty of Science, IBN TOFAIL University Kenitra, Morocco

Background and objectives: Malnutrition is one of the greatest problems facing developing countries, including rural regions of Morocco, in terms of wasting and stunting among school children. The aim of this study was to determine the prevalence and the risk factors associated with stunting and wasting among school children in a rural area of ANTI Atlas of Morocco.

Methods: The prevalence of stunting and wasting were calculated according to WHO recommended cut-off points to define stunting and wasting. Chi-square tests, logistic regression analysis were used to investigate the relationship between the prevalence of stunting and wasting and the sociodemographic factors.

Results: A total of 162 children (64 boys and 98 girls), aged 12 - 15 years. Results revealed 22.8% of stunting and 35.2% of wasting. Child age ($p = 0.027$), illiteracy of the mother ($p = 0.004$) was determinant factors with wasting. Stunting was significantly associated with gender ($p = 0.03$) and parents' employment ($p = 0.009$).

Conclusions: In this area of study, Malnutrition remains a major problem among school children. Parents' Level education and stunting were determinant factors in this health problem.

Key words: Malnutrition, stunting, wasting, school children, morocco

PO389**PREVALENCE AND DETERMINANTS OF VITAMIN D DEFICIENCY IN ADULTS AGED 65 YEARS AND OVER.**

F. Granado-Lorencio^{1,2}, *I. Blanco-Navarro*^{1,2}, *B. Pérez-Sacristán*¹, *E. Donoso-Navarro*², *R A. Silvestre-Mardomingo*²

¹Unidad de Vitaminas, Servicio de Bioquímica Clínica, Hospital Universitario Puerta de Hierro-Majadahonda

²Servicio de Bioquímica Clínica, Hospital Universitario Puerta de Hierro-Majadahonda

Background and objectives: In the elderly, malnutrition is a highly prevalent condition and a major contributor to increased morbidity and mortality. Dietary intake surveys indicate that vitamin inadequacy is widespread even in apparently healthy elderly. Our aim was to assess the nutritional status of vitamin D in subjects > 65 y and its relationship with demographic and nutritional factors, acute phase reactants and renal function.

Methods: Serum 25-OH-vitamin D was determined by ultra-fast liquid chromatography in 304 subjects >65 years (75.5 y ± 7.3; 211 women). Potential determinants of vitamin D status were also recorded if available including sex, age (65-75 y, 76-85y and 86-100y), season (official calendar dates), origin of the sample (hospitalized versus non-hospitalized (out-patients)), nutritional markers (albumin, total cholesterol), acute-phase reactants (ferritin, C-reactive protein (CRP)) and renal function (serum creatinine, glomerular filtrate).

Results: Mean (CI 95%) serum levels of 25-OH-D was 48.1 nmol/l (44.3, 52.0) and the prevalence of vitamin D deficiency (<50 nmol/l) reached 63%. Serum 25-OH-D correlated with serum albumin (r= 0.31, p<0.001), CRP (r=-0.24, p=0.052) ferritin (r=-0.25, p=0.009) and creatinine (r=-0.21, p=0.014). A significant decreasing trend was observed across the three age groups and the prevalence of deficiency changed from 53% (65-75y) to 84% (85-100y). Vitamin D deficiency also varied depending on the season (48-52% in summer-fall, 73-74% in winter-spring), and according to the origin of the sample, reaching a prevalence of 94% in hospitalized patients. Subjects with low serum albumin and acute phase response (high levels of ferritin and CRP) consistently displayed lower serum concentrations of vitamin D.

Conclusions: In the elderly, prevalence of inadequate vitamin D status is high. Age, season, hospitalization, poor nutritional status and presence of inflammation significantly affect the serum levels of 25-OH-vitamin D and thus, the prevalence of vitamin D deficiency.

Key words: Vitamin D, Vitamin deficiency; elderly, malnutrition.

PO390**DETERMINATION OF 3 EPI-25-OH-VITAMIN D3 IN INFANTS: IMPACT ON VITAMIN D STATUS ASSESSMENT**

F. Granado-Lorencio^{1,2}, *L. Muñoz Garcia-Heras*², *I. Blanco-Navarro*^{1,2}, *B P. Sacristán*

¹Unidad de Vitaminas, Servicio de Bioquímica Clínica, Hospital Universitario Puerta de Hierro-Majadahonda, Madrid, Spain

²Servicio de Bioquímica Clínica.Hospital Universitario Puerta de Hierro-Majadahonda, Madrid, Spain

Background and objectives: In addition to bone disorders, vitamin D deficiency in infants has been associated with a wide range of adverse health outcomes in later life.

Methods: A total of 95 (surplus) serum samples of infants (< 1 year) were randomly collected. Levels of 25-OH-D3 and 3-epi-25-OH-D3 were assessed by HPLC (Tai et al., Anal. Chem., 82, 1942-48, 2010). Identification was done by chromatographic behaviour, on-line UV-Vis spectra and co-injection/co-elution of spiked samples.

Results: 3-epi-25-OH-D3 could be quantified in 70 samples (74%). Mean (95% CI) concentration of 25-OH-D3 and 3-epi-25-OH-D3 were 70.5 nmol/l (60.9, 80.2) and 32.1 nmol/l (25.8, 38.4), respectively. Mean (95%CI) of total 25-OH-D3 (sum of both epimers) was 102.6 nmol/L (90.6, 114.7). The contribution of 3-epi-25-OH-D3 (%) was 30.5 (95% CI; 25.9, 35.0; range, 4.4- 74.9%). Levels of 3-epi-25-OH-D were higher in infants <1 month (n=25) than in >1 month-12 months (n=45) (mean (95% CI); 42.1 nmol/l (30.5, 53.7) versus 26.5 nmol/l (19.3, 33.8), p=0.018). Similarly, the contribution of 3-epi-25-OH-D3 was higher in younger infants (39.8 % (31.4, 48.3) versus 25.3% (20.5, 31.0), p=0.002). Using total 25-OH-D3 levels as the reference to assess vitamin D deficiency (< 50 nmol), 71% (15/21) of infants were (mis)classified as vitamin D deficient based on 25-OH-D3 levels, reaching 85% (11/13) in those <1 month.

Conclusions: Although the physiological role of the C3-epimer remains unclear, 3-epi-25-OH-D3 should be determined for the accurate assessment of the vitamin D status in infants. Assessment of vitamin D status based on 25(OH)D3 levels may lead to misclassification compromising clinical decisions.

Key words: 25-hydroxyvitamin D3; 3-epi-25-hydroxyvitamin D3; Vitamin D deficiency.

PO391**CORRECTION OF PLASMA FERRITIN CONCENTRATIONS FOR SUB-CLINICAL INFLAMMATION IN A MALARIA-ENDEMIC AREA OF COTE D'IVOIRE**

C. Northrop-Clewes¹, F. Rohner^{1,2}, G. Raso^{3,4}, O. Aké⁵, A. Tschannen³, N. Mascie-Taylor⁶

⁴Swiss Tropical and Public Health Institute, Basel, Switzerland

⁵Institut National de Santé Publique, Abidjan, Côte d'Ivoire

⁶Department of Biological Anthropology, University of Cambridge, Cambridge, United Kingdom

Background and objectives: Many plasma biomarkers are influenced by inflammation resulting in either a depression or increase in their concentration. When the nutritional biomarker is increased, such as ferritin concentrations, inflammation will result in an underestimation of iron deficiency. It is therefore important to measure biomarkers of inflammation as well as of nutrition in surveys of nutritional status in apparently-healthy people. Objective: To correct plasma ferritin concentrations for inflammation in a malaria-endemic area.

Methods: Pre-school children (Pre-SAC) were recruited as part of a cross-sectional survey in a rural and urban area of Côte d'Ivoire. Plasma ferritin, C-reactive protein (CRP) and α -1-acid glycoprotein (AGP) were analyzed by ELISA. Ferritin concentrations were adjusted for inflammation using the meta-analysis of Thurnham et al (AJCN 2010,92:546). Microscope slides were examined for Plasmodium parasites.

Results: Overall, 49.8% and 39.2% of Pre-SAC had elevated AGP and CRP concentrations, respectively, with differences by residency; elevated AGP and CRP concentrations were 2.5 times and 2.8 times more prevalent in rural children ($p < 0.001$). Plasmodium parasites were found in 45.8% of rural and 7.5% urban Pre-SAC ($p < 0.001$). Adjusted geometric mean ferritin concentrations were significantly higher in the rural area (45.2 μ g/L compared with 29.3 μ g/L in the urban area; $p < 0.001$). Plasmodium parasites increased mean ferritin concentrations 62.9 μ g/L compared with 42.5 μ g/L in non-infected Pre-SAC ($p < 0.001$), and after correction for age, sex and residency there was still a residual difference in ferritin concentrations between those with and those without parasites (+12 μ g/L; $p < 0.0001$).

Conclusions: Concentrations of ferritin, after adjustment for inflammation, showed residual differences of +12 μ g/L in those with Plasmodium parasites, compared to those without, indicating that the meta-analysis correction for inflammation may not completely adjust concentrations when Plasmodium parasites are present.

Key words: malaria, ferritin, AGP, CRP, Pre-SAC.

PO392**COMPLEMENTARY FEEDING PRACTICES AND ACCEPTABILITY OF LIPID BASED NUTRIENT SUPPLEMENTS AMONG INFANTS IN RURAL WESTERN KENYA**

Background and objectives: Micronutrient-rich complementary foods are essential to meet infant nutrient requirements and improve growth.

Methods: Within the context of a pilot randomized trial of water, sanitation, hygiene and nutrition interventions, we evaluated the feasibility and acceptability of lipid-based nutrient supplements (LNS) for young children during a two-month in-home trial. In October 2011, we used a standardized 24 hr recall to estimate frequency of consumption of target food groups and generate an indicator of dietary diversity. Among a 50% subsample, we obtained a second infant 24 hr recall and a single infant and mother 7-day food frequency questionnaire (FFQ) in July 2012. In addition, we assessed LNS acceptability, usage and sharing. For this analysis, infants aged 6-24 months at baseline were included (n=269).

Results: Consumption of LNS on 6-7 days out of the prior week was reported by 73% of children and 89% of caregivers ranked the acceptability of LNS as 5 out of 5 ("Like it a lot"). Eleven percent of households reported sharing the LNS with other children. Children consumed a mean of 3.3 (SD \pm 1.1) food groups and 40.3% consumed \geq 4 food groups on the previous day. Animal source foods were consumed by 81% of infants, driven primarily by consumption of milk tea. We found an average increase of 1.0 (1.3) food groups during the study and a weak but significant correlation ($r=0.17$, $p=0.04$) between number of food groups consumed. Data from infant and maternal 7-day FFQs suggested lower dietary diversity among mothers compared to infants.

Conclusions: LNS has the potential to be highly acceptable in this region and should be incorporated into a broader behavior change package to improve complementary feeding practices. Acknowledgements: Supported by a grant to UC Berkeley from the Bill & Melinda Gates Foundation.

Key words: dietary diversity, complementary feeding, Kenya. Abstract category: Nutrition in infancy and childhood

PO393**DEFICIENCY OF SELENIUM IN CRITICAL CARE PATIENTS WITH SIRS**

J. Molina-López¹, M. Navarro¹, D. Florea¹, L. Sáez¹, A. Pérez de la Cruz², B. Quintero³, C. Cabeza³, M. Rodríguez Elvira²

¹Department of Physiology, Institute of Nutrition and Food Technology, University of Granada, Granada, Spain

²Units of Nutrition and Intensive Care, Hospital Virgen de las Nieves, Granada, Spain

³Department of Química Física, University of Granada, Granada, Spain

Background and objectives: Deficient status in selenium, a cofactor of the antioxidant enzyme glutathione peroxidase (GPx), together with hypercatabolic state, can affect the clinical course during the patient's stay in the intensive care unit (ICU). The resulting increase in oxidative stress has been recognized as a central mechanism in the pathophysiology of critical illnesses, particularly the appearance of multiorgan failure.

Methods: 65 critically ill patients in Granada province (southern Spain) who fulfilled the inclusion criteria: SIRS, APACHE score >15. Plasma selenium was measured with inductively coupled plasma mass spectrometry (ICP-MS). GPx activity was measured by reduction of organic peroxides by c-GPx, and selenoprotein-P was measured by immunoassay.

Results: On admission to the ICU, GPx was below reference (<5.6 U/mL) in 86.5% of the patients, decreased significantly to 60% (p<0.05) at day 7. Normal levels were not seen in any of the patient (>24 U/mL). At admission, 67.7% of the patients were selenium deficient, increasing significantly to 100% (p<0.05) at 7 day. Below-normal values of SEPP1 (<3.43 µg/L) were found in 77.3% of the patients on the day of admission, increasing to 100% at the end.

Conclusions: During their ICU stay, antioxidant GPx enzyme activity increased and plasma selenium decreased in patients studied. Selenium deficiency could lead to increased oxidative stress and increased demands on endogenous antioxidants, that could exhaust the available plasma stores of selenium. In patients admitted to the ICU, selenium intake should be monitored in order to ensure optimum antioxidant response and palliate the adverse effects of this nutritional deficiency.

Key words: Critical Care Patients, Selenium, Glutathione Peroxidase, SIRS, Nutrition

PO394**IMPACT OF SPIRULINA ON THE EVOLUTION OF THE ANTHROPOMETRIC, BIOCHEMICAL AND HAEMATOLOGICAL PARAMETERS OF HIV-INFECTED ADULTS IN OUAGADOUGOU, BURKINA FASO**

F. Bationo¹, G. Ouédraogo¹, S. Kouanda¹, B. Sondo¹

¹Research Institute of Health Sciences, Ouagadougou, Burkina Faso

Background and objectives: Malnutrition is one of the characteristics of patients infected by the human immunodeficiency virus. It is accompanied by a weight loss and a degradation of the overall condition associated with proteins and micronutrients deficiencies. Spirulina is an edible microalga, naturally rich in proteins, in vitamins, essential fatty acids, carbohydrates and other trace elements. The objective of the study is to assess the impact of a supplementation with Spirulina on the evolution of the anthropometric, biochemical and haematological parameters of HIV-infected adults in Ouagadougou.

Methods: it is about a quasi-experimental pilot study with two arms on adults infected with HIV-1 in Ouagadougou. In addition to antiretroviral treatment a group of 50 patients was supplemented with 10 grams of Spirulina per day. The control group of 50 patients received only an ARV treatment.

Results: In the two arms of the study, the anthropometric and biological parameters increased over time. The mean values were higher for the patients on Spirulina in the 9th month as far as Mid-Upper Arm Circumference (MUAC) (p=0.007), hemoglobin (p=0.002), and creatinemia (p=0.01) are concerned. A significant decline of gamma globulins was observed in the 6th month for the patients on Spirulina compared to the control patients (p=0.04). No difference in the evolution of ALAT and amylasemia was noticed between the 2 groups.

Conclusions: The 10 grams of Spirulina per day used in our study showed a positive effect on some vital biological parameters. Randomized clinical trials on large samples with longer follow-up are necessary to test these assumptions.

Key words: Spirulina, HIV, anthropometric, haematological.

PO395**PREVALENCE OF ANTHROPOMETRIC DEFICITS AND INADEQUATE PROTEIN-ENERGY INTAKE IN ADULTS WITH SICKLE CELL ANEMIA**

M L. Portela de Santana¹, A. Silva Araújo², E. Jesus Pinto³, R. Passos Jesus¹

¹Department of Nutritional Science, School of Nutrition, Federal University of Bahia, Salvador de Bahia, Brazil

²Roberto Santos Hospital, Salvador de Bahia, Brazil

³Post graduation Program of Medicine and Health, Federal University of Bahia, Salvador de Bahia, Brazil

⁴Department of Nutritional Science, School of Nutrition, Federal University of Bahia, Salvador de Bahia, Brazil

Background and objectives: Individuals with sickle cell anaemia have several clinical conditions that associated to frequent hospitalizations, as well as to precarious economic conditions, can negatively impact in the food intake, predisposing them to increased malnutrition risk. The objective was to evaluate the prevalence of anthropometric deficit and inadequate energy-protein intake.

Methods: It is an unpaired comparative study, including sickle cells anaemia adults and those without hemoglobinopathy, of both sexes. We used the Body Mass Index (BMI) to evaluate the anthropometric status and the body composition was identified by the body fat percentage (BF%) and by the corrected arm muscle area (CAMA). The dietary intake was measured by two 24-hour recall. To analyse the inadequate protein-energy intake risk it was used the approach proposed by the Institute of Medicine of the United States. Proportions were compared using the chi-square test or Fisher test. The associations were evaluated by odds ratio, and to compare the means it was used the Student t-test. A p-value less than 5% was considered statistically significant.

Results: We evaluated 60 individuals, 33 with sickle cells anaemia and 27 without hemoglobinopathy. Individuals with sickle cell anaemia had significantly higher underweight prevalence according to BMI (30,3% vs 7,4%; p=0,049; OR = 5,4), malnutrition by CAMA (78,8% vs 25,9%; p<0,001; OR= 10,6), lower %BF (39,4% vs 11,1%; p=0,019; OR=5,2). Both groups showed high inadequate energy prevalence, however protein inadequacy values were expressively lower.

Conclusions: The sickle cell anaemia adults showed higher anthropometric deficits when compared to patients without sickle cell disease. We observed high prevalence of inadequate protein and energy intakes that negatively affected the population studied anthropometric status, especially in individuals with sickle cell anaemia.

Key words: sickle cell anaemia, adults, anthropometric status, energy-protein intake.

PO396**FACTORS ASSOCIATED WITH WHEEZING AND ASTHMA IN ADOLESCENTS**

F J. Benedetti^{1,2}, F J. Benedetti^{1,2}, G B. Fischer^{1,2}, V L. Bosa^{1,2}

¹Centro Universitário Franciscano – Unifra, Brazil

²Universidade Federal do Rio Grande do Sul-UFRGS, Brazil

Background and objectives: Obesity and physical activity are interrelated lifestyle factors that may be relevant to the prevalence of asthma. Objective: Investigate the association between anthropometric and physical activity in the presence of wheezing and asthma in adolescents.

Methods: This cross-sectional study. The study consisted of adolescents aged 10-18 and enrolled in public schools in the city of Santa Maria/RS/Brazil. Symptoms of asthma were based on the ISAAC, 1998. The International Physical Activity Questionnaire (IPAQ) was used. High BMI indicates children with BMI 85th percentile (WHO, 1997). The waist circumference (WC) cutoff point was the 80th percentile (Taylor et al., 2000). The significance level adopted was 5%, and the analyses were carried out with the SPSS 11.5. The research was approved by the ethics in research committee.

Results: Have been assessed 867 adolescents with a mean age of 15.53±1.27 years, and 365(42.1%) were male. According to the ISAAC, respectively 182(20.9%) and 152(17.5%) adolescents reported having had wheezing and asthma. Of these 62(34.1%), 57(37%) were male and 120(65.9%), 95(62.5%) females (p= 0.017) (p= 0.221). 107(58.8%), 90(59.2%) watch <4 hours of television/day and 75(41.2%), 62(40.8%) >4 hours (p= 0.848) (p= 0.242). 86(47.5%), 63(41.4%) play video games <4 hour and 95(52.5%), 65(40.8%) >4 hours (p= 0.177) (p= 0.002). 131(72%), 104(68.4%) perform light physical activity, 40(22%), 34(22.4%), moderate and 11(6%), 14(9.2%) intensive (p= 0.064) (p= 0.958). Regarding BMI 128(72.3%) and 102(68%) not overweight and 49(27.7) 48(32%) overweight (p= 0.157) (p=0.399) for WC was observed that 150(84.7%), 122(81.3%) were excess and 27(15.3%), 28(18.7%) with excess adiposity abdominal (p= 0.181) (p= 0.399).

Conclusions: The wheezing was more prevalent in girls, who reported asthma more than 4 hours of play game. Although no statistical difference was observed that most practical light physical activity and a high percentage of students are overweight.

Key words: asthma, obesity, physical activity.

PO397**CHARACTERISTIC PROPERTIES OF JAPANESE FUCHA DISHES: NUTRITION, TEXTURE, AND PREFERENCE**

A. Koide¹, T. Yamauchi¹, K. Matsumoto², K. Mamiya¹, A. Yamamoto³, M. Moriyama⁴

¹Faculty of Human Life and Environmental Sciences, Nagoya Women's University, Nagoya City, Japan

²Department of Applied Life Studies, College of Nagoya Women's University, Nagoya City, Japan

³Aichi Gakusen College, Okazaki City, Japan

⁴Department of Home Economics, Aichi Gakusen University, Okazaki City, Japan

Background and objectives: Fucha-cooking, a style of Japanese monastic (vegetarian) cuisine, includes a method of cooking in which vegetable dishes are prepared in a manner to simulate fish and meat dishes. In this study, we prepared a vegetarian fucha (Fuc) version of broiled eel fillet (E) and chicken meatballs (C) and compared them with the original non-vegetarian (Con) dishes in terms of nutrition, texture, and preference.

Methods: The major ingredients of Fuc-E and Fuc-C were tofu and boiled bamboo shoots, respectively. Nutritional values were calculated using Japanese food composition table. Color parameters (L^* , a^* , and b^* values) were measured by a colorimeter. Hardness and texture were determined by a creep meter-food texture measurement system. Sensory evaluation was performed by a panel of 15 individuals (age, 41.5 ± 14.1 years) regarding five parameters using a scoring method. Data were analyzed by t-tests ($p < 0.05$).

Results: Compared with the Con dishes, the Fuc dishes contained less energy and fat, more folic acid, and no cholesterol, along with a 1.6-fold higher level of polyunsaturated fatty acids (in Fuc-E), and 2.1- and 7.2-fold higher levels of calcium and vitamin E, respectively (in Fuc-C). Fuc-E had higher lightness and yellowness values, and Fuc-C showed higher values for redness and yellowness than the controls. For hardness and texture, Fuc-E was significantly ($p < 0.05$) harder than Con-E, showing higher values for cohesiveness and gum load, while Fuc-C exhibited no significant difference in hardness but was more tender and cohesive than Con-C. Sensory evaluation showed no marked differences between the Fuc and Con dishes.

Conclusions: Due to their major ingredients, the Fuc dishes had different physical properties to the Con dishes, but both groups received similar scores on sensory taste evaluation. Given their nutritional values, Fuc dishes may serve as a potential anti-arteriosclerotic diet.

Key words: Fucha-cooking, nutrition, physicality, preference

PO399**RICH IN AGROBIODIVERSITY BUT POOR IN NUTRITION: FOOD SECURITY IN COMMUNITIES OF CHOPCCA, HUANCVELICA, PERU**

M. Scurrah¹, H. Creed-Kanashiro², S. de Haan^{1,3}, E. Olivera¹, R. Canto¹, M. Carrasco², E. Veres⁴, C. Barahona⁵

¹Grupo Yanapai, Huancavelica, Peru

²Instituto de Investigación Nutricional, Lima, Peru

³International Potato Center, Lima, Peru

⁴Universidad Politécnica de Valencia, Valencia, Spain

⁵Statistical Service Centre, University of Reading, Reading, UK

Background and objectives: The high Andean communities of Chopcca are rich in agrobiodiversity, cultivating 98 varieties of potato and several other Andean crops (broad beans, ulluco, lupin), yet have some of the highest rates of stunting in Peru (40 – 55%). This study explored the relationship between agrobiodiversity, household food insecurity (HFIAS) and nutrition.

Methods: 182 families with children 6 – 42 months of age in 4 communities were surveyed for food production, diversity, income sources and HFIAS. Dietary intake of children was evaluated by 24-hour recall on 2 non-consecutive days at times of potato production abundance (July 2010) and scarcity (February 2011). Nutritional status as recorded by the local health facilities was used.

Results: 42% of children were stunted. A weak correlation was found between better height for age and number of species cultivated (Pearson correlation 0.182, $p = 0.024$) but there was no correlation with other indicators of diversity or HFIAS. Dietary intakes showed infrequent consumption of animal source foods (ASF); farm produced meat, eggs and meat were mostly sold. A high proportion of children 6 – 24 months did not meet 80% of daily recommended intakes for iron (77%), zinc (81%), calcium (75%) or folate (61%). There were higher intakes of some nutrients during the period of scarcity due to greater consumption of ASF and in children who consumed the multi-micronutrient fortified infant food or sprinkles distributed through social programmes.

Conclusions: Agrobiodiversity, which is maintained on small, fragmented landholdings, was not associated with food security and did not protect against low dietary intakes of essential micronutrients. Intake of ASF, a good source of bioavailable micro-nutrients, was a main determinant of dietary quality. Adding small animal husbandry is considered as an option to improve diets and prevent stunting.

Key words: Agrobiodiversity, dietary diversity, food security.

PO400**THE EFFECTS OF MATERNAL ARGININE SUPPLEMENTATION DURING LACTATION ON VISCERAL OBESITY AND INSULIN SENSITIVITY OF OFFSPRING**

A. Koyama¹, L. Otani¹, T. Mori², K. Saito¹, S.I. Takahashi², H. Kato¹

¹Food for Life, Organization for Interdisciplinary Research Projects, The University of Tokyo, Tokyo, Japan

²Department of Animal Sciences, Graduate School of Agriculture and Life Sciences, The University of Tokyo, Tokyo, Japan

Background and objectives: Overnutrition during lactation is known to cause obesity in later life, and also, it is reported that arginine-supplemented pigs accumulated lipid into muscles. These facts suggest that early life nutrition might affect obesity in later life, and arginine, whose functions are related to growth, may have an important role in early life. We previously found that pups, whose dams were arginine-supplemented during lactation, were often obese when fed a high-fat diet in later life.

Methods: To investigate the mechanism of visceral fat accumulation, we performed DNA microarray analysis on mesenteric fat. Lactating Wistar rat dams were divided into 2 groups (CN and ARG) and fed a normal diet or an arginine-supplemented diet (2%). After weaning, the pups were further divided into 2 groups (CN and HF) and fed either a normal diet or a high-fat diet. The four groups are designated as CN-CN, CN-HF, ARG-CN, and ARG-HF. Oral glucose tolerance test was performed at during the 11th week. Total RNA was extracted from mesenteric fat of 12-week-old offspring and applied to DNA microarray GeneChip Rat Genome 230 2.0 Array (Affymetrix).

Results: ARG-CN and ARG-HF exhibited elevated insulin secretion after glucose loading, significant increases in body weight and visceral fat were observed only in ARG-HF. Ingenuity Pathway Analysis 7.5 of DNA microarray data suggested that genes related to inflammatory response in mesenteric fat underwent the most remarkable change in ARG-CN and ARG-HF. Representative changes were confirmed with qPCR.

Conclusions: It is suggested that maternal excessive arginine intake during lactation affected gene expression programming and led the fat cells of offspring to increase expression of inflammation-related genes, whose consequence became apparent during consumption of a high-fat diet.

Key words: arginine supplementation, visceral fat accumulation, lactation, insulin resistance

PO402**CALCULATING CHILD AGE WITHOUT BIRTH RECORDS: A NEW METHOD FOR ESTIMATING DATE OF BIRTH**

A. Kader¹, G. Das¹, J. Waid¹

¹Helen Keller International, Bangladesh

Background and objectives: An accurate birthdate is vital for assessing child nutritional status and adequate feeding practices. Caregivers in communities without an effective system of birth registration often cannot recall their child's birthdate, especially if they are illiterate. When the Food Security and Nutrition Surveillance Project was begun, no comprehensive method of estimating date of birth without birth records was identified so the project set out to devise an accurate method.

Methods: To devise a new method of estimating child birthdates, the project organized a workshop with 130 experienced Bangladeshi surveyors and field tested multiple methods.

Results: All surveyors are equipped with a daily calendar prospective for survey period and retrospective for the five preceding years. This daily calendar contains the three date systems used in Bangladesh - Bengali, English, and Arabic - as well as important and memorable events such as natural disasters and religious festivals. The enumerators are trained to ascertain the child's date of birth through four questions and to guide respondents if they have difficulty answering: On what day of the week was the child born? In what month was the child born? What was the birthweek's relative position in the month? How old is the child (in running years)? The resulting birthdate is probed through reference to events in the calendar and other factors, such as the age of other children, the mother's birth spacing, etc. The birthdates are also used to calculate child age in the field to ensure that the age matches with caregiver's perceptions. This method has been used in multiple surveys in Bangladesh since 2009.

Conclusions: Based on the success of this model in Bangladesh, field tests should be undertaken in other countries which have low coverage birth registration systems coupled with high illiteracy.

Key words: Anthropometry, date-of-birth, household-survey

Background and objectives: In recent years the prevalence of type 2 diabetes mellitus (T2DM) has increased worldwide. Diet is one of the components of lifestyle that has most been studied in the prevention of T2DM. Prospective studies have observed associations between the intake of red meat and processed meats and T2DM. This food group is a source of iron, especially of heme iron. The objective was to evaluate the link between iron intake and the incidence of T2DM in a Mediterranean population at high cardiovascular risk.

Methods: We conducted a prospective analysis of the PREDIMED cohort. We followed 1073 non-diabetic subjects (42.87% men) aged between 55 and 80 years at high cardiovascular risk, from the Reus and Pamplona centres. Diet was assessed at the study baseline using a validated, semi-quantitative food frequency questionnaire.

Results: During 8 years of follow-up, we ascertained 131 new cases of T2DM. At baseline, incident T2DM subjects consumed less coffee ($P=0.001$), and more heme iron ($P=0.036$) than non-incident. Intake of heme iron showed a positive association with T2DM incidence using Cox proportional hazards models after adjusting for dietary, anthropometric, socio-demographic and lifestyle variables. The Hazard Ratio was 1.299 (95% confidence interval, 1.016 to 1.660). In addition, we found no association between non-heme iron and the risk of T2DM.

Conclusions: Greater dietary heme iron, but not non-heme iron, is associated with an increased risk of T2DM in a Mediterranean population at high cardiovascular risk.

Key words: Heme iron, nonheme iron, iron, Type 2 diabetes mellitus, PREDIMED study.

PO404**THE MEASUREMENT OF HOUNSFIELD UNITS ON COMPUTED TOMOGRAPHY IMAGES AS A METHOD TO ASSESS FAT QUALITY**

M P. Carrasco-Benso¹, P. Gómez-Abellán¹, F. Sáez Belmonte², M. Garaulet¹, C S. Fox³

¹Department of Physiology, University of Murcia, Murcia, Spain

²Service Research Support of University of Murcia, Murcia, Spain

³Framingham Heart Study, National Heart, Lung and Blood Institute, Harvard Medical School, Framingham, MA, USA

Background and objectives: Recently, it has been proposed that the measurement of the fat density in absolute Hounsfield units (HU) directly on Computed-Tomography (CT) images may be used as a proxy to assess fat quality. However, this methodology has not been validated with histologic data. The aim of the current work was to demonstrate the validity of HU measurements for the assessment of fat quality in CT scans in 76 obese patients (50 women and 26 men) who had undergone abdominal surgery.

Methods: We assessed HU variability on CT images in comparison with Adipose Tissue (AT) characteristics including fat-cell-data (diameter, weight, area). CTs were digitalized using scanning densitometry. Absolute HU values within the range of -45 to -195 of pixels were measured in 8 regions of interest (~1 cm² each, 2 front superficial, 2 visceral, 2 back deep, 2 back superficial) to study fat density variability.

Results: Fat quality as assessed by HU variability was significantly correlated to fat-cell-characteristics. In particular, HUs values in visceral fat were inversely related to fat-cell-data of visceral AT samples ($r=-0.23$; $P=0.050$). Moreover we found a negative association between HUs values in back deep region and adipocyte size data ($r=-0.28$; $P=0.02$) and its variability ($r=-0.29$; $P=0.01$) in epiploon fat samples. Overall, worse fat quality as assessed by lower HU values was associated with an increased adipocyte size. Similar associations were found with adipocyte size variability: lower HU was associated with increased variability and as a consequence with a less organized (more chaotic) AT.

Conclusions: The measurement of fat density in absolute Hounsfield units on computed tomography images is associated with fat-cell-characteristics and may be used as a proxy for fat quality.

Key words: Computed-tomography, visceral-fat, adipose-tissue.

PO405**HIGH EFFICIENT ANALYSIS FOR LONG FREE FATTY ACID PROFILE BY ULTRAHIGH-PERFORMANCE LIQUID CHROMATOGRAPHY-MASS SPECTROMETRY**

³Research Unit for Physiological Chemistry, Kyoto University, Kyoto, Japan

Background and objectives: Free fatty acids (FFAs) have various physiological functions which depend on FFA structure. The change in FFA profile has been observed with numerous disorders such as obesity. Peroxisome proliferator-activated receptor α (PPAR α), a ligand-dependent transcription factor, regulates lipid metabolism. Activation of PPAR α is estimated to affect FFA profile. FFAs are frequently analyzed by gas chromatography mass spectrometry. However, fatty acid derivatization is necessary, which spends much time for sample preparation. The aims of this study are (a) the establishment of a high efficient analysis for FFA profile by liquid chromatography-mass spectrometry and (b) the application of this method to the analysis of the alteration of the FFA profile in mouse plasma and liver treated with bezafibrate, a PPAR α agonist.

Methods: Male KK-Ay mice were fed a high fat diet or supplemented with 0.2% (w/w) bezafibrate for 4 weeks. Sample preparation of mouse plasma and liver was deprotenation in organic solvent solution. The quantification of FFAs is achieved using ultrahigh-performance liquid chromatography coupled with time-of-flight mass spectrometry optimized the separation and ionization parameters.

Results: Here, we report a new non-derivatization method (analysis time: 15 min/sample) for the analysis of individual FFAs including myristic acid, palmitic acid, palmitoleic acid, stearic acid, oleic acid, linoleic acid, linolenic acid, arachidonic acid, eicosapentaenoic acid and docosahexaenoic acid. A high-sensitivity assay enables the quantification of FFAs using trace amounts of samples (plasma: 2 μ L, liver: 10 mg). We applied this method to the analysis of the FFA profile in mouse plasma and liver treated with bezafibrate and demonstrated a change in the profile of FFAs, particularly palmitoleic acid and oleic acid, with bezafibrate treatment.

Conclusions: It is suggested that the concentrations of palmitoleic acid and oleic acid in mouse plasma are markers of PPAR α activation.

Key words: free fatty acid (FFA) profile, lipid metabolism, peroxisome proliferator-activated receptor α (PPAR α) ultrahigh-performance liquid chromatography (UPLC), time-of-flight mass spectrometry (TOFMS)

PO406**EFFECTS OF IMPROVED-FAT-CONTENT FRANKFURTERS AND PÂTÉS ON INSULIN SENSITIVITY/RESISTANCE MARKERS OF VOLUNTEERS AT INCREASED CARDIOVASCULAR RISK. A PLACEBO-CONTROLLED STUDY**

P. Celada¹, G. Delgado-Pando², F Jiménez-Colmenero², B. Olmedilla-Alonso², F.J. Sánchez-Muniz¹

¹Departamento de Nutrición y Bromatología I (Nutrición), Facultad de Farmacia, Universidad Complutense, Madrid, Spain

²Instituto de Ciencia y Tecnología de los Alimentos y Nutrición (ICTAN), CSIC, Madrid, Spain

Background and objectives: Meat products are an important group of nutritionally dense foods of many consumers around the world. Reformulation of meat products is one of the strategies used in order to develop meat-based functional foods. Waist perimeter (WP) is considered an important marker for abdominal obesity diagnosis. Aim: To study the effect of modified frankfurters and pâtés: a) reduced-fat products (RF) (15.3%, 15.2% fat, respectively); b) n-3-enriched reduced-fat products (n-3 RF) (15.1%, 15.5% fat, respectively) and c) normal-fat products (NF) (18%, 30.8% fat, respectively) on glucose, insulin, different HOMAs and QUICKI of volunteers at high CVD risk classified according to low-normal and increased WP.

Methods: Twenty-two volunteers were enrolled in a sequential study of 3 consecutive 4-wk periods separated by 4-wk washout periods. Cutoff points for WP: 102 and 90 cm for men and women respectively.

Results: Glycemia, insulinemia, HOMA-IR, HOMA-S, HOMA-D, HOMA B and QUICKI were non-significantly affected in any of the considered periods. Changes in insulin, HOMA-S and QUICKI in the RF period tended to be different ($P < 0.07$) in volunteer with low and high WP. With respect to the low WP population, in the RF period HOMA-S ($P < 0.09$) and QUICKI ($P < 0.05$) increased; in the n-3 RF period, the insulin and HOMA-IR tended to decrease ($P < 0.08$) while QUICKI and HOMA-B to increase ($P < 0.09$); not significant change or tendency ($P < 0.1$) was observed for any parameter during the NF period. The RF and the n-3 RF periods did not induce any significant change or tendency, while the NF decreased the glucose/insulin ratio in high WP volunteers.

Conclusions: The low WP population appears as the target population because consumption of RF or n-3 RF-meat products slightly improved some glucose homeostasis markers.

Key words: reduced-fat, omega-3 enriched-meat, Frankfurters, pâtés, glucose, insulin, HOMA, QUICKI.

PO407**RURAL-URBAN DIFFERENTIALS IN LIFESTYLE AND FOOD SECURITY OF OLDER PERSONS IN IBADAN, NIGERIA***O. Ariyo¹, I O. Akinyele¹, O O. Keshinro²*¹Department of Human Nutrition and Dietetics, University of Ibadan, Ibadan, Nigeria²Department of Nutrition and Dietetics, Federal University of Agriculture, Abeokuta, Nigeria

Background and objectives: Healthy lifestyle and good nutrition are essential to promote active ageing. Knowledge of rural/urban differentials in lifestyle and food security is essential to design locality-driven programmes.

Methods: This study assessed rural/urban differences in lifestyle and food security of older people in Ibadan, Nigeria. This comparative cross-sectional survey involved 168 and 178 respondents from two urban and two rural Local Government Areas (LGAs) of Ibadan. A three-stage sampling technique was used to select LGAs, wards/communities and respondents respectively. A semi-structured questionnaire was used to collect information on socio-demographic and lifestyle profile of the respondents. Socio-Economic Status (SES) was categorised as low (6-13), moderate (14-21) and high (22-29) and lifestyle was assessed using levels of smoking, alcohol intake and physical activity. Food security was determined using household coping strategies. Data were analysed using descriptive statistics and logistic regression at 5% level of significance.

Results: Mean age was 68.9±4.7 and 69.7±4.4 years in urban and rural areas respectively. Respondents in low SES were more (6.7%) in rural than urban areas (2.4%) ($p < 0.05$). Prevalences of heavy alcohol intake (16.1%, 16.9%) and irregular physical activity (1.8%, 9.6%) were lower in urban than rural areas. Current smokers were thrice higher (13.5%) in rural than urban areas (4.8%). Food insecurity with hunger was nine-times higher in rural (16.9%) than urban areas (1.8%) while food insecurity without hunger was 17.4% and 7.1% in rural and urban areas respectively. Smoking and alcohol intake had no significant relationship with food security in both areas. The likelihood of being food insecure reduced in urban than rural when respondent had at least moderate-SES (OR: 0.15 versus 0.10) or married (OR: 0.6 versus 3.5) among other results.

Conclusions: Poor lifestyle and food insecurity were higher in rural than urban areas. Intervention programmes should direct attention to older persons in rural areas.

Key words: food security, survey

PO409**EFFECTS OF PRENATAL DHA SUPPLEMENTATION ON ATTENTION AND BEHAVIOR OF OFFSPRING AT AGE 5 Y: RANDOMIZED CONTROLLED TRIAL IN MEXICO***U. Ramakrishnan¹, L. Schnaas², A. DiGirolamo^{1,3}, A D. Quezada², W. Hao¹, B. Pallo¹, L. Neufeld^{2,4}, J. Rivera², A D. Stein¹, R. Martorell¹*¹Hubert Department of Global Health, Rollins School of Public Health, Emory University, Atlanta, USA²Instituto Nacional de Salud Publica, Cuernavaca, Mexico³CARE, Atlanta, USA⁴Micronutrient Initiative, Ottawa, Canada

Background and objectives: Docosahexanoic acid (DHA) is an important constituent of the brain that accretes during the first 1000 days of life. Evidence from well-designed intervention trials of long-term benefits of increasing DHA intakes during pregnancy is sparse. We have completed the age 5 y follow-up of offspring of women who participated in POSGRAD, a double-blind randomized controlled trial of prenatal DHA supplementation in Cuernavaca, Mexico.

Methods: Pregnant women received 400 mg/d of DHA or a placebo from 18-22 weeks of pregnancy until delivery. We assessed attention and behavior in 795 offspring at age 5 y (82% of 973 live births) using the computer-based Conners' Kiddie Continuous Performance Test (K-CPT), and the Spanish version of the Behavior Assessment System for Children (BASC-PRS) administered to the primary caregiver. We compared the groups on standardized T scores (% omissions, % commissions, HIT Reaction Times) and inattention, impulsivity and sustained attention measures for the K-CPT, and standardized summary scores for scales of hyperactivity, aggression, anxiety, depression, attention problems, executive functioning and social skills (BASC-PRS).

Results: Attrition did not differ by treatment group. The groups were balanced for maternal and infant characteristics. In intent to treat analysis, the DHA group showed improved T scores compared to the placebo group for omissions (DHA: 47.6 + 10.3; Placebo: 49.6 + 11.2; $p < 0.01$) and sustained attention (HIT RT Block Change: DHA: 50.2 + 12.2; Placebo: 52.0 + 12.5; $p = 0.04$; HIT SE Block Change: DHA: 48.2 + 10.0; Placebo: 49.9 + 9.4; $p = 0.01$). There were no differences significant at $p < 0.05$ for the other K-CPT scores, the % clinically at risk for Attention Deficit Hyperactivity Disorders, or any of the scales based on the BASC-PRS.

Conclusions: Exposure in utero to DHA may contribute to improved sustained attention in preschool children.

Key words: DHA, prenatal, supplementation, attention, preschool

PO410**NUTRIENT ADEQUACY AND ORGANOLEPTIC QUALITY OF COMPLEMENTARY FOOD MIXES MADE FROM COMBINATIONS OF DIGITARIA EXILIS, SESAMUM INDICUM AND GLYCINE MAX**

V. Ibeanu¹, N. Ene-Obong², U. Onyechi¹, G. Peter-Ogba¹

¹Department of Home Science Nutrition & Dietetics, University of Nigeria, Nsukka, Nigeria

²Department of Biochemistry, College of Medicine, University of Calabar, Nigeria

Background and objectives: Low-quality of traditional infant complementary food and inadequate feeding practices predispose under-five children in poor resource communities to under nutrition. This study evaluated the nutrient adequacy and organoleptic quality of complementary mixes made from *Digitaria exilis* (D), *Sesamum indicum* (S) and *Glycine max* (G).

Methods: *Digitaria exilis* was soaked and sundried; *Sesamum indicum* roasted and *Glycine max* boiled, fermented and sundried before milling separately into flours. The flours were combined at different ratios on protein basis to produce five multi-mixes (D70S30; D70G30; D70S15G15; D70S20G10 and D70G20S10) which were quantitatively analyzed for nutrients and their gruels organoleptically assessed for acceptability. A commercial product was used as control. All analyses were done in triplicates using standard methods. ANOVA and Duncan's multiple range tests were used to separate/compare the means. A nine-point hedonic scale was used to rate the organoleptic attributes of the mixes.

Results: D70G30 mix had significantly ($p < 0.05$) higher protein (19.26%) and folate (108.71mg) than the D70S30. The D70G20S10, D70S15G15 and D70S20G10 had 18.10%, 17.16% and 16.90% protein, respectively. The energy content of all the mixes was above 400kcal. The iron values ranged from 11.25mg in D70G30 to 13.01mg in D70S30; the calcium values ranged from 190.28mg in D70G30 to 198.34mg in D70S30. D70S30 also had the highest (7.32mg) zinc value while the D70G30 had the least (3.24mg). The protein, iron, zinc and folate values of most of the mixes met 50 – 100% of the daily requirements for the age group. The D70G30, D70S15G15, D70S20G10 and D70G30 had the highest ratings in terms of colour (6.80), texture (7.90), flavor (6.50) and general acceptability (6.70), respectively.

Conclusions: The formulated mixes had attributes of adequate complementary food but D70G30 had the best nutritional and general acceptability attributes.

Key words: leguminous oil seeds/cereals, complementary food, nutrient adequacy, acceptability

PO411**EFFECTS OF DIETARY SUPPLEMENTS; PEDIASURE AND CARNITINE ON THE ANTHROPOMETRIC INDICES IN CHILDREN WITH ALL UNDER CHEMOTHERAPY, IN AFZALI POOR HOSPITAL, KERMAN, IRAN**

A. Naderi¹, A. Shahabi Nejad², F. Doostan³

¹Assistant professor of pediatric hematology and oncology, Department of Pediatrics, Afzali Poor Hospital, Kerman University of Medical Sciences, Kerman, Iran

²Pediatrician

³Assistant professor of nutrition, Department of Nutrition, Health Faculty, Kerman University of Medical Sciences, Kerman, Iran

Background and objectives: Malnutrition is a common complication of cancer and cancer treatment. This occurs in 50% of patients. Dietary supplements may have a significant effect on the response to treatment, survival, recurrence, mortality and complications induced by chemotherapy. The effects of Pediasure and Carnitine intake on anthropometric indices in children with ALL have been investigated in this study.

Methods: This clinical trial study was conducted in 34 new cases of childhood ALL under chemotherapy, in Afzali Poor hospital. The patients were divided by randomized design into two groups; 17 cases and 17 controls (mean age 5.79 ± 3.97 and 7.17 ± 3.66 years). 100-150 cc Pediasure in every other day for one month and 50mg/kg/day Carnitine were given to case group. Anthropometric indices; Skin Fold Thickness (SFT), Weight, Height and Arm Circumference were measured at the beginning of the study and 6 months later. Anthropometric indices were compared in these two periods. Data were analyzed by using Paired t. test.

Results: Mean of SFT (mm), Weight (Kg), Height and Arm Circumference (cm) at the beginning of the study in case group were 7.2 ± 3.3 , 18 ± 9.7 , 107.3 ± 24.5 and 15.88 ± 4.2 and in control group were 10.57 ± 6.2 , 22.48 ± 11 , 115.82 ± 22.3 and 16 ± 4 respectively. After 6 months of study these indices in case group were 7.3 ± 0.8 , 18.3 ± 2.3 , 108.1 ± 5.88 and 15.98 ± 1 and in control group were 10.6 ± 1.5 , 22.88 ± 2.7 , 116.3 ± 5.4 and 16.2 ± 0.97 respectively. No statistically significant differences were noticed between groups in two periods. Although, the differences of SFT were not statistically significant, but this finding was clinically important ($p = 0.052$).

Conclusions: In spite of observed acute malnutrition in both groups, effects of dietary supplements on anthropometric indices did not show significant difference between groups. This may be related to many factors like the: 1- case group consumed only 100-150 Kcal/day energy more than the control group (we are not allowed to be free on using dietary supplement because of relapse risk and other unknown adverse effects of supple-

ments), 2- the number of studied patients and 3- the duration of intervention. Further studies are recommended.

Key words: Acute Lymphoblastic Leukemia, Anthropometric indices, Pediasure, Carnitine

PO412

THE GINGER AS A DIET INGREDIENT AGAINST TOXICITY INDUCED BY CHROMATE

O. Aouacheri¹, M. Krim¹, A. Messaadia¹, I. Maldi¹, S. Saka¹

¹Applied Biochemistry and Microbiology Laboratory, Department of Biochemistry, Faculty of Sciences, Badji Mokhtar University - Annaba, Algeria

Background and objectives: The evaluation of the effect of ginger on the modulation of toxic effects and oxidative stress induced by chromate is the objective of our study.

Methods: 50 male rats Albinos wistar were divided to five groups as follow: Group I (T) is served as control, received a mineral water by gavage (per os); group II (G) received an experimental diet with 2 % of ginger; group III (Cr) received an oral dose of potassium dichromate (15 mg/kg) and normal diet; group IV (CrG): received an oral dose of potassium dichromate (15 mg/kg) and an experimental diet containing 2 % ginger; and group V (Cr+G) received an oral dose of potassium dichromate (25 mg/kg) and an experimental diet with 2 % of ginger.

Results: The results of this study indicate that the chromate provoked a haematotoxic effect (anemia), nephrotoxic (increase concentrations of urea, creatinine, and uric acid), hepatotoxic (increase of total and direct bilirubin concentrations, ASAT, ALAT, LDH and PAL activities). The results showed also increase concentrations of cholesterol, triglyceride and total lipids. In addition, chromate has a pro-oxidant effect, which was indicated by decrease of reduced glutathione (GSH) levels in different tissues. However, the administration of ginger revealed a reduction of the intensity of oxidative stress induced by the chromate resulting in the decrease of the majority of the previous parameters concentrations.

Conclusions: We demonstrated that ginger has potent antioxidant activity, revealed by the amelioration of chromate's toxic effects. We can say that ginger has a protective effect towards damages induced by the chromate.

Key words: Potassium dichromate, Oxidative stress, Toxicity, Ginger diet

PO413

MATERNAL FOLIC ACID SUPPLEMENTATION INDUCES DIFFERENTIAL CHANGES IN THE HEPATIC TRANSCRIPTOME OF YOUNG ADULT MALE PROGENY

W H. Chu¹, L. Harland¹, P. Grant¹, M. de Blasio³, W C. Kong¹, S. Moretta¹, J. Robinson¹, M. Dziadek², J. Owens¹

¹School of Paediatrics and Reproductive Health, University of Adelaide, Australia

²Garvan Institute, Australia

³Department of Physiology, University of Cambridge, UK

Background and objectives: Maternal folic acid supplementation is regarded as a preventative measure against neural tube defects in the newborn. With folic acid being a methyl donor, maternal supplementation of which could potentially impose changes to the fetal epigenome in gestation, thereby leading to perturbations in gene expression after birth. Metabolic deregulation, as observed in non-alcoholic fatty liver disease (NAFLD), is often characterised by aberrant hepatic transcriptional profile. To assess whether this maternal dietary change may predispose progeny towards developing NAFLD in adulthood, the hepatic transcriptional profile of young adult male progeny was determined.

Methods: Female Wistar rats were fed one of two diets: Control (n=7, 2mg folic acid/kg) or Folic Acid Supplemented (n=7, 6mg folic acid/kg), from two weeks before mating until delivery. Male offspring were weaned onto a standard diet and were sacrificed on postnatal day 90 with their liver collected. Global transcriptional profiling was performed with Affymetrix Rat Gene 1.0ST Array. Data was analysed on BRB-Arraytools using class comparison. Molecular networks modulated by the differentially expressed genes were identified with Ingenuity Pathway Analysis.

Results: Twenty two genes were differentially expressed in the liver of young adult male offspring of folic acid supplemented mothers, with 10 being upregulated and 12 being downregulated. Maternal folic acid supplementation significantly upregulated the hepatic expression of acyl-coA synthase member 3 (Acs3) in the young adult male offspring (1.76 fold; P < 0.05). While aldo-keto reductase family 1 member B7 (Akr1b7) expression was detected to be significantly downregulated (0.43 fold; P < 0.05). One network with cardinal functionalities in lipid metabolism was found to be closely associated with the differentially expressed genes.

Conclusions: Maternal folic acid supplementation may promote lipogenesis in the young adult male offspring through modifying hepatic expression of the enzymes involved.

Key words: Folic Acid, Fetal Epigenome, Lipogenesis

PO414**HEPATIC TRANSCRIPTIONAL CONSEQUENCES FOR YOUNG ADULT FEMALE PROGENY FOLLOWING FOLIC ACID EXPOSURE IN GESTATION**

W H. Chu¹, L. Harland¹, P. Grant¹, M. de Blasio³, W C. Kong¹, S. Moretta¹, J. Robinson¹, M. Dziadek², J. Owens¹

¹School of Paediatrics and Reproductive Health, University of Adelaide, Australia

²Garvan Institute, Australia

³Department of Physiology, University of Cambridge, UK

Background and objectives: There is increasing epidemiological evidence to suggest prenatal nutrition to be a major determinant of metabolic health in adulthood. The underlying molecular mechanisms remain elusive; however, epigenomic and transcriptomic changes have been proposed. As the establishment of epigenetic signatures first occurs in gestation, changes in the availability of methyl donors could modify fetal epigenome, in turn conferring to differences in gene expression and metabolic phenotype after birth. Folic acid, a potent methyl donor, is widely supplemented in pregnant women to prevent neural tube defects. Given the facilitating role in which folic acid plays in the establishment of epigenetic signatures, we therefore examined whether maternal folic acid supplementation may define metabolic phenotype of adult female progeny through hepatic transcriptomic changes.

Methods: Female Wistar rats were fed one of two diets: Control (n=6, 2mg folic acid/kg) or Folic Acid Supplemented (n=6, 6mg folic acid/kg), from two weeks before mating until delivery. The liver of one young adult female offspring from each dam was collected. Transcriptional profiling was performed with Affymetrix Rat Gene 1.0ST Array and analysed with BRB-Arraytools. Upstream regulators were identified with Ingenuity Pathway Analysis.

Results: Thirty six genes were differentially expressed in the liver of young adult female offspring of folic acid supplemented mothers, with 8 being upregulated and 28 being downregulated. The expression of two significantly upregulated genes (P<0.05), *Scd1* and *Tsku*, were identified as being transcriptionally responsive to insulin. The expression of three significantly downregulated genes involved in cholesterol biosynthesis (*Idi1*, *Msmo1*, and *Sqle*) was found to be under the transcriptional control of PPARA, a pivotal regulator in lipid oxidation. Consistently, lipid metabolism was identified as the most over-represented function.

Conclusions: Maternal folic acid supplementation may disrupt lipid and cholesterol homeostasis in the young adult female progeny through modifying hepatic transcriptomic landscape.

Key words: Folate, Cholesterol Biosynthesis, Transcriptomics

PO415**STABLE ISOTOPE RATIOS OF CARBON AND NITROGEN IN THE SCALP HAIR OF PATIENTS RECEIVING ENTERAL NUTRITION**

T. Endo¹, M. Hayasaka², O. Kimura¹, Y. Hotta³, T. Tarumi³

¹School of Pharmaceutical Sciences, Health Sciences University of Hokkaido, Hokkaido, Japan

²Sapporo Higashi-Tokusyukai Hospital, Hokkaido, Japan

³Hokusei Hospital, Hokkaido, Japan

Background and objectives: We analyzed the stable isotope ratios of carbon ($\delta^{13}\text{C}$) and nitrogen ($\delta^{15}\text{N}$) in the scalp hair of patients receiving enteral nutrition to estimate the nutritional conditions of patients, because lower $\delta^{13}\text{C}$ and higher $\delta^{15}\text{N}$ in the hair were reported in the starvation for long term and the anorexia.

Methods: The $\delta^{13}\text{C}$ and $\delta^{15}\text{N}$ in the scalp hairs of patients receiving enteral feeding formula for long term and healthy persons were analyzed using isotope-ratio mass spectrometry (IRMS).

Results: The $\delta^{13}\text{C}$ and $\delta^{15}\text{N}$ values (‰) in the scalp hair of patients (n=11) were -20.4 ± 1.2 and 10.3 ± 0.7 , respectively, and significantly lower and higher than those of healthy persons (-19.1 ± 0.6 and 9.3 ± 0.5 ‰, n=114), respectively. The $\delta^{15}\text{N}$ value in the hair of patients decreased with increases of total energy, protein and carbohydrates received from the enteral feeding formula, while the $\delta^{13}\text{C}$ value tended to increase. In contrast, the body mass index (BMI) and serum albumin of the patients did not correlate to those increases received from the enteral feeding formula.

Conclusions: The values of $\delta^{13}\text{C}$ and $\delta^{15}\text{N}$ in the hair of patients receiving the enteral nutrition for long term appear to be good indicators for the nutritional conditions.

Key words: stable isotope ratio of carbon ($\delta^{13}\text{C}$), stable isotope ratio of nitrogen ($\delta^{15}\text{N}$), scalp hair, body mass index (BMI), enteral nutrition.

PO416**ABNORMAL INTESTINAL HANDLING OF SORBITOL AND MANNITOL IN PATIENTS WITH IBS: POTENTIAL CLINICAL IMPLICATIONS**

C K. Yao¹, H L. Tan², D. van Langenberg², J. Barrett³, P. Gibson³, J. Muir³

¹Department of Gastroenterology, Central Clinical School, Monash University, Australia

²Department of Gastroenterology, Eastern Health Clinical School, Monash University, Australia

³Department of Gastroenterology, Central Clinical School, Monash University, Australia

Background and objectives: Sorbitol and mannitol are polyol isomers widely distributed in food. Major dietary sources include stone fruits and pears (sorbitol), cauliflower and mushrooms (mannitol). Whilst sorbitol is poorly absorbed and induces symptoms in patients with Irritable Bowel Syndrome (IBS), the gastrointestinal effects of mannitol are unknown. We aimed to compare the absorption and symptom response of sorbitol and mannitol in patients with IBS and in healthy individuals.

Methods: A randomised, double-blinded, placebo-controlled, crossover study was conducted in 20 IBS subjects (Rome III) and 21 healthy controls. Subjects were challenged on separate occasions in randomised order with 10g of either sorbitol, mannitol or glucose (as control) in 100ml solutions and responses measured in 4-h breath hydrogen tests. Gastrointestinal symptoms during the tests were assessed using visual analogue scales.

Results: Similar proportions of healthy (67%) and IBS subjects (60%) had sorbitol malabsorption, but fewer subjects with IBS malabsorbed mannitol (20% vs 57%; $p=0.02$). Majority of healthy subjects (86%) had either concurrent malabsorption or absorption of both polyols. In contrast, 40% of IBS patients were discordant for sorbitol and mannitol malabsorption, with less than 20% malabsorbing both. Symptoms increased significantly after both polyols compared with the placebo glucose (≤ 0.05) in IBS only, but were independent of their malabsorption.

Conclusions: discordant absorption of sorbitol and mannitol occurred in patients with IBS compared to that in healthy individuals, with sorbitol more likely being malabsorbed. Polyols induce symptoms in IBS independently of their malabsorption, implying dietary restriction of polyols are warranted, irrespective of the individual's absorptive capacity.

Key words: Mannitol, sorbitol, malabsorption, irritable bowel syndrome, breath hydrogen tests

PO417**SIZE AND BODY COMPOSITION OF SWEDISH INFANTS IN RELATION TO THE NUMBER OF RISK ALLELES IN THE FTO-GENE**

E. Forsum¹, P. Henriksson¹, M. Löf², P. Söderkvist¹

¹Department of Clinical and Experimental Medicine, Linköping University, Linköping, Sweden

²Department of Bioscience and Nutrition, Karolinska Institute, Huddinge, Sweden

Background and objectives: Several genes are associated with human obesity. A common variant (rs 9939609) in the fat and obesity (FTO) gene has a particularly strong association with obesity. Carriers of the FTO risk allele tend to have a high body mass index (BMI) and a high body fat content. Some studies suggest that the relationship between FTO genotype and obesity becomes apparent during childhood while the effect of the risk allele in infancy rather is a decrease in BMI. However, the number of risk alleles has also been found to be associated with heavier and fatter infants. We studied size and body composition at 1 and 12 weeks of age in Swedish infants in relation to the number of FTO risk alleles. Materials and

Methods: Healthy full term girls (n=96) and boys (n=109) were studied for weight, length, fat mass and fat free mass at 1 and 12 weeks of age. Body composition was assessed using air displacement plethysmography. Saliva samples for identification of the FTO-genotype were collected. Regression analyses was used.

Results: The number of risk alleles was not associated with infant fat mass (g,%) but was positively associated with infant length (cm) ($P=0.007-0.033$). The interaction term "FTO-genotype x sex" was significant at 12 weeks ($P=0.047$), but not at 1 week ($P=0.067$), reflecting a relationship in boys ($P=0.001$) but not in girls. The number of risk alleles was also positively associated with fat free mass (g) ($P=0.008-0.036$) but this relationship was not significant when adjusted for infant length.

Conclusions: Our results do not confirm a previous report that the FTO risk allele is associated with more body fat in infants but suggest instead that this allele is associated with an increased body length in infant boys.

Key words: air displacement plethysmography, body composition, FTO, infancy, obesity genetics

PO418**INFLUENCE OF PHYSICAL ACTIVITY ON THE NUTRITIONAL STATUS OF OVERWEIGHT ADOLESCENTS MEASURED BY CD4+/CD8+ RATIO**

A. Veses¹, S. Gomez-Martinez¹, D. Martinez-Gomez², O. Veiga², A. Marcos¹

¹Departamento Metabolismo y Nutrición, ICTAN, CSIC, Madrid, España

²Departamento de Educación Física, Deporte y Motricidad Humana, UAM, Madrid, España

Background and objectives: CD4+/CD8+ ratio is a sensitive immunological marker of the nutritional status, whose optimal values range from 1.5-2.0, and might be altered by obesity. Some studies have shown that engagement in physical activity (PA) might have some benefits on the immune system, especially in obese subjects. Therefore, the purpose of this study was to examine whether meeting PA guidelines (i.e. 60 minutes/day in moderate-to-vigorous PA) may improve the nutritional status in overweight/obese adolescents by measuring the CD4+/CD8+ ratio.

Methods: 188 adolescents (96 females) of 2000 who were enrolled in the AFINOS study were assessed. Body mass index was calculated and the adolescents were classified according to Cole's cut-off points into two groups: overweight/obesity (n=49) and non-overweight (n=139). PA was measured by accelerometry, and adolescents were classified as active and inactive according to public health guidelines. CD4+ and CD8+ lymphocyte subset percentages were determined by flow cytometry and CD4+/CD8+ ratio was calculated. The Student's-t test was used to analyze the differences of all parameters between weight status and both PA groups.

Results: The prevalence of overweight/obesity was 26.1%. CD4+/CD8+ ratio was 1.5±0.5 in the non-overweight group and 1.4±0.5 in the overweight/obesity group (p>0.05). No significant differences were found in non-overweight adolescents between active and inactive adolescents respectively, with regard to CD4+ (36.1±6.8 vs. 37.7±6.2) and CD8+ (25.7±5.9 vs. 25.9±6.6) percentages, and CD4+/CD8+ ratio (1.6±0.5 vs. 1.5±0.5) (p>0.05). However, overweight/obesity adolescents who were active had more favourable levels in all parameters (CD4+: 37.2±6.6 vs. 32.5±8.5; CD8+: 26.5±6.2 vs. 31.1±8.1 percentages and also CD4+/CD8+ ratio: 1.5±0.5 vs. 1.1±0.5) than those overweight/obese adolescents classified as inactive (p<0.05).

Conclusions: PA by meeting public health guidelines might have some benefits on the immune system in adolescents with overweight/obesity, enhancing their nutritional status, measured by CD4+/CD8+ ratio.

Key words: Physical activity, overweight/obesity, CD4+/CD8+ratio, adolescents.

PO419**A COMPARISON OF FOOD INTAKE PATTERN OF INTELLECTUALLY CHALLENGED AND NON-CHALLENGED SCHOOL CHILDREN IN DHAKA CITY**

F. Shabnam¹

¹EEP/Shiree, Dhaka, Bangladesh

Background and objectives: The intellectually challenged children suffer undesirable nutritional outcomes compared to their counterpart. No reliable data on the food intake pattern of these children are available in Bangladesh. The objective of the study was to identify if there is any food intake differences between intellectually challenged and non-challenged children of school, aged 4-12 years in Dhaka city.

Methods: 24 intellectually challenged children of the age group 4-12 years were selected randomly from a special school in Dhaka City and age, sex matched another 24 non-challenged children were selected from another school. All the children underwent measurement of height and weight. A structured questionnaire including food frequency was administered to the caregivers.

Results: The study findings show that the mean Height for age z score (HAZ) for the 1st and 2nd group were -0.9 and 1.1 (p = 0.00) and mean Weight for age z score (WAZ) for intellectually challenged children and normal children were -0.3 and 1 (p= 0.00). Less frequent meal taken by these children was also noticed (p= 0.016). The intellectually challenged children were more likely to replace the main meal (p= 0.008) with the intake of chips, biscuits and they had more prolonged eating time (p= 0.04). These children suffer more (p= 0.039) from feeding difficulties than the normal children. The non-challenged children showed the significantly higher consumption of fast foods (p= 0.045) and the intellectually disabled children had a significant higher intake of medicine (p= 0.005).

Conclusions: Thus the study provides an important priority of the establishment and maintenance of adequate nutrition of the intellectually challenged children for their "catch up" growth. The study also highlighted inadequate food intake among these children; which place them more at risk for further malnourishment in their later life.

Key words: intellectually challenged children, food intake, Bangladesh

PO420**THE COMPARISON OF DETECTION SYSTEMS IN HPLC DETERMINATION OF CAROTENOIDS FROM SPINACH AND KALE LEAVES***M. Ligor¹, B. Buszewski¹*

¹Chair of Environmental Chemistry and Bioanalytics, Faculty of Chemistry, Nicolaus Copernicus University, Toruń, Poland

Background and objectives: For the determination of carotenoids in plant extracts the useful technique is HPLC–UV–Vis. The presence of the long chromophore of conjugated double bonds (polyene chain) in carotenoid structure, provides the distinctive light-absorbing properties. Other detection method like Corona CAD gives possibilities to determine carotenoids, chlorophylls as well as polyphenols during the one-step analysis. Moreover, the development of advanced LC/MS method has been observed especially in qualitative and quantitative analyses. Based on innovative detection technology, the useful detectors for qualitative and quantitative analyses of carotenoids have been indicated. The method validation including method linearity, precision, recovery, limits of detection and quantitation has been presented.

Methods: Methanolic extracts of fresh or frozen of spinach and kale leaves were analyzed by means of RP HPLC. An improved and simplified analytical method was optimized. Compounds were separated on C18 column. For the calibration procedure, standards mixtures of lutein, beta-carotene, cryptoxanthin in methanol were prepared.

Results: During LC/MS method, SIM mode analysis allowed to obtain LOD for lutein 0.20 ug/mL. MRM mode allowed to track the formation of fragmentation ions 551,6 - 119,2 m/z (collision energy 15), the LOQ for lutein below 0.60 ug/mL was confirmed. The values of LOD and LOQ for the lutein by means of HPLC-UV-Vis detection were 0.5 ug/mL and 1.5 ug/mL, and for Corona-CAD were 0.6 ug/mL and 1.7 ug/mL, respectively. The high concentration of lutein in extracts from frozen and fresh spinach (from 0.43 to 0.88 mg/g) was determined. The content of lutein in red kale leaves (2.04 mg/g) is higher than in green kale (1.10 mg/g).

Conclusions: HPLC-UV-Vis method allows for the selective determination of xanthophylls in plant extracts. Kale Redbor F1 (red-violet leaves) is more biological resistant, than usually cultivated green leaf kale (Winterbor F1).

Key words: xanthophylls, HPLC, detectors, mass spectrometry

PO421**DIETARY PLASMA PROTEIN SUPPLEMENTATION AMELIORATES LUNG AND INTESTINAL INFLAMMATION INDUCED BY LPS AND STAPHYLOCOCCAL ENTEROTOXIN B ADMINISTRATION IN MICE***A. Pérez-Bosque¹, L. Miró¹, M. Maijó¹, J. Polo², L. Russell³, J. Campbell³, E. Weaver⁴, J. Crenshaw³, M. Moretó¹*

¹Department of Physiology, Faculty of Pharmacy and Nutrition and Food Safety Research Institute, University of Barcelona, Barcelona, Spain

³APC Inc., Ankeny, IA, USA

⁴Proliant Health and Biologicals, Ankeny, IA, USA

Background and objectives: Previous experiments have shown that dietary supplementation with spray-dried animal plasma (SDP) can attenuate intestinal inflammation induced by *S. aureus* enterotoxin B (SEB) in rats. Plasma supplements can also alleviate the inflammatory response in a mouse model of lung inflammation induced by lipopolysaccharide (LPS). We now wanted to assess whether supplementation with SDP or with the immunoglobulin concentrate fraction (IC) are effective in mice exposed to a double challenge induced by the administration of SEB and LPS.

Methods: Male C57BL/6 mice were fed diets supplemented with 8% SDP, 2% IC, or milk proteins (Control group) from day 19 (weaning) until day 33. The challenge consisted of the intranasal administration of LPS from *E. coli* (12.5 ug) at day 32 and 6h later they received an intraperitoneal injection of SEB (25 ug). Samples were collected 24h after the LPS administration. Leukocyte populations were analysed in bronchoalveolar lavage fluid (BALF) and in mesenteric lymph nodes (MLN). Cytokine expression in lung and jejunum mucosa was determined by real time PCR.

Results: The toxins challenge increased leukocyte recruitment into BALF and MLN, as well as the percentage of activated monocytes and neutrophils (all $P < 0.05$). Both SDP and IC attenuated the effects on MLN (all $P < 0.05$) but only SDP reduced the SEB-LPS effects on lung inflammation (all $P < 0.05$). The double challenge also increased the expression of TNF α , IFN γ and IL1 β in lung tissue and jejunum mucosa (all $P < 0.05$). Both supplements attenuated the effects of toxins administration in both tissues (all $P < 0.05$). These effects were accompanied by increased expression of IL-10 in both lung and jejunum (all $P < 0.05$) but only SDP increased the expression of TGF β in both tissues ($P < 0.05$).

Conclusions: Supplementation with animal plasma proteins attenuated intestinal and lung inflammation by increasing the expression of anti-inflammatory cytokines.

Key words: intestinal inflammation, lung

PO422**DARK CHOCOLATE SWEETENED WITH STEVIA REDUCE BLOOD GLUCOSE AND CHOLESTEROL OF DIABETIC RATS**

R. Mohamed¹, A. Abed El-Moaty², E. Afifi³, N. El-Tahan⁴

¹Faculty of Home Economics, El Cairo, Egypt

Background and objectives: Stevia is herb with incredible sweetening power rated from 70 to 400 times of white sugar. The study aimed at find out the effect of dark chocolate sweetened with Stevia on blood glucose among diabetic rats.

Methods: Dark chocolate were made with standard methods, but Sugar were substituted with Stevia as a natural sweetener. The produced chocolate was evaluated through panel test and we used the product with high score. The produced chocolate was added to rats' diet in different concentration (5%, 10%, and 15% respectively). Forty eight male albino rats (weight 100±10 gram) were injected with alloxan for induction of diabetes and rats with high blood glucose were used in this study. The study was carried out on five normal rats (Negative control) and twenty five diabetic rats. The diabetic rats were subdivided into five equal groups (5 rats for each); positive control, 5% dark chocolate group, 5% sweetened dark chocolate group, 10% sweetened dark chocolate group, and 15% sweetened dark chocolate group. The experiment continued for 28 days, at the end, rats were anesthetized and killed by exsanguinations. Blood samples were collected and used for determination of glucose, total cholesterol, urea, creatinine, ALT, and AST.

Results: Food intake for the groups fed on 10, 15 % sweetened dark chocolate group was decreased. However there were no significant changes in body weight between all studied groups. In comparison with positive control group, the results showed that rats fed on 15% sweetened dark chocolate group had the lowest concentration of blood glucose, cholesterol, creatinine, ALT, and AST (P<0.05) followed by rats fed on 10% sweetened dark chocolate group.

Conclusions: The higher the dark chocolate sweetened with stevia intake the lower the level of blood glucose and cholesterol.

Key words: Stevia, Chocolate, Glucose, Cholesterol, Rats

PO423**IDENTIFICATION OF BLOOD CELL TRANSCRIPT-BASED EARLY BIOMARKERS OF METABOLIC HEALTH IN AN ANIMAL MODEL LESS PRONE TO OBESITY**

J. Konieczna¹, E M. van Schothorst², J. Sánchez¹, A. Bunschoten², M. Palou¹, C. Picó¹, J. Keijzer², A. Palou¹

²Department of Human and Animal Physiology, Wageningen University, Wageningen, The Netherlands

Background and objectives: Moderate maternal calorie-restriction during lactation has been shown to protect rat offspring against obesity development in adulthood, due to an improved capacity to handle and store excess dietary fuel. We used this model to find early biomarkers of metabolic health, focusing on molecular markers of lipid handling. To identify transcript based biomarkers we used peripheral blood mononuclear cells (PBMCs), which are easily accessible in humans.

Methods: Male and female offspring of control and 20% calorie-restricted lactating dams (CR) were studied. At weaning, a set of pups were killed, PBMCs were isolated and whole genome microarray analysis was performed. White adipose tissue (WAT) and liver were also collected for mRNA expression analyses by qRT-PCR. The remainder of the pups were sacrificed at the age of 6 months.

Results: CR-animals displayed lower body weight, food intake and fat accumulation, and improved levels of insulin, leptin and leptin/adiponectin ratio in plasma throughout life. Microarray analysis of weaned rat PBMCs identified 278 genes differentially expressed between the CR and control groups (≤0.01). Among lipid metabolism-related genes, expression of *Fasn* and *Rxb* was decreased and *Cpt1a* and *Lipe* increased in CR animals versus controls, and changes were fully confirmed by qRT-PCR. At an early age *Fasn* and *Cpt1a* expression levels in PBMCs correlated with their expression levels in WAT. Notably, *Cpt1a* expression in PBMCs correlated with hepatic expression at all time points examined, even in adult animals.

Conclusions: These findings reveal the possibility of using transcript levels of lipid metabolism-related genes in PBMCs as early biomarkers of metabolic status, potentially providing a valid biological readout for the study of metabolic processes in humans.

Key words: early biomarkers, PBMCs, calorie-restriction, lactation

PO424**NUTRITION RELATED CARDIAC RISK FACTORS IN PATIENTS WITH CORONARY ARTERY DISEASE IN A SELECTIVE HOSPITAL AT DHAKA CITY**

T. Khatun¹, D. Maqbool², M. Sarker³, A. Hoque⁴

¹Bangladesh Institute of Health Sciences (BIHS), 125/1 Darussalam, Mirpur, Dhaka, Bangladesh

²Nutrition officer, LAB AID Cardiac Hospital, Bangladesh

³Dept of Community Nutrition, Bangladesh Institute of Health Sciences (BIHS), Bangladesh

⁴Dept of Community Nutrition, Bangladesh Institute of Health Sciences (BIHS), Bangladesh

Background and objectives: Coronary artery disease is one of the leading causes of death in developed and developing countries including Bangladesh. This study was aimed to explore the association between Nutrition related cardiac risk factors in patients with coronary artery disease.

Methods: A case-control study. Two hundred (100 CAD) subjects in Lab aid cardiac hospital and 100 healthy subjects with different ranges of BMI (starting <18.5 BMI-27) were studied. Anthropometric data collected by standard techniques. Nutrient profile was taken by 24hr recall method and serum glucose by glucose-oxidase method, serum lipid by enzymatic-colorimetric method. Statistical analyses were performed by appropriate univariate and multivariate techniques using SPSS windows 11.5.

Results: Level of high physical activities and Waist circumference was found higher among the non-CAD subjects than non CAD subjects. Total energy and fat intake are strongly correlated with BMI ($p < 0.023$) and ($p = 0.37$). Carbohydrate and total energy also strongly correlated with Waist circumference ($p < 0.0001$) and (0.030). Logistic regression analysis was performed against the confounding independent variables like consumption of beef (> 2 times/wk), chicken (> 2 times/wk), egg (> 2 times/wk), fish (<1time/day), junk food (>1time/day) fruits and vegetable (<1time/day). Most of the respondents among CAD group preparation their food by fried process and non-CAD groups were used boiled food. Majority respondents among CAD group were taking extra salt ($p = 0.001$). Body mass index ($p = 0.004$), WC (male) ($p = 0.004$) and WHR (male) ($p = 0.020$) were significantly higher in CAD group than that of their counterpart non CAD subjects.

Conclusions: This study revealed that consumption of beef, egg, chicken, junk food, fish, fruits and vegetables is significantly higher risk of coronary artery events. It is clear that nutrition related cardiac risk factors should be emphasized for the prevention of coronary artery disease in our country.

Key words: Nutrition and CAD, Diet and CVD, cardiac risk factors

PO425**GASTROINTESTINAL PEPTIDE RESPONSE TO FAT AND CARBOHYDRATE: IMPLICATIONS FOR SATIETY CONTROL**

C. Gibbons¹, P. Caudwell¹, G. Finlayson¹, D L. Webb², P. Hellström², E. Näslund³, J. Blundell¹

¹Institute of Psychological Sciences, Faculty of Medicine and Health, University of Leeds, UK

²Department of Medical Sciences, Gastroenterology and Hepatology, Uppsala University, Sweden

³Department of Clinical Sciences, Danderyd Hospital, Karolinska Institutet, Sweden

Background and objectives: The macronutrient composition of foods can affect both satiation and satiety. Fat is a major risk factor for overconsumption when consumed ad libitum due to its weak effects on satiation, but its effect on satiety are less clear. Fat and carbohydrate are often used interchangeably in food and this may affect satiety. The present study examined the gastrointestinal peptide and subjective appetite response to foods high in fat or carbohydrate, eliciting normal physiological responses rather than supra-physiological levels attained during infusion studies.

Methods: Sixteen (5M;11F) healthy overweight/obese adults (Age:46y;BMI:29.8kg/m²) took part. Plasma was collected before and periodically for 180 minutes after consuming high fat (>50% energy from fat) or high carbohydrate (>80% energy from carbohydrate) meals of equal energy (590kcal), weight (685g) and protein content (~12%). Simultaneous ratings of hunger, fullness and satiety were tracked. Satiation was measured from a mixed macronutrient meal.

Results: CCK showed a greater response to the fat breakfast ($F(1,15) = 11.178$, $p < 0.01$) whereas insulin showed a greater response to the carbohydrate breakfast ($F(1,15) = 32.688$, $p < 0.001$). Ghrelin was suppressed equally by fat and carbohydrate ($F(1,15) = 0.658$, $p = 0.433$). Neither hunger, fullness or satiety responses differed after consumption of fat or carbohydrate ($p > 0.05$) and the resulting energy intake did not differ (947kcal or 939kcal; $p = 0.844$).

Conclusions: When delivered in fixed amounts, fat and carbohydrate meals eliciting markedly different peptide profiles can produce similar effects on satiety and satiation. This demonstrates that the same degree of satiety can be mediated by distinctly different peptide profiles and implies that no single peptide can be regarded as the sole biomarker of satiety. Control over satiety can be achieved via different patterns of meal related peptides.

Key Words: peptides, appetite, satiety, satiation

¹²Research Unit, Kuopio University Hospital, Kuopio, Finland

Background and objectives: Biomarkers of dietary intake can be important tools in nutrition research. The aim of the present study was to assess alkylresorcinol (AR) and â-carotene plasma concentrations during a controlled dietary intervention with healthy Nordic diet (ND); rich in whole-grain, fruits and vegetables.

Methods: Participants (n=166), 30-65 years with BMI 27-40 kg/m² and two more features of metabolic syndrome (In-

ternational Diabetes Federation definition, slightly modified), were recruited through six centers in the Nordic countries and randomized to ND or control diet for 18-24 weeks. Plasma AR and â-carotene were analyzed and nutrient intake calculated from 4-day food records.

Results: Median fiber intake increased in the ND group from 2.5 g/MJ to 4.1 g/MJ (P<0.001), and total AR fasting plasma concentration from 72.6 to 106 nmol/L, or 68% (P<0.001). AR concentration was significantly higher in the ND group at 18/24wk (P<0.001) than in the control group. ß-Carotene intake increased slightly in the ND group (P=0.073) but plasma â-carotene concentration did not change significantly throughout the study and did not differ between the groups at follow-up.

Conclusions: The ND diet results in higher dietary fiber intake and increased total plasma AR concentration compared with the control diet, suggesting AR might be a valid biomarker for a ND. No significant difference in plasma â-carotene concentrations was observed between the ND and control groups suggesting that â-carotene may not be sensitive enough biomarker of ND.

Key words: Nordic diet, dietary biomarkers, alkylresorcinols, ß-carotene

⁹Research and Education Institute of Child Health (REF) Strovolos, Cyprus

¹⁰Nestle Research Center, Lausanne, Switzerland

Background and objectives: Inflammation markers are present even in the pediatric population. In adults, studies showed that some fatty acids (FA) have antiinflammatory properties like omega-3 polyunsaturated fatty acids, whereas others promote the inflammatory state like saturated fatty acids. The main objective is to assess the relationship between blood fatty acids and inflammation, measured by hs-C reactive protein (CRP), in European children.

Methods: The IDEFICS study (Identification and prevention of Dietary- and lifestyle-induced health Effects In Children and infants) was a multicenter epidemiological study in eight European countries (Belgium, Cyprus, Estonia, Germany, Hungary, Italy, Spain and Sweden). Out of the total, 16,224 participating children, 2,600 subjects had blood fatty acids measured. Those children who had taken medication within the last week or the last 24 h were deleted due to the sensitivity of the CRP; therefore 1,413 children were used for the statistical analysis.

Results: There was no significant correlation between CRP and saturated fatty acids. Some monounsaturated fatty acids and CRP were inversely correlated ($p < 0.001$) i.e. oleic acid, eicosanoic acid and docosanoic acid; also there was a positive correlation with palmitoleic ($p < 0.001$). Regarding polyunsaturated FA, most of the omega 6 types had a positive correlation ($p < 0.001$) while some of the omega 3 types presented inverse correlations with CRP: ALA ($p < 0.001$) and EPA ($p < 0.05$), except DHA where the relation was positive.

Conclusions: No relation was found between saturated fatty acids and inflammation as a priori was expected. However, a strong inverse association was found between monounsaturated fatty acids (except palmitoleic) and CRP. Also, as it is described in the scientific literature, there was a marked difference between polyunsaturated acids; the relation was different if they were omega 3 (mostly inversely correlated with CRP, except DHA) or omega 6 (positively correlated with CRP).

Key words: inflammation, fatty acids, children

PO428

INTEREST OF SLOWLY DIGESTIBLE STARCH ON CARBOHYDRATE METABOLISM: META-ANALYSIS

S. Vinoy¹, A. Meynier¹, A. Goux¹, N. Jourdan-Salloum²

¹Mondelez Int. R&D, Nutrition Research, France

²BIOOptimize, Cormontreuil, France

Background and objectives: Decreasing glycaemic response is interesting in the prevention of metabolic diseases and has been considered as relevant by the EFSA. However, process and food composition influence dramatically the carbohydrate fate and then the metabolic consequences of carbohydrate rich foods. High slowly digestible starch (SDS) foods have been shown to provide low glycaemic response. A meta-analysis of 5 intervention studies has been done to evaluate the strength between SDS and glycaemic response, and SDS and appearance rate of carbohydrates of cereal foods.

Methods: The five selected clinical trials included from 12 to 38 non diseased subjects. All studies were randomised clinical trials with well characterised cereal products regarding macronutrient and starch digestibility (SDS content). We extracted the data to a database, and synthesized the evidence via meta-analyses and meta-regression models. The odd ratios (OR) with 95% of confidence for the adjusted random-effects models investigate the association between SDS and postprandial metabolism as glycaemic response, insulin response and appearance rate of carbohydrates (Ra).

Results: Cereal products containing high SDS ((ranging from 9 to 16g/portion), are 4,4 times more likely to generate low glycaemic response and 2,6 times more likely to generate low insulin response than cereal products containing low SDS. The link between slow exogenous Ra and high SDS was even stronger with an OR of 14,6, while it was slightly lower with disappearance rate (OR=4,2). Strong link (69%) was obtained between exogenous Ra and glycemia.

Conclusions: High SDS (> 8g/portion) in cereal foods induced a lower postprandial glycaemic response, through a slower appearance rate of exogenous carbohydrates, and with a concomitant low insulin response. This meta-analysis reinforces the interest of SDS on its impact on carbohydrate metabolism in order to prevent the risk of metabolic disease genesis.

Key words: cereal foods, carbohydrates, glycaemic response, slowly digestible starch

PO429**AWARENESS, KNOWLEDGE AND BEHAVIOR OF USING FOLIC ACID SUPPLEMENTATION TO PREVENT NTDs AMONG RURAL WOMEN IN CENTRAL SOUTH CHINA**

Q. Lin¹, F Li¹, XY. Hu¹, J. Deng¹, JC. Shi¹, WJ. Gong¹

¹Central South University, China

Background and objectives: Neural tube defects (NTDs) are the most common birth defects which contribute to infant mortality and serious disability. This pilot study is to investigate the awareness, knowledge and behavior of using folic acid supplementation to prevent NTDs among rural women in Changsha County.

Methods: Multiple-stage sampling was used to select four townships randomly, and then three villages were selected from each township. Face-to-face interview was conducted between 6th, April and 15th, June, 2012, with a sample of 130 pregnant women, 163 women who took a birth in last 12 month and 41 women at childbearing age.

Results: Most of the total sample (98.5%) reported that they had heard about folic acid but only 60% could tell folic acid can decrease birth defects risk. Intake of folic acid supplements was reported by 60.5% of the entire sample of women who plan to be pregnant. Out of these 41 respondents, 58.5% were taking folic acid supplements (56.1%) or multivitamins (2.4%) but only 14 women adhere to taking folic acid daily. The multiple logistic regression analysis results indicate that for the full sample, women who gave birth in last 12 months were 5 times (OR=5.34, 95%CI: 2.43~12.58) and women who were currently being pregnant women were 3 times (OR=3.16, 95%CI: 1.40~7.12) likely to use folic acid supplements, controlling for those who plan to be pregnant; women with awareness of continuing using folic acid for 6 months± were nearly 2.6 times (OR=2.56, 95%CI:1.47~4.44) likely to use folic acid supplements than others.

Conclusions: Special attention must be given to those who with lower education, who plan to have a baby and who are in the first trimester when intervention programs planning to be developed.

Key words: folic acid, NTDs, women, knowledge

PO430**HIGH SENSITIVITY C-REACTIVE PROTEIN AND TOTAL ANTIOXIDANT STATUS IN PATIENTS WITH CHRONIC KIDNEY DISEASE, DIABETES AND HYPERTENSION**

H. Oboh¹, S. Idogun², A. Ukwuonwo¹, J. Omole¹, E. Unuigbo³

¹University of Benin, College of Medical Science, Dept of Medical Biochemistry, School of Basic Medical Sciences, Nigeria

²Dept. of Chemical pathology, Nigeria

³Dept. of Internal Medicine, Nigeria

Background and objectives: Low grade systemic inflammation and total antioxidant status can be assessed by the levels of high sensitivity C-reactive protein (hs-CRP) and Total antioxidant capacity (TAC). The study was carried out to evaluate the levels of hs-CRP and antioxidant status in chronic kidney disease, diabetic and hypertensive subjects in the presence of traditional risk factors. The relationship between total antioxidant capacity, C-reactive protein and other risk factors like blood pressure and Anthropometric measurements were also evaluated.

Methods: A total of 180 patients (90 control, 90 test(45 males ; 45 females respectively) aged 18-76years old, diagnosed as having chronic kidney disease, Diabetes and hypertension, but clinically stable were recruited from University of Benin Teaching Hospital. The controls were apparently healthy individuals. Anthropometric measurements were carried out (weight and height to calculate the Body mass index (BMI). Serum samples were collected for hs- CRP and TAC assays.

Results: BMI increased significantly (P<0.05) in hypertensive and Diabetic patients but no change was observed in CKD. Blood pressure was increased in CKD subjects. The Diabetic subjects had normal Blood Pressure values while it was uncontrolled in the hypertensive. The results revealed that hs-CRP levels were significantly increased (P<0.05) while TAC levels were decreased in all the subjects recruited for the study. The CKD subjects showed no correlation (P>0.05) between CRP, BMI and TAC. However, in hypertensive and Diabetic patients, CRP and TAC correlated positively with BMI and blood pressure. TAC correlated negatively with CRP.

Conclusions: Low grade systemic inflammation as measured by hs-CRP and TAC was increased in the chronic kidney disease, diabetes and hypertension subjects. CRP correlated positively with BMI in hypertensive and diabetic patients.

Key words: High sensitivity CRP, Total antioxidant capacity, chronic kidney disease, Diabetes, hypertension

PO432**SIMULTANEOUS DETERMINATION OF SYNTHETIC DYE, PRESERVATIVE, ANTIOXIDANT AND CAFFEINE IN ENERGY DRINKS BY HPLC**

B. Asci¹, Aksu Dönmez¹

¹Yildiz Technical University, Turkey

Background and objectives: A novel high performance liquid chromatographic method was proposed for the simultaneous determination of synthetic dye (allura red), preservative (potassium sorbate), antioxidant (ascorbic acid) and caffeine in energy drinks.

Methods: The use of a reversed -phase C18 column (4.6mmx150mmx5µm) using a gradient elution system enabled four compounds to be separated simultaneously in a single chromatographic run in less than 10 minutes.

Results: The method was successfully validated following ICH guidelines, and it has been demonstrated to be reliable for the assay of allura red, potassium sorbate, ascorbic acid and caffeine in energy drinks. The limit of quantitations were found as 0.33,0.77,1.21,0.63 µg/mL for allura red, potassium sorbate, ascorbic acid ,caffeine, respectively.

Conclusions: A reliable analytical method is validated to measure allura red, potassium sorbate, ascorbic acid and caffeine in energy drinks.

Key words: HPLC, allura red, potassium sorbate, ascorbic acid, caffeine

PO433**ENHANCING MICRONUTRIENTS SOURCING MECHANISMS TO IMPROVE EFFICIENCY OF LARGE-SCALE OIL FORTIFICATION PROJECTS IN INDONESIA**

C. Guyonnet¹, V. Jallier¹, A. Provent¹, A. Laillou¹, R. Moench-Pfanner¹

¹Global Alliance For Improved Nutrition, Geneva, Switzerland

²Indonesian Nutrition Foundation for Food Fortification, Geneva, Switzerland

Background and objectives: Access to high-grade micronutrients is a recurring challenge which often threatens the long-term sustainability of food fortification programs. Objective. To assess the efficiency of the GAIN Premix Facility in procuring quality, affordable vitamin A for fortification of edible oil in Indonesia.

Methods: Use a global approach to procurement of standard items by combining volumes across various demand streams in

order to reduce the total cost of acquisition through economies of scale. The GAIN Premix Facility undertook a detailed analysis of vitamin A requirements across its existing customer base which served as basis for developing a reliable demand forecast. A consolidated, competitive tender was launched which resulted in the setting up of a long-term commercial agreement with the selected supplier to lock-in the most competitive price for a given period of time.

Results: The direct benefit for oil manufacturers fortifying with vitamin A is that the cost of fortification went down significantly compared to prices they would have been offered had they ordered vitamin A individually. In Indonesia, this consolidated procurement approach has allowed a 14% decrease to the unit price of vitamin A.

Conclusions: The GAIN Premix Facility demonstrated its effectiveness in acting as a global procurement platform by aggregating demand across different customers and leveraging improved prices through increased volumes. Building on the success of this effort, the GAIN Premix Facility is replicating this global approach for procurement of other standard items being procured across fortification programs worldwide.

Key words: micronutrients, oil fortification

PO434**CARDIOVASCULAR RISK FACTORS AMONG TYPE 2 DIABETIC SUBJECTS ATTENDING SELECTED DIABETES CARE FACILITIES IN BANGLADESH**

F. Saleh¹, S.J. Mumu¹, F. Ara¹, F. Afnan¹, L. Ali¹

¹Bangladesh University of Health Sciences, Bangladesh

Background & objectives: There are many risk factors for cardiovascular disease which are responsible for the majority of deaths in diabetic patients. To assess the proportion of cardiovascular risk factors among DM subjects attending different diabetes care centers at the capital city and at northern part of Bangladesh.

Methods: Under an analytical cross-sectional design 754 type 2 diabetic subjects (age >20 years) were selected from different diabetic centers situated in the capital city and northern part of the country. Sampling was done by selecting each alternative subjects attending the OPD. Data were collected by a pre-tested, interviewer-administered questionnaire. Diagnostic criteria for CVD risk factors are adopted from American Diabetic Association (ADA) and World Health Organization (WHO).

Results: The proportion of hypertension, overweight & obesity, waist circumference, dyslipidemia, physical inactivity, betel quid consumption and current smoking was 26%, 74.7%, 77.2%, 52.9%, 18.2%, 28.1% and 10.3% respectively. Among

the 402 participants for whom all measurements were available, 1% had at least one of the six risk factors (hypertension, overweight & obesity, waist circumference, dyslipidemia, smoking and physical inactivity). Only 5% had two risk factors while 20% had 3 and 25% had 4 risk factors. On logistic regression no predictors were found to be associated with hypertension. Semi urban diabetics were less likely to be obese (OR =2.1, 17.7 and 0.3 respectively). Male gender was predictors of dyslipidemia (OR=6.7) and high waist circumference (OR=14.55).

Conclusions: Overweight & obesity, waist circumference and dyslipidemia are common while current smoking is comparatively uncommon among diabetic subjects. Habitat and male gender are predictors of obesity and males are more likely to develop central obesity and dyslipidemia.

Key words: CVD risk factors, overweight & obesity, waist circumference, type 2 diabetics, Bangladesh

HYDRATION AND NON-HYDRATION DURING EXERCISE: EFFECTS ON HOMOCYSTEINE CONCENTRATIONS AND RELATED PARAMETERS

B. Maroto¹, O. López-Torres¹, A E. Diaz², C. Carru³, P J. Benito¹, M. González-Gross^{1,4}

¹ImFine Research Group, Health and Human Performance Dept, Faculty of Physical Activity and Sport. INEF, Technical University of Madrid, Madrid, Spain

²Clinical Laboratory Center of Sports Medicine, Sports Council, Madrid, Spain

³Dept of Biomedical Sciences, University of Sassari, Sassari, Italy

⁴CIBER: CB12/03/30038 Fisiopatología de la Obesidad y la Nutrición, CIBERobn, Instituto de Salud Carlos III (ISCIII), Spain

Background and objectives: The effect of exercise on total homocysteine (tHcy) levels, a risk factor for cardiovascular disease (1,2), is not clearly stated. To the best of our knowledge, there is no study which analyses the effect of hydration during and after exercise on tHcy levels. Aim: To assess the recovery of serum tHcy and related parameters with controlled hydration during and after exercise (2 h) with two different drinks (water and a sport drink).

Methods: 20 physically active male subjects (20 – 45 years) performed four stable submaximal tests of 40 minutes at 65% VO₂max on a treadmill under controlled conditions: temperature (30°C) and humidity (60%). In two of the tests the subjects drank during exercise (250ml) and in the other two tests they didn't. After all four tests the subjects were rehydrated with one of the drinks. The amount of fluid intake was the same as weight loss for each subject during each test. Blood samples

were taken before, immediately after, and two hours after completing each test. We analyzed serum tHcy, folate, cobalamin, creatine and creatinine concentrations.

Results: tHcy concentrations increased significantly during both non-hydration tests (P<0.01); however, tHcy increased only slightly without significant differences when drinking during exercise. After exercise, tHcy concentrations decreased at 2h in all four tests, but only significantly with the sports drink (p<0.01). Although an inverse correlation was found between folate and tHcy before the two non-hydration tests, no correlation was found between folate, cobalamin, creatine and creatinine with tHcy during the hydration process.

Conclusions: A better response of tHcy concentrations are shown with an adequate hydration than non-hydration protocol during acute aerobic exercise, independent of the type of fluid (water or sport drink). After exercise, tHcy significantly decreases only with the sports drink, independently of the hydration protocol during exercise.

Key words: homocysteine, exercise

PO436

EFFECT OF 'BEAN SPOT INFECTIONS' ON THE NUTRITIVE VALUE OF PHASEOLUS VULGARIS (COMMON BEAN) SEEDS

D. Steve^{1,2}

¹University of Dschang, Cameroon

²University of Ngaoundéré, Cameroon

Background and objectives: "Bean spot diseases" are causing too much loss, due to absence of resistant cultivars, the pathogens variation. It affects Yield, marketability and edibility of infected seeds in bean producing areas of the world. Valorizing *P. vulgaris* spot infected seeds in nutrition appear to be necessary. This study investigated the nutritive value of *P. vulgaris* seeds infected bean spot diseases.

Methods: 36 rats separated into six groups were used, and fed for 14 days with 10% experimental protein diets, prepare with non infected white common bean (MEX142a); infected white common bean (MEX142b); non infected brown common bean (MAC55a); infected brown common bean (MAC55b), separately cooked for 2 hours, dehydrated at 60°C and ground. Egg-white was used as standard protein. Feed intake, weight, faeces collection were recorded. Transaminases and serum creatinine were measured. Results obtained were reported as mean ± SD and statistically analyzed using one way ANOVA and student Newman Keul tests. P value of less than 0.05 was considered significant.

Results: The infection significantly (P<0.05) affected the protein content MEX142b. MAC55b showed slight increase of crude proteins. The ash contents of the infected seeds significantly increased (P<0.05) MEX142. Infected seeds were more

consumed than the non infected seeds. Proteins of infected seeds were significantly ($P<0.05$) bioavailable and lead in significant weight gain ($P<0.05$) of rats. Serum enzymes analysis showed that infected seeds had significant ($P<0.05$) low activities. MAC55b significantly increased ($P<0.05$) the PCV (packed cell volume).

Conclusions: *P. vulgaris* seeds infected by spot diseases are rich source of nutrients, its protein is bioavailable, it's seem not to be toxic, and could be nutritionally useful. (MAC55) could be more recommended for it ability of increasing PCV.

Key words: *P. vulgaris*, Bean spot diseases, Nutritive value

PO437

NUTRITION EDUCATION TO INCREASE FLUID INTAKE AMONG LOW DRINKER FEMALE TEENAGER IN INDONESIA

S. Adiningsih¹

¹Public Health Faculty, Surabaya, Indonesia

Background and objectives: Almost human body composed by water and it has vital role of functioning cell organs. Most of teenagers did not know about the functions of water for human body, and the symptoms of dehydration. Thirst study 2009 found Urinary Tract Infection (UTI) was 16.5% subjects which might be related to drinking habit. The objective of this study was to measure compliance of water intake with and without water supply in low drinker. This study was part of UTI Study conducted in accordance with the ICH GCP procedure.

Methods: An interventional, open label, controlled study in female teenagers, 19-21 years old with diagnosis of UTI, year 2011 in Surabaya city Indonesia. Eligible subjects were 39 with inclusion criteria selected by pre-screening interview from 2201 subjects suspected UTI. Subjects were divided into water group (drinking volume? 1.5 mL/day), were given advice to drink water/fluid > 2 L/day and water supply 3 bottles per day @ 600 ml. Non water group was only given an advice. Subject was evaluated every 2 weeks until Day 62 and after intervention phase finished Day 90. The evaluation was using 7 days diary to measure daily fluid/water intake and followed by urine specific gravity assessment.

Results: Drinking habit improved in both group, but average volume intake higher in water group than non-water group. The total fluid intake among water group subjects were sharply decreased in the follow up visit after 1 month, however compared to prior of intervention the fluid intake was higher. The average fluid intake was 1661.56 L/day.

Conclusions: It was hard to change behave of low drinker. The implementation of dietary guideline should be introduced at the early age in life cycle when people is already aware to drink before thirsty.

Key words: Low drinker, nutrition education, teenagers Acknowledges Aqua-Danone

PO438

HIGH MEAT AND HETEROCYCLIC AMINES INTAKE BETWEEN INDIVIDUALS WITH DELETIONS INVOLVING GSTT1 OR GSTM1 GENES POLYMORPHISMS: SITUATION IN SAO PAULO-BRAZIL

A. Carvalho¹, J. Steluti¹, A. Mendes¹, R. Fisberg¹, D. Marchioni¹

¹Department of Nutrition, Faculdade de Saúde Pública, Universidade de São Paulo, São Paulo, São Paulo, Brazil

Background and objectives: The high red and processed meat and heterocyclic amines (HCA) consumption has been associated with higher risk of colorectal cancer. However, the risk can vary by individual genetic factors, as deletion variants of detoxifying enzymes. The objective was to investigate the red and processed meat and HCA consumption, and deletion variants of glutathione-S-transferase enzymes (GSTT1 and GSTM1).

Methods: A cross-sectional population-based survey among a representative sample (n=748) of adolescents, adults and elderly people living in Sao Paulo, Brazil, was conducted in 2010. The usual meat intake was assessed by Multiple Source Method, using two 24-hour dietary recalls. The cooking methods and doneness level of meat were obtained by a structured questionnaire. The HCA consumption was calculated using the HCA database developed by Sinha et al, (2005). The recommendation of 500g/week of red and processed meat consumption was considered excessive consumption. It was used PCR-based assays to detection GSTM1 and GSTT1 deletions.

Results: The mean of red and processed meat consumption was 102g/day, 43% more than the recommendation. The mean of HCA consumption was 378ng/day. These consumptions did not vary between groups with or without genes deletion (GSTT1 and/or GSTM1). The group that had the deletion variants of GSTT1 and/or GSTM1 and also consumed excessive red and processed meat and high HCA, was estimated in about 25%.

Conclusions: One in each four individuals in this population has a susceptible genotype that can increase the risk of colorectal cancer at this level of red and processed meat and HCA intake. In the later years, the new discipline of nutrigenomics and nutrigenetic raised the debate about the opportunity of disease prevention through individualized medicine. Our findings might add evidence to this debate, reinforcing the concept that "one size does not fit all".

Key words: Meat, heterocyclic amines, cancer, glutathione-S-transferase

PO439**GROWTH FACTORS FROM MILK AND DAIRY PRODUCTS: IS THERE AN IMPACT ON THE INCIDENCE OF CANCERS?**

S. Wetzler¹, I. Bordes¹, I. Margaritis¹, E. Kalonji¹, M. C. Boutron-Ruault²

¹Unité d'évaluation de la nutrition et des risques nutritionnels - The French Agency for Food, Environmental and Occupational Health & Safety (ANSES) – Maisons-Alfort, France

²CESP, Inserm U1018 Equipe 9, Institut Gustave Roussy, et Université Paris-Sud – Villejuif, France

Background and objectives: Growth factors (GF) are found in all tissues and fluids and are involved in several physiological mechanisms, including cell proliferation. The presence of GF in milk and dairies raised the issue of their potential role in carcinogenesis.

Methods: We summarized the epidemiological evidence relating GF, dairies consumption and cancer risk, focusing on prospective and intervention studies in humans.

Results: Meta-analyses and recent prospective studies led to conclude to a positive association between blood concentrations of Insulin-like growth factor 1 (IGF-1) and the incidence of three common cancers – prostate, breast (ER+ tumors) and colorectal cancers. Evidence from technological treatment of milk and dairies, from the maturation of the large bowel and from intervention studies is in favor of a low if any contribution of exogenous IGF1 from dairies to the IGF1 blood concentration. However, there is much evidence that nutritional factors, including, but not exclusively so, milk (rather than other dairies), influence the endogenous synthesis of IGF1, through mechanisms that are not fully understood, but can involve energy or some specific types of proteins. Finally, meta-analyses conclude in three opposite directions regarding the association between dairy intake and the three cancer types associated with IGF1 concentrations. Dairies seem to be positively associated with prostate cancer risk, inversely with colorectal cancer risk, and neutrally with breast cancer risk.

Conclusions: Thus, the involvement of exogenous IGF-1 from dairy sources in cancer risk, if any, is likely to be low. While dairy but also other nutritional factors can be associated with increased IGF1 concentrations, mostly through stimulation of endogenous IGF1 synthesis, the direct relationship between these aspects and cancer risk is spurious, and if any, would depend on the cancer site. Further studies are requested to better understand the overall effect of diet on IGF1 concentrations and whether this affects cancer risk.

Key words: IGF-1, milk, cancer, dairies

PO440**A COMPARATIVE STUDY OF WEB-BASED SELF-ADMINISTERED DIETARY RECORDS AND CLASSICAL 24-HOUR TELEPHONE-BASED DIETARY RECALLS IN A BRAZILIAN POPULATION**

A. Polo Galante¹, S. Maria Voci², V. Oliveira Carvalho³, C. Colli⁴

¹Course of nutrition, Centro Universitário São Camilo, São Paulo, Brazil

²Department of Nutrition, University of São Paulo, São Paulo, Brazil

³Heart Institution, University of São Paulo, São Paulo, Brazil

⁴Department of food and experimental nutrition, University of São Paulo, São Paulo, Brazil

Background and objectives: Automated web-based systems for the self-assessment of dietary intake are becoming increasingly more popular since they are cost-effective and less time consuming than the more traditional methods. The objective of the present study was to compare the results obtained using the NutriQuanti® internet-based dietary record system with those derived from 24-hour recalls carried out by a dietitian.

Methods: A total of 268 volunteers satisfied the selection criteria and were invited to complete on-line self-assessment dietary records on three non-consecutive days within a 15-day time frame. On the day of receipt of each dietary record, a 24-hour recall covering the same period was conducted by telephone interview with a dietitian. Values of the dietary variables were adjusted for within-subject variance and energy intake. Pearson and Spearman correlation coefficients were employed in the analysis of the results obtained using the two Methods of assessment.

Results: Only 60 participants (mean age 31 years) completed all stages of the study, and of these 78.3% were female and 45% were overweight. The mean intake values of lipids, calcium, iron, sodium, vitamin B6 and vitamin C were statistically equivalent for both

Methods of assessment. Adjusted correlation coefficients ranged from 0.61 (for lipids) to 0.87 (for energy) ($p < 0.05$).

Conclusions: The NutriQuanti® internet-based dietary record system showed satisfactory agreement with the classical 24-hour recall method for use in classifying individuals and groups according to their energy and nutrient intakes.

Key words: Food intake, Nutritional status, Public health, Dietary assessment, Relative validity

PO441**NUTRITIONAL EFFICIENCY AND THE QUALITY MENU OF THE NATIONAL SCHOOL NUTRITION PROGRAM (PNAE) IN BRAZIL**

J. Yumi Toyoyoshi¹, R. Oliveira¹, M. Sineide Neres dos Santos², D. Behar¹, F. Dias Bellão¹, A. Polo Galante¹

¹Course of nutrition, Centro Universitário São Camilo, São Paulo, Brazil

²ONG Action Fome Zero, São Paulo, Brazil

Background and objectives: The adequacy of nutrition during childhood is essential, ensuring the growth and development of children. First eating habits are incorporated in childhood, so the school environment is a key to this determination. This study aim to evaluate the correlation between nutritional efficiency and the quality of the menu provided on units receiving the National School Nutrition Program (PNAE), according to the methodology Award Efficient Public Manager of School Meals 2012.

Methods: This was a descriptive study, performed by database manager of the Award Efficient Public Manager of School Meals 2012.

Results: The South region had higher amounts of actions for the nutritional efficiency, with 16.5%. Already the North had only 7.7%. Comparing these data with the quality of the menus offered to children, it was noted that there is no relationship between them, because the Southeast region showed better grades of the menus, due to serving another meal (usually milk or dairy products) and by this 'type lunch meal' is near 12pm. The South was the region with the highest prevalence of low grades (5.5%), which may be explained by a study which indicated that between regions of Brazil, the South stands out 86.5% of presenting menus with regional preparations and despite having greater availability of fruit, the consumption is low.

Conclusions: The practice of nutrition education in schools was not related to the quality of the menu offered. Although the South has better nutritional efficiency, the quality of the menu was lower. It is necessary, therefore, that education and nutritional efficiency are applied not only in theory but mainly in practice by encouraging and changing eating habits of children.

Key words: Nutrition Education. School Food. Menu Planning.

PO442**STRENGTHEN NUTRITION EDUCATION IN PRIMARY SCHOOLS, USING SCHOOL GARDENS BASED LEARNING IMPROVE FRUIT AND VEGETABLE CONSUMPTION AMONG STUDENTS AND TEACHERS.**

C. Dardano¹

¹Food and Agriculture Organization From The United Nations

Background and objectives: One of FAO priorities is assist member state to implement practical nutrition education intervention in the school. Objectives: To test the potential and effectiveness of nutrition education, school garden based learning and cooking classes in increasing the consumption of fruit and vegetables among children, teachers and parents. Theory, prior, rationale: strengthening the curriculum with topics of nutrition, food security and food safety, use school garden as a teaching tool and incorporate garden produce in school meals, increase preferences and consumption of fruit and vegetables amount school children.

Methods: 80 primary schools in rural areas of El Salvador, with a total of 3200 students and 240 elementary school teachers participate in one year program. Topics strengthened in the curriculum were; food for a healthy life, healthy and safe food, nutrition and health, family and community food security. School garden was used as a practical tool to teach practical nutrition issues, science, language arts, mathematics, social studies, food security and farming principle. Teaching material were develop, tested and validate. Outcome measures and analysis: The evaluation included a pre, post- assessment, Food frequency, food preferences and knowledge, attitude and practices questionnaire were administrate to students, teachers and parents. The use of the School garden as a teaching tool was evaluated also acceptance of the school meal menu.

Results: From baseline to final parents and teachers were more confident that they could encourage children to eat fruit and vegetables for lunch and supper.

Conclusions: The interventions development a positive environments within the education community, increasing preferences for fruit and vegetables as well as knowledge of nutrition, besides being more conscious about what they eat. Ministry of Education is implemented the program at national level.

Key words: nutrition education, school garden, beliefs

PO443**ESTIMATION OF INSULIN RESISTANCE IN MEXICAN ADULTS BY THE [13C]GLUCOSE BREATH TEST CORRECTED FOR ENDOGENOUS TOTAL CO₂ PRODUCTION***E. Ibarra¹, M. Candia², G. Alvarez², M. Valencia^{2,3}*¹Department of Obesity and Eating Behaviors, Public Health Secretary, Hermosillo, Sonora, Mexico²Department of Medicine and Health, Sciences, and the Energy Metabolism and Body Composition Laboratory, Department of Chemical and Biological Sciences, University of Sonora, Hermosillo, Sonora, Mexico³Nutrition Division, Centro de Investigación en Alimentación y Desarrollo, A.C., Hermosillo, Sonora, Mexico

Background and objectives: Type 2 diabetes is commonly preceded by a preclinical state known as prediabetes, which involves subclinical β -cell dysfunction known as insulin resistance (IR). Insulin resistance has been recognized as the key factor in the development of type 2 diabetes. Moreover, data from clinical trials have shown that IR can be reduced by weight loss and changes in lifestyle behaviors and that early interventions to reduce IR can delay or prevent the onset of type 2 diabetes. Thus, there is a need to identify individuals with IR before they develop glucose intolerance and type 2 diabetes; various methods are available, but the practical diagnosis of IR remains a challenge. A novel noninvasive method has also been proposed, involving estimation of IR based on carbohydrate metabolism of ¹³C-labeled glucose. The aim of this study was to evaluate the efficacy of the [¹³C]glucose breath test to measure IR, considering total CO₂ production in an adult Mexican population.

Methods: Fifty-eight adults underwent a [¹³C]glucose breath test with simultaneous measurement of total CO₂ production by indirect calorimetry, at baseline and 90 minutes after the ingestion of 15 g of dextrose and 25mg of [¹³C]glucose. HOMA was used as a marker of insulin resistance.

Results: We found an inverse correlation between HOMA and the breath test $\delta^{13}\text{CO}_2$ (‰), $r = -0.41$ ($P = 0.001$). After adjusting for total CO₂ production, correlations between HOMA and fasting glucose were less strong but remained significant. An ROC curve was constructed using $\delta^{13}\text{CO}_2$ (‰) and HOMA values; the cut-off point was 9.99‰ $\delta^{13}\text{CO}_2$, corresponding to a sensitivity of 80.0 (95% CI: 51.9, 95.7) and a specificity of 67.4 (95% CI: 51.5, 80.9).

Conclusions: The [¹³C]glucose breath test is a simple noninvasive procedure but was not sufficiently robust for an accurate diagnosis of insulin resistance. Our findings suggest that the test might be helpful in identifying individuals who are not IR, which in turn may contribute to improved diabetes prevention.

Key words: Diabetes, Breath Test, Stable Isotopes, Insulin Resistance

PO445**MULTIPLE MICRONUTRIENT DEFICIENCIES: THE TANZANIA DEMOGRAPHIC AND HEALTH SURVEY 2010***D. Garrett^{1,4}, V. Assey², R. Baingana³, G. Rojas⁴, S. Tata-la², G. Mulokozi², S. Kimboka*¹PATH, 2201 Westlake Avenue, Seattle, Washington, USA²Tanzania Food and Nutrition Center, Dar es Salaam, Tanzania³Department of Biochemistry, Makerere University, Kampala, Uganda⁴MEASURE DHS Project, ICF International, Calverton, Maryland, USA

Background and objectives: Vitamin and mineral deficiencies are significant public health problems in developing countries. Deficiencies of vitamin A (VA), iron and iodine are common in women of reproductive age and are linked to detrimental health outcomes. The Tanzania Demographic and Health Survey 2010 assessed the prevalence of vitamin A deficiency (VAD), iron deficiency (ID) and iodine deficiency (IDD) in a nationally-representative sample of women 15-49 years.

Methods: Dried blood spot (DBS) samples were prepared from blood obtained by finger stick from 9000 women for measurement of retinol-binding protein (RBP), a proxy for VA and transferrin receptor (sTfR) a marker of ID. VA and ID data were adjusted for the influence of infection or inflammation by testing a sub-sample of women for C-reactive protein (CRP). CRP, RBP and sTfR were determined by enzyme immunoassay (EIA). Urine samples were collected from 10000 women to estimate the urinary iodine concentration (UIC) by titration.

Results: The unadjusted prevalence of any VAD in women (RBP < 1.24 $\mu\text{mol/L}$) was 42.0%; the adjusted prevalence was 36.7%. ID (sTfR > 8.3 $\mu\text{g/mL}$) was 30.0%. The percentage of women with both ID and anaemia (Hb < 11.0 g/dL and < 12.0 g/dL for pregnant and non-pregnant women, respectively) was 14%. The median UIC in women was 160 $\mu\text{g/L}$. Thirty six percent of women were iodine deficient (UIC < 100 $\mu\text{g/L}$) whereas 22% had an optimal UIC (150-300 $\mu\text{g/L}$). The determinants of these micronutrient deficiencies will be assessed in further analysis of the data.

Conclusions: Vitamin and mineral deficiencies are prevalent among women 15-49 years old in Tanzania, with 30% of women being deficient in VA, iron or iodine. A comprehensive nutrition intervention is needed to combat vitamin and mineral deficiencies among women in Tanzania.

Key words: VAD; iron deficiency; iodine deficiency; Tanzania; Demographic Health Surveys (DHS)

PO446**DIETARY PATTERNS AND MORTALITY RISK IN THE MULTIETHNIC COHORT STUDY***S Y. Park¹, L R. Wilkens¹, B E. Henderson², L N. Kolonel¹*¹Epidemiology Program, University of Hawaii Cancer Center, Honolulu, HI, USA²Department of Preventive Medicine, University of Southern California, Los Angeles, CA, USA

Background and objectives: Overall dietary patterns may provide insights into the associations between diet and diseases that the assessment of individual foods/nutrients may not uncover. We prospectively investigated the association between three distinct dietary patterns, 'Fat and Meat' (characterized by high intake of discretionary fat, meat, eggs, and cheese), 'Vegetables' (vegetables groups), and 'Fruit and Milk' (milk/yogurt and fruit groups) and risk of all-cause, cancer, and cardiovascular mortality in the Multiethnic Cohort with more than 215,000 African Americans, Native Hawaiians, Japanese Americans, Latinos, and whites.

Methods: For this analysis, we only included 148,693 participants who reported no history of heart disease, cancer, or stroke. During 13 years of follow-up, 22,735 deaths occurred, including 7703 cancer deaths and 7926 cardiovascular deaths. Risk was estimated using Cox proportional hazard models.

Results: After multivariable adjustment using a comprehensive smoking model, Fat and Meat pattern was associated with a higher risk of all-cause (highest vs. lowest quintile: hazard ratio (HR) = 1.36, 95% confidence interval (CI): 1.27, 1.46), cancer (HR = 1.17, 95% CI: 1.04, 1.32), and cardiovascular (HR = 1.42, 95% CI: 1.27, 1.60) mortality. In contrast, Vegetables pattern was related to a lower risk of all-cause (HR = 0.85, 95% CI: 0.81, 0.89), cancer (HR = 0.88, 95% CI: 0.81, 0.96) and cardiovascular (HR = 0.85, 95% CI: 0.79, 0.93) mortality. The associations were similar in never smokers only, which suggested no evidence of residual confounding by smoking. However, Fruit and Milk pattern showed a slight increase in risk of all-cause mortality overall but no significant association in never smokers.

Conclusions: A dietary pattern high in fat and meat may increase the risk of all-cause, cancer, and cardiovascular mortality, whereas a dietary pattern high in vegetables may reduce the risk.

Key words: dietary patterns, mortality, cancer, cardiovascular disease, multiethnic cohort

PO447**OVERWEIGHT AND OBESE AMONG VERY YOUNG CHILDREN IN CHILE AND ASSOCIATION WITH EARLY DEVELOPMENT***R. Kagawa¹, L. Fernald², J. Behrman³*¹School of Public Health, University of California, Berkeley, USA²School of Public Health, University of California, Berkeley, USA³University of Pennsylvania, USA

Background and objectives: To document the prevalence of overweight and obesity among very young children in Chile and to explore the association of overweight/obesity with early childhood development. Child obesity/overweight may act through health and self-image to influence later social and economic success. This study strengthens our understanding of causal pathways by exploring whether developmental comorbidities are present at a very young age.

Methods: This study uses cross-sectional data from the first wave of the Chilean Encuesta Longitudinal de la Primera Infancia (ELPI), which is a nationally representative sample of about 15,000 children and their families. We used validated scales to measure socio-emotional, behavioral, motor, language and overall development. This study uses multivariate linear regression to estimate the association between overweight/obesity and early childhood development while controlling for confounding factors.

Results: In Chile, 35% of very young children are obese or overweight (defined as >2SD) and 21% are obese (>3SD). A higher prevalence of obese children live in urban areas (OR, 1.18; P=0.02, 95% CI, 1.025, 1.347). Controlling for opportunities for physical activity and indicators of socioeconomic position (e.g. wealth and maternal education), a higher prevalence of obesity, but not overweight, was associated with three measures of development: the Test of Psychomotor Development (Coordination: RR, -0.152; P< 0.005; 95% CI, -0.213, -0.091. Gross Motor: RR, -0.177; P<0.005; 95% CI, -0.238, -0.115) the Evaluation Scale of Psychomotor Development (RR, -0.170; P<0.005; 95% CI, -0.250, -0.090) and the Spanish adapted version of the Peabody Picture Vocabulary Test (RR, 0.077; P=0.026; 95% CI, 0.009, 0.145).

Conclusions: Early childhood obesity in Chile is associated with arrested language and motor skill development. Understanding the type of comorbidities present at a very young age can help clarify causal pathways linking obesity, development, and later social and economic success.

Key words: early childhood development, obesity, overweight

PO448**THE PROBLEM OF STUNTED CHILDREN IN INDONESIA AND ITS IMPLICATION FOR THE COUNTRY DEVELOPMENT***Atmarita¹, Soekirman²*¹The National Institute of Health Research and Development, Ministry of Health, Indonesia²Danone Institute Indonesia

Background and objectives: Chronic malnutrition problems in Indonesia are illustrated by the high prevalence of short children aged 0-59 months which close to 40 percent. This paper attempts to provide concrete recommendations based on identified risk factors for chronic malnutrition and stunting.

Methods: The descriptive assessment was apply using data collected from Basic Health Research (Riskesdas) 2010 by National Institute of Health Research and Development (NIHRD), Ministry of Health

Results: Children in Indonesia are still far behind in nutritional attainment as shown by the achievement of average height of children when they are 19 years old. Among males attained a mean height of 162.9 cm, which is 13.6 cm shorter than international WHO reference mean height for this age and 19 year old girls had a mean height of 152.8 cm or 10.4 cm shorter than the WHO height reference.

Conclusions: Impaired growth during childhood indicates less efficient development especially in the improvement of human resources. Comprehensive and integrated efforts should be urgently needed and started from the root causes of poverty affecting nutritional intake through various forms of community empowerment, including behavior changes which stimulates intervention program acceleration to combat stunting risk.

Key words: stunted children, poverty, country development

PO449**HYDROGEN GENERATED BY FERMENTATION OF DIETARY FIBER AND RESISTANT STARCH RELIEVES OXIDATIVE STRESS IN RATS.***N. Nishimura¹, H. Tanabe¹, Y. Sasaki¹, Y. Makita¹, M. Ohata¹, T. Yamamoto¹*¹Department of Nutritional Sciences, Nayoro City University, Nayoro, Hokkaido, Japan

Background and objectives: Excessive oxidative stress can trigger the onset and progression of various lifestyle diseases. Recently, the effects of hydrogen (H₂) on reducing oxidative stress have been clarified and its reduction activity in vivo has

been confirmed in rodents administered H₂ through inhalation of H₂ gas and drinking H₂ water. The aim of this study was to determine the effect of H₂ generated by fermentation of dietary fiber and resistant starch in the large intestine in rats with hepatic ischemia-reperfusion (IR) injury, an oxidative stress model.

Methods: Rats were fed diets containing non-fermentable cellulose (negative control), pectin and high amylose cornstarch (HAS; resistant starch source) for 7-14 d. On the last day of the experimental period, rats were subjected to IR treatment (ischemia 30 min, reperfusion 45 min). Portal H₂ concentrations were measured using a gas chromatography technique. The extent of oxidative stress was determined by the hepatic ratio of reduced:oxidized glutathione and plasma ALT and AST activities.

Results: The ability to produce H₂ in the large intestine was enhanced by feeding pectin and resistant starch (5-10 umol portal H₂/L) but not cellulose (0.5-1 umol portal H₂/L). A high ratio of reduced:oxidized glutathione was induced in IR rats fed pectin and HAS diets compared to control IR rats. Furthermore, plasma ALT and AST activities in IR rats fed pectin and HAS were lower than in the control IR rats.

Conclusions: H₂ generated by large intestinal fermentation could relieve oxidative stress. Large intestinal generation of H₂ potentially plays a significant role in the control of various lifestyle diseases that can be achieved through long-term dietary fiber and resistant starch intake.

Key words: hydrogen, dietary fiber, resistant starch, fermentation, oxidative stress

PO450**CORRELATIONS BETWEEN DIFFERENT ANTHROPOMETRIC MEASUREMENTS AND INDICES IN A SELECTED SRI LANKAN POPULATION- A PRELIMINARY STUDY***K N W. Walatara¹, K. Anusha¹, M F F. Nusha¹, U P K Het-tiaratchi¹, L V. Athithan¹, P P R. Perera¹*¹Department of Biochemistry, Faculty of Medical Sciences, University of Sri Jayewardenepura, Sri Lanka

Background and objectives: Prevalence of obesity is increasing rapidly in the world. In Sri Lanka the percentage of adults in overweight, obese and centrally obese categories are 25.2%, 9.2%, 26.2% respectively according to World Health Organization (WHO) cut-off values for Sri Lankans. Obesity leads to further health concerns such as diabetes, cardiovascular disease etc. There are several anthropometric measurements & indices used in assessing body fat levels such as Waist Circumference (WC), Hip Circumference (HC), Mid Arm Cir-

cumference (MAC), Body Mass Index (BMI) & Waist to Hip Ratio (WHR). Thus, the aim of this study was to investigate the correlations between these parameters with each other and age.

Methods: This descriptive cross sectional study was carried out with 46 non diabetic individuals (age: 22-60 years). Ethical approval was obtained from the Ethics committee, Faculty of Medical Sciences, University of Sri Jayewardenepura. Anthropometric measurements (weight, height, WC, HC, MAC) and indices (BMI, WHR) were obtained according to WHO and NHANES III standards and data were analyzed using SPSS version 16.

Results: BMI range of the population was 17.9 kg/m² - 36 kg/m² with 41% of the population having a BMI of >25 kg/m². BMI values showed significant correlations with HC, WC, and MAC (p<0.05). WHR indicated significant correlation with only WC (p<0.05). MAC did not yield significant correlation (p>0.05) with WHR but had significant correlations with other parameters measured (p<0.05). Participants >35 years had a WHR >0.85 and participants <35 years had a WHR <0.85. A significant correlation with age and WHR (p<0.05) was observed, however, no significant correlations were observed between age and other parameters.

Conclusions: BMI and MAC might be better parameters compared to WHR to estimate body fat levels in this population.

Key words: Anthropometric measurements, anthropometric indices, BMI, WHR, MAC

PO451

HOME BASED COMPLEMENTARY FEEDING IN COMMUNITIES OF BANGLADESH: TRIALS OF IMPROVED PRACTICES (TIPS)

S K. Roy¹, I. Kabir¹, K. Jahan¹, N. Sultana¹, I. Jahan¹, K S.¹, B. Lalita¹, M M A.¹

¹Bangladesh Breastfeeding Foundation, Institute of Public Health, Dhaka, Bangladesh

Background and objectives: In Bangladesh child malnutrition is reflected with high level of stunting and micronutrient deficiency. Appropriate complementary feeding practices are only 21% in Bangladesh (BDHS 2011). Age appropriate complementary feeding with sufficient energy & nutrient dense food can combat challenges of food insecurity and lack of access to diverse nutritious foods. The study aimed at developing complementary feeding manual with guidance for improving complementary feeding practices in Bangladesh.

Methods: A base line study was conducted all over Bangladesh on current practices of complementary feeding Based on the results from the literature review and baseline survey (FGDs, in-depth interviews and observational data) reci-

pes have been formulated considering availability, seasonality, energy density, protein content, micronutrient, minimum dietary diversity, cost, feasibility, acceptability following standard guidelines for the children of 6 to 23 months of age. Improved recipes were then tried in child in seven divisions of Bangladesh. Acceptance were evaluated using standard score card. Laboratory analyses of improved recipes for 10 ingredients were also assessed for adequacy of nutrients.

Results: All 35 recipes were well accepted by children and their care takers. A guideline and manual for appropriate CF practice considering the complementary foods, recipe options, key nutrition education messages and recommendations based on Trials of Improved practices (TIPS) carried out in Bangladesh has been developed.

Conclusions: The tested and improved recipes will be used for the children of Bangladesh to prevent malnutrition and the guidelines and the pictorial manual will help nutrition practitioners of developing countries of the world.

Key words: Home-based, Complementary Feeding, TIPS, children

⁷Aga Khan University, Karachi, Pakistan

⁸Christiana Health Care, Newark, Delaware

⁹University of Alabama at Birmingham, Birmingham, Alabama

¹⁰University of Crete School of Medicine, GR-71033 Crete, Greece

Background and objectives: Sub-optimal breastfeeding has been recognized as a leading risk factor for global burden of disease in 2010. Timely initiation of breast feeding (TIBF) or breastfeeding (BF) in the first hour is included in the essential newborn care (ENC) guidelines of the WHO and exclusively

breast feeding (EBF) is recommended for first 6 months of life but have been a challenge to achieve globally. This study determined prospectively the prevalence of TIBF and EBF at 6 weeks postnatal and factors associated with lack of TIBF and EBF in rural communities of 6 low-middle income countries trained in ENC. DESIGN/

Methods: A Maternal and Newborn Health Registry prospectively enrolled 31,608 pregnant women followed to 6 weeks postnatal in rural communities in 6 countries (Kenya, Zambia, Guatemala, Argentina, Pakistan and India) between January 2010 and December 2012.

Results: TIBF rates ranged from 28% to 91% and that of EBF at 6 weeks ranged from 85% to 99%. The significant adjusted relative risks for lack of TIBF were older maternal age (1.01), lower parity (1.02 for none, 1.03 for 1), caesarian section (1.9), LBW <1500g (1.72), 1500-2499 (1.16), multiple births (1.18), female (0.98), resuscitation (1.37), baby not placed on mother's abdomen after delivery and for non EBF were older maternal age (1.02) parity > 2 (1.34), some schooling (1.62), LBW <1500g (2.56), 1500-2499g (1.24), lack of TIBF (1.42), clean fuels for household cooking (1.32).

Conclusions: Despite standardized ENC training, rates of TIBF vary widely across countries. Reinforcement of training and alternate methods to administer breast milk to LBW or resuscitated neonates may be needed to improve TIBF, and, EBF in those that do not receive TIBF. Stakeholders to promote EBF post-partum may consider targeting older women with some education and higher parity.

Key words: Exclusively Breastfeed, Initiate Timely Breast-feeding

intervention and the process evaluation for the first year are described.

Methods: Both the intervention mapping protocol and the Comprehensive Participatory planning and Evaluation approach were used when developing the intervention. A cross-sectional study and a formative evaluation including focus groups, literature review and participatory stakeholder workshops were undertaken to inform its development. A process evaluation was conducted including the 'reach' and 'dose' of the intervention components for parents and adolescents.

Results: An intervention framework with different strategies targeting adolescents, parents and school tuck shops was developed. These strategies included individual (i.e. an interactive programme on healthy nutrition and PA) and environmental (i.e. workshops with parents and tuck shop staff and a walking trail) components. The effectiveness of the intervention on BMI, dietary and PA behaviour was evaluated through a paired-matched cluster RCT in 20 secondary schools (NCT01004367). Of the 73.3% teachers who initially agreed to participate, only 58.6% provided the classes and 23% of parents attended the workshops. In contrast, reach was high among adolescents (95%). Importantly, the intervention 'dose' was high, with 84% of classes and 100% of workshops provided.

Conclusions: The ACTIVITAL! project developed a school-based intervention tailored to the cultural needs of Ecuadorian adolescents and their environment. Intervention components were successfully implemented and reached a high dose. It's important to have clear and transparent reporting of intervention development and process evaluation, to be able to apply such interventions in similar settings.

Key words: Ecuador, process evaluation, adolescents, health promotion intervention

DESIGN AND PROCESS EVALUATION OF A PAIRED-MATCHED RANDOMIZED CONTROLLED HEALTH PROMOTION TRIAL IN ECUADOR

R. Verstraeten^{1,2}, L. Maes³, P. Kolsteren^{1,2}

¹Department of Food Safety and Food Quality, Ghent University, Ghent, Belgium

²Nutrition and Child Health Unit, Institute of Tropical Medicine, Antwerp, Belgium

³Department of Public Health, Ghent University, Ghent, Belgium

Background and objectives: Childhood obesity is increasingly prevalent in low- and middle-income countries, and effective health promotion interventions are required to tackle it. A theory- and evidence-based project 'ACTIVITAL!' aimed to design, implement and evaluate a school-based intervention to improve physical activity (PA) and dietary behaviour among Ecuadorian adolescents. The systematic development of the

PO454

ANTI INFLAMMATORY EFFECT OF CINNAMALDEHYDE ON A MICROGLIA, MG6

K.I. Minato¹, M. Hayasaka¹, A. Ohara¹

¹Department of Applied Biological Chemistry, Meijo University, Nagoya, Japan

Background and objectives: It has been known that cinnamaldehyde, isolated from leaves of *Cinnamomum mosmosmophloeum*, exhibited an anti-inflammatory effect on monocytes/macrophages. It has been reported that an active monocyte/macrophage secreted proinflammatory cytokines, such as IL-1, TNF-, IL-6, and free radical molecules, reactive oxygen species and nitric oxide (NO). These molecules have been recognized to become signal transduction molecules in management of innate and adaptive immunity. However, it is concerned that inflammatory damage would be induced, if they are secreted

excessively in monocyte/macrophage. In this study, we investigated whether cinnamaldehyde could inhibit hyper-inflammatory action in monocyte/macrophage.

Methods: MG6 is classified into microglia as murine brain macrophage. It is considered that various proinflammatory molecules were excessively produced from this microglia during activation of it. However, such chronic hyper-inflammation of microglia is recognized to induce neural disorders. We examined whether cinnamaldehyde could down-regulate expressions of proinflammatory cytokines, IL-1, TNF- α , and IL-6, and free radical such as NO in inflammatory microglia, MG6, stimulated with LPS.

Results: In this work, it was shown that cinnamaldehyde could inhibit to induce active proinflammatory cytokines. Although IL-1 mRNA expression did not change in stimulated MG6 by qRT-PCR analysis, production of active IL-1 protein might be inhibited by cinnamaldehyde. It was also suggested that an inhibition of caspase-1 production, which could converse the preform of IL-1 into active form, might contribute to this down-regulation by cinnamaldehyde. Moreover, it was suggested that this compound could down-regulate expression of other proinflammatory cytokines mRNAs and production of NO in the microglia stimulated with LPS.

Conclusions: These results suggested that cinnamaldehyde could inhibit hyper inflammatory of microglia. And, we consider that anti-inflammatory action of it could contribute to prevention from nervous disorders, and thus, cinnamon leaves could be used as effective materials for our health care.

Key words: cinnamaldehyde, microglia, MG6, anti-inflammatory

PO455

WORKFLOW OF ISOLATION AND FUNCTIONAL CHARACTERIZATION OF ORDESA'S PROBIOTIC STRAIN COLLECTION

J.A. Moreno Muñoz¹, G.C. Cifuentes¹, M. Rodríguez-Palmero¹, J. Puigjaner¹, M. Rivero¹

¹Laboratorios Ordesa, Barcelona, Spain

Background and objectives: The intestinal microbiota is an important factor for health and the evolution of diseases in humans and animals. For this reason efforts have focused in the use of different techniques to isolate and characterize bacteria with probiotic properties that could be used as preventive agents. The objective of this study was establish an effective workflow to isolate probiotic strains from human samples, including human milk, and feces of breastfeeding mothers and their babies.

Methods: Several samples of human origin including breast milk (aseptically obtained), infant feces and breast milk mother's feces have been used. Several dilutions of these homogenized samples were plate in different culture media under anaerobic conditions at 37°C. For each colony, cellular morphology and Gram stain was determined. Gram-positive rod-shaped bacteria were selected to test catalase, oxidase, aminopeptidase and F6PPK activities. Putative Lactobacillus and Bifidobacterium species were genetically identified sequencing and comparing 16S rRNA sequences obtained with the Ribosomal Database Project (<http://rdp.cme.msu.edu/>). Strains identified as a member of Lactobacillus or Bifidobacterium genus were selected to test their biochemical activities (carbohydrates profile and specific enzyme activities) using API 50CH and API ZYM, and also to establish their Random Amplification of Polymorphic DNA (RAPD) profile.

Results: More than 400 potential probiotic strains have been isolated and identified using this workflow. The genetic data obtained has been used to elaborate phylogenetic trees to evaluate biodiversity, and the biochemical data has been used to improve phylogenetic trees by elaborating biodiversity dendrograms in order to classify all Ordesa's probiotics in groups of biodiversity. A clear representative probiotic strain has been identified for each biodiversity group.

Conclusions: The workflow used to isolate and characterize strains was effective, high amount of potential probiotic bacteria have been recovered from human feces and breast milk.

Key words: gastrointestinal microbiota, infants, Lactobacillus, Bifidobacterium, probiotics.

PO456

EVOLUTION OF PHYSICAL FITNESS IN A 4 YEAR-PERIOD IN NON-INSTITUTIONALIZED ELDERLY: MADRID- EXERNET LONGITUDINAL STUDY

O. Lopez-Torres¹, R. pedrero-chamizo¹, G. Palacios¹, B. Maroto¹, D. Cañada¹, A. Meléndez¹, M. González-Gross¹

¹ImFINE Research Group, Madrid, Spain

Background and objectives: To maintain adequate physical fitness levels (PFL) in elderly is important to keep independence and life quality. The aim of this study was to assess the evolution of PFL in a 4-year period in non-institutionalized Spanish elderly.

Methods: 187 subjects (≥ 65 y) from the Madrid cohort of the Longitudinal EXERNET study were analysed twice: in 2008 and 2012 for static balance (SB), leg strength (LSt), arm strength (ASt), flexibility, agility (A), walking speed (WS) and aerobic capacity (AC) using eight test (Rikli & Jones). Parametric and non-parametric analyses were executed with SPSS. Right-arm flexibility (RAF_x), Left-arm flexibility (LAF_x) and AC were

analysed with a T test. SB, leg flexibility (LFx), A and WS were analysed with a Wilcoxon Test. Data were analysed according to sex and initial age: 65-69y: GA1; 70-74: GA2; and ≥ 75 : GA3).

Results: Mean SB (29.0-21.7s), A (5.2-5.8s), WS (16.1-17.7s), and AC (536.6-487.2 m) scores decreased significantly after the 4 year-period (first and second measurement) in the whole sample, independent of age and sex (all ≤ 0.05). Arm (-16.2/-12.6 cm) and leg (-5.0/-3.1 cm) scores improved in the 4 year-period. Decreases were more pronounced in men than in women in all tests. Significant differences were observed within GA1 for SB (38.6 - 26.6 s), arm (-14.6/ -8.1 cm) and leg (-6.4/-1.6 cm) flexibility, A (5.1-5.8 s), WS (14.9-16.6 s) and AC (597.8-531.2 m). Within GA2 and GA3 significant differences were found for A and WS.

Conclusions: Physical capacity tends to decrease in the 4 y period except for flexibility and ASt. AG1 is much more affected than the other two groups. Results show that fitness tends to worsen strongly in AG1 and in men, while the tendency in the other groups and women is not so marked.

Key words: Fitness, elderly, quality of life

PO457

FOOD AVAILABILITY AND QUALITY OF THE DIET IN HOUSEHOLD FROM SPAIN (1964-2011)

S. del Pozo¹, T. Valero¹, E. Ruiz¹, J M. Ávila¹, G. Varela-Moreiras^{1,2}

¹Fundación Española de la Nutrición (FEN), Spain

²University CEU San Pablo, Madrid, Spain

Background and objectives: The aim was to describe the food availability, the dietary patterns and some markers of dietary quality in Spanish household.

Methods: This study is based on the household consumption assessed by the National Institute of Statistics (INE) and the Spanish Ministry of Agriculture, Food and Environment (MAGRAMA) in collaboration with the Spanish Nutrition Foundation (FEN).

Results: Many differences are observed regarding the consumption of foods in Spain between the 60's and nowadays. The most important changes are observed between 1964 and 1981 in almost all food groups, especially in dairy (1964:228 g/person/day; 1981:381 g/person/day; 2011:308 g/person/day), fruits (1964:162g/person/day; 1981:283 g/person/day; 2011:291 g/person/day) and meat (1964:77g/person/day; 1981:179 g/person/day; 2011:141 g/person/day), except in oil and fats where the most important changes are observed between 1991 (54,9 g/person/day) and 2001 (35,3 g/person/day). The consumption was much higher in 1964 than in 2011 for cereals (143 g/person/day in 1964 vs. 160 g/person/day at present), oils and fats (468 g/person/day vs. 31,9 g/person/day),

legumes (1964:41 g/person/day-2011:10,7 g/person/day), and lower for fruits (162 g/person/day and 291 g/person/day in 2011) and meat (77 g/person/day (1964) and 141). Energy intake in household declined about 1000 kcal/person/day, when compared the mean consumption in 2011 (2075 kcal/person/day) with 1964 (3008 kcal/person/day). The contribution (%) of macronutrients and alcohol to energy consumption in Spain from 1964 to 2011 shows also important differences (protein 12% in 1964 vs. 15% nowadays; lipids, from 32% to 41% in 2011; carbohydrates: 53% in 1964 and 42% in 2011). The data from 1960's were much more close to the recommendations. In order to evaluate the dietary fat quality, the percentage contribution of the three fatty acid families to the total energy was calculated (1964vs.2011): SFA (8.6%vs.11.9%), PUFA (3.7%vs7.5%), whereas for the MUFA there were almost no modifications (17%vs.17,9%).

Conclusions: Social and economic changes have led to important modifications in food and dietary patterns in the last few decades, some changes have had a potential positive impact whereas others have moved the Spanish diet somewhat away from the traditional Mediterranean one.

Key words: Food-availability, household, quality-diet, food-patterns, Spain

PO458

PRODUCT FORMULATION FROM DEHYDRATED SPINACH AND CARROT: IMPACT STUDY OF THE DEVELOPED VIDEO FILM INVOLVING LOCAL LEADERS

K. Parveen¹, A. Rajendra²

¹Department of Home Science, Guru Nanak Girls Degree College, Pradesh, India Simran

²College of Home Science and Women's Development, Allahabad Agricultural Institute – Deemed University, Uttar Pradesh- India

Background and objectives: Awareness about the nutrient content of vegetables is very less especially in the rural areas where they are grown abundantly. In view of this, the present study was undertaken with the objective to produce a video film on products developed from dehydrated vegetables i.e. spinach and carrot. Its impact on rural women was then studied.

Methods: Rural women between the age of 18-35 years were selected from two villages of Allahabad district namely Malakharhar (n=40) as experimental group and Champatpur (n=40) as control group. The film entitled 'Nirjalikrit palak avam gajar se bane paushtik alpahar' was produced for nutrition education showing the importance of vegetables, their dehydration and product formulation to combat micronutrient deficiencies. Video film was shown only to the experimental group first; without discussion and then with discussion.

Results: Before nutrition education, majority of the respondents (90%) were in low knowledge category in both the groups. When the experimental group was exposed to video film, their knowledge level rose and majority of the respondents obtained medium score (67.5%) and when the same group was exposed to video film followed by discussion, their mean knowledge score further increased to 83.10 percent. Whereas there was no improvement in the knowledge scores of control group. The difference in the pre and post exposure knowledge scores (70.68 %) of experimental group was found to be highly significant ($P < 0.01$). Percent retention in knowledge was found to be 74.52, 30 days after exposure to video film.

Conclusions: Education level of respondents was positively and significantly correlated with knowledge scores of the experimental group. Therefore it can be concluded that this film can be used in teaching and popularizing of recipes developed by incorporating dehydrated vegetables.

PROMESA II STUDY: EFFICACY FOR LOSING WEIGHT OF A MULTIDISCIPLINARY WEIGHT-LOSS PROGRAMME (PRONOKAL® METHOD)

J. Pérez-Guisado¹, N. Gil², I. Sajoux³, J. Fondevila⁴

¹Departamento de Medicina, Universidad de Córdoba, Spain

²Head of Nutrition Department, CO PNK Distribution

³Medical Department, Pronokal Group

⁴Director, Punta Alta

Background and objectives: The Pronokal® Method is a multidisciplinary weight-loss programme involving diet, physical exercise and coaching under medical supervision. It consists of an active stage, divided into 3 phases with a very low calorie ketogenic diet (protein diet) followed by dietary re-education stage and maintenance stage. This study evaluates the efficacy of method for losing weight during the active and dietary re-education stages.

Methods: Prospective, multicentre, epidemiological study on the efficacy for losing weight of the multidisciplinary programme (Pronokal® Method). The patients began with the active stage, with protein diet based on products made with high biological value proteins, until they had lost 80% of their excess weight. They then began dietary re-education stage with gradual reintroduction of different foods. The physical exercise and coaching were maintained throughout. Weight-loss results and differences between genders were analysed using comparison tests Student's t-test and ANOVA.

Results: Data were recorded from 3435 patients (83% female), with mean BMI of 32.68 ± 5.83 . Mean weight loss was -17.42 kg. During the active stage, weight loss was -14.43 kg (82.8% of weight loss) ($p < 0.0001$) and during the dietary re-education stage, the weight loss was -2.99 kg (17.2% of weight loss) ($p < 0.0001$). The men lost comparatively more weight than the women, both in absolute terms and percentage-wise, during both the active stage (-13.44 kg vs. -9.90 kg; $p < 0.05$ and 11.90% vs. 11.10%; $p = 0.05$) and the dietary re-education stage (-21.06 kg vs. -15.01 kg; $p < 0.05$ and 19.22% vs. 17.72%; $p < 0.05$).

Conclusions: The multidisciplinary programme (Pronokal Method) has been shown to be effective for losing weight in men and women, although men lose more than women. The bulk of the weight is lost during the active stage with the very low calorie ketogenic diet (protein diet).

Key words: obesity, multidisciplinary, very low calorie diet, protein diet, Pronokal Method.

ORGANOLEPTIC AND NUTRITIONAL EVALUATION OF VALUE ADDED PRODUCTS PREPARED FROM GERMINATED SORGHUM (SORGHUM BICOLOR) FLOUR

V. Singh¹, S. Agarwal¹

¹College of Home Science, Maharana Pratap University of Agriculture & Technology, Udaipur, Rajasthan, India

Background and objectives: Germination is a traditional method of processing which is known to have positive effects on the nutritional quality of grains. Objective: An attempt was made to develop and assess the nutritional qualities of value added products prepared from germinated sorghum flour.

Methods: For the development of products grains were germinated for 48h and milled to obtain flour. Three products namely mathri, laddoo and sweet biscuits were prepared by incorporating germinated sorghum flour (GSF) at 20, 40 and 60% level along with one control. Sensory evaluation of products was done on 9 point hedonic rating scale by a panel of ten judges.

Results: Mathri containing 20%GSF, laddoo and sweet biscuits having 40% GSF were judged as the most acceptable by the panel members. These products were chosen for analyzing proximate composition, anti-nutrients and in-vitro protein digestibility. Moisture content of products ranged from 3.82g to 4.43g/ 100g. Crude protein content varied from 8.71 to 14.13g per100g on dry weight basis. Ladoos were found to be having highest crude fibre and ash content. Biscuits were highest in fat and energy content i.e.23.5g and 486.9kcal, respectively. In terms of minerals, iron content was ranging from 2.68-3.38mg, calcium 32.0-57.2mg, zinc 1.78-3.64mg, copper 0.78- 0.99mg

and manganese content was 2.22 to 2.67mg/ 100g on dry weight basis. Tannin was observed lowest in mathri (1.26mg/100g) followed by biscuits (1.63mg/100g) and laddoo (2.98mg/100g) on dry matter basis. However, laddoo had highest phytic acid content and also the highest percentage of in vitro protein digestibility than other products.

Conclusions: Germination is a beneficial technique for enhancing the nutritive value of sorghum. Products developed from germinated sorghum flour were very well accepted and this can create a pathway for enhancing the nutrition security of the masses.

Key words: Germinated sorghum flour, product development, sensory evaluation, nutrient composition, anti-nutrients

COULD BREAD BE A GOOD VECTOR IN FIGHTING HYPERTENSION IN MOROCCO?

A. Derouiche¹, A. Jafri¹, N. Hibbi¹, H. Taki¹, R. Saile¹, R. Hebbal², M. Jabari³, M. Alami²

¹Université Hassan II Mohamedia Casablanca, Ben M'sik Faculty of Science, Morocco

²Faculty of Medicine of Casablanca, Casablanca, Morocco

³Municipal Health Division of Sidi Othmane, Casablanca, Morocco

Background and objectives: The Moroccan Health Department estimates the national HTA prevalence to 33.6% (from which 78% aren't diagnosed). Since bread is the staple food in each Moroccan household, our objective was to evaluate the average amount of salt used in making bread in order to assess the impact of its overconsumption in causing high blood pressure.

Methods: We collected 160 bread samples (80 with salt and 80 without salt as control), between March and April 2011, from 80 bakeries in Casablanca. The quantification of salt was done using the MOHR method: based on the titration of chloride ions by colorimetric assay.

Results: The average amount of salt used in the preparation of the regular bread is 17.42±1.28g of salt per Kg of flour. Taking in consideration that the average consumption of bread by Moroccans is about 500g per day, which means that the intake of salt from bread consumption only is about 8-9 g per day.

Conclusions: These results represent about two-fold the recommendations established by the Institute of Medicine (US) in their report of 2004, which are a daily intake according to age between 1500 and 2300 mg per day of sodium (3.75 and 5.75 g per day of salt), and also the therapeutic target of 2000 mg per day of sodium (5g of salt) established by 2003 by the WHO. Since bread is a staple food in Morocco and represents the source of half the sodium intake, we can only recommend

using it as a vector for a national programme to reduce salt intake in order to fight hypertension.

Key words: hypertension, salt intake, bread, Morocco

PO462

EFFECT OF MAIZE PORRIDGE WITH AMARANTH-GRAIN OR MICRONUTRIENT POWDER CONTAINING NAFEEDTA ON IRON STATUS OF KENYAN CHILDREN: TRIAL VS. SIMULATION

C. Macharia-Mutie^{1,2}, D. Moretti³, A. M. Mwangi⁴, F. J. Kok², I. D. Brouwer²

¹Ministry of Higher Education Science and Technology, Nairobi, Kenya

²Division of Human Nutrition, Wageningen University, Wageningen, Netherlands

³Laboratory of Human Nutrition, ETH, Zurich, Switzerland

⁴Applied Nutrition Program, University of Nairobi, Nairobi, Kenya

Background and objectives: In case of policy decisions when resources are limited for intervention studies, theoretical simulations may provide a guide into choice of appropriate intervention. Efficacy trials still a gold-standard for evaluating the impact of fortification with iron-rich foods such as amaranth-grain and multi-micronutrients powder (MNP) containing NaFeEDTA to control iron deficiency (ID). We compared the effects of simulating and efficacy trial of maize porridge enriched with amaranth-grain or MNP to reduce ID in Kenyan pre-school children.

Methods: A simulation using data from two surveys from Mwingi Kenya was done. In the 1st survey (2008), dietary intake data were collected by 2-day 24hr recalls (n=197). Biochemical data (n=70) was collected in 2nd survey (2010). For an 80-day simulation and 96-day intervention (n=279; 12-59 months), porridges provided: unrefined maize porridge (control; 3.7 and 4.1 mg of iron/meal); unrefined maize (30%) and amaranth-grain (70%) porridge (amaranth group; 12.7 mg and 23mg of iron/meal); or unrefined maize porridge with MNP (MNP group; 6.2 mg and 6.6mg iron/meal; 2.5mg iron as Na-FeEDTA) respectively. Treatment effects were estimated relative to control.

Results: In simulation study, ferritin concentration increased significantly in both amaranth (1.82µg/l 95% CI 1.42, 2.34) and MNP (1.80µg/l 95% CI 1.40, 2.31, p<0.005) group. Prevalence of ID was reduced by 54% in both groups. Consumption of amaranth and MNP in the trial increased ferritin concentration by [4% (95% CI=-28, 49) and 40% (95% CI=10, 95)] while prevalence of ID reduced by 17% and 70% respectively. Change was not significant in the amaranth group.

Conclusions: Both the simulation and efficacy trial show that consumption of maize porridge fortified with MNP containing NaFeEDTA reduce prevalence of ID in pre-school children. Simulations based on incomplete scientific evidence are not sufficient to replace scientific studies as there could be over estimation of effects.

Key words: Amaranth-grain, MNP, Iron

HERITABILITY OF CHRONOBIOLOGICAL PATTERN IN HEALTHY WOMEN

J. López Mínguez¹, J.F. Sánchez-Romera², C. BANDIN¹ L. Colodro-Conde², J A. Madrid¹, J R.Ordoñana², M. Garaulet Aza¹

¹Department of Physiology Faculty of Biology, University of Murcia, Murcia, Spain

²Twin Registry, School of Psychology, University of Murcia, Murcia, Spain

Background and objectives: Chronobiology is the science which studies the biological changes in the individual along time, those which run around 24 hours, are defined as “Circadian Rhythms”. Previous studies have shown the influence of genetics and environmental factors in many aspects of life but the relative influence on the chronotype of the subject is still unknown. Thus, the aim of our study was to determine the heritability of circadian rhythmicity patterns in monozygotic (MZ) and dizygotic (DZ) twin.

Methods: The pilot study was performed in 21 pairs of female twins (12 monozygotic [MZ] and 9 dizygotic [DZ]), with a BMI 24.3±2.8 and mean age 48±2. The sample was selected from the participants in the Murcia Twin Register. Zygosity was ascertained by DNA. Circadian patterns were studied by analyzing Wrist temperature that was measured during 1 week every 10 min. Rhythmic parameters were obtained using an integrated package for temporal series analysis “Circadianware®”.

Results: MZ twins showed consistently higher intra-pair correlations than DZ twins. Particularly interesting were the correlations in amplitude [MZ:r=0.830; P=0.001; DZ:r=0.258; P=0.502]; mean temperature [MZ:r=0.803; P=0.002; DZ:r=0.229; P=0.554]; M5 [MZ:r=0.555; P=0.061; DZ:r=0.063; P=0.872] and inter-daily stability [MZ:r=0.611; P=0.036; DZ:r=0.418; P=0.262]. One exceptions of this pattern was intra-daily variability.

Conclusions: The pattern of correlations found point to moderate to high heritability for most of the variables analyzed, suggesting a relevant genetic influence in the chronobiology of the studied women. Variables with a known important effect of environment appear to be less influenced by genetic factors.

Key words: chronobiology, twins, heritability

PO464

THE EFFECTS OF DIETARY GLUTAMINE ON HEPATIC INFLAMMATORY RESPONSE AND MITOCHONDRIAL IN DIABETIC SEPTIC MICE

W.C. Chiu^{1,2}, I.T. Wang¹, Y.S. Chiu^{1,2}, S.L. Yeh¹

¹School of Nutrition and Health Sciences, Taipei Medical University, Taipei, Taiwan

²Department of Orthopedics, Shuang Ho Hospital, Taipei Medical University, Taipei, Taiwan

Background and objectives: Diabetes or sepsis may decrease mitochondrial oxidative phosphorylation and damage mitochondrial function to lead tissue hypoxia and organ dysfunction. Glutamine has immunomodulatory and mitochondrial-protective property. Thus, this study investigated the effects of dietary glutamine on hepatic inflammatory response and mitochondrial function in diabetic septic mice.

Methods: Male ICR mice were randomly assigned to diabetes mellitus control (DMC) and DM with glutamine (DMG) groups. Diabetes was induced by a single dose intraperitoneal injection of 150 mg/kg body weight streptozotocin and those mice fasting blood glucose higher than 200 mg/dL were considered diabetic. DMG group were received with a diet in which part of casein was replacing by glutamine, which provided of 25 % of total amino acids for 3 weeks. Septic mice were induced by cecal ligation and puncture (CLP) and were sacrificed at 0, 6, and 24 hours after CLP, respectively. The blood and liver were collected for further analysis.

Results: The DMG group had lower alanine aminotransferase and aspartate aminotransferase activities at 6 hours after CLP than those in the DMC group. Compare with DMC group, the hepatic cytochrome c oxidase subunit I mRNA levels in the DMG group were significantly higher at 6 hours after CLP. DMG group had a lower p65 mRNA level at 24 hours after CLP. Aspects of morphology were observed by transmission electron microscopy, the enlargement of hepatic mitochondrial damage induced by CLP. However, the structure damage in the DMG group was lower in the DMC groups. The results of hepatic mitochondrial permeability transition change were decreased less in the DMG group than those in the DMC group.

Conclusions: These results suggest that dietary glutamine may attenuate the hepatic injury by modulating hepatic inflammatory response and mitochondrial function in diabetic mice with sepsis.

Key words: glutamine, diabetes, sepsis, mitochondria

PO465

DIETARY BIOMARKERS IDENTIFIED THROUGH METABOLOMICS AND THEIR RELATION TO COLORECTAL CANCER IN THE DIET, CANCER AND HEALTH COHORT

L. Hansen^{1,2}, T. Barri², M H. Kamstrup-Nielsen³, M. Kristensen², A. Olsen¹, J. Christensen¹, K. Overvad^{4,5}, S B. Engelsen³, A. Tjønneland¹, L O. Dragsted²

¹Danish Cancer Society Research Center, Copenhagen, Denmark

²Department of Human Nutrition, Faculty of Science, University of Copenhagen, Frederiksberg, Denmark

³Department of Food Science, Faculty of Science, University of Copenhagen, Frederiksberg, Denmark

⁴Department of Epidemiology, Institute of Public Health and Social Sciences, Aarhus University, Aarhus, Denmark

⁵Department of Cardiology, Aarhus University Hospital, Aalborg, Denmark

Background and objectives: It is envisioned that advanced exploratory metabolite screening tools will provide useful insights into biomarkers for recent as well as habitual intakes of foods and their possible relation to cancer development. A unique opportunity for such investigations exists in the biobanks of cohort studies. The aim of the present study was to relate metabolite profiling patterns to incidence of colorectal cancer with focus on whole grains, fruits and vegetables.

Methods: The present study was conducted among 322 women in the prospective Diet, Cancer and Health cohort study, consisting of 163 colorectal cancer cases diagnosed during a median follow-up period of 5.9 years and 159 referents. Non-fasting blood samples and data on lifestyle and dietary factors were collected at recruitment. Plasma samples were profiled by untargeted metabolomics using liquid chromatography-time-of-flight-mass spectrometry (LC-QTOF). Observed features were represented by retention time (RT) vs. m/z pairs. The feature list was analyzed using multiple linear regression or modified Cox proportional hazards models. Features with $p < 0.05$ and $q < 0.2$ were considered potential markers and were further analyzed by MS/MS for identification. Markers were identified by standards having the same RT vs. m/z and a similar mass spectrum.

Results: A total of 641 features were observed in the negative mode and 1071 in the positive after removal of erratic features. Glucose levels were found to be related to an increased risk of colorectal cancer. An inverse association with fruit and vegetable intake was seen for the lipophilic compound identified as 1-palmitoyl-2-(5-oxovaleroyl)-sn-glycero-3-phosphocholine (POV-PC), which has been found to promote atherosclerosis.

Several other features, e.g. various amino acids as well as compounds known as polyethylene glycols (PEG's) were identified and associated to either CRC or dietary intake.

Conclusions: Metabolite profiling patterns appear to be relevant biomarkers for use in cohort studies.

Key words: Metabolomics, Colorectal cancer, Cohort study

PO466

FOOD STRATEGIES GENERATED BY HOUSEHOLDS IN POVERTY AND ITS RELATIONSHIP TO CHILD NUTRITION IN NORTHWEST MEXICO

J M. Meléndez Torres¹, G M. Cañez de la Fuente¹, J. Lemos²

¹Coordinación de Desarrollo Regional, Centro de Investigación en Alimentación y Desarrollo, AC, Hermosillo, Sonora, México

²Estudiante de la Maestría en Desarrollo Regional, Centro de Investigación en Alimentación y Desarrollo AC, Hermosillo, Sonora, México

Background and objectives: Obesity is considered by WHO as the epidemic of the twenty-first century, both in children and adults, as well as in all social strata. Mexico is a country that has the highest rates especially among children. At present, the obesity has been increase in poor communities therefore requires to be studied. Thus the aim of this study was to identify and compare different food strategies generated by households in poverty with different child nutritional status.

Methods: A descriptive – comparative, quanti-qualitative and anthropological approach was carried out. Anthropometric evaluation was performed on 182 children, aged 6 to 12 years at northwest of Mexico. Later were selected 40 poor households according to nutritional status of children and, we conducted a semi-structured interview with mothers in order to know food practices and social representations. Subsequently we could be identified food strategies.

Results: The prevalence of overweight and obesity was 31%, greater than the national average, especially in girls. The overweight was higher in girls and obesity in boys. We found also risk of stunting and stunting, the first was present mainly in boys and second one, only in girls. Practices in relation to food consumption in these households were carried out to reduce costs looking for different sources of food supply compromising the variety and quality of food. In addition, they prioritized foods that make the most of and satiate; besides flavor. They preferred thinness and beauty in women and thinness and strength in men. Differences in food strategies generated by households according to nutritional status and risk factors in early childhood were mainly in the food practices.

Conclusions: Differences were take place in access to employment, government assistance, family networks, public ser-

vices and domestic labor, diversification of supply, and food preparations.

Key words: poverty, nutritional status, food strategies, households

PO467

PORTUGUESE FOOD AND NUTRITION ACTION PLAN

P. Graça^{1,2}, M.J. Gregório²

¹Directorate-General of Health, Lisbon, Portugal

²Faculty of Nutrition and Food Sciences of University of Porto, Porto, Portugal

Background and objectives: In Portugal there is a coexistence of high prevalence of obesity with high levels of food insecurity. Food insecurity may lead to the increasing of health inequalities, namely by an unequal distribution of obesity and other diet-related chronic diseases through the most vulnerable groups. This situation prompted the Portuguese Health Ministry to define the National Program of Healthy Eating as a priority program, which aims to improve the population's nutritional status by promoting availability and physical/economic access to healthy foods thus creating conditions for all citizens to valorize, consume and integrate them into their daily routines.

Methods: Launched on March 2012, after consultation with partners and civil society, this is the first formal food and nutrition action plan in Portugal. Until that date, Portugal did not have a formal and integrated strategy.

Results: The strategy determined five objectives: (1) increase knowledge about food consumption and nutritional status of the population, its determinants and consequences (2) improve the consumer's knowledge to make them able to do more informed decisions (3) improve the availability of certain types of foods, particularly in schools, workplaces and other public institutions (4) identify and promote integrated and crossed-actions with other society sectors that encourage the consumption of healthy foods and (5) improve the qualification of professionals who can influence knowledge, attitudes and behaviours in the food field. This strategy aims to combine economic growth with improving the nutrition situation and intends to integrate the local health regions and municipalities in a solid and structured nationally program, paying special attention to health inequalities.

Conclusions: This program follows the recent recommendations of the WHO and EC, and pretends to be a multisectorial program, involving stakeholders on healthy eating promotion, addressing the current challenges of the double burden of malnutrition and the health inequalities.

Key words: food and nutrition policy, health promotion, Portugal.

EFFECT OF WATER INTAKE ON RESTING ENERGY EXPENDITURE IN HUMANS

K. Okręglicka¹, K. Niewska¹

¹The Department of Preventive Medicine and Hygiene, Medical University of Warsaw, Poland

Background and objectives: Drinking water is commonly espoused in weight loss regimens and is regarded as healthy. Recently, drinking water has been associated with a temporary increase in resting energy expenditure. However, the concept of a thermogenic effect of water is controversial because other studies have found that water drinking does not increase energy expenditure. The objective of the study was to test whether drinking water affects resting energy expenditure (REE) in humans.

Methods: In 33 healthy male volunteers (age: 23,8+/-2,5 years), normal-weight (body mass index (BMI): 23,7+/-1,9 kg/m²), we measured the effect of drinking 500 ml at room temperature (22°C) water on REE by indirect calorimetry before and 45 min after the drinks. All data are given as means +/-SD. REE after drinking of water was compared with the corresponding baseline value by a paired t test. The statistics were performed using statistical software (Statistica version 10). The level of statistical significance was set at P < 0,05.

Results: Drinking 500 ml water increase REE by 8,5+/-6,7% after 45 minutes (5,76+/-0,81 kJ/min vs 6,23+/-0,90 kJ/min; P < 0,0001). It was reported that drinking half a liter of water at room temperature increased resting energy expenditure by 30% in normal-weight healthy subjects and by 24% in overweight and obese healthy subjects on no medications after an hour. However previously and later published studies did not confirm this finding.

Conclusions: Drinking water at room temperature increase resting energy expenditure. It is necessary to confirm whether the temporary thermogenic effect of drinking water exists over a longer period throughout the day. If confirmed in other studies may be a useful adjunctive treatment in overweight and obese individuals to attain an increase in energy expenditure.

Key words: water, resting metabolic rate, thermogenesis.

PO469**ANTIHYPERTENSIVE AND TRIGLYCERIDES-LOWERING EFFECTS OF SALVIA HISPANICA SEED EXTRACT IN HYPERTENSIVE RATS INDUCED BY L-NAME**

B. González-Martínez^{1,2}, V. González-Ramos¹, E. Solís-Pérez¹, F. Gúzman²

¹Universidad Autónoma de Nuevo León, Facultad de Salud Pública y Nutrición, México

²Universidad Autónoma de Nuevo León, Facultad de Medicina, México

Background and objectives: Cardiovascular diseases are the first cause of death in Mexico being hypertension one of the main risks factor. Chia seed is rich in nutrients such as essential fatty acids, including omega-3, fiber and antioxidants. The chia has been known since pre Hispanic culture and has been used as a medicinal therapy because of the hypotensive effect and reduction of cardiovascular risk properties. In vitro studies have been performed on certain salvia seeds that possess bioactive compounds with potential ACE I-inhibitory effects

Methods: 38 Rats with hypertension induced by L-NAME were divided into 4 groups (n=8): negative control (Sham); hypertensive control (CH); hypertensive + captopril (HCA); and hypertensive + extract (HE). The group HE received P.O. 400 mg/kg/day of methanolic extract of Chia (EM) during the experiment. For 5 weeks the systolic blood pressure (SBP) was monitored; blood was collected to quantify the serum levels of C-reactive protein (CRP), total cholesterol (CoIT), (CoL-LDL) cholesterol-LDL, triglycerides (TG), and liver enzymes (AST, ALT, LDH), at the beginning and at the end of the test.

Results: We avoided the increase in SBP with the administration of the methanolic extract in the HE group. There were no significant differences in CoIT, LDL-CoL nor PCR serum levels. The TG levels of the HE group at the end were lower than in the CH group. No substantial changes in the levels of AST, ALT, LDH were found.

Conclusions: The methanolic extract of *Salvia hispanica* L., when administered orally, lowers the SBP and the serum triglyceride levels. These results and the ancient use of the Chia as food; suggest it's safe to use chia in the treatment of high blood pressure, however, more studies are needed to find the dose with the desired effect and to be recommended.

Key words: *Salvia hispanica*, methanolic extract, anti-hypertensive

PO470**ANTIMICROBIAL EFFECT OF MUNKOYO ROOTS (RHYNCHOSIA SPECIES), USED IN PREPARATION OF NON-ALCOHOLIC INDIGENOUS FERMENTED ZAMBIAN BEVERAGES-CHIBWANTU AND MUNKOYO**

M.M. Mwale¹, B. Viljoen¹

¹Department of Microbial, Biochemical and Food Biotechnology, The University of the Free State, Bloemfontein, South Africa

Background and objectives: The Munkoyo roots are used in the preparation of the beverages munkoyo and chibwantu-Zambian non-alcoholic beverages. There is inadequate information on the effects of the munkoyo roots (*Rhynchosia*) on the microbiology of these fermented beverages. There is a potential that Munkoyo roots may have antimicrobial properties, thereby contributing to the microbiological quality and safety of the beverages. Objectives: To evaluate the antimicrobial effects of the munkoyo root extracts on pathogenic microorganisms- *E.coli* and *Staphylococcus aureus*.

Methods: Samples of the Munkoyo root were purchased from different markets in Zambia and transported to South Africa. Munkoyo root extracts were prepared (hot water, cold water and methanolic (60%) extracts) and microorganisms (*E. coli* and *Staphylococcus aureus*) were prepared for the experiment. The screening for antimicrobial potential of the munkoyo root extracts was done by means of two assays; 1) the agar diffusion method and 2) growth of microorganisms in nutrient broth supplemented with root extract (hot water and methanolic (60%).

Results: For assay 1, much activity was shown against staph aureus compared to *E. coli* and the methanolic extract had more activity. For assay 2, inhibitory activity was observed against staph aureus and for *E. coli* inhibitory activity was observed within the first three hours and thereafter there was growth stimulatory activity.

Conclusions: The study gives an indication that the root types possess different active compounds both antimicrobial and microbial growth stimulatory. The results form a strong basis for further studies on the active components of the roots for possible use in preservation, as well as stimulation of growth of essential microorganism such as lactic acid bacteria, for improved food quality and safety.

Key words: Antimicrobial Effect, Munkoyo Root.

PO471**NUTRITIONAL STATUS AND HEPATITIS B INFECTION IN THE UNITED STATES (2003-2006)***E. Yu¹, S. Mehta¹*¹Division of Nutritional Sciences, Cornell University, Ithaca, New York, USA

Background and objectives: Nutritional status modulates immune response to infections and can alter the risk and course of infectious diseases, including hepatitis B. We assessed the association between nutritional status and hepatitis B virus (HBV) infection among participants (n=13,665) of the National Health and Nutrition Examination Survey (2003-2006) in the United States.

Methods: Based on available serological data (HBV surface antigen [HBsAg], core antibody [anti-HBc], and surface antibody [anti-HBs]), we categorized individuals as having: current HBV infection ([anti-HBc+, anti-HBs-]; or [HBsAg+, anti-HBc+, anti-HBs+]); previous infection or immunization (HBsAg-, anti-HBs+); or no infection or immunization (HBsAg-, anti-HBc-, anti-HBs-). We examined associations between micronutrient biomarkers, anthropometry, and HBV infection status using polytomous logistic regression, accounting for sampling weights.

Results: 1.1% of participants were currently infected with HBV; 28.4% had previous infections or immunizations. Among individuals with HBV, 50.7% were overweight or obese (body mass index [BMI]≥25 kg/m²), and 3.6% were vitamin A deficient (<70 μmol/L serum retinol). Among previously infected or immunized participants, 1.2% had vitamin B12 deficiency (<200 pmol/L), and a mean mid-upper arm circumference (MUAC) of 29.6 cm. Participants with vitamin A deficiency had 16 times higher odds of having current HBV infection (p<0.01), adjusting for sex, ethnicity, age, foreign birth, and education, compared to those with adequate vitamin A status. Those with BMI≥25 kg/m² had lower odds of having a current HBV infection (p<0.01), accounting for the same covariates, compared to participants with BMI between 18.5 and 25 kg/m².

Conclusions: Vitamin A deficiency and overweight or obesity are associated with current HBV infection in U.S. participants in NHANES. Future studies are needed to increase our understanding of etiological relationships between nutritional status and HBV infection and implications for clinical management.

Key words: Hepatitis B, micronutrients, anthropometry, surveys

PO472**VITAMIN STATUS ASSESSMENT IN YOUNG ADULTS WITH INTENSE TRAINING***M. Garcia-Hortal¹, M. Ortiz-Franco¹, J. Molina-López¹, L. Sáez-Pérez¹, M E. Planells del Pozo¹*¹Department of Physiology, Faculty of Pharmacy, Institute of Nutrition and Food Technology "José Mataix", Biomedical Research Centre, University of Granada, Granada, Spain

Background and objectives: Long and short unbalanced intake could lead on vitamin deficiencies that alter performance and the optimization of results in high intensity training. Bad eating habits in this collective could cause adverse effects. The aim of this study was to evaluate the nutritional status focused on vitamins in a young male adult collective trained with high intensity tests.

Methods: This is a cross-sectional study. Twelve men, aged 25.8 ±4.2 years, participated in this observational study voluntarily. Real nutritional intake was measured with Nutriber software, the anthropometry with bioimpedance TANITA team and specific methodology, and the physical condition was tested with practical exercises (2000m run, high jump, a circuit and pull-ups). SPSS 17.0 program was used to determine the correlation between vitamins and other parameters.

Results: The Recommended Dietary Allowance (RDA) of Energy, Protein, Lipids, Carbohydrates, Vitamin B2, Vitamin B6 and Vitamin C were 76.1%, 219.9%, 80.8%, 63.1%, 116.4%, 140.4% and 194.2%, respectively. Vitamins B2 (r=0.77; p=0.005) and B6 (r=0.72; p=0.011) were directly correlated with pull-ups. Significant associations (r=0.62; p=0.033) were found between lipids and carbohydrates intake, caused by high frequency in the intake of chocolates and biscuits food group. The intake of protein was correlated with Vitamin C (r=0.66; p=0.021). There was also a high correlation between the intake of Protein and Vitamin B2 (r=0.90; p<0.001) and Vitamin B6 (r=0.92; p<0,001). Protein intake was also directly correlated with the intake of Vitamin E (r=0.76; p=0.004) and pull ups (r=0.78; p=0.004).

Conclusions: Our results show, the group studied evinces imbalances in nutrient intake that given the association can alter the availability of other macro and micronutrients, affecting the expected results on training. For that reason assessment and optimization of nutritional intake are necessary, as well as monitoring these collectives.

Key words: Vitamin, Nutrition Assessment, Intense Training

PO473**POTENTIAL USE OF A SCORE OF GENERAL HEALTH AND QUALITY OF LIFE IN ELDERLY ABSTAINERS AND MODERATE DRINKERS**

I. San Mauro¹, L E. Diaz-Prieto¹, C. López-Ruiz¹, E. Gonzalez-Rubio¹, A. Marcos¹, E. Nova¹

¹Immunonutrition Group, Institute of Food Science and Technology and Nutrition (ICTAN)-CSIC, Madrid, Spain

Background and objectives: Regular and moderate alcohol consumption may exert favourable effects on health compared to abstinence. Our aim was to calculate and compare a score of general health and quality of life (QoL) between elderly abstainers (A) and moderate drinkers (MD).

Methods: Forty subjects (aged 55-75 years) (32 women) divided into two groups: A (n=20) and MD (n=20) (< 30g alcohol/day for women and <60g/day for men) were recruited. All subjects fulfilled a series of validated questionnaires on health and QoL and underwent fasting blood tests. Variables adding equally to the score were: 1) cholesterol >200 mg/dL or FPG > 112 mg/dL; 2) BMI > 25; 3) daily physical activity less than 30 min. walk (calculated as METs); 4) sleeping difficulties; 5) "not so good" or "bad" perception of own-health; 6) hypertension, DMII, previous episode of heart attack or stroke, or suffering two other chronic diseases (rheumatoid arthritis /asthma / bronchitis /gastric or duodenal ulcer /constipation /depression /migraine /hemorrhoids /osteoporosis /anemia) or having lowering cholesterol medication. Differences for each variable and in the total score were assessed through chi-square tests.

Results: No differences between both groups were found, however, a trend was observed for higher CVD risk biomarkers in A (14 out of 20) compared to MD (8 out of 20) (P=0.057) and also a trend for insufficient physical activity in A (5 out of 20) compared to MD (1 out of 20) (P= 0.077). Total score was, however, 38 and 37 in A and MD, respectively.

Conclusions: The score did not point out differences in general health of these elderly depending on their alcohol consumption. However, bigger samples might be necessary since some trends were observed for poorer general condition of abstainers.

Key words: moderate drinkers, general health score, quality of life

PO474**UNBALANCED NUTRIENT INTAKE IN ADULT MEN WITH INTENSE TRAINING: MINERAL STUDY**

M. Ortiz-Franco¹, M. Garcia Hortal¹, M.A. Martínez-Burgos¹, J. Molina-López¹, L. Sáez-Pérez¹, M E. Planells del Pozo¹

¹Department of Physiology, Faculty of Pharmacy, Institute of Nutrition and Food Technology "José Mataix", Biomedical Research Centre, University of Granada, Granada, Spain

Background and objectives: Nutritional assessment is important to control high intensity athletes because their increment of caloric expenditure causes increased requirements, and their eating habits are not suitable. All that results in the intake of imbalanced diets that cause adverse effects as mineral deficiencies and/or nutritional excess that alter performance and the optimization of the expected results. The aim of this study was to evaluate the nutritional status focused on minerals in a young male adult collective trained with high intensity tests. We made a nutritional evaluation, with intake habits, anthropometric measures and physical tests.

Methods: Twelve high-training men, aged 25.8 ± 4.2 years, participated in this cross-sectional study voluntarily. Real nutrient intake was measured with software Nutriber, anthropometry with bioimpedance TANITA team and specific methodology, and physical condition was tested with practical exercises (2000m run, high jump, a circuit and pull-ups). SPSS 17.0 program was used to determine the correlation between minerals and other parameters.

Results: Regarding macronutrient and micronutrient intake, the RDAs of Energy, Protein, Lipids, Carbohydrates, Calcium and Selenium were 76.1%, 219.9%, 80.8%, 63.1%, 127.2% and 155.7%, respectively. The intake of Calcium was directly correlated with pull-ups ($r=0.78$; $p=0.005$). Significant associations ($r=0.62$; $p=0.033$) were found between lipids and carbohydrates intake, caused by chocolate, cookies, biscuits, cakes, pastries consumption. Also, significant correlations were found between the intake of Calcium, Proteins and Carbohydrates, and the latter with Selenium ($r=0.61$; $p=0.036$). Energy intake was directly correlated with the intake of macronutrients and the intake of Selenium ($r=0.59$; $p=0.043$).

Conclusions: According to our results, the subjects presented an unbalanced diet that can alter the availability of other macro and micro nutrients, affecting the results on training. For that reason, nutritional assessment and the nutritional optimization are necessary as well as monitoring this type of population.

Key words: Mineral, Nutrition Assessment, High-Training.

PO475**FISH OIL DECREASE HEPATIC TRIACYLGLYCEROL AND EXPRESSION OF FATTY ACID SYNTHASE IN FRUCTOSE-FED RATS**

G S F. Castro¹, L M C S. Ambrosio¹, J F R. Cardoso², P P. Ovidio¹, A A. Jordão¹, H. Vannucchi¹

¹Department of Internal Medicine/FMRP, University of São Paulo, Ribeirão Preto, Brazil

²Department of Pathology/FMRP, University of São Paulo, Ribeirão Preto, Brazil

Background and objectives: high consumption of fructose is associated to Metabolic Syndrome. Fish oil (FO) is beneficial for the treatment of this syndrome. The objective of the present study was to evaluate the effects of different amounts of FO in hepatic triacylglycerol (TG) and cholesterol and expression of lipid metabolism genes.

Methods: initially, male Wistar rats were divided in two groups: Control (C, n=6) and Fructose (Fr, n=32) receiving 60% fructose for 60 days. After this period, animals from Fr group were divided in: FrFO7 (n=8) receiving 60% fructose and 7% FO; FrFO5 (n=8) receiving 60% fructose and 5% FO plus 2% soybean oil, and FrFO2 (n=8) receiving 60% fructose and 2% FO plus 5% soybean oil for 30 days. Afterward, the animals were sacrificed. Liver TG and cholesterol were analyzed by commercial kits after lipid extraction. Gene expression was acquired by real time qPCR from liver using SYBR Green. Relative RNA expression was standardized to the endogenous gene 18S and calculated using the $\Delta\Delta\text{CT}$ method.

Results: the amount of TG was higher in the Fr group compared to the other (FrxC and FrxOP2, $P<0.05$; FrxOP7, $P<0.01$; FrxOP5, $P<0.001$). The hepatic cholesterol was increased in the OP7 group compared to Fr and OP2 ($P<0.05$ for both). The Fr and OP2 had increased expression of fatty acid synthases compared with C group ($P<0.01$). The HMG-CoA reductase expression was decreased in the Fr, OP7 and OP5 groups compared to C and OP2 groups (CxFr, $P<0.01$; CxOP7, CxOP5, FrxOP2, OP7xOP2, OP5xOP2, $P<0.001$). The expression of long-chain-acyl-coenzyme A dehydrogenase was increased in the OP7 group compared to Fr ($P<0.001$), OP5 ($P<0.01$) and OP2 ($P<0.001$).

Conclusions: the amount of FO influence gene expression of rats fed with fructose. Also the major quantity decreases the hepatic TG.

Key words: fish oil, Metabolic Syndrome, fructose.

PO476**EFFECTS OF SOLUBILIZED OKARA (TOFU REFUSE) ON INTESTINE MICROFLORA AND GASTRIC STRESS ULCER IN MICES**

M. Ogushi¹, A. Shoji^{1,2}, M. Imai¹, S. Handa¹, M. Yoshizawa³, N. Harada¹, R. Yamaji¹, H. Inui^{1,4}, A. Wadano¹, Y. Nakano^{1,5}

¹Osaka Prefecture University, Graduate School of Life & Environmental Sciences, Osaka, Japan

³Otemae College of Nutrition, Department of Nutrition, Osaka, Japan

⁴Osaka Prefecture University, Graduate School of Comprehensive Rehabilitation, Osaka, Japan

⁵Osaka Woman Junior College, Osaka, Japan

Background and objectives: Okara (Tofu refuse) is a by-product during process of soybean. It is rich in dietary fiber, which has functional effects to prevent from lifestyle-related diseases. As the surface of the by-product is occupied by the insoluble dietary fiber, its processing into physiologically functional foods is difficult.

Methods: We have processed Okara into water-soluble material, and there investigated the solubilized Okara to use as a food with various physiological functions on mouse, especially to check effects on maintenance of intestine microflora and protection of gastric stress ulcer. Okara was autoclaved at 121°C for 1h, and digested with cellulase and pectinase (solubilized Okara). [Ex 1] Balb/c mice, eight weeks of age, were fed standard diet (control), high-fat diet and their 3% solubilized Okara-fortified diets (4 group) for 14 days. The serum and intestinal cecum were collected and analyzed their flora by real-time PCR. [Ex 2] After fasted for 16 hours, the mice were exposed to the water-immersion restraint stress according to the method of Yoneda et al., and thereafter, their serum and stomach were collected.

Results: [Ex 1] The count of the Lactobacillus in intestine cecum contents increased 10-fold in solubilized Okara diet groups, compared with control. On the contrary, that of high fat diet groups increased of 60-fold. Conversely, that of Bifidobacterium was significantly reduced in solubilized Okara diet groups. In solubilized Okara diet groups the triglyceride concentration in the plasma was less than that of control diet groups. [Ex 2] Protective rate to gastric ulcer of mice fed with solubilized Okara diet were significantly higher than that fed with control diet.

Conclusions: These results suggest that the β -1,3-glucan of Okara is an important part of the active principle for anti-ulcerogenesis.

Key words: β -1,3-glucan, tofu-refuse, intestine-microflora, gastric-stress-ulcer, mouse

PO477**MIR-21 EXPRESSION IN PATIENTS WITH CELIAC DISEASE***K. Bascuñán^{1,2}, C. Flores², F Perez-Bravo^{2,3}, M. Araya³*

¹School of Nutrition and Dietetics, Faculty of Medicine, University of Chile, Santiago, Chile

²Laboratory of Nutrigenomics, Department of Nutrition, Faculty of Medicine, University of Chile, Santiago, Chile

³Laboratory of Immunogenetics, Institute of Nutrition and Food Technology, University of Chile, Santiago, Chile

Background and objectives: Celiac disease (CD), a chronic enteropathy of the small intestine, is triggered by gluten proteins found in wheat, rye and barley. CD is characterized by an altered immune response in genetically susceptible individuals. MicroRNAs (miRNAs) are RNA molecules, small and not codable, which bind to complementary sequences of specific messenger RNAs. The expression of miR-21 (microRNA related to inflammation) has not been described in CD yet. Our aim was to evaluate the expression of miR-21 in peripheral blood mononuclear cells (PBMCs) of CD patients and healthy controls.

Methods: We studied a sample of 10 patients with CD (on gluten-free diet) and 10 healthy controls. Mean age of subjects was 35.2±9.4 years, 25% male, without age- or gender- differences between groups. A blood sample was obtained and PBMCs were isolated by Ficoll-Hypaque. Total RNA was extracted using TRIzol. The concentration and purity of the RNA samples were measured spectrophotometrically. Relative expression of miR-21 was performed using real-time PCR specific for miR21. RNUB6B expression was used as internal control. Expression levels were determined using TaqMan probes.

Results: The average expression of miR21 (CtdRmiR21) was significantly higher in CD group (27.9±.5 vs. 27.1±.8, p=0.028). After standarization, expression profile (RQ value) of the CD group showed just a trend (1.77±.93 vs. 1.08±.72, p=0.09) for higher levels of miR21.

Conclusions: These preliminary data show that the expression of Mir21, a microRNA involved in inflammatory processes, is slightly elevated in PBMCs of CD subjects. The results are interesting for a better understanding of microRNA regulation in CD disease.

Key words: Celiac disease, microRNAs, miR21

PO478**SCHOOL FOOD FORTIFICATION IMPROVES NUTRITION STATUS OF STUDENTS FROM POOR MIGRANT FAMILIES***J. Sun¹, J. Huang¹, J S. Huo¹*

¹Institute of Nutrition and Food Safety, China CDC

Background and objectives: To observe the effect of food fortification including multinutrient fortified rice, iron fortified soy sauce and VA fortified cooking oil on school children of rural-urban migratory families.

Methods: The school children in a boarding school for children of migrated families in suburb Beijing city were selected as volunteer subjects and the school cafeteria were supplied with iron fortified soy sauce, multinutrient fortified rice and VA fortified cooking oil for 10 month. Dietary survey and nutrition measurement were conducted before and after 10-month intervention with fortified foods. Hb, SF, SI, sTfR, serum Zinc and serum VA were measured with blood samples. VB1 and VB2 were measured with urine samples.

Results: Supply of fortified foods showed a significant increase on micronutrient intakes of the school children and the daily intakes of the fortified micronutrients met the requirements of Chinese AI or RNI of those micronutrients. Hemoglobin, Serum zinc, VA, urine VB1 and urine VB2 levels were significantly increased compared with baseline. sTfR level was significantly lower than that of the baseline, the rates of micronutrient deficiencies or inadequacies were significantly reduced.

Conclusions: Food fortification could be an effective and feasible approach for lowering the micronutrient deficiencies on school children of migrated people who are considered one of the most vulnerable population.

Key words: migrant school students, iron fortified soy sauce; fortified rice; vitamin A fortified cooking oil; nutrition intervention

PO479**DEVELOPMENT OF A CULTURALLY APPROPRIATE ASSESSMENT TOOL - KNOWLEDGE, ATTITUDE AND PRACTICE QUESTIONNAIRE ON CARDIOVASCULAR DISEASES AND THEIR RISK FACTORS**

P. Amarasekara^{1,2}, P. Katulanda², P A. de Silva³

¹National Hospital of Sri Lanka, Sri Lanka

²Department of Clinical Medicine, Faculty of Medicine, University of Colombo, Sri Lanka

³Department of Physiology, Faculty of Medicine, University of Colombo, Sri Lanka

Background and objectives: Cardiovascular diseases (CVDs) and cardiovascular risk factors (CVRF) are exponentially rising. Many developing countries including Sri Lanka (SL) face double burden of malnutrition and increase in non-communicable diseases (NCDs). The study objective was to develop a culturally appropriate questionnaire to assess the knowledge, attitudes and practices (KAP) regarding CVDs and CVRF in a patient population from medical clinics, by obtaining in-depth information.

Methods: A qualitative study was conducted with seven focus group discussions among the following 3 groups; doctors, health education nurses, and multi-ethnic group of patients attending health clinics. The discussions were carried out until saturation point was reached and data was independently documented by two investigators. Using this data, a structured, self administered questionnaire on KAP was developed targeting 4 main domains of general perception on health and KAP, sub domains of CVDs - diet, physical activity and lifestyle.

Results: Though CVDs and CVRF are common, there is cultural variability in the drivers and barriers towards achieving a healthy lifestyle. Qualitative data indicated the following; poor knowledge on CVDs, CVRF and their etiology, lack of suitable educational materials in the appropriate language for patients. Cultural barriers to control diseases/ risk factors were, the stigma of having a chronic disease, lack of family support, fasting and feasting for religious or cultural reasons, rejection of certain foods due to mythical beliefs regarding the foods. Other cultural problems identified included eating of large portions and leftovers due to reluctance to waste foods, preferences for certain types of unhealthy foods, living in an extended family and inadequate support from peers and employers. The KAP was developed using the above information and pre-tested.

Conclusions: This tool will contribute to build an assessment methodology for future use in epidemiology and research locally.

Key words: Cardiovascular Diseases, KAP questionnaire, Knowledge, Attitudes, Practices

PO480**EFFECT OF CARBOHYDRATE RESTRICTION DURING PREGNANCY ON THE GLUCOSE AND LIPID METABOLISM IN OFFSPRING**

S. Hirai¹, Y. Shimizu¹, R. Tako¹, Y. Koshino¹, M. Komori¹, Y. Egashira¹

¹Laboratory of Food Nutrition, Graduate School of Horticulture, Chiba University, Matsudo, Chiba, Japan

Background and objectives: Increasing evidence suggests that the origin of some metabolic disorders, which manifest in adult life, may have their roots during development. In fact, several epidemiological and experimental studies have shown that maternal undernutrition (energy or protein restriction) leading to low birth weight predisposes offspring to the development of metabolic phenotypes such as obesity. However, separate effects of the dietary energy sources during pregnancy remain unclear. In the present study, focusing on the primary source of dietary energy, carbohydrate, we investigated the effect of carbohydrate malnutrition during pregnancy on the metabolic phenotype in mice offspring.

Methods: At 10.5 days gestation, pregnant mice were divided into three groups: the control (C), the energy restriction (R), or the carbohydrate restriction (CHR). The amount of food provided for the R group was restricted to 60% of that for the C group (control diet). The CHR group was fed with 60% energy restricted diet by reducing only carbohydrate from the control diet. After parturition, all the dams were fed with control diet. At 8wks of age, offspring were fed with either normal fat diet or high fat diet (HFD) for 5 months.

Results: The R and CHR offspring were born small but caught up in body weight to C offspring within 4 days after birth. When fed a HFD, the R offspring developed pronounced weight gain and adiposity compared with the C offspring; however, these parameters in the CHR offspring were similar to that in the C offspring. Impaired glucose metabolism was also observed in the R offspring but not in the CHR offspring.

Conclusions: Carbohydrate restriction during pregnancy does not affect catch-up growth, obese phenotype, and impaired glucose and lipid metabolism induced by high fat diet in mice offspring.

Key words: Carbohydrate restriction, pregnancy, obesity

PO481**RESVERATROL ATTENUATES VASCULAR ENDOTHELIAL INFLAMMATION BY INDUCING AUTOPHAGETHROUGH CAMP SIGNALING PATHWAY**

M.T. M¹, M.L. C¹, L. Y¹, X. J¹, X.Y.L¹, Q. X¹, T. Z¹, X. Z¹, H. C¹, Y.J. F¹, J.D. Z¹ QY. Z¹

¹Research Center For Nutrition and Food Safety, Institute of Military Preventive Medicine, Third Military Medical University, Chongqing, China

Background and objectives: Resveratrol is a naturally occurring polyphenol which shows dominant effects on endothelial dysfunction with its anti-inflammatory benefits. However, the exact mechanism was not elucidated. We intended to investigate the role of autophagy in the anti-inflammatory effects of resveratrol in endothelial cells.

Methods: Human umbilical vein endothelial cells (HUVECs) were cultured. Cells were pre-incubated with different doses (0.1, 1, 10 and 20 μ M) of resveratrol and then exposed to TNF α . The effects of resveratrol on cell autophagy was detected by transmission electron microscopy, confocal microscopy, RNAi and western blot assays. The protein expression of cAMP, PKA, AMPK, SIRT1 were measured.

Results: We found that resveratrol pretreatment reduced the ICAM-1 expression in endothelial cells induced by TNF- α and increased the ratio of MAP1LC3B2 and SQSTM1 degradation in a time and concentration dependent manner. And 3-MA and Beclin-1 siRNA attenuated resveratrol-induced autophagy and further attenuated resveratrol-induced inhibition of ICAM-1 mRNA expression. Furthermore, resveratrol increased intracellular cAMP level, the expression of protein kinase A (PKA) and silent information regulator 2 (SIRT1) as well as the activity of AMP-activated protein kinase (AMPK). Finally, resveratrol-induced autophagy in TNF- α stimulated HUVECs was abolished in the presence of inhibitors of adenylyl cyclase (KH7), PKA (H-89), AMPK (compound C) and SIRT1 (nicotinamide), as well as, the siRNAs of PKA, AMPK and SIRT1 transfection, indicating resveratrol effects on autophagy were dependent on cAMP-mediated signaling pathway.

Conclusions: Resveratrol attenuated endothelial inflammation by inducing autophagy in HUVECs, which was mediated through the activation of cAMP-PKA-AMPK-SIRT1 signaling pathway.

Key words: Resveratrol; autophagy; endothelial cells; cAMP; inflammation

PO482**SURVEY FOR DIET AND NUTRITION INTAKE OF BEIJING PEOPLE IN OUT-HOME TABLE SERVICE RESTAURANTS**

Z. Wang¹, X. Xiang¹, X. Li¹, Y. He¹, X Yang¹, Y. Yang¹

¹National Institute For Nutrition and Food Safety, China CDC

Background and objectives: Now, more and more Chinese people, especially in big cities, like to choose eating away from home. It has been showed that restaurant dinner may be related to extra body weight gain, however, little is known regarding how much about dietary intake for Chinese people away from home comparing with in home. This study aims to assess dietary intake of customers in table-service restaurants, and evaluate their energy, protein, fat and sodium consumption in one dinner.

Methods: On dinner time (lunch or supper), 2204 customers randomly selected in six middle-level restaurants in Beijing, was investigated their food consumption by single blind recording their ordered dishes weight before and after eating. According to the dish recipes, cooking way, and food composition database or measured data, food consumption and energy, protein, fat and sodium intake were evaluated.

Results: In one restaurant dinner, the mean intake of foods for a standardized man included 76 g cereals, 162 g vegetables, 11 g fruits, 128 g meat, 50 g fishery products, 10 g eggs, 12 g legumes, 15 g pure energy food, 28 g oil, 7 g salt, 5.2 g dairy, 68.1 g juice, and 7.3 g alcohol, with 1112 kilo-calories, 54.6g protein, 62.3g fat, 88.0g carbohydrate, 10.7g cholesterol and 2920 mg sodium. Fat was the major energy supplier (52.7%), nearly meet one-day need.

Conclusions: There may be a need for interventions to promote healthier food choices among people eat out home.

Key words: food consumption, nutrition intake, table service restaurant

PO483**FOOD INTAKE DURING THE REST PERIOD AFFECTS THE RHYTHMS OF CARBOHYDRATE AND LIPID METABOLISMS IN RATS**

N. Sano^{1,2}, Y. Hotehama², K. Kuninobu³, N. Nouzawa¹, H. Kato¹, Y. Nishida¹

¹Department of Health Science, Prefectural University of Hiroshima, Hiroshima, Japan

²Okayama Medical Center, Okayama, Japan

³Department of Nutritional Sciences, Yasuda Women's University, Hiroshima, Japan

Background and objectives: Recent studies in animals have linked energy regulation and the circadian clock that raise the possibility that the timing of food intake itself may play a significant role in healthy metabolism. In this study, we examined the effect of food intake during the rest period on the rhythm of carbohydrate and lipid metabolisms in rats.

Methods: Eight-week-old male Wister rats were housed under a 12h light-dark cycle (lights on from 21:00 to 09:00). Rats were divided into two groups. The control group consumed three meals per day during active period (9:00, 13:00 and 17:00), and the late dinner group consumed two meals during the active period (9:00 and 13:00) and one meal at the beginning of the rest period (21:00). Rats were fed a normal diet and each group were provided equivalent amount of calories per day. After 3 weeks, blood samples were collected from the portal vein and the hepatic vein at 8:00, 12:00, 16:00, 20:00 and 24:00.

Results: There were no difference in body weight and abdominal fat, but the levels of plasma triglyceride and cholesterol increased in the late dinner group. Plasma glucose in the portal vein reflected feeding directly while that in the hepatic vein was maintained at a constant level. The hepatic glycogen had a circadian rhythm that increased by feedings during the active period, but did not increase after feeding during the rest period. Furthermore, the red muscle glycogen also did not increase after feeding during the rest period.

Conclusions: The findings of this study suggest that food intake during the rest period changes the rhythm of glycogen and lipid metabolisms.

Key words: meal timing, late dinner, carbohydrate metabolism, lipid metabolism

PO484**OMEGA-3 FATTY ACIDS IMPROVES OXIDATIVE STRESS IN WOMEN WITH POLYCYSTIC OVARY SYNDROME**

M. Rafrat¹, E. Mohamadi¹

¹Department of Community Nutrition, Faculty of Nutrition, Tabriz University of Medical Sciences, Iran

Background and objectives: Fish oil has beneficial effects in a number of disease states. It was reported that levels of long chain polyunsaturated fatty acids [n-3 LC PUFA including eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA)] were decreased in infertile women. Objectives of this study were to determine the effects of omega-3 fatty acids supplementation on some oxidative stress markers such as serum total antioxidant capacity (TAC), malondialdehyde (MDA) and paraoxonase 1 (PON1) activity in women with polycystic ovary syndrome (PCOS).

Methods: This double-blind randomized controlled clinical trial was conducted on 61 overweight or obese PCOS patients; aged 20-35 yr. Thirty of the subjects had taken 4 g/day omega-3 fatty acids and 31 were given placebo over 8 weeks. Fasting blood samples, anthropometric measurements and 3-day, 24-hour dietary recalls were collected at the baseline and at the end of the trial.

Results: Dietary intake of n-3 LC PUFA from usual diet was low in studied subjects (0.23 mg/day) and the ratio of dietary omega-6 fatty acids to omega-3 fatty acids intake was high as 63 to 1. Omega-3 fatty acids supplementation significantly decreased serum levels of MDA (P=0.01) and increased serum PON1 activity (P=0.038) compared with placebo. Changes in serum TAC levels and anthropometric measurements were not statistically significant in any groups at the end of the study (P>0.05).

Conclusions: Low dietary intake of n-3 LC PUFA is prevalent in women with PCOS. Supplementation with omega-3 fatty acids improved some indices of oxidative stress in PCOS patients and might contribute to the improvement of metabolic complications in these patients. Educational programs to encourage subjects to consume fish and marine foods also is suggested.

Key words: Omega-3 fatty acids, polycystic ovary syndrome

PO485**EFFECT OF FLAVONOIDS ISOLATED FROM GARDEN EGG VEGETABLES (SOLANUM MACROCARPUM) IN DIET INDUCED OBESED WISTAR RATS***N. Ngwa¹, N. Nnam¹*¹University of Nigeria Nsukka, Nigeria

Background and objectives: There is increased consumption of fatty foods and refined carbohydrates, which leads to increased incidence of obesity, diabetes, cardiovascular diseases, high blood pressure and cancer. There is low consumption of vegetables, which contain phytochemicals with antioxidant properties. This study was designed to determine the effect of flavonoids isolated from (*Solanum macrocarpum*) in diet induced obese Wistar Rats.

Methods: Four groups of twenty male Wistar rats were fed a highly palatable diet for 8 weeks to induce obesity resembling mild obesity condition in human population. Diet induced obese rats received rat chow and flavonoids extract daily for 21 days. Group 1 received rat chow alone; Group 2 received 0.05% of flavonoids extract and rat chow; Group 3 received 0.15% of flavonoid extract and rat chow; and Group 4 received 0.25% of flavonoid extract and rat chow. Body mass index (BMI), Total cholesterol, High density lipoprotein (HDL), Low density lipoprotein (LDL) and Triglyceride were evaluated using standard assay technique. The data were statistically analyzed using ANOVA and mean separated using LSD.

Results: Feeding the rats with obesity induced diet showed increase in BMI, total cholesterol, LDL and triglyceride levels along with decrease in HDL ($p < 0.05$). Consumption of flavonoids resulted in significant reduction in BMI, LDL, total cholesterol and triglyceride level with significant elevation in HDL cholesterol compared to the rats fed only rat chow ($p < 0.05$). It was observed that the decrease in BMI, Triglyceride, total cholesterol and LDL cholesterol level of rats fed 0.25% of flavonoids were significantly different ($p < 0.05$) from those fed 0.15% and 0.05% flavonoids.

Conclusions: The results suggest that flavonoids extract from *Solanum macranthum* has atherogenic effect which can help to reduce obesity.

Key words: Flavonoids, *Solanum Macrocarpum*, lipid profile, Obesity and Rats

PO486**PROJECT YEAH: DEVELOPMENT OF A WEB-DELIVERED THEORY-BASED INTERVENTION FOR PREVENTING EXCESS WEIGHT GAIN IN YOUNG ADULTS***K. Kattelman¹, A. White², C. Byrd-Bredbenner³, G. Greene⁴, T. ¹²Department of Human Nutrition and Foods, West Virginia University, Morgantown, West Virginia, USA

¹³Department of Molecular, Cellular, and Biomedical Sciences, University of New Hampshire, Durham, New Hampshire, USA

Background and objectives: The purpose of this poster is to describe the development and testing of a theory-based, tailored web-delivered intervention for prevention of excessive weight gain in young adults using a community-based participatory research (CBPR) model. Investigators from 14 universities in different states of the USA employed the PRECEDE-PROCEED process of CBPR process to identify and prioritize quality-of-life behavioral and environmental factors

that influence weight gain in young adults (YA). These factors were assessed for the YEAH (Young adults Eating and Active for Health) intervention via focus groups, key informant interviews, quantitative surveys, and environmental audits, and results were used to guide the development of the intervention.

Methods: YEAH was developed as a 10-week, web-based intervention with 19 interactive modules and nudges (stage-tailored messages) addressing issues highest-rated by YA: managing stress (time and sleep management, balancing relationships, and control of alcohol), improving eating behaviors (eating enjoyment, skills for choosing and assembling meals), incorporating physical activity, and managing weight with a non-diet approach. Nudges were developed to reinforce module content, cognitively tested, and sent 3 times/week via email. Participants were encouraged to set goals and track progress via YEAH's website. Anthropometric measurements, fruit and vegetable intake, physical activity, stress management, and sleep duration assessments occurred at baseline, post-intervention (10-weeks), and 15 months. Data were analyzed using PROC MIX, SAS. YA (n=1639, age=19.3±0.03 years, BMI=24.1±0.1, 66% female), who were non-nutrition/non-exercise science majors, were recruited and randomized, stratified by institution and gender into intervention (n=824) and control (n=815) with 58% retention through 15 months.

Results: Intervention participants had significant increases in vegetable intake, intentions for meal behaviors and decreases in percentage of energy from fat at 10-weeks.

Conclusions: Community involvement in the development and implementation of YEAH enhanced the intervention and increased the likelihood of a sustainable weight management program.

Key words: young adult, obesity prevention

PO487

EVALUATION OF THE QUANTITY OF MILK CONSUMED AND BODY COMPOSITION OF HIV-POSITIVE BREASTFEEDING MOTHER

W. Philomène¹, V. Kouma¹, N. Serge Hubert¹

¹Ministry of Health, Banghi, Republic of Central Africa

Background and objectives: Exclusive breastfeeding for 6 months, followed by the introduction of appropriate complementary foods while continuing breastfeeding, as recommended by the World Health Organization (WHO), are the cornerstone of child nutrition. Measuring the amount of milk consumed with conventional techniques known as 'weighing' was long and disrupted the normal diet of the child. The objective of this study is to use the deuterium oxide isotopic dilution technique to assess breastfeeding practices and the determina-

tion of body composition of lactating mothers who are HIV positive in Bangui.

Methods: 45 couples mothers/infant were recruited at 3 months after delivery. Mothers who agreed to practice exclusive breastfeeding and who gave their informed consent are retained in the study. They were either under or triple antiretroviral prophylaxis according to national protocol. Statistical analyzes were performed using Epi Info version 3.5.1.

Results: The average age of mothers was 28.7 years and the average fat-free mass of mothers was 41.2 kg. About 20% among them have a body mass index (BMI) less than 18.5 kg/m². The average age of the infants was 9 weeks and their length was 58.1 cm, 60% of infants were male. Two children infected with HIV died. The amount of milk consumed at 3 months was about 739.5±186.2 g / day, the rate exclusive breastfeeding was only 22.2%. The quantity of maternal milk consumed was highly correlated respectively to maternal BMI and maternal fat-free mass (r₂BMI=0.80 IC= [0,80 ; 0,93] ; p<0,001) and (r₂FFM= 0,97 ; IC= [0,76 ; 0,86] ; p<0,001).

Conclusions: Although the recruited HIV women were encouraged the exclusively breastfeed and they have reported that they were exclusively breastfeeding, the stable isotope study have shown that the practice of exclusive breastfeeding in the context of HIV remains very low. The ART in HIV-infected mothers reduces the transmission of HIV from mother to child.

Key words: breastfeeding, HIV, deuterium oxide

PO489

ANALYSIS OF THE MECHANISM OF ACTION OF TRYPTOPHAN INDUCED PROTEIN SYNTHESIS IN THE RAT LIVER

S. Koike¹, Y. Kabuyama^{1,2}, Y. Sato², K. Sugahara^{1,2}, F. Yoshizawa^{1,2}

¹Biological Production Science, United Graduate School of Agricultural Science, Tokyo University of Agriculture and Technology

²Bioproductive Science, Faculty of Agriculture, Utsunomiya University

Background and objectives: Tryptophan, an essential amino acid, has been identified to be able to promote protein synthesis in the rat liver. However, the details of the mechanism of action have not been clarified. To investigate the mechanism of action of tryptophan induced protein synthesis in the liver, we performed proteomic and metabolomic analysis of the liver.

Methods: Eighteen hours fasted Wistar rats were divided into 3 groups. One group of animals was sacrificed without any treatment as a control. Remaining two groups of animals were administered 135mg/100g body weight L-tryptophan by oral gavage and then sacrificed after 1h or 3h after administration.

Results: The proteomic analysis revealed that ornithine aminotransferase (OAT) expression was decreased at 1h and 3h after administration. OAT is a key enzyme of ornithine (Orn) catabolism. Liver and serum Orn level was significantly increased at 3h after administration. Moreover, the levels of spermine (Spe), which are involved in cell growth, in the liver increased at 3h after administration. It was reported that Trp administration enhanced the enzymatic activity of ornithine decarboxylase (ODC). ODC catalyzes the decarboxylation of Orn to form putrescine and is the late-limiting enzyme of Spe synthesis.

Conclusions: Based on these results, we speculate that the increases in Orn levels through suppression of OAT expression and the stimulation of ODC activity by Trp administration may lead to accelerate Spe synthesis and thereby promote protein synthesis in the liver.

Key words: amino acids, liver, protein synthesis

PO490

GLYCEMIC INDEX, GLYCEMIC LOAD AND SATIETY SENSATION IN INDUSTRIALIZED FOOD

M J. Ibarra Salas¹, M C. Mata Obregón¹, H I. Novelo Huerta¹, M E. Sánchez Murillo¹, P C. Cantú Martínez¹, A. Garza Juárez¹, F. Perez Chávez², J M. Llaca Díaz², G. Garza Sepúlveda¹, B M. Olivo Zamora¹

¹Centro de Investigación en Nutrición y Salud Pública. Facultad de Salud Pública y Nutrición, Universidad Autónoma de Nuevo León, México

²Departamento de Patología Clínica del Hospital Universitario 'Dr. José Eleuterio González' de la Universidad Autónoma de Nuevo León, México

Background and objectives: The Glycemic Index (GI) is a ranking of carbohydrate-containing foods based on the blood glucose response they elicit. Low glycemic index foods show beneficial effects in controlling insulin production. The glycemic load (GL) is a measure of the effect of food on the release of insulin. Satiety is the subjective feeling of fullness after consumption of a food. The purpose was to determine the GI, GL and the satiety sensation with the consume of industrialized foods.

Methods: 26 healthy subjects with normal biochemical markers and BMI, consumed 50 grams of glucose and the equivalent of 50 grams of available carbohydrates in 2 different foods (cereal bar and chocolate drink) on alternate days. Serum glucose was measured at the 0, 15, 30, 45, 60, 90 and 120 minutes, and also the satiety sensation with a Visual Analogue Scale.

Results: The cereal bar obtained a GI of 62.3% and a GL of 31.1 U, and the chocolate milk show a GI of 45.6% and a GL of

22.8 U. At 120 minutes of consuming the cereal bar, 38.5% felt a little hunger, and with the chocolate drink 42.3% felt without hungry.

Conclusions: The cereal bar showed intermediate GI and the chocolate drink showed low GI, and both foods had high GL. The cereal bar showed a less fullness at 120 minutes although not statistically significant. Is important to know the parameters of GI and GL and include it in the nutriological interventions in healthy and diseased persons.

Key words: Glycemic Index, Glycemic Load, Satiety

PO491

CONTROLLING THE INCREASE IN POSTPRANDIAL CIRCULATING STEARIC ACID CONCENTRATION IS CRUCIAL FOR PATIENTS WITH HYPERLIPIDEMIA TO PREVENT TYPE 2 DIABETES

S. Changhao¹, L. Ying¹, N. Lixin¹, C. Xia¹

¹Department of Nutrition and Food Hygiene, School of Public Health, Harbin Medical University, China

Background and objectives: Hyperlipidemia is strikingly common in patients with type 2 diabetes and disturbance of lipid metabolism appears to be an early event in the development of diabetes. FFAs seem to play an important role in the development of diabetes. Few studies have investigated changes in serum FFA profile in hyperlipidemia and its relation with diabetes, and all of those studies were done in the fasting state. Therefore, we investigated the dynamic changes and underlying regulatory mechanism of postprandial FFA profile in hyperlipidemia and their relation with diabetes.

Methods: Glucose tolerance was tested in hyperlipidemic patients, and serum glucose, insulin and FFA profile were determined. Male C57BL/6 mice were randomly assigned to either a low-fat diet or a high-fat diet for 16 weeks. Glucose tolerance was tested and blood glucose, insulin and FFA profile were analyzed. The expression of key enzymes involved in lipid metabolism in liver and muscle were detected. siRNA was also applied to mice and HepG2 cells to specify certain regulators.

Results: Serum stearic acid (SA) was the only fatty acid increased dramatically in the postprandial state. The elevation of SA was due to increased insulin-stimulated de novo synthesis mediated by sterol regulatory element-binding protein-1c (SREBP-1c)/acetyl-CoA carboxylase/fatty acid synthase/elongation of long-chain fatty acid family member 6 (ELOVL6) and the elongation of palmitic acid (PA) catalyzed by ELOVL6. Downregulation of SREBP-1c or ELOVL6 by siRNA reduced SA synthesis in liver and serum SA level, followed by amelioration of IR in mice. However, inhibition of SREBP-1c was more effective in improving IR than suppression of ELOVL6, which resulted in accumulation of PA.

Conclusions: Reduction of postprandial SA is crucial for preventing type 2 diabetes, and SREBP-1c is potentially a better target to prevent diabetes by decreasing postprandial SA.

Key words: hyperlipidemia, type 2 diabetes, SA, SREBP-1c

PO492

EFFECTS OF OMEGA-3 FATTY ACID SUPPLEMENTS ON GLUTATHIONE REDUCTASE AND PEROXIDASE ACTIVITY IN TYPE2 DIABETIC PATIENTS

F. Toorang^{1,2}, S. Pooya², A. Djazayeri³, Jalali⁴, S. Ebrahimpour koujan⁵

¹Cancer Research Center, Cancer Institute of Iran, Tehran University of Medical Science, Tehran, Iran

³Professor of Nutrition, Department of Nutrition and Biochemistry, School of Nutritional Sciences and Dietetics, Tehran University of Medical Sciences, Tehran, Iran

⁴Professor of Biochemistry, Department of Nutrition and Biochemistry, School of Nutritional Sciences and Dietetics, Tehran University of Medical Sciences, Tehran, Iran

⁵MS-BS in nutrition, Department of Nutrition, Schools of Health and Nutrition, Tabriz University of Medical Sciences, Tabriz, Iran

Background and objectives: Industrialization and development leads to low ratios of omega-3 to omega-6 fatty acids in diets, increasing risk of chronic diseases, e.g., diabetes. Omega-3 fatty acid supplementation may help glycemic control in diabetic patients, but there is some concern on antioxidant status. This study was conducted to determine the effect of omega-3 fatty acid supplements on antioxidant enzymes (glutathione reductase (GR) and glutathione peroxidase(GPX)) in type2 diabetic patients.

Methods: In a randomized, double-blind, placebo-controlled clinical trial, 81 adults with NIDDM were treated with omega-3 fatty acid supplements (2.7g/day) or sunflower oil for 8 weeks. Data on height, weight, and food consumption (based on 24h food recall), and drug consumption were collected. Also fasting blood samples were taken at the beginning and at the end of the study.

Results: Mean age, weight and BMI, as well as energy and carbohydrate, protein, fat, fiber, polyunsaturated fatty acids, vitamin E,C,A,B9, B12, zinc and selenium intakes and drug consumption were not significantly different between the two groups at baseline. Nor were there any significant differences with regard to these variables before and after supplementation in either group. Moreover, biochemical variables were not sig-

nificantly different between the two groups before the interventions. HbA1c % at the end of week eight was significantly lower than the baseline value in the intervention group (p=0.00) and significantly higher in the control group (p=0.02). In addition, changes in both groups were significantly different (p=0.00). GPx (20.85± 1.67 vs. 19.23±61.18 U/gHb) and GR (28.51±2.05 vs. 27.87±1.5 U/gHb) decreased, although no significantly.

Conclusions: This study suggests that supplementation by 2.7 g/day omega-3 fatty acids in patients with NIDDM decreases HbA1c but has no effects on antioxidant enzymes.

Key words: NIDDM, HbA1c, GR, GPX

PO493

HAND WASHING KNOWLEDGE AND PRACTICES AMONG SCHOOL CHILDREN IN BANGLADESH

B. Banu^{1,2}, K. Khanom¹, L. Ali²

¹Dept of Health Promotion & Health Education, Bangladesh Institute of Health Sciences, Bangladesh

²Dept of Biochemistry and Cell Biology, Bangladesh Institute of Health Sciences, Bangladesh

Background and objectives: The high incidence of diarrheal diseases and other communicable diseases among children due to poor personal hygiene remains a concern on the public health agenda in most countries. To address the problem efficiently, the study was undertaken to determine hand washing knowledge and practices among school children of Dhaka city in Bangladesh.

Methods: It was a cross sectional study amongst 273 school children studied in class VI and VII in two selected schools of Dhaka. Data were collected by pretested structured questionnaire and analyzed by appropriate univariate as well as multivariate analysis.

Results: The Mean±SD of the total score of knowledge was 36±11 and practice was 36±9 of the study subjects. Knowledge score on necessity of hand washing determined low (37%). Knowledge score (42%) on appropriate timing of hand washing found more than practice score (37%). Although most of the children (94%) found complete knowledge on appropriate hand washing materials but they did not practice hand washing properly due to unavailability of soap in school. On the other hand, in their home, they practiced hand washing properly due to presence of hand washing facilities. No children had complete knowledge on hand washing techniques which also reflected in their practice. The Mean±SD of age of children was 12±1 and most of them (81%) were from single family. These variables were found to be significantly (p<0.001) associated with total knowledge and practice score. There was also found significant positive correlation between knowledge and practice (r/p=0.177/0.001).

Conclusions: There is still lacks of knowledge and practices on hand washing among school children. Implementation of multifaceted interventional behavioral hand washing program with continuous monitoring and performance feedback and make available of hand washing facilities in school is important for improving effective hand washing practices.

Key words: Hand Washing, Knowledge, Practices

PO494

IDENTIFICATION OF NOVEL NONINVASIVE BIOMARKERS FOR DIAGNOSIS OF CALCIUM DEFICIENCY

L. Ying¹, S. Changhao¹, W. Maoqing¹

¹Department of Nutrition and Food Hygiene, School of Public Health, Harbin Medical University, China

Background and objectives: Calcium deficiency is a global public health problem. Although the initial stage of calcium deficiency can lead to metabolic alterations or potential pathological changes, calcium deficiency is difficult to accurately diagnose. To accurately assess and provide appropriate nutritional intervention, a global analysis of metabolic alterations in response to calcium deficiency was investigated in our study.

Methods: The metabolic alterations associated with calcium deficiency in a rat model were first investigated by urinary metabonomics based on ultra performance liquid chromatography coupled with quadrupole time-of-flight tandem mass spectrometry and multivariate statistical analysis. Secondly, the correlations between the dietary calcium intakes and the identified biomarkers from rat models were further analyzed to confirm the potential application of these biomarkers in humans.

Results: Urinary metabolic profiling analysis could preliminarily distinguish between calcium deficient and non-deficient rats after a 2-week low calcium diet. The reliable biomarkers of calcium deficiency were identified by a time-course analysis of discriminating metabolites in a low calcium diet experiment, repeating the low calcium diet experiment and performing the calcium supplement experiment. Twenty-seven biomarkers were identified, such as pseudouridine, citrate, oxoglutaric acid, pyrophosphoric acid, sebamic acid and indoxyl sulfate. The reliable biomarkers with regular trends of change could unravel the dynamic pathophysiological changes and accurately assess calcium-deficient rat at different stages. Significant correlations between calcium intake and the biomarkers (pseudouridine: Pearson correlation, $r=0.527$, $p=0.0001$ and citrate: Pearson correlation, $r=-0.426$, $p=0.001$) were further confirmed in urine of human.

Conclusions: We identified for the first time the reliable biomarkers of calcium deficiency in rat model. Based on further verification of the biomarkers in large population, we

anticipate that these biomarkers may be used alone or in combination as a noninvasive screening method in a large-scale population study or for the diagnosis of calcium deficiency.

Key words: biomarkers, calcium deficiency, metabonomics, urine

PO495

BARRIER IN EXCLUSIVE BREAST FEEDING PRACTICE AMONG RURAL MOTHERS IN BANGLADESH: A QUALITATIVE STUDY

M. Islam^{1,2}, S R. Mashreky¹, A. Rahman¹, F. Rahman¹, S. Ro^y2, TG. Sanhvi²

¹Centre For Injury Prevention and Research Bangladesh (CIPRB), Bangladesh

²Alive & Thrive Bangladesh, Bangladesh

Background and objectives: Malnutrition in children under two years is a major public health concern in Bangladesh. Mother's knowledge and practice related to IYCF is a contributory factor in child nutrition in Bangladesh. The study was designed to examine the knowledge, perception, practice and motivation of the mothers, their family members and the implementers on breast feeding in a rural area.

Methods: The study was conducted in a nutrition intervention area in an Upazila of Sylhet district in June-July 2011. Data was collected using qualitative

Methods including in-depth interviews and focus group discussions with mothers and family members of 0-24 month children, GO & NGO health service providers.

Results: The study showed that most of the mothers, family members and service providers had adequate knowledge on exclusive breastfeeding and colostrums feeding. However, in spite of knowing on exclusive breast feeding many of the mothers could not completely adopt this practice in their life. One of the major causes of this was lack of knowledge on how to deal with insufficient breast milk supply. Additionally, absence of family support and inspiration, limited access to information and media were other hindering factors. Most of the mothers and family members could not mention how to increase sufficient milk production and flow. Some of them only reported that mother should eat plenty of nutritious food for sufficient breast milk production. Most of the male family members did not know about it. Most of the service providers were knowledgeable on how to increase breast feeding flow however, they were not aware to counsel the community.

Conclusions: Knowledge on exclusive breast feeding was satisfactory however overall practice was found poor. Appropriate community based strategies and interventions need to be designed to improve mothers' exclusive breast feeding practice.

Key words: Knowledge, practice, exclusive breast feeding.

PO496**EGYPT NUTRITION LANDSCAPE ANALYSIS: GAPS, OBSTACLES AND OPPORTUNITIES**

G. saleh¹, D. Shehab¹, S. Khairy¹, N. Aboul Ella¹, Z. sedafy¹

¹National Nutrition Institute, Cairo, Egypt

Background and objectives: Stunting among under-five Egyptian children has reached an alarming 29%. To have a better understanding the problem and possible solutions, the Landscape Analysis (LA) study was commissioned by the National Nutrition Institute (NNI) and Ministry of Health and Population (MoHP), with support from UNICEF Egypt Office, as the first study of its kind to be carried out among Arab countries.

Methods: The Landscape Analysis is a snapshot of the current nutrition situation not based on representative sampling methodology. Four densely populated governorates were selected out of 27. Seven districts with the highest number of new births and facilities were chosen. Service delivery units included were public hospitals, family health centers and units. Four tools were used; facility checklist, structured questionnaire for health workers, Semi-structured interview tool for national level stakeholders and managers of Non-governmental organizations (NGO's). Data collection was completed between the 3rd to the 14th of July 2011.

Results: 43 facilities were visited, 134 health workers and stakeholders were interviewed, 13 FGD's were held, Protocols for vitamin A and zinc use were present in 15% of facilities. Nutritional educational materials were available in nearly (20%) of facilities. Availability of supplements: Vitamin A (2%), iron and folic for pregnant women and infants were (19%) and (47%) respectively, zinc (58%). Only 31% of health workers received training on child growth charts, 59% received training on exclusive breast feeding. Qualitative analysis showed insufficient funds for nutritional activities (10-25%), no clear Leadership, the roles of different partners are not defined with Lack of effective coordination.

Conclusions: Better use of available resources and strategic engagements with international partners to fund and provide technical expertise in various aspects of nutrition. The health system needs to be strengthened at all levels.

Key words: Landscape analysis, Egypt, stunting, scaling action in nutrition

PO497**ASSOCIATION OF TELEVISION VIEWING AND DIETARY BEHAVIOR WITH OVERWEIGHT AND OBESITY IN PRIMARY SCHOOL CHILDREN OF DHAKA CITY**

S. Sultana¹ A. Hussain², L. Ali³

¹Bangladesh Institute of Health Sciences, Bangladesh

²University of Oslo, Oslo, Norway

³Bangladesh Institute of Health Sciences, Bangladesh

Background and objectives: Childhood obesity is a major risk factor for cardiovascular disease and also increases risk for future diabetes. In a developing country like Bangladesh, televisions have become a important household item, particularly; TV advertisements may have a great impact on dietary behavior on children. The aim of the present study was to assess the possible association between dietary behavior and television viewing with overweight or obesity in Bangladeshi urban primary school children.

Methods: A cross-sectional study was conducted 1200 primary school children. Data were collected from Dhaka City. Participants (age 6-13 years) were randomly collected on the basis of predefined scoring. Subjects were classified as underweight (<90.99%), normal, (91-110%), overweight (111-120%) and obese (> 120%), if their weight-for-height values were within the ranges of the recommended median values. Duration of television viewing was categorized as <60min/day and >60min/day. Dietary history was taken by specific food frequency questionnaire. Univariate and Multivariate regression models were used as appropriate.

Results: The substantial number of overweight and obesity was found to be 31% in the study subjects. Mean fat intake was significantly higher in overweight and underweight groups (p=0.008) compared to the normal group. About 13.6% overweight and 18% obese children watched television more than 60 minutes. A significant positive correlation (r= 0.106, p= <0.04) of junk food intake with overweight and obesity and significant correlation (r= 0.292, p= <0.001) was found between TV viewing with weight for height. In logistic regression analysis, overweight and obesity were associated with TV viewing (p<0.001) and junk food taking (p=0.02) when the effects of other confounders (sex, age, parent's education, parent's income) were adjusted.

Conclusions: A substantial number of children are already overweight and obese and TV viewing and unhealthy food intakes are important contributors of weight gain.

Key words: Child obesity, Television viewing, Diet

PO498**THE ROLE OF SMALL INTESTINE AND LIVER ON THE METABOLIC RHYTHM OF AMINO ACID IN RATS FED VARIOUS PROTEIN DIETS**

Y. Nishida¹, K. Ideguchi², N. Sano¹, S. Osaka¹, T. Ichikawa³, H. Kato¹

¹Department of Health Science, Prefectural University of Hiroshima, Hiroshima, Japan

²Kawasaki University of Medical Welfare, Okayama, Japan

³Department of Nutrition and Health Promotion, Hiroshima Jogakuin University, Hiroshima, Japan

Background and objectives: The profile and concentration of plasma amino acid were maintained constant on the healthy condition. The aim of this study was to investigate the role of small intestine and liver on the regulation of plasma amino acid.

Methods: We examined the postprandial concentration of plasma free amino acid in rats fed various energy % of protein; 5%, 20% and 35%. Rats kept on a 12h light-dark cycle (lights on 2100 to 0900) and fed during a restricted time of day (1000-1600). After 3 weeks, blood samples were taken from the portal vein and the hepatic vein at 0800, 1300, 1800 and 2300.

Results: In most amino acid, postprandial plasma concentration in portal vein was elevated by response of protein intakes. However, the profile of plasma amino acid in portal vein kept on that of fasting time, such as plasma lysine concentration was the highest in the essential amino acid. Plasma concentrations of glutamate, aspartate and arginine in portal vein were maintained low levels regardless of the amount of ingestion. Postprandial plasma concentration of most amino acid in hepatic vein was lower than that in portal vein. The difference of plasma amino acid concentration between portal vein and hepatic vein, it showed the metabolic amount in the liver. Thus, postprandial liver increased the amino acid uptake with kept the profile of amino acid in portal vein.

Conclusions: These results suggest a crucial role of small intestine as regulatory on the profile of plasma amino acid. On the other hand, liver is a contributor to maintain the concentration of plasma amino acid.

Key words: amino acid, portal vein, hepatic vein, liver, small intestine

PO499**DELAYED INITIATION OF AND NON-EXCLUSIVE BREASTFEEDING AMONG CHILDREN AGED 0-23 MONTHS IN SOUTH ASIA: A POOLED ANALYSIS**

K. Agho¹, S. Rasheed², S. Miharshahi³, U. Senarath⁴, M. Dibley⁵

¹University of Western Sydney, Australia

²International Centre for Diarrhoeal Disease Research, Bangladesh (ICDDR,B), Bangladesh

³School of Population Health, the University of Queensland, Queensland, Australia

⁴Department of Community Medicine, University of Colombo, Sri Lanka

⁵Sydney School of Public Health, University of Sydney, New South Wales, Australia

Background and objectives: Early initiation of breastfeeding within the first hour and exclusive breastfeeding (EBF) improves the health and nutrition status of newborns and are the two most important determinants of infants and young child survival. This study identifies factors linked to delayed initiation of breastfeeding among children aged 0-23 months and non-EBF among children aged 0-5 months.

Methods: We pooled the most recent data from Demographic and Health Surveys in five South Asian countries (Bangladesh 2011; India 2005-2006; Nepal 2011, Sri Lanka 2006-2007 and Pakistan 2006-2007). Our analysis was restricted to the last-born child who was living with the respondent (ever-married women age 15-49 years) and the total sample was 31082.

Results: The pooled rate of early initiation of breastfeeding and EBF were 33% and 51%, respectively. Multivariate analyses revealed that non-EBF was significantly higher among mothers who delivered their babies at the health facilities (adjusted odds ratio (AOR) = 1.47) and mothers who perceived their babies to be smaller than average (AOR) = 1.28). Compared with mothers who had 7 or more antenatal visits, the odds for mothers who had 3-6 visits, 1-2 visits and no visit were significantly higher for delayed initiation of breastfeeding and non-EBF. Mothers who had secondary or more level of education and had no education were significantly more likely to delay the initiation of breastfeeding and not to give EBF compared with mother's who had primary level education. Mothers who delivered their babies by caesarean section (AOR) = 2.15) were more likely to delay initiation of breastfeeding.

Conclusions: Interventions to promote early initiation of and exclusive breastfeeding should be further strengthened in the South Asia region, with more emphasis to target mothers who are at risk for sub-optimal practices.

Key words: early initiation of breastfeeding, exclusive breastfeeding, survival, South Asia

PO500**MONITORING THE COMPLIANCE TO THE INTERNATIONAL CODE OF MARKETING OF BREASTMILK SUBSTITUTES: LABELLING VIOLATIONS IN INDONESIA**

U. Parady¹, J. Februhartanty², S. Blaney³, S. Sukotjo⁴

¹Department of Communication, University Indonesia, Depok, West Java, Indonesia

²Southeast Asian Ministers of Education Organization - Regional Centre for Food and Nutrition (SEAMEO RECFON), University of Indonesia, Jakarta, Indonesia

³UNICEF Senegal, Dakar, Senegal

⁴UNICEF Indonesia, Jakarta, Indonesia

Background and objectives: Exclusive breastfeeding rate in Indonesia is still lower than targeted by the Government. The government has adopted several legal measures to protect and promote breastfeeding. Several provisions of the International Code of Marketing of Breast Milk Substitutes (BMS) have been adopted but additional efforts are required to have it fully in force, particularly on labelling aspects. The purpose of the study was to assess the violations related to the set of articles 9 on labelling part of the Code in Jakarta, Indonesia.

Methods: The standardized protocol developed by the Interagency Group on Breastfeeding Monitoring (IGBM) to estimate the prevalence of violations of the Code was used. It combines qualitative and quantitative methods. A total of 27 labels from different types of BMS (infant formula 0-6 months, follow-on formula 6-12 months, follow-on formula 6-18 months, and growing up formula 12-36 months) was collected in different selling points of the city. Each label of each product was analysed based on 32 parameters to identify violations related to labelling.

Results: On all labels (100%) under assessment, violations of the Code were found in one or more parameters. All labels have brand name or show promotion of brand's awareness and recognition, bear company name or logo, and have pictures that idealise the use of BMS. None of the labels have information on the negative effects of bottle feeding or the difficulty of reversing decision not to breastfeed.

Conclusions: Formula labeling violations in Indonesia is of concern and it may jeopardize breastfeeding practices. Labels need to provide appropriate information about the risks of using the products and superiority of breastfeeding. Results will be used to advocate for further regulations to strengthen labeling regulations to comply with International Code of Marketing of BMS.

Key words: Formula, labels, Breastfeeding, Code, Marketing

PO501**A SHIFT IN OCCUPATIONAL PHYSICAL ACTIVITY AND ANIMAL PROTEIN CONSUMPTION LEAD TO OVERWEIGHT AMONG RURAL INDONESIAN ADULT MEN**

H. Khusun¹

¹SEAMEO Regional Center For Food and Nutrition, Universitas Indonesia, Jakarta, Indonesia

Background and objectives: Previous studies have shown that increasing overweight evidence not only in urban but also rural population. This study explored multi-layers of individual and community factors explaining overweight among rural Indonesian men.

Methods: Longitudinal data of the 2000-2007 Indonesian Family Life Survey (IFLS) was used. In the analysis, 1877 men 18-60 years in 1993 with complete follow-up were included. Overweight was defined as BMI ≥ 25 kg/m². Individual factors included age, smoking habit, occupational physical activity (PA) and animal protein consumption frequency. Heavy PA job was defined as occupations in agricultural, mining and dealing with lifting heavy things. Animal protein consumption included consumption of meat, egg and dairy products. At the next level, factors associated with the shifting of occupational PA and animal protein consumption were explored. Data was analyzed by generalized estimating equation modelling.

Results: After adjusting for age, smoking habit and animal protein consumption, men who have shifted from heavy to lower PA occupations have 2.52 (CI:1.96-3.24) higher risk of overweight over the observation period. The shift in occupational PA was partially explained by involvement in non-farming business (OR:2.40, CI:2.11-2.72) and development of factories (OR:1.24, CI:1.08-1.42). On the other hand, men who consumed more frequent animal protein has 2.04 (CI:1.38-3.03) higher risk of overweight than those who did not consume (adjusted for age, smoking habits and occupational PA). Further analysis showed that changes in animal protein consumption were associated with affluence and accessibility to market (OR:1.54, CI:1.09-2.17).

Conclusions: The study showed that increasing overweight prevalence in rural areas was associated with both the changes in PA and food consumption pattern, which in turn associated with individual factors and changes in community environment. The study suggested that changes in community environment could serve as early warning for obesity prevention effort.

Key words: Overweight, Physical activity, Animal protein consumption, Longitudinal

PO502**HIGH FRUCTOSE DIET ALTERS INTESTINAL PERMEABILITY AND ELECTROPHYSIOLOGY IN ADULT MINIPGS**

J-P. Lalles¹, M. Ochoa Frias¹, D. Bertacchini¹, C-H. Malbert¹, D. Val-Laillet¹

¹Inra, Saint-Gilles, France

Background and objectives: Increased gut permeability and resulting endotoxin leakage following high-fructose chronic intake have been advocated as etiopathological factors in nonalcoholic fatty liver disease and steatohepatitis (NAFLD, NASH). However, gut permeability data are scarce and conflicting regarding the site of barrier alteration. The only study in man suggests aspirin-induced altered colonic, but not intestinal permeability in 10 NASH patients. Therefore, we hypothesized that a high fructose diet increases permeability along the gastrointestinal tract and alters intestinal glucose absorption and gut ion exchange.

Methods: For testing the hypothesis, adult minipigs were fed similar amounts of wheat-soyabean-corn starch based diet containing 20% pure glucose or fructose for 8 weeks (n=6/treatment). Gut tissues were collected post-mortem and segmental permeability and electrophysiology were investigated in Ussing chambers (UC) under basal condition or after addition of cytochalasin B (mycotoxin blocking sugar transport and cell microfilaments).

Results: Pigs grew similarly with either diet. Basal jejunal macromolecule transcellular permeability was twice higher with fructose (P<0.01) with no difference at other sites. Basal paracellular permeability was unaffected. Under cytochalasin, ileal and colonic transcellular permeability tended to be higher with fructose (P=0.15). Basal gut electrophysiology was unaffected by diets. However, under cytochalasin net ion movement was lower in jejunum and higher in ileum (both P=0.02) and potential difference was lower (P=0.04) with fructose. Intestinal sodium-dependent glucose absorption capacity was higher (P=0.05, global effect) and carbachol-induced jejunal chloride secretory capacity was lower (P=0.055) with fructose (no differences under cytochalasin).

Conclusions: High-fructose diet increased jejunal transcellular permeability and glucose absorption capacity while decreasing jejunal secretory capacity. Cytochalasin treatment disclosed additional differences between diets for transcellular permeability and ion exchange. Work is in progress to investigate the impact of chronic fructose consumption on intestinal glucose and fructose transporters.

Key words: high-fructose diet, gut, permeability, electrophysiology, minipig

PO503**THE NUTRITIONAL VALUE, WATER USE AND NUTRIENT CONTRIBUTION OF TRADITIONAL AFRICAN LEAFY VEGETABLES**

A. Oelofse¹, W. Van Averbeke², P. Van Jaarsveld³, M. Faber³, F. Wenhold¹, Y. Beletse⁴, W. Janse van Rensburg⁴, R. Slabbert²

²Department of Crop Sciences, Tshwane University of Technology, Pretoria, South Africa

³Nutrition Intervention Research Unit, Medical Research Council, Tygerberg, South Africa

⁴Vegetable and Ornamental Plant Institute, Agricultural Research Council, Pretoria, South Africa

Background and objectives: For centuries traditional crops sustained rural populations in developing countries. Several of these crops are native to the countries where they grow and are well adapted to climatic conditions. The objectives of the study was to determine the nutrient content, agronomic practices, consumption and contribution to nutritional status of eight selected African crops.

Methods: Eight traditional crops were selected from those most commonly consumed. Nutrient content was determined using accepted standardised techniques including proximate analyses, Ion Chromatography and HPLC. Drought and heat stress analyses were done using Relative Water Content (RWC), leaf area, Cell membrane stability and reduction essays (TTC). Water use was determined using Crop evapotranspiration. Consumption of these plant foods and its contribution to nutritional status were assessed by focus groups discussion, food recall methodology and dietary calculations. The data from these plant foods were compared to that of Swiss chard.

Results: The nutrient intake data was based on children aged 4-8 years old. These traditional vegetables provided substantial amounts of vitamin A and iron. Amaranth and cowpea provided more than 75% of the RDA, while pumpkin leaves were the best source of iron and provided between 50 – 75% of the RDA for the age group. All the traditional crops had a higher degree of drought tolerance compared to Swiss chard. However, all eight crops were sensitive to water stress. Although the production was best at full irrigation, these plants could still produce edible leaves at much lower levels of irrigation.

Conclusions: The findings of this study support the promotion and use of these vegetables as food crops from both the agronomic and human nutrition perspective, especially in food insecure communities. They make a significant contribution to nutrient intake in the arid regions of the continent.

Key words: nutrition, indigenous foods, African vegetables, amaranth

PO504**METHOD NON-INVASIVE IN BLOOD OF MICRORNAS BIOMARKER FOR PREVENTIVE DIAGNOSIS OF CELIAC'S, CROHN'S, WILSON'S DISEASES WITH UNKNOWN ETHIOLOGY**

H. Boughanem¹, F. Sanchez-Jimenez², M. Macias-Gonzalez³

¹Dept I+D/Biotechnology Company Bioeasy SL, Spain

²Dept. Dietetics and Applied Nutrition/Colegio Profesional Tecnicos Superiores Sanitarios Comunidad Valenciana, Alicante, Comunidad Valenciana, Spain

³CIBER FISIOPATOLOGIA OBESIDAD Y NUTRICIÓN/Hospital Virgen de la Victoria, Málaga, Spain

Background and objectives: In the last decade, Nutrigenomics has developed into very important sector in the clinical research. Especially in identifying the association of lifestyle or eating habits particular to the development not only of complex diseases, such as cardiovascular disease and oncologic, but also rare autosomic disease difficult to diagnose and unknown etiology, such as celiac disease, Crohn's disease and Wilson's disease. Our main aim in this study is to characterize new biomarkers in blood and validate their application in disease prognosis. Among them, the identification of novel microRNAs(miRNA), which play a crucial role in the silencing of certain key genes in the development of these pathologies discussed above.

Methods: The study will include 150 patients with different pathologies described above and 150 healthy persons. Blood samples were collected after a 12-hour fast recruited by the Andalusia Cooperative Society (SCA). All participants gave their informed consent. The serum miRNA isolation is being obtained using a novel and fully automated system epMotion 5075 VAC workstation in a 96 well format (Eppendorf Iberica). For quantification end, we use real time quantitative PCR by an Eppendorf realplex (Eppendorf Iberica).

Results: Preliminary results confirm that our isolation and quantification

Methods will be useful to identify new biomarkers, which have a high sensitivity and specificity, applied to preventive diagnosis.

Conclusions: The expected results of this study will result in enough data for a statically significant relationship between the levels of miRNAs and genetic predisposition to the development of these diseases.

Key words: Celiac-Crohn-Wilson's, diseases, miRNA, biomarkers, diagnostic

PO505**A NOVEL APPROACH TO THE DESIGN OF COMPLEMENTARY FEEDING BEHAVIOUR CHANGE INTERVENTIONS**

R. Aunger¹, H. Trevaskis², M. van Liere³, E. Wulandari², V. Curtis¹

¹London School of Hygiene and Tropical Medicine (LSHTM), London, UK

²Independent Consultant

³Global Alliance Improved Nutrition (GAIN)

Background and objectives: It is widely recognized that infant child feeding practices need to be improved to reduce the burden of chronic child malnutrition worldwide. However, infant and child feeding practices are deeply ingrained in culture, habit and context, and are a complex target for behavior change intervention. Many nutrition programs develop messages that derive from scientific recommendations rather than from principles of effective behavior change (BC). Project Baduta in Indonesia aims to bring the best scientific knowledge about behavior change combined with the creative practices of industrial marketing to nutrition BC intervention design.

Methods: An innovative approach developed by LSHTM was used to design a program to promote appropriate feeding amongst children 6-24 months of age in peri-urban Surabaya. The BC approach – called 'Evo-Eco' because it originates in evolutionary biology and ecological psychology – focuses on behavior in its social, physical and biological settings, and on the motivated and habitual aspects of routines, rather than on cognitive aspects.

Results: The framing workshop generated insights on the role of prior advertising histories of complementary foods, the cultural place of milk, the tedious nature of infant feeding, the fear of wasting food, and mother's desire to reduce effort by involving infants in family feeding events. Findings led to a reorientation of project goals. Formative Research employed novel tools including video ethnography, behavioural settings analysis, motive projections, the elicitation of everyday routines, and behaviour trials. The results provided the design principles for a behaviour change intervention, set out in a creative brief.

Conclusions: This presentation outlines the approach, the methods and the results of the first stage of Project Baduta. We conclude that nutrition promotion needs to incorporate the lessons of modern BC approaches and to tap the creative skills that are normally proprietary to industry.

Key words: complementary foods, stunting, children, indonesia

PO506**EFFECTS OF VITAMIN C ON CELL CYCLE AND APOPTOSIS***S. Ebrahimipour Koujan¹, F. Toorang¹*

¹MS-BS in nutrition, Department of Nutrition, Schools of Health and Nutrition, Tabriz University of Medical Sciences, Tabriz, Iran

²MS in nutrition, Cancer Research Center, Cancer Institute of Iran, Tehran University of Medical Science, Tehran, Iran

Background and objectives: Vitamin C (VC) a water soluble antioxidant and antimutagen has dual effects on biologic systems. VC has both free-radical scavenging and autooxidizing properties as well as in cell proliferation and cell death. The aim of this article is mechanistic surveying of VC roles in cell cycle and apoptosis.

Methods: This review compromised on published articles in PubMed, GoogleScholar, sciencedirect and ovid according to key words since 1998.

Results: Regarding in vitro studies, VC supplementation with X-ray irradiation results in apoptosis in human leukemia, LH-60 cells, due to activation of pro-apoptotic factors such as Bax and caspase-8. Also high dose of VC combination with H₂O₂ by increasing oxidative stress decreases Bcl-2 expression and induces apoptosis in HL-60 cells. Moreover, treating ovarian cells with VC in presence oxidative stress enhanced cell cycle arrest at the G₂/M phase by delaying activation of cyclin B-cdc2. While, in the absence of oxidative stress, it had no effect on cell cycle. In contrast, VC in human colon carcinoma HT-29 by blocking drug-mediated apoptosis induced by oxidative stress, allow cancer cells to become insensitive to chemotherapy. Incubation of T cells with VC induces them to enter S phase. Recently, studies demonstrated VC has an anti-proliferative activity via inhibition of tRNA synthesis gene expression in HT-29 cells, and administration of high-dose VC significantly induces mitochondrial apoptosis in mesothelioma tumor cells in dose-dependent manner.

Conclusions: Although a high alimentary intake of VC contributes to cancer prevention, high level of VC may have quite different effects at various stages of cell growth, proliferation and apoptosis that may promote cancer progression. The-reby safe-dose of administration of VC and implications for a clinical use in anticancer therapies has to be discussed.

Key words: vitamin C, apoptosis, cell cycle

PO508**LUTEIN AND ZEAXANTHIN STATUS. DIETARY INTAKE, SERUM CONCENTRATIONS AND MACULAR PIGMENT DENSITY IN SPANISH SUBJECTS***B. Olmedilla-Alonso¹, R. Estévez-Santiago¹, B. Beltrán-de-Miguel², M C. Cuadrado-Vives²*

¹Departament of Metabolism and Nutrition, Institute of Food Science, Technology and Nutrition (ICTAN-CSIC), Madrid, Spain

²Department of Nutrition and Bromatology, Faculty of Pharmacy, UCM, Madrid, Spain

Background and objectives: Lutein and zeaxanthin are dietary carotenoids. Both are concentrated in retina and constitute the macular pigment. A higher concentration of lutein and zeaxanthin in blood or intake has been associated with lower risk of age related macular diseases. Objective: to assess the status of lutein and zeaxanthin by means of dietary intake, blood levels and macular pigment density (MPD) and correlations among them.

Methods: Subjects: 108 subjects (54 women). Inclusion criteria: 20-35y (young) or 45-60y (old), normolipemic, no vitamin or dietary supplements. Exclusion criteria: obesity, cataract or any ocular disease. Study approved by the Ethical Committee Clinical Research (Hosp. Univ. Puerta de Hierro, Madrid). HPLC validated method was used to analyze lutein in serum (Olmedilla et al., Clin. Chem., 43;1997). MPOD measured by the M:pod device. Statistical analysis: lutein and MPOD data expressed as mean +-SD. SPSS vs 21.0 statistical software. Lutein /zeaxanthin intake was assessed by a 3-day food record using the carotenoid database published by our group (Nutr. Hosp., 27; 2012) .

Results: Concentrations in blood (µg/dl): 13,1±7 lutein; 3,4±2,7 zeaxanthin. Concentrations in diet (µg/day): 1073±1572 lutein; 95±140 zeaxanthin. Central MPD: 0,29±0,14. Old group showed higher levels of lutein and zeaxanthin in blood and intake but when those concentrations standardized by lipids (cholesterol+triglycerides) those differences disappeared. MPD was similar in both groups. Correlations between blood and diet concentrations: r=0,223 (p=0,02) for lutein; r=0,322 (p=0,01) for zeaxanthin; r=0,255 (p=0,008) lutein plus zeaxanthin. Lutein and MPD r=0,201 (p=0,037).

Conclusions: Lutein and zeaxanthin concentrations in diet and blood are correlated. Blood concentrations of lutein, but not dietary intake, shows correlation with MPD.

Key words: lutein, zeaxanthin, diet, blood, macular pigment density.

PO509**CHEMOPREVENTIVE AND ANTI-CANCER PROPERTIES OF POMEGRANATE SEED OIL (PSO)***S. Ebrahimipour Koujan¹, F. Toorang²*

¹MS-BS In Nutrition, Department of Nutrition , Schools of Health and Nutrition, Tabriz University of Medical Sciences, Tabriz, Iran

²MS in nutrition, Cancer Research Center, Cancer Institute of Iran, Tehran University of Medical Science, Tehran, Iran

Background and objectives: In recent years, there is much interest about anticancer properties of PSO. Due to its weakly estrogenic activity, interference with cell proliferation, cell cycle, metastasis and anti-inflammatory effects. This article has tried to reveal chemopreventive and anti-cancer potential of PSO in various cancers.

Methods: This article is a review on articles published in googlescolar, pubmed, sciencedirect and ovid according to key words since 1998.

Results: Chemopreventive effects of PSO refers to its strong inhibiting ability of inflammatory enzymes gene expressions such as lipoxygenase and cyclooxygenase-2 (COX-2) as well as decreasing stimulation of cytokines such as IL-4, IL-6, IL-8 and TNF- by inhibiting ERK/MAPK transduction pathways and NF-kB activation. Also PSO has anti-proliferative and pro-apoptotic properties in cancer cells. It can promote apoptosis via p53/p21 up-regulation and caspase-3 pathway and also attenuate G0/G1 to S phase and cell cycle arrest in G1 in prostate, bladder, breast and human leukemia cancer cells. Punicic acid, a major bioactive substance of PSO via overexpression of PPAR- and increase lipid peroxidation can inhibit proliferation and induce mitochondrial apoptosis in breast and colon cancer cells. Moreover, PSO has an especial anti-proliferative activity in breast cancer cells via aromatase and 17 -hydroxysteroid dehydrogenase enzymes inhibition and antiestrogenic activities. Similarly, in skin cancer models, PSO significantly decrease tumor incidence and multiplicity. Recent in vitro and in vivo studies demonstrated PSO anti-angiogenic action in breast cancer by decreasing angiogenic factors such as IL-4, migration inhibitory factor (MIF) and vascular endothelial growth factor (VEGF).

Conclusions: In sum, PSO can potentially be used in both prevention and treatment of various cancers, but further studies needed to warranting chemopreventive and therapeutic application of PSO in humans.

Key words: pomegranate seed oil, cancer, proliferation, apoptosis, angiogenesis

PO510**THE PERFORMANCE OF THE HOUSEHOLD FOOD IN-SECURITY (ACCESS) SCALE (HFIA) IN COMMUNITIES WITH VARYING EXPOSURE TO ECONOMIC MEANS TESTING***M. Nnyepi¹*

¹University of Botswana, Botswana

Background and objectives: Experiences of food insecurity are similar across cultures. Instruments used to assess the prevalence of household food insecurity and those that evaluate households' qualification for social benefits (means testing) are similar. Whether prior exposure to means testing influences households' responses during the assessment of the prevalence of household food insecurity requires further study. The objective is compare the performance of Household Food Insecurity –Access (HFIA) instrument in two communities with varying uptakes of social benefit programmes, and thus exposure to means testing.

Methods: The HFIA instrument was administered to 742 randomly sampled households in two communities. The HFIA-scores were computed for each community and compared. Next, the null hypotheses of independence between the HFIA-scores and households wealth (per-capita income, and ownership of assets), and the prevalence of stunting were evaluated.

Results: The HFIA-scores ranges from 0-27. Higher scores indicate higher food insecurity. The mean HFIA-score for both communities was 11.0 ± 7.5 . The mean HFIA-score was lower (T-test -3.588; $p < .001$) in the low-exposure community (9.8 ± 7.7) than in the high-exposure community (11.7 ± 7.1). Higher proportions of food insecure households were observed in the lower quintiles of per-capita household income and household asset holding. Notably, 92% of households in 1st and 2nd quintile of per-capita income were food insecure. This proportion did not differ significantly between the low-exposure and the high-exposure community. Similarly, households with stunted children had significantly ($p < .05$) higher mean HFIA-scores (stunting 12.2 ± 7.5 vs 10.2 ± 7.5). Again the mean HFIA-scores for households with stunted children did not differ significantly between the low-exposure and the high-exposure community.

Conclusions: The findings suggest that HFIA tool performs similarly well in assessing household food insecurity in communities with low and high exposure to means testing.

Key words: food insecurity, means testing, stunting

PO511**ANTHOCYANIN DAILY INTAKE AND ITS ASSOCIATION WITH HEALTH INDICATORS IN COMMUNITY POPULATION***W H. Ling¹, L. Li¹, J. Lan¹*¹Sun Yat-Sen University, China

Background and objectives: the present study is to optimize a method for quantifying the contents of anthocyanins in phyto-foods, to quantify anthocyanins in common plant foods in China, providing information for the establishment of Chinese database of anthocyanins, to estimate the daily intake of anthocyanins of Guangzhou population on the basis of the quantitative data and results from the food intake survey, and then to analyze health effects of anthocyanins intake.

Methods: Phyto-foods were sampled from Guangzhou, Chongqing, Tianjin and Wuhan around China in two different seasons. The anthocyanins extracted from foods were assayed by HPLC-MS. A total of 1404 adult residents from Guangzhou community were recruited. Dietary survey was performed by using semi-quantitative food frequency questionnaire, and health parameters of the subjects were examined.

Results: A total of 200, 160, 180, and 100 items were collected from Guangzhou, Chongqing, Tianjin and Wuhan, respectively. The anthocyanin contents were analyzed by HPLC-MS, the anthocyanin food content database is established. The daily anthocyanin intake was estimated as 27 mg/D of anthocyanin aglycon, equivalent 43 mg/D of anthocyanin. The results demonstrated that anthocyanin daily intake is positively associated with HDL-C concentration ($P < 0.05$), and negatively with uric acid. Higher anthocyanins intake also decreased the risk of right-and-left carotid plaque ($P < 0.01$). However, there were no differences in BMI, TG, LDL-C, IMT and SBP in higher vs low anthocyanin daily intake.

Conclusions: The study set up the database of anthocyanin contents of plant foods, estimated the anthocyanin consumption as 43 mg/D in community population, and revealed that high dose of anthocyanins intake had higher blood HDL-C concentration and lower blood uric acid concentration, and the anthocyanin might reduce risk of right-and-left carotid plaque; s incidence rate.

Key words: anthocyanin, daily intake, lipid and HDL

PO512**THE DISTRIBUTION OF THE SNPS WHICH HAVE THE ASSOCIATION WITH IRON DEFICIENCY ANEMIA IN CHINESE***W. Piao¹, J. Huo¹*¹Institute For Nutrition and Food Safety, Chinese Center For Disease Control and Prevention, 29 Nan Wei Road, Beijing, China

Background and objectives: Iron deficiency anemia (IDA) is directed by many risk factors, and the genotype is the one of them. Single-nucleotide polymorphisms (SNPs) which associate with IDA had been discovered, and some valuable results had also been concluded. No study to our knowledge, however, has estimated the distribution of these SNPs in Chinese. We conducted a descriptive study to examine the distribution of these SNPs in Chinese.

Methods: 202 samples were selected randomly from the native children, whose age were from 8 to 12. DNA samples were obtained from the leucocytes in peripheral blood and genotyped by sequenom MassArray. 5 SNPs which had been shown that have the association with IDA in the previous study were chosen to be examined, rs877908, rs4820268, rs2543607, rs2543633 and rs2235321. The proportions of these SNPs on each allele were calculated, and the distributions of them were described.

Results: The proportions of the alleles on rs877908 were 22.4%(CC), 47.9%(CT) and 29.7%(TT) respectively. The proportions of the alleles on rs4820268 were 21.6%(AA), 48.2%(AG) and 30.2%(GG) respectively. The proportions of the alleles on rs2543607 were 2.5%(AA), 31.8%(AG) and 65.7%(GG) respectively. The proportions of the alleles on rs2543633 were 22.2%(AA), 46.5%(AC) and 31.3%(CC) respectively. The proportions of the alleles on rs2235321 were 23.1%(AA), 45.6%(AG) and 31.3%(GG) respectively.

Conclusions: The SNPs on the 5 alleles are confirmed. According to result, the potential risk of IDA in Chinese can be estimated, and the high risk genotype groups should be taken more attention on the developing of IDA.

Key words: IDA, SNPs, genotype, distribution

PO513**IS ADHERENCE TO THE GREEK MEDITERRANEAN DIET BY ELDERLY GREEK AUSTRALIANS ASSOCIATED WITH THE GREEK HOME GARDEN?**

T. Darnos-Thodis¹, C. Itsiopoulos¹, A. Kouris-Blazos¹, M. Avgoulas¹, S. Tsindos¹, E. Kaias¹, D. Panagiotakos², E. Polychronopoulos²

¹Department of Dietetics and Human Nutrition, Latrobe University, Melbourne, Victoria, Australia

²Department of Nutrition and Dietetics, Harokopio University, Athens, Greece

Background and objectives: The Australian arm of the MEDIS (MEDiterranean ISlands) study is a cross sectional survey of socio-demographic, medical history, lifestyle factors and dietary characteristics of elderly Greek Australians over 65 years of age originally from the islands of Crete and the Republic of Cyprus who migrated to Australia up to almost 60 years ago from their homeland. It aims to explore the relationships between cardiovascular disease risk factors and adherence to the Mediterranean diet using the MedDiet Score to explain the persistent low coronary heart disease mortality of Greek migrants to Australia. Growing a home garden has been documented as a form of social connectedness to one's homeland and is an identifying trait of Greek culture. It is well documented that the traditional Greek Mediterranean diet is a dietary pattern that is predominantly plant based along with a high intake of olive oil, legumes, fish, seafood and low amounts of meat and dairy. The purpose of this paper is to explore the association between a home garden and adherence to the Mediterranean diet which, in addition to acting as a vehicle for the maintenance of culture and tradition may explain the benefits to health and well-being observed in this cohort of elderly Greek Australians.

Methods: Data was collected via a lifestyle questionnaire (LQ) and a Food Frequency Questionnaire (FFQ) and included data as to whether participants grow their own produce such as citrus and stone fruits, tomatoes, onions and garlic, green leafy vegetables and certain herbs.

Results: Our preliminary findings indicate a high MedDiet Score is positively correlated with participants who report keeping a home garden, particularly those that grow tomatoes, onions and garlic.

Conclusions: It is highly likely that growing one's own home produce encourages this tradition and pattern of eating.

Key words: MEDIS, Greek Australians, culture, MedDiet Score, home gardens.

PO514**DISTRIBUTING COMPLEMENTARY FOOD SUPPLEMENT-YINGYANGBAO REDUCING THE ANEMIA IN YOUNG CHILDREN IN A COUNTY OF SICHUAN PROVINCE AFTER WENCHUAN EARTHQUAKE**

L. Wang¹, J. Huo¹, J. Sun¹, W. Li¹, J. Huang¹, L. Lin¹, Y. Zhou¹, C. Huang², J. Hu³

¹Institute For Nutrition and Food Safety, Chinese Center For Disease Control and Prevention

²Sichuan University, China

³Lixian MCH, China

Background and objectives: This study aimed to evaluate the impact of highly nutrient-dense complementary food supplement-Yingyangbao, at the time of 3 months after Wenchuan earthquake, on the anemia of young children in a county in Sichuan province.

Methods: The young children aged 6-23 months in the county were fed one sachet Yingyangbao per day. Yingyangbao were distributed for 15 months for free. The children entering 6 months age would be included. The length, weight and hemoglobin of the children aged 6-29 months were assessed at baseline (n=257) and Yingyangbao intervention for 6 (n=218) and 15 months (n=253) by cluster sampling. Growth status has not been described in the paper. The analysis was conducted based on 6-11, 12-17, 18-23 and 24-29 months.

Results: It showed that the hemoglobin concentration in each group among the 4 groups increased by 4.9, 6.4, 8.0, 9.5 g/L after 6 months and 12.7, 11.4, 16.7, 15.7 g/L after 15 months compared to the baseline, respectively. The total anemia prevalence in each group was significantly lower after 6 and 15 months than the baseline (P<0.001), except the 6-11 months group after 6 months because of fewer Yingyangbao consumption. Total moderate anemia rate decreased from 18.3% to 5.5% after 6 months, and kept decreasing to 0.8% after another 9 months. The hemoglobin concentration was significantly correlated with the amount of yingyangbao consumption (P<0.001). The anemia rate was significantly different based on the yingyangbao compliance (P<0.001).

Conclusions: It was concluded that Yingyangbao which contains quality protein, vitamins and micronutrients intervened 15 months could be effective for the improvement of anemia of young children. The study provides the support that the application of the complementary food supplements to reduce the anemia of young children in the emergency of natural disaster.

Key words: young children, anemia, nutrition intervention, complementary food supplements, Yingyangbao

PO515**EXPOSURE TO NON-SWEET MALTODEXTRIN SOLUTION REDUCES WEIGHT GAIN AND CHANGES THE PREFERENCE FOR SWEET TO PROTEIN SOLUTIONS IN PIGS**

S A. Guzmán-Pino¹, D. Solá-Oriol¹, J. Figueroa¹, J.F. Pérez¹

¹Servei de Nutrició i Benestar Animal (SNI BA), Departament de Ciència Animal i dels Aliments, Universitat Autònoma de Barcelona, Barcelona, Spain

Background and objectives: There are concerns about the consequences of a long-term consumption of caloric drinks for kids. However, the specific role of a hedonic taste or post-ingestive rewarding properties of sugars on these consequences are still unclear. A non-sweet maltodextrin (low dextrin-equivalent) allows the dissociation of both properties, while pigs are a suitable model for humans due to the innate sweet preference, but also highly developed orosensorial perception and growth potential.

Methods: The preference of thirty six piglets for protein (animal plasma 20 g/l) or sweet (sucrose 20 g/l) solutions was assessed by using a choice test (CHT) before (day 14 post-weaning) and after an ad libitum supply of water (Control) or 160 g/l maltodextrin (MTD) solution for 12 consecutive days. A one-bottle test was also performed after the CHT by offering the same protein/sweet solutions on alternate days as a measure of their appetite. Pig performance and solution intake were monitored on d7 and d12.

Results: Piglets innately preferred sucrose (64%, $P < 0.001$). No significant differences were observed on the water and MTD solution intake, but a numerical increase in MTD intake (947 vs. 759 ml) was observed from d7 to d12. Low feed intake and weight gain ($P < 0.05$) were observed for MTD (395 g BWgain/d) than control piglets (484 g BWgain/g). Sweet over protein preference and appetite was maintained in control piglets ($P = 0.03$), but those with access to MTD showed a strong preference for the protein solution (68%; $P = 0.11$) and a dramatic reduction of the appetite for sweet solution.

Conclusions: The results show that a long-term access of a non-sweet caloric drink may depress feed intake and growth, but also increase the preference of piglets for protein, suggesting a role of the post-ingestive up/down regulation for sweet/protein orosensorial perception in pigs.

Key words: maltodextrin, pig, preference

PO516**MODULATION OF EPIGENETIC STATES AND INFANT IMMUNE SYSTEM BY DIETARY SUPPLEMENTATION WITH ω -3 PUFA DURING PREGNANCY IN AN INTERVENTION STUDY**

H S. Lee¹, A. Barraza², H. Hernandez-Vargas¹, P. Sly³, C. Biessy², U. Ramakrishnan⁴, Z. Herceg¹, I. Romieu^{2,5}

³Queensland Childrens Medical Research Institute, Royal Childrens Hospital, Herston, Qld, Australia

⁴Nutrition and Health Sciences and the Hubert Department of Global Health, Rollins School of Public Health, Emory University, Atlanta, Georgia, USA

⁵Instituto Nacional de Salud Pública, Centro de Investigaciones en Salud Poblacional, Cuernavaca, Morelos, México

Background and objectives: Early-life exposures to tobacco smoke and some dietary factors have been identified as inducing epigenetic changes in genes involved in allergy and asthma development. Omega-3 polyunsaturated fatty acid (PUFA) intake during pregnancy could modulate, by epigenetic regulation, key cytokines and the maturation of Th cells. However, little is known about the mechanism by which ω -3 PUFA could have a beneficial effect in preventing allergy and asthma. We sought to test whether dietary supplementation with ω -3 PUFA during pregnancy might modulate epigenetic states in infant immune systems.

Methods: The study is based on a randomized intervention trial conducted among pregnant Mexican women who were supplemented daily with 400 mg docosahexaenoic acid (DHA) or placebo from 18-22 weeks of gestation to parturition. We applied quantitative profiling of DNA methylation states in Th1, Th2, Th17, and Treg-relevant genes as well as LINE1 repetitive elements of cord blood mononuclear cells ($n = 200$).

Results: No significant difference in promoter methylation levels was found between the ω -3 PUFA and control groups for most genes analyzed; however ω -3 PUFA significantly changed methylation levels in LINE1 repetitive elements and specific genes (IFN α) in infants of mothers who smoked during pregnancy. Furthermore, an association between the promoter methylation levels of IFN and IL13 was substantially modulated by ω -3 PUFA supplementation.

Conclusions: Our results indicate that maternal supplementation with ω -3 PUFA during pregnancy may modulate global methylation levels and Th1/Th2 balance in infants. Therefore, these epigenetic mechanisms provide attractive targets for prenatal modulation and prevention of inflammatory disorders and potentially other related diseases in childhood and adulthood.

Key words: pregnancy, fatty acids, immunomodulation

PO517**MODERATE CONSUMPTION OF A NOVEL ORANGE DRINK PROMOTES AN IMPROVEMENT IN LIPID PROFILE AND ANTIOXIDANT ENDOGENOUS COMPOUNDS IN HEALTHY MICE.**

B. Escudero-López¹, G. Berná^{1,2}, G. Herrero-Martín¹, I. Cerrillo¹, M A. Ortega¹, F. Martín^{1,2}, M S. Fernández-Pachón¹

¹Area of Nutrition and Food Sciences. Department of Molecular Biology and Biochemistry Engineering. Universidad Pablo de Olavide, Sevilla, Spain

²Centro de Investigación Biomédica en Red de Diabetes y Enfermedades Metabólicas Asociadas (CIBERDEM), Spain

Background and objectives: The beneficial effects of fruits through its antioxidant compounds have largely been confirmed. Moreover, moderate alcohol consumption confers cardiovascular protection. A low alcoholic (1%) beverage from fermented orange juice (F-OJ) could join both actions. Therefore, our aim is to evaluate the effect of this novel beverage on antioxidant markers and lipid profile in a mice animal model.

Methods: OF1 Male mice (n=28), 8 weeks old, fed with standard diet, were divided into 4 groups (n=7) during 12 weeks: i) control (drinking water), ii) orange juice in drinking water (1:10), iii) F-OJ in drinking water (1:10), and iv) aqueous alcoholic solution (1:100). The four beverages were provided ad libitum. Blood was obtained by intracardiac puncture. Plasma antioxidant capacity was evaluated by ORAC, FRAP and ABTS assays. Lipid oxidation markers were analyzed by oxidized LDL and TBARS methods. Activities of antioxidant enzymes (CAT, SOD, GR, GPX), lipid profile (TAG, TC, LDL, HDL) and levels of endogenous antioxidants (albumin, bilirubin, uric acid, total glutathione) were determined spectrophotometrically.

Results: It was found that mice ingested F-OJ showed an increase on ORAC and FRAP compared to control group but did not exist significant differences. F-OJ group showed a significant decrease vs control group in CT, LDL and TAG concentration. Furthermore, the HDL levels were significant increased with F-OJ vs control. Concerning endogenous antioxidants, albumin, uric acid and total glutathione increased significantly in F-OJ group vs control. In addition, it was found a significant decrease in oxidized LDL and TBARS values between F-OJ group and control. Any significant differences among groups were obtained in antioxidant enzymes values.

Conclusions: Fermented orange juice exerts a significant improvement in lipid profile, lipid oxidation and levels of endogenous antioxidants in healthy mice.

Key words: orange juice / mice / antioxidant markers / lipid profile.

PO518**THE USE OF A COMBINED VITAMIN B12 INDICATOR TO DETERMINE B12 STATUS IN MEXICAN ADULT WOMEN AND CHILEAN ELDERLY**

A. Brito¹, S N. Fedosov³, S. Shahab-Ferdows², R. Uauy^{1,4}, L H. Allen²

¹Institute of Nutrition and Food Technology (INTA), University of Chile

²USDA, ARS, Western Human Nutrition Research Center (WHNRC), University of California

³Department of Engineering Sciences, Aarhus University, Denmark

⁴London School of Hygiene and Tropical Medicine, London, UK

Background and objectives: B12 status has been assessed for decades by single serum/plasma B12 measurements. The analysis of combination of all B12 biomarkers attempts to improve the diagnosis of B12 status. The objective was to compare single biomarkers versus a combined indicator of B12 status in both Mexican women and Chilean elderly.

Methods: Spearman correlations and linear regression models assessed associations between single B12 biomarkers (serum B12, total-plasma-homocysteine, methylmalonic-acid, holo-transcobalamin) and B12 status using the Fedosov formula, combining single B12 biomarkers 'w=log 10[(holoTC*B12)/(MMA*tHcy)]-age factor'. Two baseline databases were used: I. RCT performed in women (20-59y,n=127) from Queretaro, Mexico, included bone-specific-alkaline-phosphatase (BAP) assessment. II. RCT conducted in 70-79y,(n=157) from Santiago, Chile included a peripheral nerve conduction study. SB12, tHcy, holo-TC and MMA were defined as >148-deficient, 149-220-marginal and >220-adequate (pmol/L); >12µmol/L-elevated; <35pmol/L-deficient, and >271nmol/L-elevated, respectively.

Results: I. sB12 was negatively correlated with BAP. No association was observed between the Fedosov formula and BAP. The combined formula significantly correlated with all biomarkers, while sB12 did not correlate with tHcy. Regression analysis showed no association between sB12 and BAP. Both sB12 and Fedosov's formula (? =0.004,p<0.001; ? =-0.416,p<0.001; ? =-0.16,p<0.001; ? =0.011,p<0.05, for sB12, tHcy, MMA and Holo-TC, respectively) were significantly associated with each B12 biomarker. II.Both sB12 and Fedosov's formula were significantly correlated with each B12 biomarker and with multiple neurophysiological parameters. However, after linear regression models were performed there were significant associations between the Fedosov's formula and each biomarker (?=0.006,p<0.001; ? =-0.04,p<0.001; ? =0.04,p<0.001; and ? =-0.0002,p<0.01, for sB12, tHcy, holo-TC and MMA, respectively), and also with sensitive nerve conduction velocity (m/sec)

of the right peroneal nerve ($\beta = 0.07, p < 0.05$). Instead, sB12 was not associated with tHcy, MMA or neurophysiology.

Conclusions: The Fedosov formula has stronger associations than single B12 biomarkers to determine B12 status. Cut-offs to define B12 status using this formula are being analyzed.

Key words: vitamin B12, Fedosov formula, biomarkers

UCP2 ALA55VAL POLYMORPHISM ARE NOT ASSOCIATED WITH WEIGHT LOSS AFTER THREE YEARS OF ROUX-EN Y GASTRIC BYPASS

C N. Ferreira¹, N M. Cury², C H. Malek-Zadeh¹, W A. Silva Junior², J S. Marchini¹, C B. Nonino¹

¹Department of Medical Science, University of São Paulo, Ribeirão Preto, São Paulo, Brazil

²Department of Genetics, University of São Paulo, Ribeirão Preto, São Paulo, Brazil

Background and objectives: Uncoupling proteins (UCPs) represent a family of carrier proteins located in the mitochondrial membrane, involved in the metabolism energy cells and may increase the energy expenditure and decrease the body weight. The Ala55Val polymorphism (rs660339) in the UCP2 gene (C>T) can be associated with the weight loss after surgery treatment for obesity. This study aimed to investigate the association of the Ala55Val polymorphism with weight loss three years after bariatric surgery.

Methods: The sample was composed of individuals with grade III obesity undergoing Roux-en Y gastric bypass. Anthropometric data were collected in the preoperative period and three years after surgery. Genotyping was performed by the method of allelic discrimination in real time PCR (Polymerase Chain Reaction) using the TaqMan pre-designed SNP Genotyping Assays kits (Applied Biosystems, Foster City, CA). Individuals with at least one variant allele were grouped and compared with those with the reference genotype.

Results: 143 subjects (79% females and 21% males, mean age 40 ± 10 years) participated in the study. In the preoperative period the mean weight was 140 ± 23.8 kg and mean excess body weight was 75.4 ± 26.6 kg. Genotyping showed 36.4% ($n = 52$) of individuals homozygous for the C allele (C/C), 39.2% ($n = 56$) heterozygous (C/T) and 24.4% homozygous for the mutant T allele (T/T). Individuals with the C/C, C/T and T/T genotypes respectively showed a loss of 55.8 ± 17.4 , 55.3 ± 21.2 and 52.7 ± 14.3 kg; 37.7 ± 9.4 , 38.6 ± 11.6 and 39 ± 7.8 of initial weight and 66.3 ± 17 , 68.6 ± 20.8 and 70 ± 12.8 of excess body weight. There was no difference in weight loss between the different genotypes groups.

Conclusions: The UCP2 Ala55Val genotype seems to have no association with weight loss three years after bariatric surgery. Financial support: FAPESP and CNPq

Key words: uncoupling protein 2, Ala55Val polymorphism, bariatric surgery, weight loss

PO520

PREVALENCE OF INADEQUACY INTAKE FOR OLDER PEOPLE: THE USE OF NATIONAL CANCER INSTITUTE (NCI) METHOD

J E. Corrente¹, L B. Souza²

¹UNESP, Biostatistics Department, Botucatu, São Paulo, Brazil

²Public Health Department, School of Medicine, UNESP, Botucatu, São Paulo, Brazil

Background and objectives: nutrition and eating habits for older people are still poor areas under investigation, being few explored and not receiving the attention due to them. In some developed countries, some studies have been done in order to identify the food intake of this age group, but in Brazil, there are few studies about this. Then, the aim of this study is to calculate the prevalence of inadequacy intake of micro and macro nutrients for older people using National Cancer Institute (NCI) method.

Methods: a representative sample of 365 older people were chosen at random and interviewed at home collecting data using three 24-hour recalls. This sample were chosen from a data set of older people from the city of Botucatu, São Paulo, Brazil, set up to investigate quality of life. Socio demographic data from these older people were also collected. The data from the 24-hour recall were transformed in consumption of macro and micronutrients using Nutrition Data System (NDS) software. The prevalence of inadequacy of micro nutrients were calculated using NCI method through the routines MIXTRAN and DISTRIB for SAS software and the EAR as cutoff. For macro nutrients, the inadequacy were calculated using Acceptable Macronutrient Distribution (AMD-IOM) categorization.

Results: 62,6% of the older people from the sample were female, 58% were married, 66,7% had primary school, 44,7% were hypertensive. It was found that the consumption of macro nutrients for the older people was adequate. For micronutrients, it was found that vitamin D and E, calcium and copper presented the most inadequate intake.

Conclusions: the NCI method was efficient to estimate the prevalence of inadequate intake and it is very important to establish policies in order to clarify the importance consumption of these nutrients for this age group.

Key words: older people, nutrients, inadequacy, prevalence, intake.

PO521**CLINICAL USEFULNESS OF HISTORICAL HEIGHT LOSS AND CURRENT HEIGHT/KNEE HEIGHT RATIO IN THE NUTRITIONAL ASSESSMENT OF THE ELDERLY**

K. Akiko¹, T. Kiyoshi², Y. Kosei³

¹Osaka Shoin Women's University, Japan

²Kyoto Women's University, Japan

³Hyogo Medical College, Sasayama Medical Center, Japan

Background and objectives: Height loss (HL), quite common in the elderly, is not merely caused by aging, and most often due to the osteoporotic vertebral fracture (VFX), which is associated with impaired ADL (activity of daily living), QOL (quality of life), and increased mortality. HL, however, has received little attention in the nutritional assessment of the elderly. Then, two indices were evaluated for their predictive usefulness and cutoff value for VFX; historical height loss (HHL) and current height (CH)/knee height (KH) ratio which we newly propose. .

Methods: 151 postmenopausal women visiting the orthopedic outpatient clinic were studied. VFX was radiographically confirmed. HHL was defined as the difference between the patients recalled maximal height and the current height. The rationale for CH/KH ratio is that KH is little affected by aging or VFX, and would be of value when HHL is unknown.

Results: HHL was significantly larger and CH/KH ratio was significantly lower in sixty-two subjects with VFX than those without it. Receiver operator characteristics curve has revealed the good predictive values of these indices for VFX, the area under the being 0.84 for HHL and 0.73 for CH/KH ratio. The sensitivity and specificity were both 79% for HHL at the cut-off value of 4.0 cm, and 91% and 47% respectively for CH/KH ratio at 3.3. Using this cutoff value for HHL, the negative predictive value (NPV) was high across a wide range of theoretically simulated fracture rate encountered in most clinical practice, whereas the positive predictive value (PPV) was low. The results were similar with CH/KH ratio.

Conclusions: Both HHL and CH/KH ratio well predicted the presence of VFX, and are likely to be of value in the nutritional assessment of the elderly.

Key words: Historical height loss, Knee height, Vertebral fracture

PO522**EXPLORATORY ASSESSMENT OF DIETARY PRACTICES WITH EMPHASIS ON FAT INTAKE TRENDS IN A RURAL SETTING IN HARYANA, INDIA**

A. Singh¹, V. Gupta², K. Lock³, S. Ghosh-Jerath²

¹All India Institute of Medical Sciences, New Delhi, India

²Indian Institute of Public Health-Delhi, PHFI, New Delhi, India

³London School of Hygiene and Tropical Medicine, UK

Background and objectives: India is witnessing a nutrition transition and there is limited data on overall consumption patterns (household and commercially prepared). Objectives of the study were to assess a) dietary intake patterns in rural population b) trends in dietary fat (including trans fat) intake and c) compare food inventory and 24-hr recall as a dietary assessment tool.

Methods: Dietary surveys were conducted in 260 households (systematic random sampling) in purposively selected villages using a 3-day inventory and 24-hour recall. Snacks from local shops were sampled for trans fat content. Serum lipid profile and anthropometry was done in a subset (130).

Results: Mean energy intake was 92% of RDA and median fat intake was 41.5 gms/day. 65% households consumed more than one type of oil with mustard oil and ghee being the most commonly used, and hydrogenated oils being consumed in 9%. 57% were consuming market prepared snacks (mostly confectionery/sweets/packaged snacks with a median daily consumption of 60, 36 and 42 gms respectively) with children being common consumers. The trans fatty acids in sampled snacks included C:16:1t, C18:1t and C:18:2tt. Oil consumption assessed through inventory had a significantly higher median than by 24-hour recall. Agreement analysis between the two tools showed an ICC coefficient of 0.348 (oil), 0.499 (cereal), 0.247 (vegetables) and 0.771 (dairy). The serum cholesterol correlated with household dietary fat intake ($p < 0.01$).

Conclusions: Dietary trends indicated high consumption of commercially prepared snacks in children with potential implications for future chronic disease development. The variation observed in ICC between food groups necessitates careful choice of dietary assessment tools and understanding inherent sources of error in different methods.

Key words: oils, snacks, dietary assessment tools This work was supported by a Wellcome Trust Capacity Strengthening Strategic Award to the Public Health Foundation of India and a consortium of UK universities.

PO523**LEPTIN INDUCES THE ACTIVATION OF PROTEIN RELATED WITH ENERGY HOMEOSTASIS IN C2C12 MUSCLE CELLS***F J Garcia^{1,2}, Y. Nozhenko², A M. Rodriguez^{1,2}, A. Palou^{1,2}*¹CIBER Fisiología de la Obesidad y Nutrición²Laboratory of Molecular Biology Nutrition and Biotechnology, University of the Balearic Islands, University of the Balearic Islands

Background and objectives: Leptin is key in energy metabolism regulation, and skeletal muscle is one its target tissues. AMP-activated protein kinase (AMPK) is a master regulator of energy fuel by sensing the intracellular AMP/ATP ratio (AMP is an allosteric regulator which promotes AMPK phosphorylation). When AMPK is activated by phosphorylation, it activates energy-producing processes such as fatty acid oxidation, while inhibiting energy-consuming processes such as lipogenesis. Among multiple targets, AMPK phosphorylates acetyl-CoA carboxylase (ACC), inhibiting it, and thus stimulating mitochondrial oxidation of fatty acids.. Additionally the serine/threoninespecific protein kinase (AKT) signaling pathway is involved in the control of glucose utilization. We aimed to study, in skeletal muscle cells C2C12, the time-course response to 50ng/ml of Leptin treatment in the expression and phosphorylation of the proteins mentioned above.

Methods: C2C12 differentiated myotubes were treated with 50ng/ml of leptin for 0, 30', 6h, 12h and 24h. Time-course changes in protein expression in non-treated cells were also monitored. Protein levels of phosphoAMPK/AMPK, phosphoACC/ACC and phosphoAKT/AKT were analyzed by Western blot.

Results: With respect to time controls, 50ng/ml leptin significantly increased the ratios phosphoAMPK/AMPK and phosphoACC/ACC at the short-term (15'), significantly decreasing afterwards (6h and 12h respectively). In contrast, the ratio phosphoAKT/AKT did not change.

Conclusions: Leptin treatment rapidly and transiently activates AMPK together with its downstream target ACC, suggesting that the energy/lipid consuming pathway activation by Leptin in muscle cells can be mediated, at least in part, by activation of AMPK.

Key words: Leptin, AMPK, ACC, AKT, C2C12 muscle cells

PO524**LINKS AMONG DIETARY HABITS OF FIRST-FORMERS AND FAMILY SOCIOECONOMIC STATUS IN LITHUANIA***U. Žaltauskė¹, A. Petrauskiene¹, E. Albavičiūtė¹*¹Institute of Health Research, Academy of Medicine, Lithuanian University of Health Sciences, Kaunas, Lithuania

Background and objectives: Dietary habits are known to be influenced by a wide range of social and economic factors. The aim was to explore and analyses the key determinants of nutritional habits of 7-8 year old children within a socioeconomic family framework.

Methods: A cross-sectional survey of a national representative sample of first-formers was performed in ten districts of Lithuania participating in the 2nd round of WHO European Childhood Obesity Surveillance Initiative – COSI. The data were collected by means of Family questionnaires, which were filled by parents of first-formers in randomly selected schools. The questionnaires were completed by 5308 parents (response rate 88.4 %). Correlation among variables was evaluated by χ^2 , binary logistic regression was used to calculate odds ratio (OR) and its 95% confidence interval (CI).

Results: Daily fresh fruits and vegetables consumption was higher among children whose parents had high education level. It was established that odds ratio to have breakfast for children of high educated mothers was 1.3 times more in comparison with children of low educated mothers. Odds ratio of children breakfast consumption was 1.3 times higher in families with average income (adjusted by parent's age and education) in comparison with low income families. It was determined that chance to eat fresh vegetables every day was 2.5 times higher among these children's whose mothers were older (40 years and more) in comparison with children of young mothers (<29 years). Risk to consume soft drinks with sugar was 1.7 times lower among first-formers whose mothers had high education in comparison with children of low education level mothers.

Conclusions: Correlation was observed between healthy eating habits of first formers and better educated parents though important factors were income and age.

Key words: first-formers, dietary habits, socioeconomic status

PO525**DIFFERENTIAL METABOLIC EFFECTS OF HEPATIC MONOUNSATURATED FATTY ACIDS***M. Strable¹, J. Ntambi^{1,2}*¹Department of Nutritional Sciences, University of Wisconsin-Madison, Madison, USA²Department of Biochemistry, University of Wisconsin-Madison, Madison, USA

Background and objectives: Stearoyl-CoA desaturase (SCD) catalyzes the de novo synthesis of monounsaturated fatty acids (MUFA) from saturated fatty acids. Past work revealed that SCD1 deficiency impairs hepatic lipogenesis and protects against the development of diet-induced adiposity and obesity. Our objectives were to determine if hepatic MUFA synthesis is sufficient to restore the impaired lipogenic program in SCD1 global knockout mice (GKO) and to determine if the major MUFA products of the SCD1-catalyzed reaction exert differential metabolic effects.

Methods: To address our objectives, we produced liver-specific transgenic mice expressing either human SCD5, which preferentially synthesizes oleate (18:1n-9), or mouse SCD3, which preferentially synthesizes palmitoleate (16:1n-7), and introduced these transgenes into SCD1 GKO mice. The mice were fed a lipogenic high-sucrose very-low-fat diet for 10 days.

Results: Hepatic oleate synthesis induced hepatic lipogenic gene expression more than palmitoleate did whereas palmitoleate synthesis significantly induced hepatic mitochondrial fatty acid oxidation gene expression. Additionally, oleate synthesis restored body weight and liver triglycerides to wild-type levels while palmitoleate synthesis did not significantly change these phenotypes. Hepatic oleate synthesis also increased plasma glucose levels to a greater extent than did hepatic palmitoleate synthesis.

Conclusions: Overall, these results suggest that endogenously synthesized hepatic MUFA are involved in the regulation of de novo lipogenesis, fatty acid oxidation and gluconeogenesis and that oleate and palmitoleate exert differential effects on these pathways.

Key words: stearoyl-CoA desaturase, oleate, palmitoleate, adiposity, de novo lipogenesis. Supported by NIH

PO526**VOLUME AND PATTERNS OF PHYSICAL ACTIVITY IN RURAL CAMBODIAN CHILDREN AGED 15-MONTHS***M. Christine Ogden¹, J. Skau¹, N. Roos¹, C. Ritz¹, D. Sok², S. Brage³, H. Friis¹, D. Faurholt-Jepsen¹*¹Department of Nutrition, Exercise and Sports, University of Copenhagen, Denmark²Department of Fisheries Post-Harvest Technologies and Quality Control (DFPTQ), Fisheries Administration (FiA), Ministry of Agriculture, Forestry and Fisheries, Cambodia³MRC Epidemiology Unit, Institute of Metabolic Science, Box 285, Addenbrooke's Hospital, Hills Road, Cambridge, CB2 0QQ

Objective: Physical activity among toddlers residing in low-income countries remains relatively unexplored. The main purpose of this study is to contribute to fill out a knowledge gap regarding the prevalence and patterns in Cambodian toddlers' physical activity.

Methods: As part of a nutrition intervention study, 416 toddlers aged 13-17 months wore accelerometers GT3X+ Actigraph accelerometers for six consecutive days. Vertical activity counts for each 2s epoch were utilized to generate collapsed and diurnal activity. Total activity was expressed as mean counts per minute (cpm) and validated cutpoints of <100cpm and >1680cpm were applied to classify sedentary activity (SED) and moderate-to-vigorous physical activity (MVPA), respectively. Gender discrepancies in collapsed activity were analysed using multiple linear regression models. Differences in diurnal activity patterns between genders were tested using linear mixed models with subject treated as random effect. Study group, age and monitoring time were controlled for in all models (minimally adjusted). In fully adjusted models also weight-for-height z-score and acquisition of WHO gross motor milestones were fitted as covariates.

Results: Accelerometry data was retrieved from 375 children (M: n = 201) of which 25% and 11% presented chronic and acute malnutrition, respectively. Children spent the majority of time sedentary (78.6%, SD: 3.5) and demonstrated low levels of total activity (318.4, SD: 88.7) and MVPA (6.7%, SD: 2.0). Over the whole monitoring period (fully adjusted), girls were 1.4% (95% CI: -2.3; -0.5) more sedentary than boys. In turn, diurnal activity patterns revealed increased sedentary behaviour (2-3%, p<0.01) and lower levels of MVPA (-1%, p<0.05) among boys between 8:00-10:00PM.

Conclusion: Both genders displayed a low-active-high-sedentary profile. Longitudinal monitoring of physical activity levels and changes in activity patterns from the onset of early childhood should be prioritized. However, early prevention of

physical inactivity may be more effective during gender-specific time points.

Keywords: Sedentary Behaviour, MVPA, Accelerometer, Food-insecure, Early Childhood

PO527

FOOD CONSUMPTION AND MACRONUTRIENT INTAKE IN RELATION TO SERUM BRANCHED-CHAIN AND AROMATIC AMINO ACIDS IN YOUNG ADULTS

V. Mikkilä¹, P. Würtz², R. Freese¹, M. Fogelholm¹, P. Soinen^{3,4}, A. J. Kangas³, J. Raiko⁵, S. Männistö⁶, M. Ala-Korpela^{3,4,7}, O. Raitakari⁵

¹Department of Food and Environmental Sciences, University of Helsinki, Helsinki, Finland

²Institute for Molecular Medicine, University of Helsinki, Helsinki, Finland

³Computational Medicine Institute of Health Sciences, University of Oulu, Oulu, Finland

⁴NMR Metabolomics Laboratory School of Pharmacy, University of Eastern Finland, Kuopio, Finland

⁵Research Centre of Applied and Preventive Cardiovascular Medicine, University of Turku, Turku, Finland

⁶Department of Chronic Disease Prevention, National Institute for Health and Welfare, Helsinki, Finland

⁷School of Social and Community Medicine, University of Bristol, Bristol, UK

Background and objectives: Serum branched-chain (BCAA) and aromatic (AAA) amino acid levels are predictors of future risk of diabetes. The aim of this study was to identify diet-related determinants of these amino acids.

Methods: Circulating BCAA (leucine, isoleucine and valine) and AA (phenylalanine and tyrosine) were quantified by nuclear magnetic resonance spectroscopy from fasting serum samples of 1903 young men and women from the population-based Cardiovascular Risk in Young Finns Study (age 30-45 years). Food consumption and macronutrient intakes were assessed using a validated 131-item food frequency questionnaire.

Results: In linear regression models controlled for age, sex, waist circumference and total energy intake, BCAA and AAA were found to be in a significant, positive association with the consumption of meat, and in a negative association with wheat, rye and vegetables ($p < 0.01$ for all). In further analyses, we constructed substitution models for amino acid associations with macronutrient intakes by source. When replacing

carbohydrates, protein intake from foods of animal origin was positively associated with both BCAA and AAA ($p < 0.01$), and fat intake from all sources with BCAA ($p = 0.02$). In contrast, protein intake from foods of vegetable origin was in a strong, negative association with both BCAA and AAA ($p < 0.001$) in a model with an additional adjustment for vegetable consumption. In more detailed calculations on dietary intake among this cohort, the main sources of vegetable protein were cereal, potatoes and rice. Animal and vegetable protein intakes have the strongest associations with the circulating amino acid levels, but to opposite directions.

Conclusions: Vegetable protein has earlier been associated with a lower risk of diabetes, possibly due to its relatively higher amount of non-essential amino acids leading to differences in insulin/glucagon activity, but the effective mechanisms still remain elusive. Diets rich in vegetable protein may also indicate generally distinctive dietary and lifestyle patterns.

Key words: amino acids, food consumption, protein

PO528

SECULAR GROWTH OF CHILDREN IN INDONESIA

S. Sandjaja¹

¹Center For Applied Health Technology and Clinical Epidemiology, Bogor, Indonesia

Background and objectives: Indonesia has experienced socio-economic growth during several decades of development. In other industrialized countries, improvement of living conditions, health status, dietary consumption, there is secular trend of linear growth to its potential. This presentation aimed to provide evidence of secular growth on Indonesian children overtime.

Methods: The study reviewed scientific articles or studies in former Netherland Indies and Indonesia from 1942 to 2010, with large sample, covered most areas of Indonesia, sound scientific methodology, age 5 year old above. Three studies by Gorter in 1942 (> 30,000 children), Yayah in 1984 (10,000 children) and secondary data of anthropometry of RKD (Riset Kesehatan Dasar, Baseline Health Research) conducted nationwide in 2010 (> 90,000 children). This presentation use two older articles and analyze data of RKD 2010.

Results: Compared to WHO child growth standard, height of Indonesian children is shorter 6.0-13.8 Cm. There is 0.3-3.5 Cm increase of height over 70 years since 1942. Child height in RKD 2010 varied according to residence and socio-economic status. Children in Jakarta were taller 1.6-4.2 Cm compared to the rest of the country. Socio-economic status, is also associated with linear growth, that children of highest socio-economic status (quintile-1) is the tallest, and quintile-5 is the shortest. The difference of height is between 1.6-4.2 Cm.

Conclusions: Height of Indonesian children 5-19 year old in 2010 is lower than WHO Standard, an increase of linear growth compared to that in 1942. RKD 2010 showed that height of children differ by place and socio-economic status.

Key words: secular trend, height, Indonesian children

PO529

ASSOCIATION OF POSTNATAL CATCH-UP GROWTH WITH BODY COMPOSITION INDICES OF CHILDREN AT 2 YEARS OF AGE: A PROSPECTIVE COHORT STUDY

G J M. Nanayakkara¹, K D R R. Silva¹

¹Department of Applied Nutrition, Faculty of Livestock, Fisheries & Nutrition, Wayamba University of Sri Lanka, Sri Lanka

Background and objectives: Small size at birth followed by postnatal catch-up growth relates with greater risk of childhood obesity and adulthood chronic diseases. Aim: To determine the factors associated with postnatal catch-up growth and the association of latter with the body composition indices of children at 2 years of age.

Methods: 128 term infants were recruited from a Public Health Unit in Sri Lanka and followed up from 4 mo to 24 mo of age. Birth characteristics were recorded. Growth and body composition were measured longitudinally. Body composition was estimated using skinfold thickness (SFT). Subjects were divided into three groups; catch-up growth, catch-down growth and no change in growth based on change in weight-for-age Z score (WAZ) between birth and 2 years.

Results: Children who showed catch-up growth (gain in WAZ >0.67) had significantly ($P < 0.05$) lower birth-weight (lighter) and birth length (shorter) compared to catch-down growth (decrease in WAZ >0.67) group. Catch-up growth group showed significantly higher BMI-for age Z score (heavier), sum of SFT, tricep and subscapular (proxy for central fat distribution) SFT, fat mass, fat mass index (fatter) and fat free mass compared to catch-down growth group at 2 y. Infants who showed catch-up growth were more likely to have significantly higher BMI-for age Z scores (OR=7.00) and fat free mass (OR= 4.73) compared to no change in growth group at 2 years. Infants who showed catch-down growth were significantly less likely to have higher fat mass (OR= 0.32), fat mass index (OR= 0.27) and percentage body fat (OR=0.41) compared to no change in growth group at 2 years.

Conclusions: The children who showed catch-up growth were lighter and shorter at birth and they are heavier, fatter and had greater central fat distribution at the age of 2 y.

Key words: postnatal, catch-up growth, low birth-weight, body composition

PO530

COMPROMISED GUT PERMEABILITY, INFLAMMATION, AND STUNTING AMONG 24 MONTH OLD CHILDREN OF RURAL BANGLADESH

K. Schulze¹, S. Mehra¹, R. Merrill¹, S. Shaikh², H. Ali², AA. Shamim², L. Wu¹, P. Christian¹, K P. West, Jr.¹

¹Center For Human Nutrition, Johns Hopkins Bloomberg School of Public Health, Bangladesh

²The JiVitA Project, Johns Hopkins University in Bangladesh, Gaibandha, Bangladesh

Background and objectives: Stunting (height-for-age Z-score, HAZ, <-2) remains a public health problem among children of developing countries. Nutrition interventions alone have had modest effects on stunting, perhaps due to insufficient attention to compromised gut integrity and inflammation on growth. We examined these factors in 24 mo old children, followed since birth, in rural Bangladesh.

Methods: At 24 mo, data on gut integrity and inflammation were assessed in n=177 children, of whom growth from 12 to 24 mo was available in n=140, reported here. Gut permeability (urinary lactulose:mannitol, L:M) was determined, and serum was assessed for indicators of gut (endotoxin antibodies) and systemic infection (total immunoglobulin G, IgG), inflammation (c-reactive protein, CRP) and a growth factor (insulin-like growth factor-1, IGF-1). Biochemical indicators were log-transformed to normalize distributions for correlation analysis.

Results: Children gained 3.7-17.4 cm from the 12 to 24 mo visit, but HAZ differed by -0.15 ± 0.73 and declined in 58.6% of children. At 12 and 24 mo 42.9% and 51.4% of children were stunted, respectively. Change in HAZ from 12 to 24 mo was inversely associated with 12 mo HAZ ($r = -0.43$, $p < 0.0001$), positively associated with IGF-1 ($r = 0.19$, $p = 0.03$), and inversely associated with compromised gut integrity by L:M ($r = -0.26$, $p = 0.03$, $n = 72$). Elevated L:M occurred in 74.0% of children and 21.9% had elevated CRP. CRP and IGF-1 were inversely related ($r = -0.30$, $p = 0.0005$), and total IgG was associated with CRP ($r = 0.18$, $p = 0.04$) and endotoxin antibodies ($r = 0.17$, $p = 0.04$).

Conclusions: Compromised growth and gut integrity were common among rural Bangladeshi children. Growth from 12 to 24 mo may be mediated by IGF-1, which declined with concurrent inflammation, itself associated with evidence of infectious episodes. Investigation of factors related to stunting in these children is ongoing.

Key words: stunting, gut permeability, infection, inflammation, Bangladesh

PO531**FOOD SAFETY KNOWLEDGE, ATTITUDES, PRACTICES OF TRADITIONAL FISH HANDLERS AND CONSUMERS IN GHANA**

N. Amuna¹, P. Amuna², A M. Rahman², L. Nicolaidis¹, A. Westby¹

¹Natural Resources Institute, University of Greenwich, Greenwich, UK

²Medway School of Science, University of Greenwich, Greenwich, UK

Background and objectives: Many communities in Ghana depend heavily on fish as an important protein source. Fish industry plays a vital role in livelihoods security and export diversification. However, availability of information regarding food safety awareness, attitudes and practices among traditional fishing communities and consumers. We sought to investigate microbial hazards in fish from the Ghana market including practitioner and consumer behaviour relating to safety.

Methods: We recruited 109 consumers and 115 fish handlers across different districts along the Accra coastal belt using a cluster sampling procedure and designed a survey instrument to investigate food safety practices, attitudes, and knowledge of traditional fish handlers and consumers of traditionally processed fish products.

Results: A higher percentage of consumers (78.9%) compared with food handlers (61.7%) identified microorganisms as the main risk to food safety ($p < 0.001$). However, a slightly higher percentage of food handlers (60.0%) than consumers (56.0%) identified pesticides as the main risk to food safety ($p = 0.0004$). Poor safety practices were found with 45.0% of consumers and 64.3% of food handlers only washing their cutting board with water after trimming fish and over 70% of respondents lacking knowledge of differences between cleaning and sanitising. The majority of respondents (>92%; $p < 0.05$) were knowledgeable of good personal hygiene requirements but this was very often not translated into improved food safety practice. A significant minority of consumers (22.2%) and food handlers (23.5%) had the misguided perception that rotating food to use the oldest food first was bad food storage practice ($p < 0.05$). The majority of respondents displayed poor knowledge of HACCP.

Conclusions: The inability to translate basic food safety and hygiene knowledge into practice could prove a major barrier to effective food safety management in the traditional fish sector in Ghana. These findings provide an opportunity to review current training provision and practices.

Key words: survey, food safety, common practice

PO532**BREAKFAST SKIPPING AND FIRST BORN STATUS ARE ASSOCIATED WITH OBESITY AMONG ADOLESCENT SCHOOL GIRLS IN SRI LANKA**

T. Roopasingam¹, K M. Rathnayake¹, V P. Wickramasinghe²

¹Department of Applied Nutrition, Faculty of Livestock, Fisheries and Nutrition, Wayamba University of Sri Lanka, Makandura (60170), Sri Lanka

²Department of Paediatrics, Faculty of Medicine, University of Colombo, Colombo, Sri Lanka

Background and objectives: Global prevalence of adolescent obesity is rising at an alarming rate. This study aimed to identify the nutritional and behavioral risk factors associated with obesity among adolescent girls.

Methods: In this case-control study, a total number of 200 adolescent girls (age and ethnicity matched, 100 cases- BMI for age Z score $\geq +2SD$ and 100 controls- BMI for age Z score between $-2SD$ to $+1SD$) aged 14 to 18 were classified according to WHO growth standards. An interviewer administered questionnaire was used to assess socioeconomic status, dietary pattern, birth and pubertal characteristics (age of first menarche, menstrual pattern). A 3-day diet diary and long version of international physical activity questionnaire were used to assess total energy intake and expenditure of energy from physical activity, respectively. Independent sample-t-test and binary logistic regression analyses were used to compare the mean values and examine the significant predictors associated with obesity, respectively.

Results: There was a significant difference in the BMI (31.3, 20.2kgm⁻², p value=0.0001), waist circumference (90.8, 68.2 cm, $p=0.0001$), mean energy intake (2235.4, 1921.7kcal, $p=0.0001$) and total energy expenditure from physical activity (1844.3, 894.5 MET-min/ week, $p=0.0001$) among cases and controls, respectively. The strongest association with obesity was observed for high income (odds ratio- 2.97, 95% CI, 1.10-7.98, p value-0.031), first born status (2.57, 1.17-5.66, 0.019), skipping breakfast (4.19, 1.87-9.36, 0.000), > 2 hours of TV viewing/day (2.67, 1.20-5.95, 0.017), irregular menstruation (3.60, 1.08-12.02, 0.037), both parental obesity (4.10, 1.55-10.85, 0.004) and high energy intake (6.03, 2.63-13.82, 0.000).

Conclusions: High income, first born status, breakfast skipping, >2 hours of TV watching, irregular menstruation, parental obesity and total energy intake are major potential determinants of obesity among adolescent girls. There is an urgent need to implement effective public health interventions to reverse this trend.

Key Words: Adolescents, obesity, risk factors

PO533**THE INFLUENCE OF GENETICS ON MATERNAL WEIGHT GAIN DURING PREGNANCY**

S. Altmäe¹, T. Anjos¹, F.J. Torres-Espínola¹, M. Marti², L. García-Valdés¹, M C. Martínez-Zaldívar¹, P. Brandi¹, R. Moreno-Torres¹, J C. Alvarez³, C. Entrala³, J. Florido², C. Campoy^{1,4}

¹EURISTIKOS Excellence Centre for Paediatric Research, University of Granada, Granada, Spain

²Department of Obstetrics and Gynecology, University of Granada, Granada, Spain

³Department of Legal Medicine, University of Granada, Granada, Spain

⁴Department of Paediatrics, School of Medicine, University of Granada, Granada, Spain

Background and objectives: The total amount of weight gain during pregnancy is determined by many factors such as psychological, behavioural, family, social, cultural, and environmental factors. Additionally, there is a genetic component also on body weight and propensity to gain weight. However, there is still no clear evidence of the role of maternal genetics in pregnancy weight gain. In this study we aim to analyse if maternal genetic variation in a set of genes influences mother's weight change during pregnancy.

Methods: A total of 128 women from the PREOBE Study* were included in the study taking into account: a) weight gain from pre-pregnancy time to pregnancy week 34 (mean weight gain was 9.87±5.81 kg), b) age of the woman when entering the study (mean age 31.20±4.2 years), c) maternal BMI before pregnancy (mean BMI 26.27±4.96) and d) development of gestational diabetes. The following genotypes were analysed: ADRB3 T/C rs4994, GNB3 T/C rs5443, LEP19 G/A rs2167270, LEP2548 G/A rs7799039, LEPR G/A rs1137101, MC4R134 G/A rs12970134, MC4R313 T/C rs17782313, MC4R616 G/A rs2229616, MC4R633 G/A rs17700633, PPAR C/G rs1801282, UCP2 C/T rs659366. Statistical analysis was performed using the SPSS 20.0 version. Hierarchical step-wise regression analysis was applied. In the first block the cofounders were forced to be entered into the model, and in the second block we entered all the polymorphisms studied using step-wise method, so that the model will retain only those, which would significantly predict the weight change.

Results: Out of the 11 studied polymorphisms only LEPR (Leptin receptor gene) G/A predicted the weight change (β coefficient 1.4, $p=0.023$) in the PREOBE Study population. This means that with one risk allele (A) the increment in the weight gain was 1.4 kg during pregnancy (from pre-pregnancy up to week 34 pregnancy), with confidence interval (C.I.) 0.2-2.7.

Conclusions: These results suggest that the LEPR G/A polymorphism influences weight change during pregnancy in our study sample, contributing to a higher maternal weight gain.

Further investigations including larger populations are needed in order to fully access the influence of this and others genetic polymorphisms. Acknowledgement: *Supported by the Andalusian Government. Economy, Science and Innovation Ministry (PREOBE Excellence Project Ref. P06-CTS-02341).

Key words: genetics, gene polymorphisms, maternal weight, obesity,

PO534**IMPACT OF MATERNAL BODY MASS INDEX AND GESTATIONAL DIABETES ON NEONATAL OUTCOME**

I. Rusanova¹, A. Jerez-Calero², I. Ibañez-Casas^{1,3}, L. García-Valdés¹, J C. López-Robles¹, M J. Piqueras¹, R. Moreno-Torres¹, M C. Padilla⁴, C. Campoy^{1,2} and the PREOBE Research Group.

¹EURISTIKOS Excellence Centre for Paediatric Research, Granada, Spain

²Department of Paediatrics. University of Granada, Spain

³CIBERSAM University of Granada

⁴Department of Obstetrics and Gynecology, Clinical University Hospital San Cecilio, University of Granada, Spain

Background and objectives: High pre-pregnancy BMI and gestational diabetes (GD) are important risk factors to delivery neonates large for gestational age (LGA). Our objective is to analyze whether mother's body mass index and GD, depending on their metabolic control have an influence on the risk for LGA infants.

Methods: A total of 195 mother-baby pairs participants in the PREOBE project were studied. The pregnant women were classified depending on pre-gestational BMI: 77 were healthy normo-weight pregnant women (BMI<25 kg/m²), 56 overweight (OW) (25≤BMI<30 kg/m²) and 62 obese (OB) (BMI≥30 kg/m²). 28.2% of them developed GD. Pregnant women were assessed at 24, 34 and at delivery. HbA1c % was used to follow the metabolic control in GD, and determined by HPLC. Offspring were classified into small, normal and LGA for gestational age at birth, following Lubchenko classification.

Results: Increased risk to be born LGA where demonstrated in the offspring born to OW and OB mothers (OR=2.393, $P=0.033$), independently if they developed GD or not. GD did not show any influence on this risk (OR=1.118, $p=0.793$). All GD mothers were treated and supervised by Endocrinologists; the HbA1c were within normal range, but significantly higher than in pregnant women without GD (NoGD) in all time points (week 24: GD=5.38±0.25 vs NoGD=4.43±0.04; week 34: GD=5.02±0.09 vs NoGD=4.67±0.04; week 40: GD=5.16±0.10

vs NoGD=4.86±0.05) (all P's < 0.05). Conclusions: Our results show that high mother's BMI greatly influences the risk for LGA infants. The potential risk of macrosomia in babies born to mothers with GD might be narrowed by a good metabolic control during pregnancy and preventing overweight and obesity during pregnancy.

Acknowledgement: *Supported by the Andalusian Government. Economy, Science and Innovation Ministry (PREOBE Excellence Project Ref. P06-CTS-0234).

Key words: Obese pregnant women, gestational diabetes, large for gestational age, metabolic control.

WEB DATABASE OF NUTRITIONAL COMPOSITION AND ECONOMIC COST OF FISH AND SEAFOOD AS A NEW TOOL TO PROMOTE CONSUMPTION IN SPAIN

E Ruiz¹, T. Valero¹, S. del Pozo¹, J M. Ávila¹, G. Varela-Moreiras^{1,2}

¹Fundación Española de la Nutrición (FEN), Madrid, Spain

²Universidad CEU San Pablo, Madrid, Spain

Background and objectives: Nowadays, the importance and interest in healthy eating and its relation to fish & seafood consumption is well established. However, tendencies for some vulnerable groups of population (e.g. children and adolescents) show a marked decrease for this food group. Therefore, it seems critical to promote new tools in order to stimulate its consumption by using new communication technologies (e.g. interactive and updated web). Therefore, since 2003, the Spanish Nutrition Foundation (FEN) has been collaborating with the Spanish Ministry of Agriculture, Food and Environment (MAGRAMA), through contracts and agreements, in order to carry out promotion of fish and seafood consumption. The aim of the present study was to design, as part of the campaign of year 2012, a Web Database of nutritional composition and economic cost of fish and seafood.

Methods: The database contains 75 fish species (52-fish, 17-seafood and 6-canned fish and seafood). Data have been compiled from different food composition tables (Moreiras et al.2011, Mataix et al.1998, etc.). Food servings and Recommended Dietary Allowances (RDA) for the Spanish population have been obtained from Moreiras et al.2011.

Results: Web Database was divided into four sections: NUTRITION INFORMATION (nutritional composition of fish and seafood selected per 100g o portion), NUTRITIONAL CALCULATOR (determined by age, sex and physical activity, the contribution of selected fish to individual recommended intakes of energy and nutrients), COST (calculate the price in euros per unit of energy or nutrient provided by the selected

fish) and NUTRITIONAL COMPOSITION TABLES (to compare the nutritional values of different fish species). This Web database is targeted to consumers and professionals and may be accessed at: http://www.fen.org.es/magrama/calculadornutricional/index_App.html. The number of visits in 2012 was 7,535.

Conclusions: Information and ICT technologies as tools to disseminate nutrition composition could support nutrition education to consumers and professionals.

Key words: database, web, fish, nutritional-composition.

PO536

WEIGHT LOSS MAY BE ACCELERATED THROUGH A CHRONONUTRITION-BASED PROTEIN DIET

R. Bravo¹, L. Franco¹, J. Cubero², C. Galán¹, M. Mesa¹, C. Jarne³, A B. Rodríguez¹, C. Barriga¹

¹Chrononutrition laboratory, Faculty of Science, Department of Physiology, University of Extremadura, Badajoz, Spain

²Health Education Laboratory, Science Education Area, University of Extremadura, Spain

³YSONUT Laboratories

Background and objectives: Chrononutrition is the field of Chronobiology that establishes the principle of consuming foodstuffs at times of the day when they are more useful for health, improving, therefore, biorhythms and physical performance. Both tryptophan and tyrosine amino acids have been postulated as chrononutrition tools because of their metabolites functions in the body. Our aim was to analyze if a Chrononutrition-based diet designed to improve biological rhythms in obese rats can improve weight loss with respect to a Chrononutrition non-based diet.

Methods: Twenty-four rats participated in this assay for six weeks. Eighteen obese rats were separated in three groups: first group (diet A) was fed with a control diet for rats (N1=6); second group (diet B) was fed with a human protein diet adapted for rats (N2=6); third group (diet C) was fed with a human protein diet adapted for rats and supplemented with 125 mg tryptophan and 375 mg tyrosine once lights turned off (N3=6). A fourth non-obese control group (N4=6) was established in this assay.

Results: At the end of the sixth week the diet C was the only group who showed a significant correlation in weight loss. Diet B showed a decrease in body weight although diet C weights were more similar with respect to the non-obese control group.

Conclusions: Chrononutrition may be used to improve weight loss in rats, therefore, we propose its use for obese humans.

Key words: Chrononutrition, obesity, protein diet, weight loss

PO537**SERUM MARKERS OF INFLAMMATION AND OXIDATIVE STRESS IN HEALTHY INDIVIDUALS AND PATIENTS WITH METABOLIC SYNDROME***K. Araujo¹, D. Carías¹*¹Laboratorio de Nutrición, Universidad Simón Bolívar, Caracas, Venezuela

Background and objectives: Metabolic syndrome (MS) is a combination of metabolic disturbances accompanied by oxidative stress and inflammation. The aim of this study was to evaluate the prevalence of metabolic syndrome in an adult population and to establish its relationship with serum markers of inflammation and oxidative stress.

Methods: A sample of 139 adults of 21-60 years of age (76 women and 63 men), was studied. Blood pressure, serum glucose, serum lipids, basal insulin, uric acid (UA), oxidized LDL, IL-6, vitamins A and E, total antioxidant capacity of plasma (FRAP) and C-reactive protein (CRP), were measured, and the insulin resistance (IR) was calculated by HOMA (homeostasis model assessment). Weight, height and waist circumference (WC), were measured and the body mass index (BMI) was calculated. MS was diagnosed according to the criteria of the National Cholesterol Education Program (NCEP-ATP III).

Results: The prevalence of MS was 35% (men 40%, women 30%), being higher in the older age groups. Subjects with MS showed higher values in anthropometric variables, clinical and biochemical, compared with healthy individuals, with the exception of HDL-C, which was lower. Low HDL-C, hypertriglyceridemia, and increasing WC, were the risk factors most prevalent. Adults with MS showed a higher prevalence of low values of the ratio Vitamin E/triglycerides, higher values of AU and oxidized LDL, as well as PCR, compared to healthy subjects.

Conclusions: A high prevalence of MS was found and this syndrome was associated with a lower antioxidant protection and an increase in markers of inflammation and oxidation, which can greatly increase the cardiovascular risk.

Key words: Metabolic syndrome, oxidative stress, inflammation, obesity, insulin resistance.

PO538**DETERMINANTS ASSOCIATED WITH REGULAR WEIGHTING OF UNDER FIVE CHILDREN IN POSYANDU IN KELAPA GADING SUBDISTRICT, JAKARTA, INDONESIA, IN 2011***H. Umniyati¹*¹YARSI University, Jakarta, Indonesia

Background and objectives: A Posyandu is an integrated health post as an extension unit of Puskesmas (community health center) providing several under-five child health programs, especially regularity of weighting every month, basic immunization and vitamin A, additional food provision. Monitoring of child growth in Posyandu is a very important activity in order to know early children growth faltering. Data of National Basic Health Research (RISKESDAS) 2010 the percentage of regularity weighing was only 49.4%.

Methods: A cross-sectional study was conducted to interview 96 mothers of under-five children randomly selected from 7 neighborhood blocks in sub-district of Kelapa Gading, Jakarta. The multivariable analysis were done to analyze strength of association (using odds ratios) between several potential determinants and the regularity of mothers to weight their children in Posyandu. Weighting 4 times or more within the past 6 months, was considered to be regular.

Results: The proportion of mothers weighting their children regularly in Posyandu in sub district Kelapa Gading was 47.9%. The older the mothers the lesser the probability to weight regularly their children. Mothers who know that Posyandu can provide Vitamin A and basic immunization freely for their children were 2.7 times and 4.3 times respectively more likely to weight their children regularly, as compared to mothers who do not know. Closer distance between mother's house and Posyandu gave the mothers higher probability to weight their children regularly, as much as 18.5 times, as compared to farther distance. The likelihood of working mothers to weight their children regularly, were 18.3 times, as compared to the likelihood of house wife mothers.

Conclusions: Mother's age, knowledge about the programs of Posyandu, distance between mother's house and Posyandu, and mother's occupation status were important determinants of likelihood to weight their children regularly in the Posyandu.

Key words: Posyandu, regularity of weighing, under-five children

PO539**ENERGY AND NUTRIENT INTAKES FROM COMPLEMENTARY FOODS AND CAREGIVER RESPONSIVE FEEDING PRACTICES AMONG 405 BANGLADESHI INFANTS AND YOUNG CHILDREN <24M***G. Guldán¹, A. Vijayakumar¹, S I. Azim¹, A. Begum¹*¹Asian University For Women, Bangladesh

Background and objectives: Bangladesh's under-five stunting prevalence, at 43%, is among the highest 24 country rates globally, while wasting in 2011 was 16%, and underweight 36%. Although exclusive breastfeeding is increasing, complementary feeding is more problematic, moreso for those up to 12m than those aged 12-23m. To design an intervention to improve complementary feeding and growth, detailed diets and feeding practices must be understood. However to date, little such information is available. This research aimed to explore infant and young child feeding (IYCF) among 405 (52% males; 73% rural) infants and young children up to 24m from 6 locations.

Methods: Caregivers were interviewed cross sectionally about IYCF practices and responsive feeding. Dietary intakes from 24h-recall and food frequency interviews were analyzed using Nutritionist Pro dietary analysis software version 5.0.0, while statistical analyses were performed using the PASW/SPSS package version 19.0 (SPSS Inc., Chicago, IL USA).

Results: Fully 66%, 74% and 86% of infants and young children aged 6-8.99m (n=74), 9-11.99m (n=46), and 12-23.99m (n=142), respectively, did not receive recommended energy amounts for their age group. Most, 82%, 92%, 86% and 85% of those aged 6-23.99m (n=262) also did not consume, respectively, adequate iron, zinc, calcium or vitamin A from their complementary foods. Food frequency results additionally showed that while >5% of infants <6m were fed rice, potatoes, orange/yellow fruits, other fruits, milk products, meat or poultry, fish and sugar, 32-61% of young children 12-23.99m were not fed these foods daily. Only 39-55% of caregivers of infants aged 8-23.99m responded positively to each of the four responsive feeding questions.

Conclusions: Extremely suboptimal energy and nutrient intakes and suboptimal responsive feeding practices were found. This information can be used to help inform future complementary feeding interventions for this high-risk group.

Key words: complementary feeding, infant and young child feeding (IYCF), Bangladesh

PO540**HEPCIDIN, INFLAMMATION AND IRON STATUS IN PREGNANT WOMEN IN KAMPALA, UGANDA***R. Baingana¹, H. Tjalsma², J. Enyaru¹, L. Davidsson³, D. Swinkels²*¹Department of Biochemistry, College of Natural Sciences, Makerere University, Uganda²Department of Laboratory Medicine, Laboratory of Genetic Endocrine and Metabolic Diseases, Radboud University Nijmegen Medical Center³Nutritional and Health-related Environmental Studies Section, Division of Human Health, IAEA, Vienna, Austria

Background and objectives: The production of hepcidin, a key iron-regulatory protein, is up-regulated when iron is abundant and in the presence of infections and inflammation. It is down-regulated by iron deficiency and erythropoietic activity. Its role in pregnancy has not been characterized in settings with a high burden of infection. Objective: To describe the relationship between hepcidin, iron status indicators and indicators of infection/inflammation in pregnant women in Kampala, Uganda.

Methods: We examined the relationships between serum hepcidin, hemoglobin, ferritin, serum soluble transferrin receptor (sTfR), AGP and CRP in 151 HIV-negative first trimester paucigravidae recruited during antenatal visits in Kampala, Uganda. Serum hepcidin was measured by a combination of weak cation exchange chromatography and time-of-flight mass spectrometry.

Results: Mean±standard deviation (SD) hemoglobin was 11.8±1.7 g/dL. Anemia (hemoglobin <11 g/dL) was present in 29.1% (95% CI 21.9-36.3) of the mothers. Mean ±SD ferritin was 61.8±66.8 µg/L, while the median was 38.3 µg/L (inter-quartile range (IQR) 19.5-75.5 µg/L). Mean±SD sTfR was 5.46±2.0 µg/ml; median was 5.0 µg/ml (IQR 4.2-6.4 µg/ml). Using ferritin<12 µg/L and sTfR >8.3 µg/mL respectively as cutoffs, 10% (95% CI 5.1-14.7) and 6.6% (95% CI 3.6-11.0) of the women were iron deficient. Mean±SD CRP was 22.1±25.2 mg/L; median was 15.5 mg/L (IQR 11.7-20.8 mg/L). Some 58.9% (95% CI 51.1-66.8) of the women had CRP>5mg/L. Median hepcidin was 1.95 nmol/L (IQR 1.30-4.53 nmol/L) for the women with hepcidin>0.5 nmol/L (N=62). Log hepcidin was significantly correlated with log ferritin (r= 0.578; p=0.000), but not with log hemoglobin, log sTfR, log AGP, or log CRP. Log ferritin was significantly correlated with CRP (r=0.264; p=0.000) and AGP (r=0.299; p=0.000).

Conclusions: The findings suggest a disconnect between hepcidin and inflammation in pregnancy. Further examination of this relationship in pregnancy in the context of a high burden of infection is warranted.

Key words: hepcidin; inflammation; iron; pregnancy; Uganda

PO541**A NEW MEASUREMENT OF MALNUTRITION***J. Xu*¹¹Michigan Dept of Community Health (MDCH), USA

Background and objectives: A. Malnutrition means “bad” for both over- and under- nutrition. It can result from a lack of macronutrients and/or micronutrients, or both. My consideration is: What is ‘bad’? Which and How much is in lack? B. We need a new measurement in Malnutrition. We already have anthropometric, such as ‘%WL’, ‘BMI’, ‘MAMC’ by taking body measures for diagnosis, when problem occurred. Can we predict malnutrition, preventively? The work of “Overall Nutrition Quality Index (ONQI)” by Dr. Katz DL et al of Yale University, encouraged the author. The ONQI article considered to cover 40,000 - 50,000 or more of food supply in US and the world, by giving each food a score. A fact is: the nutrients of food are not independent, especially when calories is included. Thus, classical statistics, such as a linear regression can not work, because the condition of “(mutually) Independent, Identical Distribution (iid)” lost. This model started in United Kingdom around 1950, later was named as “Spatial Autoregression Models (SAM).” Its calculation is huge, causing difficulty. Decades later, advanced computer became available, but still could not help resolving the problem for reason unknown. C. The author started SAM in 1994, fortunately soon found a resolution with precision, with dimension high. His work continued, till 1998, the author made the following two presentation. 1. “The Construction of Parameter Estimation in Spatial Autoregression Models,” presented at the “Sunbelt XVIII and Fifth European International Social Network Conference” in Barcelona, Spain, May 1998. 2. “The Spatial Autoregression Models and Its Application in Social Sciences,” presented at the “International Sociology Association XIV World Congress” in Montreal, Canada, July 1998. The author’s dissertation is entitled “Spatial Autoregression Models: Its Solutions of Parameter Estimation and Application”, Michigan State University, December 1998.

PO542**ARE NUTRITION LABELS ON PACKED FOODS USEFUL TOOLS IN REDUCING SODIUM INTAKE?***Z. Buyuktuncer-Demirel*¹, *H T. Besler*¹¹Department of Nutrition and Dietetics, Faculty of Health Sciences, Hacettepe University, Ankara, Turkey

Background and objectives: Nutrition labelling on food products has emerged as a prominent policy tool for promoting healthy eating. Providing information about salt or so-

dium content of packaged foods on their labels might help consumers to reduce their dietary sodium intake. This study aimed to scrutinize the nutrition labelling practice in terms of provided information about sodium or salt content of packaged foods sold in Turkish markets.

Methods: Data were obtained from food labels of 1620 packaged foods collected from the most branched three supermarkets in Turkey. Labels of food products included in the study were categorized into eleven groups: dairy products; meat, poultry, seafood and their products; fats and oils; pulses and pastas; instant soups; flours and bakery products; canned foods, pickles and pastes; snacks, light and diabetic products; breakfast products; salts, spices, dressings, dips and bouillons; ready-to-eat meals. A checklist was used to record the existing information about salt and sodium content of the products, and health/nutrition claims or logos related to link between dietary salt/sodium and health.

Results: Nutrition label was obtained on the 75.1% of packed foods. The information about salt and sodium content was provided respectively on 2% and 24.4% of the labels. The salt content (in grams) was mostly provided on the labels of frozen products (meat, poultry and seafood) and spreads, whereas the sodium content (in mg) was mostly given on the labels of snacks. The nutrition or health claim related to salt or sodium content of the product was obtained only on the 2.5% of food labels. No food label with a logo related to salt/sodium content was obtained.

Conclusions: The information about salt or sodium content of products, provided on the food labels, should be improved for promoting food labels as efficient nutrition education tools in reducing sodium intake.

Key words: nutrition label, salt, sodium

PO543**ASSOCIATION OF CALCIUM INTAKE TO BONE STRUCTURE AND STRENGTH INDEXES OF ADOLESCENT SWIMMERS***A. Gómez Bruton*^{1,2}, *A. González-Agüero*^{1,3}, *A. Gómez-Cabello*^{1,2}, *A. Matute-Llorente*^{1,2}, *C. Julian-Almárcegui*¹, *J.A. Casajus*^{1,2}, *G. Vicente-Rodríguez*^{1,2}¹GENUD Research Group, Universidad de Zaragoza, Spain²Department of Physiatry and Nursing, Universidad de Zaragoza, Spain³Department of Sport and Exercise Science, Aberystwyth University, UK

Background and objectives: It is well know that calcium (Ca) is required for normal growth and development of the skeleton and is a critical factor in the acquisition of optimal

peak bone mass. However, dual energy X-ray, which is oftenly used for assessing bone mass, does not evaluate bone structure which is also important for bone health. This research therefore aims to study the influence of Ca intake on bone structure in adolescent swimmers.

Methods: Ca intake was evaluated in a total of 40 swimmers (19 males) (14.36±1.83 y) with a Ca frequency-questionnaire. Peripheral quantitative computed tomography (pQCT) was used to evaluate volumetric bone mineral density (vBMD), cortical-thickness, and to calculate resistance to fracture load in X and Y axes, stress strain index (SSI) in X and Y axes, and polar strength strain index (SSIPOL) at the non-dominant radius and tibia. Bivariate Pearson's correlations were performed between Ca and pQCT values. For those pQCT values that showed a significant correlation with Ca, a linear regression was performed to evaluate the influence of Ca on the previously mentioned bone parameters including age, height, and subtotal-lean in the model.

Results: Independently of age, height and lean mass, Ca intake accounted for 10% of radius total and cortical vBMD and 11 and 21% of tibia total vBMD and tibia cortical-thickness respectively (all $p < 0.05$). Ca was not associated to any of the strength indexes evaluated.

Conclusions: Although Ca may partially explain vBMD for radius and tibia, this nutrient was not associated to any bone strength indexes in our sample, suggesting that Ca could influence BMD, but by itself may not be enough to achieve stronger bones. Further studies assessing other factors such as physical activity or other nutrients are needed in order to explain more relations with vBMD or bone structure.

Key words: bone, calcium, swimmers

PO544

EFFECT OF SOYBEAN OIL QUALITY FORTIFIED ON THE RETENTION OF VITAMIN A IN MOROCCO

B. Lamyae^{1,2}, C. Rachida^{1,2}, R. Mohamed³, M. Najat¹, A. Hassan¹

¹Diet and Nutrition Laboratory, Sciences School, Ibn Tofail University, Kenitra, Morocco

²Physiopathology and Nutrition laboratory, Sidi Mohamed ben Abdellah University

³Department of Chemistry and Food Technology, IAV Hassan II, Rabat

Background and objectives: vitamin A is a micronutrient which is considered essential for growth and development. Food fortification, a strategy to fight against the Vitamin A deficiency. In Morocco, soybean oil is widely consumed (32g/d/p) by all population and thus represents a suitable vehicle for fortification by vitamin A. Objective: To determine,

during storage, the effect of the quality of soybean oil on the retention of vitamin A.

Methods: Soybean oil is fortified by vitamin A palmitate, with two doses (33.3 and 66.6 IU/g). Fortified oil samples are distributed in replicate, in transparent PET bottles and stored for 6 months under different temperature conditions (ambient 42°C) and light (diffuse daylight, fluorescent light, dark). The content of vitamin A residual soybean oil is fortified Fixed-end of each month by HPLC. This analysis is accompanied by determination of peroxide value (meqO/kg) and acidity (% m/m as oleic acid) in order to determine respectively the degree oxidative and hydrolytic alteration.

Results: 1- During 6 months of storage, the fortified soybean oil undergoes oxidative essentially altered. 2 - Fluorescent light causes a remarkable increase in the peroxide from the very first month of storage (5.76 meqO/Kg). 3- temperature and diffuse light showed no specific effect on the peroxidation of soybean oil fortified (6meqO/kg). This value is lower than the regulatory limit of 10meq O /Kg. 4 - No correlation was found between the peroxide value of soybean oil fortified and the rate of degradation of vitamin A.

Conclusions: Vitamin A was stable in soybean oil under the conditions of Moroccan cooking and storage, it appears that: 1- Soybean oil fortified with vitamin A affects mainly by peroxidation. 2- Diffuse light or temperature did not have a specific effect on the degradation of vitamin A. 3- fortified oil may be traded even after 6 months of production.

Key words: oil fortification, vitamin A, soybean, degradation

PO545

DIET, NUTRITION AND ENERGY EXPENDITURE AT THE CATALAN GALLEYS S. XIV AND XV

F. Drobnic¹, V. Pons¹, J. Mirallas¹, P.A. Galilea¹

¹Sports Physiology Dept. Olympic Training Center Girsane-CAR, Spain

Background and objectives: Galleys were ships during XIV-XV century used as an everyday goods transportation and war. We aimed to evaluate the nutritional content of the diet and energy expenditure of the oarsmen, in the Mediterranean galleys of XIV and XV century.

Methods: Library documentation in relation to the customs, food, diet, navigation models of ships of the time. Dietary analysis through the Composition Tables of CESNID.

Results: The daily ration of the galley was monotonous, half cup of garbanzo bean stew, a kilo of cake (bizcuit) and about two liters of water. Good rowers received also some bacon and a liter of wine. The diet was improved and increased on the eve of battle. In high speed navigation the rower had to be provided with one liter of water per hour. Considering the oarsmen

as an adult male 19-30 years, 75kg and 1.67m, caloric ration would correspond around 3.000 Kcal energy expenditure, whereas additional work in the galley rowing would approach to 5.000 Kcal/day the needs. Prevalence of vegetable protein over animal, with a modest fat intake, a lack of calcium intake and a lack of vitamin C. During a 10-hour day and an effective working time of 7.5 hours and a regular navigation (4 knots), the galley rower would need a caloric intake of 2.663 Kcal (355 Kcal/h) developing an average oxygen uptake of 19,4 ml/k/min. During an 8-hour day and an effective working time of 6.5 hours with a simulated combat naval navigation (3-6 knots), caloric intake would be 3.338 Kcal (513 Kcal/h), oxygen uptake 23.9 ml/kg/min.

Conclusions: The work done during row doesn't require high energy expenditure except in combat situations. The nutritional content, although it may be somewhat deficient in some trace element, was well adapted to the energy requirements to all the navigation speeds.

Key words: nutrition, requirements, exercise

PO546

KNOWLEDGE AND ATTITUDES ON NUTRITION AND HEALTH: A MIXED METHODS STUDY OF IRISH ADOLESCENTS

S. Fallows¹, A. O'Sullivan¹

¹University of Chester, Cheshire, UK

Background and objectives: Male and female adolescents (aged 16-18 years) were compared on: 1. nutrition knowledge 2. attitudes on nutrition and health

Methods: There were two phases - quantitative by validated questionnaire (Parmenter & Wardle, 1999), followed by qualitative through group interviews. 110 secondary school students (59 boys: 51 girls) aged 16-18 years from two state schools in Dublin, Ireland participated phase one of this study and 12 students from the same schools were for phase two.

Results: Phase 1 showed the students to have a good nutritional knowledge, with a mean score of 52.58±10.19 out of a possible 110. There was no significant difference in nutrition knowledge scores between girls and boys (p=0.62). Girls displayed a slightly higher mean score (52.55±10.09 compared to 51.58±10.36). The questionnaire tested knowledge on four aspects of nutrition knowledge: 1. Dietary advice; 2. Food source; 3. Food choices; and 4. Diet-disease relationships. Students demonstrated a good level of knowledge on dietary advice (92.7% of participants answered over 55% correctly) but displayed low scores for the other three sections of the questionnaire. Qualitative research demonstrated clear differences in attitudes to health and healthy eating between girls and boys. Girls were more positive on healthy eating. Girls reported eating "healthy" options whereas boys took a more "relaxed" view and were ha-

ppy with fast food choices. Girls were able to report positive influences on their healthy choices whilst boys were driven by their peers.

Conclusions: This study shows that whilst knowledge scores may be similar for girls and boys there are quite substantial differences between the sexes with respect to food perceptions, attitudes and food choices.

Key words: Adolescents, Ireland, knowledge, behaviour

PO547

INTERACTIVITY - A DECISIVE FACTOR IN A WEB PLATFORM TO PROMOTE HEALTHY EATING

P. Graça^{1,2}, S. Gonçalves

¹Directorate General of Health, Lisboa, Portugal

²Faculty of Nutrition and Food Sciences of the University of Porto, Porto, Portugal

Background and objectives: Less healthy lifestyles are increasingly present in the day-to-day lives of citizens. In this sense, it is crucial to promote the ability of individuals to make informed decisions. Information on food, health and obesity is abundant, yet often suffers from the following problems: bias, poor scientific reasoning, complex language, little interaction and weak capacity to respond to citizens demands. To try to address these questions, a web site, constructed in 2008, was hosted on the Directorate General of Health and organized to permit easy access, easy understanding and providing a functional organization. What makes this innovative tool is the availability of mixed tools. Some of these tools only provide information. Others enable greater interaction and solving of daily problems. Recipes are available, mobile applications, newsletters, FAQs and other tools. The aim is to gradually make the site a space to exchange knowledge, incorporating the collaboration of many partners and health professionals and increasing their cooperation.

Methods: Using the Google Analytics® we analyzed data on demand throughout one year and which areas of the site were used most and which areas are the most sought after. With more than 10 000 views every month measurement tools had by far more views compared with information alone.

Results: It was found that pages that are most sought are those that incorporate more interactivity particularly measurement tools, like BMI calculator and areas dedicated to provide support to create menus for schools and recipes.

Conclusions: The design of web sites should encourage and empower citizens to have greater control over decisions and actions affecting their health, enabling them to take a more active and participatory role in the system and the processes of decision making.

Key words: web nutrition platform, interactivity

PO548**INTAKE OF FAT AND ANTIOXIDANT VITAMIN IN PARKINSON AND ALZHEIMER DISEASES IN A RURAL REGION IN JALISCO, MEXICO**

M. Navarro Meza¹, M R. Benavides Gómez¹, B M. Solís Quiñones¹, F. Santoyo Telles¹

¹CICAN Centro Universitario del Sur, Universidad de Guadalajara, México

Background and objectives: Neurodegeneration is a complex and multifactorial disorder that affects the central nervous system (CNS), such as Alzheimer's and Parkinson's. Studies have proposed that an inappropriate intake of lipids and the vitamins and antioxidants deficiency are involved in the development of neurodegeneration. In contrast the intake of vitamins A, C and E could be protective effects. Epidemiological studies suggest that intake of saturated fatty acid (SFA) and cholesterol could be associated with dementia and cognitive impairment.

Methods: In this study we evaluated lipids and vitamins (A, E, and C) intake in patients with possible neurodegeneration (Alzheimer and Parkinson) (n=20) and control patients (n=41), of ages 50 to 89 years from rural region that attended to health center in south of Jalisco, Mexico in a period between January to December 2012. It's a descriptive and comparative study, the intake was carried out by recording and food consumed during 24 hours and groups the food. Significance of differences between means was calculated by multivariate analysis for covariate adjusting. The data was analyzed in SPSS program 19.0 to ≤ 0.05 .

Results: Significant differences were shown a consumption of vitamin C ($p=0.016$) and saturated fatty acid ($p=0.032$) in the control group, in the evaluation by grouping food it was found a high fruit intake ($p=0.000$), vegetables ($p=0.037$), oils and fat ($p=0.002$). Patients showed a higher consumption of cereals ($p=0.017$), animal foods high in fat ($p=0.024$), whole milk ($p=0.000$). Both controls and patients with low socioeconomic status prevailed, (60 and 45%). The 40% of patients and 85% of controls reported engaging in housework.

Conclusions: The patients included in this study presents a high intake of vitamin C, this is consistent with the food groups such as fruits and vegetables, which could be related to the sociodemographic characteristics of the region.

Key words: neurodegenerative diseases, nutrition, vitamins

PO549**ARE IMPRECISE MEASUREMENTS INFLATING STUNTING PREVALENCE IN DEVELOPING COUNTRIES?**

W.L. Conde¹, N.M. Altoé², A.E.M. Rinaldi^{1,3}

¹School of Public Health, University of São Paulo, Brazil

²Master of Preventive Medicine, School of Medicine, University of São Paulo, Brazil

³School of Medicine, Federal University of Uberlândia, Brazil

Background and objectives: We start from three assumptions: mean and standard deviation (SD) are not statistically independent; height and weight are not biologically independent and anthropometric performance influences more height measurement than weighing. Our aim is estimating differences among observed and expected SD in anthropometric surveys.

Methods: Data comes from 96 Demographic Health Survey (DHS) – 46 countries and 51 others calculated by Zugno and Grummer-Strawn (2009). We calculated mean and SD of weight and height from children under five years (WHO-2006 standard Z scores). We regressed SD over mean for height and weight. Next, we predicted expected SD for height and weight. The formula $\text{probit}[-2 \cdot (\text{mean} - \text{SD}) / \text{SD}]$ was used to estimate prevalence of stunting with observed and predicted SD. From differences in density functions (p) of predicted and observed SD Z scores for height and weight we estimated the overcharge in prevalence of observed data.

Results: In zero mean is expected a SD of 1.19Z (IC95% 1.07Z; 1.31Z) for height and 1.12Z (IC95% 1.08Z; 1.16Z) for weight. The b coefficients from regression of SD over mean are -0.23 (IC95% -0.31; -0.14) for height and -0.16 (IC95% -0.21Z; -0.10Z) for weight. Such figures make, in zero mean, SD of height 1.06 higher than SD weight while across distribution SD of height is 1.45 higher than SD weight. We inspect changes for SD b coefficients across mean distribution's third. In weight mean distribution changes are discrete and b coefficient keeps negative signal; in height, distribution changes are huge and b coefficient changes signal across third. Prevalence of nutrition deficit is higher by 3 relatively to weight in superior third of height mean and higher by 2 in inferior third.

Conclusions: Figures indicate that height measurement is less precise than weight at same survey. Prevalence of stunting is influenced according to country height mean value.

Key words: anthropometric measures, children, nutritional status.

PO550**IMPORTANCE OF THE SUPPLEMENT OF VITAMINS AND MINERALS IN BONE AND MUSCLE STRESS**

P. Freitas¹, A. Cosendey¹

¹Rio de Janeiro, Brazil

Background and objectives: The athletic performance has steadily risk of injuries and bone fractures due to high intensity training. The stimuli are varied and when subjected to mechanical stress, the bone tends to respond with bone deformities, can lead to stress fractures and muscle injuries. The vitamin and mineral supplementation appears to be effective in reducing these stresses. Objectives Assess the importance of supplementation of vitamins and minerals in bone and muscle stress

Methods: Case study of a triathlon athlete, 35 years; together for 3 years, 2011, 2012 and 2013. Analyzes were made of vitamin deficiencies and stress through bone and muscle Metabolic Profile of Dr. Cosendey, which operates by detecting early organ dysfunction, poisoning and nutritional imbalances. Following are proposed recommendations for vitamins and minerals in time to prevent the aggravation of pre-existing problems.

Results: The bone stress measured by percentage relative to the recommended range, ie up to 100%, was high in the first step, 242%. In 2012 that figure has dropped significantly, 54% in 2013 and dropped to 2%. This decrease bone stress was also accompanied the decline of muscular stress 131% in 2011, 95% in 2012 and 66% in 2013.

Conclusions: The results show that supplementation of vitamins and minerals is directly linked to decreased bone and muscle stress. These results are very important, since it reduces the chances of injury in athletes.

Key words: vitamins, minerals, bone stress, muscle stress

PO551**NEW METHOD OF DIAGNOSTIC ANALYSIS FOR NUTRITION- PERFIL METABÓLICO DR. COSENDEY®**

P. Freitas¹, A. Cosendey¹

¹Rio de Janeiro, Brazil

Background and objectives: The method is an innovative tool to help diagnose sub-clinical and treatment for rebalancing organic. Studying cellular stress excessive each organ or tissue of the body, detecting imbalances at an early stage, such as organ dysfunction, intoxication, imbalance of micro and macro nutrients, level of stress in the cells of various organs, degree of hydration of tissues, before the onset of signs / symptoms and onset of illnesses. Objective Present a new method for diagnostic analysis and its significance for nutrition.

Methods: The method is done from a simple blood draw and with the help of specific software, provides a lot of information about the person. Presents accurate reports that reveal how your body is in relation to its optimal operating at current lifestyle. And yet, reveals what behaviors to be adopted to get closer to 100% of their potential.

Results: The results are shown through charts, with a report containing a summary of several studies, performed by a highly trained team, and aided by computerized diagnostic systems and artificial neural networks back-propagation (RNAR). The RNAR numerous variables correlated in the client very short time, with error rates well below the agreed worldwide.

Conclusions: The Metabolic Profile Dr Cosendey® presents itself as an innovation in the diagnostic method of analysis, since it intervenes in the initial stage of a disease process, recognizing the kind of suffering and why it is happening. It also allows the nutritionist to leave the subjectivity present results of all variables and physiological changes, in addition to the rates prevailing physiological states as dysbiosis, ketosis, oxidative stress, insulin peripheral resistance (highly recurrent)and aiding in the early treatment of disease.

Key words: diagnosis, nutrition, disease

PO552**ELEVATED CARDIOMETABOLIC RISK IN OVERWEIGHT AND CENTRALLY OBESE NORMAL WEIGHT SPANISH CHILDREN OF PRESCHOOL AGE**

⁶Department of Biostatistics, Gillings School of Global Public Health, University of North Carolina-Chapel Hill, NC USA

⁷Department of Nutrition, Gillings School of Public Health, University of North Carolina-Chapel Hill, NC, US

Background and aims: Overweight has been associated with metabolic dysfunction in late childhood and adolescence, but few studies have explored these relationships at preschool

age. As most studies have focused on metabolic syndrome components such as lipids and glucose, little is known about how overweight in early life may relate to other cardiometabolic markers. It is also uncertain whether, central obesity among children of normal weight is related to metabolic dysfunction, or the types of markers known or thought to be related to metabolic syndrome.

Methods: This cross-sectional analysis included 254 children aged 4.5 years from the Spanish INMA-Sabadell birth cohort. We measured body mass index (BMI), waist circumference, blood pressure (BP) and plasma levels of total cholesterol, HDL, triglycerides, apolipoprotein B/A1, C-reactive protein, C-peptide, leptin, TNF-alpha, sICAM and sVCAM. Overweight was defined as an age-and-sex-specific BMI z-score \geq 85th percentile (WHO reference). Children with waist-to-height-ratio >0.5 were classified as centrally obese. Logistic regression was used to assess whether, compared to normal weight children with lower waist-to-height-ratio overweight or centrally-obese normal weight children had elevated cardiometabolic risk defined based on the lowest tertile of each marker, adjusting for age, gender, and race.

Results: Overall, 22% of children were overweight; 21% of children of normal weight were centrally obese. Compared to non-centrally obese normal weight children, overweight children had increased odds of low HDL, and of elevated triglycerides, leptin, TNF-alpha, sICAM, C-peptide and elevated systolic and diastolic BP. Among normal weight children, centrally obese children had increased odds of elevated leptin and sVCAM compared to non-centrally obese children. C-reactive protein was unrelated to weight status.

Conclusions: Overweight was associated with multiple markers of metabolic function at preschool age. Further, markers not typically assessed in metabolic syndrome analyses were associated with central obesity among normal weight children.

Key words: Overweight, obesity, metabolic syndrome, cardiometabolic biomarkers

PO553

INFLUENCE OF TWO FUNCTIONAL INGREDIENTS ON THE PLASMA CONCENTRATIONS OF LEPTIN, GHRELIN AND GLUCAGON LIKE PEPTIDE1 IN LEAN AND OBESE RATS

J. Alcalá-Bejarano¹, M. Olivares², L. Pérez Martínez², M. Yeste², P. Aranda¹, M. López-Jurado¹, G. Urbano¹, J. M. Porres¹, M. D. Yago¹, M. Mañas¹, E. Martínez-Victoria¹

¹Department of Physiology, Institute of Food Technology, University of Granada, Granada, Spain

²Department of Biomedicine, Biosearchlife, Spain

Background and objectives: “Globesity” is the term that the WHO uses to define the increase in obesity in the world from 80’s onwards. Public organizations in collaboration with food industry are working to develop different functional ingredients as one of the strategies planned. The aim of this work was to investigate in lean and obese rats the effect of two functional ingredients in circulating levels of GLP1, ghrelin and leptin, hormones involved in the control of weight and food intake.

Methods: Sixty male Wistar rats were given free access to food and water. We set three “lean” groups fed during 10 weeks with AIN-93M diet (Control) and two modified AIN-93M (E1 and E2) added each one with one functional ingredient and three “obese” groups fed for 10 weeks with the obesogenic diet (Research Diets[®]) and then another 10 weeks with experimental diets. Experiments were conducted to determine the plasma concentrations of the above hormones in fasting conditions. Hormone assay was performed by Luminex X-MAPTM.

Results: The fasting plasma concentration of ghrelin was similar in lean and obese rats. However, concentration of leptin and GLP-1 were significantly higher in obese animals. The intake of the two functional ingredients modified, in lean, but not in obese rats, the fasting concentrations of ghrelin and GLP-1 for E1 and ghrelin, leptin and GLP-1 for E2. When comparing fasting concentrations of different hormones in lean and obese rats given the two functional ingredients there were no differences.

Conclusions: Diet-induced obesity modifies fasting concentrations of ghrelin, leptin and GLP-1. The presence in the diet of two functional ingredients (E1 and E2) modifies their fasting concentration, which may affect body weight.

Key words: Functional ingredients, hormones, rats

PO554**BRAZILIAN NUT: A WAY TO IMPROVE GLUTATHIONE PEROXIDASE ACTIVITY IN ELDERLY WITH MILD COGNITIVE IMPAIRMENT***B. Cardoso¹, S M F. Cozzolino¹, W. Jacob-Filho²*¹Faculty of Pharmaceutical Sciences, University of São Paulo (USP), São Paulo, Brazil²Division of Geriatrics, University of São Paulo Medical School (USP), São Paulo, Brazil

Background and objectives: Mild cognitive impairment (MCI) is a nosological entity proposed as an intermediate state between normal aging and dementia, and it is frequently associated with decline to Alzheimer's disease (AD). Studies support the hypothesis that oxidative stress plays an important role in the pathogenesis of AD. This oxidative stress may be initiated by a decline of glutathione peroxidase (GPx) activity. This selenoenzyme is an essential line of defense against free radicals acting against hydrogen peroxide and lipid peroxidation, protecting brain against oxidative stress. These observations have prompted studies of antioxidants to decrease oxidative damage and improve cognition. Thus, we examined the hypothesis that the daily consumption of Brazilian nut would have benefits on GPx activity in elderly with MCI. This nut is recognized not only for its selenium content but also for its high selenium bioavailability.

Methods: Twenty elderly with MCI (76.6±4.2 y old) were studied. They were randomly divided in two groups: Brazilian Nut group (BN, n=11) received one nut (around 5 g, averaging 57.75 µg Se/g) a day for 6 months, and Control group (CG, n=9) did not receive anything. Erythrocyte GPx activity was determined using the commercially available Randox® kit.

Results: GPx activity was not different between groups in baseline (BN=252.66±87.78 U/L; CG=247.28±70.16 U/L; p>0.005). However, after 6 months treatment, GPx activity was significantly higher in BN (335.02±119.80 U/L; p<0.001), while CG showed a slight, but not significant decrease (237.27±73.90 U/L; p>0.05).

Conclusions: The data revealed that the consumption of only one Brazilian nut a day (5 g) during 6 months was effective to increase erythrocyte GPx activity. Brazilian nut is an excellent option of supplying selenium through a normal diet, so it can be recommended to MCI patients in order to reduce oxidative stress damage.

Key words: selenium, oxidative stress, glutathione peroxidase

PO555**MARINE OMEGA 3 FATTY ACIDS PREVENT THE TRANSMISSION OF MATERNAL-FETAL OBESITY AND INSULIN RESISTANCE IN RATS.***N. Guriec¹, C. Le Foll¹, A. Résonet¹, J. Delarue¹*¹Federation of Food and Human Nutrition, Department of Nutritional Sciences, Hospital and University of Brest, Brest, France

Background and objectives: We investigate whether fish oil FO into a high fat (HF) diet in pregnant rats impedes IR in offsprings.

Methods: Rats randomized into 3 groups receiving for 6 weeks a control diet (C: 13% corn oil), a HF diet (60% corn oil) or a HF diet with ω3 (HFω3, 40% corn oil + 20% FO (TG 1050 Quick Silver®, Polaris Pleuven). An OGTT was performed at T + 6 w, before coupling. Following weaning (D21), male pups nursed by each of the 3 groups of rats were randomized to receive over 6 w (D63) either C diet or HF diet without ω3 (6 groups of pups). OGTT performed on D21 then D63.

Results: 1) Rats before coupling were obese and IR (data not shown). 2) Pups at D0 weight of pups born to C: 8.1 ± 0.2 g; HF: 10.2 ± 0.4 g (p <0.05 vs C); HLω3: 8.0 ± 0.3 g. At D21 pups born to C: 36.0 ± 0.6 g; HL: 46.6 ± 1.4, (p <0.05 vs C) HFω3: 32.8 ± 4.3 g, (p <0.05 vs HF). AUC glycaemia at D21 not different between C, HF, HFω3. At D63, T/T: 9699±99 vs 1222. AUC insulinaemia C: 36.4±6.4; HF: 53.0±5.1, p<0.05; HFω3: 29±3. At D63, AUC glycaemia not different between 3 groups; AUC insulinaemia in pups consuming the HF diet: C: 163.4±21.3; HF: 295.6 ±52.4, p<0.05 vs C; HFω3: 101.7±2.0, p<0.01 vs HF.

Conclusions: Pups born to mothers fed a HF diet rich in ω3 did not develop IR at weaning or in adulthood.

Key words: omega 3, fetal programming

PO556**HEALTH-RELATED QUALITY OF LIFE AND FOOD VARIETY OF EUROPEAN ELDERLY**

C. Morais¹, C. Afonso¹, B. Oliveira^{1,2}, M. Lumbers³, M. Rats³, M D V. Almeida¹

¹Faculdade de Ciências Da Nutrição E Alimentação Da Universidade Do Porto

²Laboratório de Inteligência Artificial e Apoio à Decisão, Instituto de Engenharia de Sistemas e Computadores do Porto – Tecnologia e Ciência

³Food, Consumer Behaviour and Health Research Centre, University of Surrey, Guildford, Surrey GU2 7XH, UK

Background and objectives: Research on the variety of food consumption is scarce but is of potential relevance due to its role in the wellbeing and quality of life of elderly populations. We aimed to identify the associations between health-related quality of life and variety of food consumption.

Methods: The sample included 3291 elderly aged 65+ years stratified by sex, age (65-75, 75+ years) and living circumstances (living alone, living with others). The participants belonged to 8 European countries: Denmark, Germany, Italy, Poland, Portugal, Spain, Sweden and United Kingdom. Data was collected by a food variety questionnaire and the SF-8 Health Survey. The FV score (FVS) was calculated by the sum of food items consumed in the previous week. We computed summary scores for all domains, including general health perception (GH), vitality (VT) and mental component (MCS). The analysis included a descriptive analysis by country and Spearman correlation between the SF8 scores and the FVS.

Results: The total mean value for FVS was 28.30 (SD= 6.326), with higher values for Sweden (31.32, SD= 6.007) and UK (29.88, SD= 6.346), and lower for Italy (26.59, SD= 5.810) and Portugal (27.34, SD= 6.724). For the MCS, we found lower values for Portugal (48.06, SD=10.189) and Italy (49.15, SD= 8.563), and the highest for Denmark (54.59, SD= 6.712) and UK (53.05, SD=8.420). The FVS presented a low correlation with all health scores ($p < 0.001$), with higher values for VT (0.205) and GH (0.191).

Conclusions: Countries with lower FVS, as Italy and Portugal, presented also the lower values for the mental component and the ones with higher scores (Denmark and UK) presented the highest values, suggesting a possible association between food variety and mental well-being.

Key words: food variety, health-related quality of life, elderly

PO557**MUSCLE MASS AND MUSCULAR STRENGTH IMPACT OF A SUPPLEMENTATION WITH NUTRALYS® PEA PROTEINS OR WHEY PROTEINS IN VOLUNTEERS PARTICIPATING IN PHYSICAL TRAINING.**

¹Expert Centre for Performance, UFR STAPS, Dijon, France

²Roquette Frères, France

³Chair of medical evaluation of health claims, ESC Dijon, France

Background and objectives: Protein supplementation in sport nutrition is of common use today. Our study aims at comparing the muscular impact of a supplementation with NUTRALYS® pea proteins or whey proteins.

Methods: Males, aged 18 to 35 years practicing a moderate or occasional sport, were given 25 g of either NUTRALYS® pea proteins (n=52) or whey proteins (n=54) or placebo (n=54) twice a day for twelve weeks in a randomized placebo-controlled clinical trial. In addition, volunteers participated in a moderate muscular training. The impact of the supplementation was assessed using thickness measurement of the biceps brachii using ultrasonography, muscle strength, body composition and weight.

Results: All groups were comparable at baseline. In all groups, biceps brachii thickness (primary endpoint) displayed a significant increase as a result of muscular training. Muscle relative increase tended to be significant between groups in the total population ($p=0.09$). Using sensitivity analysis on previously less muscularly developed volunteers (Maximum concentric Strength 1-RM at inclusion $< 25\text{Kg}$), this increase was significantly different between groups ($p=0.01$). Absolute changes in muscle thickness were also significantly different between groups ($p=0.01$). A Scheffe test on all groups as well as a t test comparing NUTRALYS® versus placebo confirmed that the overall difference observed came from a statistical difference between NUTRALYS® and placebo. Although an increase in the biceps brachii thickness was observed with whey supplementation, it was not significantly different from placebo. Secondary outcomes (muscle strength, weight, body composition) did not vary significantly between groups and results obtained from a supplementation with whey or with NUTRALYS® were similar.

Conclusions: In addition to an appropriate training, the consumption of NUTRALYS® pea protein promoted a significant increase of the muscular mass as compared to placebo and especially for people starting or returning to a muscular training.

Key words: pea proteins, muscle, sport nutrition

PO558**OVERWEIGHT AND OBESITY IN XAVANTE INDIANS FROM MATO GROSSO, BRAZIL**

L P. Soares¹, L J. Franco¹, A L D. Fabbro¹, A S. Silva¹, D S. Sartorelli¹, L F. Franco², P C. Kuhn², R S. Moisés², J P A B. Vieira-Filho²

¹Departamento de Medicina Social, Faculdade de Medicina de Ribeirão Preto, Universidade de São Paulo, Ribeirão Preto, Brasil

²Escola Paulista de Medicina, Universidade Federal de São Paulo, São Paulo, Brasil

Background and Objectives: It has been observed a considerable increase in the prevalence of overweight and obesity and chronic non-transmissible diseases (DCNT) among Brazilian indigenous population, which can be attributed to dietary changes and reducing the frequency and intensity of physical activity. The aim of this study was to evaluate the prevalence of overweight and obesity in XavanteIndians, that live in the Central Brazil, and are recently undergoing an intense change in their traditional life style.

Methods: A cross-sectional study was carried out among 947 Xavante Indians from theSão Marcos and Sangradouro/Volta Grande reservations. We considered gender, age and anthropometric variables: weight, height, body mass index (BMI), waist circumference (WC), hip circumference (HC) and waist / hip ratio (WHR). To evaluate the nutritional status, we adopted the criteria recommended by the World Health Organization for BMI. For WC and WHR were considered the benchmarks of the Brazilian Society of Cardiology. We used descriptive statistics and Chi square test. Data were analyzed with SPSS version 17, which set a significance level of 5%.

Results:The examined population was composed by 464 men and 483 women, aged 20 years or more (43.03 ± 19.35). Prevalence rates across the study population were: overweight (34.6%), obesity (50.7%), waist circumference compatible with very increased risk – ≥88cm in women and ≥102cm in men (58.9%) and WHR compatible with increased risk – ≥0,80 for women and ≥0,95 for men (79.8%). In general, the prevalence was higher in women and in the age-group40 to 59 years.

Conclusions: The results demonstrate a worrying nutritional status between adults XavanteIndians, with high prevalence of overweight and nutritional indicators consistent with DCNT risk, especially among women. It is necessary to be adopted strategies for prevention and control of overweight among indians.

Key words: overweight, obesity, anthropometry, indigenous population

PO559**PREVALENCE OF OVERWEIGHT AND OBESITY IN SCHOOLCHILDREN 2-12 YEARS OLD FROM FERNANDÓPOLIS-SP, BRAZIL**

L M. Soares Franciscon^{1,3}, F. Pires³, C P. Guerra Silva^{2,3}, E T. Pires³, F. Pacheco³, A P. Souza Martins^{2,3}, A J. Flores Cassenote^{3,4}

¹Camilo Castelo Branco University - Fernandópolis, São Paulo, Brazil

²Fernandópolis Educational Foundation - Fernandópolis, São Paulo, Brazil

³OI Project of Childhood Obesity - Fernandópolis, São Paulo, Brazil

⁴Faculty of Medicine of São Paulo University, São Paulo, Brazil

Background and objectives: The current obesity epidemic has the main characteristic the impact in the pediatric community. Data from the Brazilian Society of Pediatrics (SBP) and the Brazilian Institute of Geography and Statistics (IBGE) show that reaches more than 5 million Brazilian children and increased in 30 years, 14% in males and 8% in females. The aim of this study was to determine the prevalence of overweight and obesity among schoolchildren 2-12 years, in the municipality of Fernandópolis, SP, in 2009, separating the results by gender and type of school.

Methods: We conducted a cross-sectional study, with analysis of 2409 students from 14 schools of Fernandópolis / SP, Brazil (-20 ° 17'02" Latitude and Longitude -50 ° 14 '47"). The sample consisted of 1209 (51.0%) females and 1798 (74.6%) students from private institutions. Anthropometric data assessed: body weight in kg and height in meters. The diagnosis of obesity or overweight was made according to the cutoff international table proposed by NCIN IEH.

Results: the prevalence of overweight schoolchildren was 34.7% (836), and 15.3% (368) were considered obese. Among females 36.2%, with 15.6% obese and, in males, 29.28%, with 13.62% obese (p = 0.154). The prevalence of obesity among public school students was 11.5%, and in particular of 20.6% (p = 0.002).

Conclusions: The prevalence of overweight and obesity in Fernandópolis for students from 2 to 12 years, agrees with the levels of Brazil. Between the sexes, unlike the literature, there were no statistical differences. We observed significant differences in overweight and obesity in private schools, which is used by a population more economically advantaged, corroborating other studies. Thus presents the peculiarities of Fernandópolis, demonstrating the importance of conducting regional studies, which will propose new models of action to combat the advance of this epidemic.

Key words: obesity; overweight; Brazil; schoolchildren.

PO560**QUANTITATIVE ASSESSMENT OF BREASTFEEDING PRACTICES IN MOROCCAN LACTATING WOMEN DURING 6 MONTHS AFTER BIRTH USING STABLE ISOTOPIC DILUTION TECHNIQUE**

C. Ghizlane¹, EH. Nourddine¹, EK. Khalid¹, A. Hassan¹, M. Najat¹

¹University Ibn Tofail, Faculty of Sciences, Department of Biology, Morocco

Background and objectives: The evaluation of breast milk intake is of particular importance for setting future breast-feeding recommendations and to investigate success strategies for breastfeeding promotion. Exclusive breastfeeding during the first 6 months of an infant's life is an important factor for optimal growth and health of the child. Moreover, the assessment of postpartum changes in maternal body composition provides important information on her nutritional status and for identifying intervention strategies aimed at improving living conditions. In Morocco, this is the first time that breastfeeding practices and human milk intake have been quantified, and that changes in maternal body composition postpartum have been assessed.

Methods: This study included 32 mother-baby pairs. The exclusive breastfeeding rate, intake of human milk and water from other sources, and the body composition of the mothers were measured at 1st, 3rd and 6th month postpartum by using the deuterium oxide dose-to-mother technique.

Results: Results showed that the exclusive breastfeeding rate was 33.3% at the first month, 26.7% at the third and 12.5% at the sixth. Mean intake of breast milk was 615.6 g/d, 741.9 g/d and 843.6 g/d at 1, 3 and 6 months respectively. As expected, there was a significant change in the mothers' body composition between the first and sixth months. As a proportion of body weight, fat free mass increased by 13.4% and fat mass decreased by 33.4%.

Conclusions: In conclusion, the rate of exclusive breastfeeding in Morocco remains low, despite advice on the benefits of breastfeeding, clearly showing a resistance to change the behaviour of these mothers.

Key words: Exclusive breastfeeding, body composition, deuterium.

PO561**EATING RATE IS ASSOCIATED WITH EATING BEHAVIORS ACCORDING TO GENDER AND OBESITY**

S. Park¹, W-S Shin²

¹Semyung University, Korea,

²Hanyang University, Korea

Background and objectives: To compare the differences in eating behaviors and masticatory performances between genders or obesity status, and to determine the associations between eating behaviors and masticatory performances in both genders according to obesity status, twenty four (50% M and 50% F) adults were matched on age, gender, obesity status and dental health.

Methods: Eating behaviors were assessed by the Three Factor Eating Questionnaire (TFEQ) and chewing performances were measured using electromyography (EMG) while eating a boiled-rice (150 g).

Results: Compared with lean participants, obese participants had significantly higher level of disinhibition ($p < 0.05$ for M; $p < 0.01$ for F). Chewing performances were not significantly different by obesity status. Males had greater bite size ($p < 0.05$ for lean; $p < 0.01$ for obese) and chewing power ($p < 0.001$) and faster eating rate ($p < 0.01$ for lean; $p < 0.05$ for obese) than females. Females habitually chewed more ($p < 0.01$ for lean; $p < 0.05$ for obese) and had longer meal duration ($p < 0.05$) than males. In lean males, the eating rate was negatively ($r = -.812$, $p < 0.05$) associated with disinhibition and total number of chew (TNC) was positively ($r = .902$, $p < 0.05$) associated with the hunger sensitivity on the TFEQ. In obese males, the eating rate was negatively ($r = -.860$, $p < 0.05$) associated with cognitive restraint and positively ($r = .871$, $p < 0.05$) associated with the hunger sensitivity. No significant associations between eating behaviors and chewing performances were observed in females.

Conclusions: In conclusion, disinhibited eating was differentiated in obese adults. Eating behaviors were related to the rate of ingestion or TNC in males but not in females. Therefore, gender specific intervention and counseling aimed to improve the eating rate could be promising for the eating behavioral treatment in the obese.

Key words: obesity; gender; eating behavior; TFEQ; eating rate

PO562**CONSUMPTION EFFECT OF CALORIC AND NON-CALORIC BEVERAGES ON FOOD INTAKE IN RATS**

M. Hagen¹, K. Cony¹, J. Goularte², G. Sanvitto²

¹Department of Internal Medicine, Nutrition Course and CESAN-HCPA, Federal University of do Rio Grande do Sul, Porto Alegre, Brazil

²Department of Physiology, Institute of Basic Health Sciences, Federal University of Rio Grande do Sul, Porto Alegre, Brazil

Background and objectives: The consumption effect of caloric and non-caloric beverages on food intake is controversial and studies in this issue are sparse and inconclusive. In several animal experimental researches, it has been evidenced a reduction in solid food intake during the exposure to caloric soft drinks. On the other hand, in human studies, it has not been observed compensation in energy intake in individuals exposed to sucrose beverages. The present study aimed to evaluate the effect of caloric and non-caloric soft drink on the quantitative and qualitative intake of solid food in rats.

Methods: Thirty twenty-one-day male rats were divided into 3 groups: control group (standard diet and water “ad libitum”), caloric soft drink group (standard diet, caloric soft drink and water “ad libitum”) and non-caloric soft drink group (standard diet, non-caloric soft drink and water “ad libitum”). The animals received treatment within 17 weeks.

Results: The consumption of caloric and non-caloric soft drink at the end of treatment did not cause changes in total energy intake, body weight and intra-abdominal fat. However, the caloric soft drink consumption resulted in a reduction in solid food intake, increased carbohydrates consumption and high total liquids intake. While the non-caloric soft drink intake didn't influence the total intake of solid food at the end of treatment.

Conclusions: it was concluded that exposure to and intra-abdominal fat during the evaluation period. However, the caloric soft drink caloric and non-caloric soft drink caused no changes in total energy intake, body weight intake influenced the amount and the quality of solid food consumed. The non-caloric soft drink intake didn't influence the food intake.

Key words: Food consumption; soft drink intake; rats.

PO563**A QUALITATIVE INTERVIEW STUDY ON ETHICAL ASPECTS OF MARKETING AND FOOD ADVERTISING FOR CHILDREN. EVALUATION OF PERCEPTIONS, ATTITUDES AND BELIEFS OF PARENTS**

J.J. Hernández-Torres¹, J.C. López-Robles¹, V. Macías¹, C. Iribar², M.T. Miranda³, C. Campoy^{1,4}

¹EURISTIKOS Excellence Centre for Paediatric Research, University of Granada, Granada, Spain

²Department of Human Physiology, University of Granada, Granada, Spain

³Department of Biostatistics, University of Granada, Granada, Spain

⁴Department of Paediatrics, University of Granada, Granada, Spain

Background and objectives: The “obesity risk” has become a major concern of the food industry since the World Health Organisation in 1998 recognised obesity as a problem of epidemic proportion. If advertising for food high in fat, sugar and salt alone does not make children and adolescents fat, it is an important contributory factor to their overweight. This study attempts to fill this apparent gap by examining parents' ethical views of food advertising targeted at children and adolescents in Spain.

Methods: Qualitative interviews were conducted with a total of 280 parents of children and adolescents aged between 3 to 16 years, who were recruited through state schools in the city of Granada (Spain). A semi-structured interview schedule was developed based in the aim of the study and relevant literature. Different scales were designed to analyze behavioral intentions and ethical judgments (dependent variables). As independent variables, moral intensity, idealism, relativism, attitude toward food advertising aimed at children and adolescents, and attitude toward the parents' use of nutrition information were obtained. Qualitative analysis and ANOVA was used with the SPSS version 20.0.

Results: Parents' perceptions regarding the importance of ethics and social responsibility in relation to food advertising for children and adolescents can be explained by both dimensions of moral philosophies. Those who are more idealistic tend to perceive ethics and social responsibility to be important, and less relativistic parents tend to perceive these aspects as important.

Conclusions: The survey results partly indicate that there is a positive relationship between ethical values and parents' perceptions regarding the importance of ethics and social responsibility of food advertising and marketing for children and adolescents. In general, parents consider that the ethical corporate environment appears to be conducive to ethical and socially responsible behavior within enterprises.

Key words: Food advertising, ethics, parents' perception, children and adolescents.

PO564**EFFECT OF TAURINE SUPPLEMENTATION, ASSOCIATED WITH NUTRITIONAL COUNSELING, ON ENERGY METABOLISM IN OBESE WOMEN**

F T. Rosa¹, V. Suen¹, K. Pfrimer¹, E. Ferrioli¹, J S. Marchini¹, E C. Freitas²

¹Department of Internal Medicine, Faculty of Medicine of Ribeirao Preto, University of Sao Paulo, Sao Paulo, Brazil

²School of Physical Education and Sports of Ribeirao Preto, University of Sao Paulo, Sao Paulo, Brazil

Background and objectives: Researchers found decreased levels of plasma taurine in obese subjects and animals and reduced expression of an important taurine synthesis enzyme. These evidences, coupled with findings that taurine supplementation increased mRNA levels of transcription factors involved in energy expenditure and β -oxidation in rats fed high fat diets highlighted the use of taurine in obesity treatment. Thus, the aim of the present study was to investigate whether taurine supplementation improves energy metabolism in obese subjects.

Methods: A double-blind placebo controlled study was conducted. Sixteen obese volunteers were divided into two groups stratified by BMI and age, and supplemented with taurine (3g/d) or placebo for 8 weeks. The volunteers also participated in a weekly nutritional counseling group. Plasma taurine, weight, BMI, body composition (by deuterium dilution), total energy expenditure (by doubly-labeled water) and resting energy expenditure and substrates oxidation (by indirect calorimetry) were evaluated just before and after supplementation. Energy metabolism data was adjusted for body composition.

Results: both taurine and placebo groups showed significant reductions in weight (-4 vs -4 kg, respectively), BMI (-2 vs -2 Kg/m², respectively) and body fat (-4.2 vs -4.1 kg, respectively) without significant differences between groups ($p > 0.05$). Taurine group showed significant increase in total energy expenditure after 8 weeks of supplementation (2248 ± 273 to 295 ± 264 kcal/day, $p < 0.01$) compared to placebo (3025 ± 265 to 2796 ± 270 kcal/day, $p > 0.05$). There were no differences between groups for resting energy expenditure and carbohydrate oxidation. It was found a slight but not significant increase in fat oxidation by taurine supplementation (81 ± 9 to 92 ± 9 gram/day) and decrease by placebo (96 ± 8 to 88 ± 9 gram/day).

Conclusions: taurine is able to improve total energy expenditure in obese.

Key words: taurine, obesity, energy expenditure, fat oxidation.

PO565**IMPACT ASSESSMENTS CONDUCTED AT TIME OF EXIT INCONSISTENTLY PREDICT LONGER TERM PROGRAM BENEFIT IN TITLE II FOOD ASSISTANCE PROGRAMS**

B. Rogers¹, J. Coates¹, K. Houk¹, E. Kegode¹, L. Sanchez¹, J. Andrews¹, J. Fierstein¹, A. Blau¹, T. Galante¹

¹Friedman Nutrition School Tufts University, Division of Development and Growth, Department Child and Adolescent, School of Medicine and University Hospital, Geneva, Switzerland

Background and objectives: U.S. food aid programs support health, watsan, and agricultural development to promote food security in poor communities. Impact evaluations are regularly conducted at program exit and compared to baseline.

Methods: We repeated evaluations in Bolivia, Honduras and Kenya 2-3 years after exit using similar survey methodology complemented with qualitative methods and compared behavioral and impact indicators at the two periods to assess and identify determinants of sustainability.

Results: Outcomes showing success at exit were inconsistently sustained at followup. Income from agriculture showed substantial increases from baseline to endline in Bolivia and Honduras, reflecting continued technical assistance and free inputs, but generally fell significantly at followup. Use of improved agricultural practices increased to above 90% at endline in all countries; but declined significantly (Bolivia, Honduras) or were maintained (Kenya) at followup. Availability of piped/improved water increased baseline-endline in all countries; was maintained or increased in Bolivia, Honduras, but declined significantly in Kenya. Prevalence of stunting/wasting had declined significantly by exit in all countries; rates continued to decline in Bolivia and Honduras but rebounded in most places in Kenya. Conversely health care practices were widely adopted by endline in all countries but declined significantly (Bolivia, Honduras) when CHW home visits did not provide continued reinforcement. Continued feeding of infants during illness was well adopted at exit but declined significantly in all countries. Improvements in exclusive breastfeeding were maintained or improved.

Conclusions: Sustainability of program effects on behaviors and impact indicators is not necessarily reflected in results of evaluations conducted at program exit. Assessment of longer term benefits requires attention to sustainability strategies and repeated impact evaluation in later years.

Key words: Food Aid, Sustainability, Exit Strategies

PO566**CONTRIBUTION OF STABLE ISOTOPES TO VALIDATE THE PRACTICE OF BREASTFEEDING IN BURKINA FASO**

N M. Coulibaly¹, C T. Ouedraogo¹, A N. Zeba¹, J-B. Ouedraogo¹

¹Institut de Recherche en Science de la Santé, Direction Regionale de L'Ouest, Burkina Faso

Background and objectives: Breastfeeding is widespread in Africa but only limited information is available on this practice. The ultimate goal of this study was to evaluate the national breastfeeding promotion program in a rural area of Burkina Faso.

Methods: A cohort of 46 mothers who agreed to practice exclusive breastfeeding up to 6 months was followed with their babies. Data were collected at birth (1-2 week) and at 2, 4 and 6 mo. At each period, we used the deuterium oxide 'dose-to-mother' technique to determine human milk (HM) intake as well as the non-HM water intake. The deuterium enrichment in saliva samples collected from the mothers and their babies was analyzed by FTIR (Fourier Transform Infrared spectrometry). Exclusive breastfeeding was assessed if the non-HM intake didn't exceed 25g/d.

Results: In all, 39 mother-baby pair completed the study. The mean [95%CI] HM was 576.9 [507.1, 642.7] g/d at birth. It increased ($p < 0.0001$) to 849.5 [789.2, 909.7] g/d at 2 mo and reach a maximum of 913.7 [851.9, 975.6] g/d at 4 mo, then it knew a non significant decrease to 887.4 [824.4, 950.5] g/d after 6 mo. The non-HM was 44.6 [25.5, 63.8] g/d at birth and reach the maximum of 187 [137.7, 236.5] g/d at 6 mo but at each time the baby weight was strongly correlated to the HM ($p < 0.0001$ and $r = 0.84$ at birth, 0.82 at 2 mo, 0.77 at 4 mo and 0.76 at 6 mo). The exclusive breastfeeding was 41% at birth, 21% at 2 mo, 15% at 4 mo and none of these women reached 6 mo of exclusive breastfeeding.

Conclusions: The deuterium dilution method enable us to prove that breastfeeding is not really implemented as recommended by the WHO and national authorities.

Key words: human milk, breastfeeding, deuterium oxide.

PO567**ZINC SUPPLEMENTATION FOR THE TREATMENT OF CHILDHOOD DIARRHEA IN INDIA: THE ASSOCIATION BETWEEN PROVIDER KNOWLEDGE AND PRACTICE**

L. Lamberti¹, C. Fischer Walker¹, S. Taneja², S. Mazumder², R. Black¹

¹Johns Hopkins School of Public Health, Department of International Health, Baltimore, MD, USA

²Center for Health Research and Development, Society for Applied Studies, New Delhi, India

Background and objectives: Therapeutic zinc supplementation reduces diarrhea duration and severity among children under-five. The DAZT project is currently scaling-up zinc in Bihar, Gujarat and Uttar Pradesh (UP), India. Activities include supply chain support and training for informal private sector rural medical practitioners (RMPs) and public sector Accredited Social Health Activists (ASHAs) and Anganwadi Workers (AWWs). In order to understand influences on provider practices and zinc coverage, we assessed the association between reported zinc knowledge and observed zinc prescribing.

Methods: We conducted cross-sectional assessments of RMPs (N=97) in UP, and ASHAs (N=330) and AWWs (N=330) in Bihar/Gujarat. Providers were directly observed during one treatment interaction with a diarrhea case 2-59 months of age and subsequently interviewed. Survey responses regarding zinc use, dose and duration were used to compute zinc knowledge scores for each provider on a 7-point scale. Multiple logistic regression was conducted to assess the association between observed zinc prescribing and zinc knowledge score, controlling for characteristics of the provider and observed child.

Results: Zinc was prescribed by 65.5% of AWWs, 78.5% of ASHAs and 28.9% of RMPs. In the public sector, the odds of zinc prescribing were elevated by 77% (OR: 1.77; 95% CI: 1.57-2.01) per point increase in zinc knowledge score, controlling for provider (i.e. ASHA/AWW), state (i.e. Bihar/Gujarat), and age of observed child (i.e. <6 months/≥6 months). In the private sector, the odds of zinc prescribing were about two-fold higher (OR: 2.17; 95% CI: 1.50-3.16) per point increase in zinc knowledge score, controlling for RMP education (<14 years/≥14 years) and the observed child's age in months.

Conclusions: The practice of advising zinc for under-five diarrhea treatment may be positively influenced by zinc knowledge. Thus, programs aiming to scale-up adequate diarrhea management in India should invest resources in RMP, ASHA and AWW training.

Key Words: Zinc, Diarrhea, Children, India

PO568**PERSISTENCE OF RECOVERY FROM MALNUTRITION AND HIV PROGRESSION AMONG HIV+ ADULTS GRADUATING FROM THE ETHIOPIAN FOOD BY PRESCRIPTION PROGRAM**

J. Coates¹, K. Sadler², E. Bontrager¹, S. Ghosh³, D. Suri³, Y. Kidane¹

¹Tufts University Friedman School of Nutrition Science and Policy, USA

²Valid International

³Nevin Scrimshaw International Nutrition Foundation

Background and objectives: Determine 6-month persistence of effects of RUTF supplement provided to malnourished HIV+ adults with MAM or SAM (BMI <= 18.5) also receiving standard ART care on nutritional status.

Methods: RUTF was provided to subjects with MAM or SAM and that were pre ART or ART for up to 6 months at 15 clinics (n=1956), with 8 matched comparison clinics (n=639). Longitudinal nutritional and HIV status data were collected. Recovery was defined as having a BMI >= 18.5 recorded for 2 or more consecutive visits. Six months after program exit, nutritional status was re-evaluated in treatment group participants.

Results: Persistence data were collected 6 months after program exit for 17% of treatment group subjects, of which 45.3% had recovered from malnutrition and 54.7% remained malnourished. Of those recovered, 80.0% maintained or improved their BMI at >= 18.5, while 20.0% relapsed to become malnourished again. Of those that were discharged from the intervention as non-responders, 33.7% maintained or improved their BMI, while 66.3% remained malnourished.

Conclusions: Our results suggest that nutritional support that promotes recovery from malnutrition in the short term can have longer-term benefits for health and nutrition status of people on ART. This finding should be interpreted with caution because of the low proportion of total exits that could be followed-up at 6 months.

Key words: BMI, malnutrition, nutritional supplementation

PO569**OXIDATIVE STRESS IN EPILEPTIC CHILDREN AND ADOLESCENTS UNDER INDICATION TO KETOGENIC DIET PROGRAM IN BRAZIL**

P. Lima¹, L. Sampaio², D. Murakami², M. Prudencio¹, N. Teixeira¹

¹Department of Nutrition, School of Public Health - University of Sao Paulo, Sao Paulo, Brazil

²Children's Institute, Clinical Hospital of School of Medicine - University of Sao Paulo, Sao Paulo, Brazil

Background and objectives: The ketogenic diet (KD) is indicated for the treatment of refractory epilepsy with reduction of more than 50% of seizures. However, one of the main adverse effects are the changes of lipids profile, that isn't very well studied. The aim of this paper is to evaluate the oxidative stress and to analysis of antioxidants intake KD.

Methods: The concentration thiobarbituric acid reactive substances (TBARs) was determinate in plasma after fasting 12 hours. After 12h of fasting blood samples was collected from children and adolescents. From plasma lipid profile (TC, LDL, HDL, TG) were evaluated. Analysis of TBARs were performed by standard method. Dietary intake was assessed by three food records in the program Food Processor (Esha Research®). Score-z body mass index for age (ZBMI/I) was standardized for status nutritional classification.

Results: The program included 18 subjects, both gender with 1.4 to 15 years old. According to ZBMI, 50% of the patients were eutrophics, 16.67% with risk of overweight or overweight and 33.3% had obesity or severe obesity (WHO 2006, 2007). The average TBARs level was 3.97 (0,92) µmol/ml. This profile was negatively correlated with retinol intake (r=-570, p=0,021). However, alfa-tocoferol, beta-carotene and others vitamins monitored didn't showed correlation with TBARs. Mean values of lipid profile were CT 160 (29) mg/dl, LDL 94 (25) mg/dl, HDL 44 (12) mg/dl, VLDL 17 (8) mg/dl, TG 84 (42) mg/dl. There weren't correlation with TBARs versus status nutritional.

Conclusions: The result showed that intake of Retinol is associated with the concentration of TBARs, suggesting a negative oxidative profile of epileptic children after to start the ketogenic diet.

Key words: oxidative stress, obesity, vitamins

PO570**WHOLE AND REFINED GRAINS HAVE DIFFERENTIAL EFFECTS ON CARDIOMETABOLIC MARKERS IN OVERWEIGHT INDIVIDUALS WITH NORMAL FASTING GLUCOSE VERSUS PREDIABETES**

⁷Center for Excellence in Nutrigenomics, The Pennsylvania State University, University Park, PA, USA

⁸Department of Nutritional Sciences, The Pennsylvania State University, University Park, PA, USA

Background and objectives: Epidemiological studies show that higher whole grain intakes are associated with lower risk of type 2 diabetes. We measured body composition and metabolic biomarker responses in individuals with prediabetes (PD; fasting glucose ≥ 100 mg/dL) and normal glucose levels (NG; < 100 mg/dL) on healthy diets containing either whole (WG) or refined grain (RG) products.

Methods: A randomized, controlled-feeding, parallel study was conducted in abdominally obese individuals who had or were at risk for metabolic syndrome. Participants were randomized to WG (n=24) or RG (n=25) diets for 12 weeks (6 weeks isocaloric, 6 weeks hypocaloric). Body composition and metabolic biomarkers were measured at baseline, 6 and 12 weeks. Screening and baseline glucose values were averaged to determine PD (WG: n=9, RG: n=8) or NG (WG: n=15, RG: n=17) status.

Results: Compared to the NG group, the PD group had higher glucose (PD: 103.3 ± 4.4 , NG: 93.3 ± 4.4 mg/dL, $P < 0.0001$) and tended to have higher BMIs (PD: 34.4 ± 2.8 , NG: 32.8 ± 4.1 kg/m², $P = 0.09$) at baseline. Fasting glucose was lowered in NG individuals on both diets after 12 weeks (WG: -2.4 ± 5.4 , RG: -1.4 ± 4.8 mg/dL); however, glucose reductions in PD participants occurred on the WG diet only and not the RG diet (WG: -7.5 ± 5.3 , RG: 0.3 ± 5.4 mg/dL; $P = 0.08$). PD individuals on the RG diet tended to experience weaker reductions in BMI ($P = 0.07$), % abdominal fat ($P = 0.06$), CRP ($P = 0.09$) and IL6 ($P = 0.03$) compared to the other subgroups – PD on the WG

diet and the NG group. PD was completely resolved on the WG diet (n=9/9) and in only 13% (n=1/8) of the RG group.

Conclusions: For individuals with prediabetes, all RG products should be substituted with WG to aid in glucose and weight control.

Key words: whole grain, cardiometabolic, prediabetes

PO571**BIVARIATE ANALYSIS: AGREEMENT BETWEEN VALUES OF WAIST CIRCUMFERENCE OR BODY MASS INDEX IN THE DIAGNOSIS OF EXCESS FAT IN ADOLESCENTS**

D. Oliveira¹, W. Conde¹

¹School of Public Health - University of Sao Paulo, Sao Paulo, Brazil

Background and objectives: Reassess relations between the diagnosis of nutritional risk based on body mass and body composition is an addition important for study of nutritional assessment. Objective: To assess the performance of the BMI or WC in the diagnosis of excess fat in adolescents.

Methods: We used data of 1816 adolescents in the study 'Health and nutrition of schoolchildren the city of Sao Paulo.' Nutritional status was described by BMI, WC and body composition - inferred by phase angle and sum of skinfolds. Diagnostic odds ratio (DOR), AUC values and bivariate graphs based on body composition values were analyzed to assess the ability of BMI and WC in screening for adiposity according to BMI classifications (reference Brazilian and international) and the criterion of WC (reference Dutch).

Results: BMI and WC shows a positive correlation ($r > 0.70$) with fat folds. In both sexes, the three criteria suggest proper identification of excess fat mass ($AUC \geq 0.90$) and high levels of specificity and sensitivity. The DOR values are 64.6 and 38.6 for BMI by national and international reference, respectively and 38.3 for boys in DC. In girls, the same sequence values are 49.5, 56.2 and 31.9. A comprehensive analysis of indicators, based on the DOR or vector graphic, indicates that the performance of the BMI is greater than the WC in both sexes. The bivariate analysis of the body compartments used in this study is noteworthy since the same analysis gathers standardized values of two different dimensions of body composition.

Conclusions: Overall performance of BMI to discriminate between individuals with and without excess body fat is higher than WC. The results support the use of BMI for monitoring the health of adolescents and, for the first time present this evidence based on bivariate analysis of body composition.

Key words: Body Composition. Nutritional Assessment.

PO572**FINDING EVIDENCE TO DEMONSTRATE THE EFFECTIVENESS OF HUMAN-RIGHTS BASED APPROACHES TO NUTRITION AND HEALTH PROMOTION**

C. de la Cruz¹, S. KC², J. Amare³, E. Girerd-Barclay⁴

¹Department of Public Health, Faculty of Health and Medical Sciences, Copenhagen University, Copenhagen, Denmark

²Public Health Nutrition and Food Policy Department, Metropolitan University College, Copenhagen, Denmark

³Department of Integrated Food Studies, Aalborg University, Copenhagen, Denmark

⁴Save the Children Sweden, S 107-88 Stockholm, Sweden

Background and objectives: Promoters of human Rights (HR) submit that all people should be well-informed about HR, empowering them to claim their rights. HR principles oblige governments to promote, protect, and respect HR. Sixty years after the Universal Declaration of HR (UDHR), and 20+ years since the Convention on the Rights of the Child (CRC), many adults and children are deprived of one or more basic HR. A HR framework offers the most substantial approach to nutrition and health promotion, by addressing cause and effect. The study aimed to document available evidence of the effectiveness of a HR-based approach in promoting nutrition and health among two vulnerable groups, women and children, in order to justify its adoption by the global community.

Methods: A literature review of scientific and peer-reviewed articles, and grey literature was carried out to identify sources of evidence on the effectiveness of a HR-based approach to nutrition and health promotion within the past decade. Case studies were developed on HR-based nutrition and health promotion in Mali, Ethiopia and the United States of America (USA).

Results: A lack of research on the effectiveness of rights-based approaches to nutrition and health promotion has resulted in the scarce availability of scientific evidence to justify their adoption by governments and other duty-bearers. Needs-based approaches are more widely known and assessed, possibly discouraging substantial shifts to rights-based frameworks.

Conclusions: A HR framework to promote global maternal and child health is promoted universally as the most appropriate, holistic, effective and sustainable approach to public health and nutrition promotion, yet lacks substantial scientific evidence to demonstrate its relative or overall advantages, compared to needs-based approaches. Further research is vital to gather evidence on interventions in order to justify the adoption of rights-based approaches to nutrition and health promotion.

Key words: HR-based approach, effectiveness

PO573**ASSOCIATION OF BMI AND NUMBER OF SIBLINGS AMONGST CHILDREN IN PERU: RESULTS OF A LONGITUDINAL STUDY**

M R. Liria¹, M E. Penny¹

¹Instituto de Investigación Nutricional, Lima, Perú

Background and objectives: The number of siblings has been shown to be one of the factors associated with overweight and obesity in children. This study evaluated the association between number of siblings and the risk of overweight and obesity in a cohort of children followed in the Young Lives Project, Peru.

Methods: Analysis was conducted on longitudinal data of 1870 children measured on 3 occasions: round 1: 5 and 22 months of age; round 2: 53 and 75 months; round 3: 85 and 105 months. Nutritional status was evaluated using BMI Z-score (WHO 2006). Overweight/obesity was classified as z-score > 1 SD. The OR for risk of overweight/obesity was the independent variable and the number of siblings as categorical variable: 0, 1 and 2 or more siblings. Data was weighted according to the study design and adjusted for sex, age of child at round 1, maternal BMI and education, a household well-being index and geographic region (Lima, coastal Peru, highland or rain forest).

Results: 37%, 23% and 23% of the children had no siblings at rounds 1, 2 and 3 respectively. 25%, 30% and 31% had 1 sibling at each round respectively. Having 2 or more siblings was associated with 36% lower risk of overweight and obesity than no siblings when comparing data between rounds 1 and 3 (OR: 0.64; IC 95%:0.42-0.97) and 41% lower risk between rounds 2 and 3 (OR: 0.59; IC 95%: 0.39-0.88).

Conclusions: Having siblings was associated with lower risk of overweight and obesity. The number of siblings could favour greater activity of the children and/or the distribution of food consumed in the household. Studies are required to identify the factors that favour lower risk.

Key words: obesity, overweight, siblings, Young Lives, Peru

PO574**GUIDELINE DEVELOPMENT BASED ON CONSUMER NEED**

T. Gill¹, S. Boylan¹, P. Vita¹

¹Boden Institute, University of Sydney, Sydney, NSW, Australia

Background and objectives: Nutrition-focussed guidelines usually commence with a review of the evidence and only once the core guidelines have been developed are attempts made to accommodate the range of issues important to consumers. We

propose that to improve the relevance and understanding by consumers that guideline development should commence with an assessment of consumer needs and understanding and an identification of factors influencing their food and nutrition behaviours. These should guide the evidence reviews and guidelines framework rather than vice versa. The objective of this study was to assess the content of guidelines driven by an assessment of consumer needs compared against statement derived from a traditional evidence review.

Methods: Prior to the development of a set of guidelines for weight management in the community, we undertook a review of the literature and defined the key messages supported by that review. The guideline development process took a different route beginning with consumer focus groups to identify current consumer understanding, priorities around weight and their perceived needs for information. Literature reviews then focussed on addressing those needs and correcting any consumer misunderstanding around weight control. The final guidelines were developed by a health communications group. We compared our purely evidence-based statements against these guidelines to identify any key variations.

Results: There was a good level of agreement between the two sets of messages but divergence in the way messages were framed, the priority they were given and the level of tailoring to different sectors of the population. The consumer guidance also addressed issues defined as important by consumers but not by the evidence review.

Conclusions: Consulting with consumers early in guidelines development process does not pervert the evidence base and may allow guidelines to be more relevant and engaging to consumers.

Key words: Guidelines, consumers, behaviour change, obesity

motion of nutrition, livelihoods and agriculture linkages; and high-impact nutrition and hygiene practices in Odisha, India. Building on an agricultural extension platform for the development/ dissemination of participatory videos, community videographers showcase improved practices, often starring early adopters of high-impact behaviors.

Methods: The adaptation of the Digital Green model was piloted in thirty villages in two blocks of Keonjhar District. Community-led formative research informed the development/ adaptation of a UNICEF training package for a range of community agents involved in the project, and the production of context-specific nutrition and agriculture-focused video content. Activities are supported by a local community-development NGO, where community agents use low-cost video cameras, simple editing equipment, and battery operated pico projectors for bi-weekly disseminations. Videos feature mothers and other community members, speaking in their own language, about their individual personal experiences with selected key nutrition practices. The approach uses a “dialogue” or “reflective” process among peers, rather than a traditional nutrition education approach of outside “experts” informing clients. Data on intention to adopt, and verification of adoptions of key behaviors is collected and organized using near real-time analytical dashboard, facilitating decision-making and the production of subsequent videos.

Results: This new application of participatory video for nutrition social and behavior change is stimulated high interest within both the nutrition and agriculture communities. Routine behavior adoption data, and implementation tools are being compiled to provide guidance for adaptation, and scale-up.

Conclusions: This project highlights the potential of community-led video for fostering both social and individual behavior change. Tools, videos and findings from monitoring related to behavior adoption will be shared with participants.

Key words: participatory video, behavior change

PO577

BODY IMAGE, DISTURBED EATING ATTITUDES, WEIGHT CONTROL BEHAVIORS OF FEMALE MIDDLE SCHOOL STUDENTS ACCORDING TO THE BODY MASS INDEX

H.K. Moon¹, H.J. Song¹

¹Department of Food and Nutrition, University of Dankook, Korea

Background and objectives: Perception of body image is the potential predictor of attitude for the diet. Misconception for body image for female students is unexplored in Korea. In this study, body shape satisfaction, eating attitude and weight control will be examined by the Body Mass Index(BMI).

Methods: 407 female students (aged 12-16 years), completed the survey. Satisfaction of self-body shape, Risk of Disturbed Eating Attitudes (Eating Attitude Test : EAT-26), and Weight control Behavior are examined. Height and Weight were measured. Cutoff points for gender- and age-specific BMI percentile were based on the 2007 Korean National Growth Charts. Data were analyzed using SPSS (Ver 18.0).

Results: Distribution of the subjects by BMI were 1.8% of underweight, 73.2% of normal, 14.2% of overweight, and 10.9% of obese. There are significant differences between self perceived current body image and self perceived ideal body image. The dissatisfaction of body image is higher in obese than other groups ($p < 0.001$). 51.3% of studied female students unsatisfied with their body image, while 2.6% were very satisfied. Among unsatisfied students with their body image, underweight were 3 (42.9%), normal were 150 (52.1%), overweight were 23 (42.6%) and obese were 25 (58.1%). EAT-26 total scores were significantly higher in obese group (overweight : 16.50 9.03, obese : 16.33 7.16) compared with nonobese group (underweight : 10.71 1.79, normal : 13.72 8.10) ($p < 0.05$). Attempted to weight control were significantly different by BMI ($p < 0.001$).

Conclusions: This study concludes that there are desire to become thin in female students, even those with normal BMI. Many female students are dissatisfied with their body image. It is harmful to their health and nutritional status. These findings suggest there are needs to encourage female students for maintaining health weight. Higher score of EAT-26 was associated with dissatisfaction of self-body image. It leads to unhealthy behaviors among obese female students.

Key words: Eating Attitude Test, BMI

PO578

FACTORS ASSOCIATED TO AUTO-DECLARED HYPERTENSION IN A POPULATION-BASED STUDY IN CAMPINAS/SP - BRAZIL

L. Marin-Leon¹, A.M. Segall-Corrêa¹, D. Camargo¹

¹Department of Public Health, State University of Campinas, Brazil

Background and objectives: Hypertension is a chronic health problem, associated to complications that decrease quality of life and increase health expenses. Objectives: To describe demographic, socioeconomic and health variables associated with hypertension.

Methods: Cross-sectional study with a population-based random sample of adults 18 years or older living in an industrial city of one million inhabitants in the state of Sao Paulo. A household survey was carried out in 2011-2012 and 546 people were interviewed. Hypertension was considered present when people informed that they had had this diagnosis made by a

physician. A multiple logistic regression model was built with independent variables that were associated with hypertension at a significance level of less than 0.20 in the univariate logistic regression; variables with $p < 0.05$ remained in the final model.

Results: The prevalence of hypertension was 31.6% varying from 13.3% among 20-34y to 56.4% among 60y and older. The only food meaningfully associated to hypertension was eating green leaves less than daily (OR 1.79 95%CI 1.19-2.69). Variables that remained in the final regression model were age range, occupation, having cholesterol problem, diabetes and overweight/obesity defined by anthropometry; with a higher chance of hypertension among people 50 years and older (OR 2.52, 95%CI 1.57 - 4.04) ($p < 0.001$); without formal permanent occupation (OR 2.08 95%CI 1.20-3.60) ($p = 0.008$), cholesterol problem (OR 2.38 95%CI 1.49-3.79) ($p < 0.001$), diabetes (OR 2.64, 95%CI 1.37-5.07) ($p = 0.004$) and overweight/obesity (OR 1.72, 95%CI 1.03-2.88) ($p = 0.040$). Although being in hypertension on the mean of three measures of arterial pressure at the survey is correlated to the dependent variable, it was included in the model because the correlation coefficient was relatively low (0.280) (OR 2.63, 95%CI 1.60-4.32%) ($p < 0.001$).

Conclusions: health factors associated to hypertension are those described to integrate the metabolic syndrome.

Key words: hypertension; diabetes; obesity; chronic diseases

PO579

EXPERIMENTAL DESIGN OF REVERSED-PHASE HIGH PERFORMANCE LIQUID CHROMATOGRAPHIC CONDITIONS FOR SIMULTANEOUS DETERMINATION OF CAFFEINE, ALLURA RED, PONCEAU AND CARMOISINE

T. Dinç¹, B. Aþçý¹, O. Aksu Dönmez¹

¹Yildiz Technical University, Turkey

Background and objectives: Box-Behnken design for three factors and three levels was applied to optimize the chromatographic conditions of the RP-HPLC separation of caffeine, allura red, ponceau and carmoisine. Using the C18 reversed phase column, the influence of pH, flow rate and solvent ratio of mobile phase were investigated. To study of effects of selected three factors fifteen runs are used. The resolution was chosen as analytical response. The optimum conditions for this determination were found to be pH 7, flow rate 1.2 mL-1, solvent ratio 20:80 acetonitril/buffer. As a result the separation is accomplished in a short analysis time with a good resolution for all components peaks of interest. The optimized method was successfully applied to the determination of caffeine, allura red, ponceau and carmoisine in food.

Key words: Caffeine, allura red, ponceau, carmoisine, RP-HPLC determination.

PO580**KETOGENIC DIET [KD] AS A SUCCESSFUL TREATMENT FOR FEVER INDUCED REFRACTORY EPILEPSY SYNDROME [FIRES]**

R. Sudhakar¹, JS. Goraya²

¹Department of Dietetics, Dayanand Medical College & Hospital, Ludhiana 141001, Punjab, India

²Department of pediatrics, Dayanand Medical College & Hospital, Ludhiana-141001, Punjab, India

Background and objectives: Status Epilepticus [SE] is associated with a high risk of morbidity and mortality despite the availability of Anti Epileptic Drugs [AEDs]. **OBJECTIVE :** To establish the role of KD in Refractory Status Epilepticus [RSE].

Methods: A 7 yr, 6 months old boy with FIRES successfully treated with KD

Results: A previously healthy, male admitted to the Pediatric Intensive Care Unit [PICU] with recurrent partial seizures with secondary generalization. EEG showed electrographic seizures from bilateral temporal lobes with generalization. Treated with multiple AEDs including Valproate, Levetiracetam, Phenobarbital and Phenytoin but electrographic seizures persisted. Midazolam infusion did not stop the seizures. Intravenous Methylprednisolone was ineffective. IVIG was initiated but seizures continued. A 4:1 ratio KD was initiated via nasogastric tube, after which he experienced significant improvement in seizure control. Seizures stopped by day 5 of initiating the KD. Later, the patient developed choreo-athetoid movements, which resolved spontaneously over 2 weeks. Autoimmune work up including NMDA antibodies was negative. At 3 months follow-up, patient has remained seizure free on KD and anti convulsants. Repeat EEG shows only mild background slowing without any interictal epileptiform abnormalities.

Conclusions: After achieving seizure control with concurrent use of KD and AEDs the patient has continued to make progress in motor and cognitive function. FIRES associated SE patients may benefit from the inclusion of KD in their treatment regimen.

Key words: Ketogenic Diet, SE, FIRES

PO581**COMPARISON OF INFANT FEEDING PRACTICES IN TWO HEALTH SUB-DISTRICTS WITH DIFFERENT BABY FRIENDLY STATUS IN MPUMALANGA PROVINCE**

M. van der Merwe¹, L. du Plessis², H. Jooste³

¹Integrated Nutrition Programme, Department of Health, Nelspruit, Mpumalanga, South Africa

²Division of Human Nutrition, Stellenbosch University, Cape Town, Western Cape, South Africa

³Research and Projects, National Institute for Higher Education, Nelspruit, Mpumalanga, South Africa

Background and objectives: To assess the impact of the implementation of the Baby Friendly Hospital Initiative on infant feeding practices in two sub-districts with different Baby Friendly status.

Methods: The design was a cross sectional, descriptive, observational study with an analytical component. The study population consisted of mothers with infants from birth to six months old, attending postnatal care at primary health care facilities in the two sub-districts on the days of data collection. Data was collected through two interviewer-administered questionnaires. In Emalahleni (all public health facilities were Baby Friendly), 218 mother-and-infant pairs took part in the study and 217 in Mbombela (none of the facilities were Baby Friendly), totalling 435 respondents. Five infant feeding indicators were used in data analysis, namely: early initiation of breastfeeding; exclusive breastfeeding, exclusive replacement feeding and mixed feeding rates and the age of introduction of complementary foods.

Results: In Emalahleni, 11.5% (n=25) of the infants received infant formula as a first feed, compared to 34.7% (n=75) of the infants in Mbombela. Early initiation of breastfeeding occurred in 70.2% (n=134) of the breastfed infants in Emalahleni, compared to only 39.4% (n=54) of the infants in Mbombela. The exclusive breastfeeding rate was significantly higher in Emalahleni (n=131; 60.1%) compared to Mbombela (n=103; 47.5%). Mixed feeding rates did not differ significantly between the two sub-districts. The mean age of introduction of complementary foods were 45 days, ranging from birth to 4 months, which is earlier than the recommended age of 6 months.

Conclusions: The implementation of the BFHI is associated with more optimal infant feeding practices among mothers with children under 6 months of age. It is concluded that strengthening of the implementation of the BFHI will improve infant feeding practices at a community level.

Key words: Baby Friendly Hospital Initiative, Infant feeding practices, Breastfeeding

PO582**ASSOCIATION BETWEEN VITAMIN B12 STATUS AND NEURAL ACTIVITY ACROSS LIFE CYCLE: AN INDIAN SCENARIO**

S. Sambashivaiah¹, T. Thomas², S. Krishnamachari³, A. Kurpad¹, M. Vaz¹

¹Department of Physiology, St John's Medical College, Johnnangar, Bangalore, India

²Department of Epidemiology and Statistics, St John's Research Institute, Bangalore, India

³Department of Psychiatry, St John's Medical College and Hospital, Bangalore, India

Background and objectives: The true prevalence of vitamin B12 deficiency in India is unknown, however it is likely to be high which may impair absorption of vitamin B12. Objectives: To compare cardiac autonomic, peripheral neural activity and cognitive functions in elderly and young adults stratified by vitamin B12 status and following vitamin B12 supplementation. To assess autonomic nervous activity in children born to women with vitamin B12 deficiency during pregnancy.

Methods: 47 healthy elderly subjects, 79 healthy children born to deplete and replete mothers and 34 young adults were evaluated. All subjects underwent plasma vitamin B12, anthropometry, heart rate variability (HRV), peripheral neural and cognitive assessment. Young adult and elderly subjects also underwent vitamin B12 supplementation for 3 months. In sub-sample plasma MMA and Hcy were also estimated.

Results: Low frequency (LF) HRV was significantly lower in elderly participants with low vitamin B12 levels; this was reversed with supplementation. LF HRV reduced significantly (by 53%) in children of vitamin B12 deplete mothers ($P=0.03$). There was a significant association between LF and total power HRV with cord blood vitamin B12 levels. There was no difference in cardiac autonomic function in young adults of low vitamin B12 levels as compared to those of higher status. However, in a subgroup analysis there was a strong negative association between MMA and LF-HRV ($r=-0.80$, $P=0.01$).

Conclusions: Cardiac autonomic nervous activity is reduced in vitamin B12 deficient subjects across the entire life cycle. Cardiac autonomic nervous changes in vitamin B12 deficient subjects occur in the absence of peripheral neural and cognitive deficits. Plasma MMA is more strongly associated with HRV measures than plasma vitamin B12. Vitamin B12 supplementation in elderly vitamin B12 deficient subjects is associated with a significant improvement in cardiac autonomic activity.

Key words: Vitamin B12, Healthy, Autonomic nervous system, Heart rate variability, life cycle

PO583**FOOD NUTRITIONAL TABOOS AMONGST ESAN WOMEN IN EDO STATE, NIGERIA**

E. Idialu¹

¹Department of Vocational and Technical Education, Ambrose Alli University, Ekpoma, Edo State, Nigeria

Background and objectives: Food taboos can be described as beliefs that forbid the ingestion of certain foods that are highly nutritious by a particular group of people. These taboos most of the time are maintained by culture, beliefs, religion, customs and-economic status of specific groups. This paper examines food nutritional taboos among the Esan women in Edo State, Nigeria. women aged 20 years and above in the five Local Government Areas in Esanland in Edo State were the study participants.

Methods: Data were collected using a questionnaire and focus group discussion. The data collected were analysed using descriptive statistics.

Results: The result revealed among others that food nutritional taboos is one of the harmful traditional practices that exists among the Esan people of Nigeria; that its perceived harmfulness is very high and its prevalent rate is also high. The factors that subsist the practice include the following: fear of what will happen if they disobey the tradition by eating the forbidden foods; obedience to traditional norms and values and religious beliefs.

Conclusions: Based on the findings and conclusion, recommendations are advanced which includes, eradication of taboos through advocacy, mobilization, capacity building and service delivery, government intervention and institution of health education programmes that will include healthy nutrition for the masses, educating them on the disadvantages of food taboo practices and these are to be disseminated using television, mass campaign media, mobilization of community leaders and one-one reach programme for rural dwellers.

Key words: Nutrition, Advocacy, Mobilization, Health Education

PO584**NUTRITIONAL AND TOXICOLOGICAL EVALUATION OF OIL PALM ORYCTES RHINOCEROS LARVA OIL***O. Oluba¹, K. Adebisi²*¹Joseph Ayo Babalola University, Nigeria²Kwara State University, Nigeria

Background and objectives: Oil palm rhinoceros beetle larva (popularly called itu in Southwest Nigeria) is considered as a delicacy in Nigeria and are collected for food. It is indeed a good source of protein and other nutrients and it is sold along road side in the Niger Delta region of Nigeria. The oil does not contain any unusual fatty acids, and it is a rich source of essential fatty acids C18:2 and C18:3 that make up 60.3% of its total fatty acid composition.

Methods: Acute toxic potential in rats and the systemic effects and nutritional quality were assessed in a 13 week feeding study in weanling albino rats using a diet containing *Oryctes larva oil* (OLO) or soybean oil (SBO) (as the control) at a 10% level as the sole source of dietary fat. RSO did not manifest any acute toxic potential. Food consumption, growth rate and feed efficiency ratio of rats fed OLO were similar to those fed SBO.

Results: The digestibility of this oil was found to be 95%, as compared to 97% for SBO. There were no macroscopic or microscopic lesions in any of the organs which could be ascribed to the OLO incorporation in the diet.

Conclusions: Thus the current data show that OLO could be used for edible purposes. However, it will be necessary to process the oil to remove free fatty acids to make it organoleptically acceptable.

Key words: *Oryctes rhinoceros larva*, oil, nutritional quality

PO585**NUTRICION EN LA AMERICA LATINA***A. Amaral¹*¹Usp, Descalvado, Brazil

Estudios acerca de nutrición en América Latina y Brasil incluyendo la alimentación en escuelas de primer grado y problemas relacionados con la salud. Conclusiones - 45% de las escuelas no tiene una alimentación adecuada a la edad

PO586**EFFECT OF TWO-DAYS SEVERE CALORIE RESTRICTION ON ADIPOKINE SECRETION IN SUBCUTANEOUS ADIPOSE TISSUE IN OBESE WOMEN***M. Siklova-Vitkova¹, L. Rossmeislova¹, L. Malisova¹, J. Kracmerova¹, V. Stich¹*¹Department of Sports Medicine, Third Faculty of Medicine, Charles University, Prague, Czech Republic

Background and objectives: Beneficial metabolic effects of calorie restriction are found in the early stage after bariatric surgery procedures or during very-low-calorie diet (VLCD) regimens. They appear before a marked weight reduction occurs and may be caused by calorie restriction per se. Modulation of endocrine function of adipose tissue could play a role in this process. The aim of this study was to examine the secretion of adipokines in adipose tissue during early stage of VLCD.

Methods: 13 obese women (BMI 33,3±1,3 kg/m², fat mass (FM) 40,2±2,5 kg) were examined at the 3rd and 60th day of VLCD (providing 3400 kJ/day). Body composition (using bioimpedance), blood sampling and needle biopsies of subcutaneous abdominal adipose tissue (SCAAT) were performed. Secretion of a set of adipokines (leptin, interleukins (IL)-6,-8,-10, TNF α , macrophage-chemoattractant-protein (MCP-1)) was measured in the conditioned medium of the biopsy-derived explants of SCAAT incubated in Krebs/Ringer phosphate buffer for 4 hours. Insulin resistance was assessed using Homeostasis Model of Assessment (HOMA-IR).

Results: On day 3, body FM did not change (40,2±2,5 vs 40,1±2,6 kg, NS), HOMA-IR was lower (2,41±0,25 vs 1,64±0,16, p<0,01) and secretion of all of the adipokines was not changed when compared with the pre-diet condition. On day 60, FM was lower (p<0,001), HOMA-IR was lower (p<0,01), secretion of leptin was lower (p<0,05) and secretions of IL-8, IL-10, MCP-1, and TNF α were higher (for all of them p<0,05) when compared to the pre-diet condition.

Conclusions: Secretion of adipokines from SCAT is not changed at the early stage (3rd day) of VLCD. This suggests that the diet-induced modulation of adipokine secretion in adipose tissue is not involved in pathogenesis of the early metabolic changes induced by severe calorie restriction without weight loss.

Acknowledgement: Study was supported by PRVOUK grant of MSMT Czech Republic

Key words: very-low-calorie diet, adipose tissue, adipokine

PO854**IMPACT OF PERINATAL DIFFERENT INTRAUTERINE ENVIRONMENTS ON CHILD GROWTH AND DEVELOPMENT IN THE FIRST SIX MONTHS OF LIFE – IVAPSA BIRTH COHORT**

V L. Bosa¹, J R. Bernardi¹, M. Nunes¹, A R. Reis¹, A B. Mucellini¹, E N. Gonçalves¹, I C R. Werlang¹, M B. Alves¹, M L. de Brito¹, P B. Rocha¹, R. da S. Corrêa¹, R. de S. Escobar¹, R S. Reis¹, C H. da Silva¹, P P. Silveira¹, M Z. Goldani¹

¹Núcleo de Estudos da Saúde da Criança e do Adolescente, Hospital de Clínicas de Porto Alegre, Faculdade de Medicina, Universidade Federal do Rio Grande do Sul, Brazil

Background and objectives: Epidemiological studies in different parts of world have shown the relation between the influences of perinatal events and impact the individual's health in the medium and long term. The aim was describe the effects of variations in perinatal environmental on children's health in the first six months of life.

Methods: This is a thematic, prospective, birth cohort to assess the interactions between the maternal phenotype during gestation (maternal smoking, hypertension, diabetes-DM, intrauterine growth restriction-IGR) and their associations with outcomes related to growth, behavior and neurodevelopment. Participants were postpartum women assisted by Grupo Hospitalar Conceição and Hospital de Clínicas de Porto Alegre (HCPA) residing in Rio Grande do Sul, Brazil. Six interviews were performed at home (7, 15 days and 3 month) or at the clinical research center (CRC) in HCPA (postpartum, 1 and 6 month). Interviews were conducted with 90 mother-child pairs (16 DM; 24 smoking; 13 hypertension; 10 IGR; 27 control groups). The main race reported was Caucasian (54). The mean age was 26.3 years (16.5-41.5 years) and the average education was 8.63 years. Only 18 (20%) women reported being unmarried.

Results: Multiparous were 60 (66.7%), with an average of 2.05 (\pm 1.32) children. The average family income was 670.3 (\pm 331) dollars. The average number of people living in the home was 4.9 (2-13 persons). The average Body Mass Index before pregnancy was 25.3 kg/m² (overweight). Most of the children were vaginal delivery (51), being more prevalent in boys (47). Mean weight, length and head circumference of children at birth was 3132.1 (\pm 538.0) g, 47.7 (\pm 2.6) cm and 33.9 (\pm 1.7) cm, respectively.

Conclusions: The research is not concluding and the sample is small and descriptive results, but we emphasize the following schedule and meeting the targets set in relation to outcomes.

Key words: Infant, DOHaD, Programming, Barker hypothesis.

PO1425**WORKING TIME CAN INFLUENCE DIET QUALITY**

K. Hemiö^{1,3}, K. Viitasalo², S. Puttonen³, J. Lindström¹

¹Department of Chronic Disease Prevention, National Institute For Health and Welfare, Helsinki, Finland

²Finnair Health Services, Vantaa, Finland

³Human Factors at Work, Finnish Institute of Occupational Health, Helsinki, Finland

Background and objectives: Shift work is known to increase risk for chronic diseases. To prevent the harmful effects more detailed knowledge of shift workers' lifestyle habits are needed. Particularly studies on women are lacking. Our aim was to determine the effect of different working times on dietary intake.

Methods: The occupational health care of an airline conducted type 2 diabetes prevention programme. The health check-up included physical examinations, laboratory tests and a questionnaire containing a validated 16-item food intake questionnaire. Intake of fat (E%), saturated fat (E%), sucrose (E%), fiber (g), vitamin C (mg), vitamin D (μ), and iron (mg) were calculated. Altogether 1347 employees were eligible for analyses. They were divided into three working time groups: day work, shift work and in-flight work. Nutrient intakes between the working time groups were compared using analysis of variance.

Results: In men, the energy intake from fat and saturated fat was the highest in shift work group and the lowest in in-flight work group (fat 33.4 E% vs. 32.5 E%, $p < 0.05$; saturated fat 12.4 E% vs. 12.1 E%, $p < 0.05$). After adjustment for age and education the differences between the groups were no longer statistically significant. Male in-flight workers had lower intake of iron than the other male workers. In women, energy intake from sucrose was the highest in in-flight work group (8.8 E%) compared with day work group (8.3 E%, $p = 0.02$). Adjustment for age, education, or stress did not affect the association. There were no differences between the groups in the intake of fiber, vitamin D, or vitamin C among men or women.

Conclusions: Irregular working hours may impair diet quality and increase the risk for chronic diseases. Nutrition counselling should be part of shift workers' health check-up to lower the risk for chronic diseases.

Key words: shift work, diet quality

PO1697

THE RELATIONSHIP BETWEEN SUBJECTIVE SYMPTOMS OF COMPLAINT AND DIETARY, EXERCISE HABITS OF SCHOOLCHILDREN

K. Miyanishi¹, H. Kojima², N. Tanabe¹, H. Sone¹, F. Arai¹, A. Tamura¹, Y. Kontai¹

¹Department of Health and Nutrition, Nigata, Japan

²Geriatric medical center of Niitsu, Nigata, Japan

Background and objectives: Physical and psychiatric complaint are increasing problem among Japanese schoolchildren. The purpose of this study was to examine the relationship between subjective symptoms of complaint and the dietary and exercise habits in schoolchildren.

Methods: A questionnaire on fatigue content, physical and psychiatric complaints of 19 items was administered to 166 male and 170 female schoolchildren 5th grade, and data from properly completed questionnaires were analyzed by the χ^2 test and a p-value of less 0.05 was considered to indicate a significant result.

Results: In male, fatigue in the whole body was related to low frequency of protein products and vegetable at breakfast, want to lie down was low frequency of protein consumption at breakfast and dinner, feel stiff in the shoulders was low frequency of vegetable at dinner, ach of waist and hand was low frequency of dinner, dizziness was low frequency of dinner and high midnight snacks, in males. In females, feel stiff in the shoulders was related to high frequency of protein products consumption at dinner and midnight snacks, constipation and diarrhea were related high frequency of protein products consumption at dinner and midnight snacks, constipation and diarrhea were related high frequency of dinner and midnight snacks consumption.

Conclusions: Complaint was related to low frequency consumption of protein products and vegetables, vegetables at breakfast and dinner, and low frequency of dinner, high frequency consumption of midnight snacks in males. In females, Complaint was related to high frequency consumption of protein products at dinner and midnight snacks.

Background and objectives: It is well known that osteoporosis are affected by aging and insufficiency gravity stimulus as the human walking. The present study investigate the influence of such resistance training as drop jump compare to low impact exercise as swimming in improving of bone minerals.

Methods: The study was carried out with 21 Wister rats divided into three groups each 7 rats, i.e. resistance exercise, low impact exercise and control. It is well known that osteoporosis are affected by aging and insufficiency gravity stimulus as the human walking. The present study investigate the influence of such resistance training as drop jump compare to low impact exercise as swimming in improving of bone minerals. The experiments were performed after basically 5 weeks breeding. During experiments periods for 8 weeks all animals were given standard laboratory diet and water feed freely per day. It was increased physical activity effects on drop jump from 25cm(1 week), 30cm(2 week), 35cm(3 week) to 40cm(4-8 weeks) as high impact training. In swimming group exercise were performed swimming 1 hour per day in 5 times per week by automatically pumping wave. The present study was carried out allowed experiments on laboratory animals in Nippon Sport Science University accordance to the principles of laboratory animal care.

Results: No significant changes in body weight in response from initial week to until 5 weeks were observed. Significant change in increasing was observed in 6 and 7 weeks training body weight ($p < 0.05$). After each one week exercise, hole femoris bone was isolated, bone density diagnosis both bone mineral content(BMC,g) and bone mineral density (BMD, g/cm²).One-way ANOVA was used for statistical analysis of data between difference group, and $P < 0.05$ was accepted for significance.

Conclusions: We observed more increased BMD in high impact training. However there was no significant difference in muscle mass.

Key words: training, bone minerals

²Molecular Biology and Gene Therapy Institute, CUCS, University of Guadalajara, Guadalajara, Jalisco, México

³O.P.D. Hospital Civil of Guadalajara "Juan I. Menchaca", Guadalajara, Jalisco, México

Background and objectives: Activation of hepatic stellate cells is crucial in liver fibrosis, which is perpetuated by growth factors and pro-inflammatory molecules. Caffeine has been shown to be able to modify these events in vitro studies. The aim was to determine if caffeine prevents experimental liver cirrhosis.

Methods: Liver cirrhosis was induced in Wistar rats. Animals were treated with caffeine (15mg/kg/day). The fibrosis degree and inflammatory infiltrate were evaluated and classified by Knodell index. Inflammatory infiltrate was quantified by immunohistochemistry. Gene expression was analyzed by QRT-PCR for Col-1, CTGF, TGF- β 1, TNF- β , IL-1 β , IL-6, SOD and CAT. Nrf2 and the activation of Snail-1 was analyzed by western blot. Expression of TNF- β was checked by ELISA, and the activity of SOD and CAT antioxidant enzymes was determined by zymography.

Results: Treatment with caffeine decreased fibrosis index. Knodell index also showed lower levels of fibrosis and necroinflammation. Expression of pro-fibrogenic genes CTGF, Col-1 and TGF- β 1, and pro-inflammatory genes TNF- β , IL-6 and IL-1 β significantly decreased in rats that received caffeine. Caffeine treatment decreased CD11b positive areas. SOD and CAT expression was greater in animals treated with caffeine, and we found a strong correlation with the enzymatic activity. Lower levels of the transcription factor Snail-1 were detected in treated rats, in contrast to NRF2, which increased in the presence of caffeine.

Conclusions: Our results suggest a potent effect of caffeine to limit pro-fibrogenic and pro-inflammatory response even in the presence of an inducer of liver cirrhosis. The mechanisms by which caffeine acts involve inhibition of transcriptional factor Snail -1, down-regulation of the expression of pro-fibrogenic genes as well as the activation of transcription factor Nrf2 which in turn activate the antioxidant enzyme systems, result-

ing in the prevention of inflammation and fibrosis. This results could be applied in different types of fibrosis.

Key words: Caffeine, hepatic cirrhosis, antifibrogenic, anti-inflammatory, antioxidant.

PO3301

ERYTHROCYTE ZINC PROTOPORPHYRIN IN SOUTH AFRICAN CHILDREN IS NOT AFFECTED BY LOW LEVEL LEAD EXPOSURE BUT BY SAMPLE PREPARATION (FREEZING)

B. Troesch¹, C M. Smuts², M E. Van Stuijvenberg³, M B. Zimmermann⁴

¹Nutrition Innovation Center, DSM Nutritional Products, Kaiseraugst, Switzerland

²Centre of Excellence in Nutrition, North-West University, Potchefstroom, South Africa

³Nutritional Intervention Research Unit, Medical Research Council, Cape Town, South Africa

⁴Institute of Food, Nutrition and Health, ETHZ, Zurich, Switzerland

Background and objectives: Increased erythrocyte zinc protoporphyrin (ZnPP) is an indicator of iron deficiency (ID), along with serum ferritin (SF) and transferrin receptor (TfR). However, ZnPP may also be elevated by lead exposure and chronic lead poisoning is widespread in poor urban areas. Our objective was to determine the usefulness of ZnPP as an indicator of ID in the presence of elevated serum lead (SPb) and to test the impact of freezing samples on the results.

Methods: We analyzed iron, lead and infection (C-reactive protein (CRP)) status in 1'106 South African children in an area with low infection rate and high prevalence of moderately increased SPb. In a subsample (n=190), we measured ZnPP additionally in fresh samples. The relationship between ZnPP and SPb was assessed using multiple-regressions with SF and TfR as co-variants. ID prevalence for each indicator was determined using established cut-offs. Correlation between fresh and frozen samples was determined using Pearson's correlation coefficient. Results: Prevalence of infection was 2.6% (CRP>10 mg/L) and did not affect the results significantly (p>0.05). ID prevalence ranged from 4.9% (SF) to 100% (ZnPPfrozen) and mean SPb was 5.3 μ g/dL (Bootstrapped 95%-CI 5.0-5.5 μ g/dL). We found no significant relationship between SPb and ZnPP (p> 0.05), even after correction for SF and TfR. ZnPP in fresh and frozen samples correlated well (r=0.988, p<0.001), but showed an intercept of 24 μ mol/mol heme, partially explaining the high ID rate according to the latter. Prevalences vary as they reflect different ID stages and due to the chosen cut-offs.

Conclusions: ZnPP is a promising indicator for iron status due to the simplicity of use in a field setting. However, before

its use can be advocated, adequate cut-offs for fresh and frozen samples respectively are needed. Also, the lack of effect of moderately elevated SPb on ZnPP needs to confirmation.

Key words: Zinc protoporphyrin, Iron deficiency, Lead

PO3306

BLOOD CELL TRANSCRIPTOMICS AS A SOURCE OF BIOMARKERS OF ARTICULAR HEALTH

J. Sánchez¹, M L Bonet¹, J. Keijer², E M. Van Schothorst², I. Möllner³, C. Chetrit⁴, D. Martínez-Puig⁴, A. Palou¹

¹Laboratory of Molecular Biology, Nutrition and Biotechnology (Nutrigenomics), University of the Balearic Islands and CIBER Fisiopatología de la Obesidad y Nutrición (CIBEROBN), Palma de Mallorca, Spain

²Human and Animal Physiology, Wageningen University, Wageningen, The Netherlands

³Instituto Poal de Reumatologia, Barcelona, Spain

⁴Bioiberica S.A., Palafolls, Spain

Background and objectives: We aimed to explore the feasibility of using total human blood RNA as a source of biomarkers of articular health improvement related to glycosaminoglycan (GAG) intake.

Methods: Healthy individuals with joint discomfort were enrolled in a prospective nutritional randomized, double-blind, placebo-controlled study. The supplemented group ate a yoghurt containing Mobilee™ - a preparation containing hyaluronic acid (65%) and other GAGs from rooster comb. The effect of Mobilee intake was evaluated in terms of functional and quality-of-life parameters. Whole-genome microarray analysis of blood samples from a subset of 20 subjects collected pre and post intervention was assessed.

Results: The daily supplementation with Mobilee significantly reduced pain intensity as compared to placebo. 165 known genes were differentially expressed in blood cells between Mobilee and placebo groups post-intervention, but not pre-intervention ($p < 0.05$; fold-change > 1.2). Some of them are related to GAG metabolism and extracellular matrix dynamics. In particular, a lower expression of glucuronidase-beta, matrix metalloproteinase 23B (MMP23B), xylosyltransferase II and heparan sulphate 6-O-sulfotransferase 1 (HS6ST1) was found in the Mobilee group. Correlation analysis indicated that the higher the expression of MMP23, involved in the breakdown of extracellular matrix, the higher the pain intensity, and the higher the expression of HS6ST1, responsible for 6-O-sulfation of heparan sulfate, the lower the indicators of knee muscular strength.

Conclusions: Genes related to GAG metabolism and extracellular matrix dynamics are differentially expressed in blood cells between the supplement and placebo groups post-intervention, and the expression of some of these genes correlated with indicators of articular pain and muscular strength. Thus, expression levels of specific genes in blood cells could be used as biomarkers of therapeutic benefit of preparations that promotes articular health.

Key words: Biomarker, glycosaminoglycan, articular health.

RESISTANT STARCH PROMOTES INCREASED FAT OXIDATION IN HEALTHY ADULTS

E. Giles¹, H. Kennon², I. Brown¹, J. Higgins³

¹Division of Diabetes, Endocrinology, & Metabolism, University of Colorado, Anschutz Medical Campus

²Department of Emergency Medicine, University of Colorado, Anschutz Medical Campus

³Department of Pediatrics, University of Colorado, Anschutz Medical Campus

Background and objectives: Resistant starch (RS) is any starch that is not completely digested in upper digestive tract and, so, passes to the bowel where it acts as dietary fiber and is a good substrate for fermentation. This study was conducted to determine the effect of RS consumption on whole body total energy expenditure (TEE) and substrate oxidation in healthy adults.

Methods: This was a randomized, single-blind, cross-over study. 18 healthy adults spent 24h in a whole room calorimeter to measure TEE and substrate oxidation rates in response to two different diets which were matched for total energy and macronutrient content (15% protein, 30% fat, 55% carbohydrate): 1) a digestible starch (DS) diet containing 0% RS, and 2) a RS diet containing 5% RS. All subjects were in energy balance for 3d prior to calorimetry and during the 24h calorimetry period.

Results: There was no difference in TEE or protein oxidation between the DS and RS diets. However, RS consumption caused a 30% increase in fat oxidation ($p = 0.049$) with a concomitant 20% decrease in carbohydrate oxidation ($p = 0.025$) relative to the DS diet. These data agree with an earlier report which showed that RS consumption increases fat oxidation relative to DS ingestion in adults. The current data, however, show that this is not associated with any change in TEE.

Conclusions: RS consumption, relative to DS, does not cause any change in TEE so its ingestion is unlikely to promote weight loss. However, changes in substrate oxidation that occur in response to a RS diet are likely to cause favorable changes in body composition over time. Thus, RS may prove useful for

successful weight maintenance and could possibly aide obesity prevention in conjunction with other lifestyle factors.

Key words: Resistant starch, fiber, energy expenditure, fat, obesity, substrate oxidation.

PO3300

COMPREHENSIVE LIST OF ENDOGENOUSLY PRODUCED VITAMIN D3 METABOLITES

I. Bendik¹, H. Hubert¹, C. Kilpert¹, L. Weber², Pr. Weber³, C. Carlberg⁴

¹Department Human Nutrition and Health, DSM Nutritional Products Ltd, Kaiseraugst, Switzerland

²Ontochem GmbH, Halle (Saale), Germany

³Nutrition Science & Advocacy, DSM Nutritional Products Ltd, Kaiseraugst, Switzerland

⁴Department of Biosciences, University of Eastern Finland, Kuopio, Finland

Vitamin D3 is essential for the maintenance of human health. It can be obtained either by diet or is synthesized in the skin from 7-dehydrocholesterol under the essential control of UV-B radiation. Vitamin D3 is then metabolized to 25-hydroxyvitamin D3 (25(OH)D3), the prevalent form of vitamin D in serum, and further to its hormonal active form, α ,25-dihydroxyvitamin D3 (α ,25(OH)2D3). α ,25(OH)2D3 acts as pleiotropic endocrine hormone via the transcription factor VDR and is involved in many physiological processes, such as the control of metabolism, cellular growth and immune functions. Some vitamin D3 metabolites, such as 25(OH)D3 or 24,25(OH)2D3, have been well described, while on others detailed information is largely elusive. Based on the triage theory of Ames (PNAS 2006;103:17589-94) additional endogenously produced vitamin D3 metabolites may serve similar functions in the human body as α ,25(OH)2D3 or could be used as nutritional biomarkers. In order to obtain a most comprehensive overview on vitamin D3 metabolites, we employed the ontology-based knowledge management (Ontochem) approach. The Ontochem Miner (OCMiner) protocol compiled all published endogenously produced vitamin D3 derivatives formed by the human body. OCMiner uses novel algorithms that allow interconnecting chemical and biological ontologies in published data. The present approach was limited to vitamin D3 metabolites, i.e. vitamin D2, D4, D5, D6 or D7 were excluded. However, already for vitamin D3 we could identify more than 50 vitamin D3 metabolites, which were reported since the 1960's. The finding of this large group of vitamin D3 compounds was surprising and requests future follow-up activities to explore their function and roles. The approach, the vitamin D3 metabolite ontology and potential applications in terms of nutritional biomarkers will be discussed.

Key words: Cholecalciferol, vitamin D3 metabolites, triage theory.

PO3303

PROFILING OF GLYCEMIC INDEX OF RICE SAMPLES USING HIGH RESOLUTION MELTING TECHNOLOGY

K. Bhaskaran¹, P. Kadamb, A. Amaldoss

¹Temasek Polytechnic, Singapore, Singapore

Background and objectives: Currently for regulatory and labelling purposes, the Glycemic Index (GI) of foods has to be determined by in-vivo testing which is expensive and time consuming. Thus, we looked at exploring novel and highly sensitive technology like High Resolution Melting (HRM) technology that was developed recently. HRM is used for the genetic analysis which can detect mutations, epigenetic differences and polymorphisms in double-stranded DNA. In this project, HRM is used to detect polymorphisms such as single base changes (SNPS) in the 16 different rice samples.

Methods: In vivo GI testing of 16 different types of local rice samples were conducted in an accredited GI testing laboratory. This was followed by genetic analysis using HRM technology. Genome sequences of rice were sourced from gene bank, conserved sequences were located and specific primers were designed to distinguish low, medium and high GI of rice samples. **Results:** The in vivo GI values of the 16 rice samples were categorised based on low, high and medium GI classification. This was then compared with the HRM profile. There a positive correlation between in-vivo GI values and HRM profile of rice.

Conclusion: The HRM technology is a novel, sensitive, cost-effective, high throughput technique, which can be used as a screening tool to characterise various rice samples, which can be beneficial to farmers, traders and end users.

Key words: Glycemic Index, High Resolution Melting technology.

PO3305**ESSENTIALITY OF NUTRIENTS: NEW FRONTIERS**

P. Jones¹, S. Jew², J.M. Antoine³, P. Bourlioux⁴

¹Richardson Centre For Functional Foods and Nutraceuticals, University of Manitoba, Canada

²Danone Institute International, France

³Groupe Danone, France

⁴French Academy of Pharmacy, France

Background and objectives: The objective was to examine existing definitions of nutrient essentiality and surrounding concepts.

Methods: An environmental scan for scientific literature was conducted January 2013 using combinations of the terms “criteria”, “definition”, “essential nutrient”, “nutrient essentiality”, and “conditionally essential nutrient”, using the search engines PubMed and Google Scholar. Contemporary nutrition textbooks were also consulted and hand searching carried out within the reference lists of textbooks and articles. Inquiries were forwarded to international regulatory bodies asking whether the terms “nutrient” and/or “essential nutrient” are regulated in their respective jurisdictions.

Results: They were reviewed by a panel of international experts. Results: Based on current definitions, a “nutrient” includes food constituents from six broad categories (minerals, water, carbohydrates, lipids, proteins and vitamins). “Non-nutrients” were defined as food constituents which do not fit in the six aforementioned categories, (e.g., phytochemicals, pigments and additives). Regulatory bodies including EFSA, FSANZ, HC and the US FDA do not currently have regulated definitions for the term “essential nutrient”, and generally refer to standard definitions found in textbooks. Definitions for the terms essential nutrient, non-essential nutrient, and conditionally essential nutrient were thus collated from various documents and textbook sources. Other terms have been proposed to describe food constituents which may not be considered essential in the traditional sense yet still provide additional health benefits. These include “lifespan essential” in reference to polyphenols; “physiological modulators”, originally proposed for antioxidant vitamins, but also applicable to many other food constituents; and “desirable”. The importance of the gut microbiome was not taken into account in the definition of essentiality nor nutrients.

Conclusions: In summary, existing categorization of nutrients as essential needs to be expanded to reflect advances in current science, as well as evolving definitions of the concepts of essentiality.

Acknowledgements: Supported by Danone Institute International.

Key words: Nutrient essentiality, guidelines, recommendations, food.

PO3307**BIOMARKERS OF DAIRY FOOD INTAKE IN ERYTHROCYTES**

A. Berriozabalgoitia¹, M. Virto, J.C. Ruiz de Gordo¹, G. Amores¹, M. de Renobales¹, L.J.R. Barrón²

¹Lactiker Research group; Biochemistry and Molecular Biology, University of the Basque Country/EHU, Vitoria-Gasteiz, Spain

²Food Technology, Faculty of Pharmacy, University of the Basque Country/EHU, Vitoria-Gasteiz, Spain

Most nutritional and epidemiological investigations study the relationship between the intake of dairy products and the development of cardiovascular disease using dietary surveys to determinate food intake. Coefficients of variation tend to be high, probably due to the high degree of subjectivity of dietary surveys, among other possibilities. In the literature, few studies show that some odd chain fatty acids (FA) (C15:0 and C17:0) and some trans isomers of C16:1 and C18:1 FA can be used as biomarkers of dairy fat intake, because they are present almost exclusively in ruminant foods.

A crossover intervention study was carried out (n=10) in two different groups, for 36 days. Half of the participants followed a daily diet of over 400g of whole fat dairy products during the first 18 days, while the other half had no dairy products. On day 18 both groups change diets. Blood samples were collected at the start, the change of diet and the end of the study.

FAs from erythrocytes were methylated by adding sequentially sodium methoxide and boron trifluoride. FAMES were extracted with hexane and separated by GC/FID, on a 100 m CpSil88 column. Peak identification was done by retention time and quantification by the internal standard method.

Of the 46 FA quantified, only 8 are presents in dairy foods. The erythrocyte concentrations of C17:0, vaccenic and ruminic acids highly correlated with dairy food intake ($r=0,7332$; $r=0,7689$; $r=0,7804$; $P<0,05$; respectively). These FA could be used as biomarkers of dairy food intake.

Key words: Biomarkers, dairy fat, fatty acid, erythrocytes.

¹²Department of Epidemiology and Community Medicine, University of Ottawa, Ottawa, Canada

¹³Department of Social & Environmental Health Research, Faculty of Public Health & Policy, London School of Hygiene and Tropical Medicine, London, UK

Background and objectives: Under-nutrition contributes to five million deaths of children under five each year. Throughout the life cycle, under nutrition contributes to increased risk of infection, lowered cognitive performance, chronic disease in adulthood, and mortality. In order to intervene effectively, we need to understand what works, what doesn't, and why. The aims of the present study were: 1 to assess the effectiveness of feeding programs for children aged three months to five years. 2 To undertake an implementation evaluation.

Methods: We included RCTs, CCTs and CBAs. Programs provided energy and nutrients through: hot or cold meals, snacks, take-home or home-delivered rations. Recipients had to be aged three months to five years, from all countries. We used standard systematic review methods and evaluated implementation, including nutritional quality of the food.

Results: Searches identified 29387 papers: 290 were retrieved and 28 studies met inclusion criteria; 26 were from LMIC. Energy provided in 15 studies ranged from 20% to 157% of the recommended daily allowance (RDA) and protein ranged from 18% to 425% of the RDI. Our meta-analyses showed small (.26 cm) significant effects on height gain in RCTs, but no other effects on growth. A few studies showed effects on cognitive ability (SMD = 3.06, 95% CI = 2.6 to 3.6) and psychomotor development (SMD = 1.4, 95% CI .56 to 2.2) in RCTs. We will present results of subgroup analyses by age, initial nutritional status, nutritional adequacy, and delivery mode. Our implementation review identified potential reasons for the ineffectiveness of some programs, including: inadequate energy, redistribution of food within the family, lack of supervision, pipeline breaks, caregiver stress and child disease.

Conclusion: This review provides evidence that feeding programs for young children can work, but that many do not. Our review suggests several ways that program design can be improved.

Key words: Feeding programs, implementation, systematic review

PO587

SUPPLEMENTARY FOOD FOR LACTATING MOTHERS

M. Mostafa¹, L. Tawfik², M. El-Sayed², E. Hassan²

¹Department of Food Science and Technology, Faculty of Agriculture University of Minufiya, Shebin El-Kom, Egypt

²Department of Nutrition and Food science, Faculty of Home Economics, University of Minufiya, Shebin El-Kom, Egypt

Background and objectives: Previous survey revealed deficits and nutritional deficiencies among the Egyptian vulnerable groups. Protein energy malnutrition had seen most frequently in infant and young children especially in rural areas and among families of low income. Accordingly, this study aimed to prepare high protein supplementary food for lactating mothers to protect them against malnutrition and its associated diseases.

Methods: Two formulas were prepared based on indigenous commodities through twin extruder technique capable of meeting nutritional requirements at minimal cost. These formulas consisted of extruder mixture of wheat semolina, soy protein, yeast, fenugreek, skimmed and full cream milk powders, sugar, lecithin, 13 vitamins and 10 minerals were fed to 120 lactating mothers daily (24 grams) for 3 months in Abo El-Rich Hospital, Cairo. Socioeconomic data including health status, food habits, food consumption patterns, food intake and anthropometric measurements were collected before and after study. Also, laboratory investigations on blood serum for hematocrit, calcium, albumin and hemoglobin before and after feeding were carried out. All data were statistically analyzed and significance was tested using Chi-Square test.

Results: The supplementation process was effective to increase percent satisfaction of RDA requirements. The increment percentages were 54% to 55%, 120% to 128%, 29.6% to 44.6%, 23.7% to 27.6% and 228% to 240% for calories, protein, calcium, phosphorus and iron respectively. As for vitamins the increment percentages were 185.5% to 685%, 118% to 131% and 63% to 73.6% for vitamin A, vitamin C and niacin respectively. All the anthropometric measurements increased due to the effect of supplementary food when compared to (Jelliffe1966).

Conclusion: The continues supplementary food including protein, vitamins and minerals has an improving effect on health status of lactating mothers in general and their children in particular.

Key words: Intervention, lactating, formula

PO588

DIETARY PRACTICES OF PREGNANCY WOMEN AND ITS EFFECT ON THEIR PREGNANCY OUTCOME-TAMALE (NORTHERN REGION)

Y. Agyemang¹

¹Personal Service, Kumasi, Ghana

Background and objectives: This study was conducted in the Tamale metropolis in the Northern Region. Three main hospitals in the metropolis were selected on the basis of selection criteria. The aim of the study was to identify the dietary practices of pregnant women and the effect on the pregnancy outcomes in the study area. The study population was defined as mothers who had delivered and were within their first four weeks. One hundred and thirty-one mothers were interviewed in all. The objectives of the study included the dietary practices of the women during pregnancy, factors that could influence pregnant women to pick up certain dietary practices, level of education, knowledge about nutritional requirements during pregnancy and the frequency of their food consumption.

Methods: The methodology used in the study included semi-structured questionnaires, secondary data as well as observation.

Results: Educational levels of the respondents were quite sufficient as 40.5% of the women had never received any form of education and 59.5% of them were educated either non-formally or formally. The level of knowledge of the women on the nutritional requirements during pregnancy was high as 77.9% of the respondents were taught at the ANC what to eat and what not to eat during pregnancy. From the study, it was realized that the respondents' main source of energy was from their staple food (TZ) and other sources from yam, banku and fufu. They gained minerals and vitamins from their soups and stews which were prepared from vegetables (green leafy vegetables, tomatoes, garden eggs and others).

Conclusions: It is therefore recommended in the study that pregnant women should be encouraged to increase their intake of foods especially protein, minerals and vitamin rich foods to promote healthy growth of both mother and child.

PO589

AN INVESTIGATION INTO CHILD FEEDING PRACTICES OF YOUNG MOTHERS FROM TSHILATA VILLAGE, VUWANI, LIMPOPO PROVINCE, SOUTH AFRICA

L. Maliwichi¹, A. Nesengani¹

¹Department of Consumer Science, University of Venda, Thohoyandou, Limpopo Province, South Africa

Background and objectives: The aim of this study was to explore infant practices of young mothers residing in Tshilata village.

Methods: Snowballing method was used to select 20 young mothers (with children aged six months to three years) that were willing to take part in the study. Data were collected during face to face interviews using a structured questionnaire. Qualitative information was obtained from open ended questions that used probes to get more information from the respondents' responses. Quantitative data from structured questionnaires were analyzed using descriptive statistics to generate frequencies. Content of qualitative data were analyzed to generate themes that formed units of analysis.

Results: The findings revealed that 60% of young mothers were taught about child feeding by the nurse before their children were born and 65% were taught by relatives after their children were born. While 65% of young mothers were encouraged to eat fruits only 35% were encouraged to eat vegetables. Introduction of solid food was early in a large proportion (65%) of the mothers. A 24 hour food recall showed that only a few children were given foods from different food groups and the feeding frequency was low. About 55% of the mothers wanted the government to help them to access employment.

Conclusions: There seem to be limited nutrition intervention programmes in the form of nutrition education at clinics targeting young mothers and pregnant women. As a result many mothers are not breastfeeding exclusively for the recommended six months; introduced solids early; were not feeding children a variety of foods from the different food groups. Intervention programmes need to improve mothers' access to nutrition information. Nutrition Intervention Programs need to be broader and must assist mothers' access basic resources and skills for employment and self employment.

Key Words: child feeding, breastfeeding, weaning practices

PO590

EVALUATION OF OXIDATIVE STRESS AND OXIDANT DEFENCE IN PREECLAMPSIA.

E. Zare¹

¹Private, Tehran, Iran

Background and objectives: To evaluate the parameters of oxidative stress and anti oxidant defense in preeclampsia.

Methods: Study was carried out on pregnant and non pregnant women attending in the Obstetrics ward of imam hospital, tehran. Each serum sample was evaluated for malondialdehyde (MDA), a product of lipid peroxidation process as a marker for oxidative stress and reduced glutathione, superoxide dismutase, and catalase for antioxidant enzyme activity and a comparison drawn and analyzed using t-test and (2) test.

Results: The levels of MDA (a lipid peroxidation product) increased significantly in pregnancy compared to non-pregnant females and further significantly increased in preeclampsia compared to normal pregnant females. The other factors were found to be increased in preeclamptic females as compared to normal pregnant females.

Conclusions: Preeclampsia is found to be a condition with markedly increased oxidative stress as is evidenced by highly significantly increased levels of MDA, a marker of lipid peroxidation. Levels of antioxidant enzymes, viz. reduced glutathione, superoxide dismutase, catalase and vitamin E have been found to be increased in preeclampsia as compared to normal pregnant females. This may be a compensatory mechanism for handling the increased oxidative stress.

Key words: preeclampsia, oxidative stress, pregnancy

PO591

MATERNAL VITAMIN DEFICIENCY INCREASE THE RISK OF PREECLAMPSIA

M. Homayon¹

¹Private, Tehran, Iran

Background and objectives: Vitamin D has direct influence on molecular pathways proposed to be important in the pathogenesis of preeclampsia. We aimed to assess the effect of maternal 25-hydroxyvitamin D [25(OH)D] concentration on the risk of preeclampsia and to assess the vitamin D status of newborns of preeclamptic mothers.

Methods: nested case-control study was conducted. Patients included nulli parous pregnant women with singleton pregnancies who developed preeclampsia (n=100) or did not develop pre eclampsia (n=300). Women's banked sera were newly measured for 25(OH)D. The main outcome measure was preeclampsia.

Results: Adjusted serum 25(OH)D concentrations in early pregnancy were lower in women who subsequently developed preeclampsia compared with controls. Newborns of preeclamptic mothers were twice as likely as control newborns.

Conclusions: Vitamin D supplementation in early pregnancy should be explored for preventing preeclampsia and promoting neonatal well-being.

Key words: vitamin D, pregnancy, preeclampsia

PO592

THE EFFECT OF ATTITUDES TO NUTRITION AND HEALTH ON CONSUMPTION OF FAT, FIBRE AND FOOD INTAKE VARIETY IN POLISH GIRLS

L. Wadolowska¹, J. Czarnocinska², J. Kowalkowska¹, E. Babicz-Zielinska³, M. Jezewska-Zychowicz⁴, K. Sobas¹, W. Kozirok³

¹Department of Human Nutrition, University of Warmia and Mazury, Olsztyn, Poland

²Department of Human Nutrition and Hygiene, Poznan University of Life Sciences, Poznan, Poland

³Department of Trade and Services, Eating Behaviour Research Group, Gdynia Maritime University, Gdynia, Poland

⁴Department of Organization and Consumption Economics, Warsaw University of Life Sciences, Warsaw, Poland

Background and objectives: No relationship has been identified between pro-healthy or non-healthy nutrition behaviour and attitudes towards nutrition and health in Polish girls. The aim of the study was to analyze attitudes towards nutrition and health on selected characteristics of food intake in girls.

Methods: The research involved 232 girls aged 13-21 years. Using three food frequency questionnaires fibre intake, fat intake and food intake variety were determined. Attitudes towards nutrition and health were assessed using the Health Concern Scale (HCS) and the Health Taste Attitude Scale (HTAS).

Results: The mean index of food intake variety was 28.4 foods/week (range:0-60), mean fibre intake was 16.1 points (range:0-36), while mean fat intake was 18.4 points (range:0-52). In HCS neutral attitudes (30-50 points) were found in 72% girls, negative attitudes (10-19 points) in 19% girls, while positive attitudes (51-70 points) in 10% girls. In HTAS neutral attitudes (114-190 points) were found in 93% girls, positive attitudes (191-266 points) in 6% girls. None of girls presented a negative attitude (38-113 points). Girls from the upper-positive tercile of attitudes in subscales HTAS-1: interest-in-health had the odds ratio for adequate fat intake (<22 points) of 3.01

(95%CI 1.29; 7.03) in comparison to girls from the central-neutral tercile (OR=1.00). Girls from the lower-negative tercile of attitudes in subscale HTAS-2: light-food had the odds ratio of adequate fat intake (<22 points) of 2.19 (95%CI 1.03; 4.66) in comparison to girls from the central-neutral tercile (OR=1.00). The relationship between fibre intake or food intake variety and attitudes of girls in HCS, HTAS and its subscales was non-significant.

Conclusions: Positive attitudes of girls towards health and negative attitudes towards light food promoted better food choice and lower fat intake, but no significant effect on fibre intake or food variety intake was observed.

Key words: attitude, food intake, girls, health

Acknowledgements: The study was financed within the framework of NCN project no. N N404 068540

PO593

THE EFFECT OF AGE ON FOOD INTAKE VARIETY IN REPRESENTATIVE SAMPLE OF POLISH GIRLS AGED 13-21 YEARS

L. Wadolowska¹, J. Kowalkowska¹, J. Czarnocinska², E. Babicz-Zielinska³, M. Jezewska-Zychowicz⁴

¹Department of Human Nutrition, University of Warmia and Mazury, Olsztyn, Poland

²Department of Human Nutrition and Hygiene, Poznan University of Life Sciences, Poznan, Poland

³Department of Trade and Services, Eating Behaviour Research Group, Gdynia Maritime University, Gdynia, Poland

⁴Department of Organization and Consumption Economics, Warsaw University of Life Sciences, Warsaw, Poland

Background and objectives: Attitudes to the daily diet change with age under the influence of environmental stimuli and individual personal development. Knowledge on changes in the diet of Polish girls in the period of adolescence and maturity is limited. The aim of this study was to analyse the effect of age on variation in food consumption in girls.

Methods:Analyses were conducted on 1107 girls from the representative sample of Polish girls aged 13-21 years. A total of 2104 individuals were randomly selected from the PESEL data base. Interviews were conducted with 52.6% respondents from the initial sample. The food intake frequency method was used to assess food intake variety, which was expressed in the number of foods consumed within a week (range: 0-60foods/week). The validated Food Intake Variety Questionnaire (FI-VeQ) was used.

Results: The mean food intake variety index in the total sample was 31.1 foods/week, for girls aged 13-15 years 31.3 foods/week, for girls aged 16-18 years 31.0 foods/week, while for girls aged 19-21 years 30.9 foods/week ($p > 0.1$). An unacceptable food intake variety (below 34 foods/week, i.e. below 66 percentile) was found in 68%, 70% and 71% girls aged 13-15, 16-18 and 19-21 years, respectively ($p > 0.1$). A very good variety of food consumption (40-60 foods/week) was observed in 10%, 9% and 10% girls, aged 13-15, 16-18 and 19-21 years, respectively ($p > 0.1$).

Conclusions: In Polish girls aged 13-21 years in terms of their food intake a relatively limited variety was observed, which did not depend on age. Stability of nutrition-related behaviour was shown for food variety and its earlier development in the pre-adolescent period and prior to maturity. Results indicate the need to provide an early influence on nutrition-related behaviour of girls starting as early as the childhood period.

Key words: age, food intake variety, girls

Acknowledgements: The study was financed within the framework of NCN project no. N N404 068540.

⁵Research and Development, Nutrition, PepsiCo Europe, Berkshire, UK

⁶International Life Sciences Institute European Branch, Brussels, Belgium

⁷Bracket, Goring-on-Thames, UK and Centre for Human Psychopharmacology, Swinburne University, Melbourne, Australia

Background and objectives: Increasing interest in the effects of particular foods and/or nutrients on cognitive function stems from the desire to understand how cognitive

performance may be influenced by nutrition over the life course, from neurodevelopment to cognitive decline. A first step in determining if and how foods/nutrients may exert a significant influence on cognition is to have a battery of tests that can be used in experimental trials as valid surrogates or (bio)markers of the neural processes of cognitive performance. Tests chosen to measure cognitive function should meet multiple study-specific requirements and have the support of a consensus within the scientific community that allows them to be used as evidence for consideration of nutritional benefit claims by regulatory expert panels.

Methods: The International Life Sciences Institute, European Branch assembled an Expert Group to evaluate tests specific to various cognitive domains and key features of each as applicable to nutrition intervention studies, particularly in the elderly where cognitive abilities may decline.

Results: Markers in the following cognitive domains were reviewed: Memory (verbal, visual, spatial, and spatial working memory), attention (selective and sustained), information processing speed, executive function, and global or general cognitive function. Evaluation features of cognitive domains reviewed included: •Underlying brain correlates •Validity •Reliability and correlates between tests •Sensitivity to nutritional interventions •Appropriate target populations.

Conclusions: This review provides guidance for nutritionists, neuropsychologists, psychiatrists, and neurologists interested in assessing mental health in terms of cognitive performance and for scientists wishing to test the effects of food or food components on cognition.

Key words: cognition, memory, attention, executive function, nutrition, validation

COLOSTRUM AND MATURE MILK COMPOSITION OF LACTATING WOMEN IN UMUAHIA, URBAN NIGERIA

P. Ukegbu¹, A. Uwaegbute¹, I. Ijeh¹

¹Dept of Human Nutrition and Dietetics, Michael Okpara University of Agriculture, Umudike, Abia State, Nigeria

Background and objectives: This cross sectional study evaluated breast milk composition of colostrum and mature milk of mothers in Umuahia.

Methods: The study was conducted among 27 lactating women volunteers aged 26-35 years who participated in a longitudinal study aimed at determining the 'effect of maternal nutrition and body composition on lactation performance'. Colostrum and mature breast milk samples were collected at 2 days and 6-8 weeks postpartum, respectively. Samples

were analysed for macro and micronutrients using standard methods. Data was analysed using means (SD) and t-test.

Results: The mean values for energy, protein, fat and lactose in colostrum were 64 ± 0.04 kcal, 1.4 ± 0.01 g, 2.58 ± 0.07 g, and 5.50 ± 0.11 g, respectively, while the levels in the same macronutrients in mature milk were 0.69 ± 0.01 kcal, 1.09 ± 0.26 g, 3.32 ± 0.06 g and 6.75 ± 0.05 g, respectively. The mineral composition of colostrum were calcium (141.45 ± 1.08 mg/L), iron (0.63 ± 0.04 mg/L), zinc (5.5 ± 0.16 mg/L) and magnesium (41.16 ± 2.00 mg/L). The levels in the same micronutrients in mature milk were 231.44 mg/l, 0.54 ± 0.03 mg/l, 5.95 ± 0.22 mg/l and 62.41 ± 7.77 mg/L, respectively. There were differences in colostrum and mature milk concentration of protein and iron ($p<0.05$). All the nutrients in the breast milk samples were adequate except calcium when compared to standards.

Conclusions: The levels of nutrients obtained in this study are consistent with past studies in developing countries.

Key words: mature milk, colostrum, composition, lactation

ASSESS OF A SCHOLAR MENUS VALIDATION PROGRAMME IN THE HEALTH DEPARTMENT OF ELDA (ALICANTE)

G. Arroyo Fernandez¹, A. Jimenez Lopez¹, J. Paya Molina¹, A. Cremades Bernabeu¹, A. Subiela Escriva¹, P. Velez Lasso¹, J. Molina Navarro¹

¹Public Health Center of Elda, Alicante, Spain

Background and objectives: A Childhood Obesity Prevention program has been developed in our department. Scholar menu validation and posterior reemission of results to each center, along with a series of recommendations for improving it, are some of the activities involving the program. The impact of this program within the six year it has been operating has been analyzed in this paper.

Methods: 6 years longitudinal research of menus served in the department. The software DIETSOURCE 1.2 has been used to analyze the nutritional composition of menus served in all educational centers with school dining room in the department between years 2007 and 2012. A total of 58 centers where analyzed. Statistical software Epi Info 6.04 was used for statistical treatment and analysis of all data.

Results: In 2007 proteins were 21.02% (SD = 2.10) of macronutrients, lipids were 41.11% (SD= 6.81) and carbohydrates were 38.35% (SD = 6.95). Scholar menus are this year closer to OMS recommendations, being now within recommended percentages for both for lipids with 30.37% (SD = 6.01) of total and carbohydrates with 52.63% (SD = 6.34), that were high and low respectively; and for proteins that are within the normal values (16.99% , SD = 1.72). A lineal regression analysis has been de-

veloped being the lipids and carbohydrates tendency lines the most notables with an R2 of 0.84 and 0.97 respectively. The less notable case is proteins (0.83) with a sharp decrease in second year and keeping stable afterwards.

Conclusions: The scholar menus assessing and reemitting back results to schools strategy has been found to be effective. This strategy provides a series of individual as well as general recommendations.

Key words: School, menu, nutritional , obesity, preven

PO597

ASSESSING THE PATTERN OF MEALS IN SCHOOL-GIRLS WITH EATING DISORDERS IN COMPARISON WITH HEALTHY GROUP, 2010

R. Roustaei¹, M. Hajifaraji¹, A. Houshiar Rad¹, T. Zowghi¹

¹National Nutrition And Food Technology Research Institute, Faculty of Nutrition Sciences And Food Technology, Shahid Beheshti University of Medical Sciences, Iran

Background and objectives: Nutrition status is strongly affected by Eating Disorders. Present study was carried out to determine the snacks and meals' pattern in secondary school girls with eating disorder compared to healthy group.

Methods: In this descriptive cross-sectional study, 2734 high school students were selected with a stratified random sampling from 5 distinct of Tehran regarding to pupils population in each distinct. Two-stage approach was used to diagnose eating disorders. At the first phase, screening was done using validated Farsi translation of EAT-26 questionnaire. In the 2nd Phase, subjects were evaluated by Eating Disorder Diagnostic Inventory questionnaire and a supplementary clinical interview. Then, 255 diagnosed ED and 285 healthy individual, completed meals pattern questionnaire. Data were analyzed by χ^2 and Fisher tests using SPSS.ver17.

Results: The most frequent pattern of meal consumption during the day (32%) was 2 meals in case group and 3 meals plus a snack in control group. The most skipped meal in both groups was breakfast, 40.7% and 38.2% in case and healthy groups, respectively. The most common breakfast in both groups was bread and cheese with tea or milk. 75% of ED subjects and 86.7% of healthy group reported the permanent consumption of lunch ($p<0.05$). Lunch was combination of cereal, meat and vegetables in case group (21.8%) and cereal, meat and dairy products in control groups (21%). Skipping dinner was significantly higher ($p<0.001$) in ED subjects than healthy ones, 14% and 1.2% respectively. Dinner was commonly the combination of cereals, meat and vegetables in both groups. The majority of subjects were consuming 1 snack per day.

Conclusion: Reduction and elimination of meals can considerably affect adolescents' dietary intake which respect to their nutritional vulnerability, is considered as an important point.

Key words: adolescent, eating disorder, meal pattern

PO599

THE RELATIONSHIP BETWEEN EATING HABITS AND STRESS RESPONSE IN YOUNG STUDENTS

M. Kurotani¹, M. Nakade²

¹Department of Home Economics, Aichi Gakusen University, Okazaki, Aichi, Japan

²Department of Health and Nutrition, Tokaigakuen University, Nagoya, Aichi, Japan

Background and objectives: Recent changes in social environment have led to changes in eating habits in young students, and problematic eating habits such as eating alone and skipping meals are becoming a concern. The purpose of this study was to clarify actual circumstances regarding lifestyle habits, eating behavior, and stress response in young students and to examine the relationship between their stress response and factors such as lifestyle habits and eating behavior.

Methods: In March 2009, self-administered questionnaires were given to dependants of employees in Company A that ranged from fourth grade elementary school students to high school seniors. Excluding those that were incomplete, analysis was conducted on responses from 116 students. Questionnaires consisted of (1) questions on subjects for personal attributes, (2) questions relating to stress response (psychological stress response and physical stress response), and (3) questions relating to lifestyle habits (such as eating habits and lifestyle satisfaction).

Results: Comparing students who ate instant food once a week or more with those who did not showed students who ate instant food to have stronger physical stress response ($p<0.001$), worse temper and anger ($p<0.001$), increased lethargy ($p<0.001$), and more feelings of depression and anxiety ($p<0.01$). Comparing students who ate fast food once a week or more with those who did not showed students who ate fast food to have more feelings of lethargy ($pp<0.01$) and of depression and anxiety ($p<0.01$).

Conclusions: Among lifestyle habits, previous studies have already confirmed a link between skipping breakfast and stress response. The present study confirmed that consumption of instant food and fast food is also associated with stress response. These results suggest that dietary education from early on can help students develop stress-coping techniques.

Key words: eating habits, sleeping habits, stress response, dietary education, health support

PO600

FOOD SOURCES OF VITAMIN D AND ITS DEFICIENCY IN LATVIAN MALES

A. Shitova^{1,2}, Z. Zarinsh³

¹Sanatorium "Jantarnij Bereg", Riga, Latvia

²Riga Stradins University, Riga, Latvia

³Faculty of Rehabilitation Sports, Riga Stradins University, Nutrition and Education, Riga, Latvia

Background and objectives: Over 50% of population is found to suffer from vitamin D deficiency. Vitamin D deficiency in Europe, Northern Europe, Asia and Africa, especially in elderly people was revealed by many epidemiological researches.

Methods: There were included 134 males aged 45-80. None of the research participants have taken any vitamin D supplements or supplements containing vitamin D. Serum vitamin D level was detected in all the participants ((25 hydroxyl vitamin D: 25(OH)D) and the amount of the consumed vitamin D was determined. The participants height and weight were measured to calculate BMI. The survey was conducted to acquire information about the amount of vitamin D consumed with food.

Results: Insufficient Vitamin D intake was detected in 78,4%, vitamin D deficiency with consequent low vitamin D serum level in 94,1 %. Mean data: vitamin D in food 6,9 µg, 25(OH)D - 16,9 ng/mL, BMI 28,1 kg/m, age 59,4 years. The amount of vitamin D in food statistically reliably directly correlate with serum vitamin D level ($r=0.961$; $p=0.01$), and there is an inverse correlation with age ($r=0.226$; $p=0.009$). D vitamin serum level correlate inversely with age ($r=0.184$; $p=0.033$). No statistical reliable correlation was found between serum 25 (OH) D levels and BMI. Major food sources of Vitamin D are fat-rich sea fish, eggs, dairy product.

Conclusions: Insufficient intake of vitamin D with food and low serum level is marked in males of advancing age. Vitamin D levels directly correlate with vitamin D intake. Not found statistically significant correlation between vitamin D levels, vitamin D diet and BMI, but indirectly correlates with age.

Key words: body mass index, vitamin D, fat-rich sea fish

PO601**THE ENERGY REQUIREMENT OF SENEGALESE EXCLUSIVELY BREASTFED INFANTS IS COVERED BY HUMAN MILK UNTIL 6 MONTHS OF AGE**

S. Wade¹, A. Agne-Djigo¹, K M. Kwadjodé¹, N. Idhou-Dossou¹, A. Diouf¹, A T. Guiro¹

¹Université Cheikh Anta Diop de Dakar, Senegal

Background and objectives: Exclusive breastfeeding until 6 months of age is advised as the best practice to feed infants. The aim of this study was to measure the infants' energy intakes from human milk in 6-months-old Senegalese lactating infants in order to assess the adequacy of WHO recommendations.

Methods: A comprehensive study was undertaken in 59 mother-infant pairs. Breast milk intake was measured by the dose-to-the mother deuterium oxide turnover method, and energy content of milk was estimated on the basis of creamatocrit in full milk samples. Infants' energy intakes were calculated using daily breast milk intake and the fat content of milk.

Results: Of the 59 mother-infant pairs enrolled, 15 infants were exclusively breastfed (Ex) while 44 were partially breastfed (Part). Infants' breast milk intakes were significantly higher in the Ex group (992±135 g/d, n = 15) compared to the Part group (828±222 g/d, n = 44, p = 0.009). Breast milk energy content as well as infant growth was comparable in both groups. However, infants' energy intake from human milk was significantly higher in the Ex group than in the Part group (364 ± 50 vs. 289 ± 66 kJ/kg/d, p= 0.000). Human milk alone covered WHO recommendations in the Ex group, but not in the Part group.

Conclusions: At 6 months of age, growth of the Senegalese infants was not affected by their feeding pattern, yet energy intake from breast milk was low in partially breastfed infants. In contrast, exclusively breastfed infants receive adequate energy from human milk which is the most complete food for infants. Advocacy of exclusive breastfeeding until 6 months should continue to be strengthened in Senegal.

Key words: exclusive breastfeeding, partial breastfeeding, infant energy intake, Senegal.

PO602**RELATIONSHIP BETWEEN UNSATURATED FATTY ACID (DHA) WITH THE GROWTH AND DEVELOPMENT OF SEVERE MALNOURISHED CHILDREN UNDER TWO YEARS**

A. Lamid¹

¹National Institute For Health Research And Development, Indonesian Ministry Of Health, Indonesia

Background and objectives: Malnutrition remains a public health problem in Indonesia. Children under two years with severe malnutrition will experience obstacles in growth and development. Adding DocosaHexaEnoic Acid (DHA) as unsaturated fatty acid into food supplement for severe malnourished children has been done to increase the intake of fatty acids such as DHA and its growth and development.

Methods: The research site was at Nutrition Clinic in Bogor. The research sample was severe malnourished children aged 6-24 months with inclusion criteria was a parent willing to participate and exclusion criteria; children do not have severe complications or fatal acute infection and children do not have congenital abnormalities. Then, samples were grouped into 2 treatment groups that received regular packets (control) and got the regular package plus DHA (DHA). The duration of intervention lasted for 3-months. Data collected: weight, height (growth), clinical examination, and dietary intake of DHA and the child development (Motoric and Psychomotor Development). Data were analyzed using t test.

Results: Results showed improved growth and development of DHA group but the improvement was found no significant differences compared to the control group (p> 0.05). Intake of DHA is higher in DHA group than in the control group but there was no significant relationship between DHA intake with child development (p> 0.05).

Conclusions: Adding DHA into food supplement for children should be considered the adequacy of calorie and protein intake of the children

Key words: unsaturated fatty acid, docosaHexaEnoic Acid, severe malnutrition, growth and development.

PO603**COST AND EFFECTIVENESS OF TRAINING AND SUPERVISION OF FRONTLINE WORKERS ON EARLY BREASTFEEDING PRACTICES IN BANGLADESH**

S. Talukder¹, T. Greiner², K. Dewey³, R. Haider⁴, D. Farhana¹, S. Chowdhury¹

¹Nutrition, Eminence, Dhaka, Bangladesh

²Nutrition, Hanyang University, Seoul, Korea

³Nutrition, University of California Davis, California, USA

⁴Nutrition, THAN, Dhaka, Bangladesh

Background and objectives: The objective of this operational research was to test whether community volunteers training could be an effective way of improving behaviors and whether it was cost effective to add supervision to the training in a relatively isolated, low-income rural area of Bangladesh.

Methods: The study was randomized by union and a total of 124 villages from 9 unions of three upazilas were included under project. Front line workers from the two intervention areas received a 5-day training course. A baseline survey and at end of this project after six months an endline evaluation was carried out both intervention and control areas with a representative samples using a similar questionnaire.

Results: The proportion initiating breastfeeding within one hour increased greatly in both intervention groups, but only marginally in the control area. The practice of offering prelacteal feeds declined in all three areas but training decreased it more and supervision more still. Exclusive breastfeeding (children <3 months of age) was also increased, though similarly in the Intervention 1 and 2 areas while little change occurred in the control area. Adding the cost of employing a supervisor more than doubled the cost of the intervention and also increased impact but not cost effective.

Conclusions: While further research is needed on a larger scale, this study already provides evidence adequate to argue that TBAs in rural Bangladesh should be provided with a modified training course on IYCF issues and they can make substantial influence over practices.

Key Words: TBA, exclusive breastfeeding, cost effectiveness.

PO604**ASSESSING PRESENT BEHAVIOR OF MOTHER'S AND HEALTH WORKERS TOWARDS IYCF PRACTICES, IN NORTHERN RURAL PART, BANGLADESH.**

D. Farhana¹, S. Talukder¹, H. Ebbing², R. Rehana Amin²

¹Eminence, Dhaka, Bangladesh

²ACF, Dhaka, Bangladesh

Background and objectives: The objective of this study was to identify the insights of communities IYCF behavior and front line workers experiences during providing nutrition services to figure out effective strategy to modify program design in preventing childhood malnutrition.

Methods: This study was cross sectional and followed both quantitative and qualitative methods. Total, 363 beneficiaries and 56 local level field staffs of National Nutrition Program (NNP) were interviewed and 12 FGDs were conducted with family members and community leaders.

Results: Socio demographic information shows that, more than two- third of respondents are relatively young (age 16 to 25), of them more than one third had family income ranged 3000-6000 BDT. However, almost all mothers have good knowledge on initiation and exclusive breastfeeding but poor knowledge on child's proper age of introducing CF. In this KAP survey, less than 50% mothers had knowledge on meal frequency. Staffs knowledge on different aspects of IYCF also assessed. Training may have an effect on their knowledge and the findings shows that, on an average, 48.8% of Field Staffs from the entire study area expressed their satisfaction with duration of the training period. However, dissatisfaction has also been observed in some places of study areas. Almost two-third field staffs informed that they arrange meeting with the community people and counseled mother frequently while they faced any problem. Around three fourth of the field staffs suggested that creating awareness amongst mothers as well as their family members can improve existing child feeding practices.

Conclusions: With little modification of monitoring and supervision of field staffs and partnering with other organizations can be explored more to enhance the outcome of the intervention and further strengthen it.

Key words: IYCF, KAP, pregnant women, lactating women.

PO605**DIETARY BEHAVIOR AND NUTRITIONAL STATUS OF THE SELECTED ADOLESCENT GIRLS IN DHAKA CITY**

K. Poddar¹, S. Irin¹, A. Bhuyan¹

¹Food and Nutrition Department, Bangladesh Home Economics College under University of Dhaka, Bangladesh

Background and objectives: Adolescence is a transitional stage of physical and mental human development generally occurring between puberty and legal adulthood but largely characterized as beginning and ending with the teenage stage. The aim of the present study was to investigate the dietary behavior and nutritional status of the selected adolescent girls in Dhaka City.

Methods: A descriptive cross-sectional study was conducted among 210 adolescent girls of aged 10-14 years to assess their dietary practices, life style pattern and nutritional status. A questionnaire both structured and unstructured was used to collect relevant information.

Results: Results show that 24.7% of the girls were underweight (BMI <18.5), 54.8% were within normal limits (BMI 18.5-24.99), and 6.2% were obese (BMI >30). Majority of the studied adolescent girls like to consume normal foods (60.9%). On the other hand 19.1% and 20% prefer fast foods and rich foods respectively. Only 25.1% adolescent girls consume four or more meals per day which is recommended by nutritionist. Others (74.9%) take two or three meals per day. The studied adolescents consume rice frequently in three meals that is breakfast, lunch and dinner. Protein source meat, fish and egg consumption was inadequate in their meals analyzing three days food consumption history. All types of vegetables were frequently consumed by all the adolescent girls. They consume milk and fruits occasionally.

Conclusions: Adolescent girls in Bangladesh especially school girls from the family of low income get insufficient nutritious food by which their physical and mental growths do not get fulfilled.

Key words: BMI: Body Mass Index

PO606**CASE-CONTROL STUDY ON ANEMIA AMONG ELDERLY WOMEN IN THREE DISTRICT OF CHINA**

P. Song¹

¹Institute of Nutrition and Food Safety, Chinese Center for Disease Control and Prevention, Beijing, China

Background and objectives: Anemia affects about one-quarter of world's population and various conditions are associated with anemia including nutritional deficiency, infectious diseases and genetic mutations.

Methods: A case-control study was performed in 1938 women samples (50-70 years old) where 949 case (hemoglobin <120g/l) and 989 control (hemoglobin >130g/L) from three provinces of China. Each participant was interviewed and a basic health examination was done. Those with serious diagnosed diseases were excluded from our study. After an overnight fast, venous blood samples were collected and questionnaires on diet, life style, medical history and physical activity were completed. Blood indices such as serum iron, ferritin, transferrin, total iron-binding capacity, transferrin saturation, free erythrocyte protoporphyrin and C-reactive protein were tested.

Results: After SAS 9.1 statistical analysis we found that anemic women have lower BMI (22.08±3.22 vs 23.16±3.51 kg/m²), waist circumference/height ratio (0.49±0.06 vs 0.51±0.06), less soybean food intake (median (lower quartile, upper quartile) was 5.56 (0.33) vs 11.11 (0.40) µg/d), lower hemoglobin (113.83±6.97 vs 140.57±8.50 g/l), serum iron (13.55±5.52 vs 16.68±5.74 µmol/l), ferritin (108.44±86.41 vs 132.08±92.73 ng/ml), and transferrin saturation (20.64±9.33 vs 25.23±9.53 %) levels but higher free erythrocyte protoporphyrin concentration (43.81±23.10 vs 39.62±17.83 µg/dl) than non-anemic women, the differences were statistically significant by t test and chi-square test. Iron deficiency was defined as persons with one of following status: transferrin saturation <16%, serum ferritin concentration <15 ng/ml, free erythrocyte protoporphyrin/hemoglobin ratio >3.0 µg/g. People with both iron deficiency and anemia were regarded as iron deficiency anemia (IDA), thus the percentage of IDA was 34.42%. Logistic regression models showed that the odd ratio and 95% CI of BMI, waist circumference/height ratio and soybean food was 0.72 (0.63-0.93), 0.66 (0.41-1.05) and 0.80 (0.64-1.00) respectively.

Conclusions: It was possible to improve the hemoglobin concentration by increasing BMI, waist circumference/height ratio and soybean food intake.

Key words: anemia case-control study elderly women

PO607**FEEDING PRACTICES AND NUTRITIONAL PARAMETERS OF CHILDREN AGED 6-14 YEARS IN MAKEPE MISSOKE (CAMEROON)**

W. Djeukeu Asongni¹, M. Kana Sop¹, M. Mananga², N. Nolla¹, I. Gouado¹, Tetanye Ekoe³

¹University of Douala, Cameroon

²University of Yaounde I, Faculty of Medecine, Cameroon

³University of Yaounde I, Faculty of Science, Cameroon

Background and objectives: The national demographic and health survey in 2004 in Cameroon showed that malnutrition was implicated in the death of 50 % children less than 5 years. However, in there is too little information concerning nutritional statut after that age. The aim of this study was to evaluate some nutritional parameters of children aged of 6 to 14 years in Makèpè Missokè, (Douala-cameroon).

Methods: Two hundred and fifty five students children of 6 to 9 years (63.9 %) and children of 10-14 years (36.1 %) were recruited in "Bilingual Confidence School Group". Their nutritional status was evaluated after the analysis of anthropometric parameters (height for age, weight for age and BMI for age). Nutritional indicators were calculated using WHO Anthroplus 2007 and Epi info 2000. Protein energy malnutrition was evaluated biochemically by the determination of albuminemia in the blood of 99 children, using the colorimetric method with bromocresol green. Foods habits and practices were assessed during a survey in that school using questionnaires. Statistical analyses were performed by SPSS.

Results: Stunting was observed at 18.0 %, wasting at 5.1 % and overweight at 1.6 % in children. Stunting was frequent in families of more than 5 persons and in families where mothers had the lowest instruction level (primary). Protein energy malnutrition determined by albuminemia was found in 16.2 % of the study population. There was a significant difference between the average albuminemia of stunted children (37.6 ± 7.7 g/l) and albuminemia of unstunted children (48.9 ± 11.1 g/l).

Conclusions: Foods habits and practices showed that the foods of those children was diversified but consumption of fruits and legumes was low. An imbalance diet characterized by an excess of fat and carbohydrates, and a deficit of fiber and protein, was found in their diet. keys words: malnutrition, albuminemia, stunting, Cameroon

PO608**PREVALENCE AND TRENDS OF CHILDHOOD MALNUTRITION IN GHANA**

C. Nti¹

¹University of Ghana, Legon, Ghana

Background and objectives: Malnutrition is currently the leading cause of the global burden of disease and has been identified as the underlying factor in about 50% of deaths of children under 5 years of age in developing countries. This paper reviews the prevalence and trends of malnutrition among Ghanaian children during the past two decades.

Methods: A review of nutrition data provided by the Ghana Demographic and Health Survey between 1988 and 2008.

Results: Between 1988 and 2008, the prevalence of stunting reduced from 35% to 28%. At the same time, the percent of children underweight fell from 23% to 14%. The prevalence of stunting however remained the same (9%) over the 20 year period. The percentage of children who were overweight increased from less than 1 percent in 1988 to 5 percent in 2008.

Conclusions: Child nutritional status, in terms of weight-for-age and height-for-age, has improved over the years. However stunting is still a problem. Another development of concern is the increasing trend of childhood overweight and obesity. To continue making progress, there is the need to intensify intervention programmes currently in place such as the Accelerated Child Survival and Development approach, Micronutrient supplementation, Food Assisted Child Survival project and Behaviour Change Community Programme. Attention needs to be given to young/child feeding practices, maternal empowerment and community resources to ensure optimal childhood nutrition. Issues related to poverty would have to be tackled as it leads low purchasing power and hence inadequate dietary intake. All these would help reduce childhood malnutrition further.

Key words: Malnutrition, stunting, underweight, overweight

PO609**IMPACT OF NUTRITION AWARENESS OF MOTHERS ON NUTRITIONAL STATUS, IQ & ICDS COVERAGE OF THEIR CHILDREN IN WEST BENGAL, INDIA***D. Chaudhuri¹, K. Bhowal¹*

¹Department of Biochemistry and Nutrition, All India Institute of Hygiene and Public Health (West Bengal University of Health Sciences), Kolkata, West Bengal, India

Background and objectives: Physical and intellectual development of a child is mainly dependent on the early nourishment and care by their mother. Integrated Child Development Services (ICDS) is also having a significant role to achieve this among pre-school Indian children, particularly the underprivileged. However, availing the benefits of ICDS for the children is dependent on the nutrition awareness of their mothers. The objective of the study was to assess the impact of nutrition awareness of mothers and ICDS coverage on the nutritional status and IQ development of their children.

Methods: Nutritional status and IQ of 158 rural primary school children between 6-8 years (86 boys and 72 girls) of West Bengal, India was assessed by BMI and Raven's Progressive Matrix test, respectively. ICDS coverage for the children was confirmed from the ICDS centre records. Nutritional awareness of the mothers was assessed by a self structured pre-tested knowledge, attitude and practices (KAP) questionnaire.

Results: 54%, 29%, 41% of the students were underweight, stunted & thin, respectively while 4% were overweight according to BMI. 6%, 25% 10% & 59% of them achieved B, C, D & E intelligence grade, respectively. 89% children were under ICDS coverage & 41.2% of their mothers had acceptable level of KAP score.

Conclusions: Significant positive correlation between mothers nutrition awareness and nutritional status of their children ($p < 0.05$) as well as ICDS coverage for them ($p < 0.01$) exist. However, though positive but insignificant correlation observed between ICDS coverage and nutritional status as well as IQ of the children.

Key words: children, mothers, BMI, IQ, ICDS.

PO610**COMPARATIVE STUDY OF NUTRITIONAL STATUS OF BOARDING AND NON-BOARDING PUPILS IN SELECTED SCHOOLS IN THE ACCRA METROPOLIS***F. Intiful¹, L. Ogyiri¹, A. Amoako-Mensah¹, R. Steele-Dadzie¹*

¹University of Ghana, Accra, Ghana

Background and objectives: Ghana is currently being faced with the double burden of over and under nutrition among school age children. The quality of diet served at school goes a long way in determining the nutritional status of school children. In Ghana there is a popular perception that diet served in the boarding school is of poor quality compared to diet served at home. The aim of the study was to assess the nutritional status of boarding and non-boarding pupils aged 8 to 10 years in the Accra Metropolis, Ghana.

Methods: A cross-sectional study was conducted among 124 pupils in three private schools with boarding facilities in the Accra Metropolis, Ghana. A two day 24 hour dietary recall was used to assess dietary information. Anthropometric measurements of weight and height were taken. WHO Anthroplus software was used to determine WAZ, HAZ and BAZ. Ghanaian food composition tables were used to estimate the nutrients in foods eaten by subjects. Analysis of data was done using the Statistical Package for Social Sciences (SPSS, version 20.0). Descriptive statistics such as means and percentages were used. T-test was used to determine differences between nutritional status of boarders and non boarders.

Results: The prevalence of stunting, underweight, overweight and obesity among the pupils were 0.8%, 0.8%, 12.1% and 11.3% respectively. Among the 8-8 years 11 months group, non boarders had significantly higher intakes of fat ($p=0.035$), vitamin B1 ($p=0.002$) and vitamin C ($p=0.007$). With all groups combined, the study saw no differences between the nutritional status of the boarders and non boarders.

Conclusions: Overweight and obesity were found to be high among the children. Also no significant differences were observed in the dietary intakes of both the boarders and non boarders.

Key words: Pupil, boarders, non boarders, Ghana

PO611**COMPARATIVE STUDY OF IODINE NUTRITURE OF SCHOOL-AGE CHILDREN (6-12 YEARS) AT LOCAL GOVERNMENT LEVELS IN NIGERIA**

V. Ojukwu¹, O. Keshinro², W. Afolabi³, A. Adebowale⁴, C. Oguntona³

¹The International School, University of Ibadan, Ibadan, Nigeria

²Department of Human Nutrition, University of Ibadan, Oyo State, Nigeria

³Department of Nutrition & Dietetics, Federal University of Agriculture, Abeokuta, Ogun State, Nigeria

⁴Department of Food Science & Technology, Federal University of Agriculture, Abeokuta, Ogun State, Nigeria

Background and objectives: Iodine Deficiency (IDD) and control programmes and monitoring need to be constantly sustained due to the fact that IDD simply reappears if salt iodisation is interrupted (WHO/UNICEF/ICCIDD,2007). Hence it is imperative to reassess iodine nutrition of communities after several years of iodised salt in Nigeria. The aim of the present study was to determine and compare the current iodine status of the school-age children in two local government areas (LGA) of Ibadan.

Methods: Four hundred primary school consisting of 200 males and 200 females children aged 6–12 years were recruited from ten schools in the areas of study using a simple random sampling technique. Casual urine samples were collected from the children and analyzed for urinary iodine using ammonium persulphate method. Salt samples were also collected from households of the studied children and analyzed for iodine content using titrimetric method. Thyroid volume size was determined also by palpation method.

Results: Median urinary iodine excretion in these school-age children was 106g/l. The proportion of population with urinary iodine levels below 100g/l in the two areas of study were <50% and <20% with levels below 50g/l, hence, revealed optimal iodine nutriture. The analysis of table salt from the households showed that 92% and 78.5% (11.5%<benchmark) of households in Ibadan–North LGA and Ido LGA respectively consumed salts with adequate iodine content. The Total Goiter Rate (TGR) in this study was 20% which is < 5% benchmark. The study indicated presence of visible goiter in Ido LGA (3%) and Ibadan–North LGA (8.5%).

Conclusions: The TGR which was the criterion for IDD elimination despite the recorded optimal iodine nutriture asserted that it takes longer to correct goiter prevalence than urinary iodine after implementation of Universal salt iodization (Delange et al., 1999).

Key words: urinary Iodine, Goiter rate, households iodine content

PO612**PREVALENCE OF METABOLIC CHANGES ASSOCIATED WITH BODY WEIGHT IN CHILDREN AND ADOLESCENTS AT A REFERENCE CENTER FOR NUTRITIONAL TREATMENT**

L. Rodrigues¹, S. Koifman²

¹Federal University of the State of Rio de Janeiro (UNIRIO), Rio de Janeiro, Brazil

²National School of Public Health (ENSP) the Oswaldo Cruz Foundation (Fiocruz) - Rio de Janeiro - Brazil

Background and objectives: The nutritional profile has changed in world population over last decades, with a reduction in the prevalence of low weight and an increase in overweight. These nutritional changes associated with high rates of cardiovascular diseases emphasize the importance of monitoring its risk factors in children. The objective of this study was to describe the distribution of anthropometric and biochemical variables in a sample of children and adolescents according to the occurrence of weight excess (WE).

Methods: A cross-sectional descriptive study comprising children and adolescents (2-18 yr) attending a nutritional pediatric outpatients center in Rio de Janeiro, between 1997 y 2009, was carried out. The following secondary data base were collected: age, sex, sexual maturity, BMI (z-score), waist/abdominal circumferences, blood pressure, birth weight (BW), diary activities, WE family history, lipidic profile and glycemic levels. Descriptive statistics, independent samples t test, logistic regression of metabolic changes were ascertained with 95% confidence intervals.

Results: The total sample included 942 individuals, being 53.5% female. All anthropometry parameters showed high distribution in WE, where BMI ranged from -5.9 to +9.1. The cholesterol and LDL-c had similar distributions. The HDL-c and triglycerides were superior without WE and with WE, respectively. The logistic model showed the following risk estimates to the presence of overweight: age over 10 years (OR= 1.78), TG>100 mg/dL (OR= 2.26), TC>150 mg/dL (OR=1.73), PN> 4.0 kg (OR= 4.64), familiar obesity (OR=2.76), presence of physical activity (OR=0.57) and BW<2.5 kg (OR= 0.43). The WE sample showed higher parameters distribution of age, weight, BMI, BW, TG curves and lower values of HDL-c comparatively to the no-WE sample, which are exposed to a broader range of risk factors for CVD. Family history of obesity, lack of physical activity, and the adolescence were the most significant variables for the occurrence of WE in the studied sample.

Key words: adolescence, risk factors, obesity

PO613**LONGITUDINAL STUDY OF THE STATURO-PONDERAL STATUS ACROSS FOUR COHORTS OF MIDDLE SCHOOL STUDENTS IN NORTH WESTERN MOROCCO***R. Sbaibi¹, Y. Aboussaleh¹, K. Ateilah¹*¹Nutrition and health laboratory, Ibn Tofail University, Morocco

Background and objectives: this study aims to compare the statural-ponderal status across 4 cohorts of the middle school students (2009 until 2012) and verify the stability of the prevalence of malnutrition in the only middle school in the rural county Sidi El Kamel. **Methods and subjects:** The statistical analysis of anthropometric indices allowed to compare the stature and weight status across four cohorts of the middle school students; its size are (295, 675, 775, 410); 2155 in total; the ages vary from 11 to 19 years.

Results: A global average of 9.6 % stunting was found during the four years study. The analysis of variance (ANOVA) with one factor confirms the equality of the means of the Z score of 4 cohort for the 4 forms of malnutrition ($p > 0.05$). Stunting ($F=2.6$; $ddl=3$; $p=0.06 > 0.05$); Underweight ($F=1.7$; $ddl=3$; $p=0.17 > 0.05$); Risk of overweight ($F=1.4$; $ddl=3$; $p=0.24 > 0.05$); obesity = 1.2; $ddl=3$; $p=0.33 > 0.05$).

Conclusion: a longitudinal study reveals a stable prevalence of weight and height deficit exceeding the WHO growth reference 2007 for adolescents and a less frequent obesity.

Key words: Adolescents, Stunting, Morocco

PO614**BREAST MILK INTAKE OF 9-MONTH OLD ZAMBIAN INFANTS GIVEN FORTIFIED COMPLEMENTARY FOODS***V. Owino¹, L. Kasonka², J. Wells³, S. Eaton³, M. Sinkala², A. Tomkins³, T. Darch³, S. Filteau⁴*¹Winfoods Project, University of Nairobi, Kenya²University Teaching Hospital, Lusaka, Zambia³Institute of Child Health, University College London, UK⁴Department of Nutrition, London School of Hygiene & Tropical Medicine, UK

Background and objectives: Adequate complementary feeding is crucial to health in late in infancy and early childhood. We assessed the effect of industrially processed fortified complementary blends with or without α -amylase on breast milk intake of Zambian infants.

Methods: Infants were randomized at 6 months of age to receive either a fortified blend (CBM, $n = 37$) or a similar blend with α -amylase (CBMA, $n = 44$) for 3 months. Breast milk intake was measured at 9 months by the deuterium-dose-to-the-mother dilution technique in the two groups and in a control group of infants ($n = 69$) not receiving the study blends.

Results: Breast milk intake was not significantly ($p = 0.87$) different among the groups [CBM: 614 (SD 271) g/dl, CBMA: 635 (SD 193) g/dl and control: 653 (SD 221) g/dl. There were no significant differences in total energy intake ($p = 0.63$) among the three groups. The average breast milk intake observed is higher than published values for older infants obtained by test-weighing likely due to insensible water loss and inability to measure milk intake at night by test-weighing.

Conclusions: The consumption of the study blends did not reduce breast milk intake, but displaced traditional complementary foods; α -amylase addition had no additional benefit. Such blends may be used to improve nutritional status and health of infants in developing countries.

Key words: Breast milk intake, infants, deuterium-dose-to-the mother method.

PO615**EATING PATTERNS OF BRAZILIAN ADOLESCENTS AND THEIR COMPLIANCE WITH THE FOOD GUIDE PYRAMID***C. C. Enes¹, B. Slater²*¹Faculdade de Nutrição, Pontifícia Universidade Católica de Campinas, Brazil²Faculdade de Saúde Pública, Universidade de São Paulo, Brazil

Background and objectives: Adolescence is a crucial period for the development of dietary behaviors; they continue into adulthood and influence the risks of chronic diseases later in life. The health of children and adolescents is dependent upon food intake to provide sufficient energy and nutrients to promote optimal physical growth, social and cognitive development. The objective of this study is to determine to which extent adolescents are meeting healthy eating recommendations and to explore associations between background variables, physical activity, and nutritional status.

Methods: 480 adolescents from fifth grade of public schools of Piracicaba, Sao Paulo, Brazil were enrolled in this cross-sectional survey. A Food Frequency Questionnaire was administered to obtain food intake information. Foods were aggregated into 8 groups according to Brazilian Food Guide Pyramid. Height and weight of all participants were measured. Physical activity pattern was determined by questioning about participation in regular sport activities, how much time spent watching TV, playing computer games.

Results: The mean age of the participants was 11.1±0.82 and 54.6% were female. According to body mass index (BMI) 35.6% were overweight. No adolescent met all the recommendations of the Brazilian Food Guide Pyramid. Only 7.3%, 6.5%, 1.7% and 13.1% of adolescents met the recommendations of fruits, dairy products, vegetables and cereals, respectively. Eating patterns showed no difference between gender and nutritional status. Physically active adolescents consumed more fruits, dairy products and cereals.

Conclusions: Adolescents are not having healthy eating patterns and their eating habits do not meet the recommendations of the Brazilian Food Guide Pyramid.

Key words: adolescent, food guide pyramide, eating patterns

PO616

AUTOPHAGY ALLEVIATES NEURODEGENERATION CAUSED BY THIAMINE DEFICIENCY

Z. Ke¹, Y. Meng¹, Y. Yong¹, J. Luo¹

¹Key Laboratory of Nutrition and Metabolism, Institute for Nutritional Sciences, Shanghai Institutes for Biological Sciences, Chinese Academy of Sciences, Shanghai, China

Background and objectives: Thiamine deficiency (TD) causes mild impairment of oxidative metabolism and region-selective neuronal loss in the brain, which are mediated by neuronal oxidative stress, endoplasmic reticulum stress, and neuroinflammation. The molecular mechanism for TD-induced neuronal death is still unclear.

Methods: We hypothesized that autophagy might be activated and be responsible for neuronal damage in the TD brain. Mice and neuroblastoma cell line, SH-SY5Y cells, were used to verify the hypothesis.

Results: The results demonstrated that TD induced the accumulation of autophagosomes in neurons in the thalamus measured by transmission electron microscopy, and the upregulation of autophagic markers, LC3-II, Atg5 and Beclin1 measured with western blotting. TD also increased the expression of autophagic markers and induced accumulation of LC3 puncta in SH-SY5Y cells. TD-induced expression of autophagic markers was reversed once thiamine was re-administered. Both inhibition of autophagy by wortmannin and downregulating the expression of Beclin1 by siRNA potentiated TD-induced death of SH-SY5Y cells. In contrast, activation of autophagy by rapamycin alleviated SH-SY5Y cell death induced by TD. Intraperitoneal injection of rapamycin stimulated neuronal autophagy and attenuated TD-induced neuronal death in the submedial thalamus nucleus (SmTN) of mice. TD inhibited the phosphorylation of p70S6 kinase, which suggested mTOR/p70S6 kinase pathway involved the TD-induced autophagy.

Conclusions: These results suggested that autophagy is neuroprotective in response to TD-induced damage to the brain, and opened a new avenue for neurodegenerative diseases caused by mild impairment of oxidative metabolism.

Key words: autophagy, oxidative stress, neurodegeneration, thalamus, vitamin B1

PO617

SOCIOECONOMIC DISPARITIES IN DIETARY INTAKES AND DIETARY QUALITY OF FRENCH ADOLESCENTS AGED 11-17 YEARS

P. Drouillet-Pinard¹, C. Dubuisson¹, J.L. Volatier²

¹Dietary Survey Unit, French Agency for food, Environmental and Occupational Health Safety (ANSES), Maisons-Alfort, France

²Office of Scientific Support for Risk Assessment, French Agency for food, Environmental and Occupational Health Safety (ANSES), Maisons-Alfort, France

Background and objectives: In European adolescents, a lower Socioeconomic Status (SES) has frequently been associated with a lower dietary quality, a lower intake of Fruits and Vegetables (FV), fish, dairy products and a higher intake of starches, snacks or soft drinks, but few data are available for France. The objective of the current study was to examine these associations in a representative sample of French adolescents aged 11-17 years.

Methods: Data from the second French national food consumption survey (INCA2, 2006-2007) were used. Information on food consumption and nutrient was available. Dietary quality indicators included: Dietary Diversity (DD) score, Nutrient Adequacy Ratio (NAR), dietary Energy Density (ED). SES indicators included: occupational and educational level of the adolescent's adult caregiver, household income, composite indices of SES. Multivariate regression analyses were performed on 881 adolescents.

Results: According to the SES indicators, adolescents in a lower SES context have a significant ($p<0.05$) lower mean intake of FV, yoghourts and cakes-pastries; and a higher mean intake of processed meat, dairy desserts and soft drinks. No significant association was found with fish consumption. They also have a significant lower NAR and DD score ($p<0.04$). No significant association was found with dietary ED. The largest differences were mainly observed for the caregiver's educational level. For instance, adolescents whose caregiver has a low educational level have a mean FV intake of 241 g/d (vs 312 g/d for higher level) and a mean NAR of 77.8% (vs 80.5%).

Conclusions: French adolescents in a lower SES context have lower FV and higher soft drinks' intakes and a lower die-

tary quality. The parents' educational level seems to be the most influential factor. This suggests the need for specific messages to improve food intake to meet dietary recommendations and to reduce health inequalities in nutrition.

Key words: dietary quality, socioeconomic status, French adolescents

PO618

SOCIOECONOMIC DISPARITIES IN DIETARY INTAKES AND DIETARY QUALITY OF FRENCH CHILDREN AGED 3-10 YEARS

P. Drouillet-Pinard¹, C. Dubuisson¹, J.L. Volatier²

¹Dietary Survey Unit, French Agency for food, Environmental and Occupational Health Safety (ANSES), Maisons-Alfort, France

²Office of Scientific Support for Risk Assessment, French Agency for food, Environmental and Occupational Health Safety (ANSES), Maisons-Alfort, France

Background and objectives: In European children, a lower Socioeconomic Status (SES) has frequently been associated with a lower dietary quality and a lower intake of Fruits and Vegetables (FV), fish, dairy products and a higher intake of starches, snacks or sugar drinks, but few data are available for France. The objective of the current study was to examine these associations in a representative sample of French children aged 3-10 years.

Methods: Data from the second French national food consumption survey (INCA2, 2006-2007) were used. Information on food consumption and nutrient was available. Dietary quality indicators included: Dietary Diversity (DD) score, Nutrient Adequacy Ratio (NAR), dietary Energy Density (ED). SES indicators included: occupational and educational level of the child's adult caregiver, household income, composite indices of SES. Multivariate regression analyses were performed on 574 children.

Results: According to the SES indicators, children in a lower SES context have a significant ($p < 0.05$) lower mean intake of FV, yoghourts and confectionary; and a higher mean intake of starches, meat, milk, soft drinks, and pizzas-sandwiches. No significant association was found with fish consumption. They also have a significant lower NAR, higher dietary ED and lower DD score ($p < 0.02$). The largest differences were mainly observed for caregiver's educational level. For instance, children whose caregiver has a low educational level have a mean FV intake of 211 g/d (vs 286 g/d for higher level) and a mean NAR of 84.2% (vs 85.5%).

Conclusions: French children in a lower SES context have lower FV and higher starches and soft drinks' intakes and a

lower dietary quality. The parents' educational level seems to be the most influential factor. This suggests the need for specific messages to improve food intake to meet dietary recommendations and to reduce health inequalities in nutrition.

Key words: dietary quality, socioeconomic status, French children

PO619

RISK OF CHILDHOOD MALNUTRITION AT 24 MONTHS RELATED TO SMALL FOR GESTATIONAL AGE AND LOW BIRTH WEIGHT IN RURAL WESTERN CHINA

Y. Cao¹, T. Wang¹, L. Zeng¹

¹Xi'an Jiaotong University College of Medicine, Xi'an, China

Background and objectives: China as the biggest developing country continue to experience a large burden among children in rural area. Poor fetal growth continues to be high and with subsequent growth faltering in the first two years childhood malnutrition. The primary aim of this study was to assess the relationship between fetal growth restriction and childhood malnutrition at 24 months.

Methods: A longitudinal follow-up of a subset of newborns ($n=1032$) whose mothers were randomly assigned to receive the supplements of folic acid, iron-folic acid or multi-micronutrients daily during pregnancy in the original trial was conducted. Children's weight and length were measured at 24 months of age. Anthropometric indices weight-for-age Z-score, length-for-age Z-score and weight-for-length Z-score were calculated with WHO Anthro 2005 (WHO, 2006) and WHO Child Growth Standards 2006. Relative risk (RR) and 95% confidence intervals (CI) were estimated by Logistic regression model compared with reference category.

Results: Small-for gestational age (SGA) of newborns were significantly associated with their stunting (RR 2.57, 95%CI 1.74 - 3.78), wasting (RR 6.16, 95%CI 1.37 - 27.78) and underweight (RR 8.41, 95%CI 3.78 - 18.69) at 24 months of age compared with adequate-for-gestational age (AGA). Low birth weight (< 2.5 kg) of newborns also increased the risk of stunting (RR 2.20, 95%CI 1.04 - 4.62), wasting (RR 21.21, 95%CI 4.57 - 98.41) and underweight (RR 11.00, 95%CI 4.33 - 27.93) at their 24 months of age compared with those newborns with birth weight ≥ 2.5 kg.

Conclusions: Fetal growth restriction increased the risk of childhood under-nutrition at 24 months in northwestern rural China, with implications for programs and policy focusing on pregnant women and more broadly maternal nutrition.

Key words: stunting, birth weight, small for gestational age

PO620**IRON DEFICIENCY ANEMIA: A BURNING HEALTH ISSUE AMONG ADOLESCENCE IN DEVELOPING COUNTRIES***S. Chauhan¹, A. Dalal¹, D. Bala¹*

¹Department of Community Medicine, Smt. NHL Municipal Medical College, Ahmedabad, Gujarat, India

Background and objectives: In India, adolescents represent over 1/5th of the population. Adolescent girls, at this stage need macro and micro-nutrients to support growth spurt and meet body's increased demand for iron during menstruation. Hence, to study problem of micro-nutrient deficiencies in adolescent girls, study was carried out. The aim of the present study was to assess micro-nutrient deficiencies by clinical examination and Iron deficiency anemia by estimating Hemoglobin(Hb) level among girls.

Methods: A cross-sectional study was carried out among 467 adolescent girls belonging to slums during a period of 18 months in 10 wards of Ahmedabad Municipal Corporation. Girls were selected by Simple Random Sampling technique using Random tables. Clinical examination was carried out to detect micro-nutrient deficiencies and Hb estimation was done using cyanmethemoglobin method after obtaining written consent from parents/guardians of the girls. Appropriate statistical test were applied.

Results: Mean Hb was 10.18±1.28 gm /dl. The prevalence of anemia was 85.9%. Mild, moderate and severe anemia was observed in 59.1%, 26.2% and 0.6% girls respectively. On clinical examination, 9% girls had signs of Vitamin-A deficiency, 28.1% had refractive errors and 0.6% had signs of iodine deficiency. The difference observed in different BMI categories and proportion of girls with anemia was highly significant ($p=0.012$). A Strong negative correlation was observed between age of girls and mean Hb concentration (" r "=-1) which was statistically significant ($p=0.001$). A significant association was observed between birth order and anemia ($p=0.009$). In multivariate logistic regression model, low level of education among mothers (odds ratio[OR]:4.26, 95% confidence interval[CI]:2.42-7.51); not consuming Vitamin-C (OR:2.70, 95% CI:1.59-4.58) and consuming tea after meal (OR:1.7, 95% CI:1.2-3.11) remained significant correlates of anemia in this population.

Conclusions: As age of the girls increases, body's demand for iron also rises. Therefore, importance of regular consumption of green leafy vegetables and iron rich foods should be taught to girls right from the childhood by parents, teachers and health workers.

Key words: anemia, adolescence, hemoglobin

PO621**ASSESSMENT OF ENERGY EXPENDITURE AND IRON STATUS OF PREGNANT WOMEN IN URBAN AND RURAL COMMUNITIES IN NIGERIA***I. Onimawo¹, U. Onuorah²*

¹Ambrose Alli University, Ekpoma, Nigeria

²Michael Okpara University of Agriculture Umudike, Nigeria

Background and objectives: The study was carried out to evaluate the energy expenditure and iron status of 400 pregnant women in their various trimesters from two hospitals (urban and rural) in Umuahia in Abia State.

Methods: The subjects were randomly selected. Anthropometric measurements, haemoglobin level, packed cell volume, serum ferritin level, energy intake and energy expenditure assessment were carried out on the study population using standard procedures.

Results: Results of the analysis showed that the mean BMI of the mothers-the first, second and third trimesters were 25.25±3.81, 26.24±3.37 and 30.64±17.61kg respectively. Arm circumference values ranged between 9.74, 9.85 to 11.15 cm in the third trimester. Abdominal circumference ranged from 48.24±10.56 to 49.26±10.61. The result further showed that 19%, 12.8% and 0.5% had mild, moderate and severe anaemia respectively. A total of 40% of the pregnant women in the rural areas had various forms of anaemia as against 24.5% in the urban areas. A total of 32.2% of the pregnant women had iron deficiency anaemia. The prevalence of iron deficiency anaemia was also significantly associated with the trimesters ($\chi^2 = 22.58, p = 0.00$).

Conclusion: The study found that the pregnant women had a positive energy balance. About 12% and 14% of the women in their second and third trimester respectively had protein intake above the recommended intake. A total of 40.0% of rural women were anaemic.

Key words: anaemia, energy expenditure, pregnant women, body composition.

PO622**EFFECT OF SUPPLEMENTATION OF IRON –FOLIC ACID RICH BISCUITS ON ANAEMIC ADOLESCENT GIRLS**

A. Thomas¹, R. Rajasolim²

¹Department of Home Science, C.M.S College, Kottayam, Kerala, India

²St.Teresa's College, Ernakulam, Kerala, India

Background and objectives: Anemia is a major public health problem in India widely prevalent among adolescents. Adolescence for a girl is a period of physical and psychological preparation for safe motherhood. Early marriage, early conception and anemia during adolescence reduce growth velocity and increase the risk of maternal health, pregnancy complications, obstructed labor and low birth weight. The present study was aimed to reduce the incidence of anemia and also to improve the health status of adolescent girls through micronutrient supplementation.

Methods: 500 adolescent girls (12-19 yrs) were interviewed on socio-economic background, anthropometric details, menstruation details, dietary pattern, influence of individual and environmental factors on dietary pattern, knowledge regarding nutrition and anemia etc. Hemoglobin levels of 202 subjects revealed that 57% were anemic. Two groups of 50 subjects each were constituted. One group were supplemented with five biscuits (20 g each) daily, rich in iron and folic acid, adjunct to main meals, other group formed control. The supplementation was for three months and the impact was analyzed biochemically.

Results: The results revealed that, supplementation in the form of iron and folic acid rich biscuits made a significant improvement in all the parameters studied. Total iron, hemoglobin and serum folic acid levels of the experiment group were compared with control group and significant improvement was observed in experimental group with one percent level ($p < 0.01$) significance.

Conclusions: Supplementation of iron and folic acid rich biscuits serve as an effective strategy to combat iron and folic acid deficiencies.

Key words: adolescent girls, anaemia, supplementation, folic acid, iron

Background and objectives: Prospective studies in non-Mediterranean populations have consistently related increasing nut consumption to lower coronary heart disease mortality. A small protective effect on all-cause and cancer mortality has been suggested. To examine the association between frequency of nut consumption and mortality in individuals at high cardiovascular risk from Spain, a Mediterranean country with relatively high nut intake.

Methods: We evaluated 7,216 men and women aged 55-80 y randomized to one of three interventions (Mediterranean diets supplemented with nuts or olive oil and control diet) in the PREDIMED (PREvención con DIeta MEDiterránea) study. Nut consumption was assessed at baseline and mortality was ascertained by medical records and linkage to the National Death Index. Multivariable-adjusted Cox regression was used to estimate hazard ratios (HR) for mortality by frequency of nut consumption.

Results: During a mean follow-up of 4.8 y, 323 total deaths, 81 cardiovascular deaths and 130 cancer deaths occurred. Nut consumption was associated with a significantly reduced risk of all-cause mortality (p-trend <0.05, all). Compared to non-consumers, subjects consuming nuts >3 servings/wk (32% of the cohort) had a 39% lower mortality risk (HR: 0.61; 95% CI: 0.45, 0.83). A similar protective effect against cardiovascular and cancer mortality was observed. Participants allocated to the Mediterranean diet with nuts group who consumed nuts >3 servings/wk at baseline had the lowest total mortality risk (HR: 0.37; 95% CI: 0.22, 0.66).

Conclusions: The frequency of nut consumption was associated with a significantly reduced risk of mortality in a Mediterranean population at high cardiovascular risk.

Key words: nuts, PREDIMED study, mortality, cancer, cardiovascular.

INTervention)- Study (publication in press) was carried out in order to optimize the nutritional status of such patients. As the phase angle of the bioelectrical impedance analysis (BIA) is a valued marker to evaluate the quality of nutritional status it was examined if the phase angle of the geriatric patients could be improved through the intervention.

Methods: The intervention was designed as a controlled parallel intervention trial and compared the protein-energy intake of geriatric patients from protein-energy optimized meals (intervention group) with common meals (control group). The phase angle of bioelectrical impedance (BIA) was measured with Bodystat 1500[®]MDD in a multi-frequency (5/50kHz) technique on the right side of the body in supine position at the beginning (week 1) and at the end (week 36) of the intervention-time. The statistical evaluation was done using the non-parametric Wilcoxon-Rang-Test. P-value<0.05 was considered statistically significant. 85 institutionalized, geriatric patients take part. 82% (70) were female and 18% (15) were male. In the intervention-group data of 39 patients with a mean (\pm SD) age of 84.8 (\pm 7.8) years and a mean (\pm SD) BMI of 26.5 (\pm 3.9)) and in the control-group data of 46 patients with a mean (\pm SD) age of 83.7 (\pm 10.8) years and a mean (\pm SD) BMI of 25.9 (\pm 5.4) were evaluated.

Results: In the intervention-group median (\pm SD) phase angle (3.6 (\pm 0.88)/3.7 (\pm 0.82)) increased significant (p<0.05) and decreased (3.3 (\pm 0.73)/ 3.1 (\pm 0.53)) significant (p<0.05) in the control-group.

Conclusions: The phase-angle-evaluation indicated an optimized nutritional status in the intervention group. It shows that institutionalized, geriatric patients benefit from protein-energy-interventions to optimize their daily meals.

PO625**PREVALENCE AND SEVERITY OF MALNUTRITION AMONG INFANTS AND YOUNG CHILDREN IN AN HIV AND MALARIA PRONE RURAL SETTING, WESTERN KENYA**

S. Konyole¹, J. Kinyuru², S. Omollo¹, B. Owuor³, N. Roos⁴, H. Friis⁴, B. Estambale¹, V. Owino¹

¹University of Nairobi, Institute of Tropical and Infectious Diseases (UNITID), University of Nairobi, Nairobi, Kenya

²Department of Food Science and Technology, Jomo Kenyatta University of Agriculture and Technology, Juja, Kenya

³Department of Biology, Catholic University of Eastern Africa, Nairobi, Kenya

⁴Department of Human Nutrition, University of Copenhagen, Copenhagen, Denmark

Background and objectives: Malaria and HIV are highly prevalent in Western Kenya. There is scarcity of data on the nutritional status of infants and young children in this setting. We aimed to determine the prevalence and severity of malnutrition among children aged 6-24 months in a rural District in Western Kenya.

Methods: In a cross-sectional survey conducted between November and December 2011, we measured nude weight and recumbent length among 618 infants and young children aged 6-24 months in Mumias District, Western Kenya. Weight and length data were used to calculate the prevalence and severity of stunting, wasting and underweight.

Results: Mean WLZ was -0.10 (95% CI:-0.20; 0.00), mean WAZ was -0.57 (95% CI:-0.67;-0.46) while mean HAZ was -0.90 (95% CI:-1.04; -0.77). HAZ for girls was significantly higher ($p=0.009$), thus Infant sex was a determinant for undernutrition with boys more affected than girls. The prevalence of stunting, wasting and underweight were 30%, 4%, and 20%, respectively. A greater proportion of children aged 18-23 months were stunted (44%) and underweight (34%) compared to younger infants ($p<0.01$). 12% of all infants were severely stunted while 1% and 5% were severely wasted and severely underweight, respectively. Infants of older caregivers (women) were significantly lighter/shorter than those of younger caregiver ($p=0.008$).

Conclusions: Malnutrition is highly prevalent and severe in this area placing children 6-24 months at high risk of premature death. More attention is needed for boys who are more affected than girls. There is need for context relevant interventions to combat malnutrition in this region and other similar settings.

Key words: stunting, wasting, malnutrition, infants and young children, Western Kenya.

PO626**EFFECTIVENESS OF AN EDUCATIONAL INTERVENTION ON NUTRITION AND PHYSICAL ACTIVITY FOR ADOLESCENTS**

E. González-Jiménez¹, G. Cañadas-De la Fuente¹, J. Schmidt-Río-Valle¹, C. García-García², M. Tovar-Galvez³

¹Departamento de Enfermería. Universidad de Granada. Granada, Spain

²Departamento de Medicina Legal, Toxicología y Antropología Física, Universidad de Granada, Spain

³Universidad de Granada, Granada, Spain

Background and objectives: Recent studies show an alarming increase in levels of overweight and obesity among children and adolescents. The objectives of this survey were two-fold: firstly, to verify if an educational intervention improves the nutritional state of a sample of students and, secondly, to check if students adopt good eating habits and healthy physical activity, after implementing a health educational intervention.

Methods: The sample consisted of 91 adolescent between 15 and 17 years old, 46 males (51.1%) and 44 females (48.9%), from a public educational center in Almería (Spain). The survey was conducted in three phases. The first stage comprise the second half of September 2012. In this stage, an assessment of the nutritional status of all the students was done by an anthropometry. The second stage (from October 2011 to the first half of June 2012), was to implement the educational intervention on healthy eating and physical activity. And the last phase was extended to the second half of June 2012, where the intervention was evaluated.

Results: After the intervention, all the students significantly improved their nutritional state, regardless their age ($p<0.000$). Regarding the adoption of healthy habits, significant differences were obtained in test Kreceplus scores ($p<0.000$). No significant differences were found for physical activity after the intervention ($p=0.568$).

Conclusions: These results show the effectiveness of the procedures applied in this intervention to modify eating habits. In conclusion, the practice of physical activity is still a big problem in the study population.

Key words: educational intervention, obesity, nutritional status, physical activity.

PO627**POSITIVE ASSOCIATION BETWEEN ACTIVITY ENERGY EXPENDITURE AND APPENDICULAR SKELETAL MASS INDEX IN A GROUP OF BLACK SOUTH AFRICAN URBAN WOMEN**

H. S. Kruger^{1, 2}, L. Havemann-Nel¹, C. Botha¹, H. H. Wright¹, S. J. Moss², E. Wentzel-Viljoen¹, A. Kruger³

¹Centre of Excellence for Nutrition, North-West University, South Africa

²Physical Activity, Sport and Recreation, North-West University, South Africa

³Africa Unit for Transdisciplinary Health Research, North-West University, South Africa

Background and objectives: The European Working Group on Sarcopenia in Older People (EWGSOP) defines sarcopenia as appendicular skeletal mass (ASM) index (ASM/height squared [ASM/h²]) < 5.5 kg/m² in women, plus a criterion of low muscle strength or low physical performance. There is a lack of data on the prevalence and determinants of sarcopenia in Africans. The aim of this study was to determine the prevalence and determinants of sarcopenia in a group of urban black women aged 43-100 y in South Africa.

Methods: In this longitudinal study, anthropometric, demographic and physical activity measurements (by questionnaire) were done in 2005, 2010 and 2012. Dietary intakes were measured (2005 and 2010) by quantitative food frequency questionnaire. DXA was used to measure ASM in 2012 and ASM/h² < 5.5 kg/m² was used as criterion 1 for sarcopenia. Grip-strength < 20 kg was the additional criterion for low muscle strength and gait speed < 0.65 m/s over 6 m was the criterion for low physical performance. Determinants of sarcopenia were assessed using multiple regression analysis with ASM/h² as the dependent variable. Age, HIV status, smoking, dietary intakes and physical activity measured by questionnaire during 2005 and 2010 and by accelerometer/heart rate monitor (Actiheart) in 2012 were covariates in different models.

Results: According to the EWGSOP definition 12.7% of the women were sarcopenic. After the 14.8% HIV-infected women were excluded, 7.9% were sarcopenic. In the total group, the negative association between age and ASM/h² was not statistically significant. Only HIV-status and activity energy expenditure (by Actiheart) were significant predictors of ASM/h². When HIV-infected participants were excluded, animal protein intake and activity energy expenditure were positively associated with ASM/h².

Conclusions: HIV-infection, animal protein intake and activity energy expenditure were the most important predictors of sarcopenia in a group of urban African women.

Key words: African women, sarcopenia, physical activity, HIV

PO628**USING COMMUNICATION SKILLS TO IMPROVE MOTHER'S PRACTICE ON INFANTS AND YOUNG CHILD FEEDING AND NUTRITIONAL STATUS OF THE CHILDREN**

H. Cao^{1,2}, L. Nguyen²

¹Science & Research Management Department, National Institute of Nutrition, Hanoi, Vietnam

²Vice-Director, National Institute of Nutrition, Hanoi, Vietnam

Background and objectives: Malnutrition is public health problem in Vietnam, one of reasons was improper mother's practices on breast-feeding (BF) and complementary feeding (CF). So improving nutritional status of children by correctly feeding them is necessary. To determine changes of mother's practices on breast and complementary feeding according to WHO criteria and nutritional status of children under 24 months.

Methods: Two repeated cross-sectional studies in pairs of mothers and their children under 24 months were conducted in Phu Tho and Quang Ngai province in 2008-2010. During intervention time, mothers had been consulted by trained nutritional collaborators with 7 home visits in intervention time and group discussion focused on practices: early BF, exclusive BF, proper time for introducing complementary food, sufficient amount of complementary meals, diversity of complementary food, child illness care and feeding, continuing breast feeding, using fortified complementary food

Results: After 2 year of intervention: Prevalence of initiate breastfeeding with one hour increased, exclusive breast feeding increased from 46.1% up to 86.2 and from 27% to 42%. Prevalence of children aged 12-15 months and 20-23 months continuing breast feeding increased from 79% to 86.5% and from 11.1% to 31.9%. Prevalence of children aged 6-23 months consumed vitamin A rich food increased 21.1% to 38.2% and diversity of food increased from 49.6% to 82.4%. Anthropometric index of children were improved: WAZ, HAZ respectively from -0.85±0.97 and -1.16±1.08; up to -0.58±0.90 and -1.03±1.02. Hemoglobin concentration was increased from 111.2 ± 10 g/L up to 112.8 ± 10 g/L. Prevalence of underweight and stunting significantly decreased from 13.0% down 4.7% and from 24.1% down to 16.7%, prevalence of anemia was decreased from 38.4% into 24.4%.

Conclusions: Nutrition collaborator's skill consulting help mothers up-graded infants and young child feeding practices and help children improve nutritional status.

Key words: children, feeding, practices, nutrition

PO629**BIOPSYCHOLOGIC NUTRITIONAL SYSTEM- PHYSIC AND BREATHING TECHNIQUES***C. Angel'*

¹Unicancer (Cancer patient attention department), Tomas Uribe Uribe Hospital, Tulua, Valle, Colombia

Background and objectives: To Prevent disease and maintain health through Biopsychologic Nutrition, * 1 * 2 given that the function of nutrition is to restore tissues and regain energy. * 1 As we eat we are affected by external stimuli psychic, mental or emotional, which modify our biological response. * 2 (Registered Nationwide, Copyright. Filing 1560 of February 28, 1994)

Methods:-By Applying nutritional correction which ensures proper handling of biological solids, liquids and air (gas feed). -With physical and breathing techniques in order to improve, activate and detoxify organs, glands and systems, and to balance mental states.

Results: In 48 years of study, research and practice abroad and in the country, including in public sectors as well as private and also educational environments at hospitals Direct-Care: 4944 people Indirect-Care: 11773 people Broadcast in Regional Radio and Television (2000-2010), on National (2012). -Patients record are being systematized for further studies. A book is being written for illustrating students and health care personal

Conclusions: Changing eating behaviors -awareness against poor eating habits. -Knowledge of nutritional values of foods and techniques applicable in daily routine.

Key words: Nutrition, Joy, Health (NAS)

PO630**GENDER DIFFERENCES BY SKIPPING BREAKFAST IN MOOD STATES AND NERVOUS SYSTEM OF SCHOOL CHILDREN**

M. Moriyama^{1,2}, A. Koide², T. Yamauchi³, A. Yamamoto⁴, K. Oba⁵

¹Department of Home Economics, University of Aichi Gakusen, Okazaki, Aichi, Japan

²Department of Life Studies and Environmental Science, University of Nagoya Women's, Nagoya, Aichi, Japan

³Department of Food Science and Nutrition, University of Nagoya Women's, Nagoya, Aichi, Japan

⁴Aichi Gakusen college, Okazaki, Aichi, Japan

⁵Department of Food and Nutritional Science, University of Chubu, Kasugai, Aichi, Japan

Background and objectives: Studies on the relationship between breakfast consumption and cognitive function, knowledge, attitude and behavior of school children are few. Ages of the primary school children are the best growing period and increasing their appearances as a result of gender differences in the life cycle.

Methods: We searched the gender differences by breakfast omitting on the activities of the sympathetic nervous system and mood states in 32 students (5th grade) of an elementary school. We compared the difference of amylase activity as a marker of the activity of sympathetic nervous system, 6 values of POMS (profile of mood states) and 3 values of VAS (Visual Analogue Scale) as a mood states in both cases of breakfast feeding and skipping. Amylase activity and POMS and VAS were measured before and after Kraepelin and Stroop tests in fourth period.

Results: In the values of POMS, Tension (T), Anger (A), Fatigue (F), Confusion (C) by boys and values of T, Depression (D), F and C by girls in the case of breakfast skipping (BS) were significantly higher than the case of feeding (BF) before the tests. After the tests only 3 values by boys were higher, while all 6 values of POMS include Vigor (V) were more significant difference by girls of BS than that of BF. Furthermore values of VAS (sleepiness, lassitude and hunger) and amylase activity of BS were higher than that of BF by girls before and after tests.

Conclusions: The present results suggest that breakfast skipping gives much more effect to girls than boys in the sympathetic nervous system and mood states. We may suggest that these huge metabolic changes of girls caused by breakfast skipping are associated with cognitive function or problem solving.

Key words: gender differences, skipping breakfast, mood states, nervous system, school children

PO631**PREVALANCE OF ORTHOREXIA NERVOSA AMONG ADOLESCENTS AND YOUNG ADULTS***A. Ercan^{1,2}, S. Altun², D. Özkahya², S. Güler²*¹Baskent University, Health Science Faculty, Department of Nutrition And Dietetics, Ankara, Turkey²T.C. Istanbul Bilim University, Department of Nutrition and Dietetics, Istanbul, Turkey

Background and objectives: Healthy nutrition is generally considered as positive behavior by the general public but people who exhibit highly sensitive behavior about their consumption of healthy nutrition carry the risk of developing orthorexia nervosa (ON) in the future. The aim of this study was to determine the prevalence of orthorexia nervosa among adolescents and young adults.

Methods: The study included 438 female (66.1%), 225 male (33.9%), totally 663 university students with a mean age of 22.8±2.07 years. There were two subgroups by age as adolescents (29.7%) and young adults (70.3%). The 44.8% of the students were educated in health related departments. A self-reported questionnaire about demographic and anthropometric information was administered. The ORTO-15 test was used to propose a diagnostic proceeding and to try verify the prevalence of ON. ORTO-15 scale used for diagnosis of orthorexia symptoms consists of 15 questions and a 1-to-4 likert type scale. Consistent and valid ORTO-15 test described people at and under 33 points with Turkish standards as orthorexic. Data were analyzed by SPSS 11.5 statistical software for Windows.

Results: The mean BMI of females and males were 21.19±3.19 kg/m² and 23.69±2.91 kg/m². The prevalence of underweight and obese among participants was 13.4% and 17.4% respectively. There was no significant correlation between BMI and ORTO-15 mean scores. Mean score of the participants from the ORTO-15 test was 38.2±3.43 and there was no statistically difference by gender and education programs. But young adult group (38.4±3.47) had higher mean score from ORTO-15 than adolescent group (37.7±3.30) and the differences between groups were statistically significant (p<0.05). A total of 9.7% of the participants scored below 33 in the ORTO-15 test.

Conclusions: Healthy eating obsession (Orthorexia nervosa) is one of the psychosocial problems. For solving this problem, effective nutrition education is essential.

Key words: orthorexia nervosa, BMI, prevalence

PO632**STUDIES ON MILK FAT OF DIFFERENT SOCIOECONOMIC GROUPS OF BENGALI MOTHERS IN DIFFERENT STAGES OF LACTATION***S. Roy^{1,2}, S. Ghosh¹, P. Dhar², M. Ghosh¹*¹Department of Chemical Technology, University of Calcutta, India²Department of Home Science, University of Calcutta, India

Background and objectives: Human milk is the best food for the neonates as it meets the needs of growing infants. The lipid fraction of milk is more important as it has many important physiological roles in neonates. The study aims to determine the total lipid content, fatty acid composition, cholesterol and phospholipids content of colostrum, transitional milk (TM) and matured milk (MM) of Bengali mothers of three different socioeconomic groups, lower income group (LIG), medium income group (MIG) and higher income group (HIG). Particle size of milk fat globules was also determined.

Methods: Samples were collected from 250 healthy, aged 17-35 years, non-smoking, full-term, non-vegetarian mothers belonging to LIG (n=91), MIG (n=69) and HIG (n=90). Socioeconomic status and details of food consumption were analyzed by food frequency questionnaire. Lipid was extracted and fatty acid composition was determined by gas liquid chromatography after converting fatty acids into methyl esters. Cholesterol and phospholipids contents were determined by the method of Toshiaki Ohshima (2001) and Chen et. al. (1956), respectively. Milk fat globule size was analyzed by Particle Analyzer, Delsa Nano-C (A53878) from Beckman Coulter, Mumbai, India.

Results: Lipid contents mostly showed greater values towards matured milk from colostrum in each group. Phospholipids and cholesterol contents also showed the similar fashion as lactation progressed. MIG-colostrum and MM showed the highest amount of saturated (40.41±7.46) and monounsaturated fatty acid (41.50±2.54) respectively, whereas, HIG-TM and colostrum composed with highest n-6 (19.15 ± 1.07) and n-3 (6.99 ± 1.87) PUFA respectively. Erucic acid (C22:1n-9) and nervonic acid (C24:1n-9) were two important fatty acids present in Bengali mothers' milk. Fat globule size of colostrum, TM and MM were 3917.9±358.33, 1543.3±136.14 and 844.88±232.28 respectively.

Conclusions: May be compared with other countries, but further study with higher number of subjects is required.

Key words: PUFA, food frequency questionnaire, particle size.

PO633**EATING BEHAVIOUR AND BODY IMAGE CONCERNS IN ADOLESCENTS***E. Köseleler¹, S. Metin¹, Y. Kaya¹, M. Saka¹, G. Kiziltan¹*¹Baskent University, Health Science Faculty, Department of Nutrition And Dietetics, Ankara, Turkey

Background and objectives: There has been an increased awareness of the prevalence of body image problems and disordered eating behavior in children and adolescents. The aim of this study was to determine body image and eating behaviours in adolescents.

Methods: The study was conducted on 590 high-school students with a mean age of 16.8±1.14 years. Eating behaviours and body image concern were assessed by The Eating Attitudes Test (EAT-26) and Social Physique Anxiety Scale (SPAS). The EAT-26 is the most widely used screening eating disorder. A score at or above 20 on the EAT-26 indicates a high level of problematic eating behaviors. The SPAS questionnaire is a tool used to measure Social Physique Anxiety and high score reflects high anxiety level. Body weight and height were determined and body mass index(BMI) was calculated and evaluated by WHO standards. All data was evaluated by SPSS13.0 for Windows.

Results: Participants of the study were 58.8% female, 41.2% male. The percentages of the girls and boys with a BMI ≥85th percentile were 11.5% and 22.5%, respectively. The 18.5% of the girls and 13.5% of the boys were underweight (BMI≤15th percentile). The mean scores of EAT-26 and SPAS of girls were higher than boys ($p<0.05$). In girls, there were positive correlations between BMI and EAT-26 ($r=0.136$, $p=0.011$) and SPAS ($r=0.226$, $p=0.000$) score. Among girls and boys the percentages of the abnormal eating behaviour and the high anxiety were 23.9%, 62.2% and 11.5%, 47.1%, respectively. The SPAS score was positively correlated with the BMI percentiles of all individuals ($r=0.158$, $p=0.000$).

Conclusions: Obesity in adolescence may have serious health and psychosocial consequences. Adolescents, especially girls are at high risk for abnormal eating behaviours and social physique anxiety.

Key words: body image, eating behaviours, self-esteem, adolescents

PO634**EVALUATION OF APPETITE AND NUTRITIONAL STATUS OF PREGNANT ADOLESCENTS***E. Köseleler¹, A. Ercan¹, G. Kaz-Itan¹, S. Gürda¹, E. Güzel¹*¹Baskent University, Health Science Faculty, Department of Nutrition And Dietetics, Ankara, Turkey

Background and objectives: Adequate nutrition is essential to maintain health at every stage of life. Nutritional needs differ across various age groups and with certain health conditions. Adolescence pregnancy is one such instance in which nutritional needs are differ. The aim of this study was to determine the nutritional status of pregnant adolescents.

Methods: A total of 100 pregnant adolescents with a mean age of 20.1±2.14 years participated in this study. Pre-pregnancy body weight, current body weight, height and nutritional status were determined via a questionnaire. Body mass index (BMI) was calculated and evaluated by WHO standards. All data was evaluated by SPSS 13.0 for Windows.

Results: The mean gestational age of pregnant adolescents was 30.0±7.01 weeks and the mean of parity was 1.31±0.58. The mean pre-pregnancy and current BMI of pregnant adolescents were 21.2±3.58 kg/m² and 25.1±3.95 kg/m², respectively. According to pre-pregnancy BMI, 18.0% of pregnant adolescents were underweight, 70.0% were normal, 8.0% were overweight, 4.0% were obese. The mean body weight gain during pregnancy was 9.6±5.38 kg. The 42.0% of pregnant women identified their appetite as inappetent and 16.0% of them identified their appetite as anappetent. The average number of main meals and snacks consumed by pregnant adolescents were 2.4±0.55 and 2.7±0.96, respectively. The majority of individuals (68.0%) were skipping meals mostly lunch meal (37.8%). The mean daily energy intake of pregnant adolescents were 3490.7±952.20 kcal. The percentages of the energy from carbohydrate, protein and fat were 45.1%±5.36, 13.1%±2.16 and 41.7%±6.06, respectively. Dietary intake of vitamin A, folic acid, calcium and iron didn't meet the DRI recommendations.

Conclusions: Adolescents who become pregnant can be nutritionally at risk. Many adolescents do not have good eating habits and their diets are often high in fat and calories. So, pregnant adolescents need professional nutritional assistance.

Key words: adolescent pregnancies, nutrition, appetite, BMI

PO635**THE EFFECT OF DIFFERENT AMOUNTS OF FRUCTOSE CONSUMPTION ON SOME ANTHROPOMETRIC MEASUREMENTS AND BIOCHEMICAL PARAMETERS**

E. Kösele¹, G. Kiziltan¹, A. Kut², M. Saka¹

¹Baskent University, Health Science Faculty, Department of Nutrition And Dietetics, Ankara, Turkey

Background and objectives: An increase in high fructose corn syrup, as well as total fructose, consumption over the past ten years has been linked to a rise in obesity and metabolic disorders. The objective of this study was to determine the relations between some biochemical parameters, anthropometric measurements and dietary fructose consumption.

Methods: The study was planned on 90 (41 men, 49 women) healthy individuals with a mean age of 31.9±7.15 years. A questionnaire was administered to determine personal characteristics and anthropometric measurements [height, body weight, waist circumference, body mass index (BMI)]. The nutritional status was determined by food-frequency questionnaire and three days 24-h dietary records. Some biochemical parameters were also determined. All data was evaluated by SPSS 13.0 for Windows.

Results: The mean daily dietary fructose consumption was 42.3±22.74 g and the men's consumption of fructose was higher than women's (p<0.05). The daily dietary fructose consumption was higher in 41-50 age groups (44.3± 19.55 g) and the main source of fructose was sucrose. The percentages of fructose from energy were 7.2% in men, 5.7% in women. The percentages of the participants that consumes fructose daily ≥50 g and ≥10% of the total energy was 33.3% and 18.9%. There were significant positive correlations between the energy intake (r=0.717, p=0.000), body weight (r=0.267, p=0.011) and fructose consumption. The participants who consumed ≥50 g fructose have higher waist circumferences, serum glucose and total cholesterol levels than the participants who consumed <50g fructose but the differences were not statistically significant (p>0.05).

Conclusions: As a conclusion, dietary fructose from added sugar may cause some health problems. So, the healthy preference of fructose source in diets is fruit and the amount of safe dietary intake of fructose may accept as 10% of total energy.

Key words: fructose, high fructose corn syrup, obesity, chronic diseases, nutrition

PO636**EXCLUSIVE BREASTFEEDING: PREGNANT WOMEN'S AWARENESS AND HEALTHCARE PROVIDERS' PRACTICES DURING ANTENATAL VISITS IN MOROGORO, TANZANIA**

H. Mbwana¹, C. Conlon², P. von Hurst²

¹Department of Food Science and Technology, Sokoine University of Agriculture, Morogoro Tanzania

²Institute of Food, Nutrition & Human Health, Massey University, New Zealand

Background and objectives: In Tanzania about 42% of children below five years are stunted due to chronic malnutrition. Exclusive breastfeeding (EBF) may be an effective strategy to protect infants from malnutrition. Therefore, it is important to disseminate accurate information on breastfeeding recommendations to pregnant women attending antenatal visits. The aim of the present study was to assess the awareness of exclusive breastfeeding among first time pregnant women attending antenatal clinics, and breastfeeding counselling practices of healthcare providers, for alignment with the WHO recommendations.

Methods: A cross sectional study of eighty first time pregnant women attending antenatal clinics (ANC) at Mzumbe Health Centre and Tangeni dispensary, and six nurses providing care in these facilities was undertaken. Questionnaires were used to evaluate women's breastfeeding knowledge and future intentions to breastfeed and nurses' breastfeeding knowledge and counselling practices.

Results: Women's knowledge in EBF was generally poor; there were no differences in breastfeeding knowledge between the two facilities. About 94% of women had never received breastfeeding counselling at the ANC, 61% received EBF information from their mothers, 37.5% said glucose water should be given immediately after delivery, only 23.8% planned to introduce solids at six months, the majority indicating that they would start solids at a younger age. Common reasons for introducing solids were; baby will be old enough (55%), baby will be hungry (32.5%), advised by the nurse (7.5%). Only one nurse had received training on breastfeeding, nurses' knowledge of WHO breastfeeding recommendations was poor; however nurses had satisfactory knowledge of how to solve breastfeeding problems. Only three nurses said they educate mothers about exclusive breastfeeding.

Conclusions: Findings highlight a need to focus on delivering information and education to women and nurses.

Key words: breastfeeding, knowledge, healthcare providers, pregnant women

PO637**VIA® INSTANT COFFEE ENHANCES EXPLOSIVE BENCH PRESS PERFORMANCE**

M C. Powers¹, S. Kirk¹, C. Goggin¹, R. Smith¹, A. Slotta¹, A. Betro¹, K. Santana¹, A. Cox¹, K. Dreger¹, A. Hubbell¹, L. Lowery¹

¹Department of Human Performance and Sports Business, University of Mount Union, Alliance, Ohio, USA

²Nutrition, Exercise & Wellness Associates, Ltd., Cuyahoga Falls, OH, USA

Background and objectives: There has been debate on whether caffeine intake enhances performance in resistance trained individuals. This study tested a new, highly caffeinated coffee product, Via® instant coffee (VIA). We hypothesized that VIA consumption will increase ($p < 0.05$) muscle explosiveness in resistance-trained (8.0 ± 4.3 y) college-aged students ($n = 12$; 22.5 ± 4.7 y) compared to themselves in a decaffeinated condition (DCF).

Methods: After 24 hours of dietary control and caffeine abstinence, fasted subjects performed three separate repetitions of strict Smith bench press under two conditions (VIA, DCF), with trials separated by 48-72 hours. The peak force (FOR), peak power (POW), peak velocity (VEL), and maximum rate of force development (RFD) of the VIA trial were compared to DCF. FOR, POW, VEL, and RFD were measured via Ballistic Measurement System (BMS) linear displacement, XPV6+ (Innervations, Inc. South Australia, Australia). **Results:** Results suggest a significant increase in FOR (VIA 551.6 ± 263.2 N vs DCF 542.8 ± 262.7 N; $p = 0.027$); POW (VIA 505.2 ± 246.4 W vs DCF 471.6 ± 233.4 W; $p = 0.004$); VEL (VIA 1.21 ± 0.14 m/s vs DCF 1.12 ± 0.13 m/s; $p = 0.0008$); and RFD (VIA 1546.3 ± 884.9 N/s vs DCF 1409.3 ± 7585.5 N/s; $p = 0.024$).

Conclusions: These preliminary data support the hypothesis that explosive muscle performance increases under the influence of Via® instant coffee.

Key words: caffeine, resistance exercise, sports nutrition, neuromuscular.

PO638**EFFECTS OF VIA® INSTANT COFFEE ON EXPLOSIVE SQUAT PERFORMANCE**

C. Goggin¹, S. Kirk¹, M.C. Powers¹, R. Smith¹, A. Slotta¹, A. Betro¹, K. Santana¹, A. Cox¹, K. Dreger¹, L. Lowery¹

¹Department of Human Performance and Sports Business, University of Mount Union, Alliance, Ohio, USA

²Nutrition, Exercise & Wellness Associates, Ltd., Cuyahoga Falls, Ohio, USA

Background and objectives: Caffeine is commonly considered a performance enhancer during resistance training. A new, highly caffeinated instant coffee product, Via® (VIA), was tested in this study. We hypothesized that VIA consumption would increase ($p < 0.05$) explosive squat performance in resistance-trained (8.0 ± 4.3 years) university students ($n = 12$; 22.5 ± 4.7 y) in a double blind experimental design.

Methods: Fasted subjects performed three repetitions of strict Smith squat under two conditions (VIA, decaffeinated VIA [DCF]), after 24 hours of dietary control and caffeine abstinence, with trials separated by 48-72 hours. The peak force (FOR), peak power (POW), peak velocity (VEL), and maximum rate of force development (RFD) of the VIA trial were compared to DCF. Ballistic Measurement System (BMS) linear displacement, XPV6+ (Innervations, Inc. South Australia, Australia) was employed.

Results: Results reveal a significant increase in VEL (VIA 1.655 ± 0.223 m/s vs DCF 1.588 ± 0.215 m/s; $p = 0.006$). There was no significant increase in FOR (VIA 1505.3 ± 281.9 N vs DCF 1518.3 ± 319.9 N; $p = 0.698$); POW (VIA 1927.12 ± 527.9 W vs DCF 1878.88 ± 565.93 W; $p = 0.301$); RFD (VIA 4327.5 ± 1257.05 N/s vs DCF 4268.83 ± 1141.76 N/s; $p = 0.793$).

Conclusions: These preliminary data suggest enhancement of velocity but no other performance variables after ingesting VIA. Given other findings from our laboratory, future research should focus on differences between upper and lower body performance after ingesting caffeinated drinks.

Key words: caffeine, resistance exercise, sports nutrition, neuromuscular

PO639**ACTION OF THE NAGOYA HEALTH COLLEGE-HEALTH CARE IN THE ELDERLY PERSON**

N. Katayama¹, A. Hosono², N. Andou¹, H. Itou¹, N. Iwata¹, N. Kawajiri¹, E. Kawada¹, E. Shimizu¹, A. Shimoda¹, K. Shimoyama¹, K. Suzumura¹, Y. Nagumo¹, T. Mizuno¹

¹Nagoya Women's University, Japan

²Nagoya City University Graduate School of Medical Sciences and Medical School, Japan

Background and objectives: Japan is super aged society. Therefore there is the risk that health insurance system will fail in the near future. In each area, Public health center plays a key role and opens up health club. Nagoya Women's University does the healthy college in cooperation with Mizuho Public Health Center in Mizuho-ku of Nagoya City. This healthy college is carried out every year. The purpose of this healthy college is that an elderly person lives long healthily.

Methods: The participants of the healthy college were recruited by the public information magazine of Nagoya City. The elected applicant can participate in a healthy college performed in Nagoya Women's University. The content of six times of lectures is as follows: 1) Sense of taste and smell, 2) Low GI food, 3) Sleep apnea syndrome, 4) High quality of sleep, 5) Medicinal herbs dish, 6) Exercise. The participant was measured blood pressure, weight and percent of body fat every time. In addition, questionnaire survey was carried out before and after the college, about dietary habits and exercise custom.

Results: The age of the 28 participant are 65±3. The height, weight and percent of body fat were as follows: 156.3±6.05 cm, 54.6±9.9 kg, 22.3±3.5 kg/m², 32.1±4.9%. Twenty three people who participated in the healthy college were improved dietary habits. Twenty four people who participated in the healthy college were improved exercise custom.

Conclusions: Even if the BMI level was a standard, the participant body mass of fat was much. There were many people whom the quality of the sleep had not well. However, dietary habits and exercise custom of many people were improved by participation in Nagoya health college.

Key words: elderly person, healthy college, Food habits, Exercise custom, ody fat

PO640**THE EFFECT OF WEIGHT LOSS DIET AND OMEGA-3 FATTY ACIDS ON BODY WEIGHT AND SOME BIOCHEMICAL PARAMETERS IN PATIENTS WITH POLYCYSTIC OVARY SYNDROME**

G. Çadıran¹, G. Kızıltan², H. Patýrođlu³

¹Bayındýr Hospital, Ankara, Turkey

²Bařkent University, Health Science Faculty, Department of Nutrition and Dietetics, Ankara, Turkey

³HP Clinic, Gynecology, Obstetrics and Infertility Center, Ankara, Turkey

Background and objectives: Being overweight and insulin resistant are prevalent in polycystic ovary syndrome (PCOS) patients. This study was planned to investigate the effects of weight loss diet and omega-3 fatty acids on body weight and some biochemical parameters in patients with PCOS.

Methods: The study was conducted on 22 new diagnosed obese (BMI=25.0-35.0 kg/m²) PCOS patients with a mean age of 27.4±4.87 years. There were three groups. First group (n=8) was treated with only metformin, the second group (n=8) was treated with the combination of metformin and weight loss, the third group (n=6) was treated with the combination of metformin and omega-3 riched weight loss diet. Nutritional status was determined by three days 24-h food records and evaluated by Dietary Reference Intake (DRI) recommendations. Anthropometric measurements and some blood biochemical parameters were evaluated at baseline, at the end of the 4th and 8th weeks. All data was evaluated by SPSS 13.0 for Windows.

Results: At the baseline, the dietary energy, carbohydrate, protein, fiber, cholesterol, vitamin and mineral intakes were similar among groups. In all groups, dietary fat intake was higher than DRI recommendations (between 2nd and 3rd groups; p<0.05). There were no statistically significant anthropometric changes in 1st group, but in 2nd and 3rd groups, after the treatment, the body weight, body mass index, waist circumference, body fat ratio, fat-free mass and fat-free mass index values were significantly decreased at the end of the 8th weeks (p<0.05). In the 2nd and 3rd groups, serum total cholesterol levels were decreased after 8th week (p<0.05). The serum fasting insulin levels and HOMA-IR values were statistically different between 2nd and 3rd groups (p<0.05).

Conclusions: Weight control is very important in PCOS patients for regulation of blood parameters and preventing from complications.

Key words: PCOS, metformin, weight loss diet, omega-3 fatty acids

PO641**MATERNAL MICRONUTRIENT-RICH FOODS INTAKE AND BIRTH SIZE IN EGYPT***E. Nayera¹, Hassan^{1,2}, S. El-Masry¹, S. Gabrial²*¹Biological Anthropology Dept., National Research Centre, Cairo, Egypt²Food Science and Nutrition Dept., National Research Centre, Cairo, Egypt

Background and objectives: Adequate supply of nutrients is probably the most important environmental factor affecting pregnancy outcome, mainly birth size. The aim of the present study was to investigate relationship between maternal nutrition and birth size in a cross-sectional study of 434 healthy pregnant Egyptian women and their neonates, focusing on macronutrient intake, diet quality specially micronutrient content; maternal and neonatal anthropometry.

Methods: Maternal weight, height and body mass index (BMI), food intake (was assessed using food frequency questionnaire of 12 food categories at each of the three trimesters of gestation) and haemoglobin levels were recorded. Neonatal birth weight; lengths (crown–heel, trunk, upper and lower arm); circumferences (head, mid-upper arm, chest, waist, hip, thigh and calf), and skin fold thickness (triceps, biceps, suprailiac and sub scapular) were attempted.

Results: Frequency of carbohydrate intake was not associated with birth size for both genders, but frequent intake of fat and protein during third trimester showed a significant relation with girl's birth size. High fat intake during third trimester was associated with triceps SF for boys and waist circumference and BMI of girls. However, birth size was strongly associated with improved maternal intake of milk and green leafy vegetables all over gestation and fruits from second trimester till late gestation leading to improved fetal growth. Significant positive correlation between maternal anthropometric variables with neonatal birth dimensions was observed and the effect was more evident in girls than boys for BMI and head circumference. Significant negative correlations were found between maternal haemoglobin levels and birth size.

Conclusions: Birth size was strongly correlated with maternal anthropometry and consumption of micronutrient-rich food at all stages of gestation. This suggests that micronutrients may be important limiting factors for fetal growth.

Acknowledgements: mothers and their neonates; without them, this study couldn't be completed and National Research Centre for funding.

Key words: maternal, micronutrient intake, birth size

PO642**COMPLEMENTARY FEEDING PRACTICES IN SOUTHEAST ASIAN COUNTRIES***M S V. Amarra¹, P. Chan¹*¹International Life Sciences Institute Southeast Asia Region, Singapore

Background and objectives: In 2010, the WHO released a set of indicators for assessing infant and young child feeding (IYCF) practices to enable assessment of the situation regarding breastfeeding and complementary feeding of children at the population level. Indicators were incorporated into nationwide household surveys, particularly the Demographic and Health Surveys (DHS) and Multiple Indicator Cluster Surveys (MICS). This report reviews the latest DHS and MICS results on complementary feeding practices in Southeast Asian countries – Philippines, Indonesia, Cambodia, Vietnam—and compares complementary feeding of breastfed and nonbreastfed children age 6–24 months.

Methods: WHO indicators for assessing infant and child feeding practices were obtained from country DHS and MICS reports: timely introduction of complementary foods, minimum meal frequency, minimum dietary diversity, minimum acceptable diet, and consumption of iron-rich and iron-fortified foods.

Results: Timely introduction of complementary foods was lowest in Vietnam (50.4%), followed by Indonesia (75%), Cambodia (87.7%), and Philippines (89%). Majority (69–78%) of children in these countries were given iron-rich and iron-fortified foods. Breastfed children in Cambodia, Indonesia, and Philippines received better quality complementary diets than nonbreastfed children. The proportion of breastfed vs nonbreastfed children who received a minimum acceptable diet was 28.2 vs 10.9%, respectively in Cambodia, 52.5 vs 8.3% in Indonesia, and 68.2 vs 40.5% in Philippines. A similar pattern was obtained for the indicator minimum meal frequency – i.e., 78.8 vs 61.7% (for breastfed vs nonbreastfed children, respectively) in Cambodia, 67 vs 11.9% in Indonesia and 80.7 vs 48.2% in Philippines.

Conclusions: In certain countries, complementary feeding of breastfed children is more likely to conform with IYCF recommendations. Studies are needed to identify factors underlying differential complementary feeding of breastfed and nonbreastfed children in Southeast Asia and whether the WHO indicators reflect adequate energy and nutrient intakes.

Key words: complementary feeding, Southeast Asia, child feeding

PO643**DIETARY DIVERSITY AS A CORRELATE OF UNDER-NUTRITION AMONG SCHOOL AGE CHILDREN IN SOUTHWESTERN NIGERIA***M. Olumakaiye*¹

¹Department of Family, Nutrition and Consumer Sciences, Obafemi Awolowo University, Ile Ife, Nigeria

Background and objectives: Dietary diversity has been recognized as a key element of high quality diet, which is assumed to be a proxy nutrient adequacy. This study was conducted to determine the association between undernutrition and dietary diversity among school-age children in southwestern Nigeria.

Methods: This current study is a cross-sectional study of school aged children. 600 school children were randomly selected from six private and six public schools in the region. A standardized FAO-published 24-hour diet recall questionnaire for calculating a dietary diversity score was adapted, tested, and used for all students. Weight and height measures were taken and weight-for-age, height-for-age, and weight-for height Z scores were calculated to determine the prevalence of underweight, stunting, and wasting respectively.

Results: The average age for students in the study was 8.3 years. Significant differences existed between students in private and public schools in BMI-for-age ($p=0.025$), in dietary diversity scores ($p=0.034$) and in undernutrition ($p=0.003$). No private school children exhibited underweight or stunting, but 11.7% were overweight or obese. No public school students were overweight. Stunting ($p=0.024$) and wasting ($p=0.018$) correlated significantly with lower dietary diversity scores. The food groups at the lowest levels in the children's diet were organ meats, milk and milk products, eggs, and vitamin A rich fruits and vegetables.

Conclusions: A dietary diversity score may be useful in identifying school children at risk of undernutrition and the food groups most often lacking in local diets. Methods of increasing dietary diversity in meals at school and at home are likely to benefit children at nutritional risk.

Key words: dietary diversity, undernutrition, school children, Nigeria

PO644**EMPOWERING WOMEN COOPERATIVES TO RAISE MALNOURISHED CHILDREN LIVING STANDARDS IN HUYE DISTRICT/RWANDA***G. Kamaliza*¹, *C. Karangwa*², *J B. Gahutu*³, *A. Symaldino*⁴, *D. Kabakambire*⁵, *F. Mukanyangezi*⁶

¹Department of maternal and child nutrition, Rwanda Village Concept Project (RVCP), Rwanda

³Department of physiology, University teaching hospital of Butare, Rwanda

⁴Department of Maternal health, GlobeMed, USA

⁵Department of pediatrics, University of teaching hospital of butare, Rwanda

⁶Department of pharmacy, National university of Rwanda, Rwanda

Background and objectives: In Rwanda, chronic malnutrition poses a serious threat to the mental and physical development of nearly half (45%) of all children under five and has been identified as an underlying factor in 43% of deaths in children under five. In rural areas of Rwanda, 154,000 children continue to die each year before their fifth birthday, mostly from preventable causes. Women in the rural community are taught repeatedly about proper maternal health and child nutrition, but lack of means to achieve it. The objective of the intervention was to better respond to women and newborn's health needs, by enabling them to produce and growing vegetables and fruits.

Methods: Providing knowledge and skills on children nutrition and maternal health to the 50 rural women cooperative with severely malnourished children received at Huye health center/Rwanda from January 2012 to December 2012. We provided through education sessions and then established Akarima k'Igikoni (Kitchen garden), household consume its product and provision of small livestock (goats) to produce organic fertilizer to use in gardens. Promoting production and consumption of fruits and vegetables at families, growing of micronutrient-rich foods (soya, groundnuts, mushrooms, sweet potato varieties that contain carotene) to improve nutrients intake for malnourished children.

Results: A child was 5 kgs, after attending teaching sessions and establishing kitchen garden for proper feeding, the kid is now 14 kgs. Rural malnourished children attending huye health center reduced from 48% to 23% among 50 women participants, after completing maternal health education sessions. Cooperative enabled local women to raise the standard of living.

Conclusions: Income generation cooperative enabled rural women to raise the standard of living for their family, provided proper nutrition for their kids. Women cooperatives could be used to improve children nutrition.

Key words: malnutrition, cooperative, garden, rural

INFANT AND YOUNG CHILD FEEDING PRACTICES AND CHILD UNDERNUTRITION IN RURAL, CHINA

Y Y. Wang^{1,2}, W. He², C M. Chen^{1,2}

¹ILSI Focal Point In China, Beijing, China

²Chinese Center for Disease Control and Prevntion, Beijing, China

Background and objectives: To explore infant and young child feeding (IYCF) practices and determine the association between feeding indicators and nutritional status of children aged 0-23 months in rural, China

Methods: Data from the 2010 China Food and Nutrition Surveillance survey were used. A sample of 4094 children was obtained with stratified random cluster sampling method. Information on feeding practices was obtained by interviewing the caregivers, anthropometric measurements were conducted. New WHO feeding indicators were used to assess child feeding, and nutritional status was determined according to WHO child growth standards.

Results: Only 11.9% of infants were put to the breast within 1 hour of birth, and 37% of infants younger than 6 months were exclusively breastfed. About 90% of infants aged 6-8 months received solid, semi-solid or soft foods, 62.2% of children aged 6-23 months old met the minimum criteria for dietary diversity, 69% received the minimum meal frequency, and 43.2% had a minimum acceptable diet. Regression model indicated that children who achieved minimum acceptable diet had higher Height-for-age Z-score ($p < 0.05$), desired feeding frequency was associated with higher Weight-for-age Z-score ($p < 0.05$); Logistic regress models confirmed that children with minimum acceptable diet had lower risk of underweight (OR=0.56, 95% CI 0.38, 0.82).

Conclusions: The result highlight the importance of IYCF practices as determinants of child growth outcomes, greater efforts should be made to improve sub-optimal practices in rural, China, from timely initiation of breastfeeding and exclusive breastfeeding for 6 months to diet diversity, especially minimum acceptable diet.

Key words: breastfeeding, WHO feeding indicators, under-nutrition

⁴PATH, Seattle, WA, USA

⁵Kenya Medical Research Institute, Kisumu, Kenya

⁶International Potato Center, Kampala, Uganda

⁷Makerere University, Kampala, Uganda

⁸Kenya Agriculture Research Institute, Kisumu, Kenya

Background and objectives: Vitamin A deficiency (VAD) is a significant burden among children less than 5 years old and pregnant and lactating women especially in sub-Saharan Africa. We assessed the levels of vitamin A and prevalence of VAD among children age 6-23 months in 2 counties in western Kenya.

Methods: Dry Blood Spot (DBS) samples were obtained from 1850 infants in a community-based cross-sectional survey. Lab analysis of retinol-binding protein (RBP) was carried out on a random subsample (n=881) of infants using a rapid enzyme immunoassay (EIA) technique to estimate vitamin A status. Values were adjusted for influence of inflammation using C-reactive protein (CRP, > 5 mg/L) and population prevalence of VAD (RBP < 0.70 μ mol/L) estimated.

Results: Mean (geometric \pm SD) concentration of RBP was low (0.88 ± 0.42 μ mol/L) and consequently the inflammation-adjusted mean (\pm SE) prevalence of VAD was high ($29.6 \pm 1.6\%$) in this population. The level of CRP was within normal range (0.37 ± 1.74 mg/L) whilst $8.6 \pm 0.9\%$ of the children had subclinical inflammation (CRP > 5 mg/L). The prevalence of VAD did not differ by child sex (Chi-squared, $c^2 = 0.68$, $p = 0.41$), child nutritional status (wasting ($p = 0.75$) and stunting ($p = 0.40$)), reported child intake of vitamin A capsule within the past 1 year ($p = 0.22$), maternal vitamin A nutritional knowledge (Chi-squared, $c^2 = 0.20$, $p = 0.66$), or reported maternal intake of vitamin A capsule within 2 months of delivery ($p = 0.44$).

Conclusions: Prevalence of VAD in this sample of infants was high irrespective of intake of vitamin capsule or maternal vitamin A nutrition knowledge. A sustainable food-based intervention in this area of western Kenya to combat VAD especially in pregnant women and infants is warranted.

Key words: vitamin A deficiency, sub-Saharan Africa, retinol-binding protein, C-reactive protein, western Kenya.

PO647**URINARY EXCRETION LEVELS OF WATER-SOLUBLE VITAMINS IN PREGNANT AND LACTATING WOMEN IN JAPAN**

T. Fukuwatari^{1,2}, M. Sano¹, C. Hiratsuka¹, K. Suzuki¹, S. Aoki¹, C. Nagai¹, S. Sasaki², K. Shibata¹

¹Department of Nutrition, School of Human Cultures, The University of Shiga Prefecture, Hikone, Japan

²Department of Social and Preventive Epidemiology, School of Public Health, The University of Tokyo, Tokyo, Japan

Background and objectives: The dietary habits of pregnant and lactating women are important for meeting the nutritional needs of both the women and their children. Recent studies have shown that the urinary excretion levels of water-soluble vitamins can be used as biomarkers for the nutritional status of these vitamins. The objective of this study is to determine changes in the urinary excretion levels of water-soluble vitamins during pregnant and lactating stages.

Methods: The design used was cross-sectional study. Control women (n=37), women in the 2nd (16-27 wk, n= 24) and 3rd trimester of pregnancy (over 28 wk, n=32), and early- (0-5 mo, n=50) and late-stage lactating (6-11 mo, n=49) women took part in the survey. A single 24-h urine sample was collected one day after the completion of a validated, self-administered comprehensive diet history questionnaire to measure water-soluble vitamins.

Results: The mean age of subjects was 32 years, and mean height was 160 cm. The average intakes of vitamin B6 and folate were lower than the estimated average requirement value for the Japanese Dietary Reference Intakes during pregnancy. Urine nicotinamide metabolites and folate levels were higher in pregnant women than in control women. Urine excretion level of vitamin B1 decreased during lactation and that of pantothenic acid decreased during pregnancy and lactation. These results suggest that these changes reflect the increase of nicotinamide synthesis from tryptophan during pregnancy, increase of vitamin B1 and pantothenic acid requirements during pregnancy, and excretion of pantothenic acid to breast milk.

Conclusions: These results provide valuable information for setting the Dietary Reference Intakes of water-soluble vitamins for pregnant and lactating women.

Key words: vitamin, pregnancy, lactation, human, urine

PO648**SLEEP QUALITY IN THE SURVIVAL OF ELDERLY TAIWANESE: ROLES FOR DIETARY DIVERSITY AND PYRIDOXINE IN MEN AND WOMEN**

Y.C. Huang¹, M.L. Wahlqvist^{2,3,4,5}, M.S. Lee^{4,5}

¹Graduate Institute of Life Sciences, National Defense Medical Center, Taipei, Taiwan

²Institute of Population Health Sciences, National Health Research Institutes, Taiwan, ROC

³Department of Epidemiology and Preventive Medicine and the Monash Asia Institute, Monash University, Melbourne, Australia

⁴School of Public Health, National Defense Medical Center, Taiwan, ROC

⁵Monash Asia Institute, Monash University, Caulfield East, Victoria, Australia

Background and objectives: Diet may contribute to sleep and all-cause mortality among elderly men and women.

Methods: The representative Nutrition and Health Survey in Taiwan for elders during 1999–2000 was used. Some 942 men and 923 women aged. The representative Nutrition and Health Survey in Taiwan for elders during 1999–2000 was used. Some 942 men and 923 women aged. Participants were examined and fasting blood taken. Sleep quality was classified as poor, fair or good. Death Registry linkage until December 31, 2008 provided all-cause mortality.

Results: For women, but not men, poor sleepers had significantly lower vegetable and vitamin B-6 intakes, compared to good sleepers ($P < 0.05$). For men, but not women, good and fair sleepers had a lower risk of death compared to poor sleepers after relevant adjustments with corresponding hazards ratios (HR) (95% confidence intervals (CI)) of 0.60 (0.42–0.87) and 0.55 (0.36–0.86). The joint HRs for “DDS > 4 and good sleep” were 0.38 (0.22–0.66) for men and 0.52 (0.30–0.88) for women compared with “DDS results: For women, but not men, poor sleepers had significantly lower vegetable and vitamin B-6 intakes, compared to good sleepers (compared with “insufficient and poor sleep” for men and women, respectively; for women, PLP adequacy provided significantly reduced HRs for good and poor sleep.

Conclusions: Sleep quality played a more important role in mortality for men than for women. Sufficient dietary diversity in men could offset the adverse effect on mortality of poor sleep. In women, PLP predicts mortality more than does sleep.

Key words: vitamin B-6, DDS, sleep, gender, mortality

PO649**UNDER-NUTRITION LOWERS LEARNING AND MEMORY ABILITY AMONG CHILDREN AGE 5-6 YEARS OLD IN BOGOR-INDONESIA***E. Palupi^{1,2}, A. Sulaeman², A. Ploeger¹*¹Department of Organic Food Quality and Food Culture, University of Kassel, Germany²Department of Community Nutrition, Bogor Agricultural University, Indonesia

Background and objectives: Insufficient nutrient intake during golden period (0-5 years) may influence brain development which is not possible to be paid-off on later life. Indonesian Ministry of Health reported that 17.9% Indonesian children have suffered of under-nutrition in 2010 (13% in West-Java). However, the current status needs to be identified to expand coverage. The objectives were to determine the current nutritional status of Indonesian children age 5-6 years old, to assess whether the nutritional status influenced their brain development, and to identify factors from their baby's history associated with their growth.

Methods: A survey base on cross-sectional study design was conducted to identify the nutritional status, brain development score (IQ, EQ, learning, and memory ability using Projective Multi-phase Orientation method), and some history of baby birth (birth method, birth weight, and exclusive breast-feeding) among 225 children age 5-6 years old from 7 different rural and urban areas in Bogor, West-Java and Indonesia, between November to December 2012.

Results: The prevalence of under-nutrition children age 5-6 years old in Bogor-Indonesia was 13.57%. Learning ability between under-nutrition- (n=30) and normal- children (n=179) were 44.13±29.43 and 46.98±27.03, respectively (p<0.05). Memory ability between severe acute malnutrition- (n=51) and normal- children (n=170) were 46.65±11.13 and 50.49±11.92, respectively (p<0.05). Emotional quotient (EQ) between children who did (n=111) and did not receive exclusive breast-feeding (n=110) were 374.28±46.35 and 367.51±35.88, respectively (p<0.05).

Conclusions: In Bogor-Indonesia, the current prevalence of under-nutrition children age 5-6 years is still high. This under-nutrition lowers their learning and memory ability. Children who received exclusive breast-feeding had a higher EQ score. Stronger efforts are needed to support the exclusive breast-feeding and nutritionally appropriate foods especially during their golden period to support their optimal growth.

Acknowledgements: This study was supported by Faculty for the Future program from Schlumberger Foundation.

Key words: under-nutrition, brain development, Indonesian children.

PO650**LEARNERS' PERCEPTIONS, ATTITUDES AND BEHAVIOUR TOWARDS HEALTHY EATING-THE INFLUENCE OF A NUTRITIONALLY-REGULATED TUCK SHOP***N. Koen¹, F. Bekker¹, M L. Marais¹, D G. Nel²*¹Division of Human Nutrition, Faculty of Medicine and Health Sciences, Stellenbosch University, Tygerberg, Western Cape, South Africa²Centre for Statistical Consultation, Faculty of Medicine and Health Sciences, Stellenbosch University, Tygerberg, Western Cape, South Africa

Background and objectives: Tuck shops at schools often offer unhealthy items that are energy dense and high in fat and/or sugar with a low content of vitamins, minerals and dietary fibre. The availability of these items often prevent learners from making healthy food choices, since children tend to choose unhealthy foods when given a choice. The objectives were to investigate the influence of a nutritionally-regulated tuck shop on children's perceptions, attitudes and behaviour towards healthy eating in Afrikaans medium, co-education primary schools in Bloemfontein, South Africa.

Methods: In a cross-sectional survey with an analytical component, grade 2-7 learners in a school with a nutritionally-regulated tuck shop (n=116) and a school with a conventional tuck shop (n=141) completed a questionnaire, while six learners per grade took part in focus group discussions. Questions related to lunchbox contents and perceptions, attitudes and behaviours towards the tuck shop and healthy eating. Nutritional information on the food items available for purchase was also collected.

Results: The lunchboxes of children in a school with a nutritionally-regulated tuck shop contained significantly (p<0.05) more healthy items (fruit, water, muffins) as well as significantly more unhealthy items (sweets and chips). Children in a school with a nutritionally-regulated tuck shop liked certain fruits and vegetables significantly (p<0.05) more than children in a school with a conventional tuck shop. The items offered by the nutritionally-regulated tuck shop contained about half the kilojoules than items offered by the conventional tuck shop. Younger learners were more positive towards their nutritionally-regulated tuck shop than older learners. Children in both schools shared similar perceptions regarding the tuck shop and healthy eating.

Conclusions: The value of controlling the type of items available for purchase during school hours can be counteracted by lunchbox contents and certain fixed eating patterns, perceptions.

Key words: tuck shop, healthy eating, children

PO651**OVERWEIGHT, OBESITY, AND EARLY-LIFE FEEDING PRACTICES AMONG UNDERFIVE CHILDREN IN LEBANON**

N. Hwalla¹, L. Nasreddine¹, F. Naja¹, A. Mehio Sibai², N. Adra¹

¹Department of Nutrition and Food Sciences, Faculty of Agricultural and Food Sciences, American University of Beirut, Beirut, Lebanon

²Department of Epidemiology and Population Health, Faculty of Health Sciences, American University of Beirut, Beirut, Lebanon

Background and objectives: Childhood obesity is an increasing public-health problem worldwide. Recent evidence suggests that early-life feeding practices influence the risk of later-onset obesity; where studies demonstrate a protective role of breastfeeding, while duration of breastfeeding and timing of complementary food introduction also seem to play a role. Plausible explanations include protective effects of human milk constituents on growth patterns and metabolic pathways that may program changes in body composition. The objectives of this project were to: 1) Investigate overweight and obesity prevalence among Lebanese underfive children, 2) Characterize breastfeeding and complementary feeding practices, and 3) Examine the association between feeding practices and overweight/obesity in underfive children.

Methods: A cross-sectional nationally representative study was conducted on 1,031 Lebanese underfive children randomly selected from households by stratified cluster sampling. Sample-size calculations were based on an estimated prevalence of 13% of preschool overweight and obesity (2% error and 95% confidence interval).

Results: Preliminary data from the six governorates of Lebanon revealed: 1) Overweight and obesity prevalence of 11.8% and 3.3% among underfive children, respectively, 2) Low rates of exclusive breastfeeding (13%) with the introduction of complementary foods before the recommended age of 6 months, 3) Prevalent introduction of complementary foods (32%) earlier than the internationally accepted age of 4 months, and 4) Statistically significant association between complementary food introduction before 6 months and overweight among underfive children.

Conclusions: Preliminary findings reveal suboptimal breastfeeding and complementary feeding practices, providing preliminary characterization of early-life feeding practices in Lebanon. Promotion of exclusive breastfeeding and timely introduction of complementary foods are effective interventions that can curtail growth faltering and obesity in young children; possibly decreasing the risk of NCDs. Evidence-based protocols are needed to implement country-specific interventions to tackle available nutritional problems and feeding practices among the underfive population.

Key words: obesity, underfive, children, Lebanon, feeding practices

PO652**DEPRESSION AND PSYCHO-PHARMACEUTICAL USE ASSOCIATED WITH MALNUTRITION IN INSTITUTIONALIZED ELDERLY CITIZENS IN PRAGUE, CZECH REPUBLIC**

J. Rambousková¹, M. Procházka¹, M. Andil¹

¹Third Faculty of Medicine, Charles University, Prague, Czech Republic

²Centre for Research of Diabetes, Metabolism and Nutrition, Department of Nutrition, Third Faculty of Medicine, Charles University, Prague, Czech Republic

Background and objectives: To evaluate the relationship between depression, use of psycho-pharmaceuticals and nutritional status (assessed in an earlier study) among healthy institutionalized elderly citizens.

Methods: In an earlier study, 815 elderly, aged 65 and older (80% female), living in retirement homes in Prague, participated in a nutritional status assessment; from that group, 544 residents were included in the present study (75% female) and depression was assessed using the Geriatric Depression Scale (GDS), 15 points version. An earlier study of nutritional status, which was assessed using the Mini-Nutritional Assessment (MNA questionnaire), revealed malnutrition was correlated with (1) mild to severe depression, and (2) the regular use of psycho-pharmaceuticals.

Results: Severe depression was identified in 109 (20.0%) and mild depression in 241 (44.3%) participants. More women than men experienced depression (66.8% vs 54.9%, resp.). Previously identified malnutrition was closely associated with depression. The MNA score (0–30 pts) was significantly lower in those with severe depression (19.5) and mild depression (22.2) compared to those without depression (25.3). Use of psycho-pharmaceuticals was also positively correlated with nutritional status assessed using the MNA ($r=0.56$; $p<0.001$).

Conclusions: Study results confirmed a close relationship between depression and malnutrition among the population of institutionalized elderly citizens in Prague. Further studies are needed to determine possible ways to influence nutritional status through treatment of depression, which could include psycho-pharmaceuticals.

Key words: depression, institutionalized elderly, malnutrition

PO653**DIETARY HABITS AND CARDIOVASCULAR DISEASES IN ADULTS AND ELDERLY IN CROATIA***D. Kenjeric¹, T. Šarić², M L. Mandić¹, I. Banjari¹*

¹Department of Food and Nutrition Research, Faculty of Food Technology Osijek, University of Osijek, Osijek, Croatia

²Agriculture and Food School Požega, Požega, Croatia

Background and objectives: Preventive mass approach to cardiovascular diseases (CVDs) implies stimulation of lifestyle modifications with the aim of moderate risk factors lowering in general population. One of the most important preventive measures is modification with respect to dietary habits. The aim of this study was to determine dietary habits and incidence of CVDs in studied population and to evaluate if the community intervention is needed.

Methods: 100 subjects of 40 to 70 ages were recruited for this study. The study encompassed anthropometric measurements and short questionnaire on dietary and lifestyle habits and CVDs morbidity.

Results: Data analysis revealed that 55% of participants are overweight and 27% obese although 64% of participants perceive themselves as persons who take care of their health. At the same time 61% of participants had confirmed diagnosis of at least one of the studied health problems (hypertriglyceridemia, hypercholesterolemia, hypertension, myocardial infarction and stroke) and 50% of those with health problems had reported more than one problem simultaneously. Results of dietary questionnaire have shown that dietary habits are inadequate. Comparison of selected food group intakes with guidelines for the people with CVDs revealed that alignment is the weakest with respect to the fish consumption where only 3% of participants declared to eat fish 2-3 times a week, followed by 20% of participants who take fruits more times a day, while red meat was consumed 2-3 times a week or less in even 72%, and eggs once a week or less in 76% of participants.

Conclusions: Low alignment with dietary guidelines for CVD patients and the belief of taking good care of health implies the need of community intervention with the aim of reducing the incidence of CVDs and their outcomes.

Key words: CVDs, dietary guidelines, adults and elderly

PO654**QUALITY OF NUTRITION IN ELDERLY NURSING HOME RESIDENTS***D. Kenjeric¹, I. Divković¹, I. Banjari¹, M L. Mandić¹*

¹Department of Food and Nutrition Research, Faculty of Food Technology Osijek, University of Osijek, Osijek, Croatia

Background and objectives: Daily menu of elderly persons, as well as its nutrient content and energetic value should be adjusted to physiological changes in this population. To achieve recommended intake, food should be of high nutrient density. The aim of the study was to determine the energy and nutrient content of food served in a nursing home in Bosnia and Herzegovina.

Methods: Energy value and nutrient content of food was calculated from all meals during one month period. Obtained values were compared to the recommendations for the elderly based upon a presumption that the whole portion was eaten.

Results: The mean energy content of the served food was 2567±367 kcal per day with the contribution of carbohydrates, fats and proteins of 47%, 37% and 16% respectively. The crude intake of proteins, fatty compounds and carbohydrates was higher than recommended. Considering micronutrients, the intake of vitamin C, niacin, pyridoxine, folic acid, vitamin A, vitamin D, vitamin E, magnesium and zinc was very low while the amounts of calcium, potassium, copper were slightly lower than the recommended. The intakes of thiamine, riboflavin, vitamin K, cyanocobalamin, phosphorus, iron, selenium, sodium were satisfying or higher than recommended. The values were quite unequal and varied substantially according to age and sex.

Conclusions: Although the result showed that it is possible to achieve sufficient energy and nutrient intake from the served food, fact that many nursing home residents won't eat the whole portion but just a part could have an important impact in raising the risk of malnutrition. Therefore it would be useful to make a broader study in which real food consumption would be determined in residents.

Key words: energy value, nutrient content, food, nursing home, elderly

PO655**MILK CONSUMPTION OF UNIVERSITY STUDENTS***E D. Ciracioglu¹, H. Yardimci¹, A O. Ozcelik¹, S. Gurel¹*¹Nutrition and Dietetics, Ankara University, Ankara, Turkey

Background and objectives: Milk contains most of the essential nutrients for growth and it consists one of the main food groups which has to be consumed everyday. Milk is the best source of calcium which plays an important part in body functions during lifespan. The study is planned and conducted to determine the milk consumption of college students who attend Ankara University and live in dorms.

Methods: 190 Turkish and 20 foreigner students participated in the study (n=210). Data collection was made by a questionnaire. SPSS was used to evaluate data.

Results: Median age for female (56.7%) and male (43.8%) students is 21 and 22 years, respectively. 42.9% of them regularly drink milk (n=89) and 43.8% of the participants stated they made a habit of drinking milk in pre school period and 63.3% of them are encouraged to drink milk by their parents. 37.1% of the participants stated they consume milk for its nutritional value, 33.3% of them consume it before sleep and 71.9% of them apply no heat on it. Among the students who consume milk, 27.1% of them consume it 3-4 times a week, 24.0% of the subjects twice a month, 21.4% of them 1-2 times a week, 20.3% of them everyday and 7.3% of them 5-6 times a week. 33.3% of the subjects who state they drink milk everyday, consume ≥ 500 ml /day. Mean consumption amount is 280 ml (male: 290 ml, female: 250 ml) which is statistically significant according to gender.

Conclusions: The development of dietary habits that include the frequent intake of milk during childhood and adolescence is likely to lead to higher calcium intake in later years. Recommendations to the public should continue to emphasize increased calcium intake, perhaps most effectively achieved by increasing milk consumption.

Key words: Turkey, milk consumption, students

PO656**SOCIODEMOGRAPHIC DETERMINANTS OF FRUITS AND VEGETABLES CONSUMPTION AMONG ELDERLY IN ILA-ORANGUN, NIGERIA***M. Ogunkunle¹, A. Oludele²*¹Department of Human Nutrition, University of Ibadan, Ibadan, Oyo state, Nigeria²Department of Home Economics, Osun State College of Education, Ila-Orangun, Osun state, Nigeria

Background and objectives: Low consumption of fruits and vegetables has been implicated in the occurrence of many chronic non-communicable diseases. This study was designed to describe the frequency of consumption of fruits and vegetables and identify socio demographic factors that determine consumption of fruits and vegetables among the elderly.

Methods: This cross sectional study with a sample size of 382 participants was carried out in Ila-Orangun, Southwest, Nigeria. Multi stage sampling technique (three stages) was used for sample selection. Data on socio demographic characteristics and frequency of consumption of fruits and vegetables per day were collected using a validated semi-structured interviewer administered questionnaire and Food Frequency Questionnaire respectively. Chi square and logistic regression analysis were used to evaluate association between variables and identify sociodemographic factors that contributed to inadequate consumption of fruits and vegetables. Level of significance was set at 5% ($p < 0.05$) and 95% CI.

Results: Majority (87.7%) of the subjects consumed fruits and vegetables less than five times per day. Monthly income, educational status, gender and marital status were significantly associated with frequency of fruits and vegetables consumption ($p < 0.05$). Inadequate fruits and vegetables consumption were higher among females (OR=2.36; 95%CI=1.01-5.61), married participants (OR= 2.46; 95%CI=1.22-6.10), those with monthly income less than 10,000 (OR=1.18; 95%CI=0.61-2.29) and those who have no formal education (OR= 1.12; 95%CI=0.78 to 1.61). Occupation and age did not significantly influence consumption of fruits and vegetables among the elderly ($p < 0.05$).

Conclusions: Majority of the subjects did not meet the minimum WHO recommendation for consumption of fruits and vegetables per day. Gender, marital status, monthly income and educational status influence fruits and vegetables consumption. Nutrition education to enlighten the public on the importance of frequent consumption of fruits and vegetables and healthy eating habit should be put in place.

Key words: sociodemographic determinants, fruits and vegetables consumption, elderly

PO657**PUERPERAL FACTORS THAT MAY INFLUENCE IN THE ESTABLISHMENT OF ORAL REFLECTIONS OF NEWBORN TO START OF BREASTFEEDING SUCCESSFULLY***C. Freiberg¹, V. Soares¹*¹Universidade Guarulhos, São Paulo, Brazil

Background and objectives: The effectiveness of measures to promote breastfeeding depends mainly on the identification of mothers at increased risk of not starting or stopping early lactation. The combination of these factors and the type of delivery has been associated risks. To assess factors that may influence the puerperal establishment of specific oral reflexes of newborns to start breastfeeding successfully.

Methods: We evaluated 101 mothers, in popular obstetric center, between 20 and 34 years old. It was found as early signs for breastfeeding: the preparation of prenatal care; delivery type; sucking and swallowing reflexes soon after birth; maternal socio-cultural conditions. **Results:** 66% have professional activity. 27% were married, indicating that many mothers do not have support from their partners and, therefore, unable to share their difficulties and responsibilities. 69% of infants born between 37-40 weeks and 9% had preterm deliveries. 67% had adequate prenatal care. 43% had cesarean deliveries (CD). Mothers with cesarean have more difficulty due to bad positioning or inappropriate emotional involvement. Furthermore, CD slows or hinders change for first feeds. The endocrine responses of mother and newborn after delivery indicated that surgery causes pain and drowsiness and uses of anesthetics and analgesics affect the interaction between mother and baby. In the delivery room was checked: baby placed in his chest had good catches; they tried the nozzle and grabbed the breast; if the areola is made visible at the top above the baby's mouth. The data showed that breastfeeding was successful in 79% of patients immediately after delivery.

Conclusions: We must invest in the education of women and adequate attention in prenatal, with access to qualified health services. You need to know the structural factors, social and cultural rights, to direct the development of public health policies that result in more information to disadvantaged populations.

Key words: breastfeeding - lactation

PO658**MATERNAL DIETARY PATTERNS ARE ASSOCIATED WITH OXIDATIVE STRESS IN PREGNANCY***S L. Loy^{1,2}, K N S. Sirajudeen², J M. Hamid Jan¹*¹Nutrition Programme, School of Health Sciences, Universiti Sains Malaysia, Malaysia²Department of Chemical Pathology, School of Medical Sciences, Universiti Sains Malaysia, Malaysia

Background and objectives: Metabolic and physiological changes throughout gestation predispose a pregnant woman to systemic oxidative stress. Exaggeration of oxidative damage in pregnancy was shown to impose substantial effect on adverse pregnancy outcomes. This study aimed to investigate the association between maternal dietary patterns and oxidative stress in pregnant women.

Methods: This longitudinal study was conducted from April 2010 to October 2011 in Kelantan, Malaysia. A total of 163 pregnant women aged 19-40 years were recruited in second trimester and followed up in third trimester of pregnancy. Maternal blood samples for the analysis of DNA damage, lipid peroxidation and protein oxidation were collected in both periods. Two dietary patterns (Healthy and Less-healthy) were identified using factor analysis from a semi-quantitative food frequency questionnaire.

Results: In second trimester, multiple linear regression analysis indicated that Healthy dietary pattern was significantly associated with decreased protein carbonyl ($r=-0.04$, $p<0.001$), whereas Less-Healthy dietary pattern was significantly associated with increased DNA damage ($r=0.22$, $p<0.009$). In third trimester, Healthy dietary pattern was shown to associate significantly with decreased DNA damage ($r=-0.12$, $p=0.043$) and plasma malondialdehyde ($r=-1.00$, $p=0.003$), but no association was detected between Less-Healthy dietary pattern and oxidative stress markers. These findings suggest the modifiable nature of oxidative stress by dietary patterns. Healthy dietary pattern which was characterized by antioxidant and micronutrient rich food play a protective role in combating oxidative insults in pregnancy. In contrast, Less-Healthy dietary pattern which was characterized by high sugar, sodium, fat and meat intake, tends to induce more oxidative damage in pregnancy.

Conclusions: Maternal dietary patterns are associated with oxidative stress in pregnancy. Adherence to Healthy dietary pattern is therefore encouraged to maintain a good antioxidant balance in pregnancy. This work was supported by Universiti Sains Malaysia Research University Grant Scheme.

Key words: dietary patterns, nutrition, oxidative stress, pregnancy

PO659**MACRONUTRIENT INTAKE AND INADEQUACIES IN COMMUNITY-DWELLING OLDER ADULTS, A SYSTEMATIC REVIEW**

S. Ter Borg^{1,2}, L. de Groot², D. Mijnders³, S. Verlaan¹, Y. Luiking¹

¹Medical Nutrition, Danone Research, Centre of Specialised Nutrition, Wageningen, The Netherlands

²Division of Human Nutrition, Wageningen University, Wageningen, The Netherlands

³School CAPHRI, Department of Health Services Research, Maastricht University, Maastricht, The Netherlands

Background and objectives: Older adults (>65 years) are at risk of nutrient deficiencies. This systematic review creates a comprehensive overview of the nutrient intake and possible inadequacies in community-dwelling older adults.

Methods: Pubmed and Embase were screened for eligible publications up to October 2011 and data from national nutrition surveys was added. Eligibility was assessed by two independent reviewers. Main exclusion criteria were mean age <65 years, absence of intake data and data from non-Western countries. Median nutrient intake data were compared with the acceptable macronutrient distribution range (AMDR), for energy and protein with the estimated average requirement (EAR).

Results: 43 studies were eligible. Median daily energy intake was 2181 kcal in men and 1744 kcal in women, both are below the EAR of 2530 and 2000 kcal respectively. Median daily carbohydrate intake was 245 g (46En%) in men and 204 g (48En%) in women, which are below the AMDR of 55-75En%. Median daily protein intake was 80 g (15En%) in men and 67 g (16En%) in women, which are within the lower half of the AMDR of 10-35En%. EAR cut-point analysis indicated that 9% (men) and 8% (women) did not reach the protein EAR of 0.66 g/kg bodyweight/day. Median daily fat intake was 80 g (35En%) in men and 69 g (36En%) in women, which is at the upper end of the AMDR (20-35En%). Saturated fatty acid (SFA) intake was 13En%, above the upper-AMDR (10En%). Mono-unsaturated fatty acid (MUFA) intake was 13En%, below the AMDR (15-20En%). Poly-unsaturated fatty acid (PUFA) intake was 5En%, slightly below the AMDR (6-11En%).

Conclusions: Community-dwelling older adults might be at risk of energy, carbohydrate, protein, MUFA and PUFA inadequacies. Total fat intake is relatively high, particularly SFA intake. Nutritional screening and implementation of guidelines, specific for the nutritional needs of older adults, are advised.

Key words: macronutrient, deficiencies, community-dwelling, older adults

PO660**LABELING OF COMMERCIALY PROCESSED COMPLEMENTARY FOODS: A MARKET SURVEY ON CODE COMPLIANCE IN ACCRA, GHANA**

R. Aryeetey¹, M. Ambenne¹

¹University of Ghana, School of Public Health, Ghana

Background and objectives: Although Commercially Processed Complementary Foods (CPCF) can contribute to meeting dietary needs of infants and young children, they have been associated with unethical marketing practices that undermine practice of exclusive breastfeeding for six months. The study assessed CPCF labeling compliance to the code on marketing of breast milk substitutes (CMBMS), and the National Breastfeeding Promotion Regulation (NBPR), in Ghana.

Methods: A variety of CPCF were purchased from child welfare clinics, fuel station shops, supermarkets, 'mother/baby' care shops and pharmacies in the La and Osu Klottey sub-metropolitan areas in Accra. The labels were evaluated against best practice indicators proposed by the MIYCN Working Group based on the CMBMS, and also indicators based on the NBPR. An overall compliance was determined based on intensity of compliance to the indicators.

Results: The CPCF purchased included cereal-based products, fruit juices, fruit and vegetable purees, milk-based products, and combination meals; seventy-five percent were imported. One hundred of the 108 products identified were labeled in English and thus included in analysis. None of the products complied with all labeling requirements of CMBMS or NBPR; 84% and 17% of product labels complied with at least 50% of NBPR and 50% of CMBMS indicators, respectively. Only 5% of labels had content indicating importance of exclusive breastfeeding for 6 months. Additionally, only 5% of labels warned against the hazard of introducing CPCF product earlier than 6 months as required by the NBPR.

Conclusions: Labeling of most CPCF sold in Accra does not comply with NBPR and CMBMS requirements. Enforcement of local law on labeling of CPCF is urgently needed.

Key words: complementary foods, compliance, labeling, Ghana

PO661**DEVELOPMENT OF DIETARY PATTERNS DURING THE FIRST THREE YEARS OF LIFE**

L B B. Andersen¹, C B. Pipper³, R. Bro², K T. Ejlerskov¹, U H. Gondolf⁴, K F. Michaelsen¹, C M. Mølgaard¹

¹Department of Nutrition, Exercise And Sports, University of Copenhagen, Copenhagen, Denmark

²Department of Food Science, University of Copenhagen, Copenhagen, Denmark

³Department of Public Health, University of Copenhagen, Copenhagen, Denmark

⁴National Food Institute, Technical University of Denmark, Copenhagen, Denmark

Background and objectives: The intake of specific foods and nutrients in toddlerhood may be related to current and later health. However whole-dietary patterns of the first years of life are possibly even better markers for growth and health outcomes, but little is known about these patterns. The objective was to characterize the development of dietary patterns from 9 to 36 months of life by using principal component analysis (PCA).

Methods: The diet of 330 healthy term infants (the SKOT-cohort) was recorded for 7 consecutive days in pre-coded food records at 9, 18 and 36 months of age. Dietary patterns were identified and described by PCA and a classification method was developed, to characterize individual development of dietary patterns, based on scores from the PCA.

Results: Two main dietary patterns were identified: An age gradient describing transition from baby food, like breast milk and formula, to family food, and a health gradient, dividing the participants into having healthy and less healthy diets. The health gradient covered family food items as fish, vegetables and rye bread (healthy) to sweets, sugary drinks and chips (less healthy). The development of these dietary patterns from 9 to 36 months was classified by combining the individual scores for each age for each child and children were grouped with similar patterns. This classification showed tracking of food patterns especially between 18 and 36 month, where the children ate family food.

Conclusions: Development of early dietary patterns is complex but can to some extent be characterized by PCA. Early tracking of dietary patterns supports the relevance of early health promotion.

Key words: dietary pattern, toddlerhood, PCA, SKOT

Acknowledgements: We are extremely grateful to all the families who took part in this study and the SKOT team who had put a lot of effort into collecting and handling data.

PO662**EFFECTS OF PROTEIN INTAKE ON CARDIOMETABOLIC HEALTH IN CHILDREN: A SYSTEMATIC REVIEW**

T. Voortman¹, E H. van den Hooven¹, A. Vitezova¹, E T M. Leermakers¹, S. Sedaghat¹, A. Buitrago-Lopez¹, A. Sajjad¹, P K. Bautista¹, C L. Ars¹, A. Tharner¹, W M. Bramer¹, A. Hofman¹, J F. Felix¹, O H. Franco¹

¹Department of Epidemiology; Erasmus MC; University Medical Center; Rotterdam; The Netherlands

Background and objectives: Previous studies show that high protein intake in childhood can lead to increased body mass index and obesity. Protein intake might therefore also negatively affect cardiometabolic health in children. Studies in adults however suggest beneficial effects of protein intake on obesity, blood pressure, and lipid profile. Whether protein intake is related to cardiometabolic outcomes in children is unclear. Therefore, we conducted a systematic review of the literature to evaluate the associations of protein intake with cardiometabolic health in children.

Methods: The databases Embase, Medline, Scopus, and the Cochrane library were searched for relevant studies (September 2012). Included were interventional and observational studies in healthy children up to the age of 18 years, in which the relation between protein intake and cardiometabolic outcomes was reported. Cardiometabolic outcomes included were: metabolic syndrome, blood pressure, arterial properties, blood lipids, and measures of insulin sensitivity. Study selection, data extraction and study quality evaluation were performed by two independent investigators.

Results: In the systematic search, 5974 abstracts were initially identified. For 309 abstracts the full-texts were retrieved. After the selection process, 55 studies were included, which were all observational studies. No consistent associations were observed for protein intake in relation to metabolic syndrome, arterial properties, insulin sensitivity, or blood lipids. Of the 20 studies reporting blood pressure as an outcome, 4 found a negative association, one reported a positive association, and the other studies observed no significant association between protein intake and blood pressure.

Conclusions: The currently published literature does not show consistent effects of protein intake on cardiometabolic health in children. Future studies could be improved by using validated dietary assessment methods, incorporating longer follow-up, and adjusting the results for total energy intake and body weight.

Key words: protein intake, cardiometabolic health, children, systematic review

PO663**RISK OF UNDERNUTRITION AMONG ELDERLY SENEGALESE MEN AND WOMEN IS ASSOCIATED WITH DISABILITY IN FOOD PREPARATION ACTIVITY**

O. Diop-Sow^{1,2}, B.P. Sow², A. Diouf¹, M. Coumé², N. Idou-Dossou¹, S. Wade¹

¹Laboratoire de Nutrition, Département de Biologie Animale, Faculté des Sciences et Techniques, Université Cheikh Anta Diop de Dakar, Sénégal

²Centre Médico-Social de l'Institut de Prévoyance Retraite du Sénégal (I.P.R.E.S.), Dakar, Sénégal

Background and objectives: Few studies have addressed the nutritional status of elderly African. The aim of this study was to assess the prevalence of undernutrition in elderly men and women in Senegal and the relationship between undernutrition and physical dependency.

Methods: Cross-sectional study was conducted in 141 Senegalese elderly men (n=78) and women (n=63) aged 60 to 85 y attending Centre Médico-Social de l'I.P.R.E.S. (medical institute for retired persons) as outpatients. After a clinical examination, fat free mass (FFM) was measured by bioimpedance analysis (BIA) using a prediction equation developed in a multiethnic elderly population including Senegalese. Undernutrition was defined by FFM below the 10th percentile of FFM distribution in a reference population. Risk of undernutrition was defined as FFM between the 10th and 25th percentile. Dependency was measured using a questionnaire on activities of daily living and instrumental activities of daily living. Logistic regression model was used to identify risk factors associated with undernutrition.

Results: FFM was significantly lower in the women (41.4±6.6 kg) compared to the men (50.8±6.7 kg, p<0.0001). Undernutrition affected more men (48.7%) than women (22.2%, p=0.0012). However risk of undernutrition affected similarly men and women with an overall prevalence of 14.2%. Women were more independent than men to perform food preparation activity (74.6% vs 5.1%, p<0.0001). Although undernutrition is associated with disability in food preparation activity (OR=4.1), the relationship between risk of undernutrition and food preparation activity is stronger (OR=9.5).

Conclusions: Risk of undernutrition as well as undernutrition is high in elderly Senegalese outpatients. Food preparation activity is a significant risk of malnutrition, particularly in the elderly men and need attention while implementing appropriate nutritional interventions.

Key words: undernutrition, elderly, I.P.R.E.S., BIA, Senegal.

PO664**IRON AND FOLATE STATUS AND THEIR DETERMINANTS IN A NATIONALLY REPRESENTATIVE SAMPLE OF BELGIAN PREGNANT WOMEN**

S. Vandevijvere^{1,2}, H. Van Oyen¹, R. Moreno-Reyes²

¹Department of Public Health and Surveillance, Scientific Institute of Public Health, Belgium

²Department of Nuclear Medicine, Free University of Brussels, Belgium

Background and objectives: Folic acid deficiency during pregnancy may lead to neural tube defects (NTD) in the foetus. Iron-deficiency anaemia is associated with adverse neonatal health outcomes. Folate and iron status were determined in a representative sample of Belgian pregnant women and their determinants were assessed.

Methods: The women were selected through multi-stage proportionate-to-size sampling. Blood samples were collected and a questionnaire was completed face-to-face with a study nurse. Erythrocyte folate concentration was measured by chemoluminescence, haemoglobin (Hb) using a Beckman Coulter Haematology Analyzer and serum ferritin (SF) and transferrin receptor (sTfr) concentrations by immunoassay.

Results: In total 1311 pregnant women participated and women with a lower socio-economic status were well represented. Median erythrocyte folate concentration was 436 ng/ml among first-trimester and 496 ng/ml among third-trimester women. In the first trimester, 39% of women had a erythrocyte folate concentration below 400 ng/ml, whereas 15% of the first-trimester women had a erythrocyte folate concentration below 300 ng/ml. Among first-trimester women, 69.1% reported taking folic acid-containing supplements of which 41.2% started taking them before pregnancy. For third-trimester women, these percentages were 76.2% and 21.9%, respectively. Approximately 40% of third-trimester and 6% of first-trimester women had SF levels less than 15 µg/L. Of the third-trimester women, 23% were iron-deficient non-anaemic (SF <15 µg/L and Hb ≥110 g/L), 16% had iron-deficiency anaemia (SF <15 µg/L and Hb <110 g/L), and approximately 7% had tissue iron deficiency (sTfr >8.5 mg/L). The median body iron stores were 8.1 mg/kg among first-trimester women, but only 3.6 mg/kg among third-trimester women.

Conclusions: It was found that 39% of the first-trimester pregnant women had a folate status that might not be optimal to prevent NTD. Iron deficiency and iron-deficiency anaemia were frequent in third-trimester women. Guidelines are needed in Belgium to optimize folate and iron status during pregnancy.

Key words: iron, folate, pregnancy

PO665**INSULIN RESISTANCE AND VITAMIN D DEFICIENCY IN CHILEAN OLDER PEOPLE.**

B. Angel¹, H. Sánchez¹, L. Lera¹, X. Cea¹, C. Albala¹

¹Institute of Nutrition And Food Technology (INTA), University of Chile, Santiago, Chile

Background and objectives: Vitamin D (vitD) may play a role in glucose homeostasis through its effect on insulin synthesis, secretion and sensitivity. Different studies have reported an inverse association between 25(OH)D levels and risk of diabetes, insulin resistance, HTA and metabolic syndrome. The aim of the present study was to examine obesity and metabolic disorders associated with vitD deficiency/insufficiency in Chilean older people.

Methods: Cross sectional study in 1186 community-dwelling subjects 60-98 y (807 women) residing in Santiago Chile. Plasma levels of 25(OH)D were determined by radioimmunoassay. Glucose, insulin and CRPus, were measured in a fasting blood sample. Blood pressure and complete anthropometry were measured. The relationship between vitD and metabolic disorders was studied using multivariable logistic regression models.

Results: Mean serum 25(OH)D was 63.2±33.1 nmol/L (men 66±33.0; women 62.0±33.2, p=0.048). 25(OH)D levels were under 75 nmol/L in 73% of men and 67% of women (p=0.020). Insulin resistance was present in 17.4 % of all subjects and obesity in 37.6% of women and 26.3% of men (p<0.001). Significant negative crude association between 25(OH)D across BMI categories was found in the total sample (p<0.001). Crude association of vitD<50nmol/L with obesity (p=0.002), waist circumference (p=0.011), Insulin resistance (p<0.001), metabolic syndrome (p=0.004), HTA (p<0.001) and Age>70 y (p<0.001) was observed. After age, sex, waist circumference and season adjustment, vitD<50nmol/L was associated with increased risk of insulin resistance, OR 3.12 (95% IC 1.66-5.86) p<0.001.

Conclusions: High prevalence of vitD deficiency/insufficiency was observed in the Chilean older people. VitD deficiency is associated with insulin resistance. In the future, randomized controlled trials are needed to establish a cause-effect relationship between vitD deficiency, obesity and its metabolic consequences.

Key Words: vitamin D deficiency, insulin resistance, obesity and older people. Funded by Fondecyt 1080589.

PO666**EFFECT OF DHA SUPPLEMENTATION DURING PREGNANCY AND LACTATION ON INFLAMMATORY SIGNALING IN PREGNANT WOMEN AND THEIR NEONATES**

N. Kajarabille^{1,2}, Y. Rodriguez³, J.A. Hurtado², M. Peña², L. Peña-Quintana³, S. Lage⁴, P. Sanjurjo⁴, F. Lara-Villoslada⁵, J.J. Ochoa¹, on behalf of NUGELA working group

³Pediatrics, Hospital Materno Infantil, Las Palmas de Gran Canaria, Spain

⁴Pediatrics, Hospital de Cruces, Barakaldo, Spain

⁵R&D, Department LACTALIS PULEVA

Background and objectives: DHA supplementation has shown beneficial effects during pregnancy and infant development. Most studies are focused on visual and neural development. However, there are poorly studied areas, in particular the effect of DHA on inflammatory signaling, although the beneficial effects of DHA on this process are generally accepted. The aim of the present study was to evaluate the effect of DHA supplemented dairy drink consumption during pregnancy and breastfeeding on the expression of various cytokines in mothers (pregnancy, delivery and breastfeeding) and their newborns (birth and 2.5 months of age).

Methods: 60 women were randomly assigned to two intervention groups: A) Control Group (n=30): they will intake 2 glasses/day of the control dairy drink, and B) Supplemented Group (n=30): the women will take 2 glasses/day of the supplemented dairy drink (400 mg DHA/day). Dietary intervention began in week 28th of pregnancy and concluded when the mother stopped breastfeeding the baby. Samples of blood were obtained from the mothers (pregnancy, delivery and lactation), from the umbilical vein and arteries and from the newborn at 2.5 months postpartum. IL-2, IL-4, IL-6, IL-10, TNF-α and IFN-γ plasma levels were determined using a panel from Luminex xMAP technology.

Results: IL-2 was higher in the supplemented mothers during breastfeeding, whereas IL-4 shows the lowest values in the supplemented group at delivery and lactation, being higher in umbilical cord vein. IL-6 was lower in the supplemented group at delivery in umbilical cord vein, and finally IL-10 was higher at delivery, in umbilical cord artery and during breastfeeding. TNF-α was lower value in supplemented mothers and their neonates, compared with the non-supplemented groups. Finally, INF-γ did not show any difference between groups.

Conclusions: Supplementation with DHA supplemented dairy drink modulates the inflammatory signaling, increasing the anti-inflammatory and diminishing in the pro-inflammatory cytokines.

Key words: DHA supplementation, inflammatory signaling, pregnancy, breastfeeding, newborn

PO667

NUTRIPLUS PROGRAM IMPROVE MATERNAL AND CHILD NUTRITIONAL STATUS AND NUTRITIONAL KNOWLEDGE IN MULTI-CULTURAL FAMILY

Y.J. Oh¹, A.R. Cho¹, S.Y. Na¹, H.J. Lee¹, H.J. Lim¹, Y.H. Yang¹, Y.O. Lee¹

¹Nutrition And Health Service Team, Korea Health Promotion Foundation, 14 Ga-gil, 76 gukhoedae-ro, yeongdeungpo-gu, Seoul 150-868, Korea

Background and objectives: This study investigated whether the NutriPlus program improved maternal and child nutritional status, nutrition knowledge and attitudes in multi-cultural family. The NutriPlus program is developed to improve maternal and child nutritional status in South Korea. Each participant receives specifically designed home-delivered supplementary food packages and nutrition education for 6 to 12 months. The number of multi-cultural family has been increased in South Korea with a dramatic rise of international marriage since 1990's. They have several dietary problems: skipping meal, unbalanced diet, excessive intake of instant food, lack of nutritional knowledge, etc.

Methods: This study included maternal women (n=820) and 1-to 5- year-old children (n=1,851) participating in the program in 2011. Anthropometric, biochemical, and dietary information was collected on maternal woman and children. Participant nutritional status was determined by anemia prevalence and intake level of 8 main nutrients. Nutrition knowledge and attitude information was collected from the children's guardian before and after the program. All analyses were conducted with SAS 9.1 for Window.

Results: The number of children with weight-for-height and height-for-weight percentile less than 10 significantly decreased ($p<0.001$). Anemia prevalence decreased from 70% to 16% ($p<0.001$) and MAR (mean adequacy ratio) was also significantly increased from 0.71 to 0.84 ($p<0.001$).

Conclusions: The NutriPlus program improved maternal and child nutritional status, nutrition knowledge and attitudes in multi-cultural family. Results suggested that more consideration should be given to ways to more education and training opportunities for participants of multi-cultural families including the husbands and the mothers-in-law to improve understanding of other country's food culture and cultural diversity. This project was funded by the Ministry of Health and welfare in South Korea.

Key words: multi-cultural family, maternal and child nutrition status, nutritional knowledge

PO668

THE HEALTHY FRESH FRUITS PROGRAM : EFFECT OF FRUITS AND VEGETABLES INTAKE AMONG LOW-INCOME ELEMENTARY SCHOOL STUDENTS

Y.J. Oh¹, H.J. Lee¹, A.R. Cho¹, S.Y. Na¹, H.J. Lim¹, Y.H. Yang¹, Y.O. Lee¹, K.S. Hong¹

¹Nutrition and Health Service Team, Dept of Health Promotion, Korea Health Promotion Foundation, Seoul, Korea

Background and objectives: This study investigated whether the Healthy Fresh Fruits Program improved fruits and vegetable intakes, nutritional knowledge and attitudes in low-income elementary school students. The lower income parents often report that high cost of fruits and vegetables was major barrier to buying more fruits and vegetables. Lower income families have cut their grocery shopping cost resulting in rising food prices and recession. Fruits and vegetables have been reported for the prevention of childhood obesity because of their low in fat, sodium, high in fiber, vitamins, minerals, and satiety value. The prevalence of childhood obesity of low-income family in South Korea generally has been a bigger problem than one of upper-income family.

Methods: This program is based on the behavioral change theory and targeted for elementary-aged children from low-income family in an after school program of Seoul, Korea. The six lessons of nutrition education and one serving size fruits package in twice a week for four months in 2012. Nutrition education, including healthful diet and food hygiene, were designed to increase consumption of fruits and vegetable.

Results: A pre-and post-test were used to assess changes in knowledge and self-reported behavior related to fruits and vegetables consumption. Results of evaluation with 789 participants revealed significant increases in consumption of fruits, improve of nutritional knowledge and fruits preference ($p<0.05$).

Conclusions: This program was successful in increasing fruits and vegetables consumption and improving nutritional knowledge & attitudes. This project was funded by the Ministry of Health and welfare in South Korea.

Key words: childhood obesity, nutrition education, fruits and vegetable intake

PO669**DEVELOPMENT AND ACCEPTABILITY OF LOCALLY DEVELOPED READY-TO-USE COMPLEMENTARY-FOOD-SUPPLEMENTS (RUCFS) IN URBAN SLUM SETTINGS OF DHAKA, BANGLADESH**

T. Ahmed^{1,2}, N. Choudhury¹, Ml. Hossain¹, MM. Islam¹, B. Schumacher², S. dePee³, N. Tangsuphoom⁴, J. Muiruri², R. Fuli², M. Parveen², S. Sarker¹, KP. West Jr.⁵, P. Christian⁵

¹ICDDR,B, Dhaka, Bangladesh

²World Food Programme, Dhaka, Bangladesh

³World Food Programme, Rome, Italy

⁴Food Science Unit, Institute of Nutrition, Mahidol University, Thailand

⁵Center for Human Nutrition, Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, USA

Background and objectives: Inadequate energy and micronutrient intake during childhood is a major public health problem in many developing countries including Bangladesh. Locally produced ready-to-use complementary food supplements (RUCFS) can improve growth, development and micronutrient status of children. The study was conducted to develop recipes for RUCFS and to test their acceptability among children.

Methods: A checklist was prepared of available and commonly consumed food ingredients that have the potential of being used for RUCFS. Linear programming was used to determine possible combinations of ingredients and required micronutrient premix composition, and samples were prepared in the icddr,b food-processing lab. To test the acceptability of the RUCFS recipes compared to Pushti-packet (a cereal based food-supplement), an acceptability trial was conducted among 90 children aged 6-18 months in a slum in Mirpur, Dhaka, Bangladesh. The mothers were asked to rate the color, flavor, mouth-feel, and overall liking of the RUCFS by using a 7-point hedonic scale (1=dislike extremely, 2=dislike moderately, 3=dislike, 4=neither dislike nor like, 5=like slightly, 6=like moderately, 7=like extremely).

Results: Two RUCFS were developed, one based on rice and lentils and the other one on chickpea. Mean response for each sensory quality of all products was more than 6. The two developed RUCFS scored significantly better compared to Pushti-packet in terms of 'overall liking'. Children were offered 50 g of food and they consumed (mean±SD) 26.1±15.1 g RUCFS and 17.1±14.3 g Pushti-packet which took them 20.9±9.6 minutes. There was no significant difference between two RUCFS consumption, but there was a significant difference between chickpea-based RUCFS and Pushti-packet (28.4 vs 17.1 g) consumption.

Conclusions: Locally available food ingredients were used to develop RUCFS. The study results suggest that rice-lentil

and chickpea-based RUCFS are highly acceptable. Research is underway to assess efficacy of both local RUCFS in improving child growth.

Key words: acceptability, locally-developed, food-supplements

PO670**FRUIT PREFERENCES AND INTAKE AMONG PORTUGUESE SCHOOLCHILDREN**

B. Franchini¹, R. Poínhos¹, M D V. de Almeida¹

¹Faculdade de Ciências da Nutrição e Alimentação, Universidade do Porto, Porto, Portugal

Background and objectives: Preferences are major determinants of fruit intake. We explored the relationships between preference and intake of different types of fruit among Portuguese schoolchildren.

Methods: This study was carried out as part of the Pro Children European project. A sample of 3,083 Portuguese children (10-14 years old) was evaluated, regarding fruit intake (self-administered questionnaire using 24-hour recall) and food preferences of different types of fruit (five-item scale with response options ranging from "like very much" to have not tried"). The intake of each fruit was compared between children with high ("like very much") or low preference for each type of fruit.

Results: Fruit mean intake was 154.1 g/day. Major contributors to total fruit consumption were apple (34.4%), banana (19.7%), orange (12.0%), tangerine (11.9%) and pear (11.9%). Preference for each fruit was associated to higher consumption of that fruit. Preference for orange or tangerine was associated to higher consumption of both fruits. Preference for apple or banana was associated with lower consumption of tangerine. Preference for tangerine was associated to lower pear consumption.

Conclusions: The results of this study may be useful to plan interventions to increase fruit intake among schoolchildren, namely regarding the selection and combination of fruit types to be used in taste testing and other exposure activities.

Key words: fruit, intake, children, preferences, Portuguese.

PO671**REGIONAL AND SEX VARIATION IN THE INTAKE OF DIFFERENT FRUIT TYPES AMONG PORTUGUESE SCHOOLCHILDREN**

B. Franchini¹, R. Poínhos¹, M D V. de Almeida¹

¹Faculdade de Ciências da Nutrição e Alimentação, Universidade do Porto, Rua Dr. Roberto Frias, Porto, Portugal

Background and objectives: A wide range of demographic determinants, such as sex and region, influence fruit intake. The aim of this study was to compare the intake of different types of fruit among Portuguese schoolchildren by sex and region of residence.

Methods: A sample of 3,083 Portuguese children (10-14 years old) was evaluated, regarding fruit intake (self-administered questionnaire using 24-hour recall), as part of the Pro Children European project. The percentual contribution of different types of fruit to total fruit intake was compared by sex and region of residence (North, Center, Lisbon area, Alentejo and Algarve).

Results: Mean fruit intake was 154.1 g/day. Major findings include: the higher intake of fruit in the North and Algarve; higher contribution of banana to boys' fruit intake, and of tangerine, pear and other fruits to girls'; higher contribution of orange to total fruit intake in Lisbon area, banana in Alentejo and Algarve, tangerine in Center and Algarve, and pear in Algarve.

Conclusions: These findings may prove useful in tailoring region-specific interventions to increase fruit intake among schoolchildren, as taste testing and other exposure activities should consider prior consumption of different types of fruit in specific groups.

Key words: fruit; intake; Portuguese children; sex; region.

PO672**DIETARY INTAKE OF LACTATING WOMEN IN UMUAHIA, URBAN, NIGERIA.**

P. Ukegbu¹, A. Uwaegbute¹, J. Anyika¹

¹Department of Human Nutrition And Dietetics, Michael Okpara University of Agriculture, Umudike, Abia State, Nigeria

Background and objectives: Lactating women constitute a vulnerable segment of the population. This is because adequate nutrition during lactation is important for both the mother and the infant. This cross section study was carried out to evaluate the dietary intake of lactating women of two socioeconomic groups in Umuahia urban, Nigeria.

Methods: A total of 213 lactating women (126 from low socioeconomic group (LSEG) and 87 from medium socioeconomic group (MSEG)) were randomly selected from a group of mothers attending postnatal clinics at the Federal Medical Centre, Umuahia. A structured, validated and pre-tested questionnaire was used to obtain information on socio-demographic characteristics. Information on dietary intake was collected using 24 hour dietary recall, weighed inventory and food frequency questionnaire over a 2 days period (a weekday and a weekend day). Mean nutrient intake was estimated and expressed as percentage of FAO/WHO recommended nutrient intake. Data was analysed means (SD) and t-test, while Chi square was used to determine relationship between categorical variables.

Results: Mothers from the MSEG were more educated and had higher total family income than the LSEG ($p < 0.05$). Mean intake of fat and calcium were significantly higher in the MSEG ($p < 0.05$). Intake of energy, protein, calcium and vitamin A were insufficient in both groups. The percentage of energy obtained from carbohydrate, protein and fat were 82.7%, 8.2% and 15.2% for LSEG, while 86.1%, 9.2% and 20.6% were obtained for the MSEG. Consumption of meat and meat alternate as well as leafy/non leafy vegetables and fruits were higher among the MSEG on a daily basis than the LSEG.

Conclusions: Nutrition education programs should be intensified in health facilities/centers in order to sensitize women on the importance of adequate nutrition during this period.

Key words: lactating women, food consumption pattern

PO673**MEAL PLANNINGS OF HIGH SCHOOL STUDENTS IN TURKEY**

E.D. Ciracioglu¹, H. Yardimci¹, A.O. Ozcelik¹

¹Nutrition and Dietetics, Ankara University, Ankara, Turkey

Background and objectives: Gaining healthy eating habits during childhood/adolescence may cause to continue the habit in adulthood too. This study was made to identify the meal plannings of high school students.

Methods: The study has conducted with 497 students (male: 236, female: 261). Data collection was made by a questionnaire and SPSS program was used to evaluate data. WHO data was used to evaluate BMI percentiles (5-19 years-old). Questions about snack choices were evaluated by using the $T = 3T1 + 2T2 + T3$ formula. T stands for total score and T1: first choice, T2: second choice, T3: third choice. Derivative was BMI.

Results: The mean age of students was 15.90 ± 1.00 years, mean BMI was 20.92 ± 2.99 kg/m². 68.4% of the subjects were in normal range according to BMI. 62.0%, 73.0% and 83.7%

of them stated they consume breakfast, lunch and dinner everyday, respectively. 51.2% of them consumed snacks and most common first choice was bread and cheese (877 points), second was toast (346 points) and third was fruits (336 points). Most common drink between meals was tea as first choice (1039 points), coffee for second choice (455 points) and carbonated drinks for third choice (381 points). There were various answers for skipping meals, lack of time was the most common reason for skipping breakfast (64.0%), students' lack of appetite was the most common reason for lunch and dinner (43.3% and 53.1% respectively) Among the subjects who consume breakfast (n=308), lunch (n=363) and dinner (n=416) regularly, the ratio of ones who have normal range BMI is 67.2% for breakfast and lunch and 67.3% for dinner.

Conclusions: Gaining the ability to choose healthy foods during childhood and adolescence is important to lower the risk of some chronic disease in later years. It's important to provide education to parents about healthy nutrition.

Key words: students, meal planning, high school

PO674

MILK CONSUMPTION PATTERNS IN RELATION TO TOTAL DIETARY INTAKE: THE CASE OF MALAYSIAN URBAN CHILDREN AGED 1-10 YEARS

G L. Khor¹, Z M. Shariff², S L. Huang², M. Mohamad¹, B. Nisak², Y M. Chan², Y S. Chin², O P. Leong³, W. Chee¹, J. Bindels³

¹International Medical University, Kuala Lumpur, Malaysia

²Universiti Putra Malaysia, Kuala Lumpur, Malaysia

³Danone Dumex, Malaysia

Background and objectives: Food consumption patterns in emerging economies have generally shifted from a dependency on diets high in plant protein and carbohydrates to one that is increasingly rich in animal protein and fats. Milk consumption in relation to total dietary intake of children is not well documented in rapidly developing countries, including Malaysia. This study assessed milk consumption behaviour among young children from the suburbs of Kuala Lumpur city.

Methods: A total of 749 children aged 1-10 years representing different socioeconomic background were recruited from day care centres (1-3 years), kindergartens (4-6 years) and primary schools (7-10 years). For dietary intake of children aged 1-6 years, parents were interviewed using 24-hour diet recalls and food records. Children aged 7-10 years were interviewed based on 24-hour recalls.

Results: Out of the total, 605 (82.0%) children were milk drinkers, highest in ages 1-3 years (91.2%), followed by 86.1% and 73.7% among ages 4-6 and 7-10 years, respectively. The

mean amount of milk consumed was 789 ml (~4 cups), 498 ml (~2 cups) and 286 ml (~1 cups) for ages 1-3, 4-6 and 7-10 years, respectively. Ages 1-3 years taking >3 cups of milk/day had significantly higher intake of total food, calories, carbohydrate, vitamins A, C, D, B1, B2, Ca and Fe than children taking 2-3 cups/day. Likewise, ages 1-4 years taking >3 cups had significantly higher vitamin D, Na and Ca intake compared to the same ages taking 2-3 cups/day. No significant differences were found between milk consumption patterns and nutritional status for all ages.

Conclusions: While milk intake confers nutritional benefits, excess milk consumption, especially in ages 1-3 years raises concerns for the potential lack of dietary diversity and risk of overweight, a growing problem in Malaysia.

Key words: milk consumption, Malaysian children

PO675

ASSESSMENT OF NUTRITIONAL CONTENT OF COMMERCIAL BABY FOODS IN THE UK

A. Garcia¹, A. Parrett¹, C. Wright²

¹Human Nutrition, School of Medicine, College of Medical, Veterinary & Life Sciences, University of Glasgow, Glasgow, United Kingdom

²Peach Unit, School of Medicine, College of Medical, Veterinary & Life Sciences, University of Glasgow, Glasgow, United Kingdom

Background and objectives: The introduction of solid foods provides infants with crucial nutrients for growth and development. The World Health Organisation (WHO) recommends introduction of solid foods at 6 months. United Kingdom (UK) guidelines also encourage use of home-cooked foods, but commercial products are frequently used. Health care professionals are often asked to advise about the suitability of these foods. We aimed to describe the types and nutritional content of commercial baby foods available in the UK.

Methods: All baby foods produced by 6 UK manufacturers October 2010-February 2011 were identified. Nutritional information for each product was collected from manufacturers' websites, shelved products in store and via direct email enquiry. Using the names and food labels they were classified according to texture, content and suggested age for use.

Results: Out of 479 products, 364 (79%) were ready-made purees, 44% (201) of these were aimed at infants from 4 months and 65% were sweet foods. The energy content of these purees was almost identical to breast milk (282 (59) kJ per 100g) with only slightly higher protein: purees 2.3 (1.2) breast milk 1.3 g per 100 g and much lower than family foods (e.g. potatoes mashed with butter and cheese 567 kJ; 4.16 g per 100g)

Conclusions: The UK baby food market mainly supplies soft spoonable foods, the majority of which are sweet, and are targeted mostly to an inappropriate age. The composition of baby foods is strictly regulated by law which may explain the similarity with breast milk. However, as a result they do not serve the intended purpose of enhancing the nutrient density of infants' diets and do not provide with suitable textures and flavours. Furthermore they may confuse users about appropriate weaning age.

Key words: weaning, infant feeding, food labels

PO676

DIETARY INTAKE AND NUTRIENT SCORES OF FREELIVING ELDERLY IN UMLAZI TOWNSHIP (KWAZULU NATAL)

X. Mkhize¹, W. Oldenwage-Theron², C. Napier³

¹Mangosuthu University of Technology, South Africa

²Vaal University of Technology, South Africa

³Durban University of Technology, South Africa

Background and objectives: Umlazi is the second largest township in South African in terms of population. The objective of the study was to determine the dietary intake and nutrient scores of the elderly (>60 y) in this township of Umlazi, KwaZulu-Natal, South Africa.

Methods: The dietary assessment methods used, included three 24 hr recalls, one food frequency questionnaire analysed using a Food Finder 3 program. EAR values, means, standard deviation and nutrient intakes were calculated and compared with the DRI's interpreted by a bio-statistician.

Results: The top five foods consumed were, maize meal (100%), tea (100%), chicken stew (40.0%), brown bread (57.3%) and white cooked rice (56.9%). The energy contributions showed that 89.2% of the women consumed a diet <100% of Estimated Average requirements (EARs) and all the men consumed <100% of the EARs. For protein 63.0 % women and 91.1% of the men consumed <100% of the EARs for protein. Dietary fibre intake was 86.5% for women and 33.3% of the men consumed <100%. Results indicated low intakes of the majority minerals and vitamins for both genders due to low intake of fruit and vegetables, <400g per day for the mean RDA intake values. Total fat intake was 20% (for both genders) within the WHO, 2003 nutrient intake goals. The mean FVS (\pm SD) for all the foods consumed from all the food groups in a period of seven days was 25.8 (\pm 14.6), revealing poor dietary diversity scoring.

Conclusions: Low micronutrients and a high carbohydrate diet was observed in this group, maize meal being the main staple, this could be one of the causes of weight gain in this community. Strategies of improving micronutrient consumption are essential in this community.

Key words: elderly, diet, nutrients scores

PO677

BODY FAT MASS DISTRIBUTION AS A DETERMINANT OF RESTING METABOLIC RATE VARIATION IN OLDER ADULTS

M. Ruiz¹, P. Sanhueza¹

¹Nutrition and Public Health Department, University of Bío- Bío, Chillán, Chile

Background and objectives: The resting metabolic rate (RMR) not only depends on fat-free mass but is also influenced by fat mass, especially by body fat distribution. The objective was to analyze the body fat mass distribution as a determinant of the variation of the resting metabolic rate in healthy adults aged 60 to 85 in Chile.

Methods: An analytical transversal study was carried out on 37 women aged 60 to 85 years. The anthropometric assessment to determine body fat distribution included weight, height, BMI, and waist/hip circumference. The RMR was determined by the indirect calorimetry method after overnight fasting and for 30 minutes at complete physical and mental rest. The following exclusion criteria were considered: fever, respiratory disease, anaerobic metabolism, use of hypo- and hypermetabolic medication, and alcohol, caffeine, and tobacco consumption. The Pearson correlation was determined for the quantitative relationship of the variables. A variance analysis (ANOVA) was performed.

Results: The nutritional status of the sample showed that 5.41% of the subjects were thin, 56.76% normal, 10.81% overweight, and 27.03% obese. Mean RMR was 1101.22 \pm 242 kcal/d, which varied according to BMI. Gynoid fat distribution was significantly correlated with a higher RMR in the women under study ($p < 0.05$).

Conclusions: The older adult women with android fat distribution exhibited a higher RMR than those with gynoid distribution as a direct consequence of greater metabolic activity.

Key words: resting metabolic rate, senior, fat distribution, indirect calorimetry

PO678

EVALUATION OF THE NUTRITIONAL STATE IN CHILDREN OF 10 TO 14 MONTHS OF TWO MUNICIPALITIES OF CITY HAVANA.

A. Dominguez¹

¹National Institute of Nutrition And Hygiene of The Foods, Havana, Cuba

Background and objectives: Evaluation the clinical state, anthropometric, dietary and biochemical of the state of children's iron of 10 to 14 months of age of two municipalities of City of the Havana.

Methods: One carries out a traverse descriptive study, in children of 10 to 14 months of age residents in two municipalities of City of the Havana; the evaluation of 80 children was designed following the approaches of the sampling probabilistic. One carries out dietary survey for collection of consumption of foods for 3 days and epidemic where the data related with the state of the boy's iron were picked up. One carries out mensuration of weight and supine longitude, biochemical evaluation of the iron state and physical exam.

Results: The ingestion of foods reflected a desbalance in the contribution from the macronutrients to the energy, with a high consumption of proteins and fatty. The iron ingested, vitamin C and vitamin A, it was faulty in most of the children. He/she was 26.9% of anemia, classified as slight, indicative of iron deficiency. The evaluation anthropometrics indicates that most of the children are in the range of normality. The variables measures in the epidemic survey didn't keep significant causal association with the anemia in the boy. The clinical indicators didn't show alterations related with the anemia.

Conclusions: The results of the evaluation in this group of children didn't show the malnutrition existence for defect and the anemia only stays as the main problem of health in this group of risk.

Key words: evaluation, mensuration, macronutrients, anemia

Methods: 24 hours dietary recall was conducted with the mothers who have children 6–36 months, both well nourished and malnourished. Moreover market survey was conducted to assess the types of foods available in the market and the costs per local unit. Mix of food was made to develop menus and the nutrient content was analyzed using food composition table. Menus were developed using locally available and affordable foods and nutritional composition was assessed comparing with the recommendation.

Results: cassava, maize, wheat floor, potato, sweet-potato, small fish, banana, mango, cabbage, amaranth, ground-nut, beans and haricot beans were the major affordable complementary foods identified in the community. 2 menus of 250gms, equivalent to the child stomach, were developed using different foods. The menus consisted of an average of 629.5 Kcal energy (600-800 Kcal), 322.9 REA of Vitamin A (300 REA) and 28.4 mg of vitamin C (15–25 mg) and 3mg of Zinc (3-5 mg) needs of a child meal. However, in both contexts the iron 5.7 gm and protein 21.6gm which could not meet the 10 mg and 25–27 gm need per child meal respectively.

Conclusions: local foods which commonly lack animal sources could not meet the protein and iron needs of children for optimal growth. Hence, programs need to focus on promoting interventions that can improve access to animal source foods.

Key words: food composition, animal sources, daily need, local foods

LIGHT EXERCISE AFTER HIGH-FAT MEAL SUPPRESSES POSTPRANDIAL SERUM TRIGLYCERIDE IN HUMANS

W. Aoi¹, H. Yamauchi¹, S. Wada¹, A. Higashi¹

¹Laboratory of Health Science, Graduate School of Life And Environmental Sciences, Kyoto Prefectural University, Japan

Background and objectives: The effect of exercise performed on the day of meal intake on postprandial triglyceride (TG) concentration, which is an independent risk factor for cardiovascular disease, is unclear. The present study investigated postprandial TG concentration following low-intensity exercise, consisting of brisk walking and light-resistance exercise, performed before or after meal intake.

Methods: Ten healthy young subjects consumed a relatively high-fat diet. All subjects participated in each of the 3 trials: rest, exercise before meal, and exercise after meal. In the exercise trials, subjects performed brisk walking following light resistance exercise, either 60 min before or after meal intake. Blood samples were collected before, and 2, 4, and 6 h after meal intake. The fat utilization was measured by indirect calorimetry analysis.

Results: Exercise reduced the transient elevation in serum TG concentration observed 2 h following meal intake in the post-meal trial (131 ± 67 mg/dL) when compared with the sedentary trial (172 ± 71 mg/dL, $d = -1.00$). This was also observed in the pre-meal trial, although the effect was less pronounced ($d = -0.57$). The TG concentrations in VLDL, LDL, and HDL fractions were also decreased in both exercise trials, while the integrated triglyceride values following meal intake showed a greater decrease in the post-meal trial ($d = -1.23$) than the pre-meal trial ($d = -0.47$). The concentration of serum growth hormone was drastically increased after exercise in both trials. Fat utilization was higher in the exercise trials than in the sedentary trial, especially after meal consumption

Conclusions: Light exercise performed on the day of meal intake can effectively suppress postprandial TG concentrations, especially when performed after meal intake.

Acknowledgements: This study was supported by Grants-in-Aid from the Japan Society of the Promotion of Science (23700776).

Key words: high-fat diet, low-intensity exercise, lipid metabolism

RANDOMIZED DOUBLE-BLIND CROSS-OVER STUDY OF A NUTRITIONAL SUPPLEMENT SPECIFIC FOR PATIENTS WITH NEURODEGENERATIVE DISEASES OVER INFLAMMATORY AND CARDIOVASCULAR RISK BIOMARKERS

C E. Garcia-Rodriguez¹, M D. Mesa¹, M V. Martin¹, M C. Rico¹, L. Campaña¹, M. Perez-Rodríguez², A J. Perez de la Cruz³, A. Gil¹

¹Department of Biochemistry And Molecular Biology II, Institute of Nutrition And Food Technology

²VEGENAT, S.A. Research and Development Department, Puelblonuevo del Guadiana, Badajoz, Spain

³Clinical Nutrition and Dietetic Unit, University Hospital Virgen de las Nieves, Granada, Spain

Background and Objectives: An adequate nutrition could be useful in the improvement of patients with neurodegenerative diseases. The aim of this study was to assess the effects of a specific supplement for patients with neurodegenerative diseases (Supressi®) over inflammatory and cardiovascular risk biomarkers, compared with a nonspecific diet (T-Diet Plus High Protein®) when administered as enteral nutrition for three months.

Methods: 98 patients with neurodegenerative diseases were randomly divided into two groups A (n=51) and B (n=47). Sub-

jects in group A were supplemented Supressi® for three months and a nonspecific product (T-Diet Plus High Protein®) during the next three months. Patients in group B received initially the nonspecific diet during the first three months followed by the experimental product other three months. Plasma levels of inflammatory and cardiovascular risk biomarkers were determined at baseline and after three and six months by immunoassay, with MILLiplex™ kits using the Luminex200® system based on the xMap™ technology. We examined the effect of the diets with t test for paired samples ($p < 0.050$).

Results: After receiving Supressi® for three months, there was an increase of the hormone leptin. Administration of T-Diet Plus High Protein® during three months leads to an increase of resistin along with a significant decrease in monocyte chemoattractant protein (MCP)-1. Furthermore, a tendency to decrease ($p = 0.065$) was observed for soluble intercellular adhesion molecule (sICAM)-1, after ingestion of control diet.

Conclusions: The new supplement maintains plasma levels of inflammatory and cardiovascular risk biomarkers similarly to the nonspecific diet, while increases the hormone leptin involved in the regulation of food intake and energy balance, what may indicate a better nutritional status in these patients with high risk of malnutrition.

Key words: neurodegenerative diseases; nutrition; supplement.

PO682

CHANGES IN THE VALUES IN THE PHYSIOLOGICAL INDEX BY THE HYDRATION IN THE MALE JUNIOR HIGH SCHOOL SOFT TENNIS PLAYERS

A. Kunitomo¹, C. Kageyama², M. Ban³, H. Suzuki⁴, S. Kikunaga¹

¹Department of Foods and Human Nutrition, Notre Dame Seishin University, Japan

²Department of Human Nutrition, Chugoku Gakuen University, Japan

³Department of Management, Osaka Seikei University, Japan

⁴Interactive Sports Education Center, Okayama University, Japan

Background and objectives: Dehydration by the perspiration during the long hours of training causes the rise of body temperature, and not only induces the fall of exercise performance but also causes heatstroke. Appropriate hydration is important for prevention of dehydration. In order to find out a proper condition of hydration for players, the present study has investigated the fluid intake by athletes.

Methods: The 11 male junior high school soft tennis players participated in the study. They were asked for drink water as

much as they liked. Then, the amount of hydration was measured. In addition, rehydration rate and amount of perspiration were calculated based on the sum of the values of both weight loss and fluid intake. The investigation of the values in the physiological index was performed before and after the exercise. Measurement items were body weight, blood glucose concentration, blood lactate concentration, body temperature, physical activities, and heart rate.

Results: Body weight was decreasing during the exercise, and rehydration of about 70 percent of the players was insufficient. The more blood lactate concentration was observed 120 minutes after the exercise than immediately after the exercise. A particularly high value of blood lactate concentration was observed among the players who did not have enough hydration. The degree of fatigue of the players tended to increase as time passed since immediately after the exercise.

Conclusions: These results suggested that in the free fluid intake by thirst of mouth, hydration cannot be carried out fully to the degree with which the amount of perspiration is compensated. We would like to further find out the most appropriate quantity and timing of fluid intake per person and to specify the most appropriate rehydration method which eventually would lead to mitigation of players' fatigue.

Key words: hydration, soft tennis players, blood lactate concentration

DEVELOPING ELDERLY ANTHROPOMETRIC CHAIR (BODY MASS INDEX METER) BASED ON ARM SPAN, KNEE HEIGHT, AND SITTING HEIGHT

*F. Hutasuhut*¹

¹Public Health Nutrition Dept., Faculty of Public Health, University of Indonesia, Depok, Indonesia

Background and objectives: Height in elderly is difficult to be measured due to osteoporosis, scoliosis, kyphosis, etc. Arm span, knee height, and sitting height can be used to predict the height. However, some anthropometric measurements with different positions are not effective because of discomfort. Three predictors of height in one tool like a chair can overcome the problems. The study aimed to develop Body Mass Index/BMI Meter for elder's nutritional status assessment with an easy and practical measurement.

Methods: The study design was cross sectional using anthropometric measurement toward 300 healthy older, aged over 60 years, able-bodied, stand still, and resided in Jakarta and Depok. Upper leg length, lower leg length, pelvic width, shoulder width, elbow height, shoulder height and patellar height were measured to design the chair. Validity test for the chair conducted on 100 elderly whom resided in West Jakarta.

Results: Mean age of respondents was 61.6 years with 87 years age as the highest and 48 years age as the lowest. Men had greater results than women related to the upper and lower legs length, shoulder width and height, and patellar and elbow height. Mean of anthropometric parameters measured in men had a value greater than the women, unless the width of the pelvis. Male posture was higher and larger than female. Since body dimensions was took into account, male generally larger than women, except for several particular parts such as hip, etc. The validity of anthropometric chair from the sensitivity (85-100%), specificity (70-80%), positive predictive value (80-90%) and negative predictive value (80-100%).

Conclusions: BMI Meter is practical tool to measure the nutritional status of the elderly at once without the need to change the measurement in varying position, as it merely done while sitting.

Key words: anthropometric chair; elders'; arm span; knee height; sitting height

²Laboratory of Food Science, Graduate School of Life and Environmental Sciences, Kyoto Prefectural University, Japan

³KOHJIN Life Sciences Co.,Ltd, Japan

Background and objectives: Glutathione is a major redox couple in animal cells and plays important roles in antioxidant defense. Redox balance of glutathione is used as a marker of antioxidant status during exercise. However, it is unclear about relationship between intake of glutathione and exercise. The present study investigated the effect of glutathione intake on muscle fatigue induced by exercise in mice.

Methods: ICR mice (8 weeks old) were divided into four different groups: sedentary, sedentary treated with glutathione (5 μ l/g body weight), exercise, and exercise treated with glutathione. After 2 weeks of treatment, exercise groups performed treadmill running at 25 m/min for 30 min. Immediately after running, intermuscular pH was measured, and soleus muscle and blood were collected for the measurements. Proteins were extracted from the muscle samples and peroxisome proliferator-activated receptor-g coactivator-1 α (PGC-1 α) was

measured by western-blotting. Using DNA extracted from the muscle, *g*-action and cytochrome *c* oxidase subunit β U were amplified by polymerase chain reaction. Mitochondrial DNA (mtDNA) was determined using ratio of both copy numbers.

Results: Plasma non-esterified fatty acids after exercise was significantly decreased in the mice fed diet with glutathione compared with those fed normal diet ($p=0.023$). Blood lactate and glucose were not significantly changed between groups. Intermuscular pH was decreased by exercise ($p<0.001$), while this reduction was inhibited by addition of glutathione to the diet ($p=0.030$). The level of PGC-1 α protein was significantly elevated in glutathione diet compared with normal diet ($p=0.049$). mtDNA was significantly higher in glutathione treatment than in normal control ($p=0.007$).

Conclusions: Glutathione improved lipid metabolism during exercise via PGC-1 α activation, which inhibited the decrease of intermuscular pH.

Key words: glutathione, PGC-1 α , lipid metabolism, skeletal muscle

IDENTIFYING OBESOGENIC DIETARY FACTORS AMONG EGYPTIAN OBESE ADOLESCENTS

M. Zaki¹, L. Hussein², R. Bassyouni²

¹National Research Centre, Biological Anthropology Department, Medical Research Division, National Research Centre, Egypt

²Department of Nutrition, National Research Centre, Egypt

Background and objectives: The growth of the fast-food industry has led to an increased consumption of food prepared away from home that is high in total and saturated fat, but low in dietary fiber, calcium and iron. The present study aims to identify specific obesogenic dietary factors among Egyptian obese youth.

Methods: The study was conducted on 300 (150 males and 150 females) obese adolescents and 200 lean subjects. They were participated in the project entitled "Obesity among Youth: Lifestyle and Genetic Factors" funded by the Science and Technology Development Fund, Egypt. Dietary intakes were assessed by 24 h dietary recall and Food frequency Quantitative questionnaire [FFQ]. The average months for the Quartiles of intake were computed for the common food groups. The "Youth Healthy Eating Index" (YHEI), which focuses on healthy and unhealthy eating behaviors, was measured to assess the overall diet quality.

Results: Estimate of energy intake by the 24 h dietary recall reveals low reporters relative to expected based on weight maintenance energy requirement. FFQ denotes higher estimat-

ed daily energy intakes among the obese subject compared with the respective estimated 24-h dietary recall. The diet quality showed lower estimated intakes of specific micronutrients among the lean and obese. Estimated quintiles of consumption of bread, rice; fried chicken, cheeses, eggs and drinks was positively correlated with obesity in both sexes. Estimated daily intakes of total vegetables and fruits were significantly higher among lean males compared with the respective intakes among the obese males.

Conclusions: The present results support earlier findings that low intake of vegetables and fruits are among the obesogenic dietary factors. The application of YHEI has the potential to assess the diet quality and distinguish between lean and obese groups.

Key words: obese adolescents; youth healthy eating index; Quartiles of food intakes.

²Department of Clinical Nutrition, Dongduk Women's University, Seoul, Korea

³Department of Preventive Medicine, Hanyang University, Seoul, Korea

⁴Department of Psychiatry, Hanyang University, Seoul, Korea

Background and objectives: Diet quality has received growing attention in relation to many diseases because it better reflects the complexity of the diet. We examined the association between diet quality and cognitive function in Korean older adults.

Methods: The subjects were 808 older adults participating in the Yangpyeong Cohort Study between July 2009 and August 2010. Diet quality was evaluated by alternate Mediterranean Diet Score (aMDS) and the Recommended Food Score (RFS). aMDS and RFS were calculated by using a food frequency questionnaire. Cognitive function was assessed by Korean version Mini-Mental State Examination (MMSE-KC).

Results: Thirty-six percent of the subjects were classified into cognitive impairment group. aMDS was inversely related to the risk of cognitive impairment after adjusting for exercise and supplement (5th vs 1st quintile, OR 0.44, 95% CI 0.26-0.73, p for trend=0.0149). RFS was also inversely associated with the risk of cognitive impairment after adjusting for exercise and supplement (5th vs 1st quintile, OR 0.44, 95% CI 0.27-0.72,

p for trend=0.0005). After stratified analyses by sex, in male subjects, aMDS was negatively related to the risk of cognitive impairment. RFS was inversely associated with the risk of cognitive impairment in female subjects.

Conclusions: These results suggest that good quality of diet may help preventing or postponing cognitive impairment. Further studies are warranted to confirm the findings in different research settings.

Key words: diet quality, cognitive function, older adults

ADHERENCE TO A NEW NORDIC DIET IN PREGNANCY IS ASSOCIATED WITH REDUCED RISK OF EXCESSIVE GESTATIONAL WEIGHT GAIN

E R. Hillesund¹, E. Bere¹, M.I. Haugen², N.C. Øverby¹

¹Department of Public Health, Sports and Nutrition, University of Agder, Kristiansand, Norway

²Division of Environmental Medicine, Department of Food Toxicology, Norwegian Institute of Public Health, Oslo, Norway

Background and objectives: The health properties of the New Nordic Diet (NND) are increasingly being investigated in response to awareness of sustainability and public interest in eating local and traditional foods. The purpose of the present study was to investigate the association of NND adherence with risk of excessive gestational weight gain (EGWG) in the Norwegian Mother and Child Cohort Study (MoBa).

Methods: A diet score was constructed from relevant items of the food frequency questionnaire (FFQ) completed by pregnant women in the MoBa study in week 22 of pregnancy. The score comprises ten subscales summarizing meal pattern, intake of fruits, root vegetables, kale, potatoes, oatmeal porridge, whole grain bread versus white bread, foods from the wilderness (fish, game and berries), milk versus juice, and water versus soft drinks. Each subscale was dichotomized by the median and assigned a value of “0” or “1”. Adding the subscales yielded a score from 0 to 10 with increasing score indicating higher adherence to the NND. EGWG was defined as gestational weight gain in excess of the range considered optimal and recommended by the Institute of Medicine (2009) according to pre pregnancy BMI. For analysis participants were grouped into “low”, “medium” and “high” NND-adherence, and the relative risk of EGWG across groups was analyzed with multi-nominal logistic regression.

Results: 56771 pregnant women were included in the study. Moving from low to high NND-adherence was associated with reduced odds of experiencing EGWG in the crude model (OR: 0.837; 95%CI: 0.795, 0.882) and after adjusting for energy intake, pre pregnancy BMI, length of gestation and physical activity level (OR: 0.875; 95%CI: 0.825, 0.928).

Conclusions: Higher adherence to this a priori defined New Nordic Diet was associated with reduced risk of experiencing EGWG.

Key words: New Nordic Diet, excessive gestational weight gain, diet score

PO688

BREAST MILK ADIPONECTIN IS ASSOCIATED WITH MATERNAL DIETARY INTAKE AND INFANT GROWTH

H.J. Jan Mohamed¹, S.L. Loy¹, M. Mohamed¹, Y. Wang²

¹Nutrition Program, Universiti Sains Malaysia, Kubang Kerian, Kelantan, Malaysia

²Pharmacology Department, University of Hong Kong, Pokfulam, Hong Kong, China

Background and objectives: Adiponectin, a circulating anti-inflammatory adipocyte protein, is associated with lower adiposity and is also present in human milk. Nutrients from human milk have been shown to play a significant role in affecting infant growth and development. However, the possible factor related to adiponectin in breast milk and its effect on early growth of infants is not extensively studied. This study aimed to determine the associations of adiponectin concentration in breast milk with maternal dietary intake and infant growth at 2 months of lactation.

Methods: A total of 138 pairs of healthy mother-infant were enrolled from the University Sains Malaysia Birth Cohort Study between 2009 and 2011. All participants were healthy and term infants breastfed exclusively at least 2 months. Breast milk adiponectin at 2 months of lactation were measured by enzyme-linked immunosorbent assay. Maternal anthropometry data were obtained by standard measuring protocol, while dietary data were collected by 24-hour dietary recall method. Infant growth was assessed by using the World Health Organization standards.

Results: Breast milk adiponectin was ranged from 2.81 to 37.13 ng/ml. Among all the maternal dietary factors at 2 months of lactation, only maternal vitamin C intake showed positive correlation ($r=0.19$, $p=0.031$) with breast milk adiponectin concentration. Low adiponectin in breast milk was associated with higher weight-for-age Z score ($r=-0.24$, $p=0.005$) and higher body mass index-for-age Z score ($r=-0.20$, $p=0.017$) among infants at 2 months of age, adjusted for confounders.

Conclusions: Breast milk adiponectin was influenced by maternal vitamin C intake and it is associated with infant body size.

Key words: adiponectin, human milk, infant growth, nutrition, pregnancy

PO689**RELATIONSHIP BETWEEN DIETARY ENERGY DENSITY AND 5-YEAR AGING IN HEALTHY FREE-LIVING JAPANESE ELDERLY**

M. Aki^{1,2}, R. Watanabe¹, K. Muramatsu¹, A. Yoshihara², H. Miyazaki²

¹Department of Health and Nutrition, University of Niigata Prefecture, Niigata, Japan

²Department of Oral Health Science, Niigata University, Niigata, Japan

Background and objectives: Recently, it is known that the dietary energy density is associated with the gender, age and race because their dietary habits are different. However, the reports on the dietary energy density of elderly people have been limited, particularly about Asian race including Japanese. In the present study therefore, we examined whether dietary energy density changes with increasing of age in healthy free-living people over the age of 75 in Japan.

Methods: The subjects were 225 (113 men and 112 women) free-living Japanese elderly over the age of 75, and were randomly selected from a longitudinal interdisciplinary study of aging. Dietary habits during the preceding month were assessed using a brief-type self-administered comprehensive diet history questionnaire (BDHQ) for Japanese. Estimates of dietary intakes for 58 food items, energy, and the dietary energy density were calculated based on foods only. All statistical analyses were carried out with SPSS version 17.0.

Results: As for energy intakes in both genders, there were no significant differences between age of 75 and age of 80. Energy intakes at the age of 80 were 2.258 kcal/d (men), and 1.942 kcal/d (women). Dietary energy density significantly increased from 1.24 ±0.14 kcal/g to 1.29 ±0.18 kcal/g in women ($p \leq 0.01$) but did not change in men (from 1.29 ±0.18 kcal/g to 1.30 ±0.19 kcal/g). At the age of 75, dietary energy density in men was higher than that in women ($p \leq 0.05$). However, the sex differences on dietary energy density were not found at the age of 80.

Conclusions: Findings indicate that dietary energy density was higher with increasing in age in healthy free-living older Japanese women.

Key words: free-living elderly, dietary energy density, aging

PO690**MEDITERRANEAN DIETARY PATTERNS IMPROVE MINERAL INTAKE AND BIOAVAILABILITY IN ADOLESCENTS**

I. Seiquer¹, M. Mesías¹, P. Navarro¹

¹Instituto de Nutrición, EEZ. Consejo Superior de Investigaciones Científicas (CSIC), Armilla, Granada, Spain

Background and objectives: Adolescence constitutes a period of nutritional risk due to increased dietary requirements for growth and development and the special adolescent's dietary habits. Minerals are essential in this period of life, as they are involved in numerous structural and physiological functions such as skeleton mineralization or sexual maturation. The aim of this study was to evaluate the effects of consuming a varied diet based on Mediterranean patterns on mineral intake and bioavailability in adolescents.

Methods: 20 male adolescents aged 12.9±1.14 years were involved. The study had a longitudinal design, divided into two periods: a 3-day basal period, during which the subjects consumed their usual diet (UD), and a 28-day nutritional intervention period, in which an intervention Mediterranean-type diet was provided (MD). Dietary mineral utilization was assessed by means of mineral intake in food and mineral output in feces and urine, as measured by flame absorption spectrophotometry (Ca, Mg, Fe, Zn, Na and K) or colorimetrically by the vanadomolibdate procedure (P).

Results: Adherence to Mediterranean diet was greatly improved during the intervention period. Dietary intake of some minerals, like Ca or Fe, did not change between diets, but significant differences were found in others (P, Mg, Zn, Na and K). Bioavailability of the most minerals (calculated as percentage of retained from ingested) was enhanced during the MD consumption, even those with similar intakes (Ca 23.9% and 39.4%; Fe 8.3% and 21.1%, for UD and MD, respectively).

Conclusions: A varied diet based on Mediterranean patterns during adolescence greatly improves bioavailability of minerals, which may have healthy effects and help to prevent related diseases in the adult age.

Key words: Mediterranean diet, adolescence, minerals, bioavailability.

PO691**COMBATING CHILD MALNUTRITION IN SRI LANKA: USE OF EVIDENCE-BASED NUTRITIONAL INTERVENTIONS**

U. Senarath¹, S. Godakandage², H. Jayawickrama², A. Wickramasinghe³, I. Siriwardena⁴, M. Dibley⁵

¹Faculty of Medicine, University of Colombo, Sri Lanka

²Family Health Bureau, Ministry of Health, Sri Lanka

³Office of the Medical Officer of Health -Mahara, Sri Lanka

⁴Institute for Health Policy, Colombo, Sri Lanka

⁵Sydney School of Public Health, University of Sydney, Australia

Background and objectives: Child under-nutrition remains a significant public health problem in Sri Lanka despite its good mortality and morbidity indicators. According to the Demographic and Health Survey (DHS) 2006-07, prevalence of stunting, wasting and underweight among children under 5 years was 17.3%, 14.7% and 21.1% respectively in 2006-7. Approximately 25% of children aged 6-59 months were anaemic. This paper aims to review the implementation of evidence-based interventions to tackle childhood under-nutrition in Sri Lanka.

Methods: Reports of nutrition surveys, intervention studies, programme evaluations, and reviews were studied through a desk-review. Unpublished data in reports, presentations and dissemination seminars were obtained from the relevant investigators and/or organizations. Secondary data analyses were performed using the DHS 2006-7 data.

Results: Promotion of breastfeeding was satisfactory as exclusive breastfeeding rate was 76% according to the DHS. However the minimum acceptable diet was only 50% among children 6-11 months age. Many other evidence-based interventions to reduce child malnutrition are existent in Sri Lanka, such as food supplementation; supplementation of Vitamin A and multiple micronutrients; iron, folic acid and calcium supplementation in pregnancy, and universal promotion of iodized salt. The micronutrient supplementation reaches more than 80% of the target population, however the coverage of food supplementation was low. The issues identified as requiring further improvement include ineffective targeting, equity, quality, coverage of low performing areas such as complementary feeding and food supplementation, and participation of non-health sectors.

Conclusions: Sri Lanka has already given high priority to many of the evidence-based interventions, but should ensure their effective implementation with high coverage and quality. There should be effective targeting of food assistance and supplementation programmes, with due attention to food insecure populations.

Key words: undernutrition; infant feeding; breastfeeding; nutrition interventions; supplementation; Sri Lanka

PO692**DETERMINANTS OF STUNTING AMONG CHILDREN AGED 6-23 MONTHS IN SRI LANKA**

U. Senarath¹, S. Godakandage², H. Jayawickrama², A. Wickramasinghe³, I. Siriwardena⁴, D. Attygalle⁵, R. Jayatissa⁶, M. Dibley⁷

¹Faculty of Medicine, University of Colombo, Sri Lanka

⁴Institute for Health Policy, Colombo, Sri Lanka

⁵Health and Nutrition Specialist, UNICEF, Sri Lanka

⁶Medical Research Institute, Ministry of Health, Sri Lanka

⁷Sydney School of Public Health, University of Sydney, Australia

Background and objectives: The trend of childhood stunting indicates a slow decline in Sri Lanka, despite improvement of many health indicators. This study aimed to determine the immediate, underlying and basic 'factors' associated with stunting in children 6-23 months age.

Methods: Sri Lanka Demographic and Health Survey 2006-07 was a cross-sectional household survey and interviewed ever-married women aged 15-49 years, and measured heights and weights of their children under 5 years of age. Our analysis was restricted to 1991 children aged 6-23 months. Prevalence of stunting (height-for-age Z score <-2) was cross-tabulated against independent variables, with 95% confidence intervals. Multiple logistic regression model was used to calculate adjusted Odds Ratio (OR).

Results: Prevalence of stunting was 18.5% (95% CI;16.3, 20.9) among children aged 6-23 months. Neither complementary feeding practices (minimum dietary diversity, meal frequency and acceptable diet) nor childhood illnesses (acute respiratory illness, diarrhoeal disease) were significantly associated with stunting. An increasing trend in stunting was observed with increasing age of child. Male sex (OR=1.33), low birth weight (OR=3.33) and lower maternal height (OR for height <150cm=2.54) were also significant predictors of stunting. Underlying factors of stunting include: poorest wealth quintile (OR=1.85), having 3 or more children in family (OR=1.64) and poor paternal education (fathers with primary or no schooling, OR=1.49). Lesser antenatal clinic visits during pregnancy was associated with higher risk of stunting (OR=1.37). Residential sector (tea estate sector, OR=1.95) and maternal employment (working mothers, OR=1.39) were among significant basic determinants.

Conclusions: Since maternal short stature and low birth weight were found to be strong predictors, an integrated action through lifecycle approach would be required to break this

viscous cycle. Socio-economic factors have a large impact on stunting which requires effective inter-sectoral coordination to tackle this issue.

Key words: stunting; chronic undernutrition, protein-energy malnutrition; risk factors; Sri Lanka

⁵CIBERDEM, Hospital Clínic de Barcelona, Barcelona, Spain

⁶Universidad Pública de Navarra, Pamplona, Spain

⁷SportVital, Andorra la Vella, Andorra

Background and objectives: Exercise and nutritional supplementation programs designed to result in a long-lasting metabolic improvement should consider the status of muscle, body composition and inflammatory markers. Protein intake constitutes a fundamental element to obtain an increase in the muscular mass. The objective of this study was to evaluate the effect of a combined routine that included strength and endurance exercises and a post-exercise supplementation with leucine-enriched milk whey protein on muscular mass, muscular strength and inflammatory markers in healthy and DM2 sedentary subjects.

Methods: We performed a clinical, randomized, double-blind study with 35 healthy volunteers (n=17) and DM2 volunteers (n=18) that underwent a 16 weeks training program. A subgroup of healthy volunteers received a supplement or a placebo 30 minutes after performing exercises. Each individual was clinically assessed at the beginning and at the end of the study, including muscular strength, body composition, diet and biochemical serum parameters.

Results: All the groups slightly increased their muscular mass (between 0.3% and 2.1%) and the leg muscular strength measured with a 1RM test increased (p<0.05) in subjects that

received the protein supplement (41.7%), placebo (44.5%) and controls (13.7%). Plasma TNF- α concentration decreased in all of them (-13.1% supplement, -19.6% control and -26.1% placebo). Adiponectine plasma concentration increased in control (16%) and supplement (2.7%) groups, and slightly decreased in the placebo group (-8%). IGF-1 plasma levels increased in the supplement (3.8%) and control (1.8%), and decreased in the placebo group (-1.7%). However, at this moment, all these changes in plasma cytokines are not statistically significant.

Conclusions: There have been positive changes in terms of muscle strength and in some plasma cytokines levels but protein supplementation showed no statistically significant effects.

Key words: exercise, protein supplementation, inflammatory biomarkers, muscle

PO694

SURVEY OF DIETARY PATTERN AMONG ADOLESCENT GIRLS OF AHMEDABAD CITY, GUJARAT, INDIA

A. Dalal¹, S. Chauhan¹, D. Bala¹

¹Department of Community Medicine, Smt. NHL Municipal Medical College, Ahmedabad, Gujarat, India

Background and objectives: Adolescence, one of the nutritional stress periods of life with profound growth, comes with increased demands for energy, protein, minerals and vitamins. India is facing dual problem of under-nutrition and obesity among adolescents. So it was decided to assess nutritional status and current dietary pattern among adolescent girls.

Methods: A cross-sectional study was carried out among 520 adolescent girls during August, 2011-July, 2012. A stratified, 2-stage, random, cluster sampling was done, first schools were randomly selected and then frame was stratified by sex and socioeconomic class (SEC). Dietary survey was done using 24hr recall method. Nutritive value tables (ICMR) for Indian foods were used for calculating nutrient intakes.

Results: Mean age of the girls was 14.72±2.5 years. Under-nutrition was observed in 27.7% girls while overnutrition in 8.9% girls according to CDC criteria for BMI, a significant difference was observed between nutritional status of girls and SEC ($\chi^2=20.37$, Df=4, p<0.0004). Overall mean calorie intake was 978.07±310.74 kcal, deficient by 50.8% of Recommended Dietary Allowance (RDA) for age, mean protein intake was 27.74±9.34 gms, deficient by 54.3% of RDA for age, mean fat intake was 34.89±15.5 g, excess by 62.9% of RDA for age, mean calcium intake was 469.69±234.61 g, deficient by 11.4% of RDA for age and mean iron intake was 19±7.8 g, deficient by 28.7% of RDA for age. A statistically significant difference (p<0.0001) was observed in calories, fat, protein, calcium and iron intake with SEC respectively (Kruskal-Wallis). Mean calorie intake

from junk food was 212.6+93.96 kcals, which contributes to 21.7% of total calorie intake.

Conclusions: Overall intake of essential nutrients was below the RDA for age whereas almost 1/3rd of total calorie intake was from junk food. Nutritional status of adolescent girls contributes to nutritional status of community. As a preventive strategy, there is a need to apply health and nutritional education program for inculcating healthy life styles.

Key words: adolescence, nutrients, RDA

PO695

DUTCH INFANTS AT RISK OF EXCESSIVE VITAMIN D INTAKE THROUGH COMBINED INTAKE FROM (FORTIFIED) FOODS, INFANT FORMULA, AND DIETARY SUPPLEMENTS

J. Verkaik-Kloosterman¹, M. Beukers¹, M. Jansen-van der Vliet¹, A L M. Dekkers¹, M C. Ocké¹

¹National Institute For Public Health And The Environment (RIVM), The Netherlands

Background and objectives: In the Netherlands, the vitamin D fortification policy and supplementation advice recently changed. Supplementary 10-µg/d is advised for infants up till 4 y. Besides infant formula, other foods may be fortified with vitamin D. Addition of vitamin D to margarines is encouraged. The aim of this study was to estimate the risk of excessive vitamin D intake from all sources for the current (2011) fortification practice and supplementation advice.

Methods: Data from the Nutrition Intake Study (2002; N=941 7-19 months) was used. Infants consuming mother's milk were excluded. Consumption data collected on 2 independent days with a diary was combined with food composition data from 2011. Two scenarios for vitamin D content in infant formula, 1) as labeled, 2) legal maximum according to European legislation (overage). All infants were assigned to take a daily 10-µg vitamin D supplement. Habitual vitamin D intake was estimated using SPADE and compared with the UL.

Results: Predicting the 2011 situation, the medium habitual total vitamin D intake was 13-21-µg for infants 7-19 months, decreasing with age. Of infants 7-11 months, 4-12% exceeded the UL (25-µg). Using the legal maximum vitamin D content (3 µg/100 kcal) in infant formula resulted in a medium habitual total vitamin D intake of 13-25-µg for infants 7-19 months, decreasing with age. Of infants 7-11 months, 23-54% exceeded the UL. Infants 12 months and over did not exceed the UL of 50-µg in both scenarios.

Conclusions: In case of combined intake from infant formula, (fortified) foods and supplements, vitamin D intakes above the UL occur among infants; especially infants aged 7-11 months and with an overage of the labeled vitamin D content

of infant formula. For long-term intakes above the UL health risks (e.g. hypercalcaemia) cannot be excluded.

Key words: vitamin D, infant, excessive intake

PO696

FOOD HABITS AND DIETARY PATTERNS OF PREGNANT WOMEN IN URBAN AND RURAL AREAS OF DEYANG REGION, SICHUAN PROVINCE OF CHINA

H. Gao¹, C. Stiller^{1,3}, V. Scherbaum^{1,3}, Q. Wang², H. Bie-salski³, E. Hormann⁴, A. Bellows¹

¹Institute of Social Sciences in Agriculture, Gender and Nutrition (430b), University of Hohenheim

²Medical Society of Deyang City, Sichuan, Public Health Bureau of Deyang, People's Republic of China

³Institute of Biological Chemistry and Nutrition (140a), University of Hohenheim, Germany

⁴Europäisches Institut fuer Stillen und Laktation, Kramsach, Austria

Background and objectives: Micronutrient deficiencies and low energy intake tend to occur during the reproductive period of women in China. In accordance with traditional Chinese culture, pregnant women are commonly advised to follow a specific set of food habits. To assess dietary intake and identify risk factors for nutritional inadequacy in pregnant women from urban and rural areas of Deyang region, Sichuan province of China.

Methods: Cross-sectional sampling was applied in two urban hospitals and five rural clinics (randomly selected) in Deyang region. Between July and October 2010, a total of 203 pregnant women in the third trimester, aged 19-42 years, were recruited on the basis of informed consent during antenatal clinic sessions. Semi-structured interviews on background information and 24-h dietary recalls were conducted.

Results: In the study area, pregnant women's dietary energy originated excessively from fat (39%), was slightly carbohydrate deficient (49.6%), and reached the lower limits for protein (12.1%). Although cereals such as rice and wheat were still the main staple food in comparison to national statistics, there is a declining share of cereals whilst the proportions of meat, dairy products and vegetable oils are rising. Compared to rural areas, women living in urban areas had significantly higher RNI fulfillment levels for energy (106.1 vs 93.4%), fat (146.6 vs 119.7%), protein (86.9 vs 71.6%), vitamin A (94.3 vs 65.2%), zinc (70.9 vs 61.8%), iron (56.3 vs 48%), calcium (55.1 vs 41%) and riboflavin (74.7 vs 60%). The likelihood that pregnant women follow traditional food recommendations was higher in rural (80%) than urban (65.1%) areas.

Conclusions: In order to reduce the use of cooking oils and improve the consumption of cereals, vegetables and dairy products, pregnant women in Deyang region need access to culturally sensitive nutrition education sessions.

Key words: food habits, 24-hour dietary recall, pregnancy, China

PO697

PROTECTIVE EFFECT OF DAIRY FAT ON BRAIN DHA LEVELS OF YOUNG RATS BORN FROM ALA-DEFICIENT OR ALA-RICH MOTHERS

B. Delplanque¹, Q. Du², J.C. Martin², P. Le Ruyet³

¹NMPA, CNPS, Université-Paris-Sud, Orsay, France

²INRA1260/Inserm1025, Fac de médecine de la Timone, Marseille, France

³Lactalis R&D, 8 Fromy, Retiers, France

Background and objectives: DHA is the major brain FA and omega-3 deficiencies during gestation/lactation could have dramatic impacts on health during adulthood. The aim of the present study was to evaluate: 1/ the impact of dietary deficient or ALA-rich diets during gestation/lactation on the brain DHA levels of post-weaning young males submitted to deficient or ALA rich-diets; 2/ the specific impact of different matrix: butter fat compared to rapeseed oil diets to restore or maintain brain DHA levels in young rats born from deficient or ALA-rich dams.

Methods: Two groups of dams were fed during gestation and lactation with either a deficient ALA-palm diet containing minimal ALA level (0.4%) or a protective ALA-rich (8%) pure rapeseed oil diet. After weaning, 3 groups of young males born from deficient and ALA-rich dams received a 10% fat diet for 6 weeks, either (i) as ALA-deficient-palm diet (ALA 0.4%), (ii) ALA-low-butter diet (ALA 0.8%), (iii) ALA-rich-rapeseed diet (ALA 8%).

Results: - New-born and weaning pups from deficient dams showed brain DHA levels 2 times lower than those from ALA-rich-dams. - The brain DHA levels of the post weaning rats were more dependent of the dams status than of their own diet: an ALA-rich diet during gestation and lactation is protecting against ALA deficiency during post-weaning growth, while an ALA-rich diet post-weaning allow a recovery for those born from deficient-dams, but never reach the values of those born from ALA-rich-dams. - Butter fat, despite 10 times less ALA than rapeseed oil (0.8% vs 8%), is as efficient as rapeseed to restore the Brain DHA level in young rats born from deficient-dams and to maintain similar levels for those born from ALA-rich-dams. The same low n6/n3 ratio in these two type of fats (3 while 25 for palm) and the complexity of the composition of dairy fat could be part of their protective effect. Partially granted by Lactalis

Key words: dairy-fat, brain, DHA, ALA.

NUTRITIONAL EVALUATION AND RECOMMENDATIONS IN A PRIMARY SCHOOL OF VISEU

M.J. Lima¹, A.F.S. Alegre¹, E.A. Martins¹

¹CI&DETS Department of Food Science, IPV-Escola Superior Agrária de Viseu, Viseu, Portugal

Background and objectives: The diet quality is a major factor regarding the healthy growth of children. The prevalence of childhood obesity in the “developed countries” has increased in the past decades. This became an important issue in public health nutrition. This work reflects a nutritional analysis of a 1st /2nd cycle college education throughout the workweek. The aim was to verify whether the school feeding was balanced and provided enough nutrients to allow optimal growth and development of children in these ages (6-15 years).

Methods: The Dietary Guidelines for Americans 2010 was used to choose a healthy eating pattern. In order to access the different nutritional values it was used, as benchmark, the DIAL analysis program.

Results: In terms of cooking methods, it was noted the predominance of techniques that led to higher caloric intake of food, especially frying (shallow and deep). The Wednesday and Thursday days had nutritional values that disrupt the parameters of a healthy diet: overall energy intake and high percentage of lipids. Meals of Monday, Tuesday and Friday were balanced.

Conclusions: Among the analyzed menus, the Monday one was more balanced and adjusted to the physical activity in this age group (considering that children exercise twice a week). An economic estimation of the served menus was also object of study.

Key words: children, cooking methods, nutritional evaluation.

PO699

NUTRITIONAL ASSESSMENT OF SOME MENUS SERVED AT THE AGRARIAN SCHOOL OF VISEU-ESAV

M.J. Lima, F. Varandas, C. Marques

¹CI&DETS, Department of Food Industry, ESAV-IPV, Quinta da Alagoa, Estrada de Nelas, Viseu, Portugal

Background and objectives: The concern for prospective nutritional meals has increased over time. Adolescent's obesity constitutes an important issue to be studied in Portugal. Moreover, recent studies affirm that more than 30% of our adolescents have severe obesity problems. This study was performed in order to evaluate the nutritional quality of the menus served at Agriculture School of Viseu- ESAV, throughout a workweek,

aiming to improve the quality menus as a way to prevent chronic diseases associated with food. The main objectives of this study were to characterize the kind of nutrition offered for students of age 18 to 25 and evaluate if the practiced menus were according to the Dietary Guidelines for Americans 2010, chosen as a healthy eating pattern.

Methods: The program DIAL was used in order to achieve the caloric and the nutritional values. An economic perspective of the menus served was also practiced. School canteens, while educational spaces with food supply, must be concerned with the principles of a balanced diet. The weekly menus were compiled in a coherent and balanced menu, in terms of nutrition, pleasant, appealing and satisfying nutritional needs of young adolescents.

Key words: adolescents, menus, nutritional assessment.

PO700

ENERGY INTAKE AND MACRONUTRIENT DISTRIBUTION OF A GROUP OF ADULT WOMEN IN VALLADOLID (SPAIN)

M J. Cao^{1,2}, M J. Castro^{1,2}, E. Quinto¹, J M. Jimenez², V. Niño², A. Nayo²

¹Instituto Endocrinología Nutrición Ienva, Universidad Valladolid, España

²Departamento Enfermería, Universidad Valladolid, España

Background and objectives: A balanced diet allows completing the basic needs and prevents or reduces the risk of certain disorders or diseases. Energy and nutrients must be present in adequate amounts to achieve it.: The aim of the present study was to establish the energy intake averaged values of macronutrients for women between 40 and 60 years old in the city of Valladolid (Spain).

Methods: A sample of 500 women was selected through random sampling. They were asked to fill a food-consumption frequency questionnaire (Martin Moreno et al 1999). The daily amount of consumed food was obtained. The total daily intake of each nutrient is obtained taken into account the contributions from all foods. The table published by Anta Ortega et al. (2008) was used. The results were compared with the recommendations established by the Spanish Societies Federation of Nutrition, Food and Dietetics (FESNAD 2010).

Results: The amount of consumed energy is a 105.2% of the recommendation for the averages of the age, weight and activity variables. The macronutrients were distributed as follows: proteins: 18.04%. carbohydrates: 40.10%. lipids: 41.90%.

Conclusions: The studied diet provides a higher energy input than the energy intake values cited by the recommendations. The macronutrients contribution to the daily energy

intake deviates from the recommendations. The diet provides an excessive amount of proteins, a low quantity of carbohydrates, and a high amount of lipids. That pattern can contribute to the development of overweight and obesity, and to the increase of cardiovascular risk in women in the selected group of age.

Key words: energy, proteins, carbohydrates, lipids, women, health.

PO702

MEDIA INFLUENCE OF TELEVISION IN NUTRITIONAL STATUS OF PRESCHOOL

E L. Bagatini Saud Ferro¹, D. Fernandes Boraschi¹, M. Luca Coral¹, D. Elias Goulart de Andrade Miranda¹

¹Curso de nutrição, da Universidade de Franca, Franca, São Paulo, Brasil

Background and objectives: The diversity of industrialized food advertised by television media can influence children's eating habits standards, once the first years of life of a child are claimed to be the phase when the eating habits are established. The excessive and regular consume of these kind of food may harm children's health throughout adulthood. Most industrialized foods are rich in fats and refined carbohydrates, presenting a high energy power what may decrease the consumption of healthy food. The aim of this paper is to identify the television media influence on the nutritional preschool condition, aged between 3 and 5 years of a private institution and to relate the results with the consumptions of candies.

Methods: It was applied a survey about children's eating habits and preferences to the parents. By calculating the BMI/age it was measured the nutritional condition of each child. The data obtained from anthropometric measurements were related to the results of the survey about children's eating habits applied.

Results: It was verified that 81.8% of preschoolers were eutrophic, 15.2% were overweight and 3% were thin. These children had tried candies for the first time when they were between 1 and 3 years old, 88% used to go to the supermarket with their parents and participated in the food buying selection. The first contact with the TV had occurred between the ages of 1 year and 5 months with a daily routine of 1 to 2 hours in front of TV for 79% children and 51% used to have at least one meal in front of TV.

Conclusions: It is believed that the media advertisements are essential elements to encouragement of unhealthy foods consumption and as an intervention for obesity prevention strategy.

Key words: television, preschool, nutritional condition.

PO703**A QUALITATIVE STUDY EXPLORING PARENTS' VIEWS AND PERCEPTIONS OF OVERWEIGHT AND OBESITY IN PRE-SCHOOL CHILDREN IN SCOTLAND**

F. Douglas¹, J. Clark^{2,3}, L. Craig¹, A. Gilmartin³, C. Commerford², G. McNeill³

¹Public Health Nutrition Research Group, Rowett Institute of Health And Nutrition, University of Aberdeen, Aberdeen, Scotland

²NHS Grampian, Aberdeen, Scotland

³University of Aberdeen, Aberdeen, Scotland

Background and objectives: The UK Child Health Surveillance Programme (CHSP) reported that 8.6% of children born in 2001 were obese (BMI \geq 95th centile of the UK 1990 reference data) at 3.5 years of age compared to 7.9% of those born in 1995. There is growing policy maker and health professional interest in preschool weight management interventions to halt or reverse this trend. However, little is known about how UK parents view this issue, and the extent to which they believe it is a problem requiring intervention. This paper presents the results of research which explored these issues with 34 parents in the north-east of Scotland.

Methods: Parents were recruited by invitation through preschool nurseries. Nine focus groups were held with mothers of preschool children. Focus groups lasted between 45-90 mins, were audio-recorded, transcribed verbatim and analysed thematically.

Results: The majority of study participants were native English speakers from higher SES backgrounds. The main emergent themes were: 1. Concern about classifying pre-school children as overweight or obese 2. Parents using a wide range of different information sources to judge their child's weight status 3. Scepticism about current reference standards and use of BMI scores for children 4. Confusion regarding weaning practice and portion size, and lack of faith in health professionals' advice about these issues 5. Home cooking being synonymous with healthy eating 6. Competing family perspectives regarding foods and portion sizes for children.

Conclusions: This research indicates significant challenges exist for health professionals in engaging parents in preschool weight management interventions in Scotland. However, many parents are struggling with 'getting the balance right' related to when and how to wean young children and instil good eating habits in a world they perceive as full of food temptation and contradictory advice.

Key words: pre-school children, overweight, weight management, parents' views, qualitative research

PO704**SOCIOECONOMIC INEQUALITY IN DIETARY DIVERSITY SCORE AMONG SCHOOL CHILDREN IN A REGION OF SOUTHWESTERN, NIGERIA**

M. Olumakaiye¹

¹Department of Family, Nutrition and Consumer Sciences, Obafemi Awolowo University, Ile Ife, Nigeria

Background and objectives: Dietary diversity has long been recognized as key element of high quality diets. This study aimed to assess socioeconomic variables and the relationship with dietary diversity of school children in a region of southwestern, Nigeria.

Methods: This is a cross-sectional study of 600 school children attending both private and public schools. A standardized FAO-published 24-hour diet recall questionnaire for calculating a dietary diversity score (DDS) was adapted, tested, and used to collect dietary diversity data. A structured interview scheduled was also used to elicit information on availability of household assets which was used as a proxy for wealth status used as socioeconomic indicator. Respondents were classified according to level of dietary diversity and wealth status as low, moderate and high. Logistic regression analysis was used to assess the relationship between dietary diversity and wealth status. Data were disaggregated according to type of school attended by the school children.

Results: Mean age and household size of the respondents was 8.28 \pm 1.44 and 6.43 \pm 2.26 respectively; both higher in public than private schools. For the wealth status (39.3%) and DDS (30.0%) of private school children were categorized as high compared to 32.0% and 18.3% in public school respectively. DDS was more related to higher socioeconomic status in private school children. High (OR=1.05, CI=0.51-2.18) and moderate (OR = 1.25, CI = 0.05-3.16) wealth categories in private school children had an increased DDS compared with the low wealth status group. While among the public school children, only high wealth status group had a likelihood of increased DDS (OR=1.84, CI=0.37-2.10).

Conclusions: Wealth related inequalities existed for children from both school types. Socioeconomic inequalities determined the dietary diversity score of school children in the region of southwestern Nigeria.

Key words: dietary diversity, wealth status, school children, Nigeria.

PO705**NUTRITIONAL STATUS OF 3-9 YEAR OLD CHILDREN IN THE ISLAND OF BORNHOLM: BASELINE ANTHROPOMETRIC DATA FROM PROJECT SOL-BORNHOLM**

T. Buch-Andersen¹, S. Carlsen¹, H. Reinbach¹, B. Mikkelsen¹, F J A. Perez-Cueto¹

¹Research Group For Meal Science And Public Health Nutrition, Department of Planning, Aalborg University, Copenhagen SV, Denmark

Background and objectives: Since 1947 the prevalence of overweight and obesity in Denmark has increased markedly. The Danish Island Bornholm has an above average prevalence of overweight among adults, but data on children are scarce. The objective of the present study was to determine the prevalence of overweight and obesity of 3-9 y old children from the Regional Municipality of Bornholm.

Methods: The study was based on baseline data collected in the period of September to October 2012 as a part of the multi-setting, multi-component community intervention "Health and local communities" (SoL-Bornholm). Heights and weights of children from day care centres and primary schools from the three participating communities were measured barefooted and in light clothing by research staff. Overweight and obese children were classified using international age- and gender-specific BMI cut-off values.

Results: In total 240 children were measured (52% girls/48% boys). Fifteen percent of the children were overweight and 2% obese. The prevalence of overweight and obesity did not differ between preschool and school children and there were no significant gender differences.

Conclusions: The observed 17% prevalence of overweight or obesity in Bornholm's children is worrisome. It is nearly 10% points higher than the national prevalence in Danish preschool children. The observed prevalence of overweight preschool children makes the SoL-Bornholm intervention study very relevant and calls for effective interventions in the day care setting.

Key words: BMI, overweight, obesity, Denmark, children

PO706**SEAFOOD INTAKE AND POSTPARTUM DEPRESSION**

M K. Malde¹, M W. Markhus^{1,2}, L. Dahl¹, J. Rasinger¹, V. Moe^{3,4}, L. Smith³, H M. Meltzer⁵, L L. Spongsveen³, K M. Stormark⁶, I E. Graff¹

¹National Institute of Nutrition and Seafood Research (NIFES), Bergen, Norway

²The Department of Biomedicine, Faculty of Medicine and Dentistry, University of Bergen, Norway

³Regional Centre for Child and Adolescent Mental Health, East and South, Oslo, Norway

⁴Department of Psychology, University of Oslo, Norway

⁵Norwegian Institute of Public Health, Oslo, Norway

⁶Regional Centre for Child and Youth Mental Health and Child Welfare/Uni health/Uni Research, Bergen, Norway

Background and objectives: It is evident that fish and seafood are part of a healthy balanced diet. The general Norwegian recommendation to pregnant women is to eat fish for dinner 2-3 times a week, and at least half should be oily fish. A low seafood intake in general has been shown to be associated with higher risk of depression. National and international studies have found that about 10-15% of women suffer from depression in the postpartum period. Within a large population of Norwegian mothers and infants we investigate the seafood intake and the possible impact of seafood on postpartum depression.

Methods: The design of the study is a prospective population study with prenatal enrolment of participants from nine different sites in Norway. The seafood intake was assessed in the 32th gestational week using a validated food frequency questionnaire. The participants were screened for postpartum depression using the Edinburgh Postpartum Depression Scale (EPDS) 6 weeks after delivery.

Results: Preliminary results show that the pregnant women (n=839) ate fish for dinner 1.3±0.9 times a week and fish as spread (n=835) 1.0±1.0 times/week. Oily fish for dinner was consumed 0.6±0.6 times/week. The EPDS scores (n=679) ranged from 0 to 22 with a mean of 3.6±3.4, and 9% had a score >8. Using a logistic regression model (n=679) we found that higher oily seafood intake, including supplements, decreased the odds of becoming depressed (EPDS>8, odds: 0.90, CI:0.82-0.99, p<0.05).

Conclusions: The women had low seafood intake compared to the Norwegian recommendations. Preliminary results support that higher seafood intake may be one factor that reduce depressive symptoms.

Key words: seafood intake, oily fish, postpartum depression

PO707**DETERMINANTS OF IRON DEFICIENCY ANAEMIA AMONG IN-SCHOOL ADOLESCENT IN FEDERAL CAPITAL TERRITORY (FCT)-ABUJA***K. Kalu¹, I. Akinyele¹*¹Department of Human Nutrition, University of Ibadan, Ibadan, Oyo State, Nigeria

Background and objectives: Iron Deficiency Anaemia (IDA) is a major public health problem especially in developing countries. There is a paucity of data on anaemia in adolescents in Nigeria. The objectives of this study were to elucidate the risk factors of IDA and also determine the iron status among in-school adolescents in Federal Capital Territory (FCT)-Abuja.

Methods: The study was descriptive and cross-sectional in design. One hundred and thirty-three in school adolescents aged 10-19 years were randomly selected using a simple random method from a Government Secondary School in FCT-Abuja. A semi-structured interviewer administered questionnaire was used to elicit information on possible predisposing factors. Anthropometric measurements were obtained using recommended standard procedures. Intravenous blood samples were collected from all respondents to determine haemoglobin concentration, packed cell volume, white blood cell count, blood film test, serum ferritin levels using standard haematological and enzyme-linked immunosorbent assay procedures. IDA was assessed using serum levels and haemoglobin (Hb) levels according to World Health Organization Standards.

Results: A total of 133 respondents, 26.3% were males and 73.7% were females. Among the males, 8.6% were anaemic while 91.4% were not. All the females were none anaemic. Among all predisposing factors only gender had an association with IDA ($p < 0.05$). The mean haemoglobin level and serum levels of the blood from respondent were 13.13 ± 1.56 g/dl and 78 ± 66.01 ng/ml respectively.

Conclusions: The study revealed that there is no association between age, level of education, socioeconomic status of caregiver, dietary intake and the prevalence of IDA among in-school adolescent. However, contrary to the general opinion and other research outcomes the male gender seems to be at risk in the study population, hence recommendation is necessary for the study to be further replicated with a larger sample size.

Key words: haemoglobin, iron deficiency anaemia, adolescent

PO708**PROBING THE HEMOGRAM: HEMATOLOGICAL MEASURES AND INDICES ACROSS A SAMPLE OF GUATEMALAN HIGHLAND PRESCHOOL CHILDREN ATTENDING THREE GOVERNMENT-SPONSORED DAYCARE CENTERS***M J. Soto-Méndez¹, N W. Solomons¹, K. Schümann², A. Gil³*¹Center For Studies of Sensory Impairment, Aging And Metabolism -CESSIAM-, Guatemala²Molecular Nutrition Unit, ZIEL, Research Center for Nutrition and Food Science, Technische Universität München, Germany³Department of Biochemistry and Molecular Biology II, Universidad de Granada, Spain

Background and objectives: Nutritional factors affect the bone marrow. Various micronutrient deficiencies cause anemia, but also by infectious diseases and other conditions. Without the luxury of ancillary biomarkers, diagnostic classification is limited. We sought here to explore the entire battery of information in the automated hemogram as a source of assessment insights.

Methods: Hemograms were obtained from Beckman Coulter AcT Diff Haematology Analyzer (Krefeld, Germany) analysis in 82 preschoolers attending three day-care centers in the Western Highlands region of Quetzaltenango. Information on norms for measurements, cell-counts and red cell indices (mean corpuscular volume {MCV}, mean corpuscular hemoglobin concentration {MCHC}), red cell distribution width {RDW}) were taken from the hemogram references; in the case of hemoglobin (Hb) and hematocrit (Hct), the anemia-criteria were adjusted for the 2333 m altitude above sea-level.

Results: Mean Hb was 13.1 ± 1.9 g/dl. Mean Hct was $39 \pm 3\%$. The average total red cell count was 4.84 ± 0.94 $10^6/\text{mm}^3$; 22% were erythropenic at < 4.50 $10^6/\text{mm}^3$, unadjusted for altitude. The mean white cell count was 7866 ± 2541 ; 1% were leukopenic with $< 4500/\text{mm}^3$ and 9% leukocytotic at $< 10,800/\text{mm}^3$. Average platelet count was $314,730 \pm 76,020/\text{mm}^3$, with 1% thrombocytopenic at $< 150,000/\text{mm}^3$. Specifically, with respect to anemia, 13% did not meet the age-altitude-adjusted criteria for Hb and 4% did not meet the comparable criterion for Hct. MCV values outside of the (80-100 fl) range classified rbc as microcytic in 17% and as macrocytic in 0%. MCHC values < 32 g/dl classified hypochromia in 5%. With respect to the RDW normal range of 11.5-15%, 2% had high and 0% low values.

Conclusions: In the context of potential multiple micronutrient deficiencies and interactions -- but when nutrient-status and inflammatory indicators are unavailable -- the full spectrum of data from automated hemograms may provide additional nutritional insights. Financing: Hildegard Grunow Foundation, Munich, Germany

Key words: anemia, haematology, Guatemala

PO709**NUTRITION AND HEALTH QUALITY IN ELDERLY LIVING IN ANKARA, TURKEY***E. Aksoydan¹, A. Akbal²*¹Baskent University, Department of Nutrition and Dietetics, Ankara, Turkey²Baskent University Ankara Hospital, Yapracyk Geriatri Center, Ankara, Turkey

Background and objectives: The study was conducted to determine nutrition, health status and quality of life levels of elderly people those who living in Ankara, Turkey.

Methods: The study sample consists of 150 voluntary participant who were membership of Family Life Center of Municipality of Ankara. Socio-demographic, life styles, nutritional behavior and health status data was collected with a questionnaire by face to face interview. Anthropometric measurements were done by researchers. Food consumption was measured by the 24 hour dietary recall methods. Quality of life of the participants was measured with EUROHIS-QOL 8-item index.

Results: The mean age of the participants was 67.7±6.77 years, 56% of the participants were male, 81% were married, and 54% had high school or university degree. The mean BMI was 27.9 kg/m². Forty two percent of participants were normal, 56% were overweight and obese. Sixty three percent of elderly have at least one chronic disease. The most common chronic diseases were hypertension (30.8%), cardio-vascular diseases (14.3%) and diabetes (13.2%) respectively. Energy consumption was below the recommended level in male. In both gender, while the percentage of energy from carbohydrates was low, protein consumption was recommended level. Vitamin E, folate, potassium and calcium consumption were low in both genders. Sodium consumption was far above to both genders. According to the EUROHIS-QOL 8-item index) the quality of life total score mean was 3.7±0.64. Males had significantly higher QOL scores than females in all domains. While the highest score was "relationship with other persons" (4.0±0.85), the lowest score was having "enough money to meet the needs" (3.4±0.73).

Conclusions: It is necessary to develop interventions targeted together nutrition and healthy life styles to promote health and life quality.

Key words: elderly, nutrition, quality of life, nutrient

PO710**NUTRITIONAL GUIDANCE: PREVENTING MALNUTRITION WITH FOOD INSTEAD OF SUPPLEMENTS FOR ELDERLY IN NURSING HOMES***V. Guttormsen¹, T. Nævisdal², V. Langemyr²*¹Department of Public Health, Sport and Nutrition, University of Agder, Norway²Arendal municipality, Norway

Background and objectives: Malnutrition is common amongst the elderly in nursing homes. They often neglect to regularly eat a nutritionally balanced diet throughout the day. Health care workers, working closely with this population, have often expressed a desire for more comprehensive training in the field of general geriatric nutrition instead of giving them supplements. Studies show that the characteristics of the food served is the main reason for lack of appetite and failure to eat properly. Then, as a result the patient may suffer from poor nutrition. The objective of this study is to create a guide on general nutrition for use in geriatric health care. This guide is going to emphasize the importance of eating together, to reduce the feeling of loneliness. Further, the guide will express the joy of eating for better health and how to make fun, good tasting, visually appealing and nutritionally balanced recipes that will inspire patients to want to eat more.

Methods: Development of a practical competence- guide for health care workers, which will increase their awareness of by using food as a alternative method to prevent malnutrition in nursing homes. The guide contains three parts: general nutrition, recipes adapted for individual nutritional needs, and a simple practical nutrition journal.

Results: A practical guide of 80 pages with information on general nutrition and adjusted recipes are presently produced. All workers in nursing homes in Arendal municipality in the South of Norway, will receive this guidance in effort to raise the competency of nutrition for the elderly.

Conclusions: This guide will attempt to educate the health care workers in nursing homes on how to encourage healthy eating for their patients instead of giving energy supplements and drinks typically utilized to prevent geriatric malnutrition.

Key words: Competence, Healthy eating, Elderly, Malnutrition.

PO711**ANTHROPOMETRY, BODY COMPOSITION AND FUNCTIONALITY OF NUTRITIONALLY AT RISK INSTITUTIONALIZED ELDERLY***A. Chandrasekara¹, T. Anuradha¹*¹Department of Applied Nutrition, Wayamba University of Sri Lanka, Makandura, Gonawila, Sri Lanka

Background and objectives: In under nutrition, body dimensions and body composition of elderly change affecting their functionality. The objective of the present study was to assess the body composition and its effect on the functionality of apparently healthy institutionalized elderly.

Methods: A cross sectional study was conducted using 130 elderly individuals with mean age of 75.6±7.9 y. Weight, height, demispans, mid-upper arm circumference, calf circumference, and skin fold thickness of biceps, triceps, subscapular and suprailiac were measured. Body composition was calculated using skin fold thickness (SFT) and bioelectrical impedance analysis (BIA). Functionality of elderly was determined using activities of daily living (ADL) score and time to get up and go test (TGAGT).

Results: Of total, 44% were undernourished with BMI of less than 17.5 Kg/m². Except for height, normal individuals showed higher values for all anthropometric measurements compared to those of undernourished. The fat content of normal and undernourished individuals obtained using SFT were 27.4 and 20.0%, respectively. Significant associations were reported between body composition and ADL score. Normal elderly individuals showed a positive association between fat mass index as determined by BIA and ADL score. There were no significant differences in functionality between undernourished and normal institutionalized elderly individuals.

Conclusions: Undernourished showed lower body lean mass and fat mass than those of normal elderly individuals. In addition, undernourished elderly individuals showed higher chances of having low values for indicators that represent the poor body lean status than those of normal. However, effect of favourable body composition on their functionality was not observed in the present study. Future studies are warranted with more number of participants and other methods to assess functionality.

Key words: Body composition, functionality, institutionalized, Sri Lanka

PO712**EATING HABITS AND HEALTH STATUS OF YOUNG AUSTRIAN MEN AGED 17 TO 20 YEARS IN CONTEXT TO THEIR LIFESTYLES***G. Leitner¹, P. Rust¹, I. Elmadfa¹*¹University of Vienna, Department of Nutritional Sciences, Vienna, Austria

Background and objectives: Most studies about men's health focus on adults aged 50 years and older. But it is largely unknown whether and to what extent health behaviour in young men represents risk factors for the incidence of lifestyle-related diseases in later life.

Methods: Within this cross-sectional study 1369 young men in lower Austria aged 17 to 20 years were anthropometrically investigated and interviewed about their lifestyle (nutrition, health-related behaviour and physical activity) at their investigation on the suitability of the Austrian Armed Forces. The health status was determined on the basis of biochemical parameters and compared with those of ten years ago.

Results: Anthropometric data (body weight and height, waist circumference) and health-relevant characteristics (nutritional habits, physical activity, alcohol consumption and smoking habits) as well as the frequency of cardiovascular risk factors except blood lipid and glucose levels show a clear increase in unhealthy attributes in the period of 10 years among those young men. 29 percent of 17-20 year old men are overweight, 46 percent are smokers, 80 percent consume alcohol and around one third do not participate in sport.

Conclusions: The health-detrimental tendencies increased in the last ten years considerably in the target group of young men. Efficient prevention campaigns are urgently necessary to promote and continually support a health-conscious life-style in young health.

Key words: young men, nutrition, health behaviour, physical activity, life style

PO713**KNOWLEDGE AND PREVALENCE RISKS OF MATERNAL AND CHILD HEALTH FACTORS AMONGST WOMEN ATTENDING RANGO HEALTH CENTER**

⁵Laboratoire d'analyse des délais alimentaires et des médicaments, national university of Rwanda, Rwanda

⁶HIV treatment and care, international network on pharmacy and HIV, Austria

⁷Nutrition department, rango health center, Rwanda

Background and objectives: A woman is a heart of family as a traditional belief of Rwandans that woman in a family have to take care to children related issues. Inadequate nutrition amongst breastfeeding women also contributes to a higher than average rate of babies who develop under nutrition among Rural Rwandan children. 52% of children under the age of five are stunted, 16% are underweight, and 5% are wasted, 6% of infants are born with a low birth weight in Rwanda. The objective of the research was to examine knowledge of risk factors and dangerous behaviors on maternal and child nutrition among rural women in Rwanda.

Methods: We conducted a cross-sectional survey at Rango Health center/Rwanda. Interviews were conducted using a cross-ended questionnaire on 180 women attending different health services for themselves or their children at Rango health center between February 2012 and September 2012. The survey examined the knowledge for received and gained skills on maternal and child health while they were pregnant and immediately after pregnancy to monitor the life of mothers and child nutrition and alcohol consumption, prioritizing prenatal care and contraception use.

Results: Overall, 78.1% of the women interviewed received prenatal care at the Rango Health Center; 46.3% drank alcohol while pregnant, 58.6% ate only starches and vegetables while pregnant, 47.7% received education about proper nutrition practices while pregnant, 60.8% received advices on family planning and PMTCT and finally 48.3% were using contraception at the time of survey.

Conclusions: Women attending Rango health center had a high prevalence of behaviors risks for maternal health care. Maternal and child Health education should be strengthened at all levels of the health system: at the health centers by health professionals, at village level by community health workers, NGOs and associations by emphasizing on empowering women.

Key words: women, rural, child, maternal, healthcenter

PO714**VALIDATION OF CALF CIRCUMFERENCE AS A PROXY FOR BMI IN THE SHORT-FORM MINI NUTRITIONAL ASSESSMENT IN CHILEAN OLDER PEOPLE**

L. Lera¹, C. Albala¹, H. Sánchez¹, A. Fuentes-García, B. Ángel¹

¹Unit of Nutrition, Public Health and Healthy Aging, Institute of Nutrition and Food Technology, University of Chile, Santiago, Chile

²School of Public Health, Faculty of Medicine, University of Chile, Santiago, Chile

Background and objectives: The Mini Nutritional Assessment (MNA) is a widely used tool for assessing nutritional risk and malnutrition in older adults. A short version suitable for large population studies has been proposed in 2 versions, replacing in one of them the Body Mass Index (BMI) cut points by calf circumference when BMI is not available. Our aim is to validate the two versions of short-form of MNA (MNA-SF) in Chilean older adults.

Methods: Cross-sectional study in 1137 community-dwelling subjects (age range: 60-99 years), participating in the Alexandros study. All participants completed a survey measuring socio-demographic, health, nutritional, MNA and anthropometry. The MNA includes 18 questions covering anthropometry, global assessment, dietary parameters and subjective evaluation. MNA-SF includes 6 items and has two versions: one using BMI as anthropometric variable (MNA-SF1) and other using the calf circumference instead of BMI (MNA-SF2). Diagnostic tests were used to validate the MNA-SF score against MNA score. ROC curves (Receiver Operating Characteristic) were performed to validate calf circumference using BMI < 19 as gold standard.

Results: The 31 cm cutoff for calf circumference showed high sensibility (90.9%), high specificity (80.8%) and high values for the area under the ROC curve (0.92; 95%CI: 0.84-0.99) when plotted for BMI < 19. Both the MNA-SF1 and MNA-SF2 demonstrated high sensibility and specificity with respect to MNA, although overestimate malnutrition (5.2% and 6.6% vs 2.0%) and underestimate the risk of malnutrition (19.1% and

18.1% vs 20.6%). Nevertheless both forms estimate correctly the proportion of normal people (75.7% and 75.3% vs 77.4%).

Conclusions: The MNA-SF is a screening tool simple, valid and quick to apply, very useful for population based studies, which demonstrated good accuracy to identify the group of older adults without malnutrition neither risk of malnutrition.

Key words: anthropometry, Mini Nutritional Assessment (MNA), older people. Funded by Fondecyt 1080589

PO715

SODIUM CONTENT IN BABYFOODS USED ON INFANT FEEDING DURING THE FIRST YEAR OF LIFE

R. Moreira¹, D. Silva², P. Moreira³, P. Padrão⁴

¹Faculty of Nutrition And Food Sciences, University of Porto, Porto, Portugal

²Centro Hospitalar São João, EPE, Porto, Portugal

³Research Centre in Physical Activity, Health and Leisure, Faculty of Sport, University of Porto, Porto, Portugal

⁴Institute of Public Health University of Porto, Porto, Portugal

Background and objectives: Eating habits are crucial determinants of health status of an individual, especially during childhood, as a nutritionally balanced diet will determine the state of health in adulthood. Excessive intake of salt is a risk factor for several diseases and the addition of salt to culinary preparations is not recommended during the first year of life. Most of the sodium comes from salt added to processed foods, part of the usual diet of children. This study aimed to estimate the concentration of sodium in babyfoods meals for babies with less than 12 months, from a major commercial brand available both in Brazil and Portugal, and to compare the results with reference values.

Methods: It was analyzed the amount of sodium present on the babyfoods' labels and it was used the values of minimum, maximum and median for the concentration of sodium and the proportion of compliance with Adequate Intakes (AI) of this nutrient. It was used the Mann-Whitney test with a significance of 5% of the sodium concentration across countries.

Results: Only in Portugal were found babyfoods meals without added salt. As for babyfoods meals with added salt, in Brazil the median of sodium concentration is higher than in Portugal (83.0 mg/100g vs 52.8 mg/100g, $p < 0.001$).

Conclusions: Nowadays children often eat babyfoods meals. Though in Portugal there are already some options without added salt, the majority of babyfoods are an huge source of salt and daily sodium intake can easily exceed the reference values, both in Portugal and Brazil. This reinforces the need to ensure no addition of salt to these preparations. Awareness

of industry, community and caregivers is crucial to reduce the added sodium on foods and to prevent the occurrence of diseases resulting from excessive intake of salt.

Key words: salt, sodium, babyfoods, infancy

PO716

SERUM VITAMIN CONCENTRATIONS AND DIETARY SUPPLEMENT USE AMONG PREGNANT U.S. WOMEN: DATA FROM THE NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEY, 2003–2006.

E. O'Sullivan¹, K.M. Rasmussen¹, S. Mehta¹

¹Division of Nutritional Sciences, Cornell University, Ithaca, New York, USA

Background and objectives: Contemporary data providing blood vitamin profiles of pregnant women are limited. The goal of this research was to describe the vitamin status and supplement use of adult pregnant women compared to non-pregnant women in the National Health and Nutrition Examination Survey (NHANES), 2003–2006.

Methods: Data were obtained from the NHANES, a complex, multi-stage, probability sample of the civilian, non-institutionalized U.S. population. A propensity score model was developed using logistic regression, with pregnancy status as the dependent variable and age, marital status, household income and body mass index as the independent variables. Each pregnant woman was matched by propensity score with three non-pregnant women, and serum vitamin concentrations were compared using generalized linear models. Odds ratios for vitamin insufficiency, defined using CDC cut-offs for the general population, comparing pregnant and non-pregnant women were computed using logistic regression.

Results: Dietary supplement use was significantly higher in the 576 pregnant than the 1728 non-pregnant women (80% vs 37%, respectively). Pregnant women had significantly higher mean blood concentrations of vitamins B6 (50.3 nmol/L vs 48.7 nmol/L), C (61.7 μ mol/L vs 54.4 μ mol/L), D (27 ng/mL vs 21 ng/mL), and folate (842.5 nmol/L vs 575.3 nmol/L), but lower concentrations of vitamin A (1.42 μ mol/L vs 1.74 μ mol/L), than non-pregnant women. Compared to non-Hispanic White pregnant women, pregnant women of other ethnicities had lower mean serum vitamin A, D and E concentrations and significantly increased odds of vitamin D insufficiency.

Conclusions: In this nationally representative sample, pregnant women had higher serum concentrations of several vitamins than non-pregnant women. Of public health concern are the lower vitamin concentrations and increased risk of vitamin D insufficiency in non-White women. This may be explained

ned, at least in part, by differential dietary supplement use by ethnicity during pregnancy.

Key words: pregnancy, vitamins, dietary supplements, surveys

PO717

IMPROVING COMPLEMENTARY FEEDING PRACTICES THROUGH THE ESSENTIAL NUTRITION ACTIONS (ENA) FRAMEWORK IN SOUTHERN ETHIOPIA

A. Guyon¹, M. Mehdin², A. Jirga²

¹John Snow Inc.(JSI), Arlington, USA

²John Snow Inc.(JSI), Ethiopia

Background and objectives: The USAID funded Essential Services for Health in Ethiopia (ESHE) project had the goal to reduce under-five mortality and morbidity by implementing an integrated approach within the Ethiopian government health structures, with nutrition as one component. The population covered was about 6 million. At the start of the project, challenges included the assumption that malnutrition was due only to lack of foods.

Methods: The Essential Nutrition Actions (ENA) framework was applied to provide improved nutrition support through advocacy, capacity building, interpersonal communication, and community mobilization. Emphasis is given to the programmatic integration of these nutrition actions to be taken at key contact points in the life cycle, so that they do not operate in isolation from one another and from other child survival programs.

Results: Key inputs were advocacy, partnerships, capacity building of more than 1600 health providers and 20,000 community volunteers, and behavior change with action-oriented messages based on formative research and supported by simple tools. Changes in practices were assessed through a comparison from representative cross-sectional household surveys in 2003 (1789) and in 2006 (1200). Results show that infant and young child feeding and ENA indicators, were significantly improved when compared to baseline figures (as example, 53% of children were eating 3 or more types of foods compared to 33%). The Minimal Acceptable Diet (MAD) could only be assessed by comparing project and non-project areas, respectively 24% and 12%, with 25% consuming animal source foods compared to 8%.

Conclusions: The lessons learned included that the community component with a large number of actors and contacts is critical for success; infant and young child feeding can be improved at scale using the multiple contacts and platforms.

PO718

FOOD INTAKE IN CUBAN CHILDREN ACCORDING TO BODY MASS INDEX

A. Cabrera¹, I. Puente¹, C. Viera², M E. Díaz¹, M. Hernández², V. Ruiz²

¹Department of Community Nutrition, Institute of Nutrition and Food Hygiene, Havana, Cuba

²Department of Biochemistry and Physiology, Institute of Nutrition and Food Hygiene, Havana, Cuba

Background and objectives: High food intake is associated to overweight. The aim of this study was to identify those associations in Cuban scholars.

Methods: The study included 51 overweight and 51 normal children, paired by age, sex, and socioeconomic status. Height and weight were measured and BMI was calculated. Nutrients and food portions intake were estimated using a semiquantitative food frequency questionnaire. Foods were aggregated into 7 groups according to Cuban Food Guide. Statistic analysis was carried out using Mann-Whitney test and Pearson correlation test.

Results: The average age was 8±1.0 years. Overweight children showed a higher energy, protein, fat and carbohydrates intake. Energy (p=0.04), carbohydrates (p=0.035), polysaccharides (p=0.003), vitamin A (p=0.0037), sodium (p=0.013), sausages (p=0.006), refined wheat flour (p=0.008), canned fruits (p=0.02) and cereals and tubers food group portions consumption was higher in overweight children. High associations were found between BMI and a high consumption of sausages (p=0.015), rice (p=0.002) and wheat flour (p=0.004).

Conclusions: Food, energy and nutrients intake was higher in overweight children; mainly based on cereals, tubers and refined wheat flour intake.

Key words: children, food intake, overweight.

PO719**MEASURING OF RESTING ENERGY EXPENDITURE IN YOUNG JAPANESE CHILDREN***K. Omori¹, K. Kaneko²*

¹Faculty of Education, Art and Science, Yamagata University, Yamagata-city, Yamagata prefecture, Japan

²College of Education and Human Sciences, Yokohama National University, Yokohama-city, Kanagawa prefecture, Japan

Background and objectives: The accurate assessment of resting energy expenditure is significant when estimating energy requirements. Currently there are very few reports about resting energy expenditure in young Japanese children. We designed a hood method which does not require a mask, and measured resting energy expenditure in Japanese children to collect data, as well as to develop a practical measuring method.

Methods: The subjects were five children aged from 2 to 7 years old. The subjects ate nothing after supper on the day before the experiment. In the morning, the subjects were kept at rest, lying down with a transparent plastic hood covering the head, which was connected to a portable gas monitor (AR-1, Arcosystem Inc., Japan). We also measured energy expenditure in a 1 month-old infant with this method. Energy expenditure was calculated from oxygen consumption and carbon dioxide production, which were sampled at 1 minute intervals for about 20 minutes.

Results: Our measurements taken every three months for more than 2 years revealed that the average resting energy expenditure per weight (kcal/kg/day) was 68.0 (2 year-old boy) and 46.9 (7 year-old boy). It was observed that the values decreased as the subjects age increased. The measured values tended to be higher than the reference values of basal energy expenditure in the Dietary Reference Intakes for Japanese, 2010.

Conclusions: We could confirm the developmental changes of resting energy expenditure in young children. The subjects could maintain a stable condition with little stress, and this hood method would be useful also for elderly or disabled subjects. Further measurements will reveal individual differences of children's resting energy expenditure by gender and race. This project was supported by Grants-in-Aid for Scientific Research of Japan Society for the Promotion of Science.

Key words: resting energy expenditure, young children, the hood method

PO720**METABOLIC SYNDROME PREVALENCE IN CHILEAN CHILDREN ACCORDING TO THREE DIFFERENT CRITERIA AND ITS AGREEMENT WITH INSULIN RESISTANCE***S. Barja¹, P. Arnaiz¹, M A. Domínguez², L. Villarroel², O. Castillo³, M. Farías⁴, F. Mardones²*

¹Division of Pediatrics, Faculty of Medicine, Pontificia Universidad Católica de Chile, Santiago de Chile, Chile

²Division of Public Health, Faculty of Medicine, Pontificia Universidad Católica de Chile, Santiago de Chile, Chile

³Department of Nutrition and Diabetes, Faculty of Medicine, Pontificia Universidad Católica de Chile, Santiago de Chile, Chile

⁴Department of Obstetrics and Gynecology, Faculty of Medicine, Pontificia Universidad Católica de Chile, Santiago de Chile, Chile

Background and objectives: There is not a consensus in Metabolic Syndrome (MS) definition for children and adolescents, although its prevalence is increasing. The aim of the present study was to compare the prevalence of MS according to three diagnostic criteria for children and adolescents and to study the agreement with insulin resistance (IR).

Methods: Cross-sectional study (2009-2011) of 3325 students, 10-15 years old, from schools in Puente Alto County, Santiago, Chile. Anthropometry was performed, measuring blood pressure (BP) and in a fast blood sample: glycemia, insulin, blood lipids. We calculated HOMA-IR (Homeostasis Model Assessment index); values >90th percentile of a normal sub-sample were considered as IR. We compared three criteria of MS: International Diabetes Federation (IDF), Cook S. and De Ferranti S. They define different cut-offs for the five components of MS (waist circumference, triglycerides, HDL-Cholesterol, blood pressure and glycemia) having abnormal at least three of them.

Results: Prevalence of MS was 3.82% for IDF, 7.25% for Cook and 20.48% for de Ferranti criterion (Cochran Q-test, $p < 0.001$). In total 859 subjects were IR (25.8%). 73.2% and 69.7% of the children diagnosed with MS according the first two criteria had IR in but only 52.7% according to the third one (Predictive Positive Values: PPV). To predict IR, each criterion had ROC-AUC of 0.60, 0.62 and 0.67 respectively (adjusted for sex and puberty). IR predicted the presence of MS according the different criteria with PPV of 10.8%, 19.6% and 41.8% and ROC-AUC for HOMA-IR was: 0.84, 0.82 and 0.76 respectively (adjusted for sex and puberty).

Conclusions: Prevalence of MS varies significantly according to different criteria. IDF and Cook's criteria are similar predictors for IR (even the former has higher cutoffs for MS

components), better than de Ferranti's. HOMA-IR was a good predictor of the three MS criteria.

Key words: metabolic syndrome, children, insulin resistance

PO721

EXPLORING THE ASSOCIATION BETWEEN OBESITY AND DEMENTIA.

C. Albala¹, H. Sanchez¹, L. Lera¹, B. Angel¹, X. Cea¹

¹INTA, Universidad de Chile, Chile

Background and objectives: Recent studies have shown that obesity, besides its well known association with excess of mortality and chronic diseases, increases the risk of dementia. The objective of this study is to explore the risk of dementia associated with obesity in community-living Chilean older people.

Methods: Longitudinal study based in the follow up of the participants of the youngest cohort of ALEXANDROS, designed to study disability associated with obesity in Chilean older people. In 2007/2008 home interviews including history of chronic diseases, self-reported disability/functional limitations, screening test for dementia, physical performance, anthropometry, dynamometry and blood pressure were done in 937 people free of dementia, born between 1940 and 1948. In 2010/2011 available participants were 768 (69.8% women), 22 were died and 147 were lost to follow up (15.7%). Dementia was defined with a test validated for Chile consisting in MMSE score <22 and a score >5 in the Pfeiffer activities questionnaire.

Results: At baseline 36.2% of the participants had IMC >30Kg/m² (25.1% of men and 40.9% of women). The 4 y cumulative incidence of dementia was 10.3% (n=79), higher in women than in men (11.9% vs 6.5%, p=0.023). Obesity at baseline was associated with the incidence of dementia 4 y later (8.3% in non obese vs 14.0% in obese, p<0.014). After logistic regression analysis the adjusted RR of having dementia was higher in the obese than in the non-obese (RR=1.71; 95%CI 1.06-2.76, p<0.028) and increased with age (RR=1.15; 95%CI 1.04-1.28; p=0.0099) but not with gender neither diabetes nor hypertension.

Conclusions: The results allow for considering obesity as an independent risk factor for dementia. Further studies are needed to clarify the mechanisms involved.

Key words: obesity, dementia, ageing Funded by Fondecyt grants 1080589 and 1130947

PO722

FACTORS ASSOCIATED WITH CONSUMPTION OF NUTRITIONAL SUPPLEMENTS FOR PRACTITIONERS OF PHYSICAL EXERCISE IN SÃO LUIS-MA

H J F. Veloso¹, Francisca M M L. Alves¹, N A L. Cabral¹, E V. Hortegal¹

¹UniCEUMA, Sao Louis, Brazil

Background and objectives: The sports nutrition seeks to establish dietary strategies capable of improving the performance and ergogenesis. This study aimed to analyze the factors associated with the consumption of nutritional supplements by frequenting gyms in São Luís, Northeast of Brazil.

Methods: A convenience sample was defined by considering the number of academies operating in São Luís. The dependent variable was the use of supplements and the explanatory variables were time practicing the activity, schooling, weekly attendance at the academy, sex, age, self-perception of weight, smoking, goal of physical exercise, training duration, self-awareness training, self-perception of power. The association of variables were analyzed using Poisson regression, adopting a significance level of 0.05.

Results: The final sample consisted of 723 practitioners of exercise, of which 64.7% reported using some type of supplement. The majority of the sample consisted of men (47.4%). The age group 20 to 39 years was more frequent (74.4%). The professions with higher representation were 51% and 41.1% had undergraduate, 24.1% graduate, 30% had completed high school and 2.8% primary school. The smoke was observed in 3.5% of participants. Most respondents (46.1%) were physically active for over a year. Consider your own below the ideal weight (p<0.001), smoking (p<0.001), practicing physical activity 7-12 months (p=0.028) or for more than 1 year (p<0.001), practice activity physics for more than two hours (p=0.053) and consider your own training moderate (p=0.024) were associated with intense or consumption of supplements.

Conclusions: The socioeconomic, demographic and own power do not interfere in the decision regarding the consumption of supplements that are strongly associated with the characteristics of the training and dissatisfaction with body weight.

Key words: nutritional supplement, physical exercise, Poisson regression

PO723**A SYSTEMATIC REVIEW AND META-ANALYSIS OF DIETARY INTERVENTION DURING PREGNANCY ON MATERNAL HYPERTENSIVE DISORDERS AND PRETERM DELIVERY***E. Gresham¹, A. Bisquera², A. Hure¹, J. Byles¹*

¹Research Centre For Gender Health And Ageing, University of Newcastle, Newcastle, New South Wales, Australia

²Clinical Research Design IT and Statistical Support Unit, University of Newcastle, Newcastle, New South Wales, Australia

Background and objectives: Healthy eating behaviours during pregnancy have been associated with a reduction in complications for the mother and child. Hypertensive disorders are a major cause of maternal and perinatal mortality worldwide; whilst preterm delivery is the leading cause of neonatal death. The objective of this study was to systematically review the literature to determine whether dietary intervention during pregnancy affects maternal hypertensive disorders or preterm delivery.

Methods: Ten electronic databases were searched. Two independent reviewers assessed each article to determine eligibility. Studies of whole diet or dietary components that assessed either maternal hypertensive disorders or preterm delivery were included. Methodological quality was assessed and data were extracted, with results of eligible trials pooled. Meta-analysis was conducted separately for each outcome using a fixed effects model.

Results: Nineteen randomized controlled trials involving 5,947 participants were included in the review. Seventeen were of good methodological quality and two were of acceptable quality. Dietary interventions included individualised dietary counseling (n=11/19), food and fortified food products to complement diet (n=7/19) or a combination of both (n=1/19). Most trials (n=17/19) were conducted in high income countries. Meta-analysis showed no evidence of heterogeneity between trials or dietary interventions, and no evidence of bias for the hypertensive and preterm delivery outcomes. Meta-analysed data demonstrated no significant differences between women who received dietary intervention during pregnancy versus controls for maternal hypertensive disorders (Odds ratio 0.807, 95% confidence interval -0.597 to 1.09), however there was evidence of a decrease in the odds of preterm delivery for those who received dietary intervention (0.807, 0.651 to 1; p=0.05).

Conclusions: Dietary intervention decreases the odds of preterm delivery, but does not reduce maternal hypertensive disorders.

Key words: diet, gestation, hypertension, meta-analysis, randomized controlled trial

PO724**PRELACTEAL FEEDING PRACTICES IN VIETNAM: PROBLEMS AND DETERMINANT FACTORS***P.H. Nguyen¹, S.C. Keithly², N.T. Nguyen², T.T. Nguyen³, L.M. Tran¹, N. Hajeerbhoy³*

¹The Poverty, Health, and Nutrition Division, International Food Policy Research Institute, Hanoi, Vietnam

²Institute of Social and Medical Studies, Hanoi, Vietnam

³FHI 360, Hanoi, Vietnam

Background and objectives: Despite the importance of early and exclusive breastfeeding, prelacteal feeds continue to pose a barrier in several countries, including Vietnam. This study examined determinants of prelacteal feeding among Vietnamese mothers.

Methods: Data from 6068 mother-child (<6m) dyads were obtained from a cross-sectional survey conducted in 11 provinces in Vietnam in 2011. Multivariate logistic regression analyses were used to examine factors associated with prelacteal feeding.

Results: Three-quarters of infants (73.3%) were fed prelacteals in the first three days after birth. Of all mothers interviewed, 53.5% received formula milk and 44.1% water. The odds of feeding prelacteals declined with increases in breastfeeding knowledge, beliefs that social norms favor exclusive breastfeeding and confidence in the ability to control one's own breastfeeding behaviors. Women who harbored breastfeeding misconceptions had twice the odds of feeding any prelacteals (95% CI: 1.74–2.50). Health care factors increasing the odds of prelacteal feeding included delivery by caesarean section (OR:2.94, 95% CI:2.39–3.61) or episiotomy (OR:1.36, 95% CI:1.17–1.58) and experiencing breastfeeding problems (OR:1.31, 95% CI:1.04–1.66). Health staff support during pregnancy and after birth reduced the odds of feeding formula. However, family support after delivery increased the odds of feeding water to newborns. While the odds of feeding water was inversely related to mothers' education, the odds of feeding formula increased with education, household socioeconomic status and urban residence.

Conclusions: Feeding infants prelacteals is influenced by multiple factors. Significant reduction can be achieved by improving knowledge and confidence of mothers through appropriate counseling during pregnancy and ensuring tailored support by health care providers after birth, particularly in the case of C-sections. Ensuring that health facilities integrate these practices into routine ante-natal care and post-delivery management is critical.

Key words: prelacteal feeding, breastfeeding, behavioral determinants, Vietnam.

PO725**THE RELATIONSHIP BETWEEN MATERNAL PRE-CONCEPTIONAL ANTHROPOMETRIC MEASUREMENTS AND INFANT BIRTH WEIGHT IN VIETNAM**

P H. Nguyen^{1,2}, U. Ramakrishnan³, F. Young³, Y. Addo³, H. Nguyen², T. Truong², H. Pham², S. Nguyen², R. Martorell³

¹International Food Policy Research Institute, Hanoi, Vietnam

²Thai Nguyen University of Pharmacy and Medicine, Thai Nguyen, Vietnam

³Department of Global Health, Emory University, Atlanta, GA, USA

Background and objectives: The importance of a woman's preconceptional nutrition on infant and maternal outcomes is gaining recognition. However, major gaps remain and existing data on the impact of poor preconceptional nutrition status have methodological limitations related to data quality and study design. The objective of this study was to assess the relationship of maternal anthropometric measures obtained prior to conception with offspring birth weight.

Methods: We used data from an ongoing study (PRECONCEPT) in which women of reproductive age are being followed up prospectively for pregnancy outcomes in Thai Nguyen province, Vietnam. Anthropometric measurements (weight, height, mid-upper-arm circumference-MUAC, calf circumference, triceps and subscapular skinfold thickness) were obtained prior to conception and body mass index (BMI), mid upper arm muscle (MUMA) and fat area (MUFA) were calculated. The associations of maternal anthropometric measures with infant birth weight (n=354) were examined using multivariate regression modeling that adjusted for potential confounders (gender, gestational age, maternal age, education, socioeconomic status and household food security).

Results: Infant birth weight was positively associated with maternal preconceptional weight (beta = 11.6, p=0.003), height (beta = 13.0, p=0.002), MUAC (beta = 20.7.0, p=0.03), and MUMA (beta = 12.1, p=0.004). However, no significant associations were found for infant birth weight and BMI, calf circumference, triceps and subscapular skinfold thickness and MUFA. In addition, maternal weight gain during pregnancy predicted newborn weight (1 kg weight gain during pregnancy predicted a 22.8 g increase in newborn weight, P<0.001).

Conclusions: Maternal nutrition before pregnancy is an important modifiable risk factor that should be addressed in current efforts to improve birth outcomes.

Key words: anthropometry, birth weight, preconception, Vietnam

PO726**SELENIUM INTAKE AND STATUS OF SUBJECTS LIVING IN WELFARE FACILITY FOR THE ELDERLY**

H. Kanamitsu¹, I. Sato¹

¹Faculty of Food Culture, Kurashiki Sakuyo University, Okayama, Japan

Background and objectives: It is recognized that the nutritional status of the elderly is often poor due to their low intake of nutrients. This study was performed to evaluate the present nutritional status, that is, the daily intake of key nutrients including selenium and the serum selenium levels in nine elderly residents (aged >80 years) of a welfare facility.

Methods: Duplicate samples of diets and between meals snacks taken at the facility were collected over a 3-day period. There were no restrictions placed on the daily activities of the subjects in the facility. The energy and nutrient intakes were calculated based on standard tables of food composition in Japan. The selenium levels in both serum and diets were assessed by chemical analysis.

Results: In many subjects, intakes of calcium, magnesium, vitamin A, vitamin C and dietary fiber were lower than the RDAs for Japanese. Home residents who tend to eat less should improve their intake of some nutrients. The mean dietary selenium intake was 51 µg/day, which is higher than the RDA for Japanese. Moreover, the selenium intakes expressed in terms of 1,000 kcal energy intake and per kg body weight were also higher than the RDA for Japanese.

Conclusions: the mean levels of serum selenium were 76 fÊg/L, lower than the literature values for Japanese.

Key words: selenium, elderly, intake

PO727**IMPACT OF PRE-PREGNANCY PARENTAL OVERWEIGHT AND OBESITY ON OFFSPRING OBESITY: SYSTEMATIC ANALYSIS AND META ANALYSIS**

Z. Nurzalinda¹, A A. Mamun¹

¹School of Population Health, The University of Queensland, Brisbane, Australia

Background and objectives: The objectives of this study are to determine the prospective association of pre-pregnancy parental overweight and obesity with offspring obesity in short and long-term and also to examine whether maternal-offspring link of overweight and obesity is stronger than the paternal-offspring link.

Methods: A comprehensive literature search on online databases (PubMed, EMBASE, CINAHL, Web of Science, BioSis

and Google Scholar) was conducted. All longitudinal studies reporting on pre-pregnancy parental, paternal and/or maternal BMI and its categories with offspring obesity (infant, child, adolescent and adult) were systematically reviewed. Adult overweight and obesity were defined by using body mass index (weight (kg)/height (m)²) cut-off-points of 25 and 30, respectively; childhood overweight and obesity were defined based on the international standard cut-off of body mass index. Adjusted odds ratios (ORs) from selected studies were extracted, calculated, and a quality adjusted meta-analysis was performed.

Results: A total of 19 articles (n=70,662) were systematically reviewed from a database of 3366 independent articles. All of the articles reported significantly positive association between pre-pregnancy maternal BMI and offspring obesity and one article found no significant association between pre-pregnancy paternal BMI and offspring obesity. A total of seven publications were performed subgroup meta-analysis. Overall, mother and father who were overweight have a similar risk of having an overweight child (mother-offspring OR 2.42, 95%CI: 1.69, 3.44 and father-offspring OR 2.39, 95%CI: 1.88, 3.05). The odds of having obese children are higher for pre-pregnancy overweight mothers (OR 3.94, 95%CI: 3.15, 4.94) compared to pre-pregnancy overweight fathers (OR 2.56, 95%CI: 2.06, 3.18). The odds of being obese among older offspring are nearly twice than younger offspring. Our meta-analysis showed that pre-pregnancy parental BMI associated with offspring obesity in short and long term.

Conclusions: Findings of this study support the notion of implementing obesity intervention for offspring before their birth.

Key words: pre-pregnancy, BMI, offspring, obesity

PO728

CHILD FEEDING PRACTICES AMONG CAREGIVERS OF CHILDREN AGED 12-23 MONTHS OLD IN URBAN SETTING CENTRAL JAKARTA

*D. Fatmaningrum*¹

¹South East Asian Ministry of Education Organization Regional Centre For Food And Nutrition, Jakarta, Indonesia

Background and objectives: Undernutrition among young children remains a problem in many countries, mostly happen and fairly concentrated in developing countries. Optimal feeding becomes one of ways to overcome long-term consequences of undernutrition. Most of the previous studies were conducted in rural setting. In the other side, complexity in the urban setting (for instance easier access to information & ready to eat food) might have different influence on the child feeding practices. To assess practice of caregiver on child feeding

among children aged 12-23 months old and the associated factors of child feeding.

Methods: This survey was a cross sectional study, simple random sampling was performed to select respondents. Total sample of this study was 83 children aged 12-23 months old in Paseban Village, Senen Sub-district, Central Jakarta. The data was collected via interview, in-depth interview, anthropometric measurement and hemoglobin measurement of children.

Results: Based on WAZ and WHZ, more than 80% children were categorized as well-nourished children. The prevalence of underweight, wasting, and stunting was 18.1%, 13.2%, and 21.7% respectively. The prevalence of anemic children was 62.6% considered as very high public health problem. In this study, 11.98% and 10.3% children have inadequate protein and energy intake respectively. Based on feeding practices, there were more than 50% children who were still breastfeed; 73.5% of caregivers gave solid food to the child, more than half of children have meal >3 times a day; and 42.8% of children have at least 2 times snack a day. There was a significant association between energy and protein inadequacy with anemia prevalence; and a significant association between protein inadequacy with underweight.

Conclusions: The more adequate energy and protein, the better child nutritional status.

Key words: child feeding, urban setting, child nutritional status, undernutrition.

PO729

DOES THE PROVISION OF NORDIC SCHOOL MEALS INFLUENCE GROWTH AND BODY COMPOSITION OF 8-11 YEAR OLD CHILDREN?

*S. Dalskov*¹, *C. Ritz*¹, *C T. Damsgaard*¹, *M F. Hjorth*¹, *L B. Sørensen*¹, *R A. Petersen*¹, *R P. Laursen*¹, *A. Astrup*¹, *C. Mølgaard*¹, *K F. Michaelsen*¹

¹Department of Nutrition, Exercise And Sports, University of Copenhagen, Denmark

Background and objectives: A large proportion of Danish children are overweight or obese. The provision of healthy school meals may have a positive impact on children's growth and body composition. The aim of the present study was to examine whether provision of school meals served ad libitum influenced changes in height, body weight, BMI and measures of body composition among 8-11 year old children in the 'Optimal well-being, development and health for Danish children through a healthy NND (New Nordic Diet)' (OPUS) School Meal Study, supported by a grant from the Nordea Foundation.

Methods: The study was a cluster-randomized, controlled cross-over study. Each child participated in two three month periods: an intervention period (NND) and a control period.

Six-hundred-and-forty-five children with data from baseline and at least one post-intervention measurement were included. Linear mixed models with adjustment for age, gender-specific pubertal status, household educational level, order of diets and relevant random effects (school, class and individual) were used.

Results: NND increased fat percentage (0.136% points, $p=0.045$), android fat mass (FM)/total FM (0.0006, $p=0.007$) and android FM/gynoid FM (0.0024, $p=0.049$) compared to control across all three BMI categories (underweight, normal weight and overweight/obese). After additional adjustment for changes in physical activity and sleep, body weight (0.47 kg, $p=0.009$) and BMI (0.199 kg/m², $p=0.018$) were also increased by NND in the overweight children, while the effect on fat percentage across all BMI categories disappeared. No differences were seen for height, fat mass index, fat free mass index and gynoid FM/total FM.

Conclusions: The NND school meals in this setting seemed to induce a less favourable body composition. Further investigations are needed to explain these unexpected findings, as the changes in dietary intake during the intervention were regarded as healthy.

Key words: New Nordic Diet, school intervention, child nutrition, obesity, body composition

PO730

COMPLEMENTARY FEEDING PRACTICES AMONG INFANTS AGED 9 – 11 MONTHS OLD IN URBAN SETTING JAKARTA

*S. Septriana*¹

¹Department of Nutrition Science, Faculty On Health Science, Respati University of Yogyakarta, Indonesia

Background and objectives: Prevalence of undernutrition among children aged 6-11 months in Indonesia were 17.1% underweight, 15.6% were wasting, while 31.4% were stunting. DKI Jakarta, the most populated province in Indonesia, has prevalence of underweight (11.3%), wasting (11.3%) and stunting (26.6%) among under-five children. Underlying cause of the malnutrition besides the infectious diseases is inappropriate caring practice and sub optimum feeding becomes one of ways to overcome long-term consequences of undernutrition. The aim of the present study was to assess complementary feeding practice among infants aged 9–11 months old in Central Jakarta.

Methods: In this cross sectional study, 66 children aged 9-11 months old and their caregivers were recruited. The data was collected via interview, in-depth interview, anthropometric and hemoglobin measurement.

Results: Nutritional status of infants age 9-11 months old were categorized in medium public health concern for underweight (18%), low public health concern for stunting (10%) and medium public health concern for wasting (6%), however this area had severe public health problem for anemia (82%). More than 50% infants are still continue receiving breastfeeding, 90% of infants have good energy intake, however, 11% at risk of calcium inadequacy, 47% at risk of iron inadequacy and 62% of them also at the risk of zinc inadequacy, 74% have semi solid food, 70% infants have appropriate meal and snack frequencies, and 74% infants have enough food diversity in their meal.

Conclusions: Child feeding practice of infants aged 9–11 months old in this area were not optimal related to low variety of food type, which characterized in cereal based meal.

Key words: feeding practice, infants aged 9-11 months old, urban setting

PO731

ANALYSIS OF FEEDING BEHAVIOR OF CHILDREN UNDER 2 YEARS OLD IN POVERTY AREAS OF CHINA IN 2009

*L. Zhao*¹, *D. Yu*¹, *X. Qian*¹, *A. Liu*¹, *W. Yu*¹, *X. Hu*¹, *G. Ma*¹

¹Institute of Nutrition And Food Safety, Chinese Center For Disease Control And Prevention, Beijing, China

Background and objectives: Infants and young children require adequate nutrition during rapid growth and development. The study objective is to analysis the feeding situation of feeding behavior among children under 2 years old in the poverty areas of China in 2009. The result will provide scientific reference for developing strategies to improve child feeding and health.

Methods: Through stratified cluster random sampling, 2972 children under 2 years old and their parents were selected from 30 poor counties (cities) of 13 provinces (autonomous regions and municipalities) in China. The parents were interviewed by using questionnaire survey.

Results: The breastfeeding rate of the surveyed children within 6 months of birth was 47.1%, the mixed feeding rate was 44.4%, and the artificial feeding rate was 8.5%. The average time to initiation of breastfeeding was 26.9 hours, the rate of timely initiation of breastfeeding was only 8.3%, and the rate of colostrums feeding was 93.3%. The rate of weaning within 6 months old was 20.8%. The average time to add supplementary food was 4 months old, and the rate of adding supplementary food for infants within 5 months old was 50.8%. The proportion of infants and young children under 2 years old fed with formula milk powder, cereals, meat, eggs, vegetables, fruits, le-

gumes and their products stood at 27.7%, 84.8%, 61.5%, 68.1%, 61.8%, 67.3% and 46.5%, respectively.

Conclusions: The feeding practice for children under 2 years old in poor areas of China remained problematic, for example, low breastfeeding rate, early weaning, premature complementary feeding and poor complementary feeding, etc. We should strengthen feeding knowledge of parents of infants and young children through health education, improve the breastfeeding rate, continue breast-feeding in an appropriate manner, and add various types of supplementary food scientifically and timely.

Key words: poverty; feeding patterns; infants and young children; complementary feeding

PO732

THE EFFECTS ON CHILDREN'S GROWTH, HEMOGLOBIN CONCENTRATION, AND ANEMIA IN 3 NUTRITION INTERVENTIONS IN POOR RURAL, CHINA

D. Yu¹, G. Ma¹, V. Joop², B. Wanda³, Z. Fang⁴, L. Zhao¹

¹Institute of Nutrition And Food Safety, Chinese Center For Disease Control And Prevention, Beijing, China

²Centre for Nutrition and Health, Institute for Public Health and the Environment, Netherlands

³Prevention and Health Services Research, National Institute for Public Health and the Environment, Netherlands

⁴Guangxi Center for Disease Control and Prevention, Nanning, Guangxi, China

Background and objectives: In developing settings, the incidence of malnutrition rises among these young children and deficits acquired at this age are difficult to compensate for in later life. This suggests a "critical window" for prevention of growth faltering. The present study investigated the effects of three nutritional intervention approaches to improve the nutritional status of children less than 2 years in Guangxi, a poor rural area in China. These approaches consisted of nutrition education (EDUC), nutrients supplementation (SUP) and a combination of education and supplementation (COM), and were hypothesized to be effective in increasing physical growth, hemoglobin concentration, and avoiding anemia as compared to a control condition without any intervention.

Methods: The study is a stratified and cluster random program and 4 counties were randomly assigned to a control group (n=158) or one of the three intervention conditions: EDUC (n=172), SUP (n=149), or COM (n=155). The selected children received a medical examination (anthropometry, he-

moglobin test) and their caregivers completed questionnaires. The average follow up time is 6 months; dropout rates varied between 17% and 37%.

Results: As compared to the control group, hemoglobin concentration was increased and the prevalence of anemia was decreased in the SUP and COM group (p<0.05). In addition, the COM group showed an increased weight for age Z score (WAZ) and weight for height Z score (WHZ) (p<0.05).

Conclusions: Both SUP alone and the COM approaches were effective approaches because of their positive effects on hemoglobin and prevention of anemia in a short duration. The COM approach had also beneficial effects on growth indicators.

Key words: growth; children; nutritional Interventions; anemia

³Research Center, Faculty of Medicine, Ramathibodi Hospital, Mahidol University, Bangkok, Thailand

⁴Department of Chemistry and Center of Excellence for Innovation in Chemistry, Faculty of Science, Mahidol University, Bangkok, Thailand

Background and objectives: Breast milk provides adequate nutrients during the first 6 months of life. However, there were some reports of zinc (Zn) deficiency in breastfed infants. This study was conducted to determine the prevalence of Zn deficiency (ZD) in infants aged 4-6 months and factors associated with ZD in those infants.

Methods: Healthy infants aged 4 - 6 months and their mothers were enrolled in this study. Exclusion criteria were prematurity, illness, and receiving vitamin and/or mineral supplementation. Subjects were divided into 3 groups: breastfed, formula-fed, and mixed groups. Data collection included demographic data, perinatal data, given diets, and anthropometric measurement (weight and length). Data from mothers of breastfed infants included weight, height, and dietary intake

using a 24-hour dietary recall. Blood of infants and lactating mothers were collected to assess plasma Zn concentration. Breast milk was collected to analyze Zn concentration.

Results: From 176 infants and mothers, the prevalence of ZD (defined as plasma Zn concentration less than 10.7 mmol/L) was higher in the breastfed group (14.9%) than that in the formula-fed group (5.3%) and the mixed group (2.9%). Among breastfed infants, those with ZD had significantly low maternal Zn concentration compared to those without ZD. There was a higher proportion of maternal ZD in infants with ZD than that in those without ZD (67% vs 18%, $p=0.027$). There was a positive correlation between plasma Zn concentrations in infants and breast milk ($R=0.62$, $p=0.01$) and between plasma Zn concentrations in lactating mothers and their breast milk ($R=0.56$, $p=0.016$).

Conclusions: The results of this study suggests that breastfed infants aged 4-6 months may have a risk for ZD with regard to maternal Zn status and Zn concentration in breast milk.

Acknowledgement: Development potential of Thai people project.

Key words: zinc, breastfeeding, infant, zinc concentration in breast milk

their mothers were measured for anthropometry following the standard method. Data on household characteristic, dietary intake, infant feeding practice, child's disease history and mother's lifestyle habit were obtained by interviews with mothers.

Results: Prevalence of stunting and underweight was higher in NUKU than POM ($p<0.05$). Whilst food insecurity was apparently more serious in NUKU, a great economic disparity might have affected the living environment in POM, leading to severe undernutrition and high morbidity. Distribution of mothers' BMI was quite different between two sites, with higher proportion of overweight and obesity in POM (47.6%) and underweight in NUKU (20.8%). Characteristics of infant feeding practice were quite different between two study sites, which could have possibly affected the nutritional status of children.

Conclusions: Area-specific approach should be enhanced, considering differential regional characteristics affecting the nutritional status of children and mothers in PNG.

Key words: PNG, food security, double burden of malnutrition

NUTRITIONAL STATUS OF CHILDREN AND THEIR MOTHERS, AND ITS DETERMINANTS IN URBAN CAPITAL AND RURAL HIGHLAND IN PAPUA NEW GUINEA

M. Miyoshi¹, J. Hawap², N. Nishi¹, N. Yoshiike³

¹National Institute of Health And Nutrition, Japan

²Department of Health, Papua New Guinea

³Aomori University of Health and Welfare, Japan

Background and objectives: In Papua New Guinea (PNG), under-five mortality rate still remains high (75 per 1,000 live birth), and infectious diseases (e.g. malaria, ARI, diarrhea) contribute to 38% of deaths among under-five children. The situation is especially serious in rural highland, where access to health service is extremely limited and food insecurity consistently exists. On the other hand, obesity has also been increasingly significant problem in urban area, leading to double burden of malnutrition. Under this circumstance, this study was undertaken with the aim to assess nutritional status of children and their mothers in the urban capital (Port Moresby (POM)) and rural highland (Nuku district, Sandaun Province (NUKU)), as well as to investigate the association with the possible determinants.

Methods: Fieldwork was carried out in October 2010 in POM and in September 2011 in NUKU. In total 211 pairs (89 in POM and 122 in NUKU) of children aged 6-59 months and

FACTORS ASSOCIATED WITH BREASTFEEDING PRACTICES AMONG MOTHERS IN CENTRAL COAST OF VIETNAM

N. Le¹, D. Gallegos², S. Miharshahi³, H. Tran⁴

¹Faculty of Public Health, University of Medicine and Pharmacy at Ho Chi Minh City, Ho Chi Minh City, Vietnam

²School of Exercise and Nutrition Sciences, Queensland University of Technology, Kelvin Grove, Queensland, Australia

³School of Population Health, University of Queensland, Brisbane, Queensland, Australia

⁴Community Nutrition Department, Nutrition Center of Ho Chi Minh City, Ho Chi Minh City, Vietnam

Background and objectives: Promoting breastfeeding is a priority public health nutrition issue in Vietnam. Although breastfeeding has been well-studied, there is limited information on breastfeeding practices and their determinants among mothers living in Vietnam, especially at sub-national level. Exclusive breastfeeding rates, when mothers feed their infants breastmilk only in the first six months, was previously reported to be 0% in the Central Coast region of Vietnam. This study investigated the determinants influencing the practices of breastfeeding initiation and of exclusive breastfeeding among mothers living in this area.

Methods: A cross-sectional survey was conducted in two provinces in the Central Coast region of Vietnam (Quang Nam and Khanh Hoa). Interviews using a structured questionnaire involved 234 mothers having children aged less than 36 months. The questionnaire explored mothers' demographic, socio-environmental, pregnancy and maternal characteristics and breastfeeding practices. Descriptive analyses, logistic regression and survival analyses were applied to determine factors associated with the breastfeeding practices.

Results: Forty-five percent of women initiated breastfeeding within an hour after birth. Exclusive breastfeeding among infants aged six months or less was 2%. Median duration of breastfeeding was 18 months. Risks factors of not initiating breastfeeding included: having a Caesarean section, and having low birthweight infant (<2500 g). Interestingly, having support from the family was also negatively associated with breastfeeding initiation. Other fluids or food were commonly introduced to the child before he or she reached six months of age, with water being the most frequent fluid introduced (90.5%).

Conclusions: Our findings confirm the low rates of initiation and exclusive breastfeeding in the Central Coast region of Vietnam. Efforts to promote breastfeeding should consider factors such as increased rate of Caesarean sections in Viet Nam related to socio-economic changes, and the supporting roles of the mothers' relatives.

Key words: breastfeeding, determinants, Vietnam.

CLINICALLY FEASIBLE APPROACH TO EVALUATE THE QUALITY OF DIETARY CARBOHYDRATES IN SMALL CHILDREN

H. R yhti ¹, J. Jaakkola¹, U. Hoppu¹, T. Poussa², K. Laitinen¹

¹Functional Foods Forum, University of Turku, Finland

²STAT-Consulting, Nokia, Finland

Background and objectives: The quality of the carbohydrates and especially the amount of sucrose and fibre has been shown to reflect a health promoting diet. In this study, a set of simple dietary questions was developed and validated to describe the quality of carbohydrates in diet of small children, focusing on the total intake of sucrose and fibre.

Methods: Questionnaire (10 questions) regarding the intake of foods that are known to be the key sources of sucrose and dietary fibre was formulated and evaluated against seven-day food records. Finnish children (n=400) aged between 2 to 6 years completed the study. Key questions best reflecting the quality of the carbohydrates, i.e. low sucrose and high fiber intake, were identified by correlation and ROC analysis in comparison to calculated nutrient intakes from food records.

Results: Based on ROC analysis, 4 questions were identified to best describe the recommended intake of sucrose and fibre and able to differentiate children in 3 groups consuming different levels (high, moderate and low) of these nutrient (ROC-values ranging between: sensitivity 0.55-0.71 and specificity 0.31-0.48). The questions related to the frequency of consumption of 1) sugar-containing yoghurts and juices, 2) fruit, vegetables and berries, and 3) porridge and gruel. Questions related to the use of e.g. bread or candies did not differentiate between the high and low consumers.

Conclusion: These simple questions identified could provide a feasible method to obtain information about small children's dietary quality and could be used as a tool in clinical practice without the need of complicated calculations or laborious food records.

THE SCHOOL FOOD ENVIRONMENT IN ULAANBAATAR, MONGOLIA

N. Chimedtseren¹, B. Jamiyan¹, L. King², B. Kelly², Ts. Bayandorj³

¹National Center of Public Health, Ulaanbaatar, Mongolia

²Prevention Research Collaboration, University of Sydney, Australia

³World Health Organization, Ulaanbaatar, Mongolia

Background and objectives: WHO School Policy Framework suggests taking measures to create a supportive environment in the area around schools, by limiting the availability of unhealthy foods and drinks in these vicinities. The aim of this study was to identify the foods sold and promoted in schools.

Methods: Thirty public and private schools from six districts in Ulaanbaatar were randomly selected for the survey. Information on food and drinks sold and promoted within schools was collected, including in canteens or shops inside schools. Data were collected by trained observers using a purpose-designed tool in May 2012. Food and drinks were classified as core/healthy or non-core/unhealthy. Descriptive analyses were conducted to determine the types of food and drinks sold and promoted within schools.

Results: Of all individual products that were sold within schools, 33% were core food and 67% were non-core. The most frequently available product types included non-core snacks (34%), followed by core meals and non-core drinks. Together, core drinks and snacks compromised only 12% of all products. The most frequently available foods and drinks in schools were chocolate, candies, ice cream, fruit juice, sweetened coffee, tea powders and soft drinks.

Conclusions: Children in Ulaanbaatar are exposed to a wide range of unhealthy food and drinks in the school environment and healthier food and drink choices are very limited in these settings. The high availability of different varieties of unhealthy food and drinks is likely to make these products attractive choices for children. There is a need to introduce policies to guide the availability and promotion of foods within schools; including limiting the availability of unhealthy foods and drinks and promoting healthier food choices. Acknowledgement: This work was supported by the Western Pacific Regional Office of the World Health Organization.

Key words: public health, health promotion, school canteens, food environments.

CHILDREN'S STRESS INFLUENCES THEIR DIET AND EATING BEHAVIOUR.

N. Michels¹, I. Sioen¹, B. Vanaelst¹, L. Boone², C. Braet², I. Huybrechts¹, S. de Henauw¹

¹Department of Public Health, Ghent University, Ghent, Belgium

²Department of Developmental Personality and Social Psychology, Ghent University, Ghent, Belgium

Background and objectives: Psychological stress has been suggested to change dietary pattern towards more unhealthy choices and as such to contribute to overweight. Research on this topic in children is pivotal as the foundations of dietary habits are established starting from childhood and may track into adulthood. Therefore, we aim to study the longitudinal relation between stress and diet (both consumption frequency and psychological driven eating behaviour).

Methods: In about 300 Belgian children (5-12 y) of the ChiBS study, the longitudinal relation between stress and lifestyle was examined over two years. Stress was examined by questionnaires concerning negative life events (Coddington life events), problem behaviour (strengths and difficulties questionnaire) and emotions (happiness, anger, anxiety, sadness). Food consumption (sweet food, fatty food, snacks and fruit and vegetables) and eating behaviour (emotional, external and restrained eating) were measured. Cross-lagged analyses with Mplus were used to examine bidirectional relations with a total stress score and with separate stress aspects corrected for age, sex, parental education and BMI.

Results: Children with a high overall stress score reported more external eating longitudinally. Concerning the separate stress aspects, positive longitudinal associations were found with sweet food consumption, emotional eating, external eating and restrained eating. Some relations were sex dependent: a stress (problem behaviour) effect on restrained eating and

sweet food consumption only in boys and a stress (emotions and events) effect with more emotional and external eating only in girls. Moreover, reversed causation was found only in girls: negative emotions could longitudinally be predicted by more restrained eating.

Conclusions: Children's stress deteriorates their dietary behaviour with increased sweet food consumption, external, emotional and restrained eating. Moreover, reacting on stress with increased restrained eating could create a vicious circle since restrained eating also favours stress.

Key words: stress, diet, emotional eating, external eating, restrained eating

GLUTEN INTAKE IN 4- TO 19-YEAR-OLD DANISH CHILDREN AND ADOLESCENTS BASED ON A NATIONAL SURVEY

C. Hoppe¹, E. Trolle¹, R. Gøbel², M. Kristensen³, M. Lind³, T. Christensen¹, S. Husby⁴

¹Division of Nutrition, National Food Institute, Technical University of Denmark, Denmark

²Center for Basic Metabolic Research, Faculty of Health Sciences, University of Copenhagen, Denmark

³Department of Nutrition, Exercise and Sports, Faculty of Health Sciences, University of Copenhagen, Denmark

⁴Ans Christian Andersen Children's Hospital, Odense University Hospital, University of Southern Denmark, Denmark

Background and objectives: Coeliac disease (CD) affects around 1% of the Western population. Variation in gluten intake may be an independent risk factor in the CD pathogenesis, and information regarding gluten intake in the general population is scarce.

Methods: We determined the intake of gluten from wheat, barley, rye as well as oats in a cross-sectional Danish National Survey of Dietary Habits and Physical Activity 2005-2008. The study population comprised a representative sample of 537 4-19-year-old children and adolescents, recruited from the National Danish Civil Registry. The protein contents from wheat, rye, barley and oats were ascertained in the National Danish Food Composition Tables, and multiplied with amounts in recipes. The amounts of gluten were calculated as the amount of cereal protein x0.80 for wheat and oats, x0.65 for rye, and x0.50 for barley. Dietary intake was recorded every day for seven consecutive days in pre-coded food records supplemented with open-answer possibilities.

Results: Total gluten intake increased with age from 4-14 y from 8,783 mg/d to 11,184 mg/d ($p < 0.001$), and then stabilized (10,756 mg/d, $p = 0.99$) in the oldest age group (15-19 y). Gluten from wheat contributed most to the gluten intake (69%), then rye (18%), oats (13%) and barley (0.12%) from 4-14 y. However, intake of gluten from rye decreased throughout childhood and adolescence from 2,042 mg/d to 1,645 mg/d ($p = 0.002$), and among the oldest adolescents, the intake of gluten from oats (16%) exceeded that of rye (14%). Boys had higher intakes of all gluten types ($p < 0.001$), except barley ($P = 0.270$).

Conclusion: This study presents representative population-based data on gluten intake in Danish children and adolescents.

Acknowledgements: This study was supported by the Danish Strategic Research Council (project no. 09-06-5149), and Danish National Survey of Dietary Habits and Physical Activity was financed by the Ministry of Food, Agriculture and Fisheries.

SCHOOL MEALS BASED ON THE NEW NORDIC DIET IMPROVE CARDIOVASCULAR RISK MARKERS IN DANISH 8-11-YEAR-OLD CHILDREN-THE OPUS STUDY

C. T. Damsgaard¹, R. P. Laursen¹, C. Ritz¹, M. F. Hjorth¹, L. Lauritzen¹, S. Dalskov¹, L. B. Sørensen¹, R. A. Petersen¹, M. R. Andersen², S. Stender², C. Mølgaard¹, A. Astrup¹, K. F. Michaelsen¹

¹Department of Nutrition, Exercise and Sports, Faculty of Science, University of Copenhagen, Frederiksberg, Denmark

²Department of Clinical Biochemistry, Copenhagen University Hospital, Gentofte, Denmark

Background and objectives: Good eating practices during childhood may help prevent cardiovascular diseases. Increasing numbers of children and adolescents are diagnosed with the metabolic syndrome, which is a cluster of risk factors for cardiovascular disease and mortality. The New Nordic Diet (NND) is rich in health-promoting foods such as fish, whole grain, fruits, vegetables and nuts. The Optimal well-being, development and health for Danish children through a healthy New Nordic Diet (OPUS) study was supported by a grant from the Nordea Foundation. The aim of the present study was to investigate the effect of school meals based on the NND on early cardiovascular risk markers in 677 mainly normal-weight Danish 8-11-year-old children.

Methods: The OPUS School Meal Study was a cluster-randomized controlled cross-over study. Children from 3rd and

4th grade at 9 Danish schools received school meals based on the NND and their usual packed lunch (control) for 3 months each. At baseline and at the end of each period (month 3 and 6), we performed a background interview, measured anthropometry, blood pressure, heart rate, and physical activity and took a fasting blood sample, which was analyzed for serum insulin and plasma glucose, cholesterol, and triacylglycerol. The statistical analysis was performed by linear mixed models.

Results: NND reduced heart rate 0.8 (95%CI 0.2;1.5) beats/min, insulin 2.9 (1.3;4.5) pmol/L, homeostatic model assessment-insulin resistance 0.09 (0.04;0.15), and triacylglycerol 0.02 (0.01;0.04) mmol/L, as compared to control (all $p < 0.05$). However, NND evoked a 0.5 (0.3;0.6) cm increase in waist circumference ($p < 0.001$). Total and LDL cholesterol were reduced in boys only ($p < 0.01$). Adjustment for physical activity did not change the overall results.

Conclusions: School meals based on Nordic foods improved early cardiovascular risk markers in 8-11-year-old children, despite an increase in waist circumference. The impact of weight status and gender warrants further investigation.

Key words: insulin; syndrome X; cardiovascular risk.

PO741

EFFECTS OF DOCOSAHEXAENOIC ACID SUPPLEMENTATION DURING PREGNANCY IN MATERNAL AND FETAL BRAIN COMPOSITION

A. Gázquez¹, I. Hernández-Albaladejo¹, M. Ruíz-Palacios¹, A. Pagán¹, E. Larqué¹

¹Department of Physiology, University of Murcia, Murcia, Spain

Background and objectives: Epidemiological studies have shown the importance of prenatal docosahexaenoic acid (DHA) intake to improve visual and cognitive development of infants. Besides, low maternal DHA status has been associated with higher risk of postpartum depressive symptoms in the mothers. The aim of this study was to investigate brain plasticity to dietary DHA incorporation during pregnancy in both fetus and mothers.

Methods: Two groups of ten pregnant rats were fed during gestation with two experimental diets differing in their DHA content (2.5% DHA of total fat vs 9% DHA). On day 20 of gestation the animals were sacrificed. We determined fatty acids in placenta, maternal plasma as well as in liver, adipose tissue and brain of both mother and fetus. Fatty acids were extracted according to Folch et al. (1957) and quantified by gas chromatography.

Results: Pregnant rats fed the 9% DHA diet had significantly higher DHA percentage in maternal plasma than those fed the 2.5% DHA diet (22.75±0.92% DHA vs 10.96±0.40%

DHA, $p < 0.001$); similar results were found in maternal liver, maternal adipose tissue, placenta and total fetus. Fetal brain also reached significantly higher DHA content with the 9% DHA diet with respect to those of 2.5% DHA ($17.52 \pm 0.41\%$ DHA vs $12.41 \pm 0.88\%$ DHA, $p < 0.001$). Nevertheless, the DHA composition in brain of pregnant rats did not show any variation between both experimental groups ($20.08 \pm 0.24\%$ DHA vs $20.06 \pm 0.17\%$ DHA, $p = 0.957$).

Conclusions: The consumption of DHA supplements during pregnancy enhances DHA incorporation in fetal brain, but it is not suitable to improve DHA content in the adult brain of the mother that is strongly regulated.

Key words: docosahexaenoic acid, brain, pregnancy, postpartum depression.

Acknowledgements: this work was supported by a Séneca Foundation grant, Murcia, Spain.

INFLUENCE OF MODERATE-VIGOROUS PHYSICAL ACTIVITY AND EXTRA VIRGIN OLIVE OIL IN CHILDREN CATALASE ACTIVITY

M J. Oliveras López¹, J. Muros Molina², F. Martín^{1,3}, H. López García de la Serrana²

¹Department of Molecular Biology and Biochemical Engineering, University of Pablo de Olavide of Seville, Seville, Spain

²Department of Nutrition and Food Science, Faculty of Pharmacy, University of Granada, Campus Universitario de Cartuja, 18071, Granada, Spain

³CIBER de Diabetes y Enfermedades Metabólicas Asociadas, Bonanova 69, 08017 Barcelona, Spain

Background and objectives: Physical activity and Mediterranean diet have been widely accepted as the best strategies to prevent children obesity and chronic diseases. The aim was to study the effects of physical activity and extra virgin olive oil (EVOO) intake in children catalase activity.

Methods: Forty four healthy children, aged 11-12 years, were randomly divided into three groups: (i) Control group (CTL) continued with their dietary and physical activity habits ($n=15$); (ii) Physical activity group (PA) continued with their dietary habits and practiced moderate-vigorous physical activity 2 days/week ($n=15$); (iii) Olive oil group (OO) continued with their dietary habits and physical activity habits but consumed a selected EVOO during the last 4 weeks ($n=14$). The whole study lasted 6 months. Phenolic EVOO composition was analyzed by HPLC-DAD-MS. Activity of erythrocyte catalase (CAT) was measured at baseline and at the end of the intervention period. All data were analyzed by the SPSS 20.0 statistical

package (SPSS, Inc.) by one-way ANOVA followed by Bonferroni post-hoc test.

Results: CAT activity significantly increased in OO group versus CTL ($p < 0.01$) and PA ($p < 0.05$) groups after the intervention. CAT activity was significantly higher ($p < 0.05$) in PA group after the intervention, when compared with CTL and OO groups at the beginning. After the interventions, CAT activity resulted to be significantly higher in OO group than in PA and OO groups at the beginning ($p < 0.01$). Studies have proposed that intense physical exercise increases oxidative stress, usually related to reduced levels of catalase. However, polyphenols from EVOO could counteract this effect.

Conclusions: Our results show that a long term moderate-vigorous physical activity and the consumption of EVOO with suitable composition of polyphenols promote antioxidant catalase activity in healthy children.

Key words: extra virgin olive oil; physical activity; catalase enzyme; children; healthy

PO743

SNACKING HABITS AMONG MENOPAUSAL WOMEN

J. Setorglo¹, M. Steiner-Asiedu², L. Danladi²

¹University of Cape Coast, Ghana

²University of Ghana, Legon, Ghana

Background and objectives: Healthy snacking may help menopausal women meet nutrient requirements and manage their body weight. This cross-sectional study was to assess the snacking habits and perceptions of menopausal women of snacking on their body weight.

Methods: This study was conducted in 3 different Christian denominations, in Accra, among 200 menopausal women aged between 45 and 70 who volunteered to participate. Anthropometric measurements were performed by standard procedure and converted to body mass index (BMI), waist to hip ratio (WHR) and Low or High waist circumference indices (LWC or HWC). Snacking habits and perceptions were determined using structured questionnaire and compared with the anthropometric indices. Logistic regression was used to predict snacking on the occurrence of obesity.

Results: About 80.7% perceived all snacks are harmful to health ($p=0.02$) and type of fat consumed affects waist circumference (WC). Obesity risk increased as the frequency of snacking exceeded three times in a day ($p=0.04$). Most of the women snacked 3-4 times daily and fruit snacking does influence BMI ($p=0.05$) and WC ($p=0.02$). Those who consumed snack after supper were more obese ($p=0.04$). There was a decreased risk in WC among women who consumed fruit as snack (OR:0.14; CI:0.01-2.41). The risk of obesity was reduced

among those who consumed mixed vegetables daily (OR:1.39; CI:0.23-8.54). Conclusion Snacks are perceived to be bad for health outcomes. Type of snack and the frequency of consumption does predicts obesity and high waist circumference. Fruit based snacks does reduce the chance of obesity development.

Key words: menopausal women, snacking, Low waist circumference, high waist circumference

THE EFFECT OF NORDIC SCHOOL MEALS ON ILLNESS, ASTHMA, ALLERGIES, AND SCHOOL ATTENDANCE IN DANISH CHILDREN-THE OPUS STUDY

R P. Laursen¹, L. Lauritzen¹, C. Ritz¹, C B. Dyssegaard², L B. Sørensen¹, R A. Petersen¹, S. Dalskov¹, A. Astrup¹, K F. Michaelsen¹, C T. Damsgaard¹

¹Department of Nutrition, Exercise And Sports, Faculty of Science, University of Copenhagen
²Centre for Strategic Research in Education and Competence, Aarhus University, Denmark

Background and objectives: A nutritionally adequate diet in childhood is important for health and resistance of allergies and infections. This study investigates the effects of school meals based on The New Nordic Diet (NND) on asthma, allergies, illness symptoms, and school attendance in 797 Danish school children aged 8-11 years. The OPUS (Optimal well-being, development and health for Danish children through a healthy New Nordic Diet) study was supported by a grant from the Nordea Foundation.

Methods: OPUS School Meal Study was a cluster-randomized cross-over trial. Children from 3rd and 4th grade at 9 Danish schools received school meals or control (usual packed lunch) for two 3-month periods. Absence from school, occurrence and duration of illness, asthma, and allergies within a 14-day period was recorded by parental questionnaires at baseline, and after each dietary period. n-3 long-chain PUFA (LC-PUFA) status was measured in whole-blood.

Results: Less than 5% of the children experienced asthma/allergy symptoms during the study. No difference was seen in occurrence of asthma/allergy symptoms, but NND slightly reduced duration of asthma symptoms ($p < 0.001$), use of asthma medicine ($p = 0.04$), and slightly increased duration of eczema symptoms ($p < 0.001$) and use of hay fever medicine ($p = 0.001$). n-3 LCPUFA status was negatively associated with duration of eczema and asthma symptoms. A slightly increased duration, but no difference in occurrence, of cold-like symptoms was found among children eating NND in common dining areas; but not among those eating in the classroom. No difference was seen in school attendance or other illness symptoms.

Conclusions: NND-based school meals reduced asthma symptoms, likely through increased intake of fish, which also seemed to improve eczema. Small increases in eczema with NND may be due to increased variety of nuts, fruits and vegetables. The physical eating conditions seem to influence cold-like symptoms.

Key words: School meals, allergies, illness

QUANTITIES AND TYPES OF FOODS REPORTED FOR COMPLEMENTARY FEEDING IN A PERI-URBAN AREA OF SOUTH AFRICA.

M. Rothman¹, R. Moreotsenye¹, C. Berti¹, H S. Kruger¹, C M. Smuts¹, J C. Jerling¹, N M. Covic¹

¹Centre of Excellence for Nutrition, North-West University, Potchefstroom, North-West, South Africa

Background and objectives: Complementary foods are essential for optimal growth, health and cognitive development. Much information is required on changing feeding practices/patterns over time. This study preceded a randomized-controlled-efficacy trial and aimed to assess the types and amounts of complementary foods given to infants aged 6-12 months in a peri-urban community in the North-West Province (South Africa).

Methods: An observational cross-sectional survey was done involving 102 mothers/caregivers. Information on food items given to infants was obtained using a structured questionnaire. Volumes of maize-rice were used as reference amounts to estimate the serving sizes of foods provided by converting the equivalent volumes to weights. The contribution of the estimated average serving sizes to the Dietary Reference Intakes (DRIs) of selected micronutrients was determined.

Results: Eighty-three percent of mothers/caregivers reported being unemployed. The top four food items recorded were commercial pureed food (62.9%), carrots (52.9%), pumpkin (49%) and commercial infant cereal (42.2%). The average estimated serving sizes on the top four foods reported varied from 66.7 ± 45.82 g for commercial pureed food to 43.2 ± 33.95 g for pumpkin. Regarding iron intake, the carrot estimated average serving size contributed 3.25% and 3.26% of DRIs for age groups 6-8 months and 9-12 months, respectively, while pumpkin contributed 1.15% and 1.43%, respectively. For vitamin A, the estimated average serving size of carrots contributed 327.97% and 340.82% of DRIs for age groups 6-8 months and 9-12 months, respectively, while pumpkin contributed 18% and 22% of DRIs, respectively.

Conclusions: Commercial food items were frequently reported despite the high unemployment rate. The use of infant foods from animal sources are lacking in this community. The

feeding practices for infants aged 6-12 months were different from results of other South African studies. Regular monitoring is necessary to inform nutrition education/programme activities at community level.

Key words: complementary feeding, micronutrients, community nutrition

PO746

RELATIONSHIP BETWEEN MATERNAL NUTRITIONAL STATUS AND PERCEIVED INSUFFICIENT MILK IN KLATEN DISTRICT, CENTRAL JAVA, INDONESIA

Y. Esther¹, S. Fikawati², A. Syafiq²

¹Ministry of Health Republic of Indonesia, Indonesia

²Department of Nutrition, Faculty of Public Health, University of Indonesia, Indonesia

Background and objectives: Perceived Insufficient Milk (PIM) is recognized as one of main causes of exclusive breastfeeding (EBF) failure in the world. PIM is a condition where mother feels her breast milk is insufficient to fulfill infant's needs. One possible cause of PIM is inability of pregnant women to achieve recommended weight gain thus increases risk of low fat reserves to produce milk. Low production of breast milk will negatively affect mothers' confidence to breastfeed. This study aimed at understanding relationship between maternal nutritional status and PIM. Study was conducted in Klaten District, Indonesia from May to June 2012.

Methods: Data were obtained from 14 sub-district level Community Health Centers. Enumerators were breastfeeding counselor who conducted interview and observed 133 mothers having infant less than 6 months old and had stopped EBF.

Results: Mothers whose weight gain during pregnancy did not achieve recommendation have the risk of PIM twice as higher as those who achieved the recommendation (OR=2.3). Risk of PIM also higher among working mothers (OR=3.0), mothers who did not conduct early initiation of breastfeeding (OR=3.6) and mothers who did not get support from their mother-in-laws (OR=17.3). Multivariate analysis shows that pregnancy weight gain is the most dominant factor related to PIM after controlled by other related variables.

Conclusions: The study contributes answer to important yet unresolved question about the relationship between PIM and maternal nutritional status and provides input for policy makers to pay more attention to the nutritional status of pregnancy and breastfeeding mothers. It is recognized that breastfeeding promotion to mother in law is very important and needs to be initiated.

Key words: maternal nutritional status, EBF, PIM

PO747

NUTRIENT INTAKES AND PREGNANCY OUTCOMES AMONG VEGETARIAN MOTHER IN JAKARTA, INDONESIA

S. Fikawati¹, D. Wahyuni¹, A. Syafiq¹

¹Department of Nutrition, Faculty of Public Health, University of Indonesia, Depok, Indonesia

Background and objectives: Vegetarian diet undoubtedly has many advantages; however, when body metabolism is high such as in pregnancy and lactation, vegetarian diet increases the risk of nutritional deficiency. Studies provide special attention to the intakes of carbohydrates, protein, vitamin B12, Fe, Zn and folate which are important during pregnancy and lactation but not consumed adequately by vegetarian mothers. Significant relationship between maternal nutrient intake and pregnancy weight gain as well as relationships between pregnancy weight gain and birth weight have consistently been proven. However, the relationship between maternal nutrient intake and birth weight babies is not clear because of limited data. This study aimed to examine nutrient intake of vegetarian pregnant mothers in Indonesia in the relation to the outcome of pregnancy.

Methods: The study was conducted in Jakarta among vegetarian mothers who have children aged 1 month to 5 years. Total sample was 85 people selected conveniently from Indonesia Vegetarian Society database.

Results: The results showed that macronutrients intake among vegetarian mothers were higher than RDA, but the intakes of micronutrients were lower than the RDA. Intake of these nutrients (except vitamin B12 intake) was associated significantly with pregnancy weight gain. In contrast, only intake of vitamin B12 significantly associated with infant birth weight.

Conclusions: This finding suggests that vitamin B12 was utilized mainly for fetal development rather than maternal tissue development. Furthermore, based on low intake of vitamin B12 among vegetarian mothers as found in this study and considering negative impact of vitamin B12 deficiency on fetus, vegetarian mothers are expected to consume vitamin B12 supplement during pregnancy.

Key words: vegetarian, pregnancy mother, nutrient intake

PO748**BLOOD FOLATE, VITAMIN B6, VITAMIN B12, AND CREATININE AMONG THAI ELDERLY**

S. Kaewnimee¹, S. Kajanachumpol², P. Tantibhedhyangkul¹

¹Department of Pediatrics, Ramathibodi Hospital, Thailand

²Research Centre, Ramathibodi Hospital, Thailand

Background and objectives: It has been well established that plasma homocysteine (Hcy) rises and cognitive function declines with age. The hyperhomocysteinemia in the elderly has many causes, in particular, inadequate nutrition of folate, vitamin B6, vitamin B12, and age-related renal insufficiency. The aim of the present study was to determine in Thai elderly (1) Blood folate, vitamin B6, vitamin B12, and creatinine (2) Correlations among the B-vitamins, creatinine, plasma homocysteine, and cognitive function (from a separate study of the same population)

Methods: 94 Thai elderly, 25 males, 69 females, 60-80 years old, lived in 5 homes for the elderly. Major exclusion criteria included dementia and depression. Blood were determined for folate, vitamin B6, vitamin B12, and creatinine with standard methods.

Results: Abnormal values were found in the elderly as follow: plasma B6 < 20 nM 9.57%, serum B12 < 203 pg/mL 4.25%, serum folate < 3.09 ng/mL 0%, RBC folate < 140 ng/mL 0%, serum creatinine > 1.5 mg/dL 5.35%, and plasma Hcy > 15 µM 34%. Elderly with Hcy > 15 µM compared with elderly with Hcy < 15 µM had significantly lower values of B6 (p < .008), B12 (p < .001), serum folate (p < 0.001), RBC folate (p < .001) and plasma methylmalonic acid (p < 0.001). Female elderly with creatinine > 1 mg/dL compared with creatinine < 1 mg/dL had significantly higher Hcy (p < .01), while male elderly with creatinine > 1.5 mg/dL compared with creatinine < 1.5 mg/dL also had significantly higher Hcy (p = .03).

Conclusions: The present study showed that one third of Thai elderly had hyperhomocysteinemia which correlated with inadequate nutrition of folate, vitamin B6, vitamin B12, and impaired renal function. A separate study of the same group of elderly did not show correlation between plasma Hcy and cognitive function.

Key words: homocysteine, folate, vitamin B6, vitamin B12, elderly

PO749**NUTRITIONAL STATUS AND ANTHROPOLOGICAL MEASUREMENTS IN ELDERLY PEOPLE OVER 100 YEARS OF AGE. THE CUBAN 'CENTENARIO' STUDY**

C. Prado¹, E. Camps², A. Diaz de Cane²

¹Departament of Biology, Fac.Sciences, Universidad Autonoma de Madrid, Madrid, Spain

²Departamento de Fisiología, Facultad Victoria de Giron, Universidad de Ciencias Médicas de La Habana, La Habana, Cuba

Background and objectives: In Cuba the index of population aging is the 17.5%. Individuals 100 years old has also experienced a significant increase, but there is no bio-functional and nutritional assessments in this regard. To improve this situation, the Cuban Government in their National State plans has promoted a nationwide study on the entire Cuban population with 100 years of age. The basic objective is to ascertain and assessing the quality of life of the elderly and implement comprehensive improvements with multidisciplinary teams. The present study deals with the knowledge and difficulty of the assessment of the nutritional status in centenarians.

Methods: The population studied is composed by 1488 individuals that in 2008 had 100 or more. The 60.3% of centenary were women. More 95% live in their homes or with their families. Somatic anthropometric assessment (IBP) and blood analysis was made. Also the mini nutritional assessment was study.

Results: When applying the formulas and common breakpoints in the older population has been revealed that it is not indicative in these very old ages of vital cycle with different somatic and physiological situation. Two-thirds of population is categorized as malnourished, instead being a survivor population group. The values of functionality reinforce this situation which should be reviewed in future studies.

Conclusions: The authors propose the use of percentiles emanating from the characteristic somatic and physiological of this specific age, as well as determining which are the real energy needs and establish reference values for the variable hematoliquimicas in the evaluation of the nutritional status.

Key words: elderly, nutritional status, cuban population

PO750**NON-INSTITUTIONALIZED NONAGENARIANS HEALTH-RELATED QUALITY OF LIFE AND NUTRITIONAL STATUS: IS THERE A LINK BETWEEN THEM?**

S. Jiménez-Redondo¹, B. Beltrán de Miguel¹, J. Gavidia Banegas², L. Guzmán Mercedes², J. Gómez-Pavón^{2,3}, C. Cuadrado Vives¹

¹Department of Nutrition, Pharmacy Faculty, Complutense University, Madrid, Spain

²Geriatric Department, Hospital Central de la Cruz Roja, Madrid, Spain

³Older People Health Observatory directo, Villanueva de la Cañada, Spain

Background and objectives: Nonagenarian population, clearly increasing, shows different characteristics from the rest of elderly people. Health-related quality of life (HRQoL) is a way to study population health in physical, psychological and social dimensions. The aim of this study is to examine the relationship between nutritional status and HRQoL in free-living nonagenarians. The differences with younger elders (80-90 years) are also studied.

Methods: Within The Villanueva Older Health Study, 20 people (92.50±3.50 years; 80% women) make the nonagenarian subsample (whole sample: 83 non-institutionalised inhabitants >80 years, 53 women). HRQoL was assessed by EuroQoL-5D (EQ-5D) questionnaire, nutritional risk by Mininutritional Assessment (MNA) questionnaire and dietary intake by a 24-h dietary recall. Statistical significance was evaluated at 95% confidence level (p<0.05).

Results: No significant gender differences were seen in nutritional status (MNA) or HRQoL (EQ-5D) for nonagenarians. Problems in mobility dimension were more frequently reported (80%) and showed differences with the younger elderly (52.4%; p<0.05). Nonagenarians reported less anxiety/depression problems than the younger elders. According to MNA, 40% nonagenarians were at risk of malnutrition. Dietary assessment showed zinc, magnesium, potassium, folic acid, vitamin D and vitamin E deficiencies. In nonagenarians, EQ-5D index was associated with MNA (p=0.012). Self-care dimension was associated with calcium (p=0.043), niacin (p=0.022), retinol (p=0.005) and cholesterol (p=0.003) intake. Usual activities dimension was associated with niacin (p=0.002) and cholesterol (p=0.042). Pain/discomfort EQ-5D dimension was associated with protein (p=0.009), energy (p=0.05), selenium (p=0.032) and niacin (p=0.012) intake. Anxiety/depression was associated with protein (p=0.004) and selenium (p=0.017) intake.

Conclusions: Risk of malnutrition is a factor associated to HRQoL in nonagenarians. Results suggest that when energy and some nutrients intake increase, a better HRQoL is promoted although it does not seem to have a strong direct weight over it.

Key words: free-living nonagenarians, Health-related quality of life (HRQoL), EuroQoL-5D (EQ-5D), Mininutritional Assessment (MNA), dietary intake.

Acknowledgements: funded by Villanueva de la Cañada City Council.

PO751**PREGNANCY WEIGHT GAIN AND THE DETERMINANTS OF POSTPARTUM WEIGHT CHANGE AMONG GHANAIAI WOMEN**

J. Ankrach¹, A. Lartey¹, S. Adu-Afarwuah¹, E. Colecraft¹, M. Arimond², K. Dewey²

¹Department of Nutrition and Food Science, University of Ghana, Legon, Ghana

²Department of Nutrition, Program in Community and International Nutrition, University of California, Davis, USA

Background and objectives: The inability to return to pre-pregnancy weight after delivery contributes to obesity in women. This study sought to determine pregnancy weight gain and the predictors of postpartum weight change among Ghanaian women.

Methods: It involved 125 women aged 19-39 years who participated in the International Lipid-based Nutrient Supplements Project in the Manya and Yilo Krobo districts of Ghana. Weight was measured at recruitment (≤20 gestational weeks) and 36 gestational weeks. In addition to baseline weight and weight gain during pregnancy, data were also collected on other factors hypothesized or previously shown to be associated with weight retention, including age, parity, a proxy for socio-economic status, birth weight, energy intake, recall of activity and sleep, and breastfeeding practices. Multiple regression analysis was used to estimate factors significantly associated with maternal weight change from 1 to 6 months postpartum.

Results: In all, 116 women completed the study. Mean weight gain from enrolment to 36 gestational weeks was 6.7±3.4 kg (median 6.9 kg). Between 1 and 6 months, postpartum mean weight gain was 1.0±3.6 kg (median 0.7 kg). Weight gain was higher among women who were overweight at baseline, were unmarried, or had higher socio-economic status (p<0.05). There was a tendency for obese women to gain more (p=0.08) and for exclusively or predominantly breastfeeding women to gain less (p=0.07).

Conclusions: Postpartum weight retention and weight gain merit public health attention in Ghana, with special focus on women who enter pregnancy overweight or obese.

Key words: pregnancy weight gain, postpartum weight change, Ghanaian women. Funded by the Bill & Melinda Gates Foundation

PO752

FOOD FOR PRESCHOOLERS

S. Helland¹, E. Bere¹, N. Øverby¹

¹Departement of Public health, Sport and Nutrition, University of Agder, Kristiansand, Norway

Background and objectives: In Norway 11-16% of preschool children are overweight or obese. Diet in childhood is important for current and later weight development and health. To prevent obesity, literature reviews suggest that interventions should start early in life. The study Food for preschoolers aim to develop and implement an intervention directed towards preschool children, parents and kindergarten personnel, with the aim to improve children's food intake, prevent food neophobia and increase food joy and prevent development of obesity. The aim of this presentation is to describe the planned intervention.

Methods: Food for preschoolers includes a baseline study assessing selected dietary behaviors of preschool children, prevalence food neophobia and what is served in kindergartens. In total ten randomly selected kindergartens will be recruited for the intervention study, five in the intervention arm and five in the control group. Both parents and kindergarten personnel fill in questionnaires at baseline and after the intervention.

Results: The intervention is multi strategic. Children will be offered healthy Nordic food, experience food enjoyment, participate in food preparation and will be repeatedly exposed to specific food to promote acceptance. There will be a focus on children's empowerment in relation to appropriate portion sizes. Parents will be given information about responsive feeding, how to prevent food neophobia, the development of taste and importance of food enjoyment. The kindergarten personnel will make guidelines of how meals should be a central part of pedagogical work. They will also be educated in the Sape-re method on how to introduce children to varied diets and healthy eating in a hands-on way and make food a fun experience.

Conclusions: An intervention on obesity prevention in young age is developed with a focus on health through taste and food enjoyment. The intervention will be implemented in kindergartens autumn 2014

Key words: preschoolers, diet, neophobia

PO753

THE CONTRIBUTION OF NUTRITIONAL SUPPLEMENTS TO MICRONUTRIENT INTAKES IN IRISH PRE-SCHOOL CHILDREN AGED 1-4 YEARS.

F. Browne¹, J. Walton¹, A. Flynn¹

¹School of Food and Nutritional Sciences, University College Cork, Cork, Republic of Ireland

Background and objectives: There are currently no data available on nutritional supplement use in Irish pre-school children. The objective of the study was to investigate the intakes of micronutrients from all sources and contribution of nutritional supplements to micronutrient intakes in Irish pre-school children aged 1-4 years.

Methods: Analysis was based on the National Pre-School Nutrition Survey (NPNS) (2010-2011), which was carried out to establish a database of habitual food and drink consumption in a representative sample of 1-4 year old Irish pre-school children (n=500). A 4 day weighed food record was used to collect food intake data and analysis was carried out using WISP© (Tinuviel Software, Anglesey, UK), which is based on McCance and Widdowson's The Composition of Foods, Sixth Edition and the Irish Food Composition Database. The database was updated to include all nutritional supplements recorded by participants in the food diary. A supplement user was defined as respondent who consumed a nutrient containing supplement over the 4-day recording period.

Results: One fifth (20.2%) of those surveyed reported use of a nutritional supplement and of the 60 nutritional supplements consumed by pre-school children, 40% were multi-vitamins and mineral preparations, 28% were multivitamins, 12% were fish/cod liver oils, 12% were single vitamins, 5% were single minerals and 3% were multi-minerals. Nutritional supplements made a significant contribution to the intake of a range of micronutrients especially iron (18%), zinc (15%), retinol (46%), vitamin D (58%), biotin (33%), pantothenate (33%), vitamin B6 (32%), vitamins A and C (31%).

Conclusions: Nutritional supplements are consumed by one fifth of Irish pre-school children and made an important contribution to micronutrient intakes.

Key words: pre-school children, supplement use, dietary intake data The project was funded by the Irish Government under the Food for Health Research Initiative 2007-2012

PO754**FREQUENCY AND DETERMINANTS OF BREASTFEEDING IN A NATIONWIDE SAMPLE IN GERMANY**

L. Libuda¹, C. Mesch¹, M. Stimming¹, M. Kersting¹

¹Research Institute of Child Nutrition Dortmund, University of Bonn, Germany

Background and objectives: Breastfeeding is recognized as best nutrition in the first months of life. In Germany exclusive breastfeeding is recommended for at least 4 months. Major aim was to describe breastfeeding rates and determinants in a nationwide survey of mothers in Germany.

Methods: The survey was nested in the randomized controlled trial PINGU on fatty acid status optimization in infancy. Data derived from an existing panel for consumer surveys (Kantar Health GmbH). Thereof, mothers with children up to 36 months of age were selected for an online interview on mother's and children's dietary behaviour (field period: December 2010). Data of 985 mothers were weighted to ensure representativeness for mothers in Germany.

Results: In Germany, 78.3% of mothers initiated breastfeeding, 55.6% of all children were still exclusively breastfed at the age of 4 months. Both, the rates of breastfeeding initiation and exclusive breastfeeding at 4 months were significantly higher in high social classes compared with low social classes (initiation: 85.7% vs. 66.0%, $p=0.0001$; 4 month: 69.0% vs 35.7%, $p=0.0001$). Breastfeeding was initiated more frequently in first children than in later children (82.8% vs 74.2%, $p=0.001$), but exclusive breastfeeding at 4 months did not differ. In contrast, there were no differences in breastfeeding initiation according to mother's age, but a lower percentage of exclusive breastfeeding in younger compared with older mothers (50.7% vs 61.4%, $p=0.001$).

Conclusions: Rates of breastfeeding initiation is relatively high in Germany. However, only half of the mothers still exclusively breastfeed their children at the age of 4 months. Although rates of exclusive breastfeeding seem to have slightly improved since the last nationwide survey in 2005, mothers in lower social classes and also younger mothers still need support in breastfeeding.

Key words: breastfeeding, initiation, duration, determinants. Funded by the German Federal Ministry of Education and Research

PO755**UNDERWEIGHT, OBESITY AND DISABILITY IN ELDERLY COMMUNITY DWELLERS IN FRANCE: THE FRENCH NATIONAL DISABILITY AND HEALTH SURVEY, 2008**

M. Vernay¹, K. Castetbon¹

¹Nutritional Surveillance And Epidemiology Unit (USEN), Institut de Veille Sanitaire And Université Paris 13, France

Background and objectives: Underweight and obesity may constitute an important risk factor of disability in elderly. In France, epidemiological data on body mass index (BMI) among elderly are scarce at the national level. Objectives of this study were to describe the prevalence of underweight and obesity in free-living elderly in France and to investigate the association between disability and BMI categories, using data from the French Health and Disability Survey, a national interview survey, carried out in 2008.

Methods: Based on BMI (weight/height², self-reported data), the prevalence of underweight (BMI<21) and obesity (BMI≥30) were estimated in people aged 75 years or more. The association between disability (at least one restriction in activity of daily living, basic ADL or instrumental, IADL) and BMI categories, was analyzed separately by sex, using a multivariate logistic regression and taking into account the sampling design and the calibration process.

Results: Of the 4,296 participants included in the analyses (63.4% women), 14.9% [13.3-16.7] were underweight, including 5.5% [4.5-6.7] with severe underweight (BMI<19), the risk being higher in women than in men ($p<10^{-3}$). In addition, 14.6% [13.1-16.2] of elderly were obese, including 2.8% with severe obesity (BMI≥35), without gender difference. After adjustment for socioeconomic characteristics, a J-shape association was found between disability and BMI categories in men (ORa=2.7; $p=0.007$ for underweight and ORa=1.9; $p=0.005$ for obesity compared to the normal category). In women, the risk of disability increased with BMI categories (ORa=1.7; $p<10^{-3}$ for overweight and ORa=2.9, $p<10^{-3}$ for obesity).

Conclusions: Underweight and obesity are frequent among free-living elderly and associated with disability. Since populations of industrialized countries are rapidly ageing, these findings highlight the importance of maintaining a healthy nutritional status, at all ages for long-term survival and quality of life.

Key words: underweight, obesity, disability, free-living elderly, national

PO756**DIET AND NUTRITIONAL STATUS OF BREASTFEEDING WOMEN IN POLAND**

H. Mojska¹, E. Jasinska-Melon¹, I. Gielecinska¹

¹Department of Food and Food Supplements, National Food and Nutrition Institute, Warsaw, Poland

Background and objectives: Human milk is the first choice for newborns and infants. The World Health Organization recommends that infants should be exclusively breastfed for the first six months of life and then for up to two years of age or beyond, while infants receive nutritionally adequate and safe complementary foods. Although the effect of the breastfeeding mother diet on human milk composition has not been still well documented, a rational lactating women daily diet should provide right energy supply and contain all the necessary nutrients. The aim of our study was to estimate the composition of breastfeeding women diet and to compare the nutrients intake to the recommended food requirement.

Methods: The study involved 31 exclusively breastfeeding women from Warsaw, Poland in first six months of lactation. Energy and nutrients intake was estimated using 3-d dietary recall. To evaluate the quantity of nutrients in mother's diet the DIETA FAO 5.0 program was used which includes data for 1067 typical Polish dishes and foodstuffs.

Results: Mean energy content in breastfeeding women diet amounted 1942 kcal/person/day (range from 765 to 2871 kcal/person/day). Protein, fat, carbohydrates supplied accordingly 16.4% E, 33.2% E and 50.3% E. The average content of DHA+EPA reached 300 mg/person/day and covered the minimum DHA+EPA requirements during lactation. Compare to recommendations breastfeeding women diet characterized too high intake of fat, saturated fatty acids, sodium, phosphorus, iron, vitamin A and vitamin B2. Too low intake of calcium, potassium, foliate and vitamins E, B6 and C was observed.

Conclusions: Paediatricians and dieticians should give more attention to breastfeeding mothers diet to improve covering of recommended food requirements. The survey shows the necessity of a systematic education, which would be adapted to women's individual needs during lactation.

Key words: breastfeeding women, diet, nutrients

PO757**ESTIMATION OF INTAKES AND FOOD SOURCES OF SALT IN IRISH PRE-SCHOOL CHILDREN AGED 1-4 YEARS.**

M. Giltinan¹, M. Moloney¹, S. O'Flynn¹, J. Walton¹, A. Flynn¹

¹School of Food and Nutritional Sciences, University College Cork, Cork, Republic of Ireland

Background and objectives: High salt intakes in different population groups in Ireland have been previously reported. The objectives were to estimate mean daily salt intake and food sources in Irish pre-school children.

Methods: Analysis was based on the National Pre-School Nutrition Survey (2010/2011) which was carried out to establish a database of habitual food and drink consumption in a representative sample of Irish pre-school children (n=500) aged 1-4 years. A 4-day weighed food record was used to collect food intake data and analysis was carried out using WISP© (Tinuviel Software, Anglesey, UK) which is based on McCance and Widdowson's The Composition of Foods 6th edition and the Irish food composition database. The most up-to-date compositional data for sodium in foods available at the time of analysis were used. Under-reporters were excluded from the analysis.

Results: Salt intakes from food only (excluding discretionary salt) increased with age and mean daily intakes in 1, 2, 3 and 4 year olds were 2.4 g, 3.2 g, 3.4 g and 3.8 g respectively. Meat was the main contributor to salt intake accounting for 23-25% of total intake in 1-4 year olds. The contribution of cured/processed meats to salt intake increased with age from 12% in 1 year olds to 19% in 4 year olds, while the contribution of fresh meat/meat dishes decreased with age (10-6%). The contribution of bread to salt intake increased from 9% in 1 year olds to 13-14% in 3-4 year olds, while the contribution of milk decreased with age (19-7%).

Conclusions: Even when discretionary salt intake is excluded, salt intakes of Irish pre-school children exceed current target levels i.e. 2g/day for 1-3 year olds and 3g/day for 4-year olds.

Key words: salt, pre-school children, food sources The project was funded by the Irish Government under the Food for Health Research Initiative 2007-2012

PO758**ANEMIA AMONG FEMALE ADOLESCENT IN RELATIONSHIP WITH MALARIA, FOOD CONSUMPTION PATTERN AND SOCIO-ECONOMIC STATUS (SES) IN MAMUJU DISTRICT, INDONESIA**

A. Mursaha¹, N. Astuti², N. Jafar³

¹Center For Food, Nutrition And Health of Hasanuddin University, Indonesia

²Nurition Department of Medical Faculty, Hasanuddin University, Indonesia

³Nurition Department of Public Health Faculty, Hasanuddin University, Indonesia

Background and objectives: Anemia among adolescent especially female adolescent is one of the main nutrition problems in developing country. The aims of this study was to know factors contributing to anemia among female adolescent in malaria endemic area.

Methods: This study was a cross-sectional designed in household survey. This survey was conducted in a scope of District with 14 subdistricts. In each subdistrict was chosen one or more village which was done in cluster setting. There were 314 samples of female adolescent involved in this study. Data collection used questionnaire for demographic and socioeconomic data, anamneses was used to obtain the clinical symptoms of malaria, and sample blood for hemoglobin assessment was measured using Hb analyzer (Hemocue). Data analysis used SPSS version 16 and Food processor (Nutri Survey for windows). Bivariate analysis by chi-square test and multivariate by logistic regression.

Results: The study result showed the anemia prevalence was 29.9%. Anemia more prevalent in female adolescent with lack of food variation (33.6%) compared to enough of food variation (10.2%) ($p=0.001$). Respondent who had habit of breakfast had lower anemia (26.5%) than the unbreakfast (44.3%) ($p=0.006$). And the respondent who had clinical symptoms of malaria in the one last month almost twice higher had anemia (45.1%) than who had no clinical symptoms (27.0%) ($p=0.010$). Anemia also more prevalent in the respondent with low family income (32.5%) compared to the high family income (24.8%) ($p=0.156$). The multivariate analysis showed that factor with major contribution to anemia among female adolescent was food consumption pattern.

Conclusions: The food consumption pattern, breakfast, and clinical symptoms of malaria had association with anemia among female adolescent in endemic malaria area

Key words: anemia, female adolescent, malaria.

PO759**THE CONTRIBUTION OF FORTIFIED FOODS TO MICRONUTRIENT INTAKES IN IRISH PRE-SCHOOL CHILDREN AGED 1 TO 4 YEARS.**

A. Hennessy¹, J. Walton¹, A. Flynn¹

¹School of Food and Nutritional Sciences, University College Cork, Cork, Republic of Ireland

Background and objectives: Optimum micronutrient intakes are essential at all stages of life, particularly during early childhood. The addition of micronutrients to foods is a useful tool to improve nutrient intakes and reduce nutrient inadequacy in a population. The objective of the study was to investigate the contribution of fortified foods to micronutrient intakes in Irish pre-school children aged 1-4 years.

Methods: Analysis was based on the National Pre-School Nutrition Survey (NPNS), which was carried out between 2010 and 2011 to establish a database of habitual food and drink consumption in Irish pre-school children ($n=500$). A 4-day weighed food record was used to collect food intake data. Analysis of dietary intake data was carried out using WISP (Tinuviel Software, Anglesey, UK) which is based on McCance and Widdowson's The Composition of Foods, Fifth and Sixth editions and the Irish Food Composition Database. The database was updated to identify all fortified foods recorded (12.7% of the 1652 foods consumed) by participants in the food diary. For the purpose of this research, a fortified food is one in which one or more micronutrients were added to enhance the nutritive value of the food.

Results: Among the participants of the NPNS, 97% reported consuming a fortified food at least once during the recording period. In the total population, fortified foods were found to contribute significantly to intakes of micronutrients relative to their contribution to energy intake (17%), particularly for iron (39%), vitamin D (39%), folate (35%), thiamin (33%), riboflavin (32%), total niacin (24%) and calcium (23%).

Conclusions: Fortified foods are widely consumed by Irish pre-school children and make a significant contribution to micronutrient intakes in this population group.

Key words: fortified foods, pre-school children, micronutrient intakes. The project was funded by the Irish Government under the Food for Health Research Initiative 2007-2012.

PO760**GLUTEN FREE DIET HAS LOW IMPACT IN ANTI-GLIADIN ANTIBODY LEVELS IN BREAST MILK OF NURSING MOTHERS**

M. Roca¹, M. Bolonio¹, D. Hervás², E. Donat³, B. Polo³, E. Masip³, G. Castillejo⁴, E. Martínez-Ojinaga⁵, M. C. Mena⁶, I. Polanco⁵, C. Ribes-Koninckx³

⁵S. Gastroenterología Pediátrica, Hosp. Infantil La Paz, Madrid, Spain

⁶Centro Nacional de Biotecnología, Consejo Superior de Investigaciones Científicas, Madrid, Spain

Background and objectives: To study antigliadin antibodies (AGA) in breastmilk (BM) and to analyse their relationship with maternal diet, and the potential relationship with the development of celiac disease (CD) in their offspring.

Methods: Samples of mature milk were obtained at different months of lactation (1-32 m) from 23 mothers: 12 on a normal diet (ND) and 11 on a gluten-free diet (GFD) (coeliac mothers). We analyzed Secretory AGA-IgA (S-AGA) and AGA-IgA by indirect homemade ELISA. Total IgA (g/L) was measured in BM using Bethyl Laboratories ELISA kit.

Results: AGA levels vary from one mother to another, however in each mother, from the first month of lactation onwards, results show scarce variability. S-AGA and AGA-IgA were detected in BM, both in mothers on a GFD and mothers on a ND. The comparison of the estimated kernel density curves for S-AGA showed a difference between both groups, with slightly lower values for mothers on GFD. Similar results were obtained for AGA-IgA. However differences between the 2 groups of mothers did not reach statistical significance (repeated measures ANOVA, S-AGA $p=0.12$, AGA-IgA $p=0.16$); these results suggest however this was related to the low sample size: 106 observations of 23 individuals. Total IgA values varied between 0 and 1 g/L in most individuals (median 0.66 g/L and interquartile range [0.44; 0.94]). We observed a great variability among mothers, some cases showing unusually high values. To assess the relationship between IgA and the other variables, a linear mixed model approach was used. The model including S-AGA instead of AGA-IgA had a considerably higher AICC (229.2 vs 235.7), indicating that a positive association exists between levels of AGA and total IgA.

Conclusions: AGA was present in all BM samples, independently of mother's diet. Thus breastfeeding is a way of transferring antibodies to the baby, so this practice could be relevant for CD prevention in breastfed infants.

Key words: breastmilk, antigliadin antibodies, gluten-free diet.

PO761**PREVENTING ACUTE MALNUTRITION AMONG CHILDREN AGED 6 TO 23 MONTHS IN NIGER: EFFECT OF SUPPLEMENTATION AND CASH TRANSFER**

C. Langendorf¹, T. Roederer¹, S. de Pee², D. Brown³, S. Doyon⁴, A. Mamaty⁵, L. W. M. Toure⁵, M. L. Manzo⁶, R. F. Grais¹

¹Epicentre, Paris, France

³World Food Programme, Niamey, Niger

⁴Médecins Sans Frontières, Paris, France

⁵Epicentre, Niamey, Niger

⁶Regional Department of the Ministry of Public Health, Maradi, Niger

Background and objectives: Choosing the most appropriate strategy for the prevention of childhood acute malnutrition is essential in countries like Niger that face annual hunger gaps. Although fortified-blended foods and ready-to-use supplementary foods (RUSF) are effective options for large-scale preventive distributions, the role of cash transfers as a direct nutritional intervention in these contexts requires further investigation. Here, we compare different preventive strategies on the incidence of acute malnutrition and mortality among children between 6-23 months.

Methods: Exhaustive open observational cohorts including all children 60cm to 80cm, resident in 18 villages of Madarounfa, Niger over two years. Three different strategies of monthly distributions were assessed: 1) RUSF (500 kcal/d during the hunger gaps and 250 kcal/d in-between); 2) Super Cereal Plus (SC+) (800 kcal/d during the hunger gaps and 400 kcal/d in-between) and 3) cash transfer to all households with a child in the target group (43 €/month) during the first hunger gap. All children had access to the same primary health care package. Anthropometric and clinical data were collected monthly. Endpoints included wasting (WLZ < -2) and mortality.

Results: A total of 1,591 children were included in August 2011. At 5-months of follow-up, there was no difference in the incidence of wasting between cash transfer and RUSF (ref) groups (HR=1.09, 95%CI:0.89-1.33); as well as between cash

transfer and SC+ (ref) groups (HR=1.08, 95%CI:0.86-1.36). Over 15 months, incidence of wasting was similar between SC+ and RUSF (ref) groups (HR=1.09, 95%CI:0.98-1.22), as well as mortality (HR=1.04, 95%CI:0.63-1.72).

Conclusions: In a region with high acute malnutrition, 15-month supplementation with SC+ or RUSF has a similar effect on severe wasting and mortality prevention among young children. When the primary aim is to prevent malnutrition among this population, special nutritious foods may be more cost-effective than cash transfer.

Key words: Malnutrition prevention, fortified-blended food, ready-to-use-supplementary food, cash transfer, Niger

PO762

THE PROPOSAL OF A FOOD RATION FOR SOLDIERS SERVING IN POLISH SPECIAL OPERATION FORCES

P. Kler¹, D. Spychała¹, A. Nowosad¹, A. Kosińska-Każmierczyk¹, A. Bębnowicz¹, B. Bertrand¹, A. Kłos², R. Łakomy², J. Bertrand²

¹Military Research & Deployment Center For Food Services, Warsaw, Poland

²Department of Hygiene and Physiology, Military Institute of Hygiene and Epidemiology, Warsaw, Poland

Background and objectives: Training and combat activities carried out by soldiers of Polish Army Special Operation Forces in various climate and terrain conditions, at different times of a day are huge and sometimes even extreme physical exertion. The aim of the work was to work out a proposal of food ration for soldiers serving in the Polish Special Operation Forces. Total of 22 soldiers from the exclusive special military unit "GROM", taking part in the half-year preparatory training course to carry out combat operations, underwent the examination. The average age of the subjects was 30.1 years old.

Methods: Assessment of energy expenditure was based on measurements by the Polar Sport Tester 810 heart rate monitor.

Results: It was found that during 7 hours of combat training energy expenditure amounted to 1672 kcal, what was the base to determine the minimum energy value of a food ration. Based on the obtained results the food rations for soldiers serving in the special operations units and performing tasks in situations when there is lack of access to food of energy value of 1600, while protein should provide 15-25% of the energy value, carbohydrates 45-65%, and fat not more than 35% of the total energy. Based on the above assumptions, a model food ration was worked out. It consists of tinned meat and vegetable, dried beef, biscuits, a mixture of freeze-dried fruit, grain-fruit bar, coated peanuts, bitter chocolate, candy with natural coffee

extract, caramels, chewing gum with xylitol and accessories necessary to prepare and eat the meal.

Conclusions: In this set of products 15% of energy value comes from protein, 34% from fat, and 51% are provided by carbohydrates.

Key words: special forces, energy expenditure, combat rations

PO763

INFLUENCE OF GESTATIONAL DIABETES ON CHILDREN'S CIRCADIAN RHYTHMS AND THEIR ASSOCIATION WITH BOTH FETAL ADIPOSITY AND N-3 FATTY ACIDS

M. Zornoza-Moreno¹, S. Fuentes-Hernández¹, M.T. Prieto-Sánchez², J.E. Blanco², A. Pagán³, J.J. Parrilla², J.A. Madrid³, M. Sánchez-Solis¹, E. Larqué³

¹Pediatric Service, Virgen de la Arrixaca University Hospital, Murcia, Spain

²Obstetrics and Gynecology Service, Virgen de la Arrixaca University Hospital, Murcia, Spain

³Physiology Department, University of Murcia, Spain

Background and objectives: To analyze the circadian rhythm maturation of temperature, activity and sleep during the first year of life in offspring of diabetic mothers (ODM) and their relationship with fatty acid profile and obesity markers.

Methods: A prospective analysis of the children of 63 pregnant women (23 controls, 21 gestational diabetes mellitus (GDM) controlled with diet and 19 GDM with insulin). Fetal abdominal circumference was evaluated ecographically during gestation. Blood samples from the mother during the 3rd trimester and cord blood were collected for fatty acid analyses. Skin temperature and rest-activity rhythms were monitored for 3 consecutive days in children at 3 and 6 months of age. Anthropometrical parameters of the children were evaluated during the first year of life.

Results: Children from the GDM groups tended to higher fetal abdominal circumference z-score than controls at the beginning of the last trimester (p=0.077) and delivery (p=0.078). Mean skin temperature, activity and sleep were not different among the groups. However, some of the parameters that define temperature maturation and also the circadian function index (CFI) from sleep, were significantly lower at 6 months in the GDM+insulin group. Fetal abdominal circumference z-score, as a predictor of fetal adiposity, correlated negatively with the circadian/ultradian temperature rhythm (P1/Pult ratio) and CFI of sleep at 6 months (r=-0.277, p=0.037). Maternal docosahexaenoic acid (DHA) at both recruitment and at delivery was positive correlated with the circadian periodicity

of temperature at 3 months (P1/Pult) and with sleep rhythm maturation (CFI) at 6 months ($r=0.3$, $p=0.038$).

Conclusions: Fetal adiposity correlated with a worse circadian rhythm regulation in ODM while maternal DHA levels were associated with higher sleep rhythm maturation in the children. In addition, ODM insulin-treated showed a disturbed pattern of the CFI of temperature-activity at 6 months of age.

PO764

COMPARATIVE ASSESSMENT OF CHILDCARE PRACTICES, NUTRITIONAL AND DEVELOPMENTAL STATUS OF UNDER-FIVE ORPHANS AND NON-ORPHANS IN IBADAN SOUTH-WEST, NIGERIA

G. Fadupin¹, B. Atibioko¹

¹Department of Human Nutrition, University of Ibadan, Ibadan, Oyo state, Nigeria

Background and objectives: Some under-five children are more vulnerable than others due to loss of their parents, thus are deprived of basic childcare practices. This study evaluated the childcare practices, nutritional and developmental status of under-five orphans and non-orphans in Ibadan, Nigeria.

Methods: The cross sectional study was carried out using multistage sampling technique (two stages) to select 30 orphans and 60 non-orphans. Pretested, interviewer-administered questionnaire was used to collect information on the socio-demographic characteristics of the caregivers/mothers/index child and childcare practices. Nutritional status was assessed using anthropometric indices and developmental status was assessed using Developmental Assessment of Young Children (DAYC) questionnaire. Data were analyzed using descriptive statistics; chi square was used to test for association between variables.

Results: Mean age of the orphans and non-orphans was 51 ± 23 months and 50 ± 23 months respectively. High proportion (93.3%) of the orphans and (96.7%) non-orphans had adequate childcare practices. More (10.0%) orphans were wasted, 9.0% stunted and 4.0% underweight than 6.7% non-orphans that were wasted, 6.7% stunted and none was underweight. More than half (56.7%) of the orphans had average while 3.3%, 26.7%, 10.0% had, very poor, poor and below average developmental quotient remarks respectively. Majority (60.0%) of the non-orphans scored above average, 15.0% scored superior remarks while none of the non-orphans scored very poor, poor or below average developmental quotient remarks. No significant relationship was observed between the childcare practices and nutritional status of the orphans and non-orphans ($p>0.05$).

However, significant relationship was observed between their nutritional and developmental status ($p<0.05$).

Conclusions: The childcare practices given to the orphans was adequate, majority had good nutritional and developmental status. However, the non-orphans received more adequate childcare practices and also had better nutritional and developmental status than the orphans.

Key words: childcare practices, nutritional status, developmental status, under-five orphans and non-orphans, Nigeria

PO765

INFLUENCE OF GLUTEN-FREE AND NORMAL DIET ON GLUTEN CONTENT IN BREAST MILK.

M. Mena¹, M. Lombardía¹, M. Roca², C. Ribes-Koninkx², J. Albar¹

¹Servicio de Proteómica, Centro Nacional de Biotecnología, Consejo Superior de Investigaciones Científicas, Madrid, Spain

²Unidad de Gastrohepatología Pediátrica, Fundación Hospital La Fe, Valencia, Spain

Background and objectives: Breastfeeding has several beneficial effects both for the child and the mother, including a potential positive effect in celiac disease, diminishing the incidence or delaying onset of symptoms. Gluten intake through breast milk might contribute to these effects modulating the immune system and promoting an oral tolerance against gluten in the new-born. Therefore the aim of this study is to quantify gluten content in human milk and to compare the influence of diet on it in celiac and non-celiac mothers.

Methods: Mature human milk samples were analyzed in healthy mothers following a non-restricted gluten diet and celiac mothers on gluten-free diet, using the immunoassays Sandwich and Competitive R5 ELISA. These assays were optimized to achieve a complete gluten extraction avoiding antibodies and other interference components present in the milk.

Results: We observed a wide variability in results mainly when using the Competitive R5 ELISA. Most of the analyzed samples had a quantifiable content, ranging from 83 to 508 ng/mL of gliadins in celiac mothers and 60 to 386 ng/mL of gliadins in non-celiac mothers but without any statistically significant differences between the two groups. Using the Sandwich R5 ELISA, we found values ranging from 19 to 37 and 6 to 21 ng/mL of gliadins in the celiac and non-celiac group respectively. The differences found between the two assays are the expected ones as the Competitive system leads to quantify not only intact gliadins but also fragmented and small proteins.

Conclusions: These results demonstrate that there are quantifiable amounts of gluten in human milk samples but very

near to the limit of sensitivity of the techniques used, therefore, the precision of the values might not be accurate enough and further research is needed to optimize the analysis.

Key words: breastfeeding, gluten, human milk, celiac disease

PO766

COMPLEMENTARY FEEDING PRACTICES OF A PERI-URBAN SOUTH AFRICAN COMMUNITY: A SNAP SURVEY USING THE WHO-2010 QUESTIONNAIRE

N M. Covic¹, M. Rothman¹, R. Moreosteny¹, C. Berti¹, J C. Johann¹, H S. Kruger¹, M C. Smuts¹

¹Centre of Excellence For Nutrition, North-West University, Potchefstroom, South Africa

Background and objectives: Poor and sub-optimal feeding practices contribute to Infant and young child malnutrition in developing countries. In the context of the Scaling-Up-Nutrition movement quick and cost effective methods to monitor/evaluate complementary feeding practice trends over time are needed to inform programme activities. The aim was to conduct a cross-sectional survey of complementary feeding practices in a peri-urban South African community to provide a snapshot of current complementary feeding practices to inform a community intervention study.

Methods: It was an observational study using the WHO-2010 breastfeeding and complementary feeding practices questionnaire. Mothers/caregivers (n=102) of infants 6-12 months were recruited on growth monitoring days at all five clinics serving the community.

Results: Eighty three percent of mothers (n=96) reported being unemployed. Although some positive feeding practices were observed many were not ideal. 57 and 53% of infants were reported breastfed the previous day for 6-8 (n=53) and 9-12 (n=49) month old infants, respectively. Sugar water was given to 52 and 35% of infants 6-8 and 9-12 month olds, respectively. The number of times specific food items were reported given was also not ideal. Rooibos tea was given at least once the previous day for 40% of all infants (30% of 6-8 and 51% of 9-12 month olds, respectively).

Conclusions: Low nutrient dense drinks were offered to a large proportion of the infants. Such snap surveys can provide useful information on complementary feeding practices to inform interventions and/or monitor trends at community level.

Key words: complementary feeding, community nutrition, community nutrition evaluation

PO767

NUTRITIONAL STATUS ASSOCIATION WITH MOBILITY OF NON-INSTITUTIONALIZED ELDERLY PEOPLE

S. Jiménez-Redondo¹, B. Beltrán de Miguel¹, J. Gavidia Banegas², L. Guzmán Mercedes², J. Gómez-Pavón^{2,3}, C. Cuadrado Vives¹

¹Department of Nutrition, Pharmacy Faculty, Complutense University, Madrid, Spain

²Geriatric department, Hospital Central de la Cruz Roja, Madrid, Spain

³Older People Health Observatory director, Villanueva de la Cañada, Madrid, Spain

Background and objectives: Vulnerability to adverse outcomes evaluation is very relevant in the elderly to be able to prevent them. The aim of this study is to explore associations between nutritional status, risk of falls and mobility amongst free-living elderly.

Methods: Within The Villanueva Older Health Study, 73 (85.5±4.4 years; 44 women) non-institutionalised elders (>80 years) could achieve physical performance tests. Geriatric assessment tools used were: occurrence of falls in previous 6 months, physical performance (Usual gait speed (UGS-4m) and Timed Up-and-Go test (TUG)), nutritional risk (Mininutritional Assessment questionnaire, MNA) and dietary intake (24-h dietary recall). Statistical significance was evaluated at 95% confidence level (p<0.05).

Results: 19 participants (26%) fell in previous 6 months with no significant gender differences. TUG test (11.8±4.9 men and 15.9±7.3 women; p=0.007) classified 37% as normal mobility (<10 s), 46.6% frailty (10-11 s), 13.7% risk of fall (20-30 s) and 2.7% high risk of falls (>30 s). UGS test (0.7±0.4 men and 1.3±1.2 women; p=0.007) pointed out a slow UGS, <0.8 m/s, in 42.5% sample. MNA (27.1±2.0 men and 24.7±3.2 women; p<0.001) showed malnutrition in 2.3% women, and risk of malnutrition in 9.1% men and 40.0% women. Total sample showed folic acid, zinc, magnesium, vitamin A, D and E dietary deficiencies. MNA was associated with occurrence of falls (p=0.001), TUG test (p=0.007) and UGS test (p=0.048). Occurrence of falls in previous 6 months showed no association with TUG or UGS. TUG was negatively associated with vitamin B1 (p=0.018) and AGM intake (p=0.048) (oleic acid, p=0.049).

Conclusions: Being at risk of malnutrition, measured by the MNA, is associated with higher frequency of falls and impaired mobility in elderly people (>80 years). Nutrients intake little influence on TUG is observed.

Key words: risk of falls, timed up and go test (TUG), usual gait speed (UGS), mininutritional Assessment (MNA), dietary intake.

Acknowledgements: funded by Villanueva de la Cañada City Council.

PO768**PROPOSAL FOR INTERNATIONAL NUTRIENT GUIDELINES FOR MEALS FOR ELDERLY IN INSTITUTIONS***M. Dötsch-Klerk¹, A. Eilander¹*¹Unilever R&D Vlaardingen, The Netherlands

Background and objectives: Under-nutrition, often featured by underweight and/or involuntary weight loss, is a frequent and serious problem in institutionalized elderly. Providing more nutritious meals in elderly institutions can help to prevent under-nutrition. The objective of this research was to develop science-based globally applicable nutrient guidelines for meals for institutionalized elderly.

Methods: FAO/WHO recommendations for total daily diets for people over 60 years were translated into nutrient guidelines for meals. Specific guidelines were developed for energy, protein, carbohydrate and fat (quality), of which energy and protein are most critical in elderly. Fibre is also included as constipation is a very prevalent problem in elderly. For the micronutrients it was decided to focus on vitamin B12, vitamin D and calcium, which are the most critical micronutrients because of inadequate intake and/or decreased absorption. Sodium is also included as sodium intake in many populations worldwide, including the elderly, is much higher than recommended.

Results: In line with available recommendations, it was assumed that a meal should provide 30% of the total daily energy intake. Energy requirements were calculated using the appropriate basic metabolic rate equations and an average physical activity ratio of 1.5. Subsequently, guidelines for macronutrients were deduced from the energy guidelines. For micronutrients, the guidelines were set at 30% of total daily recommendation, in line with the energy guidelines.

Conclusions: The nutrient guidelines for meals can be used as basic guidelines to prevent under-nutrition in elderly living in institutions. Specific disease states that may influence nutrient requirements are out of scope of these guidelines. Although guidelines were developed for global application, feasibility and implementation may depend on differences between countries with respect to dietary habits, affordability and local food composition. This needs to be further explored.

Key words: under-nutrition, elderly, guidelines

PO769**EFFECT OF TIMED AND TARGETED COUNSELING (TTC) IN CHANGING INFANT AND YOUNG CHILD FEEDING PRACTICES IN SOUTHERN ETHIOPIA***K. Reider¹, M. Beyero², Y. Mekonnen³*¹World Vision US, Washington, DC, USA²World Vision Ethiopia, Addis Ababa, Ethiopia³Mela Research PLC, Addis Ababa, Ethiopia

Background and objectives: Peer Mothers were trained to counsel pregnant women and mothers of children under 2. The objective of the study was to evaluate changes in infant and young child feeding (IYCF) practices resulting from their counseling visits delivering age-appropriate messages on breast feeding and complementary feeding to mothers of children 0 to 18 months after two years of project implementation.

Methods: The evaluation used a quasi-experimental study design in four intervention and four control districts. The sample size included 1600 children with 800 mothers interviewed from each of the intervention and control districts i.e. 400 for 0 to 5.9 months and 400 for 6 to 23.9 months group. Individual interviews and focus groups discussions were also conducted.

Results: Initiation of breast feeding within one hour of birth increased from 65.5% to 75.2% ($p < 0.05$); colostrum feeding increased from 71.2% to 83.0% ($p < 0.0001$); exclusive breast feeding increased from 57.9% to 82.8% ($p < 0.05$) in the intervention areas after adjusting for women's education, age, religion, number of children ever born, and economic status. Minimum dietary diversity (MDD) increased from 7.2% to 10.0% ($p < 0.0001$); minimum acceptable diet (MAD) increased from 5.0% to 7.5% ($p < 0.0001$); Both MDD and MAD significantly improved compared with the control area at end line. Stunting decreased from 32.3% to 29.0% ($p > 0.05$) but was not statistically significant.

Conclusions: Age-appropriate counseling is an effective way of improving IYCF practices in rural Ethiopia. Dietary diversity remains a challenge and the changes in stunting are gradual and need longer intervention period than 2 years.

Key words: peer counseling, breastfeeding, complementary feeding

PO770**DIETARY INTAKE OF ANTIOXIDANTS AND INADEQUACIES IN DIET IN PREGNANT WOMEN IN SPAIN: INMA-ENVIRONMENT AND CHILDHOOD COHORT**

M. Villar-Vidal¹, P. Amiano^{1,2,3}, L. Santa Marina^{1,2,3}, J. Vioque^{3,6}, E. Navarrete³, C. Rodriguez-Bernal⁴, A. Tardon^{3,5}, A. Fernandez-Somoano⁵, D. Romaguera⁷, V. Dmaskini⁷, J. Ibarluzea^{1,2,3}

³CIBER de Epidemiología y Salud Pública (CIBERESP), Spain

⁴Centro Superior de Investigación en Salud Pública, CSISP, Valencia, Spain

⁵University of Oviedo, Spain

⁶Department of Public Health, Miguel Hernández University, Alicante, Spain

⁷Center for Research in Environmental Epidemiology (CREAL), Barcelona, Spain

Background and objectives: There is increasing evidence that optimal intakes of antioxidants could promote health benefits during pregnancy and lactation and in newborn infants. Therefore dietary guidelines for pregnant women gather nutritional requirements for the consumption of antioxidant rich foods such as fruits, vegetables and nuts which are frequent in the Mediterranean areas. However, there is little evidence on the degree of compliance with such recommendations in Spain.

Methods: Population of study was the Spanish "INMA-Environment and Childhood Cohort" which recruited 2585 from two Mediterranean regions (Sabadell and Valencia) and two Northern regions (Gipuzkoa and Asturias) between 2004-2008. We assessed intake from foods during the first trimester of pregnancy through a Food Frequency Questionnaire (FFQ). Vitamin A, vitamin C, vitamin E and carotenoids were calculated from specific Food Composition Tables (FCT). All estimated intake were adjusted using the energy residual method. For compliance we used the pregnancy-specific recommendations of the Spanish guidelines.

Results: Percentage of women that did not reach the minimum recommendation for fruit intake (2-3 servings/day) was 39.2% and a 47.3% for vegetables (2-4 servings/day). Their intake increased with age, physical activity and with educational degree ($p < 0.05$). Percentage of pregnant women that did not fulfil the requirements of Spanish guidelines (Dietary Recommended Intake, DRI) was 13.2 % for vitamin A (700 µg/day) and 16.2 % for vitamin C (80 mg/day), nevertheless more than 80% of the women had inadequacy of vitamin E (15 mg/day).

Conclusions: Age, education and physical activity as well as country of origin are factors significantly related to dietary intake. Young, more sedentary women and those with a low education are at risk for insufficient antioxidant-rich foods intake and non-optimal food choices during pregnancy.

Key words: Pregnancy, antioxidants, compliance

PO771**SCHOOL MEALS BASED ON NEW NORDIC DIET IMPROVE READING PERFORMANCE IN DANISH 4TH GRADE CHILDREN –THE OPUS SCHOOL MEAL STUDY**

C B. Dyssegaard¹, L B. Soerensen², A. Astrup², K F. Michaelsen², N. Egelund¹

¹Centre for Strategic Research in Education and Competence, Aarhus University, Copenhagen, Denmark

²Department of Nutrition, Exercise and Sports, University of Copenhagen, Copenhagen, Denmark

Background and objectives: Diet is hypothesised to influence cognitive function and school performance, but few studies have investigated the effect of healthy school meals. New Nordic Diet (NND) is rich in foods such as fish, whole grain, fruits, vegetables and nuts. The OPUS project "Optimal well-being, development and health for Danish children through a healthy New Nordic Diet" was supported by a grant from the Nordea Foundation. This study investigates if school meals based on NND improved concentration, math and reading skills in 8-11-year-old children.

Methods: OPUS School Meal Study was a cluster-randomized controlled cross-over study. 3rd and 4th grade children from 9 Danish schools received school meals based on NND and their usual packed lunch (control) for 3 months each. At baseline and at the end of each period children completed the D2-test of attention and age-appropriate tests of math and reading. Six-hundred-and-sixty-eight children with data from baseline and at least one post-intervention measurement were included. Linear mixed models with adjustment for age, gender, grade, month, household educational level, order of diets and relevant random effects (school, class and individual) were used.

Results: At baseline concentration performance was 130.5±22.7 [54-204] (mean±SD [range]) and the number of correct answers in math and reading tests were 32.1±11.2 [0-62] and 51.9±17.5 [9-106], respectively. The school meals improved reading performance with 3.3 correct sentences ($p < 0.001$) in 4th grade, but there was no effect in 3rd grade ($p = 0.422$). NND had no effect on concentration performance ($p = 0.609$) or math performance ($p = 0.966$).

Conclusions: School meals based on the New Nordic Diet improved 4th grade reading performance, which is a fundamental skill and a prerequisite for learning in most subjects. The difference between 3rd and 4th grade, may be caused by differences in compliance to school meals.

Key words: New Nordic Diet, school meals, child, cognition

PO772

INFANT AND YOUNG CHILD FEEDING PRACTICES IN VULNERABLE COMMUNITIES IN THE BREEDE VALLEY, WESTERN CAPE PROVINCE, SOUTH AFRICA

L. Du Plessis¹, M. Herselman¹, M. McLachlan¹, H. Nel²

¹Division of Human Nutrition, Faculty of Medicine And Health Sciences, Stellenbosch University, Cape Town, Western Cape, South Africa

²Department of Logistics, Stellenbosch University, Stellenbosch, Western Cape, South Africa

Background and objectives: The UNICEF Programming Guide (2011) recommends that the revised Indicators for Assessing Infant and Young Child Feeding (IYCF) practices (2008) be used for situation assessments in the development, planning and implementation of a comprehensive approach to improving IYCF. The Community Nutrition Security Project (CNSP) investigated the food security situation in two vulnerable communities in the Breede Valley. This project provided an opportunity to assess IYCF practices at household level. The aim of the present study was to describe the feeding practices of infants and young children aged 0-36 months based on WHO validated indicators in two vulnerable communities.

Methods: A descriptive cross-sectional baseline assessment was conducted on a representative population sample. A simple random selection of households resulted in the inclusion of 400 mother/infant pairs. Data on IYCF practices was gathered with an interviewer-administered questionnaire including 10 questions based on the WHO indicators.

Results: Mothers reported initiating breastfeeding early, i.e. putting the baby to the breast within one hour after birth, in 74% (n=242/327) of children 0-23 months of age. Fifty four percent (n=66/122) of the infants were recorded as being exclusively breastfed (EBF) between the ages of 0 and 6 months. However, cross-checking this data against the CNSP dataset, suggests significant over-reporting of EBF. This figure probably better reflects predominant and partial breastfeeding. Breastfeeding was continued in 32.5% (n=13/40) of babies (12-15 months). Eighty four percent (n=36/43) of infants (6-8 months) received solid, semi-solid or soft foods. Fifty three percent (n=108/205) of children (6-23 months) received foods from 4 or more food groups (minimum acceptable diet).

Conclusions: This IYCF profile suggests sub-optimal IYCF practices. While further validation of the data is required, the assessment can serve to inform stakeholders about IYCF problems and engage them in a multi-stakeholder process to jointly plan scaling up actions for improved IYCF.

Key words: children, feeding, indicators

PO773

FLUID CONSUMPTION OF YOUNG ELITE BASKETBALL PLAYERS

M. Vukasinovic-Vesic¹, N. Dikic¹, I. Baralic¹, T. Antic¹, M. Andjelkovic¹

¹Sports Medicine Association of Serbia, Belgrade, Serbia

Background and objectives: Lack of adequate intake of adequate fluid, as a consequence, can have weakening and reduction of sport performance. It is necessary, during physical activity, to get enough quantity of liquid because of: body temperature regulation, heart work and maintaining of blood pressure and circulation, muscle function, functioning of the gastrointestinal system, maintaining of the mental reasoning, maintaining motivation for training and sport success, preventing of subjective feeling of tiredness and fatigue.

Methods: Within the scope of the large research FIBA Europe Under 20 European Championship B division, we analyzed drinks consumed by 96 basketball players from 8 national teams. We analyzed composition of each drink they have been used during the games. Also, the quantity of liquid that was taken in was measured together with the Urine specific gravity (Usg) at the end of the game.

Results: Players age was 19±0.79 years. Total fluid intake was: 1868±816 ml (range 435-3987), sweat rate 2.7±0.9 L/h (range 5.54-1.16), Usg after the game 1026±6, average intake of water 1226 ml and average intake of sport drinks 273 ml. Sport drinks had an elevated composition of sodium and carbohydrates. One of the team due to an incorrect solution used 10% of the values suggested by the producer. We found out that players did not consume sufficient fluid to match sweat losses and 80% of all players who participated in this study were dehydrated.

Conclusions: The total quantity of liquid intake is insufficient. Undoubtedly, it is necessary to use a greater quantity of sports drinks with an adequate composition to accomplish proper rehydration. It is necessary to introduce coaches, team doctors and athletes through adequate education with the importance of proper hydration and use of sports drinks as a means of rehydration.

Key words: sport drinks, water, hydration

PO774**A CRITICAL ANALYSIS OF THE LABELS OF PROCESSED COMPLEMENTARY FOODS IN SOUTH AFRICA AGAINST INTERNATIONAL MARKETING GUIDANCE**

L. Sweet¹, J. Jerling¹, A. van Graan¹

¹Centre of Excellence for Nutrition, North-West University, South Africa

Background and objectives: Complementary food labels should protect and promote optimal infant and young child feeding practices and provide information regarding appropriate use. Objective: To describe the extent to which the labelling practices of processed complementary food sold in South Africa comply with international guidance on the marketing of complementary foods that is aligned with the principles of the International Code of Marketing of Breast-milk Substitutes (the Draft Guide for Marketing Complementary Foods).

Methods: Employing a cross-sectional study design, a comprehensive database of labels was created of products sold from June to August 2011. Label information was captured, then blinded and the order of products randomised. The Draft Guide was used to create a checklist against which the captured labelling practices were analysed.

Results: One hundred and sixty product labels of 35 manufacturers were analysed, none of which complied with all checklist criteria. Fifty-six (35%) labels did not provide an appropriate age of introduction, while 37 (23%) used images of infants appearing younger than six months. Eight (5%) labels recommended feeding the product in a bottle. Nineteen (12%) labels suggested a daily ration too large for a breastfed child, and 32 (20%) potentially promoted the manufacturer's infant formula. One hundred and two (64%) labels were not easy to read. A small number (4% and 6%) of labels failed to provide instructions for safe and appropriate preparation/use and storage respectively.

Conclusions: The labelling practices of processed complementary food labels in South Africa do not fully comply with international guidance. Such guidance must be refined and formalised by normative bodies and adopted into national legislation to contribute towards safe and appropriate use of processed complementary foods.

Key words: complementary food, food labelling, breastfeeding, infants, young children.

PO775**OXIDATIVE STRESS DURING PREGNANCY AND LOW BIRTH WEIGHT**

N. Aranda¹, M. Romeu², M. Giralt², R. Nogues², B. Ribot¹, V. Arijó^{1,3}

¹Unitat de Nutrició i Salut Pública, Grupo de Investigación en Nutrición y Salud Mental (NUTRISAM), Institut d'Investigació Sanitària Pere Virgili (IISPV), Universitat Rovira i Virgili, Reus, Spain

²Unitat de Farmacologia, Facultat de Medicina i Ciències de la Salut, Universitat Rovira i Virgili, Reus, Spain

³Unitat de Suport a la Recerca (USR) Reus-Tarragona, Institut d'Investigació en Atenció Primària, Jordi Gol i Gorina

Background and objectives: High iron levels during pregnancy could induce oxidative stress that can negatively influence the development of the foetus. Our objective was to analyse the relationship between iron levels and oxidative stress during pregnancy and low birth weight (LBW).

Methods: Case-control study nested in a longitudinal study conducted on 208 healthy pregnant women taking moderate iron supplementation and their newborns. Women were classified according their infant birth weight as Low Birth Weight (LBW) (<2500 g) or Normal Birth Weight (>2500g). General clinical and obstetric histories were collected as well as the lifestyle habits. Iron biochemical parameters (Haemoglobin (Hb), Serum Ferritin (SF) and Transferrin Saturation (TS)) were recorded at 1st, 2nd and 3rd trimester and at delivery. We used several biomarkers to establish a score (SOS) relating to oxidative stress status (glutathione S-transferase, superoxide dismutase, catalase, glutathione peroxidase, glutathione reductase, reduced and oxidized glutathione, thiobarbituric acid reactive substances and hemolysis test). Oxidative stress was determined at the end of the 2nd trimester and the total antioxidant capacity of plasma was also determined (ORAC).

Results: The average dose of iron supplementation was 43.9 mg/d (geometric mean, 95%CI: 43.6-44.1). Women in the LBW group (6.7%) had significantly higher levels of SF and TS during pregnancy and exhibit lower enzymatic antioxidant activity (glutathione S-transferase, superoxide dismutase, catalase) than women in the Normal Birth Weight group. In addition, ORAC had higher values in LBW group, probably to offset the harmful effects of free radicals.

Conclusions: We observed an association between high iron levels and oxidative stress during pregnancy and LBW.

Key words: pregnancy, iron status, oxidative stress, low birth weight

PO776**MALNUTRITION AMONG ELDERLY: A STUDY IN A SELECTED RURAL AREA IN BANGLADESH.***M D H. Ali¹, N. Karim², M H. Faruquee³, S. Lahiry⁴*¹Transparency International Bangladesh, Dhaka, Bangladesh²World Health Organization, WHO Regional Office, New Delhi, India³Department of Public Health, State University of Bangladesh, Dhaka, Bangladesh⁴Institute of Health Economics, University of Dhaka, Bangladesh

Background and objectives: Combating malnutrition is a core issue in MDGs and Vision 2021. The present cross-sectional study was to assess the food habits and nutritional status of elderly people in rural Bangladesh.

Methods: A simple random sampling method was used to select the study population from a pre-publicized medical camp for elderly population in a purposively selected village in Bangladesh. A total of 423 respondents (186 male and 237 female) were interviewed face to face using a semi-structured questionnaire and anthropometric data (measurement of hip, waist, height, weight) and blood pressure (BP) were collected. Associations between dietary intake and World Health Organization (WHO) referred Body Mass Index (BMI) range was done using cross tabulation.

Results: The nutritional status was found to be significantly associated with education, marital status, gender, number of child, and type of living. Only 10.2% male and 13.5% female elderly were found to have protein rich food more than five days in a week; the similar findings in taking fatty food, vegetable and fruits in a week. Associations between dietary intake and WHO referred BMI range revealed that no significant association is existed between BMI and food intake ($p \geq 0.05$).

Conclusions: The present study identified malnutrition as a common problem among elderly people living in rural Bangladesh and socio-demographic and socio-economic background is highly associated with the nutritional status, not the dietary pattern. Hence, management requires social forms of intervention and further study with higher sample size is needed to explore dietary influence.

PO778**NUTRITION AND DIET IN CUBAN ELDERLY WITH ALZHEIMER'S DISEASE OR MILD COGNITIVE IMPAIRMENT***Y. Lanyau-Domínguez¹, J. Llibre², C. Macías¹, B. Babsabe¹, H. Hernández¹, M. Quintero¹, C. Arocha¹, M. Díaz¹, A. Rodríguez¹, R. Suárez³, J. Soto⁴, G. Pita¹, D. Herrera¹, L. Noriega², M. Guerra², M. Calvo², M. Klibanski², Y. Sánchez², A. Rodríguez⁴*¹Department Biochemistry and Physiology, Nutrition Institute, Cuba²Center of Dementia Research, Cuba³Department of Epidemiology, Institute of Hygiene, Cuba⁴Department of Biochemistry, Hermanos Ameijeiras Hospital, Cuba

Background and objectives: Dementia is a public health problem with non reproducible association to nutritional deficiencies. The aim of the present study was to assess this association in Cuban elderly.

Methods: Cross sectional study in 428 subjects older than 65 years; 47 with Alzheimer's disease (AD), 131 with Mild Cognitive Impairment (MCI) and 250 healthy subjects from Havana city. Dementia was diagnosed using the 10/66 Dementia and DSM-IV criteria and MCI with the Hughes Clinical Dementia Rating. Hemoglobin, hematocrit, MCV, total cholesterol, HDL-C, LDL-C, triglycerides, thiamine, folic acid, cyanocobalamin and vitamin C were measured by standardized methods. Diet was evaluated using a weekly food-frequency questionnaire. ANOVA, Pearson's Chi square and prevalence ratios were used for data analysis.

Results: AD patients showed lower haemoglobin, hematocrit, MCV, total cholesterol, LDL-C, thiamine and vitamin C levels than healthy individuals ($p < 0.05$); while in MCI patients, only haemoglobin, hematocrit and total cholesterol decreased ($p < 0.05$). Lower haemoglobin and hematocrit levels were associated with higher MCI and AD prevalence. Additionally, low thiamine, folic acid, B12 and C vitamin levels were associated to higher prevalence of AD. High total cholesterol and LDL-C were associated to lower AD prevalence. Food intake was not different between groups, but fish, grains+fruits and vegetables intake was inadequate in 80%, 60% and 50%, respectively, in all subjects.

Conclusions: Those nutritional indicators are associated to MCI and AD, without identifying if they are cause or consequence of disease.

Key words: nutrition, alzheimer's disease, mild cognitive impairment

PO779**NUTRITION ASSISTANCE PROGRAM PARTICIPATION INFLUENCES HOUSEHOLD FOOD SUPPLIES AND CHILDREN'S DIETARY INTAKE AMONG MEXICAN-ORIGIN FAMILIES IN TEXAS BORDER COLONIAS**

J. Sharkey¹, W. Dean¹, C. Nalty¹

¹Program For Research In Nutrition And Health Disparities, School of Rural Public Health, TAMHSC, College Station, TX, USA

Background and objectives: Few studies have focused on determinants of household food supplies and children's dietary intake. This study examined factors associated with nutrients available in household food supplies and dietary intake among 50 Mexican-origin children residing in Texas border colonias.

Methods: Spanish-language data were collected by trained promotora-researchers in the home March to June 2010. Data included survey data, two household food inventories (HFI) of the presence and amount of food items in the home, and three 24-hour dietary recalls reported by children participants. Nutrition Data Systems for Research was used to calculate HFI and dietary intake nutrients. Adult equivalent adjustment constants (AE), based on age and gender calorie needs, were calculated based on the age-and gender composition of each household and used to adjust HFI nutrients for household composition. Data were analyzed using bivariate analysis and linear regression models to determine the association of independent variables with the availability of each AE-adjusted nutrient.

Results: Analyses showed that households in which the child participated in the National School Lunch Program (NSLP) had foods and beverages with lower amounts of total energy, protein, dietary fiber, calcium, sodium, vitamin D, potassium, vitamin C, and total fat. Participation in other nutrition assistance programs was not associated with household nutrient availability. Participation in the National School Lunch Program (NSLP) was associated with lower dietary intakes of total energy, protein, total sugar, added sugar, and total fat; increased HFI availability of sodium was associated with greater sodium intake.

Conclusions: These findings suggest that participation in NSLP and not in other nutrition assistance programs significantly influences household food purchases and dietary intake. The next step will be to examine influences on household food supplies and dietary intakes during summer months, when NSLP is not offered.

Key words: household food supplies, nutrition assistance

PO780**POST-INFANCY GROWTH IN RELATION TO COGNITIVE ACHIEVEMENT AT AGE 8 YEARS: OBSERVATIONAL COHORT STUDY IN ETHIOPIA, INDIA, PERU AND VIETNAM**

⁹Hubert Department of Global Health, Rollins School of Public Health, Emory University, Atlanta, GA, USA

¹⁰Economics and Sociology Departments and Population Studies Center, University of Pennsylvania, Philadelphia, PA, USA

Background and objectives: Nutritional programs often assume their effectiveness lessens sharply after age 2 years. However, early interventions may not prevent all growth failure, and potential for growth changes after this period and subsequent cognitive and schooling impacts are not well understood. We used cohort data from four countries to estimate the association of changes in growth post-infancy with cognition and schooling.

Methods: Using data from Young Lives, a study of 8062 children, we characterized growth between ages 1 and 8 y as recovered (stunted at 1, not at 8 y); faltered (not stunted at 1, stunted at 8 y); persistently stunted (stunted at 1 and 8 y); or never stunted (not stunted at 1 and 8 y). We also represented growth in terms of height-for-age z-score at 1 y (HAZ[1]) and height at 8 y not predicted by HAZ(1) (ucHAZ[1:8]). Measures included 1) quantitative achievement, 2) reading comprehension, 3) receptive vocabulary, and 4) whether child was over-age for grade at 8y.

Results: HAZ(1) was positively associated with quantitative achievement (effect size range across countries 0.05-0.15); reading comprehension (0.06-0.14); and receptive vocabulary (0.04-0.11) and inversely with over-age for grade (OR range 0.83-0.92). Children who recovered in stature had better outcomes than those who remained stunted and were not significantly different in many cases from those who were never stunted. ucHAZ(1:8) was positively associated with quantitative achievement (effect size range across countries 0.05-0.09); reading comprehension: (0.02-0.10); and receptive vocabulary (0.04-0.08) and was inversely associated with over-age for grade (OR range 0.81-0.85). Conclusions Improvements in child growth following early faltering might have significant cognitive achievement and schooling benefits. Hence, while early interventions are critical, improving nutrition of pre-primary and early primary school-age children also merits consideration.

Key words: post-infancy growth, schooling, cognitive development

PO781

ORAL LEPTIN SUPPLEMENTATION THROUGHOUT LACTATION AMELIORATES NEUROANATOMIC CONSEQUENCES IN THE OFFSPRING CAUSED BY MATERNAL MODERATE CALORIC RESTRICTION DURING GESTATION

J. Sánchez¹, J. Konieczna¹, A.P. García¹, M. Palou¹, A. Palou¹, C. Picó¹

¹Laboratory of Molecular Biology, Nutrition And Biotechnology (Nutrigenomics), University of The Balearic Islands (UIB) And CIBER Fisiopatología de La Obesidad Y Nutrición (CIBEROBN), Palma de Mallorca

Background and objectives: In the present study, we used an experimental rat model of moderate (20%) maternal caloric restriction during pregnancy, which is known to be associated with alterations in hypothalamic circuitry that program a higher propensity to develop obesity in the offspring, to investigate whether oral supplementation with physiological doses of leptin throughout lactation may ameliorate the developmental malprogramming effects exerted in offspring hypothalamus structure and function.

Methods: Male and female rats belonging to 3 groups were studied: the offspring of ad libitum fed dams (controls), the offspring of 20% calorie restricted dams during the first part of pregnancy (CR), and CR rats supplemented with physiological doses of leptin throughout lactation (CR-Leptin). Animals were sacrificed on postnatal day 25. Morphometric and immu-

nohistochemical studies on arcuate (ARC) and paraventricular (PVN) nucleus were performed and hypothalamic expression levels of selected genes were determined.

Results: In CR males, leptin treatment restored, at least in part, the number of immunoreactive NPY (NPY+) cells in ARC, the total number of cells in PVN, hypothalamic NPY, CART and SOCS-3 mRNA levels, and plasma leptin levels, which were decreased in CR animals. CR-Leptin males showed higher hypothalamic ObRb mRNA levels, compared to control and CR animals. In CR females, leptin treatment reverted the increased number of cells in ARC and of cell density in ARC and PVN, and reduced hypothalamic SOCS-3 mRNA expression to levels similar to controls. Leptin treatment also reverted the increased relative area of NPY+ fibers in the PVN occurring in CR animals.

Conclusions: Results suggest that leptin supplementation throughout lactation is able to ameliorate adverse developmental effects on hypothalamic structure and function, making the metabolic malprogramming induced by maternal caloric restriction during gestation reversible to some extent.

Key words: leptin, hypothalamus, metabolic-programming

COMPARISON IN THE DEVELOPMENT OF THE MICROBIOTA ALONG THE GASTROINTESTINAL TRACT OF INFANT MICE AFTER BREAST-AND FORMULA FEEDING.

C. Gómez-Gallego¹, R. Frias², G. Pérez-Martínez³, M J. Bernal⁴, M J. Periago¹, S. Salminen², G. Ros¹, M C. Collado³

¹Department of Human Nutrition and Food Science, University of Murcia, Espinardo, Murcia, Spain

²Functional Foods Forum, University of Turku, Turku, Finland

³Institute of Agrochemistry and Food Science, IATA-CSIC, Valencia, Spain

⁴Global Technology Centre For Infant Nutrition, Hero Group, Murcia, Spain

Background and objectives: The development of the human microbiome is a complex process, which may begin during the perinatal period when the infant is exposed to the mother's microbiota. Feeding practices (breast milk or formula) influence the establishment of microbiota, which is known to play an essential role for the maturation of the immune system and gastrointestinal mucosa. The aim of this study was to

compare the microbiota colonization patterns throughout the gastrointestinal tract of mice after breast- and formula feeding.

Methods: Twenty four specific pathogen free BALB/cO-laHsd mice pups (age 14 days) were randomly allocated in 2 different experimental groups (normal lactation and manufactured infant formula) for 4 days. Samples of the oral cavity, stomach, small intestine and large intestine were collected, and thereafter the main composition of intestinal microbiota was characterized by qPCR.

Results: Formula fed mice showed different microbial composition in the oral cavity and stomach compared to breastfed pups. In stomach, significantly higher levels of total bacteria ($p=0.0001$), Lactobacillus group ($p=0.001$) and Streptococcus group ($p=0.008$) were found in the breastfed group. Higher levels of total bacteria ($p=0.005$), Bifidobacterium ($p=0.060$), Lactobacillus ($p=0.005$), Bacteroides-Prevotella ($p=0.007$), Streptococcus ($p=0.001$) and Akkermansia muciniphila ($p=0.005$) were found in the small intestine of breastfed mice. Moreover, the prevalence of Enterococcus group was found to be higher in formula fed group ($p=0.005$). In the large intestine, higher levels of Enterococcus ($p=0.0001$) and Enterobacteriaceae ($p=0.0001$) groups were found in the formula-fed mice.

Conclusions: Significant differences in the microbial colonization patterns were detected along the whole gastrointestinal tract of the infant mice depending on whether the pups were breast- or formula fed, even for a short period of time, suggesting that two feeding types have a considerably different impact on the development of the gut microbiota in suckling mice.

Key words: microbiota, infant formula, lactation, animal model.

PO783

EFFECTS OF MATERNAL PALMITOLEIC-ACID SUPPLEMENTATION DURING PERINATAL LIFE IN THE OFFSPRING METABOLIC HEALTH IN RATS

M. Palou¹, J. Sánchez¹, C A. Pomar¹, C. Cabrer¹, T. Priego¹, M. Llopis¹, A. Palou¹, C. Picó¹

¹Laboratory of Molecular Biology, Nutrition and Biotechnology (Nutrigenomics), University of Balearic Islands and CIBER Fisiopatología de la Obesidad y Nutrición (CIBEROBN), Palma de Mallorca, Spain

Background and objectives: Maternal dietary fat source, more than the absolute amount, may affect offspring susceptibility to obesity and related-metabolic alterations. Palmitoleic acid (C16:1 n-7) has been proposed in animal studies to act as a lipokine, i.e. an adipose tissue-derived lipid hormone, that stimulates muscle insulin action and suppresses hepatosteatosis; however, in humans, plasma palmitoleic-acid concentration

has been positively associated with increased risk of obesity. Here, we aimed to assess whether palmitoleic-acid-supplementation during pregnancy and lactation to rat dams could affect future offspring metabolic health.

Methods: Dams were daily supplemented with palmitoleic-acid (38.5mg) or the vehicle (skimmed-milk) during late pregnancy and lactation. At day-21, offspring of control and palmitoleic-acid-supplemented dams (C and PO, respectively) were weaned and fed with standard-diet until 5-months of age, and then exposed to high-fat-diet for two-months. Blood samples were collected and animals were sacrificed to obtain liver and WAT at 7-months of age.

Results: Despite no differences in body-weight, PO-animals showed greater fat accumulation than C, particularly males. PO-animals displayed higher levels of fasted glucose and insulin (females) and HOMA-index than C. PO-males, but not females, also showed higher leptinemia. Interestingly, PO-animals, particularly females, showed lower hepatic lipid content. Hepatic mRNA levels of SREBP1c, FASN, GPAT, STAT3 and SOCS-3 showed a sex-dependent pattern, with a tendency to increase in males and to decrease in females. IRS1 and InsR were decreased in PO-animals, particularly females. In retroperitoneal-WAT, PO-animals showed higher mRNA levels of STAT3 and SOCS-3 and of ObRb and InsR (only females) than C.

Conclusions: Results suggest that maternal palmitoleic-acid-supplementation during perinatal life may affect offspring metabolic capacity, leading to protective effects against hepatic lipid accumulation under high-fat-diet; however more studies need to be done to further clarify the observed effects on insulin, leptin and glycemia.

Key words: dietary fat, perinatal life, hepatoesteatosis.

PO784

DIFFERENTIAL FERRITIN INTERPRETATION STRATEGIES TO ACCOUNT FOR INFLAMMATION RESULT IN DISCREPANCIES IN IRON DEFICIENCY PREVALENCE IN MALNOURISHED SOUTH AFRICAN INFANTS

E. Nel¹, H S. Kruger¹, J. Baumgartner¹, M. Faber¹, C M. Smuts¹

¹Centre of Excellence For Nutrition, North West University, Potchefstroom, North West, South Africa

Background and objectives: China as the biggest developing country continue to experience a large burden among children in rural area. Poor fetal growth continues to be high and with subsequent growth faltering in the first two years

childhood malnutrition. The primary aim of this study was to assess the relationship between fetal growth restriction and childhood malnutrition at 24 months.

Methods: A longitudinal follow-up of a subset of newborns (n=1032) whose mothers were randomly assigned to receive the supplements of folic acid, iron-folic acid or multi-micronutrients daily during pregnancy in the original trial was conducted. Children's weight and length were measured at 24 months of age. Anthropometric indices weight-for-age Z-score, length-for-age Z-score and weight-for-length Z-score were calculated with WHO Anthro 2005 (WHO, 2006) and WHO Child Growth Standards 2006. Relative risk (RR) and 95% confidence intervals (CI) were estimated by Logistic regression model compared with reference category.

Results: Small-for gestational age (SGA) of newborns were significantly associated with their stunting (RR 2.57, 95%CI 1.74 - 3.78), wasting (RR 6.16, 95%CI 1.37 - 27.78) and underweight (RR 8.41, 95%CI 3.78 - 18.69) at 24 months of age compared with adequate-for-gestational age (AGA). Low birth weight (<2.5kg) of newborns also increased the risk of stunting (RR 2.20, 95%CI 1.04 - 4.62), wasting (RR 21.21, 95%CI 4.57 - 98.41) and underweight (RR 11.00, 95%CI 4.33 - 27.93) at their 24 months of age compared with those newborns with birth weight ≥ 2.5 kg.

Conclusions: Fetal growth restriction increased the risk of childhood under-nutrition at 24 months in northwestern rural China, with implications for programs and policy focusing on pregnant women and more broadly maternal nutrition.

Key words: stunting, birth weight, small for gestational age

PO786

NUTRITIONAL STATUS, SEVERITY OF SENSORY SENSITIVITIES AND FEEDING PROBLEMS IN CHILDREN (3-10 YEARS) WITH PERVASIVE DEVELOPMENTAL DISORDERS.

P. Kamboj¹, R. Chadha¹, S. Ghosh-Jerath²

¹Department of Food and Nutrition, Lady Irwin College, University of Delhi, New Delhi, India

²Indian Institute of Public Health-Delhi, Public Health Foundation of India, New Delhi, India

Background and objectives: Nutritional status, severity of sensory sensitivities and feeding problems were assessed among 30 children (3-10 years) with Pervasive Developmental Disorders (PDD), attending two special schools in New Delhi, India.

Methods: The mothers of children were interviewed to elicit information on sensory sensitivities, dietary intake pattern, mealtime behavior and feeding problems of the children. This information was collected using interview schedules, Short

Sensory Profile (SSP) questionnaire, 24-hour dietary recall, semi-quantitative food frequency questionnaire (SQ-FFQ) and Brief Autism Mealtime Behavior Inventory (BAMBI). Anthropometric status of these children was assessed by measurement of weight and height. The severity of sensory sensitivities was assessed based on the SSP scores.

Results: The children were categorized as having definite difference (17), probable difference (8) and typical performance (5) which was in the order of decreasing severity. Based on z-score classification of BAZ, HAZ and WAZ, 6 children were identified as overweight or obese, 2 were severely stunted and 2 children were severely underweight respectively. A high proportion of children (1/3rd) were stunted in the definite difference category of SSP as compared to the children (1/5th) in the typical performance category. Percent adequacy of food groups ranged from 45 to 145% when compared with the balanced diet recommendations (ICMR, 2010). Percent adequacy of various nutrients as compared with RDA ranged from 51 to 304%. The severity of sensory sensitivities were significantly correlated with mealtime behaviour problems ($r=-0.46$; $p<0.05$).

Conclusions: Thus, children with PDD having severe form of sensory sensitivities who may have more mealtime behavior problems would require individualized dietary interventions to improve the acceptability and nutritional quality of their diets.

Key words: pervasive developmental disorders, sensory sensitivities, nutritional status, dietary intake and mealtime behavior problems.

PO787

THE ROLE OF LAY COMMUNITY HEALTHWORKERS IN PROMOTING EXCLUSIVE BREASTFEEDING PRACTICES AMONG HIV POSITIVE MOTHERS IN THE RURAL MALAWI

A. Bula¹, C. McCourt¹, M. Magadi¹, T. Phiri², S. Lewycka²

¹Department of Maternal and Child Health, City University London, United Kingdom,

²MaiMwana Project, Mchinji, Malawi

Background and objectives: Women in Malawi with constrained access to infant formula are encouraged to breastfeed exclusively (EBF) for 6 months as a pre-requisite to achieve MDG 4. Despite high rates of HIV and infant mortality, mixed feeding remains dominant and EBF is estimate at 74.4%. Other studies in the country have reported lower EBF rates of 4% and under-five malnutrition remain persistent. Determinants of EBF include cultural and lack of hospital and community support. Previous interventions focused on supporting breastfeeding in the maternity which significantly improved early initiation but not EBF for 6 months. Recently, interventions have been directed to promote EBF at community level using

peer counsellors. MaiMwana tested the intervention in rural Malawi.

Methods: We purposively selected and conducted 39 qualitative in-depth interviews between January-August 2012 with women, peer counsellors, key informants to explore experiences with the programme in the context of HIV following ethics approval from Malawi and City University. Data was analyzed using framework analysis.

Results: HIV positive and negative women were happy with the intervention for continuity of counselling on infant feeding. Volunteers spent more time and observed the real infant feeding modality at home. HIV positive women could tell their story to someone who was there for them. Women appreciated the importance of home counselling because they could control the type of food given to the baby unlike in the past when they go to the field and leave the child with other care takers without knowing what was given to the child increasing chances of transmitting HIV or diseases. Volunteers also gained knowledge on the importance of EBF and care for their own children or grandchildren.

Conclusion: Scaling-up community based interventions in poor communities with shortage of medical personnel is paramount to promote EBF and child survival.

Key words: EBF, peer counsellors, HIV, Malawi

PO788

FATTY ACID METABOLISM: CHANGES IN LIVER MRNA EXPRESSION IN MICE FED WITH TWO DIFFERENT BRANDS OF HOMEGENIZED BABY FOOD

E. Sánchez Samper¹, P. Andreu Miguel¹, C. Gómez Gallego¹, M.J. Bernal Cava², G. Ros¹

¹Food Sciences and Nutrition, Faculty of Veterinary, University of Murcia, Spain

²Global Technology Center for Infant Nutrition, Hero Group, Murcia, Spain

Background and objectives: For the correct development of infants during growth a balance fatty acid profile is required, being established at 1:2:1 (saturated:monounsaturated:polyunsaturated). Diets without this proportion could produce harmful effects related to overweight and obesity. The aim of our study was to characterize the impact of two different types of homogenized baby foods on the fatty acid metabolism in liver.

Methods: Thirty-six weaned C57BL/6J mice were randomly separated in three different experimental groups for a 12-week intervention groups. The groups were divided into A group fed on baby food containing 67 kcal for 100 g of food, 2.7% fat and a balanced fatty acids profile which proportion of S/M/P was 1:2:1; B group fed on baby food containing 87 kcal

for 100 g of food, 2.9 % fat and a unbalanced fatty acids profile which proportion of S/M/P was 1:2:0.5; and a control group fed on rodent chow. All groups had free access to rodent chow to avoid deficiencies in micronutrients. A and B group developed overweight compared with control. At the end of the study, samples of liver were collected and expression of genes related with fatty acid metabolism was analyzed by qPCR.

Results: We found 14 genes overexpressed in B group compared with control group ($p < 0.03$). None gene was overexpressed in A group. These overexpressed genes in B group, related with PPAR α activation, are involved in the catabolism of fatty acids, fatty acids transport through mitochondria, and triacylglycerol catabolism.

Conclusion: Our results suggest that the intake of homogenized baby food with unbalance fatty acids profile might produce up-regulation of PPAR α target genes in mice, altering the lipid metabolism compared to a balance fatty acids intake in overweight.

Key words: fatty acid metabolism, baby food, animal model.

PO789

INTERGENERATIONAL TRANSMISSION AND CHILD FEEDING PRACTICES IN DETERMINING GROWTH DURING INFANCY AND CHILDHOOD

K. Borkotoky¹, S. Unisa²

¹International Institute For Population Sciences (IIPS), Mumbai, Maharashtra, India

²Department of Mathematical Demography and Statistics, International Institute For Population Sciences (IIPS), Mumbai, Maharashtra, India

Background and objectives: This paper makes an attempt to examine the growth of children according to their birth outcomes. The key research question is; whether low birth weight (LBW) babies will be able to achieve their normal growth during childhood; and if they do, what will be the role of feeding practices, and genetic component in determining normal growth in LBW babies?

Methods: The study is based on the data from Indian National Family Health Survey covering the period from 1992-2006. Our study focuses on two groups of children; children with LBW and normal growth at age two, and children with normal birth weight but below average growth at age two. We examine the association of different household level variables and birth outcomes with growth during childhood with the help of regression analysis. In addition, Infant and Young Child Feeding (IYCF) indicators have been calculated for both the groups in order to monitor their growth pattern. Further, we apply discriminant function analysis to examine the most probable combi-

nation of variables in compensating the lagged growth.

Results: Regression results suggest that exclusive breastfeeding, timely initiation of complementary feeding with a diverse diet play an important role as growth promoting factor even for LBW babies. We also observe that genetic factors have a significant association with restrictive growth. Further, the study suggests that proper child feeding practices may help to overcome the genetic deficiencies even though there is a variation in strength of intergenerational transmission across different subgroups of the population.

Conclusions: On the basis of the study, we may say that growth during infancy and childhood is not confined solely to birth outcomes, but some external factors may also contribute significantly to compensate the birth deficits.

Key words: feeding practices, genetic component, lagged growth, discriminant function, birth deficit

PO790

FOOD INTAKE IN CUBAN INFANTS ACCORDING TO NUTRITIONAL AND SOCIOECONOMIC STATUS

A. Cabrera¹, Y. Domínguez¹, D. Silvera¹

¹Department of Community Nutrition, Institute of Nutrition and Food Hygiene, Havana, Cuba

Background and objectives: Nutritional status is associated to many factors such as socioeconomic status and feeding habits. The aim of this study was to identify those associations in a group of Cuban infants.

Methods: This descriptive study included 22 infants between 6 and 24 months of age and was carried out in Arroyo Naranjo municipality, Havana. Weight and length were measured to determine nutritional status. Nutrients and food portions intake were estimated using a semiquantitative food frequency questionnaire. Foods were aggregated into 7 groups according to Cuban Food Guide. Descriptive statistics and Spearman correlation test were used.

Results: 13% of the group was underweight, 64% was normal, 23 % was overweight. There was a strong association between nutritional status and gender ($p=0.002$). Vegetable, fruits, dairy products and fats portions consumption was low, while cereals, tubers, meats, poultry products and sugar portions consumption was high. High associations were found between mother's age and infant's length ($p=0.015$), family incomes and energy intake ($p=0.004$), family incomes and sugar portions consumption ($p=0.019$).

Conclusions: Nutritional status is strongly associated to gender, food intake and family incomes.

Key words: infants, food intake, feeding habits.

PO791

PROPAN (PROCESS FOR THE PROMOTION OF CHILD FEEDING): A TOOL FOR INFANT AND YOUNG CHILD FEEDING PROGRAMMING

C. Lutter¹, R. Mir², H. Pachón³, E. Cheung⁴, K. Sullivan³, H. Creed de Kanashiro⁵, A. Panjwani¹, J. Escobar⁶

¹Pan American Health Organization/WHO

²US Centers for Disease Control and Prevention, USA

³Rollins School of Public Health Emory University, USA

⁴UNICEF, USA

⁵Instituto de Investigación Nutricional, Peru

⁶University of South Carolina, USA

Background and objectives: Setting-specific program guidance on infant and young child feeding (IYCF), particularly complementary feeding, continues to be a challenge. To address this, we developed ProPAN, a step-by-step tool aimed at ministries of health, NGOs and international organizations.

Methods: Developed by a multi-disciplinary team of nutritionists, social scientists, epidemiologists and computer programmers and by building on field experiences in Africa, Asia, Latin America and the Caribbean.

Results: ProPAN consists of a field manual and software based on Epi Info™ for data entry and analysis. Its features include 1) Forms and guides for collection of quantitative and qualitative data; 2) Methods for integrating quantitative and qualitative data; 3) Methods for formulating, ranking, and selecting dietary and feeding practice recommendations, based on practicality, feasibility, and acceptability; 4) Software for standardized input and output of nutrition, feeding and diet information; and 5) Guidance on how to convert the resulting data into an intervention or program and to design a monitoring and evaluation strategy. The 2nd edition of ProPAN incorporates the WHO Child Growth Standards, WHO/UNICEF IYCF Indicators, a method to measure responsive feeding, questions on HIV and infant feeding, MUAC for use in emergency settings, and outputs to use with WHO's Optifood program.

Conclusions: ProPAN provides a systematic and complete tool for programming in infant and young child nutrition. It is flexible in that the modules can be used individually or as one comprehensive exercise, depending on the needs of the user. It can also be used to train nutritionists in quantitative and qualitative research methods.

Key words: breastfeeding, complementary feeding, child nutrition ProPAN was developed by PAHO/WHO and UNICEF with support from the US CDC and Emory University. ProPAN is freely available in English, French and Spanish at www.paho.org/ProPAN. The 2nd edition was funded, in part, by GAIN.

PO792**BREAST FEEDING PRACTICE IN BANGLADESH: ADDRESSING THE BOTTLENECKS WITH COMMUNITY HEALTH WORKERS IN A COMMUNITY BASED INTERVENTION OF BRAC**

M. Chowdhury¹, K. Afsana¹

¹Brac Centre, Dhaka, Bangladesh

Background and objectives: In Bangladesh 85% children were exclusively breast fed in first month of life which dropped to 35.1% just at 4th month and further at 6th month (7.3%). Only half of the babies are initiated breast feeding within first hour of life. The impact has been reflected over the prevalence of malnutrition among under five children (41% stunting and 51% anaemia) (Bangladesh Demographic Health Survey 2011). To address this issue BRAC developed comprehensive nutrition promotion activities at community level covering around 1 million under two children in rural and urban slum areas.

Methods: BRAC trained 58,000 community health workers (CHW) in diversified skills of breast feeding counseling and management of breast feeding complications. They follow children since birth till age below five years. CHWs attend home births and initiate breast feeding at first hour. During the subsequent home visits they ensure exclusive breast feeding (EBF) by counseling the parents and grandparents and manage minor problems around breast feeding. Between 181-187 days (seventh month) they demonstrate complementary food preparation using family food and emphasize on adequate quantity, proper composition and hand washing. At the same time breast feeding also continued for two years.

Results: According to MIS report, in 2012 among 405,951 born alive babies, 366,127 were breast feed at first hour and 182,322 infant continued exclusive EBF for six months. CHWs collected monthly information of child feeding and based on six months data report on EBF, not single survey. CHWs demonstrated 290,800 complementary feeding at the same time encouraged mothers to continue breast feeding.

Conclusions: CHWs can influence in early initiation when attend births. Regular household visits encouraged mothers and motivates family members' support for continuation of breast feeding, still there remains challenge in continuation for six months.

Key words: BRAC, CHW, breast feeding

PO793**DIET QUALITY OF MOROCCAN PERIMENOPAUSAL WOMEN INTEGRATED IN A MULTIDISCIPLINARY INTERVENTION STUDY**

P. Aranda¹, P. Ruíz-Cabello¹, J. Benítez², N. Moratalla³, M del Mar. Fernández¹, V. Aparicio¹, M. Errami⁴, M. Senhaji⁴

²Department of Physical Education and Sport, School of Sports Sciences, University of Granada, Spain

³Clinical Management Unit of Pinos Puente, Granada Metropolitan District, Spain

⁴Department of Physiology and pathophysiology, University Abdelmalek Essaadi, Tetouan, Morocco

Background and objectives: Northern Morocco and southern Spain are areas geographically close but with large socioeconomic and cultural differences. The aim of this study was to determine the quality of the diet of a group of perimenopausal women in southern Morocco.

Methods: The study comprised 151 women from the North of Morocco with an age ranged 45-65 years. It was carried out an assessment of the quality of the diet by a validated food survey, designed by Mataix et al. (2000) for the assessment of nutritional status of Andalusia. The data have been entered into the nutrition program AYS44, designed at the Institute of Nutrition and Food Technology of the University of Granada.

Results: Energy and fiber intake are adequate are adequate to cover the recommendations of women in this stage of life. The energy profile shows that the women's diet is normoproteic (15%) hypoglucidic (47%) and hyperlipidic (41%). The quality of dietary fatty acids according to the ratio of unsaturated / saturated fatty acids is less (2.5) than those found in Spanish women of similar characteristics (3.0) probably due to the use of argan oil and sunflower oil instead of olive oil. The average intake of vitamins is adequate, except for vitamin A which covers only 85% of the recommended intakes (RI). Mineral intake is insufficient for calcium (87% RI), zinc (92% RI) and iodine (61% IR). Statistical analysis of the data collected for this study was carried out using SPSS version 20.0.

Conclusions: Moroccan women have a worse lipid and caloric profile than Spanish women, presenting a deficit in some vitamins and minerals which are essential to prevent diseases associated with perimenopause. Nutrition education policies are mandatory for this group of women who could be health workers in their environment.

Key words: perimenopausal, Morocco, survey, Diet quality.

PO794**IN VITRO IRON AVAILABILITY FROM SIX DIFFERENT INFANTS CEREALS RECONSTITUTED WITH GROWING-UP MILK OR WATER**

L. Fernández-Palacios¹, C. Frontela Saseta¹, C. Martínez Graciá¹, G. Ros Berruezo¹

¹University of Murcia, Murcia, Spain

Background and objectives: Iron deficiency is the most prevalent nutritional disorder in developing countries. In industrialized countries, the prevalence of iron deficiency also remains the most common nutritional deficiency in the early childhood. Food fortification is an effective strategy to reduce iron deficiency.

Methods: In this study, six different commercial infant cereals (Gluten-Free Cereal, 8 Cereals, Multicereals, Cereals with Mixed Fruits, 8 Cereals with Honey, Cereals with Cacao) reconstituted with water or growing-up milk were analyzed to study possible differences in iron bioavailability. An in vitro method to simulate the gastrointestinal digestion process of infants, was applied to study the iron bioavailability from infant cereals for that enzymatic treatment was carried out in two stages involving pepsin at pH 2.0 followed by pancreatin and bile salts at pH 6.5. The incubation period was of 2 hours to mimic the transit of meal in the gastrointestinal tract of infants. Iron content was determined using a flame atomic absorption spectrometer. Solubility and dialysis of iron reconstituted with water or growing-up milk, were compared by anova one way values of $p < 0.05$ were considered significant.

Results: Infants cereals reconstituted with growing-up milk showed the highest amount of iron. However when, infants cereals were mixed with water, increase in the Fe digestibility percentage was observed compared with the same cereals mixed with growing-up milk ($3 \pm 0.2\%$) and ($1.9 \pm 0.1\%$), respectively.

Conclusions: The nutritional status of iron in infants depends, mainly, on the stores at birth, the requirements of iron for growth and bioavailability of dietary iron from fortified infants cereals. Mixing infants cereals with water seems to be an adequate strategy to improve Fe availability to prevent iron deficiency in these population such as prematurity, low birth weight, etc.

Key words: iron, bioavailability, growing-up milk, fortification

PO795**DIETARY IRON INTAKE AND IRON STATUS AMONG LACTATING WOMEN IN BHAKTAPUR, NEPAL**

S. Henjum¹, M. Manger², R C. Chandyo^{3,4}, A. Thorne-Lyman⁵, M. Ulak³, E. Skeie⁶, P S. Shrestha³, L M. Locks⁵, R. Ulvik⁷, W W. Fawzi⁸, T A. Strand^{4,9}

⁹Medical Services Division, Innlandet Hospital Trust, Lillehammer N-2629, Norway

Background and objectives: The main objective was to describe the dietary iron intake and dietary predictors of iron status and hemoglobin concentration among lactating women in Bhaktapur, Nepal

Methods: In 2008 and 2009 we included 500 randomly selected lactating women in a cross sectional survey. Dietary information was obtained by three 24-h recall interviews including personal recipes. Plasma concentrations of hemoglobin (Hb), serum ferritin and transferrin receptors were measured.

Results: The median iron intake from food was 26.4 mg and the main contributors of dietary iron were mustard leaves (25%) and beaten rice (18%). Around 90% of women had taken iron supplements during pregnancy and the mean duration of iron supplementation was 4.8 months. The prevalence of anemia was 20% ($Hb < 12.3$ g/dl) and the prevalence of iron deficiency was 5% (plasma ferritin $< 15 \mu\text{g/l}$). Higher serum ferritin levels were associated with greater intake of dietary iron intake (x (95% CI) 0.01 (0.004, 0.01)). A significant negative association between dietary iron intake and transferrin receptor was found (x (95% CI): -0.002 (0.003, 0.00)). In addition, for the women with children < 6 months, iron supplementation was positively associated with plasma ferritin concentrations (P interaction < 0.001) and negatively associated with plasma TfR (P interaction = 0.07).

Conclusions: Due to a high dietary intake of non-hem iron combined with low bioavailability, a high proportion of the women in this study were at high risk of inadequate intake of iron. Our analysis showed that higher intakes of dietary iron were associated with better plasma ferritin and transferrin receptor status and iron supplementation for at least 6 months during pregnancy was associated with better hemoglobin concentration during the lactation period.

Key words: dietary iron, bioavailability, iron supplements

PO796

DIET QUALITY IN A GROUP OF PERIMENOPAUSAL WOMEN FROM SOUTH SPAIN BASED ON FOOD FREQUENCY QUESTIONNAIRE AND MEDITERRANEAN DIET SCORE.

P. Ruiz-Cabello Turmo^{1,2}, N. Moratalla^{1,2}, E. Gregorio^{1,2}, V. Aparicio^{1,2,3}, M.M. Fernández^{1,2}, P. Aranda^{1,2}

¹School of Pharmacy, Department of Physiology, University of Granada, Spain

²Institute of Nutrition and Food Technology, Granada, Spain

³Faculty of Sport Sciences, University of Granada, Spain

Background and objectives: Nowadays, women between 45-65 years present different lifestyles to those of their previous generations which can modify the eating habits of the whole family. Our aim is to determine the quality of the diet of a group of perimenopausal women in Southern Spain, using a Food Frequency Questionnaire and the adherence to the Mediterranean Diet.

Methods: The study comprised 143 women from the South of Spain with an age ranged 45-65 years. Food frequency habits was assessed by a food frequency questionnaire developed by Mataix et al, 2000 which has been widely validated in the nutritional assessment of the Andalusian population studies. Adherence to the Mediterranean Diet was determined by using the Mediterranean Diet Score (SDM) developed by Panagiotakos et al, 2005.

Results: From the food frequency questionnaire the results were as follows: cereal (pasta, rice, bread, and non-refine cereals) (3.5 servings/day), fruit (2 s/d), nut (0.3 s/d) and water group (5.6 s/d) are relatively under the recommendations. Dairy products (2.9 s/d) and pulses group (0.5 s/d) are within the recommendations. Fish (0.9 s/d) and egg (0.3 s/d) groups slightly exceed the recommendations. Vegetables (3.9 s/d), meat and meat products (1.4s/d), sweets (1.1s/d) and dietary fat group (2.9 s/d) greatly exceed the recommendations. The women studied have occasional and moderate alcohol consumption (0.4 s/d). SDM ranges from 0-55 points, in which our

women presented an average score, equal to 33.03±4.19. Statistical analysis of the data collected for this study was carried out using SPSS version 20.0

Conclusions: In general, diet in our study group is in accordance to healthy dietary habits. However there are some food groups whose consumption should be modified. Those data indicate that our results beside others from different studies are key to the development of nutritional education campaigns aimed at perimenopausal women.

Key words: perimenopausal, mediterranean diet score, food frequency, south spain women.

PO797

CAFFEINE CONTENT AND EXERCISE-PSYCHOSTIMULANT EFFECTS OF VIA® INSTANT COFFEE

S. Kirk¹, J. Buth², M.C. Powers¹, C. Goggin¹, L. Lowery^{1,3}

¹Department of Human Performance and Sports Business, University of Mount Union, Alliance, Ohio, USA

²Department of Chemistry and Biochemistry, University of Mount Union, Alliance, Ohio, USA

³Nutrition, Exercise, and Wellness Associates Ltd., Cuyahoga Falls, Ohio, USA

Background and objectives: The purposes of this study were to objectively determine the caffeine content of VIA® instant coffee (VIA) and to elucidate its psychostimulant effects during exercise. There is little commercial information about the caffeine content of VIA. We hypothesized that VIA would increase ($p < 0.05$) subjective reports of energy, alertness, and focus during exercise in resistance-trained university students, compared to themselves in a decaffeinated (DCF) condition.

Methods: Caffeine Content: VIA and DCF individual packets were analyzed in triplicate by high performance liquid chromatography (HPLC) to determine caffeine content. The samples were constituted in deionized water, further diluted, and syringe-filtered prior to analysis. Caffeine concentrations were determined from a six-point calibration curve of caffeine standards. Exercise-Psychostimulant Effects: After 24 hours of dietary control and caffeine abstinence, fasted subjects performed resistance exercise under two conditions (VIA, DCF) separated by 48-72 hours. Immediately after exercise, subjects rated feelings of energy, alertness and focus on a five-point scale.

Results: VIA was found to contain 164±3 mg (mean +SD) per serving. For DCF, caffeine was below the calibration range (<9 mg per serving). Regarding psychostimulant effects, there was a significant increase in alertness (VIA 4.17±0.94 vs DCF 3.17±0.83; $p = 0.00013$); energy (VIA 4.50±0.67 vs DCF 3.17±0.72; $p = 0.00002$); and focus (VIA 4.33±0.78 vs DCF 3.33±0.0394; $p = 0.00394$).

Conclusions: These preliminary data reveal caffeine content for VIA substantially above reported values for regular instant coffee (164 vs 64 mg) and support the hypothesis that VIA increases exercise related perceptions of energy, alertness, and focus.

Key words: caffeine, coffee, resistance exercise, psychomotor

⁴Research Deputy Department, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran

⁵Students Research Committee, Shahid Beheshti University of Medical Sciences and Health Services

⁶Nutrition Research Department, National Nutrition and Food Technology Research Institute, Tehran, Iran

Background and objectives: Calcium is the most limiting nutrients in the Iranian household diet. Sufficient calcium intake is crucial to support growth spurt during preteen and teenage years. This study aimed to assess daily calcium intake, its major dietary sources and the association with socioeconomic status (SES) in primary school children in the city of Tehran.

Methods: In a cross-sectional study, 501 students (244 girls and 257 boys) from grades 4 and 5 of elementary schools were selected through systematic random sampling from all districts of the city of Tehran. Demographics and SES was assessed using a questionnaire through face-to-face interviews. Ca intake was assessed using a validated 60-item semi-quantitative food frequency questionnaire, specifically designed for dietary

sources of Ca. One way-ANOVA test was used to compare within-group total calcium intake in each gender and in total participants, followed by post hoc Tukey HSD test.

Results: Mean calcium intake of the children was 917.5±440.8 mg/day (girls: 901.2±447.7 mg/day; boys: 932.8±434.4 mg/day). While only 17.8% met the daily recommended intake of Ca (>1300mg/day), the intake in 59.9% was below 75% of RDA. Main contributors of Ca in the children's diet were milk and dairy products (69.3% of total calcium intake). Only 29.8% met the food-based dietary guidelines for dairy intake (>3 serving/day). No significant difference was observed between boys and girls in the intake of calcium and dairy products; however, calcium intake of girls in the middle SES district was significantly lower than boys in the same district (780.3±44.3mg/day vs 964.5± 48.5 mg/day; p<0.05) and girls in both low and high SES districts. No significant association was observed between Calcium intake of children and other socioeconomic variables.

Conclusions: Planning useful nutrition strategies for overcoming this problem seems inevitable.

Key words: calcium intake, primary school children, Tehran.

PO799

IMPACT OF DAILY CONSUMPTION OF A MICRO-NUTRIENT-FORTIFIED, LIPID-BASED NUTRIENT SUPPLEMENT (LNS) ON BREAST MILK INTAKE IN MALAWIAN INFANTS

C. Kumwenda^{1,4}, M. Haskell², J. Hemsworth³, P. Ashorn¹, K. Maleta⁴, K. Dewey²

¹Department of International Health, University of Tampere School of Medicine, Tampere, Finland

²Program in International and Community Nutrition, Department of Nutrition, University of California, Davis, USA

³Department of Nutrition and Public Health Intervention Research, London School of Hygiene and Tropical Medicine, London, UK

⁴Department of Community Health, College of Medicine, University of Malawi, Blantyre, Malawi

Background and objectives: Clinical trials have been designed to assess the effects of LNS on infant growth and development. Infants self-regulate their energy intakes, thus LNS has the potential to reduce breast milk intake. The objective of the study was to estimate breast milk intake, in a sub-sample of Malawian infants (n=358) participating in the iLiNS-DOSE trial at 9-12 mo of age, using the dose-to-mother deuterium oxide dilution technique.

Methods: In the main trial, at 6 mo of age infants were randomly assigned to receive either LNS at a daily dose of 10 g, 20 g or 40 g, or no study supplement until 18 mo of age. Breast milk intake was assessed in 9-12 mo infants using the dose-to-mother deuterium oxide technique. An oral dose of 30 g deuterium oxide was given to mothers after collecting 4 ml and 2 ml of baseline saliva samples from mothers and infants respectively. Saliva samples from mother-baby pairs were further collected at 1, 2, 3, 4, 13, and 14 d post-dosing. Deuterium enrichment of saliva samples was measured using Fourier-transform infrared spectrometer. Mean daily breast milk intake and maternal % body fat were calculated from deuterium enrichment data based on a two-compartment, steady-state model.

Results: Daily mean (SD) breast milk intake was 752 (244) g/d and did not differ by group ($p=0.51$). Mean (SD) non-breast milk oral water intake was 388 (255) g/d and did not differ ($p=0.81$) by group. Mean (SD) maternal % body fat was 21.5 (7.7).

Conclusion: Daily consumption of LNS by healthy Malawian infants did not significantly affect mean breast milk intake. Funding was provided by the Mathile Institute for the Advancement of Human Nutrition, the International Atomic Energy Agency, the University of Tampere, and the Bill & Melinda Gates Foundation.

Key words: LNS, breast milk, deuterium oxide

PO800

PATTERNS, MICRONUTRIENT AND CALORIC INTAKE FROM BEVERAGES IN OLDER ADULTS WITH MILD COGNITIVE IMPAIRMENT

B. Venci¹, N. Hodac¹, M. Shidler², S. Lee¹, R. Krikorian²

¹Department of Nutritional Sciences, University of Cincinnati, Cincinnati, Ohio, USA

²Department of Psychiatry and Behavioral Neuroscience, University of Cincinnati, Cincinnati, Ohio, USA

Background and objectives: The objective of this study was to determine patterns of beverage consumption and the contribution to micronutrients and calories from beverages in older adults with mild memory decline.

Methods: This was a cross-sectional study with 60 free living older adults (71.7±5.4 years) who had mild cognitive impairment, a risk condition for dementia. Participants were mostly female (61.7%), white-American (93.3%) with some college education or above (88.3%). Dietary data collected using 3-day food records were analyzed using Nutrition Data Systems for Research.

Results: Total daily consumption of fluid was 53.6±26.7 fl oz and water was the most frequently consumed beverage

($n=53$, median =13.3 fl oz among consumers) followed by milk ($n=49$, 5.3 fl oz), tea/coffee ($n=48$, 16.0 fl oz), and 100% fruit and vegetable juice ($n=27$, 5.3 fl oz). The nutrients of greatest contribution to the diet from beverages included vitamin D (29.4±25.5% out of total vitamin D consumption), calcium (26.4±14.5%), vitamin B2 (22.0±12.8%), magnesium (18.9±8.4%), and vitamin C (18.1±23.9%). Interestingly, only about 11% of total energy and <2% of energy from added sugar came from beverages.

Conclusions: These preliminary findings suggest that nutrient dense beverages play a substantial role in overall micronutrient intake, despite comprising a small component of daily caloric intake.

Key words: beverages, older adults, micronutrients

PO801

CHANGES IN FUNCTIONAL BIOCHEMICAL ZINC INDICES AND BONE MASS OF ADULT WOMEN DURING LACTATION

V.M. Gomes¹, D.I. Silva¹, A.G. Torres¹, F. Kamp²

¹Laboratório de Bioquímica Nutricional e de Alimentos, Instituto de Química, Universidade Federal do Rio de Janeiro, Rio de Janeiro, RJ, Brazil

²Instituto Federal de Educação, Ciência e Tecnologia do Rio de Janeiro, Rio de Janeiro, RJ, Brazil

Background and objectives: Zinc is recognized to be essential for bone metabolism and antioxidant defense, which is partially related to its structural and catalytic role for different enzymes activities. Therefore, zinc deficiency during lactation could exacerbate the bone loss inherent to this period and contribute to oxidative stress. The aim of this study was to investigate the effect of lactational period (LP) on functional biochemical zinc indices and bone mineral density (BMD) of Brazilian lactating women.

Methods: Fourteen women (31 ± 4.7 y), exclusively breastfeeding, with low zinc intake (7.7 ± 3.8 mg/d) were evaluated in two LP: 2-4wk (early lactation, EL) and 12-14wk postpartum (middle lactation, ML). Functional biochemical zinc indices [erythrocyte superoxide dismutase (SOD); erythrocyte aminolevulinic acid dehydratase activity (δ -ALAD) and in vitro zinc- δ -ALAD activation (Zn- δ -ALAD%); plasma bone alkaline phosphatase (BAP)] and measures of BMD [at total body (TBMD) and lumbar spine (L2-L4)] were assessed in both periods.

Results: Comparing ML to EL, significant reduction were observed for: δ -ALAD (18%; $p=0.002$), indicating a lower content of zinc bound and/or oxidation of thiols groups essential for δ -ALAD activity; and SOD (21.3%, $p = 0.01$), suggesting increased production of oxidants during lactation. The increa-

se on BAP activity (21.9%, $p = 0.003$), a bone formation index, and the decreases on TBMD ($p = 0.001$) and L2-L4 ($p = 0.002$), are consistent with the high rate of bone turnover during this period.

Conclusions: Our results suggest impairment on antioxidant status and also a redistribution of zinc during lactation in order to attend the high rate of bone turnover.

Key words: Lactation, zinc, bone, antioxidant. Financial support: CNPq, CAPES.

PO802

ANTIOXIDANT CAPACITY OF BOTH PLASMA AND BREAST MILK DECREASED DURING LACTATION IN ADULT WOMEN EXCLUSIVELY BREASTFEEDING

D I. Silva¹, V M. Gomes¹, M S. Rodrigues¹, AG. Torres¹, F. Kamp²

¹Laboratório de Bioquímica Nutricional e de Alimentos, Instituto de Química, Universidade Federal do Rio de Janeiro, Rio de Janeiro, RJ, Brazil

²Instituto Federal de Educação, Ciência e Tecnologia do Rio de Janeiro, Rio de Janeiro, RJ, Brazil

Background and objectives: The increased energy metabolism and the transfer of antioxidant substances to human milk could impair antioxidant status during lactation, negatively affecting maternal health. The impairment on maternal antioxidant status can also contribute to reduce the antioxidant capacity (AC) of breast milk, with possible consequences for the infant exclusively breast-fed. The aims of this study were to evaluate the effect of lactation period on AC in plasma and breast milk of adult women, and also their association.

Methods: Plasma and breast milk samples of fourteen healthy women (31 ± 4.7 y), exclusively breastfeeding, were obtained at wk 2-4 (early lactation, EL) and wk 12-14 of lactation (middle lactation, ML). Total AC (TAC) in plasma and milk samples was assessed by ferric-reducing ability (FRAP) and oxygen radical absorbance capacity (ORAC) assays.

Results: At ML, significant reduction was observed for TAC in both, plasma (35%, $p < 0.05$) and breast milk (33%, $p = 0.01$) only for FRAP assay. These results suggest oxidation of reducing agents contributors to the method during lactation. By ORAC assay it was noted a significant correlation between TAC in plasma and breast milk ($r = 0.74$; $p < 0.001$).

Conclusions: Our results suggest that exclusive breastfeeding may impair the antioxidant status of adult women, which possibly contributes to decrease antioxidant capacity in breast milk.

Key words: lactation, antioxidant capacity, breast milk. Financial support: CNPq, CAPES.

PO803

FEASIBILITY AND ACCEPTABILITY OF INTEGRATING VITAMIN A RICH ORANGE FLESHED SWEET POTATO INTO ANTENATAL CARE SERVICES IN WESTERN KENYA

Y. Machira¹, C. Levin², F. Grant³, E. Kedera¹, M. Wama-lwa³, A. Bingham¹, D. Cole⁴, J. Low³

¹Program for Appropriate Technology in Health (PATH), Nairobi, Kenya

²University of Washington, Seattle, USA

³International Potato Centre (CIP), Nairobi, Kenya

⁴Dalla Lana School of Public Health, University of Toronto, Toronto, Canada

Background and objectives: This study presents findings on the acceptability and feasibility of an integrated nutrition, agriculture and health intervention that delivers vitamin A rich, orange fleshed sweet potato (OFSP), through antenatal care services (ANC) with the goal of improving the health and nutrition of pregnant women and their infants in Western Kenya.

Methods: We explored the feasibility and acceptability of the intervention through 42 interviews with nurses, community health extension workers (CHEW), vine multipliers (VM), agriculture extension agents and district-level officials; and 24 focus group discussions with community health workers (CHW), pregnant women, and their husbands. Qualitative data was transcribed verbatim and analysed using NVivo 10.0. Content analysis was used to identify key topics, relational analysis to examine relationships between themes and respondents.

Results: Enhanced maternal and child health coupled with food security were the most recognized benefits by respondents. Mothers felt their children were less susceptible to disease and more energetic; they and their partners also valued OFSPs' shorter maturity and higher yields. Frontline health workers perceived higher ANC attendance and increased contact between mothers, their partners and children with the health system. All implementers were motivated by enhanced training, more effective nutrition messaging, tangible recommendations to improve dietary quality, community recognition, and ability to better serve their clients. CHWs emerged as key facilitators of implementation and outreach to mothers. Challenges to implementation and uptake included mothers' distance to ANC and VMs, misperceptions such as OFSP having contraceptive properties, need for continuous community sensitization, and increased workload without commensurate remuneration for CHWs and VMs.

Conclusions: Perceived benefits and motivating factors among key stakeholders outweighed challenges of integrating OFSP with ANC services. These findings contribute to other evaluation activities that assess effectiveness, feasibility and acceptability of this integrated agriculture and health intervention.

Key words: vitamin A, sweet potato, infants

PO804**CONTRIBUTION OF INTRA-ABDOMINAL AND/OR SUBCUTANEOUS ABDOMINAL AND TOTAL ADIPOSE TISSUE IN THE DEVELOPMENT OF THE CARDIOMETABOLIC RISK FACTORS IN CHILDREN**

N. Ramos-Ibanez¹, C. Gonzalez-Alvarez¹, L. Ortiz-Hernandez¹, J. Azpiroz-Leehan²

¹Departament of Health Care, Autonoma Metropolitana University, Campus Xochimilco, Mexico City, Mexico

²Departament of Electrical Engineering, Autonoma Metropolitana University, Campus Iztapalapa, Mexico City, Mexico

Background and objectives: Abdominal adipose tissue is related to metabolic disturbances. Particularly, the intra-abdominal adipose (IAAT) has physiology characteristics that appear involved in the development of hyperglycemia, insulin resistance, dyslipidemia, and hypertension in adults. The aim of the present study is to examine which kind of adipose tissue (IAAT, subcutaneous abdominal adipose tissue -SAAT- or total body fat) is associated more strongly with cardiometabolic risk factors in school children.

Methods: Volunteers were 119 children aged 6-12 years from a school of Mexico City. IAAT and SAAT were assessed with imaging magnetic resonance (Phillips 3T system) in L4-L5 region. Total body fat (BF) was evaluated with dual energy x-ray absorptiometry (Discovery Wii Hologic). Fasting glucose, insulin and lipids blood concentrations were determined, the HOMA index was estimated and systolic and diastolic blood pressures (SBP and DBP, respectively) were measured.

Results: Preliminary results showed that there were no difference in adiposity and cardiometabolic parameter between girls and boys. Partial correlations adjusted by age and sex showed that IAAT was positively associated with the concentration of triglycerides ($r=0.24$, $p<0.01$) and negatively correlated with HDL ($r=-0.25$, $p<0.01$). Meanwhile SAAT was positively associated with insulin and triglycerides concentrations, HOMA index and SBP ($r=0.44$, $r=0.35$, $r=0.42$, $r=0.19$ respectively, $p<0.01$) and negatively associated with HDL concentration ($r=-0.34$, $p<0.01$). BF was also positively associated with insulin and triglycerides concentrations, HOMA index, SBP and DBP ($r=0.35$, $r=-0.27$, $r=0.33$, $r=0.20$, $r=0.19$, $p<0.050$) and negatively with HDL concentration ($r=-0.35$, $p<0.01$).

Conclusions: Adiposity negatively influences on HDL concentration. Insulin concentration and SBP only seem to be affected by subcutaneous adipose tissue. LDL and glucose concentrations could not be altered by changes in adiposity in children. These preliminary results indicate that the SAAT is associated more strongly with cardiometabolic risk indicators than the IAAT.

Key words: children, adipose tissue, cardiometabolic factors

PO805**COMPARISON OF VEGETARIAN AND NON-VEGETARIAN ADOLESCENTS ON ANTHROPOMETRIC PARAMETERS**

G. Segovia-Siapco¹, J. Hilton¹, J. Sabaté¹

¹Department of Nutrition, School of Public Health, Loma Linda University, USA

Background and objectives: Vegetarianism (absence of meat in the diet) has become a popular trend among adolescents. We investigated if vegetarian and non-vegetarian adolescents attending Adventist schools differ in growth indices and body composition.

Methods: We conducted a cross-sectional study among 307 adolescents (163 females and 144 males), aged 12-19 years, who reported their food consumption using a web-based food frequency questionnaire designed for the study. We measured weight, height, waist and hip circumferences, and used a bio-impedance scale for fat mass and fat-free mass measurements. "Vegetarian" was defined a priori as someone with a combined intake of less than one serving per week of meat, poultry, and fish. Gender-specific BMI-for-age and height-for-age z-scores were determined using WHO growth standards. ANCOVA was performed to test differences between vegetarians and non-vegetarians on growth indices and body composition while controlling for confounders.

Results: Seventy-six (25%) participants were vegetarians, 55% of which were females and 43% Caucasians. Height-for-age z scores were significantly higher (0.20 vs -0.12, $p=0.014$) and BMI-for-age z scores were significantly lower (-0.03 vs 0.35, $p=0.010$) for vegetarians than non-vegetarians but after adjusting for hereditary and socio-economic factors, values attenuated and lost significance. The proportion of obese vegetarians was half that of non-vegetarians (4% vs 8%). Vegetarians have lower waist circumference (73.2 cm vs 74.0 cm) and fat mass (10.5 kg vs 11.6 kg) than non-vegetarians but not significantly different after adjusting for age, gender, and ethnicity. Both groups have similar waist-to-hip ratios and fat-free mass.

Conclusions: Vegetarian adolescents tend to be relatively taller, slimmer, and have less fat mass than their non-vegetarian counterparts.

Key words: vegetarian, adolescents, obesity, body composition

PO806**MATERNAL NUTRITION AND ITS CONTRIBUTION TO POOR OBSTETRIC OUTCOMES***R. Galloway¹, S. Wilson², J. Kavle¹*

¹Maternal And Child Health Integrated Program (MCHIP)/Program For Appropriate Technology In Health (PATH), USA

²Consultant, Seattle, Washington, USA

Background and objectives: Poor maternal dietary intake continues to be unaddressed worldwide. Its contribution to obstetric complications (OC) is not well-documented. The Maternal and Child Health Integrated Program (MCHIP) reviewed and synthesized main findings from the literature on the subject.

Methods: On-line searches were conducted in PubMed and POPLINE to identify randomized controlled trials, systematic reviews, observational studies, and meta-analyses related to maternal nutritional status and poor obstetric outcomes, particularly postpartum hemorrhage (PPH), sepsis, pre-eclampsia/eclampsia (PE/E), and obstructed labor (OL). A total of 213 articles were retrieved and another 107 citations identified by the “snowball technique”. Selection criteria included the study being related to the four maternal obstetric outcomes and any nutrient other than calcium or magnesium sulfate which was the subject of a recent review.

Results: A total of 46 papers were selected for review with half conducted in low/middle income countries. One analysis identified a 25% decrease in maternal mortality with a 1 g/dl increase in pregnancy hemoglobin. Four studies observed an increased risk of PPH with anemia. Vitamin A supplementation reduced maternal mortality in Nepali women but not in women in Ghana or Bangladesh. Low serum zinc status has been associated with poor labor and delivery outcomes (prolonged labor, e.g.); however, supplementation trials have not found an effect. Consuming fish oil appears to have no effect on PE/E but one study in Mexico found newborns were heavier when their mothers took n-3 docosahexaenoic acid. Maternal height is predictive of increased risk of assisted delivery with the risk 60% higher in women 146 cm to 157 cm compared with women in the highest quartile for height.

Conclusions: The evidence for maternal nutrition and OC is not overwhelming. More research is needed to evaluate if a nutritious diet, and all its substances, improves OC.

Key words: maternal, nutrition, obstetric outcomes

PO807**THE OPERATIONAL RESEARCH FOR THE WORLD RELIEF RWANDA INNOVATION CHILD SURVIVOR PROJECT, NYAMAGABE DISTRICT***J. McLean¹, K. Michaux¹, W. Li¹, M. Kabadege², F. Ngalibo³, M. Morrow², O. Wollinka²*

¹Department of Food, Nutrition and Health, Faculty of Land and Food Systems, University of British Columbia, Vancouver, British Columbia, Canada

²Maternal and Child Health Unit, World Relief, Kigali, Rwanda

³Maternal and Child Health Unit, Ministry of Health, Rwanda

Background and objectives: Nyamagabe district in Rwanda has some of the highest rates of malnutrition nationwide. While there has been success tackling both acute and chronic malnutrition, stunting has not significantly improved. Strategies are needed that target the multiple causes of stunting, specifically those that address infant and young child feeding (IYCF) across the ‘first 1000 days’ of life. This study was designed to evaluate a behaviour change innovation, which integrates existing national nutrition programming with a week-long, hands-on nutrition training curriculum designed to empower mothers of children 0-23 months and Community Health Workers (CHWs) through participatory learning. Objectives: 1. Improve IYCF knowledge, attitudes and practices of mothers and CHWs; 2. Increase the proportion of children introduced to a minimum acceptable diet of adequate consistency; and 3. Reduce stunting among children 6-23 months.

Methods: Two 30-12 cluster samples, totalling 720 mothers of children under 24 months, were randomly selected in two hospital zones in Nyamagabe district. At baseline, mothers completed a survey of IYCF knowledge, attitudes and practices and maternal and child anthropometry was measured.

Results: Only 3% of children met the minimum acceptable diet, 57% of infants 6-8 months met IYCF recommendations for timely introduction of complementary foods, 20% of children were fed iron-rich foods, stunting prevalence was 39%, and 18% had diarrhoea in the previous two weeks, with only a small percentage receiving recommended treatment (23% received ORS, 40% offered more fluids, 17% treated with zinc).

Conclusions: Our results confirm the need for an innovative approach to improve maternal knowledge and IYCF care practices that will positively affect the nutritional status of children and mothers. Existing programs have not translated into a significant reduction in stunting or prevention of diarrhoea making this research relevant as both infection and malnutrition are linked to stunting.

Key words: behaviour change, stunting.

PO808**VITAMIN A DEFICIENCY AND ANEMIA IN CUBAN PRESCHOOL CHILDREN**

B. Basabe-Tuero¹, C. Macías-Matos¹, G. Pita-Rodríguez¹, S. Jiménez-Acosta¹, C. Hernández², M. Cruz-Jorge², R. Herrera-Charro², R. O´Farril-López², I. Caldearius-Espinosa², K. Paulí-Echeverría², M. Leyva-Ávila², D. López-Sosa², Y. Vega-Castillo², E. Martín-Oramas², S. Orozco-Rodríguez², M. Concepción-Alemañez², A M. Jordán-Quintana², Z. Fuentes-Gutiérrez², C. Arocha-Oriol¹, D. Herrera-Javier¹

¹Institute of Nutrition And Food Hygiene, La Habana, Cuba

²Provincial Hygiene and Epidemiology Center, Cuba

Background and objectives: Micronutrient deficiency is an unquestionable public health problem, specially anemia and vitamin A deficiency. Many studies link vitamin A deficiency with anemia, therefore retinol deficiency impairs iron utilization. A nationwide study was conducted in Cuba to assess vitamin A status and its relationship with anemia.

Methods: A cross-sectional study was carried out in 2205 preschool children aged 6-59 month in Eastern, Center and Western of Cuba. Anemia status was assessed by hemoglobin. Plasma retinol was measured by high-performance liquid chromatography (HPLC). Biochemical indicators are expressed as mean±SD, minimum and maximum values. They were also described by the prevalence of subclinical vitamin A deficiency (0.35 to 0.70 mmol/L) and prevalence of anemia (hemoglobin <11.0 g/dL). Correlations between variables were calculated using Pearson's correlation analysis for numerical data. Odds ratios stratified by groups of age (<2years/≥2years) were used to describe associations between anemia and retinol deficiency.

Results: Mean plasma retinol concentrations were 0.98 mmol/L (western), 1.10 mmol/L (central) and 1.10 mmol/L (eastern). No child had plasma retinol concentration below 0.35 mmol/L, indicative of clinical deficiency. Subclinical deficiency of retinol was seen in 8,6% of subjects (17.0% western, 4,9 % central, 7.0% eastern). The prevalence of anemia was 20.2%, 12.1%, and 14.9% in western, central and eastern region, respectively. There were significant correlations of retinol and hemoglobin in all region (r=0.113, p=0.009 western; r=0.114, p=0.000 central; r=0.095, p=0.01 eastern). Significant association between vitamin A deficiency and anemia was found in the western region (ORMH=2.80, 95%CI 1.50-5.23); however, in eastern (ORMH=1.61, 95%CI 0.94-2.76) and central (ORMH=1.97, 95%CI 0.98-3.93) region had not statistical association.

Conclusions: Vitamin A deficiency classified as a mild public health problem in eastern and central regions. Only in the western region, where the vitamin A deficiency classified as

moderate and the prevalence of anemia is larger, and association between both was found.

Key words: Vitamin A deficiency, anemia, preschool-children

PO809**EFFECT OF LONG TERM SUGAR-SWEETENED BEVERAGE INTAKE ON BMI IN CHILDREN FROM 4 TO 12 YEARS OF AGE**

A. Cantoral¹, M. Téllez-Rojo¹, G. Rueda-Hernández¹, A. Ettinger², H. Hu³, M. Hernández-Ávila¹, K. Peterson⁴

¹National Institute of Public Health, Mexico

²Yale Schools of Medicine and Public Health, New Haven CT USA

³Dalla Lana School of Public Health, University of Toronto, Canada

⁴Human Nutrition Program, University of Michigan School of Public Health, Ann Arbor, MI USA

Background and objectives: According to the National Nutrition Survey (2006), consumption of soda was positively associated with Body Mass Index (BMI) in Mexican adolescents (10-19 years of age). For this age group, energy-containing beverages contribute to 20% of the total energy intake. The aim of the present study was to examine the relation of sugar sweetened beverage (SSB) intake over time and BMI among children from 4 to 12 years of age.

Methods: In a cohort study in Mexico City, height and weight were measured and a food frequency questionnaire was administered at three different times in 250 children between ages 4 to 12 years. BMI (kg/m²) and SSB intake (ml/day of soda, artificial juices and flavored water with sugar added) were calculated. The association between SSB intake and BMI was estimated using a random effects model, adjusting for sex, current age and current energy intake. We conducted an additional using tertiles of soda intake.

Results: At baseline (4 years of age), mean SSB intake was 370 ml/d (39% from soda); at the final measure (12 years of age) SSB intake increased to 434ml/d (44% from soda). Every 100 ml/d increase in SSB was associated with a 0.10 kg/m² BMI increase (p=0.01) while each increase of 100 ml/d soda was associated with a 0.15 kg/m² BMI increase (p=0.01). Among children in the highest tertile of soda intake, BMI was 1.21 kg/m² higher compared with the lowest tertile (p=<0.01).

Conclusions: SSB is a growing component of children's diet in Mexico. Intake starts in the preschool years and is associated with higher BMI at age 12. Public policies are needed to decrease SSB intake, especially soda intake.

Key words: sugar-sweetened beverage, BMI, children.

PO810**DETERMINANTS OF NON-USE OF ANTENATAL IRON SUPPLEMENTS AMONG PAKISTANI WOMEN: A HOUSEHOLD SURVEY***Y. Nisar¹, M. Dibley¹*¹Sydney School of Public Health, The University of Sydney, NSW 2006, Australia

Background and objectives: World Health Organization (WHO) guidelines recommend that all pregnant women should be given a 6-month regimen of a daily iron supplements (a total of 180 supplements). Pakistan follows the WHO guidelines, but the coverage is poor. The aim of this study was to determine the prevalence and risk factors for non-use of antenatal iron supplements among Pakistani women.

Methods: Data was derived from a cross sectional household survey conducted in 14 districts of USAID funded project known as Family Advancement for Life and Health in 3 provinces of Pakistan. Trained female interviewers conducted interviews with married women of reproductive age from December 2011 to March 2012. Women with a singleton live birth in the preceding five years of the survey were selected for this study (n=6267). Data was analysed by using SPSS 21 and STATA 12. Multivariate logistic regression model was constructed to identify the risk factors.

Results: Out of 6267, 2400 (38.3%) women took antenatal iron during their pregnancy. Among users, the most common source of supplements was doctors (49.4%) followed by community health workers (40.3%). The mean (SD) days of iron consumed was 76.9 (\pm 51.6) days and mean (SD) month of initiation of supplements was 5.3 (\pm 1.7) months. Risk factors for non-use of antenatal iron were women living in Punjab province (Adj OR=1.76), aged 35 years and above (Adj OR=1.40), had no education (Adj OR=1.88), had illiterate husband (Adj OR=1.44) and had no ANC visit (Adj OR=24.50) compared to their counterparts.

Conclusions: The prevalence of antenatal iron was low in Pakistan. There is a need to develop strategies to improve coverage and increase early uptake of antenatal iron supplements among Pakistani women by designing programs that address the key barriers to use of these supplements.

Key words: iron supplements, pregnancy, determinants

PO811**ASSOCIATION BETWEEN MATERNAL PRE-PREGNANCY BODY MASS INDEX, GESTATIONAL WEIGHT GAIN AND NEWBORN WEIGHT: A RETROSPECTIVE COHORT STUDY IN CHINA***Y. Zhao¹, R. Peng¹, H. Xue¹, Y. Qie¹, L. Han¹, X. Xu², Y. Zhang¹, Z. Zhang³, Y. Xia¹, T. Yang¹, X. Zhou⁴, Z. Xiong², Y. Zhang⁵, J. Liu⁵, J. Li⁶, T. Li³, M. Sharma⁷*¹School of Public Health and Management, Chongqing Medical University, Chongqing, China²The Second Affiliated Hospital, Chongqing Medical University, Chongqing, China³Children's Nutrition Research Centre, Key Laboratory of Developmental Diseases in Childhood of Education Ministry, Children's Hospital of Chongqing Medical University, Chongqing, China⁴The First Affiliated Hospital of Chongqing Medical University, Chongqing, China⁵Chongqing Maternal and Child Health Care Hospital, Chongqing, China⁶The First Affiliated Hospital of the Third Military Medical University, Chongqing, China⁷Health Promotion and Education, University of Cincinnati, Cincinnati, USA

Background and objectives: International studies have demonstrated that abnormal maternal pre-pregnancy body mass index (BMI) and gestational weight gain are the most important factors causing adverse pregnancy outcomes. It is important to examine the association in Chinese populations. The objective of this study was to determine the effect of maternal pre-pregnancy BMI and gestational weight gain on newborn's weight in China.

Methods: A total of 397 women, just after delivery, were enrolled from four big hospitals in Chongqing, Southwest China, in a retrospective longitudinal study from March 2010 to March 2012. The participants were divided into 4 subgroups (A: BMI \leq 19.8kg/m², B: BMI of 19.8-26 kg/m², C: BMI of 26-29 kg/m², D: BMI of > 29 kg/m²) based on the maternal pre-pregnancy BMI. The following parameters were included in the analysis: maternal pre-pregnancy weight and height, maternal weight just before delivery, gestational age and newborn weight.

Results: Within the A subgroup, the occurrence of low birth weight was negatively correlated with maternal gestational weight gain (P<0.05). Within A, B, C subgroup, occurrence of high birth weight was positively correlated with maternal pregnancy weight gain (P<0.05), on the contrary, within the D subgroup, occurrence of high birth weight was negatively correlated with maternal gestational weight gain (P<0.05).

Conclusions: The interaction effects of maternal pre-pregnancy BMI and gestational weight gain on birth weight in di-

fferent sub-subgroups are different. It is critical important to carry out personalized pre-pregnancy care and prenatal care for reasonable pregnancy outcome including appropriate birth weight.

Keywords: gestational weight gain, maternal body mass index, neonatal birth weight, pregnancy

PO812

RAPID BMI GROWTH FOLLOWED BY HEIGHT INCREASE PREDICT HIGH DHEAS IN 7 Y OLD CHILLEAN CHILDREN

C. Corvalan¹, R. Uauy^{1,2,3}, V. Mericq⁴

¹Public Health Unit, Institute of Nutrition And Food Technology (INTA) University of Chile

²Public Health Unit, London School of Hygiene and Tropical Medicine, London, UK

³Pediatrics Department, Catholic University, Santiago, Chile

⁴Maternal and Infant Research Institute (IDIMI), University of Chile, Santiago, Chile

Background and objectives: Accelerated weight and height gain in infancy have been associated with adrenarche. However, the exact temporality of these events remains unclear. The aim of the present study was to assess the relationship between early body mass index (BMI) and height growth and DHEAS at 7 years.

Methods: in 944 children (48% girls) of birth weights 2500-4500 g we abstracted weight and height 0-4 y from health records and measured them annually thereafter. We calculated BMI: weight/height² and defined 4 periods of interest: prenatal, 0-24, 24-48 and 48-72 months. At 7 y we measured DHEAS plasmatic concentrations. We used general lineal models to test associations, adjusting for age and sex.

Results: BMI was over the WHO reference from birth on (0.87 BMI-SDS at 7 y) while height was slightly below until 4y and increased thereafter (0.05 height-SDS at 7 y). At 7y, mean DHEAS was 29.7±1.8 µg/dl. BMI and height at birth were inversely associated with DHEAS at 7 y (β =0.1; 95% CI -0.16, -0.03 and -0.11; -0.18, -0.04, respectively). BMI gains, particularly from 2-4 y increased DHEAS levels (β =0.19; 0.11, 0.26) while height gain had a weaker association (β =0.12; 0.03, 0.20). Children with high DHEAS (>75th percentile) compared to remaining children presented significantly higher BMI from 4 y onwards (Dif BMI-SDS at 4 y: 0.30 95% CI (0.44-0.15), p <0.05) and higher height only at 7 y (Dif height-SDS: 0.21

(0.35 to 0.08), p <0.05). Analyses did not differ by sex (p >0.05)

Conclusions: In normal birthweight children, smaller size at birth, increased weight gain before 4y, and increased linear growth after 4 y were associated with higher DHEAS at 7 y; in children with high DHEAS at 7 y increased adiposity precedes and probably leads to subsequent linear growth. Funding: WCRE, Fondecyt #1100206 & 1090252

Key words: adrenarche, BMI, height, growth

BREASTFEEDING AND DEPRESSION IN PREGNANT AND LACTATING WOMEN IN MALAYSIA

C. Binns¹, A. Yusuff², A. Lee¹

¹School of Public Health, Curtin University, Perth, Western Australia, Australia

²University of Malaysia, Sabah, Malaysia, Kota Kinabalu, Sabah, Malaysia

Background and objectives: Breastfeeding provides the best nutrition for infants and lifetime benefits for health. The objectives of the study were to describe breastfeeding rates in Kota Kinabalu and association between breastfeeding and maternal depression.

Methods: A cohort study of 2072 women who were recruited at a third trimester antenatal visit in the district of Kota Kinabalu, Malaysia. The mothers were followed up at 1, 3 and 6 months postpartum. At each visit the Edinburgh Postnatal Depression Scale (EPDS) was administered and details were obtained on infant feeding. Logistic regression and Kaplan-Meier survival analysis were conducted.

Results: The any breastfeeding rates of mothers at 1 month, 3 months and 6 months postnatally were 95.9%, 88.2% and 80.7% respectively and the 'full breastfeeding' rates were, 67.2%, 49.8% and 36.1%. Using the Edinburgh scale the prevalence of antenatal depression (EPDS \geq 12) was 13.8% while the prevalence of postpartum depression was 7.6%, 7.2% and 8% at 1 month, 3 months and 6 months respectively. Antenatal depression was a strong risk factor for postpartum depression, but the prevalence of postnatal depression was lower than antenatal depression. Mothers who scored higher on the EPDS in the antenatal period had similar breastfeeding outcomes to mothers with scores within normal bounds. Breastfeeding did not increase rates of postnatal depression. Similarly the existence of postnatal depression did not influence breastfeeding duration. An additional 2.6% of mothers who developed for the first time postnatally and at the same time 6.2% of mothers who were depressed fell below the depression threshold. In the postnatal period, becoming depressed, remaining depressed or improving the EDPS score were not related to breastfeeding outcomes.

Conclusions: Depression is common in pregnancy and lactation in Malaysia, but is not related to breastfeeding outcomes.

Key words: depression, breastfeeding, Malaysia

PO814

DIET, PERCENTAGE OF BODY FAT AND AEROBIC POWER IN YOUTH SERIES OF FOOTBALL PLAYERS OF THE SANTIAGO WANDERERS CLUB

C. Valenzuela¹, V. Quiñones¹, M. Mori¹

¹Nutrición y Dietética, Facultad de Farmacia, Universidad de Valparaíso, Valparaíso, Chile

Background and objectives: For an optimal physical condition and performance a sufficient and healthy diet is fundamental. The aim of this study was to associate the diet, the corporal fat percentage and the aerobic power in football players from the Santiago Wanderers Football Club young team.

Methods: The diet quality was measured in each subject (n=46) through the healthy eating index (HEI, adapted to Chilean population) and the nutritional value of the diet through the reminder of 24 hour poll for 3 days. The aerobic power was determined through the VO₂max. The fat percentage was calculated through six skinfold using a Lange caliper. For the statistic analysis we used the SPSS Statistics V 19 software and the Pearson coefficient to correlate HEI, corporal fat percentage and VO₂max (p<0.05) variables.

Results: The age, weight and height was 17.3±1.2 years 69.9±6.8 kg and 1.70±0.1 m, respectively (mean±SD). The corporal fat percentage was 11.6±2.4%. Regarding the diet, the 89% of the subjects need changes and the 11% were having an unhealthy diet. None of the subjects obtained a healthy diet according to HEI. The energy from the diet was 2765±747 kcal on average, insufficient in relation to the nutritional recommendations for football player (3189±264 kcal). The same happened with the macronutrients (p<0.05). The average VO₂max was 58.5±4.4 ml/kg/min.

Conclusions: The diet of the football players was characterized by an insufficient nutritional value that didn't meet their nutritional requirements, with a low protein ingestion of high biological value, fruits and vegetables, which could affect their performance. No significant association was found between the three principal variables studied.

Key words: sport, diet, nutritional requirements, football, body composition.

PO815

FOOD HABITS AND LIFESTYLE AND ITS RELATIONSHIP TO THE PREVALENCE OF CHILDHOOD OBESITY IN CIUDAD GUZMAN JALISCO

M. Padilla¹, A. Cárdenas¹, A. Martínez¹, A. Lopez-Espinoza¹

¹Universidad de Guadalajara, Spain

Background and objectives: Overweight and obesity are global health problems. In Mexico more than 26% of infants are sufferers. There is little information on prevalence in local population and food habits and lifestyle related. Objective of this study was determine food habits and lifestyle infants of 8-10 years and their relationship with the prevalence of overweight and obesity in Ciudad Guzman, Jalisco.

Methods: Surveys were food habits and lifestyle to 800 primary school children, rates were estimated height for age and weight for height, BMI and nutritional status was determined according to NOM-008-SSA2-1993 NCHS tables.

Results: According to the type of data were performed ANOVA and Tukey DSF and descriptive statistical tests Ch² seeking associations (p<0.05), and calculated the odds ratio (OR) for cases and controls. SPSS software was used. Data collected demonstrated that prevalence of overweight and obesity (ow-ob) was 37.33% (33% girls and 40% boys). 87% of infants consume unhealthy energy foods (chips, crackers, cakes and sugary drinks). 30% of infants of normal weight (nw) and 20% (ow-ob) watch TV>2 hours/day during this time, 80% of ow-ob and nw consume unhealthy foods, 52% of nw and 42% of ow-ob performed physical activity over an hour / day (OR=0.66), and established retail association between less physical activity and obesity in girls (Chi²=5.75, p<0.05). The prevalence found is consistent with that expected for Jalisco, like affected more males.

Conclusions: Consuming unhealthy foods corresponds to national trend nw infants reported high consumption of unhealthy foods and more TV time, but also more time doing physical activity which appears to prevent obesity

Key words: childhood- obesity, food habits, lifestyle

PO816**KNOWLEDGE, ATTITUDE AND PRACTICE OF INFANT FEEDING IN THE CONTEXT OF HIV: A CASE IN TANZANIA**

J. Kaganda¹, M. Kibona¹, O. Mella¹, L. Nnally¹, W. Mgeni¹, F. Libaba¹, M. Rwenyagira¹, D. Katana¹, N. Joshua¹, D. Charwe¹, R. Mzimhiri¹, D. Kiondo²

¹Tanzania Food and Nutrition Centre, Dar es Salaam, Tanzania

²The Centre for counseling nutrition and health care, Dar es Salaam, Tanzania

Background and objectives: Despite the fact that there is a risk of mother to child transmission of HIV through breastfeeding, breastfeeding is still a norm practice in Tanzania. 97 percent of children in Tanzania are breastfed at some point in their life. According to the PMTCT and Paediatric HIV scale up plan, 75 percent of all infected mothers intended to exclusively breastfeed their babies. The use of pre-lacteal feeds is 31 and 24 percent in rural and urban areas, respectively. Although the implementation of PMTCT is widely covered, there has been limited postnatal follow-up to determine prevalence of actual infant feeding practices.

Methods: A cross-sectional exploratory design was employed. Stratified sampling technique was used to select mothers with children aged 6-24 months in positive and negative HIV mothers. Descriptive analysis of data was done using SPSS version 18, and t-test for comparison of means of various indices.

Results: Majority of health service providers had inadequate knowledge about infant feeding in the context of HIV and AIDS. Similarly HIV negative women had limited knowledge on recommended infant feeding practices. There was a prevailing attitude towards use of colostrum, significant positive attitude in early complementation and negative attitude towards exclusive breastfeeding. Frequency of complementary feeding was also low and unbalanced.

Conclusions: Capacity building of health service providers on essential nutrition interventions to promote, protect and support infant and child feeding and strengthening maternal and child nutrition component in reproductive and child health services is significant.

Key words: Tanzania, infant feeding practices

PO817**HOME-BASED DIETETIC INTERVENTION IMPROVES NUTRITIONAL STATUS POST HOSPITAL DISCHARGE IN OLDER PEOPLE**

A H. Hamirudin¹, A. Carrie², K. Charlton¹, K. Walton¹, L. Tapsell¹, M. Milosavljevic², G. Pang³, J. Potter²

¹School of Health Sciences, University of Wollongong, Australia

²Illawarra Shoalhaven Local Health District, New South Wales Health, Australia

³Agency for Clinical Innovation, New South Wales Health, Australia

Background and objectives: In older adults, deterioration of nutritional status during hospital admission, results in many individuals being discharged home at high nutritional risk, with little community-based support. Integrated approaches between settings are needed to improve outcomes in this group. This study aimed to test whether a model of home-based dietetic care improved dietary intake and weight status in older adults post hospitalisation.

Methods: Department of Veterans Affairs (DVA) patients aged ≥ 65 years were recruited from hospitals in a regional area of New South Wales, Australia (n=32 men, n=36 women). Nutritional status was assessed at home at baseline (2 weeks post discharged) and 3 months post discharged using diet history, food frequency checklist and Mini Nutrition Assessment (MNA). Personalised dietary advice was provided by a single dietitian based on their nutritional status. Dietary intakes were analysed using FoodWorks 2009 (Xyris Software, version 6.0). Statistical analysis were performed using paired t-test, Wilcoxon Signed Rank test and two-way ANOVA. P value was set as $p < 0.05$.

Results: Mean body weight increased significantly from 67.1 ± 13.5 kg to 68.0 ± 13.7 kg ($p = 0.048$). Mean MNA score improved significantly from "at risk of malnutrition" to "well-nourished" category ($p = 0.000$). At 3 months, underweight group (BMI < 22 kg/m²) had significantly higher mean protein (g) intake per body weight (kg) (1.7 ± 0.4 g/kg) compared to normal weight (BMI 22-27 kg/m²) (1.5 ± 0.3 g/kg) and overweight group (BMI > 27 kg/m²) (1.1 ± 0.3 g/kg). 11.2% and 14.7% subjects consumed protein and energy supplementation at baseline and 3 months respectively. 10.3% participants received "Meals on Wheels" service. Mean energy, protein, fibre and calcium intake were adequate at baseline and 3 months, with no significant difference detected.

Conclusions: Dietetic intervention with supports from community services was proven effective in managing malnutrition in older patients.

Key words: malnutrition, older adult, nutrition intervention

PO818**BREASTFEEDING BEYOND 12 MONTHS: WHO'S DOING THIS IN AUSTRALIA?***J. Scott¹, G. Koh²*¹School of Public Health, Curtin University, Australia²School of Pharmacy and Medical Science, University of South Australia, Australia

Background and objectives: WHO recommends that infants be exclusively breastfed to 6 months and that mothers continue to breastfeed until their infant is two years or older. This recommendation has been modified in a number of industrialized countries including Australia and the USA where women are recommended to breastfeed to 12 months and beyond. Despite these recommendations breastfeeding beyond 12 months is relatively uncommon in Australia and most other industrialized countries. The purpose of this study was to analyze data from the first Australian National Infant Feeding Survey (NIFS) to identify predictors of extended breastfeeding.

Methods: Multivariate logistic regression analysis was used to identify independent predictors of breastfeeding beyond 12 months.

Results: Of the 4056 NIFS participants with children 12 months or older who had ever breastfed, 3795 were still breastfeeding or had indicated a valid infant age at which they had stopped breastfeeding. Of these women, almost one third (31.2%) was still breastfeeding or had breastfed their infant for longer than 12 months. Those women most likely to breastfeed beyond 12 months were 35 years or older, had a university qualification and were either not participating in the workforce or had returned to work after their infant was 12 months old.

Conclusions: These findings indicate that workforce participation is not conducive to breastfeeding for longer than 12 months. Australian women under certain conditions are entitled to 18 weeks of Government-funded Parental Leave and an additional 12 months of unpaid leave. These entitlements fall far short of those legislated by several other OECD countries and in particular the Scandinavian countries where breastfeeding beyond 12 months is more common.

Key words: extended breastfeeding, duration, determinants

PO819**DETERMINANTS OF BREASTFEEDING AT DISCHARGE IN RURAL CHINA: A PROSPECTIVE COHORT STUDY IN SICHUAN PROVINCE***L. Tang¹, C. Binns¹, A. Lee¹, C. Luo², Z. Zhong³*¹School of Public Health, Curtin University, Perth, Western Australia, Australia²Department of Obstetrics and Gynaecology, Jiangyou People's Hospital, Jiangyou, Sichuan Province, PR China³Department of Obstetrics and Gynaecology, No.⁴Jiangyou People's Hospital, Jiangyou, Sichuan Province, PR China

Background and objectives: China experienced a rapid decline in the prevalence of breastfeeding in the late 1970s when infant formula became readily available. In response, the Chinese government introduced the 'Baby Friendly Hospital Initiative' together with regulation of the marketing of breastmilk substitutes in the 1990s. Since then, increases in breastfeeding rates were evident with several studies reporting rates above 90% at discharge. The aim of this study was to investigate the rate of breastfeeding at discharge and associated influencing factors in rural China.

Methods: A prospective cohort study on infant feeding practices was undertaken during 2010-2011 in Jiangyou, China. A total of 695 mothers (response rate 96%) were recruited from four hospitals and three health centres and interviewed at discharge. The questionnaire included detailed information of infant feeding practices and factors related to breastfeeding initiation and duration. Binary logistic regression was used to assess the determinants of breastfeeding at discharge.

Results: The breastfeeding rate at discharge was 93.5% (95% confidence interval (CI) 91.7-95.3). Perceived paternal breastfeeding preference was positively associated with the actual breastfeeding at discharge (odds ratio (OR) 4.46, 95% CI 2.15-9.28). Other significant determinants were 'receiving breastfeeding support' from staff during hospital stay (OR 3.41, 95% CI 1.58-7.34) and making the decision on feeding method during or after pregnancy (OR 0.46, 95% CI 0.22-0.93).

Conclusions: Provision of breastfeeding support in hospital and education programs targeting expectant and future parents are recommended to further increase the rate of breastfeeding at discharge in rural areas of China.

Key words: breastfeeding, China, hospital support, paternal attitude.

PO820**FORMATIVE WORK ON COMPLEMENTARY FEEDING PRACTICES AND ANEMIA KNOWLEDGE TO GUIDE THE DEVELOPMENT OF A HOME-FORTIFICATION PROTOCOL IN RWANDA**

K. Ho¹, J. McLean¹, A. Omwega², D. Collison², A. Nyirahabineza³, F. Ngabo⁴

¹Faculty of Land and Food Systems, University of British Columbia, Vancouver, BC, Canada

²Health and Nutrition Section, UNICEF Rwanda, Kigali, Rwanda

³Nutrition Unit, Ministry of Health, Kigali, Rwanda

⁴Maternal and Child Health Unit, Ministry of Health, Kigali, Rwanda

Background and objectives: Anemia is a widespread problem worldwide with approximately half of cases attributed to iron deficiency. Due to its negative impacts on health and economic development, addressing anemia is a priority in many countries. In consideration of the high prevalence of anemia among Rwandan children (77% among 6-9 month olds) and recent WHO guidelines recommending micronutrient powders (MNP) as part of infant and young child complementary feeding (IYCF) programming, the Ministry of Health and partners conducted formative research for a MNP intervention for children 6-23 months with the following objectives: 1. To explore knowledge on anemia and IYCF practices of caregivers and healthcare providers. 2. To evaluate the feasibility of home-fortification with MNP at the community and household level. 3. To inform and guide the training protocol and MNP programme development for implementation.

Methods: Eighteen focus groups and 97 key informant interviews were conducted among healthcare providers, caregivers, fathers and grandparents of young children in randomly selected clusters in two districts, Musanze and Nyaguru. Qualitative methods were used for analysis.

Results: Many misconceptions and knowledge gaps were identified regarding iron-rich foods, optimal IYCF, and anemia causes and symptoms. Tree tomatoes and green vegetables were incorrectly identified as being rich iron sources, while oedema and weight loss were considered symptoms of anemia. There was a strong interest in MNP and nutrition education with community health workers identified as trusted sources of information.

Conclusions: Advice to caregivers needs to be accurate and consistent regarding anemia and appropriate IYCF. The need for integrating a MNP protocol with nutrition education in the community was confirmed through our findings. Our results are guiding the implementation of home-fortification with MNP to improve the nutritional status of children in Rwanda.

Key words: micronutrient powders; infant and young child feeding practices; anemia; home fortification; qualitative methods

PO821**THE INFLUENCE OF DIFFERENT DURATIONS OF AEROBIC EXERCISE ON FUEL UTILIZATION AND LACTATE LEVELS IN TRAINED RATS**

Y.O. Cho¹, E.Y. Choi²

¹Department of Food & Nutrition, Duksung Women's University, Seoul, Korea

²Department of Food & Nutrition, Kyungbuk College, Yeongju-si Gyeongbuk, Korea

Background and objectives: This study investigated the influence of different durations of aerobic exercise on fuel utilization and lactate levels in trained rats.

Methods: Forty rats were fed a control diet. Additionally, the animals underwent physical training (T) or no training (NT) for 6 wk. For physical training, animals exercised on treadmill for 30 min. At the end of week 6, the animals in each group were subdivided into two groups: before exercise (BE), during exercise (DE). The BE groups were sacrificed without having performed exercise at the end of week 6. The DE rats exercised on a treadmill for 30min (DE-30), 1h (DE-1) and 2h (DE-2) immediately before being sacrificed. Glucose, protein, triglyceride (TG), free fatty acid (FFA), and lactate levels in the plasma, glycogen, TG and protein levels of liver and skeletal muscle of the rats were compared.

Results: Glucose level of control group was significantly low in DE-2. Muscle and liver glycogen levels were significantly low in DE-1 and DE-2 but there were no significant difference between DE-1 and DE-2 in trained group. Liver protein of control group was significantly low in DE-2. Muscle TG levels decrease at DE-30 in trained group. But control group decrease at DE-1. FFA levels were increase at DE-30 in trained group but in control group increase at DE-1. Lactate levels increase at DE-30 in control group but in trained group increase at DE-1.

Conclusions: It is suggested that, training may improve exercise performance by facilitating the mobilization and oxidation of fat and conserving limited carbohydrate store and may delay the onset of fatigue associated with low lactate levels. This study was supported by 2012 Research Grant of Duksung Women's University.

Key words: duration of exercise, training, glycogen, free fatty acid, lactate

PO822**BASAL METABOLIC RATE AND BODY COMPOSITION MEASURED FOR NUTRITIONAL ASSESSMENT IN RUGBY FOOTBALL PLAYERS***C. Yamashita¹, K. Yamazaki¹, S. Nakai¹, N. Komenami¹*¹Department of Food and Nutrition, Kyoto Women's University, Kyoto, Japan

Background and objectives: In recent years, nutritional management has been considered to maintain and improve the competitive power and conditioning of athletes. Rugby football players are required to build the body in relation to agility, endurance, and combative sports ability. This preliminary study was designed to evaluate the need for nutritional assessment based on basal metabolic rate and body composition in amateur rugby football players.

Methods: Thirty male amateur rugby football players (23.5±4.6 years) from one team participated in this study. Basal metabolic rate (BMR) was measured by indirect calorimetry with a Douglas bag (mBMR-D). Body weight, lean body mass (LBM), and % body fat (BF) were measured using a full body composition meter. To detect the factors influencing mBMR-D, stepwise multiple regression analysis was performed using the independent variables of age, body weight, LBM, and %BF. Energy and nutrient intakes were investigated using a food frequency questionnaire.

Results: A highly significant correlation ($r=0.901$) was found between mBMR-D and LBM, including data on other athletes. mBMR-D was found to be a useful measure and appropriate method for determining nutritional status, considering each individual's physical properties. Multiple regression analysis revealed that LBM ($f\hat{A}=0.950$) and %BF ($f\hat{A}=-0.178$) were factors affecting mBMR-D ($R^2=0.873$). When physical properties were analyzed according to playing position, BMR, LBM, and %BF of forwards (FW) were significantly higher than that of backs (BK). Significant differences were seen in body characteristics, but not energy or nutrient intake, between FW and BK.

Conclusions: The results indicate that players should receive adequate energy and nutrition to increase LBM and decrease %BF. Nutritional assessment is important to estimate the energy and nutrient requirements according to playing position.

Key words: lean body mass, body fat, physical properties, playing position

PO823**DIETARY INTAKE AND ANTHROPOMETRIC CHARACTERISTICS OF ADOLESCENT FEMALE BALLET DANCERS—A CROSS-SECTIONAL DESCRIPTIVE STUDY***K.L. Beck¹, S. Mitchell¹, A. Foskett², C.A. Conlon¹, P.R. von Hurst¹*¹Institute of Food Nutrition and Human Health, Massey University, Auckland, New Zealand²School of Sport and Exercise Science, Massey University, Auckland, New Zealand

Background and objectives: Ballet dancing requires dynamic and isometric strength yet due to its aesthetic qualities there is pressure to maintain a lean physique. Adolescent ballet dancers face the additional challenge of extra nutritional requirements for growth and development. This study aimed to investigate the macronutrient intake and anthropometric characteristics of adolescent female ballet dancers living in Auckland, New Zealand.

Methods: Female ballet dancers aged 13-18 years ($n=47$) who danced a minimum of one hour per day at least five days per week participated in this cross-sectional study. Body mass index (BMI) was determined from weight and height measurements and percentage body fat measured using Dual Energy X-ray Absorptiometry (Hologic Discovery A). Participants completed a 4-day estimated food record (analysed using Foodworks Professional 2009).

Results: Mean BMI was 19.7 ± 0.3 kg/m² and percentage body fat $23.3\pm 0.6\%$. The majority (89.4%) of dancers had a healthy weight (5th–85th percentile) using the Centers for Disease Control and Prevention BMI-for-age growth charts. Two (4.3%) of dancers were underweight (<5th percentile) and three (6.4%) were overweight (85th–95th percentile). Food records were completed by 41 participants. Mean energy intake was 8183.9 ± 337.0 kJ/day with a macronutrient distribution 17.0% protein, 50.0% carbohydrate and 33.0% fat. Mean protein and carbohydrate intakes were 78.4 ± 3.3 g/day (1.6 ± 0.1 g/kg body weight/day) and 244.8 ± 10.0 g/day (4.9 ± 0.2 g/kg/day) respectively. Eleven participants (26.9%) consumed less than 1.2 g protein/kg/day and over half (58.5%) of participants consumed less than 5 g carbohydrate/kg/day. Mean dietary fat intake was 74.1 ± 3.9 g/day.

Conclusions: While mean body composition measurements and macronutrient intakes as a percentage of total energy intake fell within the recommended range for healthy populations, a number of adolescent ballet dancers may be at risk of consuming inadequate carbohydrate and to a lesser extent, protein based on current sporting recommendations.

Key words: diet, anthropometry, ballet, adolescent, female

PO824**INFLUENCE OF MACRONUTRIENT INTAKES ON SALIVARY IMMUNOGLOBULIN A LEVELS IN ATHLETES**

K. Yamazaki¹, H. Tsujimoto¹, N. Ohya¹, C. Yamashita¹, N. Komenami¹

¹Department of Food and Nutrition, Kyoto Women's University, Kyoto, Japan

Background and objectives: Depressed immune function during intensive training is associated with the incidence of illness in athletes. Previous reports suggested that there is correlation between resting salivary immunoglobulin A (sIgA) levels and the incidence of upper respiratory tract infection (URTI) symptoms. The purpose of this study was to evaluate the physical, mental, and nutritional condition of male long-distance runners during high-intensity endurance training.

Methods: Eighteen male athletes (age, 19±1 years) participated in this study. Heart rate and rate of perceived exertion were recorded to monitor exercise intensity. Wet bulb globe temperature was measured during training. Saliva samples were collected before and after training for 6 months. Saliva flow rate and sIgA concentration were determined by enzyme-linked immunosorbent assay and expressed as secretion rate. Mood states, including total mood disturbance (TMD), were assessed by using the profile of mood states inventories. URTI symptoms were investigated by using a questionnaire. Energy and nutrient intake was evaluated by using a food frequency questionnaire.

Results: Intensive training decreased sIgA levels and increased TMD after training in a hot environment (>25 degrees C). Low sIgA levels before training were found in the presence of URTI symptoms. There was a significant inverse correlation between the sIgA level before training and energy-adjusted carbohydrate intake as well as a positive correlation between the sIgA level during training and energy-adjusted fat and protein intake.

Conclusions: These findings suggest that intensive exercise in a hot environment decreases the sIgA level after training. In addition, the sIgA level before training is associated with URTIs and macronutrient intake.

Key words: salivary immunoglobulin A, upper respiratory tract infection symptoms, profile of mood states, nutritional status, exercise

PO825**NUTRITION AND ECCENTRIC EXERCISE IN PEOPLE OVER 65 YEARS: EVIDENCE STUDY**

C. Wanden-Berghe^{1,2,6}, A. Vázquez-Morales³, J. Sanz-Valero^{3,4,6}, M D. Ruiz-López^{5,6}

¹Department of Pharmacy, CEU Cardenal Herrera University, Elche, Spain

²Home Care Unit, General University Hospital of Alicante, Alicante, Spain

³Department of Public Health and History of Science, University of Alicante, Alicante, Spain

⁴Department of Public Health and History of Science, Miguel Hernandez University, Elche, Spain

⁵Department of Nutrition and Food Science, University of Granada, Granada, Spain

⁶Communication and Scientific Documentation in Nutrition Group (CDC – Nut SENPE), Madrid, Spain

Background and objectives: To review the scientific literature about the benefits that proper nutrition and training with eccentric exercise can provide people over 65, and their possible ways of application.

Methods: Documental study by systematic technique of randomized clinical trials (RCT) published in journals indexed in international database, excluding the documents were not based on the target population (over 65 years) and / or drugs used in the intervention. Additionally, as a secondary search, the bibliographies given in the selected articles were reviewed in order to identify studies not found by the primary search (in order to reduce potential publication bias).

Results: 10 articles (RCT) were selected for review from the following countries of origin: Switzerland, USA, Canada and UK. Some are based on healthy population and other on diseases cardiovascular, musculoskeletal, Parkinson and Hemiparesis. The eccentric exercise (ECC) was applied: bikergometer, knee exercise with dynamometer, walker and exercises with machines.

Conclusions: The eccentric training is an option to reduce and prevent Sarcopenia (although there was a better response when combined with proper nutrition). Because of its low metabolic cost and reduced oxygen consumption is optimal in cardiovascular disorders, chronic illness and frailty. Decreases risk of falling and improved mobility and quality of life. The bicycle, treadmill, movements aimed at specific segments with or without load and ride on down are low cost resources that can be used. It is recommended to continue the development of research on this theme and expand the population sizes in studies including interventions for upper body segments.

Key words: eccentric exercise; health promotion; aged; sarcopenia.

PO826**A PROTEIN-ENRICHED DIET FAVOURABLY AFFECTS CARDIOVASCULAR HEALTH IN ELDERLY WOMEN UNDERTAKING PROGRESSIVE RESISTANCE TRAINING**

C. Nowson¹, S. O'Connell¹, N. Mundell¹, C. Grimes¹, D. Dunstan², R. Daly

¹School of Exercise & Nutrition Sciences, Deakin University, Burwood, Victoria, Australia

²Physical Activity, Baker IDI Heart and Diabetes Institute, Melbourne, Victoria, Australia

Background and objectives: Progressive resistance exercise (PRT) ameliorates age-related muscle loss, but the impact of a modest increase in dietary protein combined with PRT on cardiovascular risk factors in older people is unknown. We examined differences in blood pressure and blood lipid responses to a modest increase in dietary protein through increased consumption of lean red meat compared to a control diet in elderly women undertaking PRT.

Methods: Women (n=100) aged 60-90 years undertook PRT sessions twice weekly for 4 months and were randomised to either a protein-enriched diet group (PE) (160g/day lean red meat) or a carbohydrate control diet group (CC) (1 serve carbohydrate/day).

Results: Ninety-one women completed the study: n=48 PE, mean (SD) age 72.3 (6.2) years, and n=43 CC, 74 (7.3) years. The mean (\pm SE) intervention dietary protein intakes in the PE and CC groups were 1.3 \pm 0.1 g/kg/d and 1.2 \pm 0.1 g/kg/d (p<0.05). Greater decreases from baseline values for systolic and diastolic BP in PE compared to CC did not reach significance (systolic -4 \pm 1.5% vs -1.9 \pm 1.8%, P<0.30; diastolic -4.2 \pm 1.6% vs +0.7 \pm 2.5%, p<0.09). However, in women on hypertensive therapy (PE n=27; CC n=26), PE had a fall in diastolic pressure of 5.9 \pm 2.3% while CC rose 3.8 \pm 3.4% (p=0.02, between-group difference). Both groups had similar reductions in total cholesterol (2.4-3.4%) and LDL-cholesterol (4.7%, 4.8%) (all p<0.01), with no changes in body weight.

Conclusion: In older women undertaking 2 sessions/week PRT for 16 weeks, consuming an average of 1.3 g protein/kg/d by eating lean red meat had a favourable effect on blood pressure in those taking anti-hypertensive medication. PRT had a favourable effect on total and LDL-cholesterol which was independent of any dietary protein differences. In addition to the health benefits of maintaining lean mass, PRT reduces cardiovascular risk factors in older women.

Key words: Dietary protein, elderly, women, resistance training

PO827**MONITORING FINDINGS FROM A COMMUNITY-BASED PROGRAMME TO PROMOTE AND SUPPORT EXCLUSIVE BREASTFEEDING IN BANGLADESH**

R. Haider¹

¹Training & Assistance For Health & Nutrition (TAHN) Foundation, Dhaka, Bangladesh

Background and objectives: Exclusive breastfeeding is being promoted for many years, but findings of monitoring visits are not available. In our programme areas, community-based female peer counsellors have been successfully promoting and supporting exclusive breastfeeding since 1995. To ensure that good quality breastfeeding counselling is sustained, monitoring visits were undertaken regularly.

Methods: Five peer counsellors in urban Dhaka (Badda) and 7 in rural Chittagong (Anowara) counselled mothers for optimal breastfeeding in the last trimester of pregnancy, within two days of delivery, around seven days and monthly till babies complete six months. Each peer counsellor was responsible for 50-60 mothers living within walking distance of her residence. From February to December 2012, 775 lactating mothers were counselled. Programme staff aimed to monitor 10% of peer counsellors visits and randomly interview 10% of counselled mothers by using check lists. Data from observations and interviews was analysed and feedback given to the peer counsellors for improving performance.

Results: Comparisons of peer counsellors observations (n=105) and mothers' interviews (n=90) show that nearly all mothers received relevant information about optimal breastfeeding practices and were helped with correct positioning and attachment. During last 24 hours, 94% babies below 6 months were exclusively breastfed. The major gaps identified were that although 80% mothers reported expression of breastmilk had been explained to them at least once, it was not demonstrated, whereas peer counsellors demonstrated expression during 50% observation visits. Reliable signs of sufficient breastmilk could be repeated by only 58% mothers versus 79% heard during peer counsellors observations.

Conclusions: Exclusive breastfeeding prevalence was high in the programme area. Frequent monitoring of peer counsellors' visits and comparisons with mothers' reports about what they have been told and demonstrated are essential to ensure good quality counselling and sustain optimal breastfeeding practices.

Key words: breastfeeding, monitoring, observations, interviews, peer counsellors

PO828**THE INFLUENCE OF DIETARY HABITS AND PHYSICAL ACTIVITY ON BONE MASS IN FLEMISH CHILDREN**

I. Sioen¹, N. Michels¹, C. Polfliet¹, S. de Smet¹, E. Van Cauwenberghe², I. Roggen³, S. de Henauw¹

¹Ghent University, Department of Public Health, Belgium

²Ghent University, Department of Movement and Sport Sciences, Belgium

³Ghent University Hospital, Unit for Osteoporosis and Metabolic Bone Diseases, Belgium

Background and objectives: This study aimed analysing how children's bone mineral content and density (BMC and BMD) are associated with dietary habits (dairy consumption and vitamin D intake) and physical activity (PA). Moreover, the interaction between diet and physical activity on bone was studied.

Methods: Participants were Flemish children (6-12 years). Body composition and bone mass was measured with dual-energy X-ray absorptiometry (DXA), dietary habits with a food frequency questionnaire and PA with an accelerometer (minimum 3 days, 8 hours per day). In total, 272 children underwent a DXA scan and 264 had complete FFQ data. Only 202 children had matching accelerometer data, due to the limited number of accelerometers. Regression analyses were used to study the associations between diet, PA, BMC and BMD, always correcting for age, sex, puberty stage and fat mass.

Results: PA (moderate and vigorous activity) was positively associated, while sedentary activity was negatively associated with BMC and BMD. Also dairy consumption was positively associated with bone mass, but vitamin D showed no association. Moderation effect through sex was only present for sedentary activity on the BMC outcome. Only for boys, the association with BMC was significant. No moderation effect from diet and PA ($p > 0.05$) on bone mass was found.

Conclusions: Already at young age, PA and dairy consumption positively influence bone mass according to this study. Promoting PA and dairy consumption in young children will therefore positively influence their bone health and help to maximize peak bone mass, an important protective factor against osteoporosis later in life.

Key words: bone mineral density, bone mineral content, calcium, physical activity, children

PO829**CONTRIBUTION OF NUTRITION EDUCATION INTERVENTION TO YOUNG ATHLETES IN TAIPEI**

F.C. Tang¹, S.H. Lin², G.Y. Chen¹, Y.C. Huang¹, C.Y. Lin¹

¹Graduate Institute of Nutritional Sciences and Education, National Taiwan Normal University, Taipei, Taiwan, ROC

²Department of Educational Psychology and Counseling, National Taiwan Normal University, Taipei, Taiwan, ROC

Background and objectives: Exercise nutrition program should target at promoting optimal nutrient intakes by athletes, especially young athletes. To enhance the nutrition knowledge and improve the dietary practice and learning ability of young athletes, a nutrition intervention course of one semester was offered to the middle school athletes via a popular science education program.

Methods: Young athletes ($n=303$, $M=235$, $age=12-18$ y, $BMI=21.7$ kg/m²) of two middle schools (intervention group vs control group) in Taipei participated in the study. A basic nutrition course (8 lectures) was offered to the school of intervention group only, which also included two lectures with lab of meal plan and preparation, and a supermarket field trip. Each lecture of 2*50 min was given every two weeks. Intervention was separately proceeded for senior or junior athletes. Before and after the course intervention, data on dietary and physical activity survey, test for attention performance (both the reaction time and accuracy of flexibility, divided attention, and working memory), and body composition measurements were collected from the young athletes of both middle schools; which were analyzed as the criteria to evaluate the function of nutrition knowledge applied in popular science.

Results: At entry, the fat-free mass percentages of senior male, senior female, junior male, and junior female were 84.5 ± 5.3 , 76.7 ± 5.0 , 81.6 ± 6.4 , and 74.9 ± 9.9 , respectively. After the intervention, the improvement in accuracy of working memory of intervention group was significantly higher ($p=0.009$) than that of control group, but which was only found in junior, not the senior. The accuracy of working memory in junior was positively associated with their daily protein intake ($r=0.257$, $p=0.028$, $n=73$).

Conclusions: The nutrition education program should be further strengthened among the senior young athletes, especially with the dietary practice focused on the exercise nutrition knowledge.

Key words: nutrition knowledge, daily protein intake, test for attention performance

PO830**RESTORATION OF BRAIN DHA LEVELS IN YOUNG-DEFICIENT RAT IS BETTER WITH 1.5%ALA DAIRY FAT BLEND COMPARED TO 1.5% ALA VEGETABLE BLEND**

B. Delplanque¹, Q. Du², J.C. Martin², P. Le Ruyet³

¹NMPA, CNPS, Universite-Paris-Sud, Orsay, France

²INRA1260/Inserm1025, Fac de Medecine de la Timone, Marseille, France

³Lactalis, R&D, 8 Fromy, Retiers, France

Background and objectives: Achieving an appropriate docosahexaenoic-acid (DHA) status in the neonatal brain is an important goal of neonatal nutrition. Infant formulas have been gradually replacing mother's milk and are usually prepared with vegetable oils. The essential fatty acids (EFA) composition of these formulas are controlled (ALA, LA) and DHA supplementation has been more recently proposed to mimic mother-milk. In an attempt to validate the potential replacement of vegetable fat with dairy fat in infant formulas, we used the brain DHA level of rats as a nutritional model to compare the effects of blends based on dairy fat instead of palm oil providing the same EFA quantities (commonly recommended values for commercial vegetable fat formulas: 1.5% and 16%, respectively).

Methods: Three groups of rats (10 males and 10 females), born from dams fed over gestation/lactation with a low ALA-diet (0.4% FA), were fed, for 6 weeks after weaning, diets providing similar levels of ALA (1.5%, from rapeseed source), blended with (i) anhydrous dairy fat, (ii) palm oil or (iii) palm oil supplemented with DHA (0.12%). Brain FA were determined by gas chromatography at weaning and after the post-weaning diets

Results: Restoration of brain DHA levels was superior with the 1.5% ALA-dairy-fat compared to both 1.5% ALA-palm-blends (without/with DHA supplementation) for increasing brain DHA (+80%, +65% and +60%, respectively $p < 0.001$). A gender/diet interaction showed lower levels of brain DHA of males with the 1.5% ALA-palm diet, while brain DHA was similarly restored in males and females by the 1.5% ALA-dairy-fat diet or by DHA supplementation of palm diet

Conclusions: Restoration of brain DHA levels of young deficient rats is more efficient with a 1.5% ALA dairy fat blend diet compared to vegetable blends despite similar dietary ALA levels supplemented or not with DHA. Human application for infant formulas should be considered. Granted by Lactalis

Key words: dairy-fat, brain, DHA, ALA

PO831**CHALLENGES OF A COMMUNITY-BASED PEER COUNSELLING PROGRAMME TO PROMOTE AND SUPPORT APPROPRIATE COMPLEMENTARY FEEDING IN BANGLADESH**

R. Haider¹

¹Training & Assistance For Health & Nutrition (TAHN) Foundation, Dhaka, Bangladesh

Background and objectives: Although several programmes have promoted exclusive breastfeeding, there are very few which have promoted and monitored appropriate complementary feeding. In the Foundation's programme areas, community-based peer counsellors have been successfully promoting and supporting exclusive breastfeeding since 1995. To ensure that they also promote appropriate complementary feeding, monitoring visits were undertaken.

Methods: Five community-based peer counsellors in urban Dhaka (Badda) and 7 in rural Chittagong (Anowara) counselled mothers for appropriate complementary feeding when babies completed six months and monthly until 18 months. Each peer counsellor was responsible for 50-60 mothers living in her neighbourhood. From February to December 2012, 541 mothers were counselled. Programme staff planned to monitor 10% of PCs visits and randomly interview 10% of counselled mothers by using check lists. Data from observations and interviews were analysed and feedback given to the peer counsellors for improving performance.

Results: Comparisons of observations of peer counsellors visits ($n=102$) and from mothers' interviews ($n=92$) showed that nearly all the mothers received information about appropriate complementary feeding practices and were demonstrated correct amounts and consistency at end of 6 months. However 50% mothers reported they were not shown recommended consistency of foods at 9 and 12 months. During observations, intake of 4 food groups was encouraged, benefits of each food with age appropriate frequency and consistency mentioned, but actual amounts were shown in 69% of visits, and only about half the mothers could recall the benefits of each group of complementary food. Washing mothers' hands before preparation of food and feeding was mentioned, but not observed by the peer counsellors.

Conclusions: Frequent monitoring of peer counsellors' visits and comparisons with mothers reports about what they have been told and demonstrated, are essential to ensure good quality counselling and complementary feeding practices.

Key words: complementary feeding, monitoring, peer counsellors

PO832**ASOCIATION BETWEEN MICRONUTRIENTS AND THE GROWTH, BODY COMPOSITION AND EARLY MARKERS OF CHRONIC DISEASES IN CHILEAN CHILDREN**

D. Lopez de Romaña¹, G. Cediell¹, C. Corvalan¹, R. Uauy¹

¹INTA-University of Chile, Santiago de Chile, Chile

Background and objectives: The relationship between micronutrients and obesity and/or chronic diseases in early life is not clear. The objective of the study was to assess the associations between biochemical indicators of several micronutrients and the growth, body composition and early markers of chronic diseases in children.

Methods: Cross-sectional study of 300, 8-11 y children. The following measurements were obtained: 1) Anthropometry: weight (wt), height (ht), zBMI; 2) Body composition: % body fat; 3) Biomarkers metabolic risk: insulin, glucose, serum lipids, adiponectin, leptin; 4) Micronutrient indicators: hemoglobin (hb), serum ferritin (SF), serum transferrin receptors (TfR), hepcidin, plasma zinc (ZnPl) and serum VD concentrations (25OHD).

Results: 26% of children were overweight and 29% obese. None of the children were anemic or Zn deficient. 4% were Fe deficient and 28% VD deficient. No associations were found between FS or 25OHD and either wt, ht, % fat or metabolic risk indicators. A significant direct association was observed between TfR and Wt (r 0.24), ht (r 0.14), zBMI (r 0.25), % body fat (r 0.22). Significant correlations were found between hepcidin and both wt (r -0.12) and zBMI (r -0.12). ZnPl correlated with % body fat (r 0.12) and insulin (r -0.20). No significant differences in Hb, SF, hepcidin or 25OHD were found between obese (Ob) and non-obese children. Both TfR and ZnPl were significantly higher in Ob children.

Conclusions: Vitamin D status is not associated to Ht, % body fat or biomarkers of metabolic risk. Ob children had higher ZnPl and TfR concentrations than N children.

Key words: micronutrients, obesity, chronic disease

PO834**INCREASING APPROPRIATE COMPLEMENTARY FEEDING IN A RURAL DISTRICT OF BANGLADESH: IMPLICATION FOR SOCIAL MOBILIZATION**

M. Jahan¹

¹Brac Centre, Dhaka, Bangladesh

Background and objectives: BDHS reports showed that in Bangladesh, stunting, underweight and wasting are 41%, 36% and 16% respectively. After decade of stagnant exclusive breastfeeding rate which was 43% and has now improved to 64%. But the quality of Complementary feeding is still under satisfactory level, only 21%. Alive and Thrive comprehensive delivery model in Bangladesh introduced in 2009 intended to- • Increase exclusive breastfeeding (breast milk only) by almost 50 percent and reduce stunting by 10 percent in children under five. Alive and Thrive initiative aimed to develop scaled up models for preventing child malnutrition through improving Infant and Young Child Feeding (IYCF) practices • Intensive counseling, coaching and demonstration to mothers and caregivers for appropriate feeding practices of children 0-2 yrs. • Social mobilization. It raises awareness of IYCF and seeks the commitment of influential members in the community and family elders to take action for improvement of IYCF practices. In 2009, base line survey was conducted to identify facilitating factors and barriers to adopting appropriate complementary feeding approach, programmatic and behavior change communication initiatives. Main barriers for adopting appropriate complementary feeding are mothers' perception that they have insufficient breast milk and their observation that children lack an appetite. In 2012 main indicators of IYCF shows a great improvement. Early initiation of breast feeding was increase from 64% to 89%, Exclusive breast feeding from 60% to 80%, Timely initiation of complementary feeding from 57% to 93%, intake of animal protein 22% to 87% and hand washing 21% to 81%. Social mobilization can help to remove the barrier to adopt appropriate complementary feeding practices. Though these improvements are not only due to social mobilization but still it can create an environment in the community and households that supports mothers to adopt and maintain good feeding practices. IYCF, Social mobilization, Complementary feeding.

PO835**VITAMIN D INSUFFICIENT INFANTS (3 MONTHS OF AGE) HAD SUFFICIENT VITAMIN D STATUS AT 12 MONTHS OF AGE**

I E. Graff¹, M W. Markhus^{1,3}, A H. Nielsen^{1,4}, L S. Breistein^{1,5}, S. Skotheim², H C. Braarud², K M. Stormark², L. Frøyland¹, M K. Malde¹

¹National Institute of Nutrition and Seafood Research

²Regional Centre for Child and Youth Mental Health and Child Welfare/Uni Health/Uni Research, Bergen, Norway

³The Department of Biomedicine, Faculty of Medicine and Dentistry, University of Bergen, Norway

⁴Department of Human Nutrition, Faculty of life sciences, University of Copenhagen, Denmark

⁵Department of Clinical Medicine, Faculty of Medicine and Dentistry, University of Bergen, Norway

Background and objectives: Breast milk is considered to be the optimal infant diet and the postpartum period represents a time of increased maternal nutritional need due to lactation. Oily fish, fortified foods and supplements are the only significant dietary sources of vitamin D in the Nordic countries. In Norway, knowledge about vitamin D status in postpartum women and their infants is limited. The aim of the present study was to assess the vitamin D status in mothers and their infants at 3, 6 and 12 months postpartum in relation to eating habits.

Methods: This longitudinal population study from a municipality in Western Norway followed mothers and their infants from 28 weeks of gestation until 12 months postpartum. The source population was all women who were pregnant within November 2009-June 2011. The vitamin D status was assessed as serum 25-hydroxy vitamin D (25OHD) in the mothers and their infants 3, 6 and 12 months postpartum. Seafood intake was recorded through validated food frequency questionnaires.

Results: The mean level of 25OHD in the infants increased significantly from 68±40 nmol/l at 3 months to 85±16 nmol/l at 12 months of age. The lowest 25 percentile had the largest 25OHD improvement from 3 months (34 nmol/l) to 12 months (74 nmol/L) of age. At 12 months every single child had a sufficient vitamin D status (25OHD > 50 nmol/l). Among the mothers the vitamin D status at 3, 6 and 12 months after delivery was fairly stable, however just above the sufficient level of 25OHD > 50 nmol/l.

Conclusions: Insufficient vitamin D status in 3 months old infants was considerably improved at 12 months of age. The mothers had sufficient vitamin D status at all sampling points.

Key words: vitamin D status, serum 25-hydroxy vitamin D, infant, mothers, seafood

PO836**THE ASSOCIATION BETWEEN DIETARY CALCIUM INTAKE AND CHILDHOOD OBESITY IN MULTI-ETHNIC SCHOOL CHILDREN IN MALAYSIA**

S. Shohaimi¹, S I. Shariff Ishak¹, Z. Basar¹

¹Universiti Putra, Malaysia

Background and objectives: The increase in the prevalence of overweight and obesity among children in Malaysia has been a cause for concern as obesity in childhood has been shown to sustain into adulthood. Several studies have shown that calcium intake was identified to have protective effect against obesity. A cross-sectional study was conducted to determine if there is any association between calcium intake and body mass index (BMI) among children.

Methods: A total of 540 children (257 boys and 283 girls) aged between 9 to 10 years participated in the study which was conducted in the states of Selangor and Putrajaya. The height and weight for each child was measured in order to calculate their BMI-for-age. Dietary calcium and energy intakes were assessed using a previously validated calcium-focused food frequency questionnaire (FFQ).

Results: Mean BMI for boys was 20.1±5.6 kg/m² and 18.0±4.2 kg/m² for girls. The mean estimated daily calcium intake was 295.2±136.6 mg for boys and 360.8±142.2 mg for girls. There was no significant association between the intakes of calcium and dairy products with BMI. However, there was a significant difference in daily calcium intake between different ethnicities with significantly higher calcium intake for Malay boys and girls compared to the Chinese or Indians.

Conclusions: There was no significant association between dietary calcium intake and childhood obesity, however dietary calcium intake was significantly different among children of different ethnicities.

Key words: dietary calcium intake, childhood obesity, ethnicity, BMI

PO837**INFANT FEEDING PRACTICES AMONG LIBERIAN REFUGEE WOMEN DURING THE EMERGENCY AND PROTRACTED PHASES OF REFUGEE SETTLEMENT**

A. Sandow¹, E. Colecraft², G. Otoo²

¹Point Hope Ghana

²Dept. Nutrition and Food Science, University of Ghana, Legon, Accra, Ghana

Background and objectives: Optimal infant and young child feeding (IYCF) practices is crucial for child survival,

particularly in refugee situations. Research on IYCF practices among refugee caregivers is limited and it is unknown whether caregivers' IYCF experiences differ during the emergency and protracted phases of the refugee situation. The study was aimed at identifying the prevalence and determinants of optimal and sub-optimal IYCF practices of Liberian refugee caregivers in emergency and protracted refugee situations in the Buduburam Refugee Camp (BRC) in Ghana.

Methods: This was cross-sectional study involving Liberian refugee women; 1) who arrived at the BRC with children < 2 years of age during the emergency phase of the refugee situation (ERS) in 1991 (n=84) and 2) living at the BRC during the protracted phase of the refugee situation (PRS) who had children less than 2 years at the time of the survey in 2010 (n=407). Semi-structured questionnaires were used to interview the ERS and PRS women about their sociodemographic characteristics, IYCF practices, and challenges and facilitators to optimal IYCF practices. Chi-Square and logistic regressions analysis were used to identify differences in and predictors of optimal IYCF practices respectively.

Results: The PRS caregivers were more likely than ERS caregivers to have optimal exclusive breastfeeding duration (83.6% vs 68.2; p=0.05), and complementary feeding initiation (75.5% vs 8.6%; p≤0.001). Positive predictors of optimal BF initiation among PRS caregivers included being married, male child and delivery at a health facility. PRS caregivers who had received IYCF counseling had greater odds for optimal breastfeeding duration (OR 2.5; CI 1.32, 4.56) and timely complementary feeding initiation (OR 3.8; CI 1.92, 7.70).

Conclusions: Counseling on optimal IYCF is an important determinant of optimal IYCF practices in refugee situations. Caregivers in the emergency phase of refugee settlement may need increased support for improved IYCF practices.

Key words: IYCF, refugees

PO838

RELATIONSHIP BETWEEN LOWER GASTROINTESTINAL DISTRESS AND DIETARY HABITS IN LONG DISTANCE RUNNERS.

M. Matsumoto¹, Y. Kizawa¹

¹Department of Physical Education, College of Humanities and Sciences, Nihon University, Japan

Background and objectives: Gastrointestinal complaints are common matter in long distance runners. In particular, diarrhea and the frequent occurrence defecation are serious problems because of declining the performance in training and competitive events. The aim of this study was to investigate the prevalence of gastrointestinal (GI) complaints and the conditioning for these distresses in long distance runners and to

determine the relationship between dietary habit and GI complaints.

Methods: A simple questionnaire to investigate whether having GI complaints or not in training and competitive events was sent to 449 well-trained male athletes composed of 13 kinds of sports: long and short distance runner, american football, valley ball and badminton, judo, wrestling, karate, boxing and fencing, gymnast, alpine, cyclists, and rowing player and sent back by upper 90% of these groups, respectively. Furthermore, rehydration status, monthly distance of run and dietary habits in a long distance runner were investigated.

Results: Long distance runners experienced GI distress higher (57% and 49%) than other sports player (26% and 17%) in training and competitive events, respectively. The claim of chronic diarrhea was more frequent than other players in long distance runners. As for the rehydration and the dietary habits, the GI distress did not have relationship with them. On the other hand, there was a correlative tendency between the running diarrhea and monthly running distances. The causes of the diarrhea runners thought were mental stress (24%), exposure stomach to the cold (22%) and intake of cold water (18%).

Conclusions: Long distance running is caused lower tract of GI distress, and it is associated with monthly running distances. More research on the possible predisposition of athletes for GI distress during exercise is needed.

Key words: long distance runner, gastrointestinal distress, dietary habits, diarrhea, rehydration

PO839

THE ASSOCIATION BETWEEN STUNTING AND ANAEMIA AMONG SCHOOL-AGED CHILDREN AND ADOLESCENTS IN 10 LOW-INCOME COUNTRIES

E. Rousham¹, N. Roschnik², A. Hall³

¹Centre for Global Health and Human Development, SSEHS, Loughborough University, UK

²Department of Education and Child Development, Save the Children, USA

³Save the Children, UK

Background and objectives: Iron deficiency anaemia is a significant global public health problem. Few studies have examined the association between undernutrition and anaemia in male and female adolescents in disadvantaged populations. The objective of this paper is to examine the relationship between undernutrition (stunting and thinness) and anaemia among school age boys and girls.

Methods: Cross-sectional anthropometric and haemoglobin data were analysed from samples of school children aged 5-17 years within the school health and nutrition programmes

of Save the Children School (USA) from 10 low income countries (n=19,722). Z-scores of height-for-age and BMI-for-age were calculated using WHO growth references (WHO, 2006). Stunting was defined as height-for-age <-2z scores of WHO reference median, and thinness defined as BMI-for-age <-2z-scores of WHO reference median. Anaemia was classified according to recommended thresholds of haemoglobin concentration (UNICEF/UNU/WHO, 2001).

Results: Among all age groups, stunted children and adolescents were significantly more likely to have anaemia than their non-stunted counterparts. The prevalence of anaemia was 42.7% and 27.9% for stunted and not-stunted boys respectively (OR=1.98; CI 1.81-2.16). In girls the prevalences were 36.5% versus 27.3% respectively (OR 1.58; CI 1.44-1.74). Stunted adolescent boys had a higher prevalence of anaemia than stunted girls (p<0.01). There was no association between thinness and anaemia at any age.

Conclusions: These data reveal a significantly higher prevalence of anaemia in stunted boys and girls, with stunted adolescent boys being at greater risk of anaemia than stunted adolescent girls. These samples are only representative of children attending school, and actual rates of anaemia and under-nutrition may be higher among those not attending school. Among school children participating in the School Health and Nutrition programme stunting is a risk factor for anaemia, but thinness is not.

Key words: adolescent health; stunting, anaemia, haemoglobin

PO840

THE AVOIDANCE OF SPECIFIC FOODS AND BEVERAGES DURING PREGNANCY AND LACTATION IN THE WESTERN HIGHLANDS OF GUATEMALA

E M. Díaz Ruiz¹, D. Fuentes¹, R. García Meza¹, M. Vossehaar¹, N W. Solomons¹

¹Center For Studies of Sensory Impairment, Aging And Metabolism (CeSSIAM), Guatemala City, Guatemala

Background and objectives: Women's food choices during pregnancy and lactation can affect the nutrient adequacy of the diet. When providing women with food supplements, cultural customs should be respected. We sought to determine specific foods and beverages avoided during pregnancy and lactation.

Methods: 181 women (88 pregnant and 93 lactating) living in rural, semi-rural and urban areas of the department of Quetzaltenango in the Western Highlands of Guatemala were interviewed on a single occasion to evaluate dietary practices. Women were asked if they ate more while pregnant or lactating and if they avoided certain foods and beverages during these periods.

Results: 60% of the participants were of Mayan Indigenous origin and 40% were Ladinas. The vast majority of women were in the 2nd (48%) or 3rd (51%) trimester of pregnancy. Most women (74%) were breastfeeding a child in the first trimester. Almost half (49%) of the pregnant women and two-thirds (67%) of the lactating women reported eating more than usual. Significantly fewer (p<0.001) pregnant women in the rural area (23%) reported eating more than in the semi-rural (62%) and urban (62%) areas. Half (51%) of the pregnant women and one-third of (33%) the lactating women reported avoiding specific foods or beverages. Food avoidance during pregnancy was less prevalent in the rural area (43%) than in the semi-rural (55%) and urban (55%) areas and more prevalent during lactation in the urban area (47%) than in the semi-rural (29%) and rural (29%) areas. The 5 most common avoided were ice cream, beef broth, fat, coffee and chicken during pregnancy and were ice cream, black beans, chicken, potatoes, and herbs during lactation.

Conclusions: Food avoidance during pregnancy and lactation are common in the Western Highlands of Guatemala and limit food choices in critical stages of development.

Key words: Guatemala, pregnancy, lactation, food choices

PO841

CONSUMPTION OF GRUELS DURING PREGNANCY AND LACTATION IN THE WESTERN HIGHLANDS OF GUATEMALA

D. Fuentes¹, E M. Díaz Ruiz¹, R. García Meza¹, M. Vossehaar¹, N W. Solomons¹

¹Center For Studies of Sensory Impairment, Guatemala City, Guatemala

Background and objectives: Food choices during pregnancy and lactation are partly determined by cultural beliefs. "Atoles" (thin gruels) are a traditional hot drink, typically based on corn-dough (masa) and commonly consumed in Central America. Atoles are of reputed to be of important cultural significance during pregnancy and lactation in Guatemala, especially during the 40 days immediately following birth (quarantine). The objective of the current study was to determine the intake of atoles during pregnancy and lactation and its distribution within the household.

Methods: 130 women (30 pregnant and 100 lactating) living in rural and semi-rural areas of the department of Quetzaltenango in the Western Highlands of Guatemala were interviewed on a single occasion to determine usual intake of gruels. Types of gruels most commonly prepared, usual daily intakes, and distribution within the household were asked.

Results: The vast majority of women reported consuming gruels during pregnancy (83%) and lactation (97%). Three-

quarters of women reported consuming greater quantities of gruels during pregnancy (73%) and lactation (74%) than usual. The most commonly consumed gruels (in descending frequency) were: Incaparina®, cracked corn, corn dough, oats, and corazón de trigo® cereal during pregnancy and Incaparina®, corn dough, oats, corazón de trigo® cereal and maize meal during lactation. Women preferred savory and sweet gruels equally. Importantly, one-fourth of pregnant-but two-thirds of lactating women-consumed gruels prepared for themselves, and reportedly not sharing with other family members.

Conclusions: In our sample of Guatemalan women, usual intake of gruels increases during pregnancy and lactation, providing additional energy and nutrients during this critical period. The responses of these women could be important in framing a public health and educational redress to dietary imbalance during this vulnerable period. Funded by Hormel Foods Corporation, Austin, MN

Key words: Guatemala, pregnancy, lactation, food choices

PO842

LOCAL CONCEPTS OF “HOT” AND “COLD” FOODS IN GUATEMALA: EFFECT OF FOOD TEMPERATURE-QUALITIES ON EATING BEHAVIORS DURING PREGNANCY AND LACTATION

R. García Meza¹, M. Vossenaar¹, N W. Solomons¹

¹Center For Studies of Sensory Impairment, Aging And Metabolism (CeSSIAM), Guatemala City, Guatemala

Background and objectives: Numerous reports describe heightened risks of poor maternal and birth outcomes for Guatemalan women and the importance of understanding of the cultural aspects that affect women’s dietary choices. This study aimed to understand food and health choices of pregnant and lactating women living in rural and urban areas of the western highlands of Guatemala.

Methods: The reported results are from a larger study conducted in rural and urban Quetzaltenango, Guatemala. Ethical approval was obtained from the Human Subjects Committee of CeSSIAM. Participation was voluntary and no compensation was given for participation. A total of 6 focus groups (FG) with 5-12 participants were carried out with pregnant (n=17) and lactating (n=27) mothers, using open question guides and reflective dialogues to initiate the discussions. FG were digital recorded and transcribed verbatim. Data were coded using predetermined themes within the study domains using HyperResearch® software.

Results: The local concept of “hot” and “cold” attributes temperature-qualities to different food items. The balance between “hot” and “cold” properties of foods and drinks is perceived

by mothers who believe that such attributes in themselves can directly impact their health and that of their infant. The perceived impact of “hot” and “cold” properties of foods and drinks may also influence the quality and quantity of breast-milk, or may increase susceptibility to both allopathic and traditional illnesses.

Conclusions: Local narratives surrounding “hot” and “cold” foods are key in determining food choices amongst mothers, especially during lactation; the perceived effect on breast-milk production across this polarity also exerts a strong influence on a woman’s food choices following delivery. The findings of this study provided a clearer understanding of “hot” and “cold” cultural aspects that affect women’s dietary choices. Funded by Hormel Foods Corporation, Austin, MN

Key words: “hot and cold” concept, pregnancy, lactation, eating behaviors, Guatemala.

PO843

FOOD AVERSIONS AND FOOD CRAVINGS DURING PREGNANCY: A QUALITATIVE APPROACH EXAMINING EATING BEHAVIOURS AMONG MAYAN GUATEMALAN WOMEN

R. García Meza¹, M. Vossenaar¹, N W. Solomons¹

¹Center for Studies of Sensory Impairment, Aging and Metabolism (CeSSIAM), Guatemala City, Guatemala

Background and objectives: Abundant studies support the importance of nutritious and balanced diet during pregnancy as a key contributor to women’s and their infants’ health. Food aversions and food cravings can determine the type of food women would have during pregnancy and can influence diet diversity in this period. This study aims to examine perceptions on food aversions and food cravings during pregnancy among Mayan Guatemalan women.

Methods: The reported results are from a larger study conducted in rural and urban Quetzaltenango, Guatemala. Ethical approval was obtained from the Human Subjects Committee of CeSSIAM. Participation was voluntary and no compensation for participation was given. A total of 3 focus groups (FG) ranged 5-7 participants were held with pregnant women (n=17) using open questions guides and reflective dialogues to promote the discussions. FG were digital recorded and transcribed verbatim. Data were coded using predetermined themes within the study domains using HyperResearch® software.

Results: Mothers’ perceptions relate to the physiological effect of certain food items during pregnancy. These include nausea and vomiting and the resulting aversion women have to certain foods, especially during the first trimester of pregnancy. During pregnancy, food cravings were mentioned by women as

being important factors in their food choices. Acceding to food cravings was perceived as being critical in assuring the health of the fetus and pregnancy, and the success of the delivery.

Conclusions: Food choices regarding cravings and aversions during pregnancy are not only tied to gustatory preferences, but also to the perception that certain foods might benefit or harm mothers and their offspring. Information about perceived cultural and physiological aspects that affects pregnant women's dietary choices is important to design and contextualize food and nutrition interventions. Funded by Hormel Foods Corporation, Austin, MN

Key words: food aversion, food cravings, pregnancy, lactation, eating behaviors, Guatemala

PO844

ADHERENCE TO LIPID-BASED NUTRIENT SUPPLEMENT (LNS) AND IRON/FOLIC ACID TABLET (IFA) RECOMMENDATIONS DURING PREGNANCY AMONG RURAL BANGLADESHI WOMEN

K.L. Harding¹, C.P. Stewart¹, S.L. Matias¹, M. Moniruzzaman², M.K. Mridha^{1,2}, S.A. Vosti¹, K.G. Dewey¹

¹Program In International And Community Nutrition, University of California, Davis

²Center for Reproductive Health, International Center for Diarrheal Disease Research, Bangladesh, Dhaka, Bangladesh

Background and objectives: Barriers and facilitators to sustained LNS consumption have not been evaluated among pregnant and lactating women (PLW) in Bangladesh. This study aimed to assess the adherence to and acceptability of LNS and IFA to improve maternal nutrition and prevent child stunting among women participating in a community health program in two northern districts of Bangladesh.

Methods: A subsample was randomly selected from an ongoing trial aimed at assessing the effectiveness of LNS provided to PLW and their children on nutrition and health outcomes. Women were interviewed at home about their use and preferences of LNS or IFA. Due to a disruption in the LNS supply, some of the women had experience with both LNS and IFA at different times during their pregnancy (n=70), and were asked to compare LNS and IFA.

Results: Mean and median self-reported adherence was 4.8 (±3.0) and 6 (0-13) sachets per week among women receiving LNS and 5.9 (±1.8) and 7 (0-9) tablets per week among women receiving IFA (p=0.08). 21.9% and 5.6% of women given LNS and IFA, respectively, reported not consuming supplements in the previous week (p=0.02). The median overall acceptability score for both LNS and IFA was 5 (range: 1-5), "Like it a lot". Organoleptic properties of LNS were acceptable with median

scores of 4 or 5. Among the women who used both LNS and IFA, 48.6% preferred LNS and 51.4% preferred IFA.

Conclusions: These results suggest there is high acceptability of both LNS and IFA, yet a greater prevalence of non-adherers to LNS compared to IFA. Further investigation of potential barriers is needed to understand how to improve adherence to LNS during pregnancy.

Acknowledgements: Work was funded and supported by USAID's Food and Nutrition Technical Assistance III Project (FANTA)/FHI 360 and by the Fogarty International Center of the National Institutes of Health.

PO845

ENERGY AND NUTRIENT CONTRIBUTION OF COMPLEMENTARY FOODS IN 6 TO 11 MONTH OLD CHILDREN IN THE WESTERN HIGHLANDS OF GUATEMALA

M. Vossenaar¹, I. van Beusekom¹, J. Alvey¹, C.M. Doak², N.W. Solomons¹

¹Center for Studies of Sensory Impairment, Aging and Metabolism (CeSSIAM), Guatemala City, Guatemala

²Health Sciences, VU University, Amsterdam, Netherlands

Background and objectives: The WHO recommends the introduction of nutritionally-adequate and appropriate complementary feeding at 6 mo of age, with continued breastfeeding for 2 years and beyond. Our objective was to assess the nutritional adequacy of complementary foods to the diets of Guatemalan infants with continued breastfeeding.

Methods: A single previous-day record was collected from a convenience sample of mothers of 94 infants, aged 6-11 mo, in the urban area of Quetzaltenango, Guatemala. Energy and 19 selected nutrient content in complementary foods and modeled volumes of breastmilk were calculated and nutrient adequacy was assessed using the 2004 WHO/FAO Recommended Nutrient Intakes (RNIs). Nutrient densities and critical nutrient densities of complementary foods were computed to identify "problem nutrients" and main sources of these nutrients were identified.

Results: Complementary diets were adequate for protein, but inadequate for pantothenic acid and vitamins C, A, D, E, and K, as well as calcium, iron and zinc. For small girls, with limited energy allowances, riboflavin, niacin, vitamin B6 and magnesium were identified as "problem nutrients" as well. Formula milk, cow milk and Incaparina® were main sources of the nutrients ("problem nutrients"), whose recommended intakes were still not being met by the total complementary fare offered.

Conclusions: We conclude that, as persistently reported in developing countries, the complementary feeding of Guatemalan infants is nutritionally inadequate. Public health actions to continue to narrow the nutrient gap of complementary foods in infants should include maternal education in early-feeding practices to select nutrient-rich foods. Furthermore, home fortification, or special fortified foods or a combination, is likely to be required for assuring consumption of the recommended amounts of micronutrients for sound infant growth. Funded by Sight & Life, Basel, Switzerland

Key words: human milk, complementary feeding, infant feeding, micronutrient intake, Guatemala

PO846

GROWTH PATTERN OF EXCLUSIVELY AND NON-EXCLUSIVELY BREASTFED INFANTS IN UMUHIA URBAN, NIGERIA

P. Ukegbu¹, A. Uwaegbute¹, I. Ijeh¹, J. Anyika¹

¹Dept of Human Nutrition and Dietetics, Michael Okpara University of Agriculture, Umudike, Abia State, Nigeria

Background and objectives: This was a prospective comparative study carried out from April 2011 to February 2012 to assess the growth pattern of exclusively (EBF) and non-exclusively breastfed infants (NEBF) in the first six months of life

Methods: A total of 213 lactating mothers and their infants aged less than 7 days and weighing >2.5kg were recruited into the study and followed up at 6, 10, 14, 18 and 24 weeks. Infants were classified into EBF and NEBF groups based on their current feeding pattern during the follow up. Anthropometric measurements of weight and length were taken and compared with WHO curves. Data analysis was carried out using frequencies, percentages, means (SD), T-test.

Results: The rate of exclusive breastfeeding declined from 82.5% at delivery to 23% at the end of six months. The EBF infants had significantly higher mean weight and length from the 6th to 14th week than their NEBF counterpart ($p < 0.05$). Despite a decline in mean weight of EBF infants after the 14th week, they retained the higher mean weight achieved earlier. Average cumulative weight gain of 3.33 kg and 3.02 kg were recorded for EBF and NEBF infants, respectively during the six months follow up.

Conclusions: The mean weight and length of the EBF infants was comparable to the WHO curve than for the NEBF infants. This suggests that the practice of exclusive breastfeeding is adequate to sustain normal growth in infants during the first six months of life.

Key words: breastfeeding, growth pattern, WHO curve

PO847

KNOWLEDGE AND AWARENESS OF ANEMIA AMONG YOUNG ADOLESCENT GIRLS IN SOUTH SULAWESI, INDONESIA

R. Indriasari¹, E. Schubert², G. Marks²

¹Nutrition Department/Faculty of Public Health, Hasanuddin University, Makassar, South Sulawesi, Indonesia

²Nutrition Program/School of Population Health, The University of Queensland, Brisbane, QLD, Australia

Background and objectives: Anemia is one of the major nutrition problems among adolescent girls in Indonesia. Adequate nutrition to prevent anemia is required since this population group experience rapid growth and developmental changes as well as high possibility to enter early pregnancy. As dietary knowledge is critical to improve nutritional behaviors, adolescent girls should have adequate knowledge and awareness regarding anemia and dietary-related issues in order to improve their eating habits to prevent the problem. However, studies investigating dietary knowledge in Indonesian adolescent girls are insufficient.

Methods: Two phases of data collection were undertaken among school girls residing in two districts of the South Sulawesi Province. A survey questionnaire (Cronbach's Alpha=0.84) was distributed among 518 girls aged 12-15 years and qualitative in-depth interviews were performed with 19 girls to investigate their knowledge and perceived awareness of anemia. Descriptive analysis was performed for the survey data and thematic analysis was undertaken with the interview data.

Results: Knowledge of anemia was low with only 6 out of 16 items were correctly answered by at least 60% of the girls. This finding was confirmed by the results of interview, anemia is poorly understood by the girls. Both survey and interview data revealed that although the girls could recognize common symptoms of anemia, they did not clearly define causes and consequences of the problem. As a result, the seriousness of the problem and the risk of adolescent girls of developing iron deficiency anemia were not fully understood.

Conclusions: Young adolescent girls in South Sulawesi had insufficient knowledge and awareness regarding anemia. Ensuring adequate knowledge and awareness of anemia among this group is an important issue to be addressed when developing strategies to control anemia among Indonesian adolescents.

Acknowledgement: This research received grant from Neys-van Hoogstraten Foundation

Key words: adolescent girls, knowledge, anemia, Indonesia

PO848**DOES FREQUENCY OF FAMILY MEALS MAKE A DIFFERENCE AMONG ADOLESCENTS IN MALAYSIA?**

R. Fara Wahida¹, Y.S. Chin¹, S. Kaartina¹, F.C. Woon¹, M.S. Zalilah¹, M.T. Mohd Nasir¹, C. Yit Siew¹

¹Department of Nutrition and Dietetics, Universiti Putra Malaysia, Serdang, Selangor, Malaysia

Background and objectives: Despite many benefits of family meals, high prevalence of infrequent family meals was observed among adolescents. Limited study examined the consequences of family meal frequency among adolescents in Malaysia. This study aimed to determine the consequences of family meal frequency among adolescents in Kuala Lumpur.

Methods: A total of 490 adolescents (41.4% males, 58.6% females) aged 13 to 16 years from four secondary schools in Kuala Lumpur, Malaysia were involved in this study. Most of them were Malays (48.4%), followed by Chinese (39.4%), Indians (9.6%) and other ethnic groups (2.6%). Family meal frequency and adolescent's meal frequency were assessed using Eating Behaviors Questionnaire. Risk of eating disorders and self-esteem were assessed using Eating Attitudes Test-26 and Rosenberg Self-Esteem Scale, respectively.

Results: Mean family meal frequency among respondents was 5.4±2.1 days in a week. Mean intakes for breakfast, lunch and dinner among adolescents were 4.9±2.5, 5.7±2.0 and 5.9±2.0 days in a week, respectively. About a quarter of adolescents (25.5%) were at-risk of eating disorders. Mean score for self-esteem was 29.1±4.3. Frequent family meals was associated with frequent intakes of breakfast ($r=0.128$, $p<0.01$), lunch ($r=0.255$, $p<0.01$) and dinner ($r=0.324$, $p<0.01$) among adolescents. Additionally, frequent family meals among adolescents was associated with low risk of eating disorders ($r=0.105$, $p<0.05$) and high self-esteem ($r=0.136$, $p<0.01$).

Conclusions: In other words, frequent family meals play an important role in promoting frequent meal intakes, low risk of eating disorders and high self-esteem among adolescents. Thus, future nutrition-related intervention programs should encourage frequent family meals among adolescents.

Key words: family meals, meal frequency, disordered eating, self-esteem, adolescents

PO849**EFFECTS OF LONG-TERM SUPPLEMENTATION WITH A MIXTURE OF SHORT AND LONG CHAIN INULIN-TYPE OLIGOSACCHARIDES ON FAECAL MICROBIOTA IN INFANTS**

⁶Equipo Pediátrico San Francisco, Madrid, Spain

⁷Universitair Ziekenhuis, Brussels, Belgium

⁸Beneo Institute, Germany

Background and objectives: Human milk stimulates the growth of bifidobacteria because of its high oligosaccharides content. The aim of this study was to investigate whether the ingestion of infant formula supplemented with a mixture of short and long chain inulin-type oligosaccharides modulates the composition of faecal microbiota in infants.

Methods: Healthy term babies aged between 0-4 months, exclusively fed infant formula were enrolled in a multicenter, double-blind study. Infants were randomized to receive either an infant formula supplemented with 0.8 g/100 ml of oligo-fructose-enriched inulin (Synergy 1[®]) or a standard formula. Growth and clinical parameters were measured throughout the study. Stool samples were collected from a subgroup of infants at 2, 6, and 12 months of age. Bacterial populations were analyzed by qPCR. The study was approved by ethical committees.

Results: The ITT population consisted of 154 infants. Growth related variables did not differ between the two groups at any study point. Compared to the CONTROL group, bifidobacteria counts in the PRE group were significantly higher at month 6. When results were expressed as proportions of bifidobacteria in relation to total bacteria, the PRE group showed significantly higher values at month 2 and 6, but not at month 12. Total bacterial counts and proportions of Bacteroides, C. coccoides, C. leptum and Enterobacteriaceae did not differ between groups. The rate of adverse events was low and similar in both feeding groups.

Conclusions: Ingestion of infant formula supplemented with short and long-chain inulin-type oligosaccharides increases bifidobacteria populations in the faecal microbiota in infants. These differences may disappear as the ingestion of total

amounts of infant formula decrease and diversification of the infant's diet occurs. Supported in part by the Commission of the European Communities, 6th Framework Programme, contract no. 007036.

Key words: microbiota, infants, inulin, oligofructose, prebiotics

SKIPPING BREAKFAST MAY INDUCE DYSMENORRHEA AND IRREGULAR MENSTRUATION IN POST-ADOLESCENT WOMEN IN JAPAN

T. Fujiwara¹, R. Nakata²

¹Ashiya College, Japan

²Nara Women's University, Japan

Background and objectives: In recent years, increasing attention has been paid to the adverse effects of skipping breakfast on quality of life including young people. However, there were very few reports concerning the relationship between skipping breakfast and reproductive function. Therefore, in this study we examined this issue by conducting a questionnaire survey of young Japanese women who are undergoing post-adolescent maturation.

Methods: Subjects were recruited from female college students aged from 18 to 20 years old. We sent questionnaires to 2215 students, and responses were received from 2166 students between 2000 and 2011. Information regarding the aim of this study was sent with the questionnaire and consent was obtained from all participants.

Results: The severity of dysmenorrhea was significantly higher in the population that skipped breakfast. The incidence of irregular menstruation was also higher in the population that skipped breakfast, although there was no difference in the incidence of premenstrual symptoms and in body mass index.

Conclusions: These findings suggest that skipping breakfast induce menstrual disorders. Considering that body mass index was not related with skipping breakfast, rhythmic disturbance of food intake may explain these adverse effects of skipping breakfast. Since these menstrual disorders influence the quality of life of young women in the future, skipping breakfast should be re-evaluated from the perspective of female reproductive function.

Key words: dysmenorrhea, irregular menstruation, post-adolescent women, skipping breakfast

FIRST (FOOD-BASED INTERVENTION AND PSYCHOSOCIAL STIMULATION) PROGRAM: COMMUNITY-BASED INTERVENTION TO IMPROVE INTAKES OF KEY PROBLEM NUTRIENTS AND PSYCHOSOCIAL CARE

U. Fahmida¹, R. Kolopaking^{1,2}, J. Umar²

¹SEAMEO-RECFON (Regional Center for Food and Nutrition), Universitas Indonesia, Jakarta, Indonesia

²Faculty of Psychology, Universitas Islam Negeri Syarif Hidayatullah Jakarta, Jakarta, Indonesia

Background and objectives: Under-nutrition and sub-optimal development amongst under-two-year-old children in Indonesia were prevalent. This study aimed to assess effect of optimized complementary feeding recommendation (CFR) and psychosocial stimulation on intakes of "key problem nutrients", nutritional status, psychosocial care and development.

Methods: A community intervention trial using quasi-experimental design was conducted in Lombok, West Nusa Tenggara Province, Indonesia. There were four groups: control, stimulation, CFR, and CFR+stimulation (n=120/group). CFR was developed using linear/goal programming approach and stimulation was developed using locally-available resources to promote verbal, social-emotional, gross and fine motor developments. Intervention included monthly cooking sessions and weekly visits in CFR groups and weekly visits in stimulation groups. Mother's nutrition knowledge, feeding practices, psychosocial care (HOME Inventory score); child's nutrient intakes, nutritional status (Z-scores, hemoglobin), development (using Bayley Scale of Infant Development II) were measured before and after 6-month intervention. Structural equation modeling (SEM) was used to assess structural relationship between variables.

Results: Calcium, iron, and zinc were the key problem nutrients and CFR improved intakes of these nutrients directly and indirectly through improved nutrition knowledge. Stimulation improved psychosocial care. Income contributed to nutrient intake through better dietary diversity, also to psychosocial care through maternal mental health. Mother's education was positively related to psychosocial care at baseline and endline. Despite increase in nutrient intake and psychosocial care, nutritional status and development were not affected. The significant correlation at endline between psychosocial care and nutritional status and between nutritional status and development suggested that the non significant net-effect of the intervention was probably due to short duration and relatively small increase in nutrient intakes during intervention.

Conclusions: Six-month intervention with CFR and psychosocial stimulation improved intakes of key nutrients and psychosocial care but not yet nutritional status and development.

Key words: complementary feeding recommendation, linear/goal programming, nutrient intakes, psychosocial care, stimulation

PO852**EFFECT OF CONSUMPTION OF FREEZE-DRIED POWDERED YACON (FDY) ON PREVALENCE OF OBESITY, DYSLIPIDEMIA, OBESITY IN ELDERLY PEOPLE**

M. Scheid¹, Y. Moreno², G. Pastore¹, P. Genaro³

¹Unicamp, Department of Food Science, School of Food Engineering, University of Campinas, Campinas, São Paulo, Brazil

²Department of Nutrition, Centre for Health Sciences, Federal University of Santa Catarina, Florianópolis, Santa Catarina, Brazil

³University of Vale of Paraíba (UNIVAP), São José dos Campos, São Paulo, Brazil

Background and objectives: Ageing is related to changes in metabolism of glucose and lipids and anthropometric parameters. The use of prebiotics, fructooligosaccharides (FOS), has been shown a positive effect to lower fasting glycaemia, total cholesterol and lipoprotein concentration and demonstrated efficacy to against pathological conditions that are common in the elderly, including diabetes, heart disease and metabolic syndrome. The aim of this work was to evaluate the effect of daily consumptions of freeze-dried powdered yacon (FDY) on the prevalence of hyperglycemia, dyslipidemia, overweight and obesity in elderly people.

Methods: During 9 weeks elderly people received daily doses of 18 g FDY containing 7.4 g of FOS. Abdominal obesity and overweight were assessed using the body mass index (BMI) and waist circumference (WC), respectively, before and after 9 weeks. Biochemical parameters as serum levels total cholesterol, HDL-cholesterol, LDL-cholesterol, triacylglycerol, C-reactive protein and glucose were determined before and after 9 weeks.

Results: After daily consumption of 18 g FDY for 9 weeks, the results showed a significant reduction of 58.7% of hyperglycemia prevalence, reducing in prevalence of hypercholesterolemia of 33.3%, decrease in prevalence of hypertriglyceridemia of 66.7% and the prevalence of elderly with normal C-reactive protein levels increased significantly 40.6%. After 9 weeks daily consumption of 18 g FDY, the prevalence of abdominal obesity, according WC, was 30%. No significantly change in prevalence of BMI, HDL and LDL-cholesterol was revealed.

Conclusions: A daily consumption of FDY containing 7.4 g FOS for 9 weeks showed to decrease a prevalence of elderly people with hyperglycemia, hypercholesterolemia, hypertriglyceridemia and abdominal obesity, and consequently could has on benefits related with the reduction or prevention of cardiovascular disease in elderly.

Key words: elderly healthy, dyslipidemia, hyperglycemia, freeze-dried powdered yacon, obesity

PO853**NUTRITION -KNOWLEDGE, -BEHAVIOUR AND -OPINIONS OF THE ELDERLY SWISS CONSUMERS**

D. Gille¹, U. Bütikofer¹, M. Chollet¹, P. Piccinali¹, A. Schmid¹, H. Stoffers¹, B. Walther¹

¹Federal Department of Economic Affairs, Education and Research EAER, Agroscope Liebefeld-Posieux Research Station ALP, Berne, Berne, Switzerland

Background and objectives: Europe has a steady increase in people older than 60 years. The aim and need is to assure their health in order to save resources-be that of financial, medical or political origin. But the main person responsible for reaching that aim is the consumer himself. A healthy lifestyle including a balanced diet may help a lot to reach the goal of healthy ageing. In that context, it is of high importance to know about the consumer behavior and nutrition knowledge of the elderly.

Methods: A questionnaire covering the three official Swiss languages was distributed amongst a representative sample of persons aged 50 to 80 years in Switzerland between September and October 2012. It contained 50 questions of three categories: general questions about nutrition and health, milk and dairy products as well as meat and meat products (no fish). The participants were free to choose whether they wanted to complete the survey in paper or online format.

Results: 646 questionnaires were completed (487 paper, 159 online, response rate: 89%). The participants consisted of 48% men and 52% women. 92% of the participants stated that they regard their nutrition as healthy and rather healthy. At the same time, 50% of the men and women consider the information about the impact of nutrition on human health as confusing. Most participants trust their doctors in regard to information concerning nutrition whereas almost 50% do not rely in food producer's information. More interesting results will be presented.

Conclusions: Many factors influence the elderly population in regard to behaviour and nutrition knowledge. Consumer surveys are important tools to understand the needs and thoughts of elderly people. The results will be used to inform them correctly and adequately about nutrition and health.

Key words: elderly nutrition, consumer questionnaire, consumer behaviour

PO855**MATERNAL KNOWLEDGE ABOUT FEEDING EARLY IN LIFE**

V Lúcia. Bosa¹, S R. Rosa¹, J S M. Pessoa¹

¹Centro de Estudos Em Alimentação E Nutrição - CESAN, Hospital de Clínicas de Porto Alegre-Faculdade de Medicina-Universidade Federal Do Rio Grande Do Sul

Background and objectives: The introduction of appropriate foods allows the child to acquire habits that are responsible for determining their pattern of consumption in the future. Parental influence on food choices play a preponderant role in the development of children's eating behavior. Data from studies emphasize high prevalence of inadequacy in relation to infant feeding. The aim of the present study was to evaluate maternal knowledge about feeding early in life.

Methods: Cross-sectional study with mothers and children between 4 and 24 months admitted to a University hospital in Porto Alegre. Sociodemographic information were questioned, data obtained through questionnaire was built based on the Food Guide for children younger than 2 years of the Ministry of health of Brazil who underwent evaluation process content through the Delphi method. Categorical variables were described by simple frequency and percentage and quantitative variables as mean and standard deviation. The ANOVA test was used for variables with normal distribution and Kruskal-Wallis was used for skewed distribution.

Results: Of the 229 mothers and children assessed, 77.3% are C-class families, 55.5% of mothers had schooling between 9 and 11 years and 63.9% of children are well nourished. In the questionnaire, the average percentage of correct answers was 75%. We observed a significant association between maternal education and number of hits ($p < 0.001$).

Conclusions: There was a high percentage of knowledge about nutrition early in life. However it is necessary to investigate the relationship of knowledge to the practice of breastfeeding and introduction of complementary foods.

Key words: maternal knowledge, infant nutrition, feeding.

PO856**HOW DOES THE ROLE OF GRANDMOTHERS AS PRIMARY CAREGIVERS IN POOR HOUSEHOLDS, COMPROMISE THEIR OWN RIGHT TO ADEQUATE FOOD?**

K T. Rendal¹, P O. Iversen¹, W B. Eide¹, M L. Marais²

¹Department of Nutrition, Institute for Basic Medical Sciences, University of Oslo, Norway

²Division of Human Nutrition, Faculty of Medicine and Health Sciences, Stellenbosch University, Cape Town, Western Cape, South Africa

Background and objectives: South Africa is currently experiencing serious challenges affecting household food security. For the elderly, the situation is critical. Instead of being looked after by their children, they are now taking care of their grandchildren. There are concerns especially regarding grandmothers' enjoyment of social welfare systems, more specifically their use of the older persons grant to people over 60 years in relation to their right to health which includes the right to adequate food. The aim of the study was to better understand if and how the role of grandmothers (both above and below 60 years) as primary caregivers in poor households living in two communities (Zweletemba and Avian Park) in the Western Cape (South Africa), affected the realization of their own right to adequate food.

Methods: Data was collected in February 2012 using qualitative research methods. Questionnaires were completed by 45 grandmothers who also participated in 9 focus group discussions. Ten key informants were also interviewed. All interviews were recorded and transcribed using a grounded theory approach. Atlas ti was used to code transcripts.

Results: Almost all (44/45) households experienced hunger. The grandmothers were the primary caregivers in the households and their grant money did not even begin to fulfill their basic needs. Furthermore, their realization of the right to adequate food was greatly affected by living with grandchildren. The grandmothers reported sacrificing their own basic needs including food, in order to feed their grandchildren.

Conclusion: Living with grandchildren was the biggest constraint for the grandmothers' enjoyment of their access to adequate food for themselves and was identified as a major barrier to realizing their right to food and nutrition.

Key words: grandmothers, poverty, food insecurity, human rights, right to adequate food.

PO857**BREAKFAST CONSUMPTION AND STAGES OF BEHAVIORAL CHANGE AMONG BRAZILIAN HIGH SCHOOL GIRLS***S. Tucunduva Philippi¹, A C. B. Leme¹*¹Department of Nutrition, School of Public Health, University of São Paulo, Brazil

Background and objectives: The transtheoretical model (TTM) has been extensively used to guide behavior change for health promotion. Dietary applications of the TTM include fat reduction, weight control, consumption of dairy products, and fruit, vegetable and grain intake. Cross-sectional studies support the utility of the model for understanding and predicting food intake among adolescents. However, little is known about breakfast behaviors. The aim of the present study was to evaluate the self-reported breakfast consumption and the stages of change among Brazilian adolescents.

Methods: Cross-sectional study with 159 girls enrolled in public high schools in the city of São Paulo, Brazil, in 2012. A self-report validated questionnaire was used to assess breakfast consumption (days of week) and individual classification within the stages of behavioral change. The girls were classified in the stages of change by means of a specific algorithm. Descriptive analyses, student t-test and chi-square tests were conducted with difference considered significant at $p < 0.05$.

Results: The average age of the girls was 16.2 ± 1.2 years. The mean of breakfast consumption was 4.4 ± 2.5 days/week. About 47% of the girls were in the decision/preparation stage of change (mean=3.5, SD=1.2 and 95% CI 3.3-3.6). A significant relationship between the stages of change and days/week for breakfast intake was found ($p=0.000$). Although was found a significant association ($p=0.012$) with vegetables, there was no significant association with fruits intake.

Conclusions: Classification of the adolescents into the stages of change, together with self-report breakfast consumption data, enable identification of groups at risk, in accordance with their inadequate breakfast habits and resistance for change. Nutrition intervention programs should be improved if their actions are directed according to the needs of each stages of change that are identified through the methodology adopted in this study.

Key words: stages of change, breakfast consumption, adolescent girls

PO858**ASSOCIATION BETWEEN MATERNAL NUTRITION STATUS AND BIRTH OUTCOME***K. Przybylowicz¹, M. Przybylowicz², M. Grzybiak³, K. Janiszewska¹*¹Department of Human Nutrition University of Warmia And Mazury, Olsztyn, Poland²Department of Gynecology and Obstetrics and Oncological Gynecology, Provincial Specialist Hospital, Olsztyn, Poland³Department of Clinical Anatomy, Medical University of Gdańsk, Gdańsk, Poland

Background and objectives: Various maternal anthropometric criteria (pre-pregnancy weight, height, weight gain during pregnancy period) has been significantly associated with intrauterine growth. Birth weight plays an important role in infant mortality and morbidity, development, and future health of the child. Maternal nutritional status both before and during pregnancy is a well-recognized determinant of birth outcomes. The aim of the study was to examine maternal nutritional status and its relationship to infant birth weight and birth length.

Methods: The study was conducted on 510 women between the ages of 18-47 (28.1 ± 4.8 years) who were patients of hospitals in the province of Warmia and Mazury. The course of pregnancy was uncomplicated, finished with natural labor, in biological time limits. The impact of mother's nutritional status before pregnancy and weight gain on newborns weight, length, Ponderal Index was estimated by multivariate linear regression.

Results: The infant birth weight depended on mothers BMI before pregnancy and was lower in the group of underweight subjects (2988.8 g vs 3380.6 g, $p \leq 0.05$). Women with low increase in body mass during pregnancy delivered newborns with lower anthropometrics parameters. The increase in gestational weight gain of one kg resulted in statistically significant increase of birth weight by 40.1 g, increase of Ponderal Index 0.22 kg/m³.

Conclusions: Maternal BMI and gestational weight gain of pregnant women could be considered as predictive factors of birth weight of neonates.

Key words: maternal BMI, gestational weight gain, birth weight, maternal factors

PO859**DETERMINATION OF CALCIUM AND SODIUM CONTENTS IN UHT AND POWDERS MILKS MARKED IN THE CITY OF RIO DE JANEIRO - BRAZIL**

L. Rodrigues^{1,2}, A. Oliveira da Camara², O. Marino Gadas de Moraes³

¹Department of Public Health Nutrition, School of Nutrition, Federal University of the State of Rio de Janeiro, Brazil

²Department of Food Technology, School of Nutrition, Federal University of the State of Rio de Janeiro, Brazil

³Department of Food Technology, School of Nutrition, Federal University of the State of Rio de Janeiro, Brazil

Background and objectives: The milk and its derivatives, beyond primary sources of calcium, have this mineral more bioavailable to the human be. The intake of calcium is important. Low calcium intake may cause obesity, hypertension and osteoporosis. The bioavailability of calcium is influenced by sodium, since the high intake of this nutrient increases renal calcium excretion. It is not common to associate the milk consumption to increased sodium intake. Since the industrialized milk containing additives, which are usually sodium salts, is not known if the real sodium content is reported in the label. The Ministry of Health of Brazil recommends that children consume three servings of dairy products per day. Considering the mean value for sodium declared on the labels of processed milks fluids (130 mg/200 ml) and powdered milk (130 mg/26g), the consumption of 250 ml milk would contribute with about 490 mg sodium per day. In view of the above, it was decided to determine the amount of calcium and sodium in UHT milks and powders.

Methods: Were analyzed 3 different brands of UHT milk and 2 of powder milk. Calcium was measured directly in the samples by titration with EDTA and sodium by flame photometry after attack of samples with HNO₃/H₂O₂ solution (8:2) and heating. The sodium and calcium determinations were made in triplicate.

Results: For UHT milk, the mean levels for calcium and sodium were respectively: 283±7 mg/200 ml and 174 mg ± 15/200 ml. For milk powder the calcium and sodium were respectively 259±0,3 mg/26g and 121±0.7 mg/26g.

Conclusions: The results show that by drinking 750 ml of milk per day, a children consume, depending on the type of milk, between 22% and 32% of sodium intake recommended by WHO.

Key words: milk; determination; calcium and sodium contents.

PO860**EVALUATION OF NUTRITIONAL STATUS OF PREGNANT WOMEN ASSISTED IN A HEALTHCARE UNIT IN PETRÓPOLIS, RJ, BRAZIL**

V. Marins¹, J. Nogueira¹, M. Roza¹, R. Pereira²

¹Curso de Nutrição, Faculdade Arthur Sa Earp Neto, Petrópolis, Rio de Janeiro, Brazil

²Departamento de Nutrição Social, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil

Background and objectives: Nutritional requirements are increased for pregnant women; the outcome of pregnancy is highly dependent on the mother nutritional status. This study aimed to evaluate the nutritional status of pregnant women assisted in a healthcare unit in Petrópolis, RJ, Brazil, in 2011.

Methods: It is a retrospective cohort study conducted with 72 pregnant women between 20 and 44 years old. Data were collected in the medical records, being obtained information on demographic and socioeconomic conditions (age, skin color, marital status and education), obstetric history (number of previous childbirths and abortions), and anthropometric measures (initial or pre-pregnancy weight, final weight, height, initial and final BMI).

Results: Women mean age was 28 years old (SD = 5.2); 52% were white, 54% were unmarried, and 63% had only elementary education (8 years of schooling). Initial mean weight was 61.6 kg (SD = 14) with an average initial BMI of 24.2 kg/m² (SD = 5). Seven percent of the women were underweight before the pregnancy, while 17% were overweight, and 12% presented obesity. Final weight status revealed that 11% were underweight, 30% overweight, and 19% were obese. As for the total weight gain during pregnancy, 47% had adequate weight gain, 31%, excessive weight gain, and 22% presented insufficient weight gain. Only 17% of the women received nutritional counseling during the pregnancy.

Conclusion: Nutritional counseling and assistance might be important to minimize complications related to inadequate weight gain and impaired nutritional status during pregnancy and, consequently, to ensure a favorable obstetric outcome.

Key words: Pregnancy, nutrition during pregnancy, anthropometry, weight status.

PO861**BIRTH WEIGHT AND EXCESS WEIGHT IN CHILDREN ASSISTED IN A PUBLIC HEALTHCARE UNIT IN PETRÓPOLIS, BRAZIL***V. Marins¹, V. Lima¹, J. Nogueira¹, R. Pereira²*¹Curso de Nutrição, Faculdade Arthur Sá Earp Neto, Petrópolis, Rio de Janeiro, Brazil²Departamento de Nutrição Social, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil

Background and objectives: Birth weight has become an important topic of research due to its possible association with obesity and other metabolic diseases later in life. This study aimed to evaluate the association between birth weight and excess weight in childhood.

Methods: This was a retrospective cohort study conducted with 83 children between 7 and 10 years old assisted in health-care unit in the municipality of Petrópolis, Brazil. The children's weight status was assessed using the sex- and age-specific BMI z-scores of the World Health Organization reference curves. Birth weight data was obtained in medical records and classified as macrosomia: >4000 g; adequate birth weight: >3000 g and <4000 g; underweight: >2500 g and <3000 g; low birth weight: <2500g and <1500 g; and very low birth weight: <1500 g.

Results: Among the studied 83 children, 11% (n=9) were overweight (1 < z-score < 2 standard-deviation - SD), 5% (n=4) obese (2 < z-score < 3 SD), and 18% (n=15), severely obese (z-score > 3 SD). The frequency of low birth weight was 5%, 26% (n=22) were born underweight, 64% (n=53), with adequate birth weight, and the frequency of macrosomia was 5%. Among those 27 children born underweight or with low birth weight, ten were overweight, obese or severely obese. Therefore, 40% of children with birth weight <3000 g presented excess weight later in life, while, among those born with adequate birth weight, 30% developed excess weight. Nevertheless, in the studied group the risk ratio was not significant (RR=1.3; 95% IC=0.7, 2.4).

Conclusions: The prevalence of excess weight was elevated, as well as was high the prevalence of inadequate birth weight. Nevertheless, the association between birth weight and weight status in childhood was not significant. Urgent health promotion actions targeting adequate nutrition during pregnancy and childhood are needed in the studied area.

Key words: birth weight, nutritional status, overweight, obesity, childhood.

PO862**TRENDS IN LOW BIRTH WEIGHT PREVALENCE IN PETRÓPOLIS, RIO DE JANEIRO, BRAZIL BETWEEN 1994 AND 2010***V. Marins¹, C. Curioni¹, G. Ceschini¹, R. Pereira²*¹Curso de Nutrição, Faculdade Arthur Sá Earp Neto, Petrópolis, Rio de Janeiro, Brazil²Departamento de Nutrição Social, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil

Background and objectives: According to the World Health Organization in 2004, more than 20 million infants worldwide were born with low birth weight (LBW), i.e. birth weight < 2.500 g. LBW is associated with fetal and neonatal mortality and morbidity, inhibited growth and cognitive development and chronic diseases later in life. Therefore, it could be considered as a sensitive public health indicator because measure long-term maternal malnutrition, ill health, hard work and poor pregnancy health care. This study aimed to evaluate the occurrence of low birth weight children born from adult mothers in the city of Petrópolis, Rio de Janeiro, Brazil.

Methods: Ecological study evaluating LBW prevalence trends in the municipality of Petrópolis, Brazil, between 1994 and 2010 using linear regression models, having LBW incidence rate as dependent variables and time (years) as independent variables. Data on LBW prevalence and socioeconomic factors were obtained in the Birth Information System (SINASC) from the Ministry of Health, Brazil.

Results: The prevalence of LBW decreased 0.05% per year ($p = 0.09$) with a non-constant decline. Considering only the first and the last years of the time series, it was observed a reduction of 18.42% in LBW prevalence. The prevalence of LBW varied with the number of prenatal care sessions, mother's schooling, marital status, and skin color, and also with the type of delivery (cesarean section or normal), and pregnancy duration.

Conclusions: In the studied city, LBW showed downward trends, however the decrease was not statistically significant. LBW deserves attention and adequate resources since it is a powerful predictor of infant growth and survival caused by different factors including biological, socioeconomic and cultural aspects. Further studies are necessary to confirm the association with the studied variables.

Key words: low birth weight, ecological study, trends, birth information system.

PO863**TOLEDO AREA STUDY: ASSESSMENT OF DIET QUALITY, GLYCEMIC INDEX AND INSULIN RESISTANCE IN ADOLESCENTS**

J M. Martínez-Sesmero¹, T. Guillén³, A. Aragonés², S. Bastida³, F J. Sánchez-Muniz³

¹Pharmacy Department, Virgen de la Salud Hospital, Toledo, Spain

²Department of Pediatrics, Virgen de la Salud Hospital, Toledo, Spain

³Nutrition Department Faculty of Pharmacy, Complutense University of Madrid, Spain

Background and objectives: The Toledo Area Longitudinal Study (TALS) examines the influence of dietary, anthropometric and metabolic parameters at birth and their parents about different lipoprotein markers and insulin resistance (IR) in children and adolescents of Toledo Health Area. The objective is to evaluate quality diet influence and its carbohydrate profile on IR.

Methods: In a sub-sample of 53 adolescents TALS (16-17 years old), a 72-hour recall, food-frequency questionnaire with photographic were performed. The results were analyzed using the DIAL[®] software. The diet quality was determined by the Healthy Eating Index (HEI 0-100), by consumption of food groups and variety (0-10). Glycemic Load (GL) was calculated by multiplying Glycemic Index value by the grams of available carbohydrates. Insulin Resistance (IR) was assessed by HOMA-IR (≥ 1.5). Descriptive statistics (median and interquartile range) and analytical (nonparametric tests) were performed by SPSS[®] 15.0.

Results: The HEI was 64.9 (22.0) and food groups score: cereals-legumes 8.2 (2.4), vegetables 6.6 (5.4), fruits 7.6 (7.0), dairy 6.5 (3.6), meat-eggs-fish 10.0 (0.0), the food variety 5.0 (4.0). GL was 129.7 (36.3). Adolescents with HOMA-IR ≥ 1.5 compared to those with HOMA-IR < 1.5 showed less IAS (50.1 vs 68.4 $p = 0.028$) and worse scores in group intake vegetables (5.4 vs 6.8 $p = 0.078$), meat-eggs-fish (9.0 vs 10.0 $p = 0.026$), food variety (3.5 vs 6.0 $p = 0.008$) and GL (130.7 vs 121.2 $p = 0.215$).

Conclusions: The diet of adolescents in TALS is drab, with a low diet quality, high GL, aspects clearly associated with the degree of IR.

Key words: Diet quality, adolescents, insulin resistance, 72-hours recall, food-frequency questionnaire.

PO864**RELATION BETWEEN THE DEPRESSION AND THE NUTRITIOUS CONDITION IN ADOLESCENTS OF MIDDLE SCHOOLS IN MEXICO CITY**

C. Radilla¹, S. Vega², R. Gutierrez², L. Gutierrez², M. Vázquez²

¹Student of the Doctorate of Biological Sciences and of the Health, Autonomous Metropolitan University, Campus Xochimilco, Mexico City, Mexico

²Department of Agricultural and Animal Production, Division of Biological Sciences and of the Health, Autonomous Metropolitan University, Campus Xochimilco, Mexico City, Mexico

Background and objectives: The adolescence is the stage in which the human beings become vulnerable, they have existential problems, which lead them to conditions of depression and, derived to these conditions sometimes leads them in the habit of excess eating or diminish ingestion. The aim of the present study was to evaluate if the depression influences the nutritious condition of teen students of middle public schools in Mexico City.

Methods: The study sample was constituted by 142 adolescents enrolled in school from 11 to 13 years of age, being 72 women and 70 men, belonging to middle public schools in Mexico City. The conditions of depression and nutritious insolation was obtained by the 'scale HAD depression' that consists of 7 items and the Who Anthro Plus. The percentage of adolescents without depression was 69.7% (women 35.2%/men 34.5%), the percentage of adolescents with probable anxiety was 18.3% (women 10.6%/men 7.7%) and finally with significant depression 12% (women 5%/men 7%). With regard to the nutritious condition there was demonstrated that 1.4% was presenting thinness (women 1.4%), 57.7% normal weight (women 34.5%/men 23.2%), 27.5% overweight (women 10.5%/men 17%) and 13.4% obesity (women 4.2%/men 9.2%). The statistical analysis chi² of Pearson threw independence of variables ($p < 0.05$) between depression and nutritious condition. One recommends to extend the study and to correlate the nutritious condition with other variables that allow knowing the factors that predispose the increase of weight in the teenagers of secondary schools in Mexico City.

Key words: depression, teen, middle school, nutritious condition, Mexico.

PO865**FAMILY VIOLENCE AND BODY IMAGE OF ADOLESCENTS IN A HEALTH FACILITY IN THE CITY OF RIO DE JANEIRO***A M. Lourenço¹, M H. Hasselmann²*¹Department of health of the municipality of Rio de Janeiro, Brazil²State University of Rio de Janeiro, Brazil

Background and objectives: Recent studies show that domestic violence is associated with nutritional deficits, especially in young females. The relationship between sexual abuse and eating disorders has also been the subject of research in recent years. However, there are few studies that focus on the relationship between family violence and body image perceptions in adolescents. The aim of this study was to investigate the relationship between parental violence against adolescent and poor body image.

Methods: Cross-sectional study involving 201 adolescents aged 10 to 19 years enrolled in the Bolsa Família program of a health facility in the city of Rio de Janeiro, Brazil, in 2008-2009. The measurement of body image of adolescents was based on the questionnaire Body Areas Satisfaction Scale - BASS. Violence, specifically verbal and physical aggression between parents and adolescents, was measured by the Portuguese version of the Conflict Tactics Scales Form R (CTS1). Psychological violence was assessed by the scale of psychological violence against teenagers. Associations between variables were expressed as odds ratios (OR) and their respective 95% confidence intervals (95% CI) estimated via logistic regression. All analyses were developed for boys and girls separately.

Results: Among only girls, psychological violence was associated with poor body image (OR = 4.19; 95% CI, 1.37 to 12.86).

Conclusions: It is important that actions to promote and protect health also incorporate psychological violence as another factor related to body image perception in adolescence.

Key words: body image, adolescents, family violence.

PO866**A NATIONAL STUDY OF CHILEAN SCHOOL CHILDREN: RELATIONSHIP BETWEEN SUGARED NON-ALCOHOLIC BEVERAGES AND BODY MASS INDEX***J. Araneda^{1,2}, H. Amigo²*¹Department of Nutrition And Public Health, Faculty of Health And Food Sciences, Universidad del Bío-Bío, Chile²Department of Nutrition, Faculty of Medicine, Universidad de Chile, Santiago, Chile

Background and objectives: The changes in food consumption patterns in the last few years have been notable. A generalized increase in calorie consumption indicates that this intake is due to behaviors and habits acquired early in life. The objective was to evaluate the relationship between sugared non-alcoholic beverages and Body Mass Index (BMI) in Chilean school children.

Methods: The study used a population-based cross-sectional design. Multi-stage probability sampling was used to select 1074 school children between the ages of 6 and 18 residing in urban and rural areas of the country. A Quantitative Consumption Tendency Survey was applied, which analyzed the food habits and behaviors in the last 30 days. Linear multivariate models were adjusted to determine the increase in BMI per 250 ml daily serving.

Results: Of the total, 92.0% (CI = 89.9-94.2) consume sugared beverages daily with a mean of 424.3 ml (p₂₅₋₇₅=212.1-707.2). For school children who consumed more than one serving (250 cc) daily, the increase in the BMI coefficient in school children aged 6 to 13 is $\hat{\alpha}=0.49$ ($p < 0.001$) and $\hat{\alpha} = -0.01$ ($p = 0.60$) in school children aged 14 to 18.

Conclusions: Chilean school children have a high daily consumption of high-energy beverages. Consumption of sugared non-alcoholic beverages is positively associated with BMI only in school children aged 6 to 13.

Key words: school children, diet, sugared beverages.

PO867**MALNUTRITION IN JAZAN REGION, KINGDOM OF SAUDI ARABIA***Bani¹, M. Mahfouz¹*¹Jazan University, Saudi Arabia

Background and objectives: The nutritional status of young children is one of the most sensitive indicators of sudden changes in health status. The main objective of this research was to investigate the nutritional status of children less than five years and to assess the associated different factors that assumed to

influence nutritional status of the children.

Methods: Across sectional survey covered a random sample of 431 children less than five years in a randomly selected five primary health care centers in Jazan region. Data were collected using structured questionnaire designed to collect information on demographic characteristics of children, background information of the mothers and infant feeding practices. SPSS program was used for data entry and processing, p value less than 0.05 were set to be significant.

Results: Among all studied children malnutrition indicators were as follow, moderate and severe underweight was 15.9% and 12.6%, respectively. Moderate stunting was 15.9%, compared with severe 36.9%. Moderate wasting was 6.85% while severe was 7.95%. No significant difference was found between these indicators for males and females. Breastfeeding indicators revealed that 90% of the children were naturally breastfed, 29.5% of them were exclusively breastfed during the first four months of birth and 48.3% of the children were breastfed for 7-12 months. An association between mother's educational and occupational status and breast-feeding was found p value 0.036 and 0.003, respectively.

Conclusions: The study provided nutritional indicators below the average of KSA, this calls for more nutritional surveys and programs to be conducted to monitor the nutritional health of Saudi southwestern region children.

Key words: malnutrition, children, Jizan, Saudi Arabia Acknowledgement Thanks to students who collected the data, and PHC Directorate and its staff at PHC.

PO868

MOTHERS PERCEPTION, FEEDING AND CARE OF LOW BIRTH WEIGHT INFANTS IN LAGOS STATE, NIGERIA

B. Brai¹, B. Omotola¹

¹Nigerian Institute of Medical Research, Yaba, Lagos, Nigeria

Background and objectives: Low Birth Weight (LBW) infants suffer from high rates of morbidity and mortality of infectious diseases and are often underweight, stunted or wasted from the neonatal period through childhood if adequate feeding and care are not provided. Not much is known about community/mothers' perception of LBW babies, as well as their feeding and care practices. This study evaluated the feeding and care practices of LBW infants in their first four months of life.

Methods: 130 infants (65 LBW and 65 Normal Birth Weight, NBW) were studied over a period of four months from birth. Data were collected using qualitative instruments.

Results: Mean weight of the LBW and NBW infants were 2.2 ± 0.26 and 3.11 ± 0.40 kg, respectively. Mothers rated the sizes of their infants as very small (31.2%), smaller than average

(47.5%), average (14.8%) and greater than average (6.5%). 26.1% of mothers of LBW infants recognized the need for immunization compared to 4.5% of mothers of NBW. Similarly 35.4% of mothers of LBW infants recognized the need for exclusive breastfeeding compared to 15.3% of the mothers of NBW infants. However, 0% and 3.1% of LBW and NBW infants, respectively, had complete immunizations, relevant to their ages while 35.4% and 15.3% of LBW and NBW infants were exclusively breastfed. Although there was no significant difference in the care and feeding patterns of LBW and NBW infants, a process called "Agbelegbomi" in which small infants are fed herbs to increase body weight was practiced by TBAs thus hindering optimal breastfeeding.

Conclusions: The findings of this study suggest that although mothers could identify LBW infants, they do not recognize the problems/risks associated with LBW. There is need for intervention to create awareness of these problems/risks to ensure proper care of LBW infants.

Key words: infants, feeding practices, LBW, NBW.

PO869

ASSOCIATION OF BREAKFAST CONSUMPTION WITH OBJECTIVELY MEASURED AND SELF-REPORTED PHYSICAL ACTIVITY, SEDENTARY TIME AND PHYSICAL FITNESS IN EUROPEAN ADOLESCENTS: THE HELENA STUDY

M. Cuenca-García¹

¹Department of Medical Physiology, Granada University, Granada, Spain

Background and objectives: Skipping breakfast has been associated with inactive lifestyle in adolescents. The aims of this study were to examine the association of breakfast consumption with objectively measured and self-reported physical activity (PA), sedentary time (ST), and physical fitness.

Methods: The study comprised 2148 adolescents participating in the HELENA Study. Breakfast consumption was assessed by 2 non-consecutive 24 h recalls and by a 'Food Choice and Preferences' questionnaire. PA, ST and physical fitness components (cardiorespiratory fitness, muscular fitness and speed-agility) were measured and self-reported. Socioeconomic status was assessed by questionnaire.

Results: Breakfast consumption was not associated with measured or self-reported PA. However, 24 h recall breakfast consumption was related to measured ST in males and females, although results were not confirmed when using other methods to assess breakfast patterns or ST. Male breakfast consumers had higher cardiorespiratory fitness compared with occasional breakfast-consumers and -skippers, while no differences were observed in females. Overall, results were consis-

tent using different methods (all $p < 0.005$). In addition, both male and female breakfast-skippers (assessed by 24 h recall) were less likely to have a high measured cardiorespiratory fitness compared with breakfast consumers (OR: 0.33, 95%CI 0.18-0.59 and OR: 0.56; 95%CI 0.32-0.98, respectively). Results persisted across methods. Breakfast consumption was not related to muscular fitness and speed/agility in males and females.

Conclusions: Skipping breakfast consumption does not seem to be related to PA, ST or muscular fitness and speed-agility as physical fitness components in European adolescents; yet it is associated with both measured and self-reported cardiorespiratory fitness, which extend previous findings.

Key words: breakfast, physical activity, sedentarism, aerobic capacity, muscular strength, speed/agility, HELENA study.

PO870

NUTRITION AND DYSPHAGIA IN ELDERLY: THE IMPORTANCE OF SCREENING FOR EARLY IDENTIFICATION

R.C. Aquino¹, R.M.M. Goulart¹, A.P. Maeda², G. Traversari¹, L.A. Cavalcante¹

¹University São Judas, Aging Studies Programme, São Paulo, Brazil

²Centro de Referência do Idoso (CRI-Norte), São Paulo, Brazil

Background and objectives: Dysphagia is clinically very frequent in elderly and constantly associated with increased of malnutrition, dehydration and aspiration pneumonia. Early diagnosis of signs of dysphagia is important to avoid complication and guarantee an adequate nutritional status. Risk identification through dysphagia screening may positively alter health outcomes. The aim of this study was to evaluate a tool for identifying risk of dysphagia in a reference institution in São Paulo, Brazil.

Methods: This study is cross-sectional, analytic, observational, uncontrolled with convenience sample and included 422 individuals from both genders, aged between 60 and 90 years old, from July to December 2011. Because most screening tools are complex, the Brazilian Society of Geriatrics and Gerontology (SBGG) developed an instrument to identify dysphagia in hospitalized elderly and the instrument was evaluated in an outpatient reference institution. The reference institution adopts its own instrument screening that includes investigating difficulties to communicate, chew, swallow, and the frequency of choking and pneumonia. The instruments were compared and the predictive variables identified the analysis of variance (ANOVA) was conducted with a 5% significance level.

Results: Dysphagia was found in 43.1% of the sample to be used the instrument of SBGG and 13.7% when using the the

screening of the institution. The agreement was inadequate and low ($\kappa = 0.29$, $p < 0.05$). Dysphagia was associated with the weight of older males, but was not associated with age ($p < 0.05$).

Conclusions: Dysphagia was common in this population and was associated with weight, but not associated with age and early identification should provide adequate nutritional intervention.

Key words: dysphagia, elderly, screening tool.

CHILDREN FROM THE WEALTHIER HOUSEHOLDS ARE LESS LIKELY TO BE EXCLUSIVELY BREAST-FED: A STUDY FROM EAST NUSA TENGGARA, INDONESIA

H. Hadi¹, R. Amalia², G. Baldi³, E. Martini³

¹Department of Public Health, Faculty of Medicine, University of Gadjah Mada, Jl. Farmako, Sekip Utara, Yogyakarta, Indonesia

²Department of Nutrition, Alma Ata Center for Healthy Life and Food (ACHEAF), Yogyakarta, Indonesia

³Indonesia Country Office of World Food Programme, Jakarta, Indonesia

Background and objectives: About 58% of preschool children in East Nusa Tenggara, Indonesia are stunted, while exclusive breastfeeding is evident to be protective against stunting in this poor population. This study was conducted to assess whether mother's child care and socio economic status are associated with breastfeeding practice.

Methods: A cross-sectional study was conducted in Timor Tengah Selatan District. The study subjects were 408 children aged 6-24 months and their mothers. Data on mother's child care, breastfeeding history, and socio-economic status were collected using structured questionnaires by trained nutritionists.

Results: About sixty one percent (61%) of children in this study population were reported to be exclusively breastfed, and 44.1% of them were stunted. Compared to children from the poorest households (1st quintile), children from the 2nd quintile and 3rd quintile were not significantly different ($p > 0.05$) in terms of having exclusive breastfeeding. However, children from the 4th quintile were 2.1 times (OR=2.1; 95% CI=0.24-0.93) less likely, and children from the 5th quintile (the wealthiest) were 2.4 times (OR=0.42; 95% CI=0.21-0.83) less likely to be exclusively breastfed compared to children from the poorest households adjusting for the remaining demographic and socio-economic factors. Children who were not daily cared by their mothers were 3.5 times (OR=0.29; 95%

CI=0.10-0.81) less likely to be exclusively breastfed compared to children who were daily cared by their mothers adjusting for the remaining demographic and socio-economic factors.

Conclusions: Children from wealthier households and children who were not daily cared by their mothers were less likely to be exclusively breastfed. Breastfeeding promotion targeting to mothers with no daily child care and to the wealthier households could be an effective strategy to improve exclusive breastfeeding.

Key words: breastfeeding, children, household's wealth, Indonesia.

PO872

MATERNAL DECISION MAKING ABILITY AND SOCIAL SUPPORT: ASSOCIATIONS WITH INFANT YOUNG CHILD FEEDING AND NUTRITION IN RURAL NICARAGUA

S. Ziaei¹, M. Contreras¹, E. Zelaya², E C. Ekström¹

¹International Maternal and Child Health Unit (IMCH), Department of Women's and Children's Health, University Hospital, Uppsala University, Uppsala, Sweden

²Asociación para el Desarrollo Económico y Social de El Espino (APRODESE), Chinandega, Nicaragua

Background and objectives: The role of maternal caring behavior has been highlighted as an underlying factor for infant and young child feeding and nutrition. Mothers' ability to make decisions and the social support they receive to do so, may be of importance for their caring capacity. We aimed to study the associations between maternal decision making ability, their social support and feeding and nutritional status of their 0-35 months old children..

Methods: In a cross-sectional survey, data on 1371 mother-infant pairs were collected in los Cuatro Santos area, rural Nicaragua. At household visits mothers were interviewed about their decision-making ability and social support using commonly used instruments. The scores attained were turned into tertiles for analyses. Infant and young child feeding was assessed using WHO recommended key indicators. Children's height and weight was collected using standard procedures and converted to nutritional indices based on WHO child growth standards. Adjusted multivariate regression models were conducted to estimate associations between outcomes and main explanatory variables.

Results: Compare to mothers in highest tertile of decision making ability, mothers in the lowest tertile were more likely to exclusively breastfeed their infants under 6 months of age and continue breast feeding after one year. Complementary feeding practices were better among mothers within the middle

tertile of decision making capacity. Similarly, mothers in the middle tertile of social support had children with significantly higher weight-for-height and BMI-for-age z-scores as well as lower odds of wasting 0.13 (95% CI; 0.03-0.60) compared to the mothers in the highest tertile.

Conclusion: In this sample of rural Nicaraguan mothers, optimal feeding practices and higher body mass was observed more among the children of mothers with lower decision making capacity and social support but associations may not be causally interpreted. Funded by Sida

Key words: social support, decision making, children, nutrition, Nicaragua.

PO873

GLUTEN CONSUMPTION AT EARLY AGE IS DIFFERENT AMONG INFANTS FROM DIFFERENT EUROPEAN COUNTRIES. THE PREVENT-CD COHORTS

P. Crespo¹, J. Calvo¹, G. Castillejo², E. Martínez³, E. Hopman⁴, S. Vriezinga⁴, B. Funke⁴, K. Werkstetter⁵, R. Auricchio⁶, I. Polanco³, S. Koletzko⁵, R. Troncone⁶, M L. Mearin⁴, C. Ribes-Koninckx¹

¹Gastroenterology Pediatric, La Fe University Hospital, Valencia, Spain

²Hospital Universitari Sant Joan, Reus, Spain

³La Paz University Hospital, Madrid, Spain

⁴University Medical Center, Leiden, Netherlands

⁵University of Munich Medical Center, Germany

⁶University Federico II, Naples, Italy

Background and objectives: To evaluate mean daily gluten intake (MDGI) in children DQ2/DQ8 positive with a 1st degree relative with CD recruited from 2007-2010 shortly after birth (EU-PreventCD project, www.preventcd.com).

Methods: A prospective evaluation of MDGI in 11-36 months old infants in the PreventCD cohorts from Spain (Valencia, Madrid, Reus), Italy, Germany and the Netherlands, was accomplished by specific previously developed food records (FR), adapted to local dietary habits. All of FR corresponds to a period of 7 days and these were completed at 11, 12, 14, 16, 18, 22, 24, 28, 30, 34 and 36 months of age. The MDGI was calculated by the accepted method of multiplying the grams of vegetable protein, derived from gluten-containing cereals according to the food product composition, by 0.80.

Results: 906 FR (2-3 per child) were evaluated. MDGI increased progressively from 12 months onwards in all centers, the highest MDGI being registered in the older age group (25-36 months). MDGI (in grams) for Valencia, Madrid, Reus, The Netherlands and Germany are respectively: 2.95, 3.26, 2.09,

5.82, 4.09 (11-12 months); 4.35, 4.11, 4.75, 7.81, 6.54 (14-18 months); 4.80, 4.28, 4.77, 8.33, 7.21 (20-24 months) and 5.18, 4.14, 4.63, 8.91, 7.94 (25-36 months). Differences in MDGI are statistically significant between Spanish children and those from The Netherlands and Germany ($p < 0.001$), the latter 2 countries displaying more similar MDGI, except at the youngest age.

Conclusions: In the different countries MDGI increases sharply in-between 12 and 18 months of age, but it remains quite constant thereafter. However, The Netherlands and Germany have overall significant higher gluten consumption at any age. Further analysis including genetics and breast feeding as well as longer follow up of this cohort is mandatory to ascertain the true relevance of gluten intake at early ages in the natural history of CD in European children.

Key words: gluten consumption, European children.

PO874

ANEMIA PREVALENCE AMONG PREGNANT WOMEN RECEIVING CARE AT A HOSPITAL IN GHANA

V A. Sedo¹, I. Agbemafle², J. Setorglo³, M. Steiner-Asiedu⁴

¹Department of Nutrition and Food Science, University of Ghana, Legon, Ghana

²Department of Nutrition and Food Science, University of Ghana, Legon, Ghana

³School of Medical Sciences, University of Cape Coast, Cape Coast, Ghana

⁴Department of Nutrition and Food Science, University of Ghana, Legon, Ghana

Background and objectives: Anemia continues to be a global challenge particularly among pregnant women. In Africa about 20% of maternal deaths have been attributed to anemia. The objective of this study was to determine the prevalence of anemia at different trimesters among pregnant women aged 18-49 years receiving prenatal care at a Public Hospital.

Methods: This was a cross-sectional study involving 120 pregnant women. A semi-structured questionnaire was used to obtain information on socioeconomic and demographic factors, anemia knowledge and vitamin-mineral supplement use. Participants most recent hematological data on Hemoglobin level (Hb), Hematocrit (PCV), Mean Corpuscular Volume (MCV), Mean Corpuscular Hemoglobin (MCH) and Mean Corpuscular Hemoglobin Concentration (MCHC) previously determined using hematology automated analyzer were obtained from hospital records. Anemia was classified based on WHO Hb and other hematological cut-offs. Pearson chi-square test was used to investigate associations between variables.

Results: Normocytic and microcytic anemia was present among 65% and 35% of the pregnant women respectively. Some of the women (45.0%) at one point in pregnancy had anemia. The prevalence of anemia was significantly higher ($p = 0.049$) in those in their third trimester than those in their first and second trimesters of pregnancy. A high percentage (94.2%) had knowledge about anemia during pregnancy. Majority (98.3%) were using some form of supplement, however, combination of iron and folic acid were the commonest supplements among 54.2% of the pregnant women. The women's age, socioeconomic status and supplement use had no significant relationship with hemoglobin concentration ($p > 0.05$).

Conclusions: The prevalence of anemia in pregnancy is still high even though majority of the women had prior knowledge about anemia during pregnancy and were using vitamin-mineral supplements. Innovative ways to address anemia is therefore warranted.

Key words: anemia, pregnancy, supplement use, knowledge
Acknowledgement: The authors thank all the women who volunteered.

ASSOCIATIONS BETWEEN NUTRITIONAL STATUS, HOUSEHOLD FACTORS AND SPECIFIC DIARRHEAL PATHOGENS AMONG CHILDREN IN MIRZAPUR, BANGLADESH

K. Long¹, Z. Horder¹, A. Faruque², T. Ahmed², S. Ahmed¹

¹School of Population Health, University of Queensland, Brisbane, Australia

²Centre for Nutrition and Food Security, ICCDR, Dhaka, Bangladesh

Background and objectives: Childhood malnutrition determinants are multi-factorial and so causal pathways linking them require further clarification. We ascertained what household sanitation and hygiene factors and diarrheal pathogens determined nutritional status of children in rural Bangladesh.

Methods: Children with diarrhea and matched control children <60 months of age were recruited in Mirzapur, Bangladesh for the Global Enteric Multi-Center Study (GEMS) between December 2009 and December 2012. Clinical information on children was collected along with information on household hygiene and sanitation factors. A stool sample collected from each child was screened for bacterial, viral and protozoa enteric pathogens. Children's anthropometric measures were used to classify them as stunted, underweight or wasted. Associations between indices of malnutrition status and household hygiene and sanitation factors as well as diarrheal pathogens among combined cases and controls were analyzed using hierarchical logistic models.

Results: The prevalence of stunting, underweight and wasting among children was 18%, 22% and 14%, respectively. Greater caregiver's education, feces disposal, and child's age, were associated with reduced stunting and underweight while household animals increased the risk of both. Greater caregiver's education and water treatment were associated with reduced wasting. *Cryptosporidium parvum* and *Shigella flexneri* infections were significantly associated with increased stunting and wasting, respectively.

Conclusions: These results suggest that different sets of risk factors are associated with indices of short term acute and longer term chronic malnutrition. These differences are reflected in the importance of acute, severe bacterial and chronic parasite infections as proximal risk factors for these outcomes.

Key words: childhood malnutrition, risk factors, Bangladesh.

PO876

A GROWING PROBLEM IN CONSUMPTION OF ALCOHOLIC AND ENERGY DRINKS AMONG ADOLESCENTS

S. Petrova¹, V. Duleva¹, P. Dimitrov¹, L. Rangelova¹

¹National Center of Public Health and Analyses, Sofia, Bulgaria

Background and objectives: Consumption of alcoholic drinks among Bulgarian adolescents was identified as a serious problem 15 years ago but the use of energy drinks which popularity is currently increasing has not been studied. The purpose of this survey is to investigate the consumption of alcoholic drinks among schoolchildren and to estimate its trends, to examine the use of energy drinks by children and adolescents and its correlations with those of alcoholic drinks.

Methods: Cross-sectional nutrition survey on a national representative sample comprising 4322 schoolchildren aged 6-18 years was performed in 2011. Consumption of alcoholic and energy drinks for the past year was studied by Food Frequency Questionnaire. Statistical analyses were performed using SPSS v. 17.

Results: Among schoolchildren aged 10-13 years 56% never consumed alcoholic drinks, in the age 14-18 years - only 17%. At least once weekly beer consumed 38.5% of schoolchildren 14-18 years old, wine - 26.7%; spirits - 39.5% as 10% of boys reported every day spirit consumption. There is a tendency for increasing in alcohol consumption among schoolchildren comparing to findings from the national survey in 1998. This study revealed that consumption of energy drinks starts still in the age 6-9 years. Non-consumers of energy drinks (never consumed, consumed less than once monthly) were 50.4% of schoolchildren aged 10-18 years. At least one energy drink

weekly consumed 18.3% of adolescents aged 10-13 years and 33.5% of schoolchildren 14-18 years old, as 13.4% of boys in this age have ingested energy drinks every day. Co-occurrence of energy and alcoholic drinks consumption was determined among adolescents aged 10-18 years. Correlation between use of energy drinks and consumption of spirits and beer was revealed ($r=0.3$, $p < 0.000$).

Conclusion: Findings from the study are worrisome and call for effective policy measures.

Key words: alcohol, energy drinks, adolescents.

PO878

DIETARY PATTERN, FIBER AND CHOLESTEROL, OF A GROUP OF ELDERLY YORUBA IN IBADAN, NIGERIA.

I. Olayiwola¹, G. Fadupin², S. Agbato³

¹Federal University Agriculture Abeokuta Nigeria

²University of Ibadan, Ibadan, Nigeria

³Babcock University (BU), Ilisan Remo, Nigeria

Background and objectives: Elevated high density lipoprotein-cholesterol (HDL-C) concentrations have been found to influence longevity, suggesting the need to increase HDL-C concentrations in elderly individuals. This cross sectional descriptive study assessed demographic and dietary characteristics of 240 elderly subjects in Ibadan, Nigeria, including Fiber intake and lipid profiles.

Methods: All respondents filled out appropriate questionnaires in respect to dietary pattern and blood was drawn for biochemical analysis.

Results: The 240 respondents ranged in age from 60 to 95 years and included 114 (47.5%) men and 126 (52.5%) women. Their diets were high in roots and tubers, moderate in legumes and low in fruits and animal proteins and fats. Mean fiber intake was 16 g/day, energy ranged from 6136-8368 kJ/day and protein ranged from 28-50g/day. Zinc, vitamin A and B vitamin were generally low. Assessments of their lipid profiles showed that 53% of men and 70% of women had normal low density lipoprotein-cholesterol (LDL-C) concentrations. HDL-C concentrations ranged from 33-39.74 mg/dl, with 69% of men and 35% of women having normal HDL-C. Most women (80%) had normal total cholesterol (TC) concentrations. Total triglyceride concentrations ranged from 76-117 mg/dl. In addition, there is a significant different between male and female LDL and HDL. Furthermore, age affected the lipid profiles and general health of these elderly subjects. Age is associated with decreased lipid concentrations, especially of HDL-C, and decreased energy intake. Fiber intake was positively correlated with Vitamin A ($r=0.30$; $p < 0.05$), Vitamin B1 ($r=0.41$; $p < 0.05$) and Zinc ($r=0.40$; $p < 0.05$).

Conclusions: These findings suggest that fiber, age and gender have a significant effect on the lipid profiles of elderly Yoruba. Most of these subjects consumed diets rich in plant sources.

Key words: diets, lipid profile, fiber, elderly.

PO879

EARLY ADIPOSITY REBOUND IS ASSOCIATED WITH INCREASED METABOLIC RISK AT AGE 7Y IN CHILEAN CHILDREN

L. González¹, J. Kain¹, M. Garmendia¹, C. Corvalán¹

¹Department of Public Health and Nutrition, Institute of Nutrition and Food Technology, University of Chile, Santiago, Chile

Early adiposity rebound (< age 5y; EAR) has been consistently associated with increased obesity risk, but its relationship with metabolic disorders is less clear; also importantly, the mechanisms involved in these associations are not yet established. Therefore, we aimed to assess the association between timing of adiposity rebound (AR) and metabolic status at age 7, evaluating the potential role of total adiposity, adipose function, and biological maturation in these associations. In 910 children from the Growth and Obesity Chilean Cohort Study (GOCS) we built BMI curves from 0-7y and estimated the age at AR. At 7y we measured waist circumference, glucose, insulin, triglycerides and HDL-cholesterol and a metabolic risk score based on standardized scores was constructed. At 7y we also measured percentage of fat mass (adiposity), leptin and adiponectin (adipose functionality) and ultrasonographic bone age (maturation). We found that mean age at AR was 5y in girls ($5.19 \pm 1.82y$) and boys ($5.42 \pm 1.70y$) and 44% of the children had EAR. EAR was associated with larger waist circumference [?: 5.10 (95% CI: 4.29-5.91)], higher glucose [?: 1.02 (1.00- 1.03)], insulin resistance [? HOMA-IR: 1.06 (1.03- 1.09)], and triglycerides [?: 10.37 (4.01- 6.73)], and worse metabolic risk score [?: 0.30 (0.02- 0.37)]. Associations decreased significantly when adding adiposity to the models (i.e. ? waist circumference: 0.85 (0.33- 1.38) and to a lesser extent when adding functionality [i.e. ? waist circumference: 0.73 (0.14- 1.32) and maturation [i.e. ? waist circumference: 0.65 (0.10- 1.20)]. We conclude that in Chilean children younger ages of adiposity rebound predict higher metabolic risk at 7y; these associations are explained by increased maturation and adiposity dysfunction, but mostly by greater adiposity. Funding: FONDECYT # 1090252, CC has a Wellcome Trust Training Fellowship. Keywords: adiposity rebound, obesity, metabolic risk

PO880

THE RISK OF VITAMIN B12 DEFICIT ASSOCIATED WITH THE USE OF METFORMIN IN CHILEAN OLDER PEOPLE

H. Sanchez¹, D. Masferrer¹, L. Lera¹, B. Angel¹, C. Albala¹

¹Unit of Nutrition , Public Health and Healthy Aging, Institute of Nutrition and Food Technology, University of Chile, Santiago de Chile, Chile

Background and objectives: Metformin is widely used for the treatment of Type 2 diabetes and has been associated with decreased plasma levels of vitamin B12 (B12). Considering the important effects of B12 deficit in older people, the aim of the study is to estimate the risk of B12 deficit associated with the use of metformin in diabetic older subjects.

Methods: Case-Control study in 514 (73.4% female), community-dwelling diabetic subjects aged 65-74 y randomly selected from Primary Care Centers registries from Santiago Chile. The protocol was approved by the ethical committee of INTA. Cases (118) were defined as diabetic older people with low plasma B12 (<221 pmol/l). Controls (396) were comparable diabetic individuals with B12 >221<700 pmol/L. High Metformin doses were defined as Percentile 75 (>2500 mg/day). Pearson simple correlation between metformin doses and vitamin B12 levels was performed. Logistic regression models were used to explore association between low vitamin B12 and p75 metformin doses. The models was adjusted by sex, age, alcohol use and metformin time of use.

Results: Mean age of the sample was 68.2 ± 4.6 . Use of metformin was present in 74.4% (95%CI: 70.4-78.1) subjects. The metformin median doses/day was 1700 mg (IQR:850-2550) High doses of metformin was present in 23.1% (95%CI: 19.5-27.0) of the subjects similar for both men and women. Low plasma vitamin B12 was found in 31.6% (95%CI: 24.4-40.6) of men and 19.6 (95%CI: 15.7-24.0) of women ($p < 0.01$). Alcohol consumption was present in 30.9% of men and 9.1% of women. The mean time of metformin use was 8.2 months with no gender difference. The adjusted models showed an increased risk of low vitamin B12 in the subjects with using high metformin doses (OR 1.82; 95% CI: 1.07-3.08).

Conclusions: These results support considering use of >2500 mg/day of metformin as a risk factor for B12 deficit Supported by Grant FONIS SA1112092.

¹²Department of Epidemiology and Community Medicine, University of Ottawa, Ottawa, Canada

¹³Department of Social & Environmental Health Research, Faculty of Public Health & Policy, London School of Hygiene and Tropical Medicine, London, UK

Background and objectives: Under-nutrition contributes to five million deaths of children under five each year. Throughout the life cycle, under-nutrition contributes to risk of infection, lowered cognitive performance, chronic disease in adulthood, and mortality. To intervene effectively, we need to understand what works, what does not, and why. The aims of this study were, 1. To assess the effectiveness of feeding programs for children aged three months to five years. 2. To undertake an implementation evaluation.

Methods: We included RCTs, CCTs, CBAs and ITS. Programs provided energy and nutrients through: hot or cold meals, snacks, take-home or home-delivered rations. Recipients had to be aged three months to five years, from all countries. We used standard systematic review methods and also evaluated implementation, including nutritional quality of the food.

Results: 29587 papers were identified through searches: 277 were retrieved and 27 studies met inclusion criteria; 25 of these were from LMIC. Energy provided in 15 studies ranged from 20% to 157% of the recommended daily allowance (RDA) and protein ranged from 18% to 425% of the RDA. Our meta-analyses showed small (0.26 cm) significant effects on height gain in RCTs, but no other effects on growth. A few studies showed effects on cognitive ability (SMD = 3.06, 95% CI = 2.6 to 3.6) and psychomotor development (SMD = 1.4, 95% CI .56 to 2.2) in RCTs. We will present results of subgroup analyses by nutritional adequacy, age, initial nutritional status and method of delivery. Our implementation review identified several possible reasons for the ineffectiveness of some programs, including: substitution, redistribution of food within the family, caregiver burden and stress, lack of supervision and pipeline breaks.

Conclusions: We provide evidence that feeding programs for young children can work, but that many do not. Our review suggests ways in which program design can be improved.

Key words: feeding programs, policy.

PO882**FOOD INTAKE PATTERN OF INFANTS IN KOREA**

M. Yon¹, Y. Lee¹, D. Kim¹, J Y. Lee¹, E. Koh¹, J. Nam¹, H J. Lee¹, S Y. Kim², Y M. Jang², C I. Kim³

¹Korea Health Industry Development Institute, Korea

²Korea Food & Drug Administration

³Department of Health Industry & Policy, Korea Health Industry Development Institute

Background and objectives: This study was conducted to examine the food intake pattern of Korean infants, as a part of dietary intake survey on physiologically vulnerable population to hazardous materials.

Methods: With a nationwide stratified multistage cluster sampling of 50 survey sites, 250 breastfed infants were investigated during winter (December 2011 through February 2012). Information on food intake of infants was collected by proxy interviews on mothers with 24-hour recalls on 2 non-consecutive days by household visits.

Results: Among 245 infants included in the final analysis, the number of babies of early infancy (E: 0-2 months), mid-

infancy (M: 3-5 months), and late infancy (L: 6-12 months) was 80 (33%), 102 (41%), and 63 (26%), respectively. Proportion of babies fed complementary foods was 29.8% with the first introduction of complementary food at 5.4 month of age. The amounts of food groups consumed per day by M were breast milk and/or infant formula 678.4 g, grains 5.5 g, fruits 3.7 g, vegetables 0.2 g and meats 0.1 g, and those consumed by L were breast milk and/or infant formula 572.3 g, cereals 31.5 g, vegetables 12.9 g, fruits 12.4 g, meats 11.3 g, potatoes 3.3 g and legumes 3 g. Frequently consumed foods by L, except breast milk and infant formula, were white rice (consumed by 81.0%), beef (39.7%), carrots (33.3%), chicken (22.2%), broccoli (22.2%), cheese (15.9%), confectionery (15.9%), onions (15.9%), pumpkins (14.3%) and glutinous rice (11.1%). The average number of complementary foods consumed by L per day was significantly higher ($p < 0.05$) in infants of mothers with higher educational attainment (college graduate and higher) (3.9 ± 2.2) compared to infants of mothers with lower education (high school diploma and lower) (2.6 ± 1.6).

Conclusions: This result can be utilized in assessing exposure to hazardous materials through foods in infants.

Key words: Korean infant, food intake, complementary food. [This research was supported by a grant (11062KFDA732) from Korea Food & Drug Administration in 2011~2012].

PO883

HOUSEHOLD FOOD INSECURITY AND HOUSEHOLD EXPENDITURE ON CIGARETTE ASSOCIATED TO UNDERWEIGHT AMONG PRESCHOOL CHILDREN IN EAST JAVA, INDONESIA

D.R. Andrias¹, A.C. Adi¹

¹Nutrition Department, Faculty of Public Health, Airlangga University, Surabaya, East Java, Indonesia

Background and objectives: Preschool-children underweight is still prevalent in East Java Province of Indonesia. Poverty and food insecurity might be the dominant contributing factors. East Java is categorized as chronically food insecure area and one of the main provinces contribute to total number of poor population in Indonesia. On the other hand, data showed that during the crisis, household food expenditure declined, however, expenditure on cigarette did not decline. This work assesses the association of household food security and household expenditure on cigarette with preschool children underweight status.

Methods: Data was obtained from the 2010 Indonesian basic health research, consist of 2247 households with preschool children in East Java. Households were categorized as food secure if proportion of budget allocated for food was less or equal

to 60% and caloric availability per adult equivalent was more than 80% (Jonsson dan Toole, 1991).

Results: Overall, only 19.5% households were food secure. Multivariate analysis using logistic regression by including household size, food expenditure, expenditure on cigarette, household calorie availability, household food security status, child calorie consumption and child protein consumption as the candidates of predictors for underweight, showed that household food insecurity and household expenditure of cigarette significantly associated to underweight. Children living in food insecure household had 2.183 times higher risk of being underweight compared to those living in food secure household. While children from households with cigarette expenditure more than 12000 rupiahs per day had 1.296 times higher risk of being underweight.

Conclusions: This analysis concluded that household food insecurity and household expenditure on cigarette were associated to underweight among preschool children. Beside to support evidence that household food insecurity is still an emerging issue need to overcome, this analysis also suggest the importance of educating poor people to allocate their cigarette expenditure into food for their children.

Key words: household food security, underweight, cigarette.

PO884

EFFECTS OF CARBOHYDRATE SUPPLEMENTATION ON PHYSIOLOGICAL VARIABLES DURING EXERCISE IN HYPOXIA

A.V. Caris^{1,2}, F.S. Lira^{1,2}, M.T. de Mello^{1,2}, R.V.T. Santos^{2,3}, L.M. Oyama¹

¹Departamento de Fisiologia da Nutrição, UNIFESP, Brasil

²Centro de Estudos em Psicobiologia e Exercício, Brasil

³Departamento de Biociências, UNIFESP, Brasil

Background and objectives: In normoxia, carbohydrate supplementation is a classic method to delay fatigue and reduce the effects of stressful exercise on physiological variables. During exercise in hypoxia, the importance of carbohydrate metabolism increases. Therefore, it is very important to elucidate the effects of carbohydrate supplementation in this condition. This study aimed to evaluate the effects of carbohydrate supplementation on performance and physiological variables during exercise in hypoxia.

Methods: Five physically active male volunteers underwent three sessions of exercise at 70% VO₂ peak until exhaustion: (1) no supplementation in normoxia, (2) no supplementation in hypoxia, and (3) supplementation with 8% maltodextrin

(200 ml/20 minutes) in hypoxia. All procedures were randomised and double blind. The hypoxia simulated an altitude of 4500 m. The following parameters were assessed every 15 minutes during the exercise: heart rate(HR), hemoglobin O2 saturation (SaO2), rating of perceived exertion (RPE), HR/RPE, HR/SaO2, and RPE/SaO2. Statistical analysis was performed by Two-way ANOVA followed by Tukey post test, considering statistical significant $p < 5\%$.

Results: For the exercise in hypoxia, the SaO2 decreased ($p < 0.05$) and the HR/RPE and RPE /SaO2 increased within 15 minutes of exercise ($p < 0.05$ for both) relative to the corresponding values in normoxia. Additionally, the performance during hypoxia was less than that in normoxia ($p < 0.05$). No difference was observed between the exercise performed in hypoxia with and without supplementation.

Conclusions: The carbohydrate supplementation was not able to reverse the effects of hypoxia during exercise and delay fatigue. These findings are the opposite of the effects described for normoxia.

Key words: exercise, hypoxia, carbohydrate supplementation.

PO885

EFFECT OF GLUTAMINE SUPPLEMENTATION ON TH1/TH2 BALANCE DURING EXERCISE IN HYPOXIA

A V. Caris^{1,2}, F S. Lira^{1,2}, M T. de Mello^{1,2}, L M. Oyama¹, R V T. Santos^{2,3}

¹Departamento de Fisiologia, UNIFESP, Brasil

²Centro de Estudos em Psicobiologia e Exercício, Brasil

³Departamento de Biociências, UNIFESP, Brasil

Background and objectives: Several studies conducted in normoxia have suggested that glutamine supplementation attenuate the immunosuppressive effects of strenuous exercise, however little is known about the importance of glutamine during exercise in hypoxia. This study aims to evaluate the effects of glutamine supplementation on Th1/Th2 balance during exercise in hypoxia.

Methods: Five physically active male volunteers underwent three sessions of exercise at 70% VO₂ peak until exhaustion: (1) no supplementation in normoxia, (2) in hypoxia no supplementation (placebo) and (3) after 6 days of glutamine supplementation (20 g/day) in hypoxia. All procedures were randomised and double blind. The hypoxia simulated an altitude of 4500 m. Before and after the exercise, blood was collected, and the lymphocytes (1×10^5 cel) were incubated in 96-well plates containing RPMI 1640 supplemented with 2 mM glutamine, 10% homologous serum and 5 µg/ml Concanavalin A. After 48h, the supernatant was collected to measure the IL-2, IL-4

and IL-6 levels using kits from R & D Systems. Statistical analysis was performed by Two-way ANOVA post Tukey test $p < 5\%$.

Results: Exercising in hypoxia decreased the performance ($p < 0.05$) and the hemoglobin oxygen saturation (SaO₂) ($p < 0.05$) in relation to normoxia. Furthermore, no difference in cytokine levels were found relative to exercise in normoxia. However, for exercise with supplementation, there was a decrease in the IL-4 level ($p < 0.05$) and increase in the IL-6 level ($p < 0.05$), in relation to normoxia and hypoxia condition.

Conclusions: Glutamine supplementation appeared to influence the Th1/Th2 balance, attenuating the Th2 response after exercise in hypoxia. However, the supplementation was not sufficient to reverse the decline in performance caused by hypoxia.

Key words: exercise, hypoxia, glutamine, lymphocytes.

PO886

RURAL-URBAN DIFFERENTIALS IN LIFESTYLE AND FOOD SECURITY OF OLDER PERSONS IN IBADAN, NIGERIA

O. Ariyo^{1,2}, I. Akinyele¹, O. Keshinro²

¹Department of Human Nutrition, Faculty of Public Health, University of Ibadan, Ibadan, Oyo State, Nigeria

²Department of Nutrition and Dietetics, Federal University of Agriculture, Abeokuta, Nigeria

Background and objectives: Healthy lifestyle and good nutrition help promote active ageing. Knowledge of rural/urban differentials in lifestyle and food security is essential to design locality-driven programmes. This study assessed rural/urban differences in lifestyle and food security of older people in Ibadan.

Methods: This comparative cross-sectional survey involved 168 and 178 respondents from two urban and two rural Local Government Areas (LGAs) of Ibadan. A three-stage sampling technique was used to select LGAs, wards/communities and respondents, respectively. A semi-structured questionnaire was used to collect information on socio-demographic and lifestyle profile of the respondents. Socio-Economic Status (SES) was categorised as low (6-13), moderate (14-21) and high (22-29) and lifestyle was assessed using levels of smoking, alcohol intake and physical activity. Food security was determined using household coping strategies. Data were analyzed using descriptive statistics and logistic regression at 5% level of significance.

Results: Mean age was 68.9 ± 4.7 and 69.7 ± 4.4 years in urban and rural areas, respectively. Respondents in low SES were more (6.7%) in rural than urban areas (2.4%) ($p < 0.05$). Prevalences of heavy alcohol intake (16.1%, 16.9%) and irregular physical activity (1.8%, 9.6%) were lower in urban than rural

areas. Current smokers were thrice higher (13.5%) in rural than urban areas (4.8%). Food insecurity with hunger was nine-times higher in rural (16.9%) than urban areas (1.8%) while food insecurity without hunger was 17.4% and 7.1% in rural and urban areas, respectively. Smoking and alcohol intake had no significant relationship with food security in both areas. The likelihood of being food insecure reduced in urban than rural when respondent had at least moderate-SES (OR: 0.15 vs 0.10) or married (OR: 0.6 vs 3.5) among other results.

Conclusions: Poor lifestyle and food insecurity were higher in rural than urban areas. Intervention programmes should direct attention to older persons in rural areas.

Key words: lifestyle, food security, older people, rural/urban, differential.

PO887

COMPARISON OF NUTRIENT INTAKE OF OLDER PERSONS IN RURAL AND URBAN AREAS OF IBADAN, NIGERIA

O. Ariyo¹, I. Akinyele¹, O. Keshinro²

¹Department of Human Nutrition, Faculty of Public Health, University of Ibadan, Ibadan, Nigeria

²Department of Nutrition and Dietetics, Federal University of Agriculture, Abeokuta, Nigeria

Background and objectives: Adequate nutrition is essential for healthy ageing and reduction of morbidity among older persons. Knowledge of rural/urban differential is essential to design programmes that promote healthy ageing and quality of life. This study was aimed at assessing rural/urban differences in nutritional status of older people in Ibadan.

Methods: This study is comparative cross-sectional in design and involved 168 respondents from Ibadan North-West and South-West (Urban) and 178 respondents from Ido and Egbeda (Rural) Local Government Areas (LGAs) of Ibadan. A three-stage sampling technique comprising stratified, cluster and simple-random samplings was used to select LGAs, communities and respondents, respectively. A semi-structured questionnaire was used to collect socio-demographic information and Socio-Economic Status (SES) was categorised as low, moderate and high. Direct weighing method was used for dietary assessment and nutrient intake was determined using the Total Dietary Assessment software. Weight and armspan were assessed to calculate Body Mass Index (BMI) categorised as underweight (<16.5 Kg/m²), normal-weight (16.5-22.9 Kg/m²) and overweight (>23.0 Kg/m²). Data were analyzed using Chi-square test at $p < 0.05$.

Results: Respondents' mean age was 68.9±4.7 years in urban and 69.7±4.4 years in rural. Respondents in low SES were more (6.7%) in rural than urban areas (2.4%) ($p < 0.05$). In-

adequate intakes of calorie (61.3%, 52.2%), calcium (98.8%, 97.8%), zinc (82.7%, 71.9%) and vitamin B1 (51.2%, 44.9%) were higher, while protein (17.9%, 19.7%) and iron (5.4%, 7.9%) were lower in urban than rural areas, respectively. Underweight was higher in rural (24.2%) than urban (16.7%), while overweight was higher in urban (8.3%) than rural (7.3%) areas. The odds of undernutrition was six times higher in rural than urban when respondent had less than moderate SES (OR: 2.53 vs 0.432) among other results.

Conclusions: Undernutrition was higher in rural than urban areas. Nutritional intervention programmes should consider older persons in rural areas as a priority group.

Key words: nutritional status, nutrient intake, older people.

PO888

NEUROCOGNITIVE ABILITIES AND FOOD HABITS AMONG MOROCCAN CHILDREN

F. Z. Azzaoui¹, H. Hami², M. El Hioui¹, S. Boulbaroud³, A. Ahami¹

¹Equip of Clinic And Cognitive Neurosciences And Health, Faculty of Science, IBN TOFAIL University, Kenitra, Morocco

²Laboratory of Genetic and Biometry, Faculty of Science, IBN TOFAIL University, Kenitra, Morocco

³Equip of Neuroendocrine Physiology, Faculty of Science, IBN TOFAIL University, Kenitra, Morocco

Background and objectives: Some food habits could affect the balance of nutritional status and impair brain and consequently neurocognitive performances among children. The objectives of this study is to evaluate some neurocognitive abilities (short term memory, working memory and ADHD) among Moroccan children and to study the relationship between the performances in these tests and some food habits (drinking tea during/or just after meals, frequency of red meat consumption, frequency of orange juice, vegetables and fruits consumption).

Methods: The study is realized among 129 children, aged 6 to 8 years and living in urban, periurban and rural zones of Gharb plain (North West of Morocco). Memory Sub-test of WISC III (Wechsler Intelligence Scale for Children) and two questionnaires are used; one based on the DSMVI to evaluate ADHD and another about quality of life of children.

Results: The obtained results show that the important scores of memory impairments are registered among rural children compared to others group ($p < 0.01$). Besides, only 11% of urban children are hyperactive against 28% periurban and 33% rural ones. Moreover, a significant correlations between the decrease of performances of short term memory and increase of consumption frequency of tea during or just after meals ($p < 0.05$), and between decrease of performances of working me-

mory and both consumption of tea during or just after meals ($p < 0.01$) and decrease of red meat consumption are registered. The presence of ADHD is, also, correlated to the decrease of red meat consumption ($p < 0.01$).

Conclusions: Neurocognitive impairments recorded among these children appeared in connection with some food habits, but a deeper investigation is needed for studying all factors that can affect these performances (environmental, psychological and socio-economical ones).

Key words: neurocognition, children, food habits, Gharb plain, Morocco.

PO890

BODY IMAGE PERCEPTION OF SCHOOLCHILDREN IN SÃO PAULO

S. Freire¹, S. Freire², A P. Pazzini³

¹University Federal of Sao Paulo, Brazil

²University July Nine, Brazil

Background and objectives: Health promotion with a focus on healthy weight can impact children, who now have concerns about weight and body shape. This study aims to evaluate the distortion and body dissatisfaction of schoolchildren.

Methods: The study was conducted in a public school in the city of São Paulo, with 205 distributed among schoolchildren aged 7-10 years old of both sexes. Children were measured and weighed to obtain the Real BMI (BMIR) and also answered two questions about body awareness with the silhouette scale validated for Brazilian children, which indicate the value of the Actual BMI (IMCA) and Desire (IMCD). 1) Show that the figure is more like body with your own body? IMCA 2) What is the figure that shows the body you wish you had? IMCD The distortion was accomplished by the difference between the IMCA-IMCR, dissatisfaction the difference between the IMCD and IMCA and the difference between IMCD and IMCR. ANOVA was used for statistical tests comparing the mean BMI values of boys and girls by age with a significance level of $p < 0.05$.

Results: The girls 7 y old overestimate their body image, as well as all the girls evaluated when compared with boys ($p < 0.05$). The girls aged 7 and 10 y old and evaluated all the girls have desire to have a smaller body compared to boys ($p < 0.05$). The difference between the actual and desired body was higher for girls aged 9 y and for all girls compared to boys ($p < 0.05$).

Conclusions: Girls school, starting from the age of 7 and distortion reported dissatisfaction with their body weight.

Key words: behavior, body image dissatisfaction, childhood.

PO891

PHYSICAL ACTIVITY AND OVERWEIGHT IN CHILDREN AND ADOLESCENT: A CASE-CONTROL STUDY

P. Costa¹, M. Silva², M. Santana², N. Fonseca³, J. Pitangueira¹, A. Assis²

¹Science Health Centre, Federal University of Reconcavo of Bahia, Santo Antonio de Jesus, Brazil

²Nutrition School, Federal University of Bahia, Salvador, Brazil

³Nutrition Faculty, University of Brasilia, Brasilia, Brazil

Background and objectives: Overweight in children and adolescents has shown increasing occurrence both in developed as in developing countries. In Brazil, over the last 40 years it is possible to observe expressive reduction in malnutrition prevalence and a rapid increase in overweight prevalence in children and adolescent and the sedentary lifestyle is an important risk factor for this condition. Considering this, the objective of this study is to investigate the relationship between physical activity level and overweight in children and adolescents.

Methods: It is a case-control study including 372 both sexes children and adolescents aged 7-14 years registered in primary schools located in the urban area of Mutuípe, Bahia, Brazil. The case group included 112 overweight students and 224 normal weight individuals matched by sexe and age composed the control group. The main independent variable was the sedentary lifestyle. To evaluate the association between sedentary lifestyle and overweight it was used the multivariate conditional logistic regression, appropriate for case-control studies with matched groups construction, using odds ratio (OR) as a measure association.

Results: maternal schooling and obesity family history were identified as confounding variables for sedentary lifestyle and obesity relationship. Controlling for these variables, it was observed 51% greater chance of overweight in sedentary students (OR=1.51).

Conclusions: independently of maternal schooling and obesity family history, sedentary lifestyle showed associated with overweight in this population.

Key words: sedentary lifestyle, overweight, children and adolescents.

PO892**CYSTEINE SERUM LEVELS AND OBESITY IN CHILDREN AND ADOLESCENT**

P. Costa¹, M. Silva², M. Santana², N. Fonseca³, A. Assis²

¹Science Health Centre, Federal University of Recôncavo de Bahia, Santo Antonio de Jesus, Brazil

²Nutrition School, Federal University of Bahia, Salvador, Brazil

³Nutrition Faculty, University of Brasilia, Brasilia, Brazil

Background and objectives: Obesity prevalence is increasing worldwide and its occurrence has been frequent in childhood. Currently, cysteine serum levels have been identified as a possible risk factor for this morbidity and identifying this relationship may be an important finding for Public Health. Considering this, the objective of this study was to identify the relationship between cysteine high levels and obesity in children and adolescents.

Methods: it was a cross-sectional study including 603 children and adolescents of both sexes aged 7-14 years registered in primary schools located in the urban area of Mutuípe, Bahia, Brazil. The main independent variable was cysteine serum levels and it was considered the P95 value as a high level for this variable. It was calculated the frequency distribution for the descriptive analysis. To evaluate the relationship between cysteine and obesity it was performed the logistic regression analysis, using odds ratio (OR) as a measure association.

Results: It was observed that 61.3% of children with cysteine elevated levels were older than 12 years ($p = 0.03$) and 74.2% of them reported to sleep during the day ($p = 0.00$). Considering the confounding analysis, the variables maternal schooling, habit of sleeping during the day and triglycerides serum levels were confounded of the relationship between cysteine and obesity and were included in the final logistic model. The logistic regression analysis showed that obese students have 271% greater chance of presenting increased serum levels of cysteine when compared to non-obese (CI: 1.12-9.25).

Conclusions: there is a positive relationship between cysteine high levels and obesity in children and adolescents.

Key words: cysteine, obesity, children and adolescents.

PO894**DETERMINANTS OF EXCLUSIVE BREASTFEEDING AMONG MOTHERS AGED 45 YEARS AND BELOW IN KUALA LUMPUR, MALAYSIA - A QUALITATIVE STUDY**

S. Mohd Jamil¹, Y. Shern Shern¹, P. Bee Koon¹

¹Universiti Kebangsaan Malaysia (UKM)

Background and objectives: Breastfeeding is the gold standard for optimum nutrition for newborn babies. Data from the Third National Health and Morbidity Survey in Malaysia showed that only 14.5% Malaysian babies were given breastmilk exclusively in their first 6 months of life. Hence, this study aimed to identify the determinants of exclusive breastfeeding and to determine factors associated with infant-feeding decisions among mothers in Kuala Lumpur using a qualitative approach.

Methods: Mothers with infants aged below two years were interviewed using semistructured interview. Two groups of mothers participated; (1) mothers who breastfed exclusively for 6 months and (2) mothers who did not breastfeed or who breastfed less than 6 months. Interviews were recorded, transcribed verbatim and were reviewed and assessed independently by two researchers. Key themes were extracted and grouped, and secondary thematic analysis were used to explore key concepts.

Results: Data saturation was reached after interviewing eight mothers who breastfed exclusively and nine mothers who did not. Eight themes emerged as determinants of exclusive breastfeeding: (1) strong determination and self efficacy to breastfeed, (2) understanding the benefits of breastfeeding, (3) social support from family members, (4) good bonding with baby, (5) belief that breastfeeding is economical, (6) adequate exposure to information regarding breastfeeding, (7) influence of religion (8) demographic and biophysical factors. Mothers who breastfed less than 6 months found it difficult to complete the six months breastfeeding period due to (1) perceived insufficient supply of breastmilk, (2) mother returning to work after two or three months of maternity leave, and (3) inconvenience due to lack of facilities for breastfeeding in the workplace.

Conclusions: These determinants are the important basis for successful exclusive breastfeeding among Malaysian mothers. We suggest that interventions aimed at prolonging breastfeeding duration should give due consideration to these factors.

Key words: exclusive breastfeeding, qualitative, breastfeeding duration.

PO895**BODY MASS INDEX IS ASSOCIATED WITH FAT MASS IN NORMAL, OVERWEIGHT/OBESE, AND STUNTED PRESCHOOL CHILDREN IN CENTRAL THAILAND**

T. Pongcharoen¹, S. Jitngarmkusol¹, K. Judprasong¹, P. Egkantrong¹, W. Kriengsinyos¹, P. Winichagoon¹

¹Institute of Nutrition, Mahidol University, Thailand

Background and objectives: Body mass index (BMI) is widely used as a surrogate measure of adiposity. The relationship between BMI and body fatness varies by race, sex, and age and more variations have been found among children. This study aimed to investigate the relationship between BMI and fat mass determined by deuterium dilution technique among 3-5 years old children with different nutritional status.

Methods: A cross-sectional study was conducted in 15 day-care centers in central Thailand. 137 healthy preschool children were recruited according to their nutritional status: thinness [body mass index for age Z scores, (BAZ) < -2 SD], normal (-2 SD ≤ BAZ ≤ +2 SD), overweight/obesity (BAZ > +2 SD), and stunting [Height for age Z scores, (HAZ) < -2 SD]. Fat-free mass and fat mass were determined by deuterium dilution technique. Fat mass index (FMI, fat mass/ht²) was then calculated.

Results: In the thin group, girls had higher FMI compared to boys [3.2 kg/m² vs 2.8 kg/m², *p* < 0.05]. BAZ was significantly associated with FMI (adjusting for HAZ, sex, maternal education, age of children, and birth weight): for 1SD increase in BAZ, FMI increased by 0.91 kg/m² (95% CI: 0.85, 0.97). The relationship between BAZ and FMI differed by nutritional status. BAZ was more strongly associated with FMI in the overweight/obese (*r*=0.97, *p* = 0.000) and the normal (*r*=0.86, *p* = 0.000) groups than in the stunted group (*r*=0.59, *p* = 0.002); and no association in the thin group (*r*=0.13, *p* = 0.534).

Conclusions: The inconsistency in the relationship between BAZ and body fatness suggests that the ability of BAZ in reflecting the amount of fat mass differs by nutritional status in preschool children. BAZ better reflects fatness among normal to overweight/obese children, but less so among stunted and none among thin children.

Key Words: preschool children, fat mass, BMI, deuterium.

PO896**RECALL OF BREASTFEEDING DURATION IN AUSTRALIAN SURVEYS**

K. Graham¹, C. Binns¹, Y. Zhao¹, J. Scott², W. Oddy³

¹School of Public Health, Curtin University of Technology, Perth, Western Australia, Australia

²School of Medicine, Flinders University, Adelaide, South Australia, Australia

³Telethon Institute of Child Health Research, University of Western Australia, Perth, Western Australia, Australia

Background and objectives: Recall accuracy during surveys is related to the length of time between the event of interest and point of recall. In Australia, information about infant feeding is collected through cross-sectional and cohort studies. This paper aims to assess the influence of recall time in breastfeeding duration.

Methods: Duration of exclusive breastfeeding in the Perth Infant Feeding Study Mark II (PIFSII) was compared to that of the 2010 Australian National Infant Feeding Survey (ANIFS). The PIFSII was a cohort study of 587 consecutive mothers (and their infants) in Perth, Western Australia, in 2002-03. The ANIFS was a national Australian cross-sectional survey of 51,018 mothers/ carers of infants aged to 24 months in 2010-11. Both surveys included similar questions to measure exclusive breastfeeding duration. In PIFSII, questions asked of mothers related to their current practices while those in the ANIFS were asked up to 24 months after giving birth.

Results: The proportion of PIFSII infants aged four months and exclusively breastfed for four months was 11.3 ± 2.6% and the proportion for those aged six months and exclusively breastfed for six months was 0.4 ± 0.5%. The proportion of ANIFS infants reported to be exclusively breastfed for four months ranged from 24.4 ± 0.6% (95% CI) of those aged 4 months to 42.1 ± 0.3% (95% CI) of those aged 19 to 24 months at the time of the survey. ANIFS infants exclusively breastfed for six months ranged from 5.6 ± 0.3% of those aged 6 months to 18.1 ± 0.3% of infants aged between 19 and 24 months.

Conclusions: The proportion of ANIFS infants reported as exclusively breastfed for four or six months changed as length of recall increased. Breastfeeding duration is more accurately reported in prospective cohort studies.

Key words: breastfeeding, exclusive, duration, survey, methodology.

PO897**EARLY EVOLUTION OF STUNTING FROM BIRTH: A CROSS-SECTIONAL PERSPECTIVE ON LINEAR GROWTH FAILURE IN THE MAM-MAYAN WESTERN HIGHLANDS OF GUATEMALA**

A. M. Chomat¹, M. Escobar¹, A. Maldonado¹, N. Solomons¹

¹CeSSIAM, Guatemala City, Guatemala

Background and objectives: Classical under-five stunting rates derive from surveys on children 6-59 months of age. We sought to assess length-for-age (HAZ) progression within the first 6 months of life among infants from 8 rural Mam-Mayan communities in the Western Highlands of Guatemala.

Methods: Supine length was measured to the nearest 0.5 cm by standardized anthropometrics on a SECA210 infantometer, and weight to the nearest 10 g on a SECA354 balance. 53 infants 0-46 days old (35% F) and 57 infants 4-6 mo old (56% F) were recruited. Stunting was defined as <-2 SD of HAZ (2006 WHO growth standards). All analyses were done using SPSS 20.0.

Results: In the 53 newborns, mean age (days) was 21 (2-46). 41% were stunted (17% severe). Median HAZ was -1.83 (mean: -1.98±0.19; range: -5.80 to +0.53). In the 57 infants aged 4-6 mo, mean age was 148 (116-184). 53% were stunted (23% severe). Median HAZ was -2.32 (mean: -2.11±0.19; range: -5.76 to +2.24). The difference in HAZ between genders and between both age groups was not statistically significant. The median decline in HAZ units between 21 and 148 days calculates to -0.12/month. By contrast and for comparison, the median WAZ was -0.75 at mean 21 days and -1.10 at mean 148 days.

Conclusions: This, to our knowledge, is the first report on the progression of linear growth failure within the first 6 months of life. Stunting in this setting begins in utero, is disproportionately worse than weight deficit, and appears to progress throughout the first 6 months of life. Its prevention therefore is linked with maternal care strategies beginning during gestation, if not before. Funding: GWIS Nell Mondy Fellowship, McGill University Graduate Travel Award, GHR-CAPS Doctoral Fellowship.

Key Words: stunting, very young infants, indigenous, Guatemala.

PO898**RELATIONSHIP BETWEEN OVERWEIGHT AND CONCURRENT STUNTING IN VERY YOUNG INFANTS: EARLY NUTRITION TRANSITION IN THE MAM-MAYAN WESTERN HIGHLANDS OF GUATEMALA**

A. Maldonado¹, A. M. Chomat¹, M. Escobar¹, N. Solomons¹

¹CeSSIAM, Guatemala City, Guatemala

Background and objectives: Stunting (a 2 standard-deviation deficit in height-for-age, HAZ) affects 67.5% of indigenous children under 5 years of age in Guatemala. Children who are both stunted and overweight are at an increased risk of chronic disease in later life, and studies in preschool and schoolchildren have shown an association between shorter stature and excess weight. Our objective was to determine the prevalence of stunting and overweight in early infancy in a population, namely in rural Mam communities of the Western highlands of Guatemala, where stunting is prevalent by 4-6 mo, and assess for any correlation with higher weight status.

Methods: We measured height and weight in 52 boys and 50 girls in 8 communities, and determined HAZ, weight-for-age (WAZ) and body mass index (BMI). All data was analyzed with SPSS 20.0.

Results: Mean infant age (days) was 146±2. Mean HAZ was -1.95±0.15 (median: -1.76; range: -6.52 to +2.24), WAZ -0.97±0.12 (median: -0.81; range: -5.42 to +1.14), and BMI 0.28±0.10 (median 0.39; range: -2.83 to +3.45), with no significant gender difference. Stunting prevalence was 45% (27%, moderate; 18%, severe). No infants were overweight by WAZ, but 3% were by BMI. In terms of associations, height and weight were actually positively correlated (Spearman: $r=0.82$, $p=0.001$), as were HAZ and WAZ ($r=0.77$, $p=0.001$). Height and BMI were not correlated ($r=0.08$; $p=0.44$).

Conclusions: The high stunting prevalence is concerning at this early age. Prevalence of frank overweight is low to null. We did not find an increased risk for excess weight in stunted compared to non-stunted infants of 4-6 mo of age. Funding: GWIS Nell Mondy Fellowship, McGill University Graduate Travel Award, GHR-CAPS Doctoral Fellowship.

Key Words: overweight, stunting, nutrition transition, Guatemala.

PO899**THE DOUBLE BURDEN OF MALNUTRITION: PREVALENCE OF INFANT STUNTING AND MATERNAL OVERWEIGHT/OBESITY IN THE MAM-MAYAN WESTERN HIGHLANDS OF GUATEMALA**

M. Escobar¹, A M. Chomat¹, A. Maldonado¹, N. Solomons¹

¹CeSSIAM, Guatemala City, Guatemala

Background and objectives: The household double burden of malnutrition (DB), is defined as the combination of maternal overweight/obesity and infant undernutrition within the same family. It is well established that stunting increases the risk of both acute, infectious and chronic disease and is a traditional problem in Guatemala. Our objective was to determine its prevalence in rural Mam communities in the Western Highlands.

Methods: We measured height and weight in 101 mothers and their infants (4-6 mo; 50 girls, 51 boys) in 8 communities. Infant stunting (height-for-age, HAZ) and maternal overweight/obesity (via body mass index, BMI) were determined. All data was analyzed with SPSS 20.0.

Results: Mean maternal height (meters) was 1.47 (median 1.47; 1.34-1.62) and mean BMI (kg/m²) was 23.8±0.4 (median 23.2; 17.9-41.7). 11% of mothers were underweight, 24% overweight and 6% obese. Mean infant age (days) was 145±2, and mean HAZ -1.91±0.14 (median -1.75; -6.52 to 2.24), without significant gender difference. 45% of infants were stunted (28% moderate, 17% severe). Of the 30 overweight/obese women, 11 (37%) had stunted infants vs 13 (44%) expected by chance alone ($p = 0.300$).

Conclusion: The high stunting prevalence is concerning at this early age. The combination of maternal overweight/obesity and infant stunting was no more nor less than what would be expected by random-association; hence no excess prevalence of DB exists in this early (infancy) period in this specific setting. But, the apparent chance association of overweight/obese mothers with stunted infants is consistent with the evidence of Dieffenbach and Stein (2011) that household double burden may be a mathematical artifact. Funding: GWIS Nell Mondy Fellowship, McGill University Graduate Travel Award, GHR-CAPS Doctoral Fellowship.

Key words: overweight, double burden, stunting, Guatemala.

PO900**FOOD AVOIDANCE: POTENTIAL IMPACT ON DIETARY VARIETY DURING PREGNANCY AND EARLY LACTATION IN THE MAM-MAYAN WESTERN HIGHLANDS OF GUATEMALA**

M. Maldonado¹, A M. Chomat¹, N Solomons¹

¹CeSSIAM, Guatemala City, Guatemala

Background and objectives: Food choices during pregnancy and lactation directly affect nutritional intake with potential repercussions on a mother and her infant's health. Our objectives were to determine specific food avoidances during pregnancy and early lactation and understand underlying drivers and motivations.

Methods: We interviewed 144 pregnant (3rd trimester) and 145 breastfeeding (<1 month postpartum) women living in 8 rural Mam-Mayan communities in the Western Highlands of Guatemala. A short survey inquired about current food avoidances and the motivations behind them.

Results: 37% of the pregnant and 20% of the breastfeeding women reported food avoidance. During pregnancy, animal products were most commonly avoided; 26% (n=38) avoided eating meat products (14% beef, 7% chicken and 5% both beef and chicken) and 3% (n=5), eggs. The main reason reported was due to nausea, followed by new aversion. During lactation, greens (n=9, 6%), beans (n=7, 5%) and meat products (n=5, 3%) were most commonly avoided, covering 72% of all reported avoidances. The main reason reported was because greens and beans, culturally perceived as "cold" foods (in the hot-cold continuum of temperature-regulating attributes of foods and beverages), which can "cool" the breast milk and, through the imbalance, cause the lactating infant to become irritable or ill.

Conclusions: What may be important for perspective is that 63% and 80% of pregnant and lactating respondents, respectively, did not circumscribe their diet. Avoidance of specific food items, especially animal-source foods, however, is sufficiently common in these rural communities among pregnant and lactating women to potentially impact dietary variety during critical stages of infant development. Funding: GWIS Nell Mondy Fellowship, McGill University Graduate Travel Award, GHR-CAPS Doctoral Fellowship.

Key Words: Guatemala, pregnancy, lactation, food choices.

PO901**A SYSTEMATIC REVIEW AND META-ANALYSIS OF THE EFFECT AND SAFETY OF GINGER IN THE TREATMENT OF PREGNANCY-ASSOCIATED NAUSEA AND VOMITING**

J. Visser¹, E. Viljoen¹, N. Koen¹

¹Division of Human Nutrition, Faculty of Medicine and Health Sciences, Stellenbosch University, South Africa

Background and objectives: Nausea and vomiting during pregnancy (NVP) is common, and possible harmful side-effects of conventional medicine to the fetus, necessitate the need for alternative treatment options to relieve NVP symptoms. This systematic review (SR) investigated current evidence regarding ginger for the treatment of NVP. The primary objective was to assess the effectiveness of ginger in treating NVP. The secondary objective was to assess the safety of ginger during pregnancy, by identifying adverse events or side-effects.

Methods: An electronic bibliographic database search was carried out. Randomized controlled trials (RCTs) of the efficacy of ginger by any route, as treatment for NVP in pregnant women, were included. Two authors independently extracted data and assessed trial quality. RevMan5 software was used for data analysis. $p < 0.05$ was considered statistically significant.

Results: Eleven RCTs involving 1176 pregnant women were included. Ginger significantly improved the symptoms of nausea when compared to placebo (MD 1.20, 95% CI 0.56-1.84, $p = 0.0002$, $I^2=0\%$). Ginger did not significantly reduce the number of vomiting episodes during NVP, when compared to placebo, although there was a trend towards improvement (MD 0.72, 95% CI -0.03-1.46, $p = 0.06$, $I^2=71\%$). Subgroup analyses seemed to favor the lower daily dosage of <1500 mg ginger for nausea relief. Ginger did not pose a significant risk for spontaneous abortion compared to placebo (RR 3.14, 95% CI 0.65-15.11, $p = 0.15$; $I^2=0\%$), or vitamin B6. Similarly, ginger did not pose a significant risk for the side-effects of heartburn or drowsiness.

Conclusions: This review suggests potential benefits of ginger in reducing nausea symptoms in pregnancy. Ginger did not have a significant impact on vomiting episodes, nor pose a risk for side-effects or adverse events during pregnancy. Ginger could be considered a harmless and possibly effective alternative option for women suffering from the symptoms of NVP.

Key words: pregnancy, ginger, nausea, vomiting, systematic review.

PO902**EFFECT OF LONG-TERM INTERMITTENT MULTIPLE MICRONUTRIENT SUPPLEMENTATION IN BANGLADESHI RURAL ADOLESCENT GIRLS WITH NUTRITIONAL ANEMIA**

F. Ahmed¹, M. Khan², M. Akhtaruzzaman², R. Karim², G. Williams³, H. Torlesse⁴, I. Darnton-Hill⁵, N. Dalmiya⁶, C. Banu², B. Nahar²

¹School of Public Health & Griffith Health Institute, Griffith University, Gold Coast, QLD, Australia

³School of Population Health, University of Queensland, Herston, QLD, Australia

⁴UNICEF, Dar es Salaam, Tanzania

⁵Friedman School of Food Science and Policy, Tufts University, Boston, USA

⁶UNICEF, New York, USA

Background and objectives: Previous short-term supplementation studies showed no additional hematologic benefit of multiple micronutrients (MMN) compared with iron + folic acid (IFA) in adolescent girls. This study examines whether long-term once- or twice-weekly supplementation of MMN can improve hemoglobin (Hb) and micronutrient status more than twice-weekly IFA.

Methods: Anemic girls ($n = 324$) aged 11–17 y attending rural schools were given once- or twice-weekly MMN or twice-weekly IFA, containing 60 mg iron/dose in both supplements, for 52 wk in a randomized double-blind trial. Blood samples were collected at baseline and 26 and 52 wk.

Results: Intent to treat analysis showed no significant difference in the Hb concentration between treatments at either 26 or 52 wk. However, after excluding girls with hemoglobinopathy and adjustment for baseline Hb, a greater increase in Hb was observed with twice weekly MMN at 26 wk ($p = 0.045$). Although all 3 treatments effectively reduced iron deficiency, once-weekly MMN produced significantly lower serum ferritin concentrations than the other treatments at both 26 and 52 wk. Both once- and twice-weekly MMN significantly improved riboflavin, vitamin A, and vitamin C status compared with IFA. Overall, once weekly MMN was less efficacious than twice-weekly MMN in improving iron, riboflavin, RBC folic acid, and vitamin A levels. Micronutrient supplementation beyond 26 wk was likely important in sustaining improved micronutrient status.

Conclusions: These findings highlight the potential usefulness of MMN intervention in this population and have implications for programming.

Key words: anemia, micronutrients, adolescent girls, Bangladesh.

PO903**DIETARY DIVERSITY PREDICTS MEDICAL EXPENDITURES IN TAIWANESE ELDERLS**

M S. Lee^{1,2}, Y T. Lo³, M L. Wahlqvist^{1,2,4}, Y H. Chang⁵, S. Kao¹

⁴Division of Preventive Medicine and Health Services Research, Institute of Population Health Sciences, National Health Research Institutes, Taiwan, ROC

⁵Division of Health Policy Translation, Institute of Population Health Sciences, National Health Research Institutes, Taiwan, ROC

Background and objectives: More nutritious diets, as reflected in greater food diversity, is important to elderly health and survivorship. However, it is unclear how this factor affects medical costs. The aim of this study is to assess dietary quality using a dietary diversity score (DDS) and evaluate the association between DDS and medical service utilization and expenditure. **Methods:** This study evaluates the DDS (range: 0-6) of the Elderly Nutrition and Health Survey in Taiwan (1999-2000) using a 24-h dietary recall design. We linked 1781 elders to National Health Insurance (NHI) claims, excluding those with no NHI records or with catastrophic illness history; 1650 elders were eligible. Generalized linear models were used to appraise the association between DDS and annual medical utilization and expenditure.

Results: Those with a higher DDS had lower medical service utilization and expenditure for emergencies and hospitalization. After adjustment for potential confounders, emergency and hospitalization expenditures for elders with DDS = 6 were lower than those with DDS ≤ 3. However, for preventive care and dental services, a higher DDS predicted greater utilization (0.25 and 0.5 times) and expenditure (270 and 420 NTD). Findings remained unchanged when those who died in the first year or had any medical utilizations and expenditure one year prior to death were excluded.

Conclusions: Greater dietary diversity is associated with lower emergency and hospitalization utilization and expenditure, but not ambulatory services. There is a need for nutrition policy in health services for nutritionally disadvantaged groups.

Key words: dietary diversity, medical expenditures, elderly, disadvantaged groups.

PO904**INCREASING MATERNAL BODY MASS INDEX (BMI) AFTER THE FIRST TRIMESTER OF PREGNANCY HAS A POSITIVE ASSOCIATION WITH INFANT BIRTH OUTCOMES**

R. Ayande¹, G. Otoo¹

¹Department of Nutrition and food Science, University of Ghana, Legon, Ghana

Background and objectives: Maternal nutritional status, as indicated by maternal BMI, impacts on the outcome of a pregnancy. The study sought to determine the relationship between maternal nutrition and pregnancy outcomes.

Methods: Mothers with singleton deliveries (n=120) were recruited from the Maamobi polyclinic and Ridge Hospital in Accra, Ghana. Infant outcomes investigated included the following; birth weight, birth length and APGAR (Appearance, Pulse, Grimace, Activity and Respiration) scores taken at 5 minutes. Maternal weight taken continuously during pregnancy (obtained from antenatal cards), postpartum maternal weight and height were measured and used to compute BMI during the three pregnancy trimesters and postpartum. The differences between maternal BMI and birth weight were determined using ANOVA.

Results: The mean maternal BMI (M±SD) among the participants was 25.2±5.0, 26.5±5.4, 28.2±5.5 and 26.6±5.4 kg/m², respectively for the first trimester (n=35), second trimester (n=92), third trimester (n=104) and postpartum (n=108). Infant birth weight (BW) and birth length averaged 3.1±0.5 kg and 49.5±2.6 cm, respectively. Prevalence of Low BW (BW<2.5 kg) among the sample population was 10.8%. Postpartum maternal BMI was reflective of BMI during the second trimester of pregnancy (r=0.940 p = 0.000). Significant positive correlations were observed for maternal BMI and BW for the third trimester (r=0.240 p = 0.014) and postpartum (r=0.197 p = 0.042). An equal variances t test revealed a statistically reliable difference between the mean infant BW for mothers with postpartum BMI>20 kg/m² (M±SD=3.2±0.5 kg) and BMI<20 kg/m² (M±SD=2.6±0.6kg), t(105)=2.514, p = 0.013, α =0.05 as well as between the mean infant birth length for mothers with BMI>20kg/m² (M±s=49.6±2.6cm) and BMI< 20kg/m² (M±SD=46.8±1.7cm), t(96)=2.138, p=0.035, α=0.05.

Conclusions: Maternal BMI remains a major determinant of positive birth weight. Given the high prevalence of LBW in this population, public health interventions targeted at improving maternal nutritional status and not necessarily BMI should be encouraged.

Key words: maternal nutrition, pregnancy outcome, maternal BMI, birth weight, APGAR scores.

PO905**PROCESS INDICATORS FOR A RANDOMIZED TRIAL OF CELL PHONE BASED PEER COUNSELING TO SUPPORT EXCLUSIVE BREASTFEEDING IN KENYA**

S. Mbugua¹, E. Kamau-Mbuthia¹, A. Webb², S. Kalungu¹, C. Sarange¹, W. Lou³, W. Duan³, C. Dennis⁴, B. Aidams⁵, L. Nommsen-Rivers⁶, D. Sellen⁷

⁵World Vision International, Washington DC, USA

⁶Division of Neonatology, Cincinnati Children's Hospital, USA

⁷Departments of Anthropology, Nutritional Sciences and Dalla Lana School of Public Health, University of Toronto, Canada

Background and objectives: In Kenya, cell phone (CP) use is high and presents new opportunities to support breastfeeding. We examined data from a randomized intervention trial showing CP based support (CPS) increases the prevalence of exclusive breastfeeding (EBF) to identify threats to the validity of findings and evaluate quality of intervention delivery.

Methods: We randomized at third trimester low-income women attending antenatal care (ANC) at a large hospital to (i) continuous cell phone based peer support (CPS) or (ii) monthly peer support group (PSG) or (iii) standard care by existing facility-based support (SOC=control). We analyzed participant flow and process indicators to assess the quality of delivery of CPS and PSG interventions and potential biases at enrolment and through dropout.

Results: There was no difference in dropout by baseline CP access ($p = 0.119$) or intervention allocation ($p = 0.905$). Among participants with CP, there was no difference in baseline indicators by intervention allocation. Among women without CP, those allocated to PSG reported less frequent prior prenatal care (2.4 vs 2.7 times; $p = 0.039$). At baseline, women allocated to each group shared many characteristics, except hours worked outside the home (4.7, 4.0, 3.6 h for CPS, PSG, SOC; $p = 0.036$), unemployment (40.4%, 54.3%, 56.1% for CPS, PSG, SOC; $p = 0.023$).

Conclusions: Indications that cell phone based counseling is potentially as or more effective in supporting EBF than other approaches are unlikely to be attributable to poor quality of delivery of alternative intervention or unanticipated bias at allocation or differential dropout.

Key Words: breastfeeding, peer support, mHealth.

PO906**BREAKFAST CONSUMPTION IN 16-18 YEAR OLDS: CURRENT TRENDS IN CONSUMPTION PATTERNS AND THE ASSOCIATION WITH WEIGHT STATUS**

K. Adolphus¹, L. Dye¹, C.L. Lawton¹

¹Human Appetite Research Unit, Institute of Psychological Science, University of Leeds, UK

Background and objectives: Regular breakfast consumption is associated with positive outcomes on diet quality, micronutrient intake, weight status and cognitive performance in children and adolescents. Despite known benefits, data on breakfast consumption and its association with weight status in older adolescents in the UK is lacking. The objective of the study was to establish breakfast consumption patterns in a UK cohort of older adolescents in whom dietary habits may still be developing, have independence over dietary choice along with rapid development and growth.

Methods: A cross-sectional survey study was used to collect data from 297 adolescents aged 16-18 years (77.4% female). Subjects completed a 7-day food diary to report breakfast intake and questionnaire obtaining demographic information. Height and weight was recorded by trained researchers to calculate BMI z-scores. Food diaries were analysed using WinDiets software. Breakfast was considered adequate if it provided >15% of estimated Total Energy Expenditure. Breakfast eating frequency per week was classified into five categories: 1; 1-2; 3-4; 5-6; 7.

Results: Only 14.9% of subjects ate breakfast every day. Breakfast skipping was highly prevalent with 49% of subjects eating breakfast 0-2 times per week. Gender was significantly associated with breakfast consumption ($X^2=24.757$, $df=4$, $p=0.000$) with more males never eating breakfast compared with females (35.8% vs. 13.9% respectively). Breakfast consumption frequency was significantly associated with weight status ($X^2=29.987$, $df=12$, $p=0.003$) with more overweight (29.3%) and obese (48%) subjects never eating breakfast compared with normal weight (13%). Where breakfast was eaten, it provided good amounts of micronutrients vitamin B6 (mean: $0.35 \pm SD:0.03$; 23% Reference Nutrient Intake [RNI]), B12 (mean: $0.63 \pm SD: 0.05$; 42% RNI), calcium (mean: $147.2 \pm SD:126.1$; 14.7% RNI) and iron (mean: $1.89 \pm SD:1.87$; 12.8% RNI).

Conclusions: The importance of breakfast should be promoted in older adolescents on benefits to weight status and micronutrient intake.

Key words: Breakfast, adolescents, weight, micronutrient

PO907

ASSESSMENT OF NUTRITIONAL STATUS AND DEPRESSION PREVALENCE IN FREE-LIVING ELDERLY IN TABRIZ, IRAN

L. Payahoo¹, Y. Khaje-Bishak¹, B. Pourghasem¹, M-B Kabir-Alavi¹, M. Asghari Jafarabadi², A. Ostadrahimi¹

¹Student's research committee, Department of nutrition Faculty of Health and Nutrition, Tabriz University of Medical Science, Iran

²Department of epidemiology, Faculty of Health and Nutrition, Tabriz University of Medical Science, Iran

Background and objectives: Good nutritional and mental statuses are important factors that affect on fitness of elderly people. With attention to data scaring on the subjects, the aim of this study was to assess the nutritional status and prevalence of depression in the free-living elderly in Tabriz, Iran.

Methods: This cross-sectional study was carried out on 184 elderly people (male=97; female=87) with age 60 years and above. All subjects selected from daily care centers for elderly people. After explanation of the study, a written informed consent was taken. Two questionnaires including Mini Nutritional Assessment (MNA) with eighteen items and Geriatric Depression Score (GDS) with fifteen close questions were used to evaluate the nutritional status and depression prevalence, respectively. Chi-square test was used for comparison of nominal variables and spearman's correlation was employed to determine the relationship between variables.

Results: The results showed that up to 50% of subjects had poor nutrition (about 6% undernourished and about 46% at risk of malnutrition). Regarding the results of GDS test, it was revealed that about 14% of elderly people had serve depression and 28.3% had mild depression. In this study, there was a positive significant correlation between MNA and GDS tests in both gender ($r=0.416$; $p < 0.001$).

Conclusions: No acceptable level of nutritional status and depression level was observed in free-living elderly people exist. Malnutrition and depression prevalence in our population were high compared with western societies. Further studies are needed to determine other factors such as social and biological that promote quality of life in elderly people.

Key words: depression, elderly, geriatric depression score, Mini Nutritional Assessment.

PO908

COMPLEMENTARY FEEDING AND INFANT BODY COMPOSITION IN NORTHERN SPAIN

G. Rodríguez, M J. Cabero², P. Samper¹, M L. Álvarez¹, L. Monje², M. Morera³, M. Rivero³, M. García-Fuentes², L. Moreno¹

¹Department of Pediatrics, University of Zaragoza, Zaragoza, Spain

²Department of Pediatrics, University of Cantabria, Santander, Spain

³Scientific Department, Laboratorios Ordesa, Sant Boi de Llobregat, Spain

Background and objectives: Nutrition has an important role in early infant growth but specific impact of complementary feeding on infant body composition has not been elucidated. Our objective was to describe the pattern of complementary feeding intake in Northern Spain and to explore whether associations between food intake and body composition changes exist in infants 6 to 9 months of age.

Methods: Longitudinal study in 245 healthy infants (133 males), enrolled at 6 months of age and followed-up until 9 months, as part of a larger study about complementary feeding and body composition. 24-h food recall questionnaires were used to assess patterns of food intake (breastfeeding, formula, cereals, fruit, yogurt, vegetables and meat or fish porridge (VMFP)). Anthropometric variables were measured at 6 and 9 months of age under standardized methodology.

Results: Prevalence of breastfeeding was 42.3% at 6 months and 27.4% at 9 months. Percentage of infants consuming each food group at 9 months of age and mean daily intake were: formula 76.6% (472 ± 190 ml); cereals 77.4% (26 ± 16 g); fruit 68.5% (192 ± 70 g); yogurt 22.6% (131 ± 35 g); VMFP 80.6% (259 ± 108 g). Cereal consumption mostly took place added in the baby bottle during breakfast and dinner; VMFP was usually consumed at lunch while fruit for supper. Breastfed infants consumed lower amounts of both infant formula and VMFP than bottle fed infants. Variations in anthropometric values from 6 to 9 months indicated an increase in weight and height but a physiologic reduction in body adiposity. No relationship was found between food intake and anthropometric changes during this period.

Conclusions: Prevalence of breastfeeding is high in the north of Spain. The majority of infants consumed all food groups at 9 months of age. There is no relationship between the amount of foods consumed and body composition during this period.

Key words: breastfeeding, infant feeding, body composition.

PO909**NUTRITION, FITNESS AND CARDIOMETABOLIC RISK IN CHILEAN CHILDREN**

G. Weisstaub¹, E.G. Artero², C. Corvalan³, R. Uauy³

¹MD, Msc, INTA, Santiago de Chile, Chile

²Phd, University of Almería, Spain

³MD, PhD, INTA University of Chile, Chile

Background and objectives: To evaluate the association of cardiorespiratory endurance and muscle strength with cardio-metabolic risk (CMR), in a sample of school children in Santiago Metropolitan Region.

Methods: The Growth and Obesity Cohort, measured CMR (glucose, triglycerides, HDL, insulin and waist circumference / height), nutritional status (BMI, WHO 2007) and fitness (cardiorespiratory endurance (test modified 6-minute walk) and muscle strength (hand grip strength and horizontal jump) in a group of 742 children characterized from birth 2002 to age 10. Descriptive analysis was performed and CMR score was calculated (sum of Z scores for each variable) and analyzed according to nutritional status and fitness. Results were classified by fitness terciles and analyzed by multiple regression with CMR, significance differences $p < 0.05$.

Results: 742 subjects (228 boys and 448 girls) 8.3±0.6 yrs were studied: 27.6% were overweight and 22.2% obese. Normal subjects did not differ significantly in their CMR regardless of muscular fitness. Multiple regression generated odds ratio (OR) comparing individuals with poor fitness (muscle strength & 6-minute walking) and those with better fitness was 11.7 (4-34) $p < 0.001$.

Conclusions: Results show that muscle strength and cardiorespiratory submaximal resistance, are associated with an increased CMR in school children 6-9 yrs old. Results reinforce the need to consider physical fitness in childhood in order to promote healthy growth and active living.

Key words: obesity, cardiometabolic risk, fitness, cardiorespiratory endurance, muscular strength. Funding FONDECYT N° 1100206.

PO910**EFFECT OF INFANT AND YOUNG CHILD FEEDING PRACTICES ON GROWTH IN CAMBODIA AND MALAWI**

I. Jordan¹, J. Kuchenbecker¹, A. Reinbott¹, J. Herrmann¹, B. Mtimuni², O. Kevanna³, E. Muehlhoff⁴, M.B. Krawinkel¹

¹Justus Liebig University Giessen, Germany

²Bunda College of Agriculture, Malawi

³National and Maternal and Child Health Center, Cambodia

⁴Food and Agriculture Organization of the United Nations, Nutrition Division (ESN), Economic and Social Department, Italy

Background and objectives: Poor nutritional status in early infancy is associated with growth faltering, increased risk for morbidity, anemia, and mortality. This study was conducted within the IMCF research study looking at the impact of nutrition education on young children's nutritional status in Malawi and Cambodia.

Methods: A Cross - sectional nutritional baseline survey was conducted in Malawi in September 2011 at the beginning of the rainy season (n=1041) and in Cambodia in September 2012 during the rainy season (n=1029). A standardized questionnaire was administered in randomly selected households with children under two. Anthropometric measurements were taken from both parents and the child.

Results: Prevalence of stunting (HAZ < -2SD) among children was 39 % in Malawi and 22% in Cambodia. Exclusive breastfeeding rate among children below 6 months was 43% in Malawi and 83% in Cambodia. The children's diets were dominated by foods made from grains and little animal source foods. In this age group minimum dietary diversity was achieved by 61% of the children in Malawi and 44% in Cambodia, while 72% and 70%, respectively, had a minimum meal frequency. However, minimum acceptable diet was met by less than 50% of the children in Malawi and only 28% in Cambodia. Exclusive breastfeeding was significantly correlated with HAZ in Malawi ($r = 0.2$), but not in Cambodia. A low but significant association was also found for dietary diversity and meal frequency with height and weight.

Conclusions: The mean height-for-age-z-score was different in both countries which might be due to different exclusive breast feeding rates. The poor infant and young child feeding practices will need to be addressed within the nutrition education program using locally available foods to improve dietary diversity and meal frequency that can be followed by families, irrespective of their economic means.

Key words: breastfeeding, dietary diversity, growth.

PO911**THE USE OF PHOTOVOICE TO IDENTIFY MATERNAL DIETARY CONSUMPTION IN RURAL BANGLADESH**

B. Stevens¹, P. Buettner¹, A. Clough¹, K. Watt¹, J. Judd¹, J. Brimblecombe²

¹James Cook University, Australia

²Menzies Institute, Australia

Background and objectives: Maternal nutrition is associated with the survival, growth and development of the fetus. Previous formative research conducted by the lead researcher in Pirganj sub-district in northern Bangladesh identified that the male-dominant hierarchical society prevented women of different socio-economic and ethnic backgrounds from freely engaging in focus group discussions, interviews facilitated by male interviewers and other such qualitative research methods. This study aimed to better explore and thus understand maternal nutrition and its determinants through the use of Photovoice in June 2012.

Methods: A participatory research design was adopted to empower pregnant community women as they share their story and ensure a movement away from orthodox relationships between the researcher and the researched. Eight community nutrition volunteers, two supervisors and a research project coordinator participated in a one day training facilitated by the lead researcher of the project. Each community nutrition volunteer briefed and trained one to two participants (n=10) on the use of a digital camera. After a 24-hour period, cameras were collected and all pictures were printed. The community nutrition volunteers revisited the respective women, and led the participants through an in-depth interview process, pivoting around one core question, using the photos to evoke a narrative.

Results: This study identified a number of findings that reveal dietary habits and behaviours and in addition cooking practices, hygiene, household living standards, and food security.

Conclusions: The results indicate that Photovoice can be used in developing rural communities as an alternative to more commonly used qualitative research methods.

Key words: Photovoice, community nutrition, pregnant women.

PO912**PREDICTED IMPLICATIONS OF USING PERCENTAGE WEIGHT GAIN AS SINGLE DISCHARGE CRITERION IN MANAGEMENT OF ACUTE CHILD MALNUTRITION IN RURAL ETHIOPIA**

E C. Ekström¹, E. Forsén², E T. Balla^{1,3}, Y. Berhane³

¹Women's and Children's Health, Uppsala University, Uppsala, Sweden

²Charité Institute of Tropical Medicine, Berlin, Germany

³Addis Continental Institute of Public Health, Addis Ababa, Ethiopia

Background and objectives: Mid-upper-arm-circumference (MUAC) is increasingly used in identifying and admitting children with acute malnutrition for community based management of malnutrition (CMAM). MUAC is easy to use since it does not involve height assessment but its wider use also call for discharge criteria that does not need height measurement. This study examined how application of different percentage weight gain as single discharge criterion would have affected nutritional recovery depending on the children's MUAC at admission.

Methods: In rural areas of Wolaita, Ethiopia, non-edematous children (n=631) aged 6-59 months having a mid-upper arm circumference (MUAC) of <125 mm were identified when seeking admission at a CMAM program integrated into the primary health care system. By simulation, 10, 15 and 20% weight was added to their current weight and their predicted nutritional status by weight-for-height z-score (WHZ) at discharge was determined. Moderate and severe wasting according to WHO WHZ classification was used to define nutritional recovery.

Results: Applying the most commonly recommended target of 15% weight gain would have resulted in 9% of children with admission MUAC <115 mm still being moderately or severely wasted at discharge. All of those who predicted to remain severely wasted had <-4 WHZ at admission. A 10% of weight gain would have been sufficient to generate a similar proportion of recovery among children with admission MUAC 115-125 mm. Increasing the percentage weight gain targets in the two MUAC groups to 20 and 15%, respectively, would largely resolve wasting but likely also lead to increased program costs by keeping already recovered children in the program.

Conclusions: Use of percent weight gain as single discharge criterion poses risk of not being equitable as it is not proportionate to nutritional need and may lead to insufficient recovery among those with severest condition. Funded by Sida.

Key words: community-based management of acute child malnutrition, discharge criterion, Ethiopia.

PO913**MINERALS COMPOSITION IN BREAST-MILK OF VIETNAM MOTHERS**

M. Truong Tuyet¹, D. Le Hong¹, Sh. Jinno², T. Takahashi², L. Nguyen Thi¹

¹National Institute of Nutrition, Hanoi, Vietnam

²Meiji Dairies Corporations, Japan

Background and objectives: Milk composition may be influenced by several factors: the stage of lactation, the time of day, the stage of feeding, as well as maternal food intake. To determine concentration of compositions in Vietnamese mothers's breast-milk to find the relationship between some minerals levels in breastmilk and dietary intake factors.

Methods: A cross-sectional survey in 91 mothers to evaluate the breast-milk composition and diet-related factors of Vietnamese mother from 29 to 120 days of lactation period was carried out in Hanoi and Hochiminh cities. There are 60 indicators were assessed in Laboratory, including 10 minerals. The dietary intake were collected by the 24 hours recall. The food frequency were done by the Questionnaires.

Results: The level of these 10 compositions vary in large by individual. The concentration of zinc, magnesium, has a trend of decreasing by the lactating periods. It is significant differences in the some breast milk concentrations of mineral between the mothers in Hanoi and mothers in Hochiminh: the levels of phosphor, natri, in the breast milk of Hochiminh's mothers were higher markedly than that in the Hanoi's mothers. Contrasting, the levels of kali, calcium, copper, selen in the breast milk of the Hanoi's mothers was higher than in that of the Hochiminh's mothers. There are a positive and significant relationship between the level of zinc in mother diet and the level of zinc in breast milk. The selen level in breast milk was very low.

Conclusions: The level of zinc and selen were deficiency is related with the dietary intake of Vietnamese mothers.

Key words: breast-milk composition, minerals in breastmilk, lactating mothers in Vietnam.

PO914**PSYCHOSOCIAL FACTORS AS PREDICTORS OF BODY WEIGHT STATUS AMONG MALAYSIAN ADOLESCENTS**

M T. Mohd Nasir¹, L S. Law¹, A S. Hazizi¹

¹Universiti Putra, Malaysia

Background and objectives: Much effort have been made globally in trying to understand the tremendous increase in the prevalence of childhood overweight and obesity since a decade

ago. This study was conducted to examine the relationship between psychosocial factors and body weight status among adolescents.

Methods: A total of 375 students comprising 32.0% male and 68.0% female students were recruited from four public secondary schools in Sibu, Sarawak. Socioeconomic and psychosocial factors were assessed using a self-administered questionnaire. Weight and height were measured using standard procedures and body mass index-for-age (BMI-for-age) was determined.

Results: The mean age of the respondents was 16.45±0.53 years old. A total of 70 students (18.6%) were found to be overweight/obese. The percentages of overweight/obese males and females were 22.5% and 16.9%, respectively. A small proportion of students (5.0%) was categorized under the thinness group. The percentages of male and female students under the severe thinness/thinness categories were 5.0% and 5.1%, respectively. Three variables found to be associated with body weight status were eating attitudes ($r = 0.178$, $p = 0.001$), body discrepancy score ($r = 0.645$, $p = 0.0001$), and perceived socio-cultural pressure to be thin ($r = 0.392$, $p = 0.0001$). Using multiple linear regression analysis, two factors were found to have significantly contributed to body weight status after controlling for the other variables. The related variables were body discrepancy score ($p = 0.0001$) and perceived sociocultural pressure to be thin ($p = 0.001$).

Conclusions: Body image perception and perceived socio-cultural pressure to be thin were found to be the predictors for body weight status. These factors should be taken into consideration for future intervention on body weight status among adolescents.

Key words: psychosocial, body weight status, adolescents.

PO915**YOUNG CHILDRENS' NUTRITIONAL STATUS AND INFANT AND YOUNG CHILD FEEDING PRACTICES IN CAMBODIA**

A. Reinbott¹, I. Hirschmann¹, I. Jordan¹, J. Kuchenbecker¹, J. Herrmann¹, G. Kennedy², O. Kevanna³, M B. Krawinkel¹

¹Justus Liebig University Giessen, Germany

²Food and Agriculture Organization of the United Nations, Nutrition Division (ESN), Economic and Social Department, Italy

³National and Maternal and Child Health Center, Cambodia

Background and objectives: Despite economic growth, Cambodia is still among the countries with high levels of chro-

nic undernutrition. A baseline study was conducted within the IMCF research project looking at the determinants of malnutrition in Cambodia.

Methods: In September 2012 a cross sectional nutrition survey was conducted in the project area of a FAO food security project in Preah Vihear and Otdar Meanchey Province in Northwestern Cambodia. Data was collected from 1029 randomly selected households with children below two years based on a standardized questionnaire, height, weight and hemoglobin measurements of both, mother and child.

Results: Mean Height-for-age-Z-score (HAZ) varied from -0.69 at the age group 0-1.5 months to -0.82 at the age group 6-8 months to -1.65 at 21-23 months. Overall prevalence of stunting was 22%. Among the children below 6 months, 83% were exclusively breastfed. By the age of 8 months 94% of the children were introduced to complementary food. In the age group 6 to 23 months minimum dietary diversity was achieved by 44%, minimum meal frequency by 70% but a minimum acceptable diet by only 28%. Only 29% of the mothers were considered as anemic compared to 61% of the children in the age group 3-23 months. A diarrhoea episode two weeks prior to the survey was reported for 37% of the children, while 73% of the mothers knew how to prevent it.

Conclusions: The exclusive breastfeeding rate for children 0-6 months was exceptionally high compared to other countries which might have delayed the decrease of mean HAZ to the older age groups. The low prevalence of children above 6 months receiving a minimum acceptable diet emphasizes the need to improve especially complementary feeding and hygiene practices which have been very poor to prevent stunting observed in the older infants.

Key words: breastfeeding, IYCF, height-for-age-Z-score.

PO916

KNOWLEDGE CAPITAL FOR FATHERS TO SUPPORT BREASTFEEDING: STEP-BY-STEP INVESTIGATIONS IN INDONESIAN URBAN SETTING

J. Februhartanty¹, D.N. Basuki¹, A. Roshita¹, S. Muslimatun¹, A.M. Septiari², R. Suradi³

¹SEAMEO Regional Center For Food and Nutrition (RECFON), Universitas Indonesia, Indonesia

²Freelance Consultant, Indonesia

³Indonesian Perinatology Association, Indonesia

Background and objectives: Father's role in supporting breastfeeding practice is lack of exploration in Indonesian setting.

Methods: The investigation was started by reviewing existing western literatures on such phenomenon. Two quantitative surveys among 445 nursing mothers, also 168 working and 253 non-working women were done to show if fathers played roles

as perceived by mothers. Then, 13 FGDs with father-mother pairs were performed to elucidate types of father's roles in which the results were used to develop structured questionnaire for interviewing 536 father-mother pairs. Follow-up indepth interviews were done to 11 father-mother pairs who showed specific characteristics of the father's roles and its breastfeeding outcome. Furthermore, a book containing information about breastfeeding and father roles was developed. The book was tested for its benefit in improving knowledge level among 66 expectant fathers and 68 control fathers. These fathers were further intervened using text messages.

Results: Around 60% mothers with less breastfeeding difficulties admitted their spouse's engaged in discussions about child's wellbeing and helped with the household chores. Home environment especially support from father was a significant factor to influence exclusive breastfeeding for working and non-working women. One father's role found significant to breastfeeding practice was searching for information. The study estimated 60% of the fathers be exposed to breastfeeding information, 40% actively searched for information, and 20% involved in decision making of the current infant feeding practice. After book and text message interventions, the intervened fathers had increased knowledge level from 20 to 45%. Proportion of fathers who searched for information remained similar from baseline to endline, but higher than the control group.

Conclusions: Knowledge is a resource for father to strategically improve breastfeeding. Intervention must account for father's mode of information gathering which includes the mother as one entity.

Key words: breastfeeding father, working mother, book, text message, Indonesia.

PO917

SERUM CHERMERIN CONCENTRATIONS IN OBESE AND OVERWEIGHT CHILDREN BEFORE AND AFTER AN INTERVENTION PROGRAM

I. Larrechi¹, M. Rodríguez^{1,2}, G. Martínez-Castaño¹, A. Perales¹, G. Aizpuru¹, I. Lorente³, A. Sarasua³, M.P. Portillo^{1,2}, I. Díez-López³, M.T. Macarulla^{1,2}

¹Nutrition and Obesity Group, Department of Nutrition and Food Science, University of The Basque Country (UPV/EHU), Vitoria-Gasteiz, Alava, Spain

²CIBER Fisiopatología de la Obesidad y Nutrición (CIBERObn), Vitoria-Gasteiz, Alava, Spain

³Paediatric Endocrinology Section, Álava University Hospital, Vitoria-Gasteiz, Alava, Spain

Background and objectives: Chemerin is a hepatic chemoattractant protein. Recently it has been known that this molecule is also expressed in white adipose tissue from ani-

mals and adult humans. Thus, it has been hypothesized that chemerin acts as an adipokine related to obesity. The aim of this study was to analyze if serum chemerin concentrations in obese/overweight children were related to their obesity grade, and to determinate the effects of an obesity treatment on serum chemerin concentrations.

Methods: Forty obese/overweight children (25 girls, 15 boys) 8-13 year-old and their parents followed an intervention program of 11 weekly sessions of 90 min, named 'niñ@s en movimiento', designed to modify nutritional and psychological aspects, as well as lifestyle habits. Before and after the program, body weight, height and waist circumference were measured, relative body mass index ($rBMI = [\text{individual BMI}/\text{BMI at } 50^{\circ} \text{ percentile for age and gender } /100]$) and relative waist circumference ($rWC = [\text{individual WC}/\text{WC at } 50^{\circ} \text{ percentile for age and gender } /100]$) were calculated, and serum chemerin concentrations were assessed by ELISA. Data were analyzed using statistical paired or unpaired Student's t tests.

Results: A significant decrease in $rBMI$ and rWC values was observed after the intervention program ($P < 0.001$), and obesity prevalence decreased from 44% to 28% in this children group. In addition, serum chemerin concentration also decreased (64 ± 3 vs 57 ± 2 ng/ml, $p < 0.001$). Significantly higher chemerin concentrations were found in obese children when they were compared with overweight children, either before or after the intervention program ($p < 0.05$). No differences between both genders were found.

Conclusions: Serum chemerin concentration is directly associated with children obesity grade, and it decreases after an obesity children treatment.

Key words: chemerin, childhood obesity, obesity treatment
Research funded by Instituto de Salud Carlos III (RETIC PREDIMED and CIBERobn) and Government of the Basque Country (IT-386-10 and IT-512-13).

PO918

MALNUTRITION IN BRASILIAN ELDERLY: EFFECT OF SENSORY CHANGES

R. Machado¹, M.A. Coelho¹

¹UFRJ – INJC, Rio de Janeiro, Brazil

Background and objectives: Malnutrition in the elderly has important effects morbidity and mortality. The association between malnutrition and sensory study has been given in recent years, the impact that these problems can lead to health of the elderly. The quantity, selection and processing of food are limited by alterations of taste sensory smell, hearing and hypo salivation that causes dry mouth, is also associated with poorer nutritional indicator. The objective is to examine the association between malnutrition and sensory changes in taste,

smell, hearing and xerostomy in institutionalized elderly in Rio de Janeiro - Brazil.

Methods: This cross-sectional study, data were obtained from 344 elderly residents of long-term institutions in the municipality of Rio de Janeiro, Brazil. Malnutrition has been identified through the Mini Nutritional Assessment, MNA. A questionnaire was applied to detect the reduction of self-perception of taste, smell, vision and dry mouth. Multivariate analyses by logistic regression were adjusted for age.

Results: Malnutrition was detected in 25 elderly (8.3%). The variable reduction hearing (Odds Ratio (OR): 2.14; confidence interval (CI), 95%: 0.86 to 5.31), decreased vision (OR: 1.66, 95% CI: 0.57 to 4.79) and reduction of the palate (OR: 1.81, 95% CI: 0.19 to 16.8) were more likely to malnutrition, but not statistically significant. The variable xerostomy presented three times greater chance of developing malnutrition with statistical significance (OR: 2.95, 95% CI: 1.21 to 7.19).

Conclusions: Xerostomy is significantly associated with 3 times greater chance of developing malnutrition, as well as other sensory changes showed some influence. It is important to concern not only with food quality, but also make sure that it is actually being ingested. Sensory physiological changes in the elderly and can lead to malnutrition by reducing intake, worsening the prognosis of your health.

Key words: elderly, malnutrition, nutritional assessment.

PO919

CULINARY WORKSHOPS IN HEALTH PROMOTION AND SPORTS PERFORMANCE: AN EXPERIENCE WITH BRAZILIANS ADOLESCENTS TENNIS PLAYERS

G. Vedovato¹, C. Juzwiak²

¹Institute of Health and Society, Federal University of Sao Paulo, Brazil

²Department of Human Movement Science, Institute of Health and Society, Federal University of Sao Paulo, Brazil

Background and objectives: Food cooking is widely used as a nutritional intervention strategy to encourage healthy dietary changes. Our objective is to describe the experience of adopting culinary workshops as an educational tool for adolescent tennis players, aiming the promotion of healthy eating and optimal performance.

Methods: Activities were planned as part of a food and nutrition program conducted from February/2010 to December/2012 developed for a tennis competition team (10 to 18 years old), aimed to improve athletes' food knowledge, practices and behaviors. In addition to individual counseling athletes participated in group activities (n=23), using different dy-

namics. Four culinary workshops were held using cooking as structural axis of an educational method and focusing specific topics: (1) Sports beverages prepared with fruits (to encourage adequate hydration practices); (2) Healthy snacks to eat during exercise (to maintain blood glucose levels and improve performance); (3) Postexercise meals (food strategies for recovery); (4) Sensory stimulus and tasty dishes with vegetables (to improve the intake of food sources of antioxidants).

Results: The workshops presented average participation of 12 athletes. The meetings provided an important space for dialogue and sharing of knowledge and practices about healthy eating and individual strategies related to exercise performance. The nutritionist played a key role as a mediator of the discussion to improve the quality of information and to encourage food behaviors changes. The workshops were effective to address athletes' sensorial, cognitive, symbolic and procedural dimensions. Furthermore, they were essential to complement other activities of the program, especially due to the possibility of athletes understanding how to prepare and organize their own food, adequate to training sessions and competitions periods.

Conclusions: This experience shows the potential of the culinary workshop as a participatory approach to address specific issues in sport in order to promote health and performance.

Key words: cooking, food and nutrition education, adolescent health, tennis performance.

PO920

EFFECT OF A NUTRITIONAL INTERVENTION ON PHYSICAL RECOVERY – EVALUATION OF A CARBOHYDRATE-PROTEIN ISOTONIC DRINK

A. Meheust¹, T. Bernard², J. Louis³

¹Oxylane Research, Health Lab, Villeneuve d'Ascq, France

²Université de Toulon, LAMHES, EA 6309, La Garde, France

³Université de Nice Sophia Antipolis, LAMHES, EA 6309, Nice, France

Background and objectives: Optimising the recovery period between training sessions is key to maintain an optimal performance at each session. Nutrition is one of the main strategies for recovery to restore hydration status, glycogen stores and to enhance proteo-synthesis. An isotonic drink Complex Recuperation® (CR), formulated according to these targeted functions, has been tested on well-trained cyclists to evaluate its effects on performance after fatigue.

Methods: 10 well-trained cyclists (men: 22.4 ± 3.2 y.o.) performed 3 sessions, each separated by one week. During the first session each subject underwent a full medical check, a training

on a 30 min Time Trial (TT) and the evaluation of maximal aerobic speed. During the two next sessions, after a specific protocol leading to glycogen depletion (Jentjens et al., 2001) cyclists were randomly assigned in two recovery strategies, in a cross-over design. One was a specific dose of carbohydrates and protein (CR) and the other one was a placebo (PL), to be ingested immediately after the glycogen depletion protocol, every 15 min and during 3 hours. Each of these 2 sessions was realized during 2 days, where diet was controlled. Dependant variables were a 30 min TT and an all out test to identify Maximal Muscular Cycling Power (MMCP). Subjective parameters of fatigue, perceived effort and investment were also evaluated.

Results: After CR ingestion, MMCP was maintained (+1.1%, NS) whereas significant alteration was observed after PL (-5.3%, $p < 0.05$). A similar pattern was observed for TT with a performance maintained after CR (+0.4%, NS) but decreased after PL (-3.9%, $p < 0.05$).

Conclusions: Results indicate a significant maintained performance for TT and MMCP after CR ingestion. This could be related to an adequate replenishment of the muscle glycogen stores by the carbohydrates and protein drink.

Key words: recovery, physical performance, carbohydrates, proteins, cycle.

PO921

NO EFFECT OF BINDING FOLATE RECEPTOR AUTOANTIBODIES ON MATERNAL OR CORD FOLATE STATUS IN A LONGITUDINAL PREGNANCY STUDY

M I. Berrocal-Zaragoza^{1,2,3}, P. Cavallé-Busquets^{2,4}, J D. Fernandez-Ballart^{1,2}, E V. Quadros⁵, J M. Sequeira⁵, M M. Murphy^{1,2,6}

²IISPV and CIBER Fisiopatología de la Obesidad y Nutrición (CB06/03) Instituto Carlos III, Spain

³Financial support: Fundació Caixa Sabadell, Spain

⁴Unit of Obstetrics and Gynaecology, Hospital Universitari Sant Joan de Reus, Spain

⁵Departments of Medicine and Cell Biology, State University New York (SUNY)-Downstate Medical Center, Booklyn, New York, USA

⁶Financial support: Comisión Interministerial de Ciencia y Tecnología, Spain (SAF2005/05096); The Spanish Ministry of Health (Instituto de Salud Carlos III, Fondo de Investigaciones Sanitarias), project PI:10/00335; Institut d'Investigació Sanitària Pere i Virgili, Tarragona, Spain

Background and objectives: “Blocking” autoantibodies prevent folate entering the cell via the folate receptor and are associated with infertility and grave developmental defects. Binding autoantibodies that bind to the epitope of the folate receptor have been described but how they affect folate transport, status or pregnancy outcome is not known. The aim of this study is to investigate the presence of binding autoantibodies during pregnancy or in the cord and their effect on maternal and cord folate status and birth weight.

Methods: 187 participants from the Reus-Tarragona Birth Cohort (“NUTCIR” phase) were studied. Plasma folate and binding autoantibodies were determined at <12, 15, 24–27 and 34 gestational weeks (GW), labor and in the cord. A multiple linear regression model (MLRM) was fitted to investigate the association between binding autoantibodies and birth weight and was adjusted for BMI, parity, smoking during pregnancy, prenatal iron and folic acid supplement use, socioeconomic level, gestational age at birth and fetal gender.

Results: 69% of the participants had binding autoantibodies during pregnancy or in the cord. Their prevalence throughout pregnancy was: <12GW (53.6%), 15GW (55.8%), 24–27GW (50.0%), 34GW (50.0%), labor (48.0%), cord (51.8%). Plasma folate concentration (nmol/l) in carriers/ non-carriers [mean (SD)]: <12GW [29.02 (18.63)/ 34.40 (31.10)], 15GW [26.28 (14.97)/ 27.05 (18.46)], 24–27GW [12.99 (9.84)/ 13.99 (10.39)], 34GW [10.88 (8.65)/ 10.95 (10.59)], labor [10.83 (8.39)/ 15.05 (35.14)], cord [25.03 (12.29)/ 23.11 (11.70)] did not differ. Neither did any of the studied lifestyle or obstetric variables. However, carriers were older than non-carriers: 32.4 (4.2) years versus 29.5 (4.7), $p < 0.001$. MLRM ($r^2=0.466$, $p < 0.001$): binding autoantibodies during pregnancy or in the cord were associated with an average increase of 214.89 g in birth weight ($p < 0.01$).

Conclusions: Folate receptor binding autoantibodies in the mother or in the cord did not affect folate status but were associated with increased birth weight.

Key words: autoantibodies, folate receptor, pregnancy.

PO922

THE RELATION BETWEEN DIET AND ALLERGEN CONCENTRATIONS IN BREAST MILK; OVALBUMIN CONCENTRATIONS AND LACTOFERRIN LEVELS IN BREAST MILK

M. Hara¹, N. Momose², S. Furukawa²

¹Showa Women’s University, Tokyo, Japan

²Jissen Women’s University, Tokyo, Japan

Background and objectives: Regardless of the consumption of the same amount of allergen-related foods, allergens were detected in some breast milk samples while not in the

others. Breast milk is a secretory fluid. Therefore, concentrations of secretory fluid could potentially be linked with the concentration of allergens in the breast milk. Thus, the total protein and the levels of one particular protein, lactoferrin, in the breast milk were measured.

Methods: The concentration of ovalbumin in breast milk was measured using an enzyme-linked immunosorbent assay (ELISA) kit, previously reported by us. The limit of ovalbumin level in breast milk is 312 ng/ml. The Lowry method was used for measuring the total protein. A Lactoferrin Human ELISA Kit was used to measure the lactoferrin levels. Therefore, we investigated cases wherein the level of ovalbumin was below or above 312 ng/ml.

Results: We found no significant difference when we compared the total protein level between breast milk with ovalbumin below 312 ng/ml and that above 312 ng/ml. When we compared the lactoferrin level between breast milk with ovalbumin below 312 ng/ml and that above 312 ng/ml, a significant difference was observed. Consequently, if the ovalbumin level in breast milk is >312 ng/ml, the lactoferrin level is high, while if the ovalbumin level is <312 ng/ml, the lactoferrin level is low ($p < 0.01$).

Conclusions: When evaluating the concentrations of ovalbumin in breast milk, the lactoferrin levels might be used as the point of reference.

Key words: Allergen, ovalbumin, lactoferrin, breast milk.

PO923

A STUDY ON CHANGES IN FOOD PREFERENCES OF INFANTS AND THEIR MOTHERS

R. Ueda¹

¹Department of Child Education, Teikyo University of Science, Yamanashi, Japan

Background and objectives: What is the most effective approach in trying to prevent biased nutrition in food and nutrition education (shokuiku)? The purpose of this study was to survey the food preferences of infants and their mothers.

Methods: The survey items included 21 types of foods reported to be the most disliked by infants. Inquiries were made to 720 mothers in Tokyo in 2012.

Results: The majority of those surveyed were unable to eat food items during infancy. Fifty percent of the mothers surveyed became able to eat those items by the age of 17, 15, 15, 15 years, respectively. However, the oldest age at which they became able to eat those foods was 35, 30, 30, and 30 years, respectively. Thus, the survey revealed that as people grow up, the variety of foods that they can eat broadens, but that such changes differ between individuals. It was also revealed that foods that were reported as being their mothers’ favorites, such

as onions, carrots, and tomatoes, were being consumed by the infants surveyed at relatively earlier ages. Reasons for starting to eat formerly disliked foods included, in order of importance, aging (33%), modeling after their mothers (30%), and curiosity (25%); being forced to eat the food accounted for only 7.0% of those surveyed.

Conclusions: Children should not be forced to eat foods that they do not like, mothers should continue to provide an appropriate food environment with a long-term prospective. It should be kept in mind that mothers need to set a good example so that their children can model after them, and to try and draw curiosity from their children.

Key words: food preferences, nutrition education, shokuiku.

PO924

SNACKING AND INFANT YOUNG CHILD FEEDING PRACTICES IN A RURAL AREA OF NICARAGUA

M. Contreras¹, E. Zelaya², L. Å. Persson¹, E.C. Ekström¹

¹Women's and Children's Health, Uppsala University, Uppsala, Sweden

²Asociación para el Desarrollo Económico y Social de El Espino (APRODESE), Chinandega, Nicaragua

Background and objectives: Infant young child feeding (IYCF) practices are of great importance for child health. Guidelines on good practices and their assessment have been issued by international agencies. Potentially negative practices such as consumption of high fat and sugar/salty snacks and drinks are not commonly reported but may be an issue. Our aim is to describe IYCF practices complemented with information on snack consumption in a society undergoing the nutrition transition.

Methods: In rural northwestern Nicaragua household visits were made to 1371 mother and child (0-35 m old) pairs displaying the complete population of the study area. Cross-sectional data was collected from June to November 2009 using 24 h recall instruments and subsequently generating feeding indicators as recommended by WHO. In addition, information on commonly consumed snacks and sweet drinks was also collected.

Results: While breastfeeding was common (98%) in the first months of life and continued (60%) in the second year, only 34% of the 0-5 m olds were exclusively breastfed. Mixed feeding by use of powder milk (9%) and/or formula (13%) started in the first two months. Consumption of snack foods was common (22% of 4-5 m and 55% of 6-8 m). Complementary feeding was deemed acceptable for only 41% of the infants (6-11 m) due to limitations in dietary diversity (50%) and meal frequency (32%). The largest limitation (in 75%) was in consumption of vitamin A-rich fruits and vegetables. At same time

consumption of snacks was high with 92% of the 24-35 m olds having consumed a snack the previous day with preference for sweet items.

Conclusions: There were limitations in practicing recommended feeding behaviors, raising concerns related to undernutrition. At the same time, snack consumption appeared high. Whether snacking may contribute to prevent undernutrition, increase overnutrition or both needs study. Funded by Sida

Key words: breastfeeding, child, diet, snacks, Nicaragua.

PO925

INFANT AND YOUNG CHILD FEEDING PRACTICES AND NUTRITIONAL STATUS IN NICARAGUA: ASSOCIATIONS WITH HOUSING QUALITY, FOOD SECURITY AND MATERNAL EDUCATION

M. Contreras¹, E. Zelaya², L. Å. Persson¹, E.C. Ekström¹

¹Women's and Children's Health, Uppsala University, Uppsala, Sweden

²Asociación para el Desarrollo Económico y Social de El Espino (APRODESE), Chinandega, Nicaragua

Background and objectives: Socio-economic characteristics such as household economic situation, food security and maternal education are critical underlying determinants for infant young child feeding and nutrition. They are commonly interrelated and their independent contribution needs to be better understood when efforts are made to improve children's situation. In the context of a society in nutrition transition this study evaluates associations between these factors and child feeding and nutrition in rural Nicaragua.

Methods: Cross-sectional data was collected from May to November 2009 at household visits including 1371 children aged 0-35 months and their caretakers. Information on infant young child feeding and nutrition was collected using standard WHO guidelines. A validated experience-based questionnaire assessed food security, whereas housing quality served as proxy for household economic situation. Both these determinants were categorized into tertiles in analyses. Maternal education was categorized as <5 years, 5-9 years and 10 or more years.

Results: Independently, lowest level of education was associated with a higher proportion of exclusive breastfeeding (EBF) (OR for not EBF: 0.19; 95% CI: 0.07, 0.51) but, at older age, also with lower achievement of minimum dietary diversity (DD) (OR for not DD: 2.04; 95% CI: 1.36, 3.08) and lower HAZ (Beta: -0.34; CI: -0.59, -0.09). The lowest and middle levels of food security were associated with lower DD (OR for not DD: 1.47; CI: 1.05, 2.05) and lower HAZ among infants under 6 months (Beta: -0.73; CI: -1.26, -0.19). Further, housing quality was related with lower WHZ in the older children (Beta: -0.22; -0.42, -0.03).

Conclusions: In this study lower maternal education was

associated with both favorable and unfavorable outcomes, though the favorable effect on EBF may not be interpreted as causative. Lower levels of food security were systematically associated with more unfavorable outcomes. Funded by Sida

Key words: child, nutrition, food security, education.

PO926

PREDICTORS OF DECLINE IN DIET QUALITY IN OLDER AGE - FINDINGS FROM THE HERTFORDSHIRE COHORT STUDY

S. Robinson¹, M. Edwards¹, K. Jameson¹, H. Syddall¹, E. Dennison¹, C. Cooper¹, A. Aihie Sayer¹, C. Gale¹

¹MRC Lifecourse Epidemiology Unit, University of Southampton, Southampton, UK

Background and objectives: Poor nutrition is common in older people, but little is known about influences on food choice at this age. Dietary 'resilience' may be of importance, explaining how some older adults are able to maintain a diet of adequate quality. The objectives of this study were to identify determinants of change in diet quality over a 10-year period in a cohort of older community-dwelling adults.

Methods: At baseline (1998-2001), the diets of 222 men and 221 women, aged 59-71 years were assessed by administered food frequency questionnaire. Principal component analysis identified a 'prudent' pattern, characterized by frequent consumption of fruit, vegetables, wholegrain cereals and oily fish. A prudent diet score was calculated for each participant; the score was used as an indicator of their diet quality. Participants provided information on demographic, medical and psychosocial factors. At follow-up (2011), diet was re-assessed; prudent diet scores and change in scores from baseline were calculated.

Results: Mean (SD) change in prudent diet score over 10 years was -0.142 (1.120) in men and -0.339 (1.076) in women, indicating an overall decline in diet quality with increasing age. Change in prudent diet score was not related to social class, BMI, smoking, physical activity, marital status or number of co-morbidities at baseline. Whilst there were no associations between change in prudent diet score and the extent of social support or size of social network at baseline, there were associations with participation in social and leisure activities. In men, for a one point increase in activity, change in prudent diet score increased by 0.013 (95% CI 0.001, 0.025) $p = 0.042$. In women, the equivalent change was 0.018 (0.006, 0.031) $p = 0.005$.

Conclusions: In community-dwelling older adults, participation in social and leisure activities appears to be protective with respect to quality of diet.

Key words: diet quality, ageing, resilience.

PO927

ANTHROPOMETRIC AND COGNITIVE PARAMETERS MAY AFFECT LOW ENERGY REPORTING IN ELDERLY

M. Yannakoulia¹, T. Dardiotis², M. Kosmidis³, G. Hadjigeorgiou², N. Scarmeas⁴

¹Department of Nutrition and Dietetics, Harokopio University, Athens, Greece

²School of Medicine, University of Thessaly, Karditsa, Greece

³Lab of Cognitive Neuroscience, School of Psychology, Aristotle University of Thessaloniki, Thessalonik, Greece

⁴School of Medicine, National and Kapodistrian University of Athens, Athens, Greece

Background and objectives: Accurate assessment of energy intake is crucial for the assessment of nutritional status. Energy misreporting may result from conscious or unconscious underreporting and interviewer-related reasons. In elderly, high rates of low energy reporting exist, mainly associated with low educational level and greater body mass index (BMI). The potential role of cognitive decline has been previously discussed. Aim of the present analysis was to investigate prevalence and characteristics of low energy reporters (LERs) in an elderly Greek cohort.

Methods: The study population is located in Larissa, the largest city of central Greece. Subject selection was based on a random sampling of elderly >65 years old. So far, 760 non-institutionalized individuals were enrolled. They have undergone detailed clinical, neurological and neuropsychological assessment (including the Mini-Mental State Examination, MMSE). BMI was calculated from measured weight and height values. Dietary intake was evaluated with the use of a validated food-frequency questionnaire. Adherence to the Mediterranean Diet was evaluated through MedDietScore. The Determine Checklist was used for nutrition risk screening. Following the method of Goldberg et al participants were classified as LERs and non-LERs.

Results: 25% of the population were LERs. Compared to non-LERs, LERs had significantly lower consumption of all food groups, lower MedDietScore, lower percentage of energy from dietary fat and higher from protein. Furthermore, LERs had significantly higher BMI compared to non-LERs ($p < 0.001$), lower MMSE Score ($p = 0.02$) and, interestingly, higher Determine score ($p = 0.04$), indicating higher malnutrition risk. After adjustment for potential demographic and lifestyle confounders, lower energy reporting was significantly associated with female sex, higher BMI and lower MMSE score.

Conclusions: Measures of cognitive function may be necessary when evaluating energy intake in the elderly. This issue

needs further investigation as energy misreporting may influence the study of diet-disease relationships in this age group.

Key words: underreporting, elderly, dietary assessment.

PO928

ANEMIA CONTROL PROGRAMS AND DECREASING ANEMIA PREVALENCE IN RWANDA

E. Micomyiza¹, R. Galloway¹

¹Maternal And Child Health Integrated Program (MCHIP)/Program For Appropriate Technology In Health (PATH), Rwanda

Background and objectives: In Rwanda between 2007/8 and 2010, anemia decreased from 29% to 20% in pregnant women and 48% to 38% in children 6-59 months. To better understand why anemia prevalence has decreased, we reviewed the change in program coverage.

Methods: The 2007/8 and 2010 Rwanda Demographic and Health Surveys were used to determine the change in anemia in both pregnant women and children 6-59 months and changing coverage of iron intake, malaria control, deworming, and other related programs.

Results: Only 1-2% of women and children tested positive for malaria in both surveys. Anemia in pregnant women decreased by 31% over the period with moderate and severe anemia decreasing by 33% and 93%, respectively. Sleeping under long-lasting insecticidal nets (LLINs) increased from 60% to 72%. Women consuming any iron-folic acid supplements (IFAS) increased from 41% to 73%. However, most women were receiving <60 IFAS and only 3% of women received >60 IFAS in 2010. Deworming in pregnancy increased from 18% to 39%. Anemia prevalence in children 6-59 months declined by 26% but most of the decline took place in children 24-59 months compared with children 6-23 months. Most of the decline occurred for severe anemia in both age groups. There was an increase in the consumption of iron-rich foods by children (from 8% to 20%), an increase in deworming (from 70% to 86%) with only 31% coverage in younger children group compared to over 90% in older children, and children sleeping under LLINs (from 56% to 70%).

Conclusions: This analysis shows that anemia prevalence can be decreased by increasing the coverage of anemia control programs. While there is still work ahead to increase iron intake and expand helminthes and malaria control, Rwanda has made promising strides to expand coverage of programs that will reduce anemia.

Key words: anemia, malaria, deworming.

PO929

FOOD INTAKE AND NUTRITIONAL STATUS OF PREGNANT AND LACTATING WOMEN IN SELECTED URBAN SQUATTERS AND CONCERN WORLDWIDE'S INITIATIVE IN BANGLADESH

A. Azim¹, Z. Rahman¹, I. Rasul¹

¹Urban Context, Concern Worldwide, Dhaka, Bangladesh

Background and objectives: Concern Worldwide, Bangladesh is implementing the 'Integrated Urban Nutrition Project' from 2011-2015 targeting selected urban squatters of two major cities named Dhaka and Chittagong. The project intends to integrate nutrition services into the existing Primary Health Care (PHC) system as current urban health service delivery system does not integrate nutrition as component. One of the objectives of the project is to improve the nutritional status of pregnant and lactating through utilizing nutritional services provided through existing PHC networks and improve the household income by involving women into income generation activities (IGA). IGA activities are introduced in project from December 2012. The project works in partnership with five local NGOs.

Methods: A baseline survey on household food security situation was conducted in December 2012 to understand the nutritional status and food consumption pattern of pregnant and lactating women in urban squatters. For the survey, two stage cluster sampling design were followed to select 720 women.

Results: In surveyed areas the prevalence of global acute malnutrition in pregnant and lactating mothers by MUAC using a cut-off of less than 22.0 cm was 17.4%. Of them, 8.7% were severely malnourished with MUAC below 21.0 cm. Dietary diversity score showed, 48% women consumed meal from 5 to 6 food groups 24 hours prior to survey. Compared to household level less percentage of women (HH: 27%, Mother: 18%) availed 8 or more score. Further analysis revealed women who consumed less diversified meal higher number of them were severely malnourished (45%).

Conclusions: Individual counseling and group counseling are introduced to PHC services from where mothers receive appropriate information on food intake during pregnancy and lactation. Different awareness raising programme at community and IGA are initiated at household level to improve food security situation in squatter areas.

Key words: pregnant, lactating women, nutritional status.

PO931**VIOLATION OF BMS CODE IN DHAKA CITY**

S B. Salam^{2,3}, T. Ahmed^{2,3}, S. Sartaz², F. Sheherin², K. Monira², N. Jahan², K. Ferdouse^{2,3}, S. Israt^{2,3}, K. Jaha^{1,3}, S S. Saliheen Sultana², S K. Roy^{1,3}

¹Bangladesh Breastfeeding Foundation, Institute of Public Health, Mohakhali, Dhaka, Bangladesh

²Dept. of Food & Nutrition, College of Home Economics, Azimpur, Dhaka, Bangladesh

³Nutrition Foundation of Bangladesh, Lalmatia, Dhaka, Bangladesh

Background and objectives: Breast milk is a exclusive nutritional source that cannot be replaced by any other food, including infant formula or breast milk substitute (BMS). There are some specific clauses in the national laws to regulate the marketing practice of BMS products in Bangladesh in accordance with international regulations (Code 1984). The objectives was to find out the extent of code violation and the way violations are talking place.

Methods: In 2009, we submitted a qualitative study which was carried out in Dhaka city and that includes 6 Focus Group Discussion (FGD) and 9 In Depth Interview. Selected mothers (children aged 0 to 24 months), doctors, health workers were also interviewed.

Results: It was found that many manufacturing companies, mothers, doctors and health workers were violating codes. Manufacturing companies were violating the code by advertising. Mothers were being attracted by those advertisements and due to lack of education, knowledge and consciousness, they were violating the code. Almost every mother who participated in the study was not familiar with BMS Code. Only one mother said that she read something about the law on newspaper. And another mother said that this is the first time she heard about BMS code. Most of the health workers do not have any clear conception about BMS code. From all the participants one heard about it from a senior doctor but not properly. Doctors know about code but they are breaking the laws for some unknown reasons.

Conclusions: Though there are some codes on BMS but most of the people do not know this. Most of them are violating BMS codes, even those who are directly associated with breast feeding practice. As a result the infants are direct victims but not those who are violating the codes.

Key Words: BMS, BMS code, FGD, in depth interview.

PO932**MATERNAL HIV-STATUS, EXCLUSIVE BREASTFEEDING AND INFANT ILLNESS AND GROWTH IN THE FIRST MONTH OF LIFE IN SEMI-RURAL TANZANIA**

S H. Pedersen¹, A L. Wilkinson¹, S. Kinung'hi², D M. Mkwashapi², A. Andreasen³, M. Urassa², J. Todd⁴, J. Changalucha², J M. McDermid¹

²National Institute for Medical Research, Mwanza, Tanzania

³Mwanza Intervention Trials Unit, London School of Hygiene and Tropical Medicine, Mwanza, Tanzania

⁴Department of Population Health, London School of Hygiene and Tropical Medicine, London, UK

Background and objectives: Exclusive breastfeeding (EBF) decreases respiratory and intestinal infections during infancy, yet studies in urban Tanzania indicate the majority of women do not EBF for the recommended six months. The objective was to determine the prevalence of EBF up to month-one in a semi-rural area of northwestern Tanzania where women may have less access to commercial infant formulas, and to determine if EBF was related to symptoms of infection and growth in the infant.

Methods: Thirty-three HIV+/HIV-exposed and 55 HIV-/HIV-unexposed mother/infant dyads were followed from birth. Infant feeding and health questionnaires were administered, and maternal and infant anthropometrics were measured. Illness was defined as symptoms of diarrhea, cough, fever, vomiting, skin rash, or unscheduled hospital/clinic visits.

Results: Only 33% of mothers were practicing EBF at month one, and HIV+ mothers were 2.4 times more likely to practice EBF during this period ($p = 0.05$). The most common foods given were water, sweetened water, and gripe water. Among HIV-exposed infants, EBF reduced the risk of infant illness by 81% ($p = 0.032$). Infants who were HIV-exposed had significantly poorer anthropometrics (weight, head circumference) even if they were EBF, however, infant length and mid-upper arm circumference (MUAC) were not significantly different. Maternal body mass index (BMI) and MUAC were significantly associated with infant anthropometrics (length, weight, MUAC, head circumference), irrespective of HIV status.

Conclusions: EBF reduced the likelihood of illness in HIV-exposed infants, but despite these benefits most mothers do not EBF. If an infant becomes ill, mothers need support and education regarding the immunological and nutritional benefits of EBF even during illness. Irrespective of feeding method, HIV-exposed infants have poorer growth outcomes and may need further monitoring/intervention to improve early growth. Easy measures like maternal BMI may help identify at-risk infants.

Key words: exclusive breastfeeding, neonatal, growth, HIV.

PO933**IMPACT OF IEC SUPPORT TO MOTHERS/CAREGIVERS ON NUTRITIONAL STATUS OF CHILDREN AGED 6-8 MONTHS, LIVING IN SLUM AREA OF DHAKA CITY**

I. Jahan¹, S K. Roy¹, S S. Saliheen Sultana², R. Sultana¹, M. Afroz², N. Das², K. Jahan¹, A. Ashraf², M. Akther², A. Rahman², F. Fatema², K. Ferdouse¹, S. Israt¹, S B. Salam¹, T. Ahmed¹

¹Bangladesh Breastfeeding Foundation, Mohakhali, Dhaka, Bangladesh

²Dept. of Food and Nutrition, College of Home Economics, University of Dhaka, Azimpur, Dhaka, Bangladesh

Background and objectives: Inappropriate infant and young child feeding practices are a major cause of the onset of malnutrition in young child. In terms of prevalence, number of children affected and severity of deficits, the level of undernutrition among children in south Asia in the world is relatively high. Here, one of the major reasons of faltering growth rate after 6 months onward is low quality CF practices. According to BDHS 2011 the rate of appropriate complementary feeding practices is only 21%. A key component of strategies for improving child nutrition is improvement in knowledge and practices related to CF among families of children 6 to 24 months of age. Aim of this study was to see the impact of IEC support provided to caregivers on improving CF practices as well as child's nutritional status.

Methods: It was a longitudinal study of experimental design, conducted for 5 months in 2011. A baseline study was done to understand the current status. Basic information on appropriate complementary feeding practices through IEC material (e.g. flipchart, poster, leaflets) along with food demonstration and recipe trial was provided to caregivers in intervention group (n=146) while no such support were provided to caregivers of control group. Anthropometric data for both baseline and end line were collected using standard measurement tools and household data were collected from the caregivers in selected slum areas using pre-structured questionnaire. Growth rate of children were monitored for 2 months.

Results: Weight gain was significantly higher in intervention group (0.66 kg vs 0.22 kg, $p < 0.003$). WAZ had improved in intervention group compared to control group (-2.73 to -1.97 vs -2.39 to -2.34, $p < 0.003$).

Conclusions: IEC support plays a positive role on nutritional status thus such actions for knowledge and skill development should be taken under urban health programs.

Key words: IEC, CF, nutritional status, recipe trial.

PO934**DIETARY PATTERN AND DIETARY RISK OF ELDERLY PARTICIPANTS OF UNIVERSITY EXTENSION PROGRAMS IN SÃO PAULO, BRAZIL**

V. Perucha¹, R C. Aquino¹, N. Gaspareto¹, K. Palma¹

¹University São Judas, Aging Studies Programme, São Paulo, Brazil

Background and objectives: The elderly are part of a population group that come expanding rapidly worldwide becoming potential victims of poor dietary habits of modern life. The aging can lead to difficulties in adaptation to the environment, increasing the vulnerability and prejudice the feeding process, elevating the incidence of malnutrition in the elderly. The aim of this study was to evaluate the dietary pattern and dietary risk of elderly participants of university extension programs in the city of São Paulo, Brazil.

Methods: We studied elderly of both genders, older than 60 years, suffering from one or more chronic diseases. For the assessment of dietary habits was administered a dietary screening instrument composed by 25 questions, developed and validated by Bailey (2009), based on a score that identifies nutritional risk in the elderly, besides four 24-h recall. The score was assessed according to the nutritional status observed and conducted a nonparametric statistical analysis, establishing a significance level of 5%.

Results: We evaluated 42 elderly (9.5% female and 90.5% male), 50% overweight, and identified possible risk in 59.5% and risk in 35.7%. There was association between nutritional status and score, which means that, the higher was the body mass index (BMI) or waist circumference (WC), the lower was Bailey's score, but the difference between the groups was not significant ($p > 0.05$). We identified a low consumption of whole grains and high consumption of sweets, and the diet of elderly at risk showed less variety of vegetables and lower consumption of fish not fried, and higher consumption of cold cuts and sausages.

Conclusions: We observed a high frequency of risk and possible nutritional risk in the population, independent of the nutritional status by BMI or WC, which can be explained by inadequate dietary pattern.

Key words: elderly, dietary pattern, nutritional risk.

PO935**USE OF HOME PARENTERAL NUTRITION IN A PREGNANT WOMAN WITH BOWEL OBSTRUCTION**

A J. Omiste Romero¹, M. Gonzalo Marín¹, I. González Molero¹, R. Vallejo Mora¹, C. Maldonado Araque¹, G M. Oliveira Fuster¹, A. Muñoz Aguilar¹

¹UGC Endocrinología Y Nutrición, Hospital Carlos Haya, Málaga, Spain

Background and objectives: Despite having an experience of about 50 years of use of parenteral nutrition as a feeding way, its use in pregnancy has less experience, existing few cases in the literature. However, parenteral nutrition provides a safe and effective option to reverse maternal malnutrition and promote normal fetal growth when oral or enteral nutrition it is not possible.

Methods: 34 years old woman of 31 weeks pregnant was admitted to our hospital for intestinal malrotation secondary to pregnancy. She was treated with a conservative treatment. However, she suffered progressive loss of weight and the fetus weight was one week less than the normal for his gestational age. Because she did not tolerate enteral nutrition we started parenteral nutrition, and after teaching the management she went home with parenteral nutrition. After starting with parenteral nutrition the patient gained weight, one kilo per week, being the fetus according to gestational age. Cesarean section was planned for breech presentation at 37 week without complications. There were not metabolic or infectious complications related to parenteral nutrition.

Results: Parenteral nutrition is necessary to maintain or restore an anabolic state when oral nutrition pathways are not feasible. In the case of pregnancy, there is very little experience in using it. Between the main indications highlights refractory gravidarum hyperemesis and pathologies with malabsorption. The composition of parenteral nutrition is similar to that used in nonpregnant patients. There is no more complications observed in pregnancy compared with non pregnant women except more frequent catheter-related complications.

Conclusions: Although some obstetricians believe the risks outweigh the benefits in the use of parenteral nutrition, if during the pregnancy it is not possible feeding by enteral nutrition, parenteral nutrition has proven to be safe for the mother and children.

Key Words: parenteral, nutrition, pregnancy, intestinal malrotation

PO936**EFFECT OF RHEOLOGICAL PARAMETERS ON PUREES SENSORY ANALYSES CARRIED OUT BY INFANTS (4-24 MONTHS)**

A M. Inarejos Garcia¹, J. Llanos López², V. Mancebo Campos¹, P. Cañizares²

¹Research & Development Department, Dulcinea Nutricion SL, Puertollano, Spain

²Chemical Engineering Department, University of Castilla-La Mancha, Ciudad Real, Spain

Background and objectives: Baby food purees must be nutritionally balanced, easily digestible and energy-dense to adequately feed infants. Most of these commercial brand purees are sensory analyzed by adults, whose perceptions do not necessarily coincide with those showed by babies or infants. Concerning the sensory attributes, viscosity is one of the most important characteristics of purees, and depends on the type of puree, ingredients and proportions, thermal treatment, etc. The objective of this work was to evaluate the influence of the rheological parameters of baby food purees from the commercial brand “Naturbaby” on the sensory analysis carried out by infants (4-24 months of age).

Methods: Baby food purees were stored at room temperature during one year, analysing viscosity by means of a Brookfield OV-II viscosimeter and, in parallel, the corresponding sensory analysis by infants during the storage period. To this end, a sensory analysis protocol was developed based on hedonic scales, sensory reactions to the puree, and the “Sensory Acceptance by Infants Ratio” (SAIR), which can be used to quantify the sensory preference.

Results: Regarding viscosity, the consistency index (k) and flow behaviour index (n) were calculated for 11 different references of “Naturbaby” purees. Moreover, the effect of autoclaving and storage time on these rheological parameters was also evaluated. All references exhibit a pseudoplastic behaviour and the value of the consistence index (k) slightly increased during storage time. Sensory analysis preference performed by adults showed different trends in comparison to SAIR in most of the references.

Conclusions: Baby food purees must be sensory analyzed by infants to assess the sensory acceptance. Within rheological parameters, the viscosity of the puree can be related to the sensory acceptance by the infants.

Key words: sensory analysis, infants, viscosity, purees Acknowledgments: Torres Quevedo Program cofunded by the European Social Fund.

PO937**CHILD FEEDING ADEQUACY IS NOT INFLUENCED BY EXCLUSIVE BREASTFEEDING DURATION***Y. Goh¹, R. Aryeetey¹*

¹Department of Population, Family and Reproductive Health, University of Ghana, Legon, Accra, Ghana

Background and objectives: Mothers of young children in Ghana believe that breastfeeding exclusively for six months impairs subsequent introduction of other foods. The current study was designed to determine whether feeding adequacy among 9-23 months old children is influenced by duration of exclusive breastfeeding.

Methods: We surveyed 300 mother-infant pairs attending child-welfare-clinic at the University of Ghana Hospital, Accra. Data collected included socio-demographic characteristics, morbidity, breastfeeding history, and maternal practices and perception on child feeding and temperament. Current child feeding was assessed using 24-hour dietary recall. Multiple logistic regression was used to identify independent predictors of child feeding adequacy.

Results: About 66% of children were exclusively breastfed for six months and only 56% were adequately fed in the in the 24 hours preceding the survey. Child feeding adequacy was unrelated to duration of exclusive breastfeeding (OR=0.73; $p = 0.30$). After controlling for child sex, age, and maternal education, the independent determinants of feeding adequacy included recent child morbidity (OR=0.41; $p = 0.03$), number of caregivers who feed child (OR=1.33; $p = 0.03$), and maternal perception that child does not like food (OR=0.25; $p < 0.01$). Child temperament was unrelated to feeding adequacy.

Conclusions: Child feeding adequacy is not affected by duration of exclusive breastfeeding. The study provides evidence to address misperceptions about exclusively breastfeeding for six months.

Key words: exclusive breastfeeding, child, dietary diversity, feeding adequacy.

PO939**IMPACT OF POMEGRANATE AND APRICOT ON TOTAL ANTIOXIDANT AND FREE RADICALS AMONG PREGNANT WOMEN***M. Ismail¹, A. El-Adawi², T. Abo Al Enyn³*

¹College of Agriculture And Veterinary Medicine, Qassim University, Saudi Arabia

²Department of Nutrition and Food Sciences, Faculty of Home Economics, Minufiya Univ. Shibin El Kom, Egypt

³Department of Nutrition and Food Sciences, Faculty of Home Economics, Minufiya Univ. Shibin El Kom, Egypt

Background and objectives: Vegetable and fruits contains considerable amounts of phytochemicals that may reduce free radicals and enhance total antioxidant levels. This study aimed at find out the effect of apricot and pomegranate on total antioxidant and free radicals levels among pregnant women.

Methods: A sample of 48 pregnant women aged 24.7±4.0 years were chosen from rural areas of Minufiya Governorate, Egypt. They were in the fifth 5th month of pregnancy, and classified into four equal groups: control group (CG) did not receive any intervention, pomegranate group (PG) received 150 g of fresh pomegranate daily; apricot group (AG) received 50 g of semi dried apricot daily; and mixture group (MG) received mixture of 75 g pomegranate and 25 g apricot daily. The intervention continued till delivery (>120 consecutive days). Mother body weight and height, hemoglobin, RBCs, PCV, total free radicals, and total antioxidants were determined at baseline and after delivery. Also, newborn weight and length were measured.

Results: the hemoglobin values at baseline of all women were below normal values and ranged from 10.0±0.2 for CG to 10.3±0.5 for AG. However, after dietary intervention it increased significantly by 22.3%, 19.4%, 16.8% among AG, MG, and PG respectively. The total free radicals decreased significantly by 52.1%, 25.3%, and 21.5% among PG, AG, and MG, respectively. Nevertheless, total antioxidants increased significantly by 166.7%, 50.0%, and 51.7% among PG, AG, and MG, respectively. As well as, newborn weight of interventions groups was significantly higher than CG.

Conclusions: Egyptian pomegranate had a favorable effects since it reduce the free radicals and increased total antioxidants.

Key Words: pomegranate, apricot, antioxidant, free radicals, pregnant.

PO940**EARLY INFANT FEEDING PRACTICES IN THE PROMISE-EBF TRIAL: PROMOTION OF EXCLUSIVE BREASTFEEDING BY PEER COUNSELLORS IN THREE COUNTRIES IN AFRICA**

I. Engebretsen^{1,2}, J. Nankunda³, V. Nankabirwa^{4,5}, A. Diallo⁶, L. Fadnes¹, T. Doherty⁷, D. Jackson⁸, E. Ekström⁹, H. Sommerfelt^{1,4}, N. Meda⁶, T. Tylleskär¹, J. Tumwine³

⁴Department of International Public Health, Norwegian Institute of Public Health, Oslo

⁵Mailman School of Public Health, Columbia University, New York, USA

⁶Centre MURAZ, Ministry of Health, Bobo-Dioulasso, Burkina Faso

⁷Health Systems Research Unit, Medical Research Council, Cape Town, South Africa

⁸School of Public Health, University of the Western Cape, Cape Town, South Africa

⁹Department Women's and Children's Health, Uppsala University, Sweden

Background and objectives: Immediate and exclusive initiation of breastfeeding after delivery have been associated with better neonatal survival and child health, and is recommended by WHO. We report early infant feeding practices in the PROMISE-EBF trial.

Methods: The PROMISE-EBF trial was a cluster randomised behaviour change intervention trial on exclusive breastfeeding (EBF) promotion by peer counsellors in Burkina Faso, Uganda and South Africa implemented in the period 2006-2008 among 2579 mother-infant pairs. Counselling started in the last trimester and mothers were offered at least five post-natal visits. Pre-lacteal feeds (defined as any non-breast milk liquid given within the first 3 days), discarding colostrum, and initiation of breastfeeding later than one hour after delivery are presented by trial arm in each country. Prevalence ratios (PR) with 95% confidence intervals (CI) are given.

Results: The prevalence of giving pre-lacteal feeds in the intervention and control arms were: 11% and 37%, PR 0.3(95% CI 0.2-0.6) in Burkina Faso, 13% and 44%, PR 0.3(95% CI 0.2-0.5) in Uganda and 30% and 33%, PR 0.9 (95% CI 0.6-1.3) in South Africa. The prevalence of not giving colostrum were: 8% and 12%, PR 0.7(95% CI 0.3-1.6) in Burkina Faso, 3% and

10%, PR 0.3(95% CI 0.1-0.6) in Uganda and 17% and 16% PR 1.1(95% CI 0.6-2.1) in South Africa. The majority in Burkina Faso (>96%) and roughly half in South Africa initiated breastfeeding after one hour with no statistically significant differences between the groups. In Uganda, the prevalence in the intervention and control groups were: 45% and 59%, PR 0.8 (95% CI 0.7-0.9).

Conclusions: The PROMISE-EBF trial showed behaviour change with less pre-lacteal feeding in Burkina Faso and Uganda. More children received colostrum in Uganda, while no clear behaviour change was seen in South Africa. The high rates of late initiation of breastfeeding is worrisome.

Key words: trial, exclusive breastfeeding, peer-counselling.

PO941**IS NUTRITION IN PREGNANCY ASSOCIATED WITH NEURODEVELOPMENTAL DISORDERS IN OFFSPRING? A SYSTEMATIC REVIEW**

S. Walker¹, N. Micali¹

¹Behavioural And Brain Sciences Unit, UCL Institute of Child Health, London, UK

Background and Objectives: Schizophrenia, ADHD and autism spectrum disorders (ASD) have all been identified as neurodevelopmental disorders but their aetiology remains largely unknown. It is likely that they result from a complex interrelationship of genes and environment. A potential environmental risk for the development of neuropsychiatric disorders, with biological plausibility, is nutrient deficiency during foetal brain development. However, research into nutrition in pregnancy and neurodevelopmental disorders has been limited and the findings often inconsistent. This study aims to review the research to date which has examined the association between pregnancy nutrition and offspring neurodevelopmental outcomes.

Methods: A PubMed search was completed for studies which related to the following groups: pregnancy, nutrients, neurodevelopment, offspring and biological marker. Exclusion criteria were: non-English language, case or animal studies, no biochemical measure of the nutrient; child assessed before 3 years of age, and outcome measure not based on a clinical diagnosis or a standardised assessment of neurodevelopmental disorders. A hand-search was also conducted.

Results: Eighty-one papers were found in the initial search. Sixty-eight were excluded. A hand-search of the references yielded two papers. In total, fifteen studies were included in the review. The fifteen studies investigate the role of prenatal vitamin D (n=4), iron (n=3), folic acid (n=2), essential fatty acids (n=2), vitamin A (n=1), homocysteine (n=1), iodine (n=1), and choline, betaine, dimethylglycine, methionine and

homocysteine (n=1). Neurodevelopmental outcome measures used include a diagnosis of schizophrenia, ADHD or ASD, or positive scores on the SDQ, CBCL or Yale Children's Inventory.

Conclusions: Thirteen (87%) of the studies report a positive association between the level of maternal prenatal nutrient(s) investigated and offspring neurodevelopment. This review suggests that there may be an association between prenatal nutritional status and neurodevelopmental disorders, particularly vitamin D, folate and iron, but further research is needed.

Key words: pregnancy, nutrition, neurodevelopment.

PO942

COMPARISON BETWEEN NUTRITIONAL STATUS, QUALITY OF LIFE, AMOUNT OF SLEEP AND FOOD INTAKE IN OLDER ADULTS OF SANTIAGO AND VIÑA DEL MAR, CHILE

S. Durán¹, S. Reyes², M. Rodríguez³

¹Universidad Autónoma de Chile, Department of Health, Santiago, Chile

²Nutrition and Food Program, University of Chile

³Universidad Santo Tomás, Department of Nutrition and Dietetics, Viña del Mar, Chile

Background and objectives: To the 2010, the elderly population corresponds to over 2 million of people. The food, retirement, socioeconomic status, health status are factors that affect the quality of life of older adults. The aim of this study is to compare the nutritional status by sex, quality of life, amount of sleep and food intake in older adults of Santiago and Viña del Mar, Chile.

Methods: The older adults were assessed with the questionnaires of quality of life of Pender, sleep survey, Epworth scale, food intake and anthropometry.

Results: The sample included 975 nondisabled participants (61.1% female) and the mean age was 71.9 ± 6.8 years. Women had higher body mass index (BMI) and height ($p < 0.001$) than men. With regard to quality of life, women have a better quality of life ($p < 0.001$), nutrition ($p < 0.001$), self-fulfillment ($p < 0.01$), exercise ($p < 0.001$), interpersonal support ($p < 0.01$) but higher stress ($p < 0.001$). There were no differences in the amount of sleep during the week and weekend between both groups, women had lower sleepiness measured by the Epworth Sleepiness Scale ($p < 0.05$). Finally, the men had a dietary deficiency of vitamin B2 and women were deficient in calcium, iron, zinc and vitamin B12.

Conclusions: Women have a better quality of life but poorer nutritional status and food intake.

Key words: elderly, quality of life, food intake, sleep.

PO943

IDENTIFY THE RISK FACTORS OF OVERWEIGHT ADOLESCENTS IN DHAKA CITY

S. Israt^{1,2,3}, S K. Roy^{1,3}, K. Ferdouse^{1,2,3}, K. Jahan^{1,3}, N. Jahan²

¹Bangladesh Breastfeeding Foundation (BBF), Bangladesh

²Department of Food & Nutrition, College of Home Economics, Azimpur, Dhaka, Bangladesh

³Nutrition Foundation of Bangladesh, Bangladesh

Background and objectives: Now-a-days over nutrition remains one of the major public health problems in the developing countries including Bangladesh. Adolescent overweight/obesity both during adolescence and adult life which include increased incidence of coronary artery diseases and hypertension, diabetes, obstructive sleep apnoea, esophageal reflux and gastric emptying disturbances, osteoarthritis and flat feet, psychological dysfunction, self esteem and social isolation, dyslipidaemia and overall increase in morbidity and mortality in later life. Therefore, it is important to identify the factors which are associated with being overweight. The aim of this study is to assess the risk factors of overweight among adolescents (10–19 years) in Dhaka city.

Methods: This case-control study was conducted at three Schools in Dhaka city of Bangladesh. Both adolescent boys and girls aged 10-19 years were selected for the study. Seventy-one overweight adolescent cases and 109 non-overweight controls were selected according to the classification of overweight by WHO.

Results: Overweight girls aged 10-12 years have taken 15% more energy than RDA. Overweight boys aged 12-15 years have taken 5% more energy than RDA, while overweight girls with same age group have taken 15% more energy than RDA. 15-19 years overweight girls have taken 21% more energy than energy. The study showed that overweight adolescents 6.41 ($p < 0.001$) times less likely to do the regular exercise compared to the normal adolescents. About 89% normal weight adolescents played outdoor games, while only 16.9% overweight adolescents played outdoor games.

Conclusions: The study showed that high energy intake was the risk factors, while regular exercise and outdoor games were the protective factors for the overweight among adolescents.

Key Words: nutritional status, energy, food pattern, physical activities, RDA.

PO944**IMPACT OF NUTRITION EDUCATION ON WEIGHT REDUCTION OF OVERWEIGHT AND OBESE ADOLESCENT GIRLS IN DHAKA CITY, BANGLADESH.**

²Department of Food and Nutrition, College of Home Economics, Azimpur, Dhaka, Bangladesh

³Nutrition Foundation of Bangladesh, Bangladesh

Background and objectives: Adolescents overweight/obesity is associated with significant immediate and long-term health problem. It was hypothesized that appropriate nutrition education on overweight/obese adolescent girls can reduce energy intake; increase physical activities. The aim of this study is to reduce excess body weight of the overweight and obese adolescent girls by providing appropriate nutrition education.

Methods: It was a prospective longitudinal study with experimental (intervention) design. This study was conducted in seven schools in Dhaka city. A total of 122 female overweight and obese adolescents were studied in intervention and comparison group. The intervention group received intensive nutrition and health counseling for two months and the comparison group did not receive any intervention. Body mass index (BMI) is a simple index of weight-for-height which was used in classifying overweight and obesity. BMI for age was used to standardize the weight.

Results: After nutrition education, in the intervention group the body weight significantly decreased about 2.21 kg ($p < 0.001$) and in the comparison group the body weight significantly increased about 0.70 kg ($p < 0.001$). The body mass index (BMI) of the intervention group significantly decreased at the end of the study ($p < 0.001$). There was significant decrease in energy intake ($p < 0.001$) as well as decreased in food frequency in the intervention group after intervention period. In the intervention group physical exercise was significantly increased at the end of the study ($p < 0.001$). Nutrition education group significantly reduced the mean duration of computer game, face book using ($p < 0.001$) and watching of TV time ($p < 0.001$) compared to comparison group.

Conclusions: The nutrition intervention was highly effective on weight reduction of overweight/obese adolescent girls. This study finding showed that reduction in body weight, decrease BMI, low food consumption, change in food habits, increase physical activities of overweight/obese adolescent girls certainly possible by intensive nutrition education.

Key Words: nutritional status, BMI, food frequency, physical activities, RDA.

PO945**CLINICAL SIGNIFICANCE OF CHANGES IN ORGANS WEIGHT DUE TO THE RESISTANCE EXERCISE UNDER FASTING**

S. Yamada¹, H. Fujita¹, A. Ohashi¹, A. Ozeki¹, H. Matsumoto¹, E. Kizaki¹

¹Department of Food & Health Sciences, Faculty of Human Life Sciences, Jissen Women's University, Tokyo, Japan

Background and objectives: In this study we have investigated the effect of exercise and nutrition on hypertrophy of skeletal muscle.

Methods: The animal used in the experimental were retired female mice. Exercise was carried out by tenotomy method. Groups were divided into four groups with five animals in each group. After the seventh day, groups of mice that ate a diet were fed for 6 days were bled and were sacrificed under anesthesia. Each plantaris muscle, the soleus muscle, the liver, spleen, kidney, and heart were removed; after that, each weight were measured by the electromagnetic scale. The no-food group began fasting the day after the start of resistance training. After five days, mice were sacrificed in a similar manner; the weight of the organs was measured in a similar manner.

Results: In this experiment, the following findings were revealed. Muscle weight increased by resistance training without the influence of the presence or absence of the meal. Hypertrophy rate was lower in plantaris muscle compared with the soleus muscle. When the meal has been ingested, resistance exercise has been found to affect the heart weight. Regardless of diet, exercise resistance is the average value; statistical difference was not observed. When resistance exercise was performed, the weight of kidney in diet group showed lower values compared to the no food group. Further, even if resistance exercise was not performed, the food group showed a statistically significantly lower value compared to the no food group. The weight of the spleen, regardless of the presence or absence of the resistance exercise, showed a low value without meals. The weight of liver was not observed the effect of the resistance exercise; we also would like to report on clinical significance of changes in organs weight due to the resistance exercise under fasting .

Key words: fasting, muscle hypertrophy, tenotomy, heart.

PO946**EFFECTS OF NUTRITION AND ENDURANCE EXERCISE ON THE DEVELOPMENT OF SKELETAL MUSCLE AND OTHER ORGAN WEIGHT***H. Matsumoto¹, H. Fujita¹, A. Ozeki¹, S. Yamada¹*

¹Department of Food & Health Sciences, Faculty of Human Life Sciences, Jissen Women's University, Tokyo, Japan

Background and objectives: Increase of maximum oxygen uptake depends on the development of cardiorespiratory, an increase of the capillary, and development of the system by increasing mitochondrial aerobic metabolism. As basic research, we have investigated the effect of exercise and nutrition on the form and function of each organ and skeletal muscle for the mouse.

Methods: The animal used in the experiment is a retired male mice. Rotary motion device was used to endurance exercise in mice. Mice were divided into four groups: exercise + meal (A group), no exercise + meal (B group), exercise + no meal (C group), no exercise + no meal (D group). Soleus was collected and weighted on the electronic balance.

Results: As a result of the effects of meal and exercise on soleus muscle weight, the effect of the meal is strongly reflected. Difference is observed statistically compare the plantaris muscle weight of group A and group C, it is believed that the percentage difference is small, the effect of meal not greatly affected. In addition, the weight of the heart was found to be greatly affected by the diet; I'd consider future mechanism for maintaining the heart weight. Furthermore, as well as heart weight, dietary intake reflects greater kidney weight, the effect of the movement was not observed. It was found that the influence of the diet significantly reflects on the weight of the liver and pancreas. Brain weight was not statistically significant difference between all groups. This means that, after the exercise by fasting, skeletal muscle and organ weight is greatly reduced, the effect of the diet was strongly reflected. We would like to examine the effects of diet and exercise on the function of each organ and skeletal muscle compared blood components in each group .

Key words: muscle, exercise, fasting, organ tissue weight.

PO947**EFFECTS OF INTAKE OF ASPARTIC ACID MAGNESIUM (D-MG) ON THE PHYSICAL FITNESS AND BODY COMPOSITION OF HUMAN***H. Fujita¹, H Matumoto¹, A. Ozeki¹, A. Ohashi¹, Y. Nakagawa¹, S. Yamada¹*

¹Department of Food&Health Sciences, Faculty of Human Life Sciences, Jissen Women's University, Tokyo, Japan

Background and objectives: Skeletal muscle atrophy is induced by the imbalance of minerals such as magnesium and calcium in skeletal muscle cells. Muscle atrophy was inhibited by intaking aspartic acid magnesium under inactive model of mouse. In this study, we have examined the effects of the intake of D-Mg on the physical fitness and body composition in female university students.

Methods: 18 women 21-22 years of age were enrolled in Jissen Women's University. Subjects were divided into three groups, each group was six and the D-Mg intake group, placebo intake group, and control group. Intake period is 91 days. And intake was (150 mg total) 3 tablets a day. Physical fitness and body composition were measured before and after ingestion of D-Mg. Furthermore, we investigated the (Ver.3.0) FFQg food intake frequency questionnaire (Ver.3.0). T-test was used to compare mean values between before and after ingestion. Critical ratio was less than 5%.

Results: A result of the investigation, magnesium intake was 302 mg in D-Mg intake group, 204 mg in placebo group and 171 mg in control group. There was a significant difference in the intake D-Mg group and the control group. In addition, positive correlation was found in Mg intake and the amount of change skeletal muscle before and after the study. Before and after the intake, the results of compared of the body composition in each group. Statistically significant increases were observed in skeletal muscle weight and amount of extracellular fluid. Weak positive correlation was observed between the grip and the rate of change of skeletal muscle mass in placebo group and in D-Mg group.

Conclusions: From these experimental results, D-Mg was found to increase the amount of skeletal muscle, it was not clear about the relationship between the muscle strength.

Key words: aspartic acid magnesium, skeletal muscle mass, university students, body composition.

PO948**SUPPLEMENTATION B VITAMINS IMPROVES COGNITIVE FUNCTION IN THE MIDDLE-AGED AND ELDERLY WITH HYPERHOMOCYSTEINEMIA**

Y. Jiang¹, D. Cheng^{1,2}, H. Kong^{1,2}, W. Pang¹, H. Yang¹, S. Sun¹, C. Huang²

¹Institute of Health & Environmental Medicine, Tianjin, China

²Sichuan University, China

Background and objectives: Recent observations showed that supplementation of B vitamins effectively lowers homocysteine levels in elderly persons with hyperhomocysteinemia. But whether cognitive impairment can be improved simultaneously is still seldom studied. The aim of this study is to determine if folic acid, vitamin B6, vitamin B12 containing supplement improves cognitive function and lowers homocysteine in hyperhomocysteinemic middle aged and elderly patients.

Methods: A total of 662 volunteers from five communities and two homes for the elderly in Tianjin city, China, were recruited. 104 Eligible participants with hyperhomocysteinemia were screened and assigned to two groups according to matched age and basic BCAT scores. 57 persons were included in the intervention group (800 µg /day of folate, with 10 mg of vitamin B6 and 25 µg of vitamin B12), and 47 patients in the placebo group. The treatment period was 14 weeks. The cognitive function as evaluated by Basic Cognitive Aptitude Tests (BCAT). The serum total homocysteine concentrations were measured before and after intervention.

Results: After B vitamins supplementation, cognitive function improved in general and four cognition items scores (digit copy, Chinese character rotation, recall answer of mental arithmetic and recognition of meaningless figures as compared with those in control group ($p < 0.05$). Serum total homocysteine concentration was significantly decreased that in control group ($p < 0.05$). While serum concentrations of folate was significantly increased in the intervention group than those in control group ($p < 0.05$). No significant changes of above parameters were observed in control group before and after intervention.

Conclusions: The supplementation of folate, vitamin B6 and vitamin B12 in middle aged and elderly patients with hyperhomocysteinemia improves their cognitive function partly and reduces serum total homocysteine levels.

Key words: B vitamins, hyperhomocysteinemia, cognition, the middle-aged and elderly, homocysteine.

PO949**ANEMIA STATUS OF INFANTS 4-6 MONTHS OLD IN A RESOURCE-CONSTRAINED SETTING**

J. Njenga¹, A. Mwangi¹, W. Kogi-Makau¹

¹Department of Food Science, Nutrition & Technology, University of Nairobi, Kenya

Background and objectives: It is often assumed that healthy full-term infants have adequate iron stores and hemoglobin that provides recyclable iron. Many infants <6 months in less-developed countries are iron-deficient. Yet, WHO/UNICEF recommends exclusive breastfeeding for the first 6 months while use of fortified complementary foods/vitamins-mineral supplements is only recommended after 6 months in breastfed children (PAHO/WHO, 2004). Iron supplementation in iron-deficient Honduran infants (4-6 months) showed an increase in hemoglobin (Domellof et al (2001). There is need to re-think the current supplementation programs targeting infants >6 months. The aim of this study is to determine anemia status among infants aged 4-6 months prior to a supplementation study.

Methods: Setting: Kenyan South Coast (INSTAPA Project). Hemoglobin (Hb) was measured in 219 infants (4.5-6 months old) using venipuncture blood samples (HemoCue Hb 301 System). Infants' anemia status was defined as Hb concentration <110 g/l (race-adjusted). Anemia status was further categorized as severe (Hb <70g/l), moderate (>70 - <90g/l), and mild (90 - <110g/l), respectively.

Results: Mean age was 5.64 months (SD 0.211). 79% of infants (n=173) were anemic. Overall, 82% (n=143) and 16% (n=29) had mild and moderate anemia, respectively. WHO/UNICEF recommendation on exclusive breastfeeding assumes that iron stores are adequate for the first 6 months. These findings concur with Domellof et al (2001) that showed Honduran infants <6 months were iron-deficient.

Conclusions: With 1:4 infants being anemic, the data strongly suggests a re-look at the iron status of children <6 months, so as to adjust existing guidelines on exclusive breastfeeding for the first six months. The high level of anemia begs the question whether caregivers are receiving correct contextual advice. 1 Dept. Food Science, Nutrition & Technology, University of Nairobi, Kenya 1E-mail contact: jnyathegi@yahoo.com.

PO950**DIETARY INTAKE AND NUTRITION KNOWLEDGE OF TURKISH NATIONAL FEMALE BOXING TEAM***E D. Ciracioglu¹, G. Ersoy², H. Yardimci¹*¹Nutrition and Dietetics, Ankara University, Ankara, Turkey²Nutrition and Dietetics, Hacettepe University, Ankara, Turkey

Background and objectives: A well planned diet is crucial for elite athletes and especially for female boxers who are known to try unhealthy methods of losing weight before the matches to compete in a lower weight category. This study aims to determine nutrition knowledge and dietary intake of national female boxing team.

Methods: The study conducted with 14 national female boxers in Turkey. Data collection was made by a 2 part questionnaire, that involves questions about nutrition knowledge in first part, and a 24 hour food consumption recall form in the second part. The top score participants can score in the first part was 125. Data were analyzed by SPSS program.

Results: The mean age of athletes was 26.4 ± 3.8 years, mean weight was 62.3 ± 11.1 kg, and mean BMI was 21.9 ± 2.7 kg/m². The mean score of nutrition knowledge was 112 ± 9.4 . The mean amount of daily water consumption was 1635.7 ± 589 ml and most common drink besides water (64.3%) was tea (21.4%). 71.4% of the athletes did not use any dietary supplements, 14.3% of the athletes used creatine and glutamine and 14.3% of them used multivitamin daily. 50.0% of the athletes stated they consumed a hypocaloric diet and 35.7% stated they dehydrated themselves to weigh less before the matches. While athletes' daily diet compared to RDA values; energy, protein, vitamins A, D, E, K, B1, B2, B6, B12, calcium, phosphorus, iron and folate were lower than recommended. Niacin, vitamin C and dietary fiber met the recommendation.

Conclusions: Turkish national female boxers had an adequate nutrition knowledge but inadequate dietary intake. Dietary habits of the athletes should be observed closely and have them have a more adequate diet of energy, protein and essential vitamins and minerals.

Key Words: sports nutrition, boxing, female athlete, Turkey.

PO951**MICRONUTRIENT DEFICIENCY AMONG MONGOLIAN CHILDREN***B. Jamiyan¹, G. Bat¹, T.S. Uush¹, B. Norov¹, W. Bradley A²*¹National Center of Public Health, Ulaanbaatar, Mongolia²Department of Global Health, Rollings School of Public Health, Emory University, Atlanta, Georgia, USA

Background and objectives: The Fourth National Nutrition Survey aimed at evaluating impact of previous nutrition interventions and identifying next steps to improve maternal and child nutrition. One of the objectives of the survey was to assess the current micronutrient status of under five children.

Methods: In total, 400 households were randomly selected from each of 4 regions and capital city. Interviews, anthropometric measurements, clinical examinations and laboratory testing methods were used.

Results: Overall, 28.5% (95% CI 24.2-33.2) of children 2-59 months of age had anemia; 0.4% (95% CI 0.1-1.3) had severe anemia, 11.3% (95% CI 8.2-15.4) had moderate anemia, and 16.7% (95% CI 13.3-20.9) had mild anemia. Overall, 20.9% of anemic children and 21.6% of non-anemia children had iron deficiency. The prevalence of iron deficiency anemia in children under two years was 6.3%, which was 1.6 times more than the prevalence in 24-59 month old children (4.2%) (RR=1.6 [1.6-6.2], $\chi^2=5.8$, $P=0.01$). The prevalence of rickets was 55.0% (95% CI 49.5-60.5) in the surveyed children under five years old. Serum level of 25-hydroxy-vitamin D (25[OH]D) was measured in 524 children aged 6-59 months; 21.8% (95% CI 16.4-28.4) had vitamin D deficiency, and 20.6% (95% CI 16.8-25.0) had low vitamin D reserve. 32.4% (95% CI 26.6-38.7) had any vitamin A deficiency defined by serum RBP level, with vitamin A deficiency had a moderate level of deficiency. Vitamin A deficiencies in children 6-23 months of age was 18.3 (95% CI 13.2-24.7) and in children aged 24-59 months 41.6 (95% CI 32.4-51.5).

Conclusions: Anemia is moderately prevalent among young children in Mongolia, especially it affects children under two years, persisting in high prevalence among these age group. The prevalence of vitamin D and vitamin A deficiencies children under five is high. Source of funding: The survey was funded by WHO, UNICEF and WV-Mongolia.

Key words: micronutrient deficiency, under five children, anemia, rickets, vitamin A deficiency.

PO952**INTRODUCTION OF SOLID FOODS TO INFANTS IN THE MALDIVES***R. Abdul Raheem¹, C W. Binns¹*¹Curtin University, Australia

Background and objectives: For optimal health and development the WHO recommends exclusive breastfeeding until six months of age followed by the introduction of appropriate complementary foods while breastfeeding continues. The objective was to document the age and types of solid foods that are given to infants in the Maldives

Methods: A cohort of 458 mothers was recruited at the antenatal clinical at the two main maternity facilities on the main island of Male'. Written consent was obtained from mothers before the first interview. Mothers were interviewed 'face to face' at 36 weeks of gestation and again at 1, 3 and 6 months after birth. The questionnaires included demographic information about parents and infant feeding including, breastfeeding initiation and duration, introduction of different foods, and the Edinburgh Postnatal Depression Scale (EPDS). The questionnaires were translated into Dhivehi and pretested before use. Ethics approval was obtained from the National Research Committee of the Maldives and Curtin University Human Research Ethics Committee.

Results: The mean age at which solid foods were introduced to infants was 5.49 ± 0.74 months (95% CI). The most common types of first solid foods given to infants were fruits (41.6%) and cereals (30.0%). 7.0% of mothers have given yoghurt as the first food to their infants. The 'any breastfeeding' rates at 1, 3 and 6 months were 98.9 %, 95.4 %, and 90.7%. Full breastfeeding rates at 1, 3, and six months were 67.6%, 52.9%, and 29.7%. Exclusive breastfeeding rates at 1, 3 and 6 months were 26.9%, 17.3%, and 7.5%.

Conclusions: Many mothers in the Maldives introduced solid foods to their infants before six months. There is a need for more education for parents on appropriate nutritious complementary foods. .

Key words: solid food, breastfeeding, fruits, cereals, yoghurt.

PO953**APPROPRIATE FREQUENCY OF ANTENATAL VISITS AND SUPPORT FROM HUSBAND IS ASSOCIATED WITH BETTER COMPLIANCE WITH MATERNAL IRON SUPPLEMENTATION IN INDONESIA***L. Wiradnyani¹, H. Khusun¹, A. Shankar²*¹Southeast Asian Minister of Education Organization-Regional Center For Food And Nutrition, University of Indonesia, Indonesia²Harvard School of Public Health, Boston, Massachusetts, USA

Background and objectives: The overall impact of large-scale maternal iron supplementation program has been limited and its effectiveness is questioned. Poor compliance of pregnant women with iron tablets consumption is one of major factors limiting the impact. This study aimed to identify factors associated with compliance of iron tablets during pregnancy in Indonesia.

Methods: The study used pooled data from the 2002/2003 and 2007 Indonesian Demographic and Health Surveys involving 16938 mothers who reported receiving or buying iron tablets during the most recent pregnancy in the last 5 years. The main outcome was compliance with taking the prescribed dose of minimally 90 iron tablets during pregnancy. Multivariate logistic regression was used to examine relationship between explanatory factors and compliance. Regression analysis was adjusted by the current age of the child from the recalled pregnancy to control for recall bias.

Results: In total, only one-third mothers consumed minimally 90 iron tablets as recommended. The odds of compliance was higher for mothers who: (a) were amongst the richest socioeconomic status (adjusted OR (aOR):1.81; 95% CI:1.57-2.08), (b) perceived no problem with access to health services (aOR:1.30; 95% CI:1.20-1.41), (c) received support from husband, i.e husband accompanied the ANC visits and had discussions with anyone on delivery-related issues (aOR:1.49; 95% CI:1.32-1.69), (d) had appropriate frequency of ANC visits (aOR:1.75; 95% CI:1.62-1.89). Mothers with their second pregnancy or more had less compliance than those with their first pregnancy (aOR:0.85; 95% CI:0.79-0.93). Except for the richest fifth quintile, household wealth quintile was not associated with compliance. Maternal education was also associated with compliance but this effect was completely explained by husband's support and appropriate frequency of ANC visits.

Conclusions: Appropriate frequency of ANC visits and support from husband increased the likelihood of pregnant women to comply with the iron tablets supplementation program.

Key words: compliance, maternal iron supplementation, Indonesia.

PO954**MILK AND DAIRY PRODUCTS: IMPLEMENTATION OF THE PROJECT APPROACH WITH SIX YEAR OLD CHILDREN**

N. Aktas¹, D.E. Angin², N. Sanlier³

¹Department of Nutrition Education, University of Selcuk, Konya, Turkey

²Department of Child Development, University of Selcuk, Konya, Turkey

³Department of Nutrition and Dietetics, University of Gazi, Ankara, Turkey

Background and objectives: It is necessary to teach kindergarteners how milk and dairy products (MaDP) provide strong bones and healthy bodies. The kindergarten where children are spending time is an effective setting for learning nutrition and increasing preference for foods (1). The aim of this study is to strengthen awareness, knowledge and consumption of MaDP among six year old children with project approach.

Methods: This study is a project based intervention which presents a project based model implementation about MaDP. The study group was formed with (n=15) six years old children in kindergarten in Konya. With the aim of assessing project study, a hedonic scale prepared by researchers to determine MaDP consumptions with faces to represent "I like", "just OK," and "I do not like", was applied to the children both at the beginning and end of the study. Moreover, children were asked to draw pictures related to their own knowledge and awareness. According to Helm and Katz (2001), getting started, developing and concluding of the project phases were practiced by classroom teacher.

Results: It was not only observed that the choices of children to consumption MaDP enjoying increased, there were also positive differences between the pictures children drew at the beginning and end of the projects. The teacher reported that children who participated the project gained effective experience through cooperating within the group.

Conclusions: This project was successful in encouraging children to provide a wealth of knowledge and developed positive tendency toward MaDP.

Key words: project approach, milk, dairy, kindergarten. 1. Plum, M. J. (1997) Nutrition Knowledge Assessment of Preschool Children. Virginia Polytechnic Institute and State University. Master of Science. Blacksburg, Virginia 2. Helm, J. H. & Katz, L. G. (2001). Young Investigators. The Project Approach in the Early Years. NewYork: Teacher College Press.

PO955**VISCERAL ADIPOSITY AND ITS RELATIONSHIP WITH ANTHROPOMETRIC AND BIOCHEMICAL PARAMETERS IN POST-PUBERTAL OBESE ADOLESCENTS**

G. Possa¹, L. C. dos Santos², H M. Lederman³, M A Z. Passos¹, M. Fisberg¹, M T. de Mello⁴, A R. Dâmaso⁵, I P. Cintra¹

⁴Departamento de Psicobiologia, Universidade Federal de São Paulo, Brasil

⁵Departamento de Ciências da Saúde, Universidade Federal de São Paulo, São Paulo

Background and objectives: Visceral adipose-tissue accumulation is linked to insulin resistance, type 2 diabetes, hypertension and dyslipidemia in adults, besides being a determinant factor to increase nonalcoholic fatty liver disease (NAFLD) prevalence in obese adolescents. The aim of this study was to evaluate the relationship of visceral adiposity with anthropometric and biochemical parameters in post-pubertal obese adolescents.

Methods: Cross-sectional study with 73 post-pubertal obese adolescents: 24 boys and 49 girls. Body composition was measured by plethysmography using the BOD POD body composition system. Visceral and subcutaneous adiposity was analyzed by ultrasound. The biochemical evaluation comprised triglycerides, serum total cholesterol, LDL-cholesterol, HDL-cholesterol, plasma glucose and insulin. Insulin resistance was calculated by means of the homeostasis model assessment of insulin resistance (HOMA-IR). Participants were distributed into two groups according to visceral fat cut-off points (<3.78 cm and > 3.78 cm). A value > 3.78 cm for visceral fat indicates risk factor to develop NAFLD for Brazilian obese adolescents. After, correlation between variables of interest was assessed by using Pearson's according to gender.

Results: The prevalence of abnormal biochemical levels was high among adolescents. Hyperinsulinemia and insulin resistance were observed in 55 and 61% of adolescents, respectively. 40% of the adolescents presented risk factor to develop NAFLD. Adolescents with a value > 3.78 cm for visceral fat presented mean body mass index (BMI), abdominal circumference, triacylglycerol, insulin and HOMA-IR significantly higher than adolescents with <3.78 cm. For boys, the best correlation coefficient of visceral fat was found with the BMI ($r = 0.76$, $p < 0.001$), while for girls it was the insulin levels ($r = 0.49$, $p < 0.005$).

Conclusions: Visceral adiposity was significantly associated with BMI, abdominal circumference, triacylglycerol, insulin and HOMA-IR, demonstrating the clinical importance of visceral adipose tissue accumulation during adolescence.

Key words: visceral adipose tissue, obesity, adolescents.

PO956

INFLUENCE OF D-MG AND D-ZN INTAKE ON THE ATROGIN-1 GENE EXPRESSION IN INACTIVITY MODEL OF MOUSE

A. Ozeki¹, K Yamamoto¹, K. Nagasawa¹, Y. Matumoto¹, H. Matumoto¹, H. Fujita¹, E. Kizaki¹, A. Oohashi¹, Y. Shigeru¹

¹Jissen Women's University, Tokyo, Japan

Background and objectives: Muscle atrophy results primarily from accelerated protein degradation and is associated with increased expression of two muscle specific ubiquitin ligases (atrogin1 and MuRF1). Recently, we demonstrated an aspartic acid-Mg(D-Mg) and an aspartic acid-Zn (D-Zn) intake inhibited muscle atrophy by tail suspension in mice. Then, we examined the atrogin1 in muscle inhibited muscle atrophy by D-Mg and D-Zn intake.

Methods: Mice were purchased from SLC Japan. They were individually housed in stainless steel cages in a temperature, humidity and light controlled room (24°C, 60%, 12 light /dark cycle). All mice were fed the MF for 7days. The mice were divided into six groups consisting of given a control (water) group, suspension (water+suspension) group, the D-Mg drink (72 mg/l in water)group, the D-Mg+suspension group, the D-Zn drink (1.1 mg/l in water) and the D-Zn+suspension group. After the experiment, all mice were sacrificed by under anesthesia. Its skeletal muscle was collected and weighted on the Electronic balance and stored at 80°C until analysis. We used miRNA easy Mini Kit, cDNA Archive kit, and real-time PCR of ABI 7000 Sequence Detector System to analyze changes in mRNA from skeletal muscle. Specific assays on demand for atrogin1 were from Applied Biosystems. While the soleus muscle weight decreased significantly in W group which was induced muscle atrophy as compared with W group which was not induced muscle atrophy, the soleus muscle weight in the D-Mg and D-Zn intake group which was induced muscle atrophy did not decrease. The D-Mg and D-Zn intake inhibited the atrophy of skeletal muscles by tail suspension like the former report. Atrogin-1 gene expression in soleus muscle was significantly reduced in the D-Mg and D-Zn intake group which was induced muscle atrophy as compared with W group which was induced muscle atrophy. These results suggested D-Mg and D-Zn intake inhibit protein degradation process in soleus muscle.

Key words: muscle atrophy, atrogin-1.

PO957

NUTRITIONAL STATUS OF CHILDREN AND ADOLESCENTS IN GUANGXI, 1989-2009

Z. Fang¹, Z. Tang¹, H. Yang¹, Q. Wang¹, L. Zhao¹, X. Liu¹, Z. Li¹, Y. Chen¹

¹Guangxi Zhuang Autonomous Region Center For Disease Control And Prevention, Nanning, China

Background and objectives: To understand the secular trends of growth and development among children and adolescents in Guangxi.

Methods: A multistage random cluster sampling method was used to draw the sample for the China Health and Nutrition Survey in Guangxi. A subsample of 2319 children and adolescents aged 2-18 years old was used in this study. Anthropometric data were measured with standard protocols. WHO/NCHS (2000) reference of Z scores was used to evaluate the children's nutrition status. Multivariate logistic regression models were used to examine the association between risk factors and malnutrition.

Results: Stunting decreased from 35.6% in 1989 to 7.5% in 2009 and underweight from 30.0% to 15.5% among children and adolescents during the same time period. Overweight and obesity doubled from 1.3% in 1989 to 2.7% in 2009 but still at very low level. Multivariate logistic regression showed that energy-protein deficiency was still the major risk factor of stunting and underweight, while excessive fat intake contributed to the increase in overweight and obesity.

Conclusions: Children and adolescents face the dual challenge of malnutrition and overnutrition in Guangxi. Malnutrition is still the major health concern among children but rapid increase in overweight and obesity should not be overlooked.

Key words: children and adolescents, stunting, underweight, overweight and obesity.

PO958

FEEDING PRACTICES AND ANTHROPOMETRIC STATUS IN CHILDREN (6 - 24 MONTHS) IN THE TOLON-KUMBUNGU DISTRICT OF NORTHERN GHANA

P. Aryee¹, T. Apenteng¹, F. Naamwindem¹

¹Community Nutrition Department, University For Development Studies, Tamale, Ghana

Background and objectives: Sub-optimal breastfeeding practice during the first half year of life is an important risk factor for childhood morbidity and mortality that are compounded by inappropriate complementary feeding. This study

was aimed at assessing the relationship between child feeding practices and anthropometric status in the Northern Region of Ghana.

Methods: This cross sectional study targeted mothers with children 6 to 24 months old in the Tolon-Kumbungu district of Northern Ghana. Child feeding practices were assessed and anthropometric measurements of weights and heights/lengths of children taken with standardized equipment. WHO growth references were used to derive indicators for stunting (H/A), wasting (W/H) and underweight (W/A), respectively.

Results: All 240 children in the study were still being breastfed. However, 64.2% were put to breast within an hour after birth and only 48.3% were exclusive breastfed in the first six months of life. 91.7% were breastfed on demand but 25% ≥ 5 times a day. Only 79.2% were receiving complementary foods (CF). Of these, 28.4% and 37.9% were started before and after 6 months respectively. Additionally, 40.8% received CF ≥ 2 a day. Prevalence for underweight was 40.0%, stunting was 28.4%, whilst wasting was 16.8%. Children breastfed ≥ 5 times a day were more likely to be underweight, stunted or wasted. Those exclusively breastfed were less likely to be wasted. Children, who were not taking CF were significantly more than 4 times, 3 times and 8 times at risk of being underweight ($p = 0.006$), stunted ($p = 0.041$) or wasted ($p = 0.016$), respectively. Children who were timely given CF were less likely to be underweight or stunted.

Conclusions: Suboptimal breastfeeding practices in infants may be compounded by inappropriate complementary feeding in contributing to the poor nutritional status of children in Northern Ghana.

Key words: breastfeeding, complementary feeding, nutritional status, children.

PO960

CHARACTERISTICS OF BREAKFAST CONSUMPTION AMONG PRIMARY SCHOOL CHILDREN AT UNIVERSITY BASIC SCHOOL, LEGON, GHANA

G. Osei Owusu¹, E. Colecraft¹

¹Department of Nutrition And Food Science, University of Ghana, Ghana

Background and objectives: Consumption of breakfast contributes to the total daily energy and nutrient intake of school age children and it is associated with improved academic performance. However, there is limited information on the breakfast habits of Ghanaian school children. The study objective was to assess the characteristics of breakfast consumption among primary school children at the University Basic School.

Methods: A questionnaire-based cross-sectional study design was used to study primary school pupils aged 8-11 years ($n=180$) at the University Basic School, Legon. Information

was collected on the sociodemographic characteristics of the children. Additionally, the children were asked to recall all foods consumed for breakfast in the past three school days. The Chi Square statistic was used to assess sociodemographic differences between children who ate breakfast daily and those who ate breakfast less regularly.

Results: About 67.3% of the primary school children consumed breakfast daily. Factors associated with regular breakfast consumption among the children included being male ($p = 0.039$), and having a mother with salaried employment ($p = 0.013$). About 48.9% of the school children consumed cocoa beverages which were accompanied with milk, bread or egg. Foods eaten for breakfast contributed approximately one-fourth of the children's RDA for energy and more than one-third of their RDA for protein.

Conclusions: About one-third of the children did not consume breakfast. Among children who regularly consumed breakfast, it contributed significantly to their energy and nutrient intakes. Efforts to encourage regular consumption of breakfast may contribute to improved quality of diet among school-aged children in Ghana.

Key words: breakfast, school children, sociodemographic characteristics.

PO961

BIOCHEMICAL INDICES OF INFANTS FED LEGUME-CEREAL COMPLEMENTARY FOOD FORTIFIED WITH MANGO POWDER, FISH-BONE POWDER AND PALM OIL

N.O. Onuoha¹, H.N. Ene-Obong²

¹University of Nigeria, Nsukka, Nigeria

²Department of Biochemistry, University of Calabar, Calabar, Nigeria

Background and objectives: There is a need to improve the micronutrient content of cereal:legume gruels recommended for use as complementary foods for infants in developing countries. This study investigated the biochemical indices of children aged 6-24 months fed a cereal-legume gruels fortified with fish bone powder (FBP), mango powder (MP) and palm oil (PO).

Methods: Four legume:cereal blends (70:30) made up of fermented maize and sorghum, roasted soybean, and dehulled cowpea were developed each providing 10% protein; maize-soybean, maize-cowpea, sorghum-soybean and sorghum-cowpea. These were fortified with PO, FBP, and MP and subjected to nutritional, microbiological and organoleptic evaluation. Fortified maize-soybean blend (with the best nutritive attributes), Nutrend (positive control) and unfortified maize-soybean blend (negative control) were fed to 24 children divided into

three groups of eight for 4 weeks. Food intakes were recorded and effects of the diets on biochemical parameters of the children were determined. Results obtained were compared with appropriate standards, using descriptive statistics.

Results: The protein, zinc and vitamin A contents (per 100 g edible portion) of the blends were well above the recommended values for complementary food, while calcium and iron were lower. The test diet elicited significant increases ($p < 0.05$) in the blood levels of zinc, β -carotene, vitamin A and hemoglobin at the end of feeding. For Nutrend the increase was significant ($p < 0.05$) only for vitamin A. There were no differences in the values obtained for the unfortified diet. Blood calcium levels decreased for all the diets ($p > 0.05$).

Conclusions: Fish bone was not effective in improving the calcium intake of the infants. Mango powder and palm oil improved zinc and vitamin A intakes. The inclusion of mango powder may have improved the availability of the iron present in the test diet.

Key words: mango/palm oil/ fish bone-fortified, complementary foods, legume:cereal blend, biochemical indices, infants.

PO962

ANTHROPOLOGY AND NUTRITION: EVALUATION OF THE NUTRITIONAL STATUS IN SEGOVIA'S CHILD POPULATION (3 TO 6 YEARS OLD)

E. García Hernández¹, C. J. García García², E. González-Jiménez³, M. T. Villar Espejo⁴, T. García Hernández⁵, B. Ansell⁵

¹Laboratory of Anthropology, University of Granada, Granada, Spain

²Department of Legal Medicine, Toxicology and Physical Anthropology, Faculty of Medicine, University of Granada, Granada, Spain

³Department of Nursing, Faculty of Nursing, University of Granada, Melilla, Spain

⁴El Greco Health Centre, Primary Care, Madrid, Spain

⁵Zaragoza, Spain

Background and objectives: In the last two decades, the prevalence of obesity among children has highly increased all over the world, even in developing countries. Biological, genetic, social and cultural influences affect in the origin and development of malnutrition (over and undernutrition). Therefore, the subject must be analyzed from a holistic perspective. Since food habits develop in early stages of life, research on early childhood makes possible the early detection of nutritional problems and also makes prevention easy. The aim of the present

study is to assess the nutritional status in 3 to 6 year-old school-children from Segovia (Spain) using standard anthropometric methods, as well as to find out their food and physical activity habits by the analysis of demographic, social, economic and behavioral variables.

Methods: This has been an observational, descriptive, analytical, transversal and retrospective study. The sample was made up of 144 children from a wide range of ethnic backgrounds with schooling in three different Public Schools in the town of Segovia during 2011-2012 academic year.

Results: Global prevalence of overnutrition was 17.4% (13.9% overweight and 3.5% obesity) and the prevalence of underweight was 8.3%. A higher prevalence of malnutrition was registered in female groups and there were no statistically significant differences ($p < 0.05$) between ethnic background and nutritional status, except for the 4 year-old group. Data reveal statistically significant differences ($p = 0.000$) between real nutritional status calculated by the Body Mass Index (BMI) and the nutritional status perceived by the parents.

Conclusions: In general terms, diet consumed by the sample studied was rich in proteins and fat, and low in carbohydrates, fruits and vegetables.

Key words: nutritional status, malnutrition, obesity, early childhood, standard anthropometric methods.

PO963

AGREEMENT AMONG DIFFERENT BMI CUT-OFFS PROPOSED FOR THE DIAGNOSIS OF OVERWEIGHT IN ELDERLY

M. L. Rossi^{1,2}, S. Dupraz¹, M. Rolón¹, L. Piaggio¹, V. Aragónes y Oroz¹

¹Nutrition Program, Ministry of Health, Buenos Aires City, Argentina

Background and objectives: There are different Body Mass Index (BMI) cutoffs for elderly in terms of changes in body composition. In elderly population attending public primary health care of the City of Buenos Aires, describe: - Nutritional Status by BMI. - Measure agreement among BMI cut-offs proposed by bibliography.

Methods: Descriptive. Transversal. Structured survey. Convenience sample over 60 yrs, both sexes, attendants to public primary care October 1-5, 2012. Variable: BMI (WHO 1998, and cut-offs proposed by Bray1988, NSI1993 and NHANESIII 2000). Data collection: Excel 2007. Statistical Analysis by SPSS 15.0. Inter-rater agreement by Kappa coefficient, p value < 0.05 .

Results: $n = 1144$. Mean age = 69.95 ± 7.69 yrs. Male(M) = 30.2% / Female(F) = 69.8%. $F = 70, 18 \pm 7, 62$ yrs, BMI = 29.68 ± 5.87 kg/m². $M = 69.40 \pm 7.83$ yrs. BMI = 28.63 ± 4.86 kg/m².

Overweight (OW): F = 77% (WHO OW + obesity (OB); 41.4% (NHANESIII), 50.3% (Bray1988), 63.5% (NSI1993). M = 78.5% (WHO OW + OB); 47.2% (NHANESIII), 43.2% (Bray), 60.6% (NSI). Slight- fair inter-rater agreement among WHO with the rest of cut-offs proposed ($p < 0.000$). The highest coefficient was with NSI ($\kappa = 0.382$, $p < 0.000$). Substantial inter-agreement between Bray, NSI and NHANES III ($\kappa = 0.742$, 0.703 , respectively) and moderate between 0.576 ($p < 0.000$ in all cases). Dichotomise diagnosis (OW YES/NO): moderate agreement (WHO to Bray $\kappa = 0.426$, to NSI $\kappa = 0.655$, to NHANESIII $\kappa = 0.362$, $p < 0.000$ in all cases). Among the latter three, agreement remained substantial.

Conclusions: It is fundamental considering the high prevalence of overweight by all the bibliographic references consulted in elderly population seeking public health care. It would be important to define adequate cutoffs to assess the nutritional status in this group of age.

Key words: elderly, BMI, overweight.

PO964

ANTHROPOMETRIC ASSESSMENT, RISK FACTORS AND PRESENCE OF CHRONIC DISEASES IN ELDERLY PEOPLE ATTENDING PUBLIC PRIMARY CARE .

M L. Rossi¹, S. Dupraz¹, M. Rolón¹, L. Piaggio¹, V. Argües y Oroz¹

¹Nutrition Program, Ministry of Health, Buenos Aires City, Argentina

Background and objectives: Our city is characterized by an aging population similar to developed countries. Little information about nutritional status in this age group is available. The trend shows a high prevalence of chronic diseases risk factors such as overweight and a low level of physical activity. Objectives: In elderly population attending public primary health care of the City of Buenos Aires, describe: the nutritional status by anthropometric measurements, the presence of chronic diseases and physical activity.

Methods: Descriptive. Transversal. Structured survey. Convenience sample over 60 yrs, October 1-5, 2012. Variables: BMI, waist circumference (WC), chronic disease (CD): (hypertension (HTN), dyslipidemia (DL), diabetes (DBT)) by reference of the respondent; and physical activity (PA). Frequency counts and measures of central tendency. Confidence interval (CI) of 95%. Data collection: Excel 2007. Analysis: SPSS 15.0.

Results: n = 1144. Mean age = 69.95 ± 7.69 yrs. Male (M) = 30.2%, Female (F) = 69.8%. F = 70.18 ± 7 , 62 yrs, BMI = 29.68 ± 5.87 kg/m². M = 69.40 ± 7.83 yrs. BMI = 28.63 ± 4.86 kg/m². Overweight (OW): F = 77% (OW + obesity (OB)) M = 78.5% (OW + OB). WC: (M) 100.93 ± 14.97 cm. (CI = 99.33-

102.53cm), 44.1% greatly increased cardiometabolic risk (WC > 102). (F) 94.90 ± 14.54 cm (CI = 93.88 - 95.93 cm) 64.6% greatly increased cardiometabolic risk (WC > 88). CD: HTA (M) = 70.4%, (F) = 66.8%. DL (M) = 42.6% (F) = 45.2%. DBT (M) = 33.6%, (F) = 25.3%. PA: M = 61.7%, F = 59.8%. Walking was the most frequent.

Conclusions: Consistent data with global trends. This should be considered to focus professional attention of attendants to primary level of public health care.

Key words: elderly, BMI, cardiometabolic risk, chronic diseases.

PO965

UNSKILLED WORKING MOTHERS ARE AT GREATER RISK FOR POOR CHILD PROTEIN INTAKE AND DIETARY DIVERSITY: AN INDONESIAN DHS 2002-2007 ANALYSIS

A. Kekalih^{1,2}, J. Februhartanty², M. Mansyur¹, A J. Shankar³

¹Community Medicine Department Medical Faculty, Universitas Indonesia, Jakarta Indonesia

²South East Asia Ministry of Education Organization Regional Center for Food and Nutrition (SEAMEO RECFON), Universitas Indonesia, Jakarta, Indonesia

³Harvard School of Public Health, Harvard University, Boston, USA

Background and objectives: Urbanization and economic growth in low-middle income countries has led to an increase in working mothers. In Indonesia, 40% of these working mothers are typically involved in unskilled labor (eg. agricultural and informal workers). They may represent the group of care-takers most vulnerable to engage in poor feeding practices, due to their socioeconomic status and associated working conditions, such as less time for infant food preparation and limited capacity for childcare. In order to appropriately target intervention programs for child feeding, it is important to assess the role of income, education and associated factors on the ability of different types of working mothers to practice appropriate infant feeding.

Methods: This study used pooled data from the Indonesia Demographic Health Survey 2002 and 2007 involving 26803 children under two-years of age (U2). Dietary diversity was compared among non-working and working mothers based on classification of the mothers' occupation: unskilled, skilled labor and professional. Using non-working mothers as the reference group, and adjusting for socioeconomic, mother, partner, child, and dwelling characteristics, the adjusted odds ratio (aOR) was calculated for the association between occupation and dietary diversity practice.

Results: Unskilled labor mother were less likely to meet criteria for minimal dietary diversity (aOR 0.81 CI95% 0.72-0.94), especially in protein-rich animal-derived or dairy foods (aOR 0.79 CI95% 0.63-0.90), meat (aOR 0.86 CI95% 0.78-1.02) and plant protein such as legumes (aOR 0.75 CI95% 0.59-0.82). In contrast, staple foods, vegetables and fruits, were similarly provided by non-working and different types of working mothers.

Conclusions: Dietary diversity and feeding of protein-rich foods for U2 children were consistently poor in unskilled working mothers, and could lead to compromised child growth. Targeted policies and interventions are urgently needed, especially given the increasing number of this unskilled group of working mothers.

Key words: working mother, dietary diversity, Indonesia.

PO967

BREAST FEEDING, EXCEPT COMPLIMENTARY FEEDING IS NOT ASSOCIATED WITH STUNTING AT CHILDREN AGED 12-23 MONTHS OLD IN INDONESIA

N. K. Aryastami¹, E. Achadi², N. Kusumawardani³, A. Basuni⁴, A. Shankar⁵

¹Center For Humanity, Health Policy And Community Empowerment, NIHRD-Ministry of Health, Indonesia

²Department of Nutrition, Faculty of Public Health, University of Indonesia, Indonesia

³Center for Public Health Technology Intervention, National Institute of Health Research and Development, Ministry of Health Republic of Indonesia, indonesia

⁴Center for Implemented Health Technology and Clinical Epidemiology, National Institute of Health Research and Development, Ministry of Health Republic of Indonesia, Indonesia

⁵Department of Nutrition, Harvard School of Public Health, Boston, USA

Background and objectives: Stunting among children under five year of age is highly prevalent (35.6% in 2010) in Indonesia. The nutritional status of the mother during pregnancy, the nature of food taken and the frequency and severity of illness during the first two years of life are the most important factors in stunting. The purpose of this analysis is to understand how the history of child feeding could explain stunting as an outcome.

Methods: This study is utilizing data from the National Basic Health Survey 'Riskesdas' 2010. This sample was restricted to children aged 12-23 months representative of the provinces throughout Indonesia where the information on the children's

feeding habits are available.

Results: Results showed, that the prevalence of stunting among children aged of 12-23 months was very high, reaching 40.4%. Breast feeding initiation within one hour was participated by 48.1% of mothers. Exclusive breast feeding was only delivered to 19.7% babies. More than half of the babies were given pre-lacteal food or drinks, while early complimentary feeding (<6 months) was given to 68.5% babies. Logistic regression results showed children born with a low birth weight was 1.8 times more likely to be stunted; boys were 1.3 times more likely to be stunted. Time of complimentary feeding of less than six months seemed to have significantly protective effect. Finally, illness at age of 0-28 days has significant correlation to stunting.

Conclusions: These results send an alarming messages that feeding practices in infants are still discouraging and is compounded by indication that growth retardation has been started since fetal stage. Stunting is significantly correlated to the independent variables of low birth weight, gender, illnesses at age 0-28 days and age at given complimentary feeding in children age of 12-23 months.

Key words: stunting, breast feeding, birth weight, neonatal illness.

PO968

WAYS TO INTERVENE AND SUPPORT ENGAGEMENT OF OLDER ADULTS WEIGHT LOSS STUDY (WISE OWLS) "C MIXED METHODS PROJECT DEVELOPING AN INTERVENTION

K. Kiezebrink¹, J. Coyle¹, P. Hoddinott², M. Witham³, A. Clarke⁴, A. Avenell¹

¹Health Services Research Unit, University of Aberdeen, Aberdeen, UK

²School of Nursing, University of Stirling, Stirling, UK

³Section of Ageing & Health, Ninewells Hospital & Medical School, Dundee, UK

⁴School of Health, Northumbria University, Benton, UK

Background and objectives: Obesity in older people in the UK is rapidly becoming a major health concern. According to the Health Survey for England 2008, 33.1% of people aged 65 to 74 years who are not in residential care have a BMI > 30 kg/m², of these 2.6% have a BMI >40k g/m². In comparison in this age group only 0.7% are underweight (BMI<18.5 kg/m²).

Methods: This study conducted a rapid review of both the qualitative and quantitative literature on deliberate weight reduction in obese older adults, followed by in-depth one to one interviews. The purpose of the interviews was to ascertain older adults' perceptions and experiences of weight manage-

ment over their life course. We also explore participants' views around obesity and older age and whether they view weight change as necessary or possible at this stage of life. Following the first interviews and the review of the literature, the research team developed vignettes describing potential interventions which seemed most likely to be acceptable, feasible and effective. The participants' views of these interventions were explored in a follow up interview.

Results: The emerging themes are: cultural hospitality, social roles, previous weight management experiences, personal motivators and barriers, social engagement, autonomy, and ability. In particular this group differs from the published literature in younger adults due to the accumulation of functional impairments and comorbid diseases. In addition their knowledge, life goals, attitudes to diet and physical activity differ from younger people.

Conclusions: The results suggest that successful weight loss is desirable, achievable and maintainable by those over 65, however that in order for this to happen it is essential that the participant feels a sense of ownership and control over the plan.

Key words: Obesity, weight loss, elderly, qualitative.

PO969

"AGRI-FRYING" THE CRITICAL PATHWAYS TO MATERNAL ANEMIA IN TANZANIA: BRINGING AGRICULTURE INTO THE CONCEPTUAL FRAMEWORK

L. Clemmons¹, T. Schaetzel¹, T. Edwin², M. Antal¹, M. Griffiths¹

¹The Manoff Group, Washington, USA

²Centre for Counseling, Nutrition and Health Care, Tanzania

Background and objectives: Maternal anemia remains a significant public health problem in Tanzania with 15% of maternal deaths attributable to anemia. Prevalence is forty percent among women 15-49 years and 53% among pregnant women (TDHS 2010). Only 35% of women consume iron-rich foods, 4% take the minimum 90+ IFA tablets, and 27% take 2 doses of SP for preventing malaria. Maternal anemia also diminishes women's physical ability to engage in agricultural labor, reducing agricultural productivity, agricultural revenue and food security. The critical pathways to maternal anemia have long offered a conceptual framework for prioritizing evidence-based health sector interventions to address this public health problem. Our objective was to expand this framework to engage the agriculture sector in addressing maternal anemia as a public health problem and as an agro-economy problem.

Results: The resulting framework, which considered current Feed The Future program interventions in the country, helps the agriculture and health sectors to identify their res-

pective roles in the control of maternal anemia and areas for strategic collaboration. The agriculture sector pathways lead to interventions supporting increased iron intake, for example through promotion of low-input technologies for growing, raising and processing and preserving iron-rich foods including animal source foods. In addition, agriculture extension can promote practices that reduce anemia by reducing exposure to schistosomiasis, malaria and intestinal worms. The Ag-Nu-Health Critical Pathways framework can be adjusted by country to address specific situations around malaria incidence, antenatal care programs and agriculture program activities. The framework was adapted for simple, user-friendly formats, including a wall poster or desktop reminder tool, for programmers and policy makers in the health and agriculture sectors to think and act using a multisectoral approach.

Key words: Anemia, multisectoral approach, agriculture, nutrition, health.

PO970

HIGH-IMPACT HOUSEHOLD ACTIONS TO PREVENT CHILD MALNUTRITION THROUGH AGRICULTURE PROGRAMS

L. Clemmons¹, M. Antal¹, T. Edwin²

¹The Manoff Group, Washington, USA

²Centre for Counseling, Nutrition and Health Care, Tanzania

Background and objectives: Recent emphasis on nutrition-sensitive development has drawn attention to agriculture as a channel for nutrition improvement. Clear guidance for how to operationalize "agriculture-nutrition linkages", especially to improve maternal and child nutrition, is lacking. Our objective was to develop a more user-friendly framework to focus agriculture interventions to improve maternal and child nutrition through household level actions that increase access to diverse and quality foods.

Methods: A situation review was conducted to analyze ideal behaviors, current behaviors, and barriers and motivators to behavior change. The process involved reviewing agriculture, nutrition and socio-cultural research and best practices in agriculture, health and nutrition programs in three countries implementing Feed the Future programming (Bangladesh, Guatemala and Tanzania).

Results: Through this process, five categories of household agriculture-nutrition actions were identified to increase access to diverse and quality foods for mothers and children: 1. DISCUSS AND DECIDE TOGETHER: Communication strategies to promote dialogue and joint decision making between couples; 2. EARN AND BUY: Interventions to increase women's access to and control of household income, and influence

women's and men's buying practices towards the purchase of nutritious foods for their families; 3. RAISE AND GROW: Appropriate technologies and approaches to help families grow diverse nutritious crops and raise animal-source protein foods; 4. PREPARE-PROCESS AND STORE: Appropriate technologies and approaches for nutritious and safe preparation, processing and storage of food and; 5. REST AND EAT: Communication strategies and labor-saving technologies to enable women more time to rest, breastfeed, and to improve intra-household food distribution. The framework pivots around pro-nutrition social change in gender norms and family dynamics.

Conclusions: Critical action identified under each category can be assessed and tailored for the local socio-cultural context and will enable practitioners to integrate nutrition into the full spectrum of ongoing agricultural activities of farming families and households.

Key words: nutrition-sensitive development, agriculture, behavior change.

PO971

UNDERWEIGHT IS A RISK FACTOR FOR IRON DEPLETION AND IRON-DEFICIENT ERYTHROPOIESIS AMONG INDONESIAN YOUNG WOMEN

S S. Sri Sumarmi¹, H. Hadi², W. Lestariana², D S. Nurdianti²

¹Department of Nutrition, Faculty of Public Health, Airlangga University, Surabaya, Indonesia

²Faculty of Medicine, Gajah Mada University, Yogyakarta, Indonesia

Background and objectives: Underweight and iron deficiency among women are very prevalent in many developing countries, including Indonesia, but it is unclear whether underweight is associated with some parameters of iron deficiency. This research was conducted to investigate the association between weight status, as measured by body mass index (BMI), and iron deficiency, among the young women. Method: A cross sectional study was conducted at 9 subdistricts, 80 apparently healthy young women (age 15-26 years) were randomly selected from premarital list. Body weight and stature were measured, BMI was calculated and compare to with age-specific BMI reference values for adolescent subjects (age 15-20 years). Underweight was defined as a BMI less than 5th percentile. Venous blood sample were collected and analyzed for Hb, serum ferritin and soluble transferrin receptor (sTfR). Iron depleted is stated if serum ferritin concentration less than 12 µg/l, iron deficiency erythropoiesis (IDE) when concentration of sTfR more than 4.4 mg/l. Result: Of the 80 subjects, 23.8% were underweight. Anemia among underweight subjects is 47.4%

compare to who were normal and overweight subjects (29.5%). Iron depleted (16.7%) and IDE (37.5%) among underweight are higher than who were not underweight (5.3%) and (13.2%), respectively. Subject who were underweight was approximately three times to be iron depleted (OR: 3.167; 95% CI: 0.7-14.335), and to be IDE (OR: 2.839; 95% CI: 1.113- 7.241) as were those were not underweight.

Conclusions: Iron deficiency is more prevalent among underweight young women and risk for iron deficiency approximately three times compare to who were those not underweight.

Key words: anemia, iron deficiency, iron depleted, iron deficient erythropoiesis.

PO972

EXERCISE-BASED INTERVENTION TO PREVENT EXCESSIVE GESTATIONAL WEIGHT GAIN: A RANDOMIZED CONTROLLED TRIAL

R. Barakar¹, M. Pelaez¹, C. Lopez¹, Y. Cordero¹, M. Perales¹, A. Lucia², J. Ruiz³

¹Facultad de Ciencias de la Actividad Física y del Deporte-INEF. Universidad Politécnica de Madrid, Spain

²Universidad Europea de Madrid, Spain

³PROFITH "PROmoting FITness and Health through physical activity" research group, Department of Physical Education and Sports, School of Sport Sciences, University of Granada, Spain

Background and objectives: We aimed to examine the effect of moderate-intensity exercise-based intervention performed from the 9th week of pregnancy on maternal weight gain. Methods. A total of 962 healthy gravidae were randomly assigned to either a standard care or exercise intervention group. The intervention included moderate-intensity aerobic and resistance exercises performed 3 times per week (50-55 minutes per session). Women were categorized according to their pre-pregnancy body mass index (BMI) into normal-weight (n=687) and overweight/obese (n=275) groups. Excessive gestational weight gain was calculated on the basis of the 2009 IOM recommendations. Gestational body weight gain was calculated on the basis of the pregravid weight and weight at the last clinic visit before delivery.

Results: Women in the intervention group gained less weight (adjusted mean difference 1.039 kg, 95%CI: 0.534-1.545, P = 0.00001) and were less likely to gain weight above the IOM recommendations (OR: 0.625, 95%CI: 0.461-0.847, P = 0.002) than women who received standard care. Main treatment effects by BMI category revealed that normal-weight women in the intervention group gained less weight (adjusted mean diffe-

rence 1.393 kg, 95%CI: 0.813-1.972, $P = 0.00003$) and were less likely to gain weight above the IOM recommendations (OR: 0.508, 95%CI: 0.334-0.774, $P = 0.002$) than normal-weight women who received standard care. No significant effect was observed in overweight/obese women, yet normal-weight women were less likely to gain weight above the IOM than overweight/obese women (OR: 0.247, 95%CI: 0.145-0.422, $P < 0.000001$).

Conclusions: Exercise of moderate-intensity performed over the second-third trimesters of pregnancy can be used to prevent excessive gestational weight gain in normal-weight women.

PO974

THE STATUS OF THIAMINE, RIBOFLAVIN AND NIACIN IN CHILDREN AGED 0~3 YEARS OLD IN URBAN AND RURAL AREAS CHINA

X. Han¹, L. Liu², Y. Hu³, Y. Zheng³, M. Yi¹, Y. Li³, D. Jiang⁴, H. Liang³, H. Zhang⁵, A. Ma³

¹Medical College of Qingdao University, China

²Tongji Medical College of Huazhong University of Science and Technology, China

³The Institute of Human Nutrition, Medical College of Qingdao University, China

⁴Service Centre for Women and Children of Shen county, Shandong province, China

⁵Qingdao product quality supervision and Inspection Institute, China

Background and objectives: Vitamins, such as thiamine (B1), riboflavin (B2) and niacin, are important to children growth and development. The study aimed to investigate the current status of B1, B2 and niacin in urban and rural infants in Shandong province.

Methods: 106 urban and 290 rural Children, aged 0~3 years old, were randomly recruited from a city and a rural area in Shandong province. Urinary sample (40 ml) was collected from each one, which was adjusted to pH 4~5 with concentrated hydrochloric acid immediately. The concentration of thiamine, riboflavin and niacin in the urine was detected by fluorescence methods.

Results: The percentages of B1, B2 and niacin insufficiencies in urban infants were 1.9%, 8.0% and 9.1%, respectively, lower than those of 4.5%, 56.7% and 27.1% in rural infants. The median concentrations of vitamin B1 in urban and rural infants were 495.0 µg/g creatinine (Cr) and 420.6 µg/g Cr respectively, and levels of thiamine in urban children aged 12~month and 24~month in urban site were higher than those in rural area ($p < 0.05$). The level of vitamin B2 was 303.1 µg/g Cr in urban infants, higher than 70.9 µg/g Cr in rural infants in each age group ($p < 0.05$). The mean levels of nicotinic acid

in urban and rural infants were 6.31 µg/g Cr and 4.22 µg/g Cr, and the nicotinic levels in children aged 6~month, 12~month, 18~month and 24~month groups in urban infants were higher than those in rural infants ($p < 0.05$).

Conclusions: There was a higher percentage of riboflavin and niacin insufficiency in rural infants. Thus, this finding should be pay attention and supplementation of these vitamins should be considered in infants, especially in rural infants. Granted by Ministry of Science and Technology, PR.China (2008BAI58B07) and DSM Fund (201208).

Key words: infants; riboflavin, thiamine; niacin; rural area.

PO975

OBESITY AND VITAMIN D INSUFFICIENCY COEXIST AMONG CHILDREN LIVING IN A MULTIETHNIC SUN-RICH COUNTRY

B K. Poh¹, A T. Ruzita¹, S. Nik Shanita¹, J E. Wong¹, S B. Budin¹, M D. Siti Haslinda², A K. Norimah¹

¹Universiti Kebangsaan Malaysia

²Department of Statistics, Malaysia

Background and objectives: Malaysia, a fast developing country close to the equator, has been known to bear the dual burden of malnutrition. However, nationwide data on complete nutritional status of Malaysian children are scarce, especially in relation to blood biochemical analyses of vitamin status.

Methods: The Nutrition Survey of Malaysian Children was carried out with the aim of assessing the nutritional status in a sample of nationally-representative population children aged 6 months to 12 years. This survey is part of SEANUTS, a multi-centric study carried out among 16000 aged 0.5 to 12 years in four countries in South East Asia. In Malaysia, a total of 3542 children were recruited using stratified random sampling method, representing close to 6 million children. Measurements included body weight, height, and serum 25(OH) D concentration.

Results: Prevalence of overweight and obesity was 21.6%; which was four times higher than thinness (5.4%) and 2.5 times higher than stunting (8.4%). Nearly half the children had vitamin D insufficiency (47.5%). The presence of high prevalence of vitamin D insufficiency is linked to inadequate intake of vitamin D and lack of sun exposure.

Conclusions: These findings reveal that obesity and vitamin D insufficiency does indeed coexist among the multiethnic children of Malaysia. This implies that strategies need to tackle both sides of malnutrition and emphasise approaches for preventing overweight and obesity as well as vitamin D insufficiency.

Key words: childhood malnutrition, obesity, vitamin D insufficiency.

PO976**DIETARY CALCIUM AND PHOSPHATE INTAKE IN THE AETIOLOGY OF RICKETS IN BANGLADESH**

S. Ahmed^{1,2}, G R. Goldberg¹, S K. Roy², R. Raqib², S. Haque³, A. Prentice¹

¹MRC Human Nutrition Research (MRC HNR): Elsie Widdowson Laboratory, Cambridge, UK

²International Centre for Diarrhoeal Disease Research, Bangladesh (ICDDR,B): Mohakhali, Dhaka, Bangladesh

³Social Assistance and Rehabilitation for the Physically Vulnerable (SARPV): Chakaria, Coxij̄s Bazar, Bangladesh

Background and objectives: To determine if low dietary calcium and phosphate intakes are involved in the aetiology of rickets in Chakaria, rural Bangladesh, where rickets is a major and relatively recent problem.

Methods: Newly diagnosed cases of active rickets (AR), with Thacher Score >1.5 with no other known disease, cases with bone deformities but not active rickets (BDNAR), and community controls individually matched as closely as possible for age, sex and village were studied. 24-hour weighed dietary records of all foods eaten were collected in the childrens' homes, and coded using an HNR in-house programme and composition tables. Data were analyzed by paired t-tests.

Results: 24 AR (12M, 12F), 38 BDNAR (28M, 10F) and controls were studied. Median (range) age was 2.7 (1.3-5.9), 3.2 (1.2-5.7), 3.0 (1.0-10.0), and 3.2 (1.7-10.6) years in AR, AR-controls, BDNAR and BDNAR-controls respectively. All children were stunted and wasted. Mean±SD weight-for-age (WAZ) and height-for-age Z-scores (HAZ) (WHO 2010 Growth Standards) for AR and AR-controls were 2.9±1.1 vs -2.1±1.1 (p = 0.006), and -4.2±1.5 vs -1.9±1.2 (p < 0.0001). BDNAR were shorter than BDNAR-controls (HAZ: -2.7±1.8 vs -1.7±1.4, p = 0.003). Mean±SD calcium intakes (mg/day) were substantially lower than UK, WHO/FAO and Indian recommendations in all groups, particularly in AR. Intakes were 156±80 vs 323±249 in AR vs AR-controls (p = 0.005), 239±166 vs 254±221 in BDNAR vs BDNAR-controls (p = 0.73), and AR vs BDNAR (p = 0.03). Phosphorus intakes (mg/day) in AR were lower than AR-controls (321±112 vs 424±155, p = 0.009). Ca:P ratio (mmol/mmol) was lower in AR than AR-controls (0.58 vs 0.77, p = 0.07).

Conclusions: Calcium and phosphorus intakes were low in all of the study children. The extremely low calcium intakes in AR children, 50% of those of controls, suggest a possible role in the aetiology of their rickets.

Acknowledgements: UK Medical Research Council U105960371 Key words Bangladesh, calcium intake, rickets.

PO977**NUTRITIONAL STUDY OF DIET AND BODY COMPOSITION IN FUTSAL PLAYERS**

A. Lizarraga^{1,2}, D. Medina², I. Palma³, D. Zomeño³, D. Florit², A. Farran³, E. Vidal⁴, P. Garrido⁵, C. Rosés⁶, A. Madoelo⁶, M. González⁵

¹Ciències Fisiològiques II Facultat de Medicina UB Bellvitge, Barcelona, Spain

⁵Estudiante Diplomatura NHD. Facultat de Farmàcia, UB, Barcelona, Spain

⁶Estudiante Grado NHD. Facultat Ciències de la Salut, Blanquerna Universitat Ramon Llull, Barcelona, Spain.

Background and objectives: Futsal (FS), also known as indoor soccer, is an intermittent high-intensity strenuous team sport played worldwide. Despite its popularity and professional competitive status there are only few scientific studies describing the physiological demands and nutritional needs of the game. The purpose of this study was to analyze body composition, spontaneous eating habits and nutritional aspects of professional futsal players.

Methods: 12 professional, male futsal players with following characteristics: (mean± SD) age 30 years (±2.69), height 179 cm (±5) and weight 78 kg (±7.32) agreed to participate in this study. Each player completed a 3-day dietary record. Energy, macronutrient and micronutrient intakes were determined using PCN-pro Program. Body composition parameters were assessed with DXA (Lunar i DXA, GE Healthcare) in order to establish the athletes profiles and their specific needs.

Results: Participants were divided into two groups whether they reached recommended intakes Burke et al (2007), (REC group) or not (NO-REC group). Total energy intake (TEI) was low (2520±440.95 kcal/day) compared to total energy expenditure (TTE): 3779±245.19 Kcal/day (33% REC; 66% NO-REC). Surprisingly none of the players meet the carbohydrate intake, accounting 39.93% of TEI (0% REC; 100% NO-REC). Protein intake was met by less than half of the players (42% REC; 58% NO-REC) accounting 17.43% of TEI. Lipids intake accounted 40.28% of TEI, exceeds the recommended 30%. (8% REC; 92% NO-REC). Cholesterol intake exceeded the recommended also; only 1 player followed the REC<300 mg. None of the players achieved 25 g/day of fibre (100% NO-REC). Vitamin D requirements were met by a small percentage as well (8% REC; 92% NO-REC).

Conclusions: Surprisingly most of the players did not meet energy, macronutrient neither micronutrient recommended intakes. Nutritional counselling is needed in order to correct the observed deficits guarantying recovery, performance and injury prevention.

Key words: nutrition, diet, physical activity, body composition, futsal.

EARLY CHILDHOOD PROGRAMS AND ATTAINING DEVELOPMENTAL POTENTIAL

L. Fernald¹, R. Kagawa^{1,2}, P. Kariger¹, J. Behrman³, D. Bravo⁴

¹Division of Community Health and Human Development, School of Public Health, UC Berkeley, USA

²Division of Epidemiology, School of Public Health, UC Berkeley, USA

³Department of Economics, University of Pennsylvania, USA

⁴Department of Economics, University of Chile, Chile

Background and objectives: The objective of the analysis was to explore the potential for early childhood programs to minimize the developmental gap for children from diverse socioeconomic backgrounds. This paper explores the potential benefits of attending private, public, any, or no early childhood program to growth and cognitive, socio-emotional and psychomotor skill development among children ages 0-5 in Chile. We also consider how the quality of the home environment, child age, and maternal education affect these associations.

Methods: This study uses cross-sectional data from the first wave of the Chilean Encuesta Longitudinal de la Primera Infancia (ELPI). We used multivariate linear regression to estimate the association between attending an early childhood program and growth, cognitive, socio-emotional and psychomotor skill development, controlling for child health and background characteristics and assessing interactions.

Results: Children that attended any early childhood program performed slightly better than children that did not attend an early childhood program on a test of verbal intelligence. These children also showed fewer behavioral problems and improved psycho-motor development with significant interactions by program participation, home environment, maternal education, and child age. Children that attended a private early childhood program performed better than children that attended a public early childhood program on a test of verbal intelligence with interaction by home environment.

Conclusions: Early childhood programs have the potential to minimize the gap in cognitive, psycho-motor and so-

cio-emotional development among children from various socioeconomic backgrounds. The potential for impact varies by child age, maternal education and the home environment in some situations.

PO979

EFFECTS OF DIETARY LIFESTYLE EDUCATION PROGRAM FOR ADOLESCENTS IN MIDDLE SCHOOLS: STUDY DESIGN OF A CLUSTER RANDOMIZED CONTROLLED TRIAL

J. Watanabe¹, M. Watanabe², M. Koga¹, K. Yamaoka³, M. Yokotsuka⁴, M. Adachi⁵, Y. Hashimoto⁴, T. Tango^{2,5}

¹Prefectural University of Kumamoto, Japan

³Teikyo University, Graduate School of Public Health, Japan

⁴Showa Women's University, Japan

⁵Nutrition Support Network LLC, Japan

⁶Center for Medical Statistics, Tokyo, Japan

Background and objectives: We developed a food frequency questionnaire (FFQW82, Adachi et al, 2008; Watanabe, et al, 2008), and reported the effects of the classroom dietary education (DLE) based on a cluster randomized controlled trial (Yamaoka, et al, 2010). The aim of the study is to evaluate the effect of the revised version of the DLE program for adolescents based on a cluster randomized trial (CRT) in middle schools. This study explores the design of a two-arm CRT on the effectiveness of the DLE based on the preliminary survey results.

Methods: The preliminary survey was conducted in 2012 for the students of junior high schools aged 12-13 in Kumamoto Prefecture, Japan. The items used for the preliminary survey were self-rated health status, lifestyle, exercise, food intakes, BMI, etc..

Results: In total, 1182 adolescents responded the survey and analyzed the association of lifestyle characteristics on BMI and health status. Especially, indefinite complaints significantly ($p < 0.05$) related to intake of breakfast. Based on the observations, the study protocol including sample size (10 clusters in total; assumptions: 120 for each cluster, power=80%, significance level=5%, effect size=0.3, ICC=0.02) and education programs were determined. The hypothesis underlying the study is that adolescents in the DLE group might improve indefinite complaints from baseline after 6-month education compared to the control group. Effects of the intervention are expected to be measured after 6 months using a self-administered questionnaire. The primary endpoint is a change from baseline of a number of indefinite complaints. Energy and nutrients intakes by meal assessed using the FFQW82 as well as body mass index

are the secondary endpoints. Outcomes are examined using a mixed model by adjusting for baseline values and other factors.

Conclusions: The proposed study will provide practical information about the usefulness of the DLE program in school education settings.

PO980

POSITIVE UNINTENDED CONSEQUENCES IN PROGRAMS FOR WOMEN'S AND CHILD NUTRITION IN BANGLADESH: SCALING UP TIPPY-TAPS

E. Williams¹, Y. Arafat², T. Williams³, A. Guyon³

¹SPRING/Bangladesh, Helen Keller International, Gulshan, Dhaka, Bangladesh

²SPRING/Bangladesh - Save the Children, Dhaka, Bangladesh

³SPRING - JSI Research and Training, Arlington, USA

Background and objectives: Bangladesh has made notable progress in reducing child mortality and morbidity. However, high rates of undernutrition remain, with 41% of children <5 stunted (2011 BDHS).

Methods: In 2012, USAID's SPRING project collaborated with Bangladesh's Food Security and Nutrition Surveillance Program conducting a baseline survey of nutrition, hygiene and agricultural practices among 770 households in SPRING's intervention areas. Respondents were asked about use of soap in handwashing over the last 24 hours and unprompted responses on reasons they washed their hands.

Results: Though up to 60% of households reported hearing messages on appropriate handwashing only 12% and 40% washed their hands with soap before feeding children and after defecation, respectively. Therefore, SPRING refined its interventions targeting pregnant and lactating women, and children under two to increase positive nutrition and hygiene practices and access to diversified diet. Through advocacy, training and supportive supervision with government and non-governmental groups, SPRING promotes adoption of 'small-doable-actions' on nutrition and hygiene following life cycle approach and has provided training to 1839 health workers and 485 agriculture and community workers. SPRING established 783 Farmer Field Schools (FFS) providing low income households with access to diversified and nutritious vegetables, fruits and animal source foods. Household 'tippy-taps' were introduced to improve adoption of hygiene practices in target households. SPRING is the first project to scale up tippy-taps to rural Bangladesh. Seventy percent of trained agriculture workers report including nutrition and hygiene with making of tippy-taps in agriculture extension sessions and approximately 6000 households participating in FFS have installed tippy-taps to date. This successful and rapid adoption of practices is attributed to

streamlined and practical messages given across multiple platforms.

Conclusions: Integrating tippy-taps into nutrition, hygiene and homestead food production seems a promising strategy to improve handwashing behaviors.

Key words: nutrition, hygiene, tippy-taps, agriculture, Bangladesh.

PO981

THE EFFECT OF DOWNHILL WALKING ON MUSCLE DAMAGE AND GLUCOSE METABOLISM ON THE NEXT DAY

A. Nakayama¹, W. Aoi¹, M. Takami¹, N. Hirano¹, Y. Ogiya¹, S. Wada¹, A. Higashi¹

¹Laboratory of Health Science, Graduate School of Life and Environmental Sciences, Kyoto Prefectural University, Japan

Background and objectives: It has been reported in animal studies, that downhill running exercise causes delayed-onset muscle damage and decreases glucose uptake into muscle compared with uphill. However, the effect of downhill walking exercise, which is a major daily physical activity for people, on glucose metabolism is not clear. Therefore, we investigated the effect of downhill walking on muscle damage and glucose metabolism on the next day of the walking in young people.

Methods: Eight healthy young men and women (age, 24.6 ± 1.6 yr) participated in this study. All subjects performed three trials (control, uphill, and downhill) in random order. In the exercise trials, uphill (+ 5°C) or downhill (- 5°C) treadmill walking was carried out at a speed of 6 km/h for 30 min. On the next day, the subjects consumed glucose solution containing 75 g glucose, and we conducted analysis of respiratory metabolic performance, blood collection, and evaluation of muscle soreness.

Results: Score of muscle soreness was significantly higher in downhill (5.8 ± 1.5 score) than in uphill (0.6 ± 0.2 score) (p = 0.014). Plasma creatine kinase was not changed by exercise. Respiratory quotient and carbohydrate oxidation did not differ between the trials. Fasting blood glucose level was significantly low in uphill (69.1 ± 3.9 mg/dl) compared with control (80.9 ± 3.9 mg/dl) (p = 0.045), although this decrease was not found in downhill (75.1 ± 3.4 mg/dl). Blood glucose levels at 30 min and 60 min after glucose intake were not different between the trials.

Conclusions: Decrease of fasting blood glucose level was found on the next day of uphill walking but not downhill, suggesting that glucose uptake induced by exercise is lower in downhill than in uphill.

Key words: downhill walking, muscle damage, glucose metabolism.

PO982**MATERNAL CALCIUM SUPPLEMENTATION DURING PREGNANCY AND BLOOD PRESSURE IN RURAL GAMBIAN CHILDREN AT 3 AND 9 YEARS OLD***G. Goldberg^{1,2}, J. Yin¹, L. Jarjou², A. Prentice^{1,2}*¹MRC Human Nutrition Research, Cambridge, UK²MRC Keneba, Cambridge, UK

Background and objectives: Reductions in population blood pressure (BP) of 2-3 mmHg decrease morbidity. Higher calcium intakes during pregnancy have been associated with lower offspring BP. More consistent effects have been reported in older children, and greater effects at higher BMI. There are no data from populations with a low dietary calcium intake e.g. The Gambia (~350 mgCa/day in adults).

Methods: Children whose mothers had participated in a randomised placebo-controlled trial (ISRCTN96502494; 1500 mgCa/day from 20 wk gestation until delivery, 525 mother-infant pairs) had height, weight, systolic (SBP) and diastolic BP (DBP) measured at 3.0±0.05 y (n=485, 48% males) and at 9.0±0.2 y (n=462, 48% males). Follow-up of all offspring was attempted. BP (DINAMAP 8100) was measured under standardised conditions. Investigators remained blinded to supplement group allocation.

Results: Data were analyzed by regression. At 3 y, mean±SD in the calcium vs placebo group was: SBP, 89.9±10.1 vs 91.8±9.7 mmHg; DBP, 54.1±8.7 vs 53.7±8.7 mmHg (p = 0.6); BMI 15.5±1.6 vs 15.6±1.4 kg/m² (p = 0.4). Weight, height and BMI did not predict BP. SBP was 2.1±1.0 % lower (mean±SE; p = 0.03) in the calcium group; there was no interaction with BMI. Corresponding values at 9 y were: SBP, 101.1±9.2 vs 101.8±8.7 mmHg (p = 0.3); DBP, 60.6±7.3 vs 62.1±7.2 mmHg; BMI, 14.6±1.6 vs 14.6±1.4 kg/m² (p = 0.8). Weight and BMI predicted BP independently of height (p = 0.0002 and 0.01). DBP was 2.5±1.1% lower (p = 0.02) in the calcium group. There was no interaction with BMI or weight.

Conclusions: Maternal calcium supplementation did not affect offspring height, weight or BMI at ages 3 or 9 y. There were small but significant effects on SBP and DBP, which at a population level are biologically meaningful. Follow-up studies in this cohort are ongoing during and after puberty.

Acknowledgements: Supported by UK MRC programmes U105960371 and U123261351

Key words: maternal calcium supplementation, children, blood pressure, Gambia.

PO983**CALCIUM INTAKE, MAJOR DIETARY SOURCES AND ITS ASSOCIATION WITH SOCIO-ECONOMIC STATUS IN PRIMARY SCHOOL CHILDREN IN TEHRAN***N. Omidvar¹, T R. Neyestani², M. Hajifaraji³, M R. Es-hraghian⁴, A. Rezazadeh^{1,5}, H. Haidari⁶, T. Zowghi⁶, S. Armin⁶*¹Department of Community Nutrition, Faculty of Nutrition And Food Technology, Shahid Beheshti University of Medical Sciences, Tehran, Iran²Laboratory of Nutrition Research, National Nutrition and Food Technology Research Institute, Tehran, Iran³Dean, National Nutrition and Food Technology Research Institute, Tehran, Iran⁴Research Deputy Department, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran⁵Students Research Committee, Shahid Beheshti University of Medical Sciences and Health Services, Iran⁶Nutrition Research Department, National Nutrition and Food Technology Research Institute, Tehran, Iran

Background and objectives: Calcium is the most limiting nutrients in the Iranian household diet. Sufficient calcium intake is crucial to support growth spurt during preteen and teenage years. This study aimed to assess daily calcium intake, its major dietary sources and the association with socioeconomic status (SES) in primary school children in the city of Tehran. Materials and

Methods: In a cross-sectional study, 501 students (244 girls and 257 boys) from grades 4 and 5 of elementary schools were selected through systematic random sampling from all districts of the city of Tehran. Demographics and SES was assessed using a questionnaire through face-to-face interviews. Ca intake was assessed using a validated 60-item semi-quantitative food frequency questionnaire, specifically designed for dietary sources of Ca. One way-ANOVA test was used to compare within-group total calcium intake in each gender and in total participants, followed by post hoc Tukey HSD test. Findings: Mean calcium intake of the children was 917.5±440.8 mg/day (girls: 901.2±447.7 mg/day; boys: 932.8±434.4 mg/day). While only 17.8% met the daily recommended intake of Ca (≥1300mg/day), the intake in 59.9% was below 75% of RDA. Main contributors of Ca in the children's diet were milk and dairy products (69.3% of total calcium intake). Only 29.8% met the food-based dietary guidelines for dairy intake (≥3 serving/day). No significant difference was observed between boys and

girls in the intake of calcium and dairy products; however, calcium intake of girls in the middle SES district was significantly lower than boys in the same district ($780.3 \pm 44.3\text{mg/day}$ vs. $964.5 \pm 48.5\text{mg/day}$; $p < 0.05$) and girls in both low and high SES districts. No significant association was found between Calcium intake of children and other socioeconomic variables.

Conclusion: Planning useful nutrition strategies for overcoming this problem seems inevitable.

Key words: Calcium Intake, Primary School children, Tehran

PO984

ANTHROPOMETRIC INDICATORS ARE ASSOCIATED WITH NONVERBAL IQ IN SOUTH EAST ASIAN SCHOOL-AGED CHILDREN

P. Parikh¹, Sandjaja², B K. Poh³, N. Rojroongwasinkul⁴, L N B. Khanh⁵, P. Deurenberg⁶

¹Friesland Campina, Amersfoort, The Netherlands

²Pesatuan Ahli Gizi Indonesia (PERSAGI), Bogor, Indonesia

³Universiti Kebangsaan Malaysia (UKM), Kuala Lumpur, Malaysia

⁴Mahidol University, Nakhon Pathom, Thailand

⁵National Institute of Nutrition (NIN), Hanoi, Vietnam

⁶Nutrition Consultant, Langkawi, Malaysia

Background and objectives: Malnutrition during school-age years can adversely impact physical and cognitive development of children, possibly compromising the economic development, health and survival of future generations. Yet, school-aged children are often not included in nutrition surveillances. The SEANUTS was planned with the overarching aim of providing comprehensive nutrition information for children ages 0.5-12 y in four of the South East Asian countries: Indonesia, Malaysia, Thailand and Vietnam. This presentation aimed to evaluate the association between anthropometric indicators and nonverbal IQ in school aged children of the SEANUTS.

Methods: Of the 8158 school-aged children (>6 y), information relevant for this study was available for 6746 children and hence, were included in this analysis. Height-for-age (HAZ), weight-for-age (WAZ) and body mass index-for-age (BAZ) z-scores were used as anthropometric nutritional status indices. Nonverbal IQ was measured using Raven's progressive matrices (Malaysia, Indonesia and Vietnam) or TONI-3 (Thailand). Odds ratios (OR) were calculated using binary logistic regression after correcting for confounders (age, gender, urban/rural, educational level of the mother, and country). Data were weighted using age, gender and urban/rural weight fac-

tors to resemble the total primary school-aged population per country.

Results: Malnutrition is clearly an issue in this region with an underweight and stunting prevalence of 21% and 19%, respectively. The odds of having below average or poor nonverbal IQ (<89) was 2 times or more with low WAZ, BAZ and HAZ. Severe obesity (BAZ > +3SD) also increased the odds of having nonverbal IQ <89.

Conclusions: Both spectrum of malnutrition are associated with nonverbal IQ in 6-12 y children, highlighting the need for targeted programs in this age group. Effective nutrition strategies in school-aged children can have a pronounced effect on cognition and potentially, in long term, contribute positively to individual and national development.

Key words: SEANUTS, school-aged children, anthropometry, nonverbal IQ.

MODIFIED MILK WITH THE ADDITION OF SUNFLOWER OIL, SELENIUM AND VITAMIN E IN THE DIET OF COWS INFLUENCING THE HEALTH OF THE ELDERLY

K. Pfrimer¹, E. Ferrioli¹, M. Salles², A. Saran-Netto³, M. Zanetti³, L. Roma-Junior², H. Vannucchi¹

¹Department of General Internal, University of São Paulo, Brazil

²Agency Paulista Agrotecnology APTA, São Paulo, Brazil

³College of Animal Science and Food Engineering, University of São Paulo, Brazil

Background and objectives: The project aimed at studying the effects of the inclusion of sunflower oil, vitamin E and selenium in the diet of dairy cows which changed the milk composition affecting the health of the elderly.

Methods: 100 old people living in nursing homes received four different kinds of milk produced according to four different diets given to dairy cows for 12 weeks. There were four groups according to the diet of the cows: control diet; control diet plus selenium and vitamin E; sunflower oil diet; sunflower oil diet plus selenium and vitamin E. The elderly were separated in four groups according to each diet. The selection criteria took into consideration disease, gender, smoking habit and cognition. Analysis of fatty acid profile was measured before and after the intake of milk.

Results: Fatty acid profile was measured after and before supplementation of the dairy cow's diet. Data were analyzed for ANOVA test and total serum cholesterol was significantly different between the groups $p = 0.00$. The mean cholesterol

of the group that received the milk from cows with modified control diet was 176.3±31.8 mg/dl before the enrichment and after treatment 171.7±29.4 mg/dl; the group that received milk from cows in the control diet plus selenium and vitamin E was 182.1±39.0 mg/dl before and after treatment 168.7±36.8 mg/dl; the sunflower oil diet was 163.7±30.7 mg/dl before and after treatment was 153.2±29.37 mg/dl and the last treatment sunflower oil diet plus selenium and vitamin E was 170.0±24.3 mg/dl before the treatment and 155.6±24.3 mg/dl after treatment.

Conclusions: the group who received milk of dairy cows with supplemented diet with sunflower oil had difference in the total cholesterol in the serum blood when compared to the control diet before supplementation.

Key words: elderly, supplementation, antioxidants, fatty acid, biochemical blood.

THE DMC-II: A PRACTICAL, RELIABLE, AND SENSITIVE TOOL FOR ASSESSING NEUROBEHAVIORAL DEVELOPMENT IN NUTRITION TRIALS

E. Prado¹, S. Abbeddou¹, E. Yakes², J. Ouedraogo³, A. Abubakar⁴

¹Department of Nutrition, University of California Davis, Davis, CA, USA

²Department of Individual, Family, and Community Education, University of New Mexico, Albuquerque, NM, USA

³Institute de Recherche en Sciences de la Sante, Bobo-Dioulasso, Burkina Faso⁴Department of Cross-Cultural Psychology, Tilburg University, Tilburg, Netherlands

Background and objectives: Adequate nutrition is necessary for the rapid neurodevelopment that occurs during gestation and infancy, laying the foundation for lifelong development of cognitive, motor, and socio-emotional skills. Benefits of nutrition interventions on neurodevelopment constitute important evidence to inform nutrition policy. Assessing neurobehavioral development in field trials in low-income countries can be challenging for several reasons, including a lack of standard tests in the local language and a lack of highly trained staff. The Developmental Milestones Checklist (DMC) is a tool developed in Kenya in part to address these challenges. It provides motor, language, and personal-social scores for children age 3-24 months. The objective of the current study was to develop and evaluate an extended version of the DMC (DMC-II) for a new cultural context in the International Lipid-Based Nutrient Supplements Project in Burkina Faso.

Methods: We added and modified a number of items. We changed the administration procedure to allow flexible administration by observation as well as parent interview. We evaluated the internal reliability, inter-interviewer reliability, test-retest reliability, developmental sensitivity, and sensitivity to stunting, wasting, and underweight of the DMC-II.

Results: The internal, inter-interviewer, and test-retest reliability of the three DMC-II scores were all greater than 0.7, indicating satisfactory reliability. In 214 children age 12-24 months, each score strongly correlated with age ($r > 0.7$). In 1.123 children age 16.8-19.9 months, the scores were sensitive to stunting, wasting, and underweight. The motor score showed the largest differences between groups, with effect sizes 0.69, 0.86, and 0.80 SD for stunting, wasting, and underweight, respectively, while the effect sizes for language and personal-social development ranged from 0.28-0.40.

Conclusions: The DMC-II is a practical, reliable, and sensitive tool for evaluating neurobehavioral development in nutrition research in rural settings in low-income countries. Funded by the Bill & Melinda Gates Foundation.

PO987

NUTRITIONAL AND BEHAVIORAL FACTORS' INFLUENCE IN BREAKFAST INTAKE OF ADOLESCENTS REGISTERED IN PUBLIC SCHOOLS IN SALVADOR, BRAZIL.

M L. Portela de Santana¹, E. Jesus Pinto², A M. Oliveira Assis¹, M E. Pereira Conceição Machado¹, R C. Ribeiro Silva¹

¹Department of Nutritional Science, School of Nutrition, Federal University of Bahia, Salvador, Bahia, Brazil

²Post graduation Program of Medicine and Health, Federal University of Bahia, Salvador, Bahia, Brazil

Background and objectives: Adolescents are a nutritionally and psychologically vulnerable group. In this phase, the occurrence of poor eating habits, such as skipping meals, is common and may be influenced by aspects related to behavior and nutritional status of the adolescent. The aim of this study is to identify the influence of behavioral and nutritional consumption of breakfast for teens.

Methods: It was a cross-sectional study involving a random sample of 1494 (852 girls and 642 boys) aged 11 and 17 years and registered in public schools in Salvador, Brazil. The participants completed the Body Shape Questionnaire (BSQ) and the Eating Attitudes Test-26 (EAT-26) and Bulimic Investigatory Edinburgh (BITE). It was obtained eating habits at breakfast, demographic, anthropometric and economic information variables and information regarding the maturation stage and

body weight self-perception. The breakfast omission was considered when the student did not perform this meal less than 6 times per week. It was used descriptive analysis to characterize the distribution of studied events occurrence and Pearson chi-square test was undertaken to evaluate possible associations between selected variables. For statistical analysis it was used SPSS.

Results: Skipping breakfast occurrence was identified in 21.5% of the students. In males, the data showed that to skip breakfast was higher in obese or overweight adolescents ($p = 0.024$), students with abdominal obesity ($p = 0.015$) and dissatisfied body image individuals ($p = 0.022$). For females, skipping this meal was associated with adolescents feeling fat/too fat ($p = 0.004$), dissatisfied body image individuals ($p = 0.005$) and students with any symptoms of eating disorder ($p = 0.000$).

Conclusions: This study showed that skipping breakfast in adolescents is influenced by nutritional and behavioral factors in males and only for behavioral factors in females.

Key words: eating disorders, skip breakfast, adolescents, body image dissatisfaction, obesity.

PO988

RISK FACTORS FOR ADOPTING EXTREME WEIGHT CONTROL AMONG PUBLIC SCHOOL ADOLESCENTS OF THE SALVADOR, BRAZIL: A CONTROL-CASE STUDY.

M.L. Portela de Santana¹, R.C. Ribeiro Silva¹, A.M. Oliveira Assis¹, E. Jesus Pinto¹, M.E. Conceição Machado¹, H. Costa Ribeiro Junior³

¹Department of Nutritional Science, School of Nutrition, Federal University of Bahia, Brazil

²Post graduation Program of Medicine and Health, Federal University of Bahia, Brazil

³Department of Paediatrics, School of Medicine, Federal University of Bahia, Brazil

Background and objectives: Adopt of the extreme weight-control behaviors are especially prevalent among adolescents who are dissatisfied with their bodies and are considered to be predictors of eating disorders. This study identifies the risk factors for extreme weight-control behaviors among adolescents in public school in Salvador, Brazil.

Methods: This is a case-control study, including cases and controls matched randomly by age and nested to a cross-sectional study. This study involves 252 adolescents, 84 cases and 168 controls of both sexes from 11 to 17 years old. The variable outcome is represented by extreme weight control behaviors, integrated by following the variables: self-induced vomiting and the use of laxatives, diuretics or medications for weight

loss. Co-variables included body image dissatisfaction, adoption of a restrictive diet, prolonged fasting and self-perception of body weight. The study also investigated the demographic and anthropometric variables and economic conditions of the students' families. Conditional logistic regression was used to identify risk factors for the adoption of extreme weight-control behaviors among adolescents.

Results: Among the adolescents investigated, risk factors for the occurrence of extreme weight-control behaviors included overweight (odds ratio [OR] 3.52; confidence interval [CI] 95% 1.39-8.85), dissatisfaction with body image (OR 4.33; CI 95% 2.04-9.20) and the adoption of a strict diet (OR 2.88; CI 95% 1.18-7.06).

Conclusions: The results of this study suggest that among adolescents, overweight, body image dissatisfaction and restrictive diet are the variables that predict the adoption of extreme weight-control behaviors.

Key words: risk factors, adolescents, weight loss, purging, case-control study.

PO989

RECOVERY OF BONE MASS AT WEANING IS INFLUENCED BY BREASTFEEDING, TIME SINCE MENARCHE AND POSTPARTUM PERIOD IN ADOLESCENT MOTHERS.

M.E.L. Diogenes^{1,5}, F.F. Bezerra^{1,2}, M.F. Taveira², P. Rezende², P. Normando², I. Pinha³, C.M. Donangelo^{1,4}

¹Instituto de Química, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil

³Hospital Maternidade Escola da Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil

⁴Escuela de Nutrición, Universidad de la República, Montevideo, Uruguay

⁵Instituto Nacional do Câncer, Hospital do Câncer II, Rio de Janeiro, Brazil

Background and objectives: Recovery of lactation-induced bone loss may not be complete post-weaning in adolescents. Physiologic and nutritional factors affecting recovery have not been fully described. We aimed to evaluate, in Brazilian adolescents ($n=30$; 13-19 y; dietary calcium ≥ 600 mg/d), changes in bone mass from lactation (L) to weaning (W) and its relationship with maternal weight, height, time since menarche (TSM), breastfeeding practice (BP), return of menses, postpartum period (PP) and use of calcium (600 mg)/vitamin D (200 IU) supplementation during pregnancy.

Methods: Bone mineral content (BMC), density (BMD)

and BMD Z-score at total body (TB), lumbar spine L1-L4 (LS), total hip (TH) and femoral neck (FN) were assessed by DXA at L (20wk postpartum) and W (58wk postpartum). Bone changes from L to W were evaluated by paired t test. Associations of changes with independent variables were examined by multiple regression models.

Results: At lactation, BMD Z-scores were -0.4 ± 1.1 (TB), -1.0 ± 1.0 (LS), -0.2 ± 1.0 (TH) and 0.0 ± 0.9 (FN), and increased ($p < 0.05$) at weaning in TB (-0.2 ± 1.2), LS (-0.5 ± 1.1), TH (0.1 ± 1.1) and FN (0.2 ± 1.1). Positive associations found were: PP with changes in BMC at TB ($p < 0.01$) and BMC and BMD Z-score at LS ($p < 0.01$), TSM with changes in BMC and BMD Z-score at TB and LS ($p < 0.05$), BP with changes in BMD Z-score at TB, LS and TH ($p < 0.05$) and calcium/vitamin D supplementation with changes in BMD Z-score at FN ($p < 0.01$).

Conclusions: These results suggest that given sufficient time postpartum, bone recovery at post-weaning of adolescents is more likely to be complete in those who breastfeed and are biologically more mature. Calcium/vitamin D supplementation during pregnancy appears also to play a role. Financial support: CNPq and FAPERJ.

Key words: adolescent, bone, calcium supplementation, lactation and weaning.

PO990

PROMOTION OF ORANGE-FLESHED SWEET POTATO IN AQUATIC AGRICULTURAL SYSTEMS FOR IMPROVED FOOD AND NUTRITION SECURITY IN BANGLADESH

S M. Allauca¹, S H. Thilsted¹, M d M. Hossain¹, B K. Barman¹, M. Karim¹, W J. Collis²

¹WorldFish, Bangladesh

²Winrock International, Nepal

Background and objectives: With the recent focus on Agriculture-Nutrition Linkages, WorldFish and its partners have expanded their activities on household pond aquaculture to include vegetable production on pond dykes and in homestead gardens. In order to increase the quantity, diversity, frequency and duration of consumption of micronutrient-rich foods -especially for women and young children- micronutrient-rich small fish are being produced together with carps in pond polyculture, and orange-fleshed sweet potato (OFSP) has been introduced. Sweet potato is not a staple food in Bangladesh; the root and leaf are consumed as vegetables. OFSP roots are rich in vitamin A and energy, and the leaves are rich in vitamin A, B and C.

Methods: OFSP was introduced to 640 households in 2011. Vines were produced and distributed for planting in October-

November. Field staff and household women were trained in production. Roots were harvested in April 2012, and leaves from January to April. Vines were easily preserved by households for planting in the subsequent season. A pilot study on household utilization of OFSP was conducted.

Results: Both leaves and roots were consumed and well-liked by women and children. Young leaves were incorporated as a leafy vegetable in common traditional meals, and roots were used in dishes such mixed vegetable curry and kichuree (a one pot meal of rice, lentils and vegetables). **Conclusions:** OFSP combined with other nutrient-rich foods such as small fish increases dietary diversity and improves the nutritional value of family diets. As women are responsible for OFSP production and harvesting, they have easy access to a nutrient-rich food source, as well as potential income generation through sale, thus increasing women's empowerment. Many more households have introduced OFSP.

Key Words: orange-fleshed sweet potato, aquatic agricultural systems, Bangladesh.

PO991

THE EFFECT OF EDUCATION IN KNOWLEDGE, ATTITUDE AND PRACTICE EARLY BREASTFEEDING INITIATION IN TOWN OF PAREPARE, INDONESIA

N. Jafar¹, F. Umar¹

¹Hasanuddin of University, Indonesia

Background and objectives: Data Indonesia Demographic and Health Survey 1997-2007 showed a decline in the prevalence of exclusive breastfeeding from 40.2% in 1997 to 39.5% and 32% in 2003 and 2007, respectively. Riskesdas 2010 the prevalence of exclusive breastfeeding was only 15.3%. This study aimed to determine the effects of education in early initiation of breastfeeding (IMD) IMD behavior in the City of Pare-Pare.

Methods: This research was a quasi eksperimen design with one group pretest-posttest. The samples were 143 pregnant women trimester 3 in the 6 of health centers in the Parepare city were educated using flip chart. To assess the practice IMD, it was conducted purposive sampling by selecting women who had educated and have spawned were 83 people. Data were collected through observation, questionnaires, and documentation. Data were analyzed using Wilcoxon test and chi-square test.

Results: The results showed an increase in knowledge scores were significantly before and after Education IMD at 4.38. An increase in the mean attitude scores before and after Education IMD were significantly at 3.16, there was an influence on the practice of knowledge IMD ($p = 0.000$) in which the respondents who did IMD was 93.2% had sufficient knowledge than less (33.3%) .

Conclusions: It was concluded that education can increase knowledge and positive attitude thus positive influence on the practice of IMD. It is necessary to intensive socialization of the importance of IMD in pregnant women to support successful breastfeeding.

Key words: early breastfeeding initiation, education, maternity.

INTEGRATING MATERNAL, INFANT AND YOUNG CHILD NUTRITION (MIYCN) AND FAMILY PLANNING (FP) SERVICES TO IMPROVE HEALTH AND NUTRITION IN KENYA

J. Kimiywe¹, E. Matiri¹, A. Ogutu¹, C. Cooper², K. Israel-Ballard³, T. Wefwafwa⁴, I. Bashir⁵, N. Kidula¹

¹Maternal and Child Health Integrated Programme (MCHIP), Kenya

²Maternal and Child Health Integrated Programme (MCHIP), Washington

³Maternal and Child Health Integrated Programme (MCHIP)/Program for Appropriate Technology in Health (PATH), Seattle

⁴Division of Nutrition, Ministry of Public Health and Sanitation (MOPHS), Kenya

⁵Division of Reproductive Health, MOPHS, Kenya

Background and objectives: Birth intervals of less than two years increase risk of stunting and underweight by 10-20%. MIYCN and FP are closely intertwined and interventions in these areas have synergistic effects on maternal and child health. The MOPHS collaborated with USAID-funded MCHIP to design and pilot integration of MIYCN and FP services at facility and community levels in Bondo District, Kenya.

Methods: Formative assessments, capacity building of health workers (n=14), community health workers (n=28), and mothers (n=32) and routine collection of service statistics in intervention sites.

Results: At baseline, mothers reported that child spacing enhanced infant growth and development. While they recognized the importance of breastfeeding, exclusive breastfeeding (EBF) postnatally for six months was not widely practiced. Barriers to EBF included: associating EBF with maternal HIV-seropositivity, and misconceptions regarding nutritional adequacy of breast milk alone for the infant. Thirteen behavioural changes were identified which guided development of behaviour change messages and materials. A "one stop shop" integration model was adapted at health facilities (clients offered both services on the same day), and integrated counselling and group activities conducted in the community. Supportive

supervision findings after one year of intervention, revealed a 50% increase in demand for nutrition and FP services and 80% increase in MIYCN-FP knowledge by both mothers and health care workers.

Conclusions: MIYCN-FP integration is feasible and effective. Results will be used to inform national scale up efforts.

Key Words: nutrition, family planning, integration, breastfeeding.

PO994

SOCIOECONOMIC DIFFERENCES IN FRUIT AND VEGETABLE CONSUMPTION, RESULTS OF THE DUTCH NATIONAL FOOD CONSUMPTION SURVEY-YOUNG CHILDREN 2005-2006

E.J. de Boer¹, H.P. Fransen¹, C. Van Rossum¹, M.C. Ocke¹, D. Van der A¹

¹National Institute For Public Health And The Environment (RIVM), The Netherlands

Background and objectives: Fruit and vegetables are important components of a healthy diet. In the Netherlands, a fruit intake of 150 g/day and a vegetable intake of 50-100 g/day for 1 to 3 year old children and 100-150 g/day, for 4 to 8 year olds, is recommended. However, most Dutch children do not meet these recommendations. Knowledge of the characteristics associated with low fruit and vegetable consumption can assist policy makers in developing strategies and programs targeted at specific social groups, areas and/or settings for increasing the consumption of fruit and vegetables among young children. The aim of this study was to examine socioeconomic (SES) differences in fruit and vegetable consumption and to identify consumption characteristics associated with fruit and vegetable intake.

Methods: Data from the Dutch National Food Consumption Survey among young children (2005-2006; n=1,279, 2-6 yrs) was used. Differences in amount and types of fruit and vegetables, (number of) food consumption occasions by SES were examined. SES was based on income or educational level of head of household.

Results: Mean total vegetable intake was 41 g/day (SD=36). Total vegetable consumption was significantly higher in children living in high-income households than those living in low-income households (mean of 48 versus 37 g/day, respectively). Mean total fruit intake was 120 g/day (SD=84). No significant differences in total fruit intake were observed between SES groups (income or educational level). A positive association between number of consumption moments and amount of vegetable and fruit consumption was observed.

Conclusions: Mean intakes of fruit and vegetables by young Dutch children are far below the recommendations. Increa-

sing vegetable and fruit consumption should be stimulated in all young Dutch children and increasing vegetable consumption particularly in children from low-income families. Policy measures could focus on encouraging more consumption moments, not only in low SES groups but in all Dutch children.

Key words: SES, DNFCs.

PO995

EARLY ADIPOSITY REBOUND IS ASSOCIATED WITH INCREASED METABOLIC RISK AT AGE 7Y IN CHILEAN CHILDREN

L. González Céspedes¹, J. Kain¹, M. Garmendia¹, C. Corvalán¹

¹Institute of Nutrition And Food Technology, Santiago de Chile, Chile

Background and objectives: Early adiposity rebound (< age 5 y; EAR) has been consistently associated with increased obesity risk, but its relationship with metabolic disorders is less clear. Also importantly, the mechanisms involved in these associations are not yet established. Therefore, we aimed to assess the association between timing of adiposity rebound (AR) and metabolic status at age 7, evaluating the potential role of total adiposity, adipose function, and biological maturation in these associations.

Methods: In 910 children from the Growth and Obesity Chilean Cohort Study (GOCS) we built BMI curves from 0-7 y and estimated the age at AR. At 7 y we measured waist circumference, glucose, insulin, triglycerides and HDL-cholesterol and a metabolic risk score based on standardized scores was constructed. At 7 y we also measured percentage of fat mass (adiposity), leptin and adiponectin (adipose functionality) and ultrasonographic bone age (maturation).

Results: We found that mean age at AR was 5 y in girls (5.19 ± 1.82 y) and boys (5.42 ± 1.70 y) and 44% of the children had EAR. EAR was associated with larger waist circumference [x: 5.10 (95% CI: 4.29-5.91)], higher glucose [x: 1.02 (1.00- 1.03)], insulin resistance [HOMA-IR: 1.06 (1.03- 1.09)], and triglycerides [x: 10.37 (4.01- 6.73)], and worse metabolic risk score [x: 0.30 (0.02- 0.37)]. Associations decreased significantly when adding adiposity to the models (i.e. waist circumference: 0.85 (0.33- 1.38) and to a lesser extent when adding functionality [i.e. waist circumference: 0.73 (0.14- 1.32) and maturation [i.e. waist circumference: 0.65 (0.10- 1.20)].

Conclusions: In Chilean children younger ages of adiposity rebound predict higher metabolic risk at 7 y. These associations are explained by increased maturation and adiposity dysfunction, but mostly by greater adiposity. Funding: FONDECYT # 1090252, CC has a Wellcome Trust Training Fellowship.

Key words: adiposity rebound, obesity, metabolic risk.

PO996

FEAST AND FAMINE: THE DILEMMA OF EXTREME CONTRASTS IN VITAMIN A CONSUMPTION IN THE WESTERN HIGHLANDS OF GUATEMALA

I. Bielderman¹, M. Vossenaar¹, D. Fuentes¹, E.M. Ruiz¹, N.W. Solomons¹

¹Center For Studies of Sensory Impairment, Aging And Metabolism (CeSSIAM), Guatemala City, Guatemala

Background and objectives: In Guatemala, vitamin A (VA) deficiency was widespread until fortification of sugar (10 µg/g) became mandatory in the 1990s. Pregnant and lactating women have a 33% and 42% higher VA requirement than women in the non-reproductive state. We examined usual intakes in two population settings in the Western Highlands of Guatemala to determine to what extent low and elevated intakes were discernible in the reproductive period.

Methods: Previous day recalls were conducted in a total of 121 women, equally divided across strata of pregnancy and lactation as well as semi-urban and urban residence. Total VA intake and its partition among preformed sources (sugar, fortified foods, animal sources) or pro-VA carotenes (plant sources) was calculated. Low VA intake was defined as <800 RE for pregnancy and <850 RE for lactation, with excessive intake (supra-UL) as >3000 µg preformed VA.

Results: The median total VA intakes (in RAE) by sub-group were: 1307 for semi-urban, pregnant women, 1021 for urban, pregnant women, 1318 for semi-urban, lactating women, and 1239 for urban, lactating women. Sugar was the main source of VA in all groups. The sugar contribution to total intake was 35.6% (semi-urban/pregnant); 46.0% (urban/pregnant); 44.1% (semi-urban/lactating); and 43.0% (urban/lactating). From the semi-urban area, 31.0 % of pregnant and 25.8% of lactating women had low VA intake; for urban subjects the proportions were 20.7% and 21.9%, respectively. Overall, 5.8% of the pooled sample had excessive VA intake.

Conclusion: Sugar fortification with VA is essential to help support an adequate vitamin intake in this population. Nevertheless, upwards of 20% still have some under-consumption of the vitamin. Paradoxically, seen concurrently on any given day is a modest incidence of intakes of preformed VA above the UL. Funded by Hormel Foods Corporation, Austin, MN

Key words: vitamin A, sugar, fortification, reproduction, Guatemala.

PO997**NUTRITION EDUCATION INTERVENTION IMPROVES NUTRITIONAL STATUS AND HEALTHCARE SEEKING PRACTICES OF PREGNANT WOMEN IN LOW INCOME SETTINGS***A. Malhotra¹, R. Kaur²*¹Lakshmibai College (University of Delhi), Delhi, India²Indira Gandhi National Open University, Delhi, India

Background and objectives: Nutrition related knowledge of pregnant women is one of the important factors in ensuring their optimal nutrition and healthcare. This investigation assessed the effect of nutrition education on the gestational weight gain and healthcare-seeking practices of pregnant women.

Methods: Two rural projects of Integrated Child Development Services (ICDS) scheme in low-income settings of outer Delhi were identified purposively to select 118 women (aged 18-35 years) in second trimester (13 to 24 weeks) of pregnancy. They were assigned to non-nutrition education (non-NE) or nutrition education (NE) group; and nutrition counseling was imparted through lectures, flip book and charts for a period of 12 weeks. Data relating to gestational weight, dietary intake (through one-day 24 hour recall coupled with food frequency questionnaire) and knowledge, attitude and practices (KAP) about nutrition and healthcare (using a pretested questionnaire) were gathered at enrolment and post-intervention. Birth outcome was also noted. Statistical analysis was carried out employing ANOVA and t test.

Results: At enrolment, majority of the subjects had inadequate intake of nutrients particularly energy (70%), protein (68%), calcium (70%) and iron (96%). Their KAP scores were poor (61.76 + 22.62 for non-NE and 60.57 + 1.0 for NE out of a maximum score of 140). Post-intervention, significant improvements were indicated in KAP relating to nutrition and antenatal care ($p < 0.001$) and in nutrient intake ($p < 0.05$). NE group reportedly consuming more iron supplements, undergoing more frequent antenatal check-ups and undertaking better immunization against tetanus. The gestational weight (in second and third trimesters), weight gain (in second trimester) and birth outcome ($p < 0.05$) were significantly better.

Conclusions: Effective nutrition education interventions can improve the nutrient intake, healthcare-seeking practices and weight gain of underprivileged pregnant women in low-income-settings and thus lead to better birth outcome.

Key words: pregnancy, dietary intake, gestational weight gain, knowledge, nutrition education.

PO998**ADHERENCE TO MICRONUTRIENT POWDER (SPRINKLES) AMONG CHILDREN AGED 6-59 MONTHS IN RURAL BANGLADESH***M. Angdembe¹, N. Choudhury², T. Ahmed², R. Haque³*¹James P. Grant School of Public Health, Dhaka, Bangladesh²Centre for Nutrition and Food Security, International Centre for Diarrhoeal Disease Research, Bangladesh (icddr, b), Dhaka, Bangladesh³BRAC Health Programme, BRAC, Dhaka, Bangladesh

Background and objectives: Micronutrient Powder (MNP) or Sprinkles can be sprinkled onto any semisolid food and can be given to young children to address iron deficiency anemia. The community health workers of BRAC (an NGO) known as Shasthya Shebikas (SS) sell MNP sachets during their regular household visits. The current major challenge relates to unavailability of data on adherence or real uptake of MNP by children. The objective was to assess adherence to MNP and associated factors among children aged 6-59 months in rural Bangladesh.

Methods: A cross sectional study was conducted among 78 children aged 6-59 months in Saturia Sub-district who fed with MNP supplied by BRAC SS in the past 60 days. Cluster sampling technique was used to select mothers with eligible children. Semi-structured questionnaire was used for interviews. A binary logistic regression model was developed to obtain adjusted odds ratios (OR) with 95% CI.

Results: Sample median adherence was calculated to be 65% (95% CI: 63.8-76.0). In multivariate analysis, age of mother in years (OR=0.77, 95% CI: 0.64-0.93), households belonging to poorer (OR=0.01, 95% CI: 0.00-0.19) and middle (OR=0.06, 95% CI: 0.01-0.54) wealth quintiles and mothers who prefer to feed flexibly (OR=0.04, 95% CI: 0.00-0.31) were significantly associated with high adherence. Further, for every one unit increase in visit by BRAC SS in the past 60 days, the odds of having high adherence significantly increased by 56% (OR=1.56, 95% CI: 1.16-2.08).

Conclusions: In the light of evidence from this study it is difficult to interpret whether an adherence of 65% is acceptable for a nutritional intervention within a program setup. But we do know that SS are the key to improving adherence through regular visits to households of MNP users.

Key words: micronutrient powder, sprinkles, adherence, Bangladesh.

PO999**USE OF SEVEN-DAY RECORDS TO ESTIMATE ENERGY AND NUTRIENT INTAKES IN SPANISH ADOLESCENTS: INFLUENCE OF DURATION OF RECORDING PERIOD**

M I. Mesana¹, T. Mouratidou¹, J M. Fernández-Alvira¹, M. Fajó-Pascual¹, G. Rodríguez-Martínez¹, L A. Moreno¹

¹GENUD 'Growth, Exercise, NUtrition and Development' Research Group, Universidad de Zaragoza, Zaragoza, Spain

Background and objectives: Three-day food records are frequently used because mis-reporting of food intake is believed to increase with recording period. The aim of this study was to describe the energy and nutrient intake in adolescents. To explore trends in reported energy intake with record period duration.

Methods: A sample of adolescents aged 13 to 18 years, from the city of Zaragoza (Spain) was recruited. In the framework of the AVENA (Alimentación y Valoración del Estado Nutricional en Adolescentes) Study, a total of 275 adolescents (107 boys and 168 girls) were studied. Data were obtained by means of a 7-day dietary record diary. Energy and nutrient intakes assessed in the first day, 3 first days and all 7 days were compared in this sample.

Results: Mean energy intake in the sample was 2005 (SD: 668) kcal. Mean energy intake in boys was significantly higher than in girls. From 7-day records, protein contributed on average 17% to the energy intake, fat 42.7% and carbohydrates 40%. Analyzing the different fatty acids, saturated fatty acids showed a contribution of 12.8%, monounsaturated fatty acids of 18% and polyunsaturated fatty acids of 5.2%. Mean intake of energy and nutrients of the assessed first day, three first days and the 7 days significantly decreased as the record period increased from day 1 to 7.

Conclusions: The studied adolescents consumed a diet high in total fat and in saturated fatty acids and low in carbohydrates. PUFAs and MUFAs intake were adequate. Observed mean intakes deviate considerably from the Spanish dietary guidelines. There was an overall trend of significant decrease of REI and the rest of nutrients from day 1 to 7.

PO1000**PREVALENCE AND DETERMINANTS OF ENERGY UNDERREPORTING IN SPANISH ADOLESCENTS PARTICIPATING IN THE AVENA CROSS-SECTIONAL STUDY**

M I. Mesana¹, T. Mouratidou¹, M. Fajó-Pascual¹, G. Rodríguez-Martínez¹, L A. Moreno¹, F. Pérez-Llamas¹, A. Marcos¹

¹GENUD 'Growth, Exercise, NUtrition and Development' Research Group, Universidad de Zaragoza, Zaragoza, Spain

Background and objectives: Underreporting is a major problem in dietary surveys of children and adolescents and findings should be interpreted with caution. The aim of this study was to assess the prevalence of underreporting in Spanish adolescents and to examine associations with anthropometric, psychological, cognitive, socio-demographic and behavioural determinants.

Methods: In the framework of the AVENA (Alimentación y Valoración del Estado Nutricional en Adolescentes) study, a total of 784 adolescents (46% males) aged 13 to 18 years from three Spanish cities (Zaragoza, Murcia and Madrid) were studied. Dietary intake was assessed using a seven-day estimated dietary record. Information on socio-demographic, psychological, cognitive and behavioural determinants was assessed by means of self-administered questionnaires. Weight and height were also measured. To assess underreporting we used the Goldberg criterion. Binary logistic regression was used to investigate the associations between underreporting and determinants.

Results: Rate of underreporting in the whole sample was 38%, similar in males and females. Weight was significantly related to underreporting (OR 1.05, 95% CI 1.04, 1.07), but not BMI (OR 0.66, 95% CI 0.38, 1.14). Usual breakfast consumption was inversely related with underreporting (OR 1.78, 95% CI 1.08, 2.94). Almost all covariates related to weight perception were significantly associated with underreporting: feeling too full or sick after meals (OR 1.45, 95% CI 1.04, 2.01), thinking of lost of control about quantity of food intake (OR 1.74, 95% CI 1.06, 2.85), having lost over 6 kilograms in the last three months (OR 4.79, 95% CI 2.08, 11.02) and thinking that they are too fat (OR 1.93, 95% CI 1.29, 2.89).

Conclusions: The prevalence of underreporting was similar in both sexes. Weight perception was a major determinant of misreporting which should be accounted for in dietary studies in adolescents.

PO1001**COMPARISON OF DAILY DIETARY ENERGY AND MACRONUTRIENTS INTAKE WITH DRI IN COLLEGE STUDENTS OF KERMAN MEDICAL UNIVERSITY, KERMAN, IRAN***F. Doostan*¹

¹Assistant professor of nutrition, Department of Nutrition, Health Faculty, Kerman University of Medical Sciences, Iran

Background and objectives: noncommunicable diseases is often related to life style including nutrition. This study was conducted to compare daily dietary nutrients intake with DRI in college students of Kerman Medical University.

Methods: In this cross sectional study thirty hundred seventy five students (221 females, 150 males, mean age 21±2.5 years) were studied. Daily intake of energy and macronutrients, fiber and cholesterol were extracted by using nutritional software N4 and compared with DRI and RDA. Data were analyzed by using student t test.

Results: Mean daily intake of Energy (Kcal), total fat, saturated, mono unsaturated, polyunsaturated fat, carbohydrate, protein (g), cholesterol (mg) and fiber (g) in studied students were 2352±36, 93.7±1.6, 27.4±0.5, 32.5±0.58, 27.5±0.54, 305±5, 80.4±1.4, 293±8.4 and 17.5±0.36, respectively. Results of present study showed that mean daily intake of energy was in the range of DRI (2200-2900 Kcal/day) for this age group. Mean daily intake of protein were higher than DRI (46-56 g/day) for this age group. Percentage intake of energy from protein was in the range of AMDR, Acceptable Macronutrient Distribution Range (10-35%). Percentage intake of energy from carbohydrate was in the range of AMDR (45-65%). Percentage intake of energy from fat was in upper level of AMDR (20-35%) for this age group. Dietary fat energy more than 30% was observed in 87.7%. Fiber intake less than 25 g/day was observed in 88.3%. Cholesterol intake more than 300 mg/day was observed in 41.9% of studied students. Percentage intake of energy from carbohydrate, fat and protein sources were 51%, 35.3%, and 13.5%, respectively. Percentage intake of energy from protein in males was significantly higher than females ($p = 0.01$). No significant difference was noticed for the others between two groups.

Conclusions: Higher daily intake level of fat and cholesterol and lower intake of fiber may be considered as a risk factor of chronic disease in later life in these students. This finding is suggested nutritional education is necessary. Totally, a tendency to eat imbalanced diet, high fat and low fiber was observed in both groups.

Key Words: chronic disease, nutrition style, college students.

PO1002**DISORDERED EATING AND UNHEALTHY WEIGHT-CONTROL BEHAVIORS AND ASSOCIATED FACTORS IN ADOLESCENTS FROM SÃO PAULO, BRAZIL***G V S. Leal¹, S T. Philippi¹, M S. Alvarenga¹*

¹Department of Nutrition – School of Public Health, University of São Paulo, Brazil

Background and objectives: Eating disorders (ED), ED risk behaviors and unhealthy weight-control behaviors (UWCB) are public health problems among adolescents because of their high prevalence and serious consequences to health. The understanding of the eating disorder risk behaviors and UWCB associated factors can help planning preventive and educational actions. The aim of this study was to identify the prevalence of ED risk behavior and unhealthy weight-control behaviors among Brazilian adolescents.

Methods: A cross-sectional study was conducted with 1167 adolescents, both genders, aged 13–19 years from 12 public schools in the city of São Paulo, Brazil. ED risk behavior was assessed using a simplified self-report questionnaire, UWCB by a yes/not question about specific behaviors that were not typically recommended for weight management and nutritional status by Body Mass Index (BMI). Peers, parents and media influence, body perception, body image and dieting were assessed by specific questions. The t test was used to evaluate the univariate associations and a multivariate logistic regression model was used to examine the factors influencing ED risk behavior and UWCB.

Results: ED risk behavior was identified among 12.2% of adolescents, mainly among females (72.5%, $p < 0.001$), and UWCB was prevalent in 31.9%, being 66.8% females ($p < 0.001$). Dieting was predictive to ED risk behavior and UWCB for both genders. Media influence and mothers that encourage dieting were predictive to UWCB among boys. Body satisfaction was a protective factor for ED risk behavior and UWCB and magazines reading was predictive to UWCB among girls.

Conclusions: The ED risk behavior prevalence was similar to the rates found in national researches. The UWCB were almost three times more prevalent and was found that these practices increase the chance to develop severe behaviors. ED risk behavior and UWCB prevention programmes should aim body image satisfaction, media literacy and dieting discouragement.

Key words: eating disorders, adolescent, risk.

PO1003**UNDERWEIGHT IS A RISK FACTOR FOR IRON DEPLETION AND IRON-DEFICIENT ERYTHROPOIESIS AMONG INDONESIAN YOUNG WOMEN**

S. Sumarmi¹, H. Hadi², W. Lestariana², D S. Nurdiati²

¹Department of Nutrition, Faculty of Public Health, Airlangga University, Surabaya, Indonesia

²Faculty of Medicine, Gajah Mada University, Yogyakarta, Indonesia

Background and objectives: Underweight and iron deficiency among women are very prevalent in many developing countries, including Indonesia, but it is unclear whether underweight is associated with some parameters of iron deficiency.

Objectives: To investigate the association between weight status, as measured by body mass index (BMI), and iron deficiency, among the young women. **Method:** A cross sectional study was conducted at 9 subdistricts, 80 apparently healthy young women (age 15-26 years) were randomly selected from premarital list. Body weight and stature were measured, BMI was calculated and compared to with age-specific BMI reference values for adolescent subjects (age 15-20 years). Underweight was defined as a BMI less than 5th percentile. Venous blood sample were collected and analyzed for Hb, serum ferritin and soluble transferrin receptor (sTfR). Iron depleted is stated if serum ferritin concentration less than 12 mg/L, iron deficiency erythropoiesis (IDE) when concentration of sTfR more than 4.4 mg/L. **Result:** Of the 80 subjects, 23.8% were underweight. Anemia among underweight subjects is 47.4% compared to who were normal and overweight subjects (29.5%). Iron depleted (16.7%) and IDE (37.5%) among underweight are higher than who were not underweight (5.3%) and (13.2%) respectively. Subject who were underweight was approximately three times to be iron depleted (OR: 3.167; 95% CI: 0.7-14.335), and to be IDE (OR: 2.839; 95% CI: 1.113- 7.241) as were those were not underweight.

Conclusion: Iron deficiency is more prevalent among underweight young women and risk for iron deficiency approximately three times compared to who were those not underweight.

Key words: anemia, iron deficiency, iron depleted, iron deficient erythropoiesis

PO1004**A DETERMINATION OF VITAMIN D STATUS AND INTAKE OF PREGNANT AND NON-PREGNANT SAUDI ARABIAN WOMEN IN RIYADH, SAUDI ARABIA**

N. AlTheyab¹, G. Liepa²

¹Queensland University, Australia

²Eastern Michigan University, Australia

Background and objectives: The objective of the present study was to determine serum 25(OH)D and PTH concentrations as well as vitamin D and Ca dietary intake in healthy pregnant (P) (n=58) and non-pregnant (NP) (n=57) Saudi Arabian women who reside in Riyadh, Saudi Arabia.

Methods: Age, occupation, skin color, smoking status, use of sunscreen, use of supplements, and sun exposure were correlated to vitamin D status. Dietary and supplement intake was also assessed.

Results: Among the participants, 75.4% (37.1% P and 38.6% NP) of the women had 25(OH)D concentrations that were below the recommended concentration [≤ 37.5 nmol/L (15 ng/ml)]. PTH concentrations were normal in 74.6% and high in 22.9% of the participants. Dietary vitamin D intake was low in 76% of the participants, whereas dietary Ca intake was extremely low.

Conclusions: Positive correlations were shown to exist between serum 25(OH)D concentrations and the use of supplements and the length of exposure to sunlight and skin tone. Vitamin D deficiency appears to be prevalent among P and NP Saudi women.

PO1005**ANALYSIS OF PHYSICAL ACTIVITY, NUTRITIONAL STATUS, SOY AND SOY-PRODUCT CONSUMPTION HABIT AS A DETERMINANT OF MENOPAUSAL SYNDROME IN ELDER WOMEN**

I. Tanziha¹, S. Lestari¹, L. Amalia¹

¹Department of Community Nutrition, Faculty of Human Ecology, Bogor Agricultural University, Indonesia

Background and objectives: Elder women gone through many changes in body composition, physiological, and psychological. One phase in women's life is menopause that occurs in older age. Menopausal syndrome has been a problem worldwide. Many researches have shown that soy-isoflavone can be a potential alternative to reduce menopausal syndrome. The objectives of this research was to analyze determinant of menopausal syndrome.

Methods: This study was a retrospective research. A population of adult and elder women participating in Life-skill Program were involved in this research. The total sample that fulfilled the inclusion and exclusion criteria was 31 menopause women. Menopausal syndrome includes menopausal symptoms, self-images, and anxiety. Multiple regression was applied to analyze the influence of physical activity, nutritional status, and the soy and soy-product consumption habit to menopausal syndrome. A logistic regression model was applied to analyze the risk factors of menopausal syndrome such as isoflavone consumption.

Results: The mean physical activity level (PAL) was 1.69 and most samples had light physical activity. Most samples were overweight (45.2%) and had an average soy and soy-product consumption (71%) that fulfilled 25% of the RDA of isoflavone consumption. The result of multiple linear regression showed that physical activity affected self-images ($r^2 = 0.206$, $p < 0.05$) and soy consumption affected anxiety ($r^2 = 0.198$, $p < 0.05$). Generally, physical activity, nutritional status, and soy isoflavone consumption have roles in menopausal syndrome ($r^2 = 0.190$, $p < 0.05$). The result of logistic regression showed that isoflavone was a protective factor to menopausal syndrome, women consuming isoflavone >30 gr or as equal as 40 gr tempeh minimally per day had lower risk in developing menopausal syndrome (OR=0.146).

Conclusions: Healthy lifestyle that maintain nutritional status, promotes physical activity, soy and soy product consumption habit may reduce menopausal syndrome.

Key words: menopausal syndrome, elder women, soy isoflavone.

INFANT SIZE AND BODY COMPOSITION IN RELATION TO THE INSTITUTE OF MEDICINE GESTATIONAL WEIGHT GAIN RECOMMENDATIONS

E. Forsum¹, B. Eriksson¹, P. Henriksson¹, M. Löf²

¹Department of Clinical and Experimental Medicine, Linköping University, Linköping, Sweden

²Department of Bioscience and Nutrition, Karolinska Institute, Huddinge, Sweden

Background and objectives: Body composition at birth may be important for later health. Effects of high or low gestational weight gains (GWG) on newborn body composition are incompletely known. The institute of medicine (IOM) provides recommendations regarding GWG for women with different body mass index before pregnancy. We investigated relationships between GWG and infant size and body composition at 1 week of age.

Methods: We measured height of 312 pregnant Swedish women who also reported their weight before conception and their gestational weight gain. Body composition of their healthy, full term, singleton infants was measured using air displacement plethysmography at 7 ± 2 days of age. GWG less than (GWG<IOM) and higher than (GWG>IOM) the IOM recommendations were independent variables in multiple regression models with GWG within the recommendation as reference.

Results: 57, 114 and 141 women gained below, within and above the IOM recommendations, respectively. GWG>IOM was associated with higher infant weight (156 g, $p = 0.008$), fat-free mass (101 g, $p = 0.022$), fat mass (55 g, 1.1 %, $p = 0.016-0.028$) but not with longer infants. GWG<IOM was associated with shorter infants (0.9 cm, $p = 0.003$), with less weight (206 g, $p = 0.007$) and fat-free mass (152 g, $p = 0.007$), but had no effect on fat mass (g, %). When adjusted for infant length, GWG<IOM was not associated with lower weight or less fat-free mass in infants.

Conclusions: Infants born to women with GWG above the IOM recommendations were heavier and fatter than infants born to women with GWG within these recommendations. Furthermore, women with GWG below the IOM recommendations had shorter infants with less fat-free mass when compared to infants of women with the recommended GWG. The lower infant weight and fat-free mass associated with GWG below the IOM recommendation was probably due to a decreased infant length.

Key words: body composition, gestational weight gain, institute of medicine.

PO1007

COMPLEMENTARY FEEDING PRACTICES AMONG MOTHERS IN SELECTED SLUMS OF DHAKA CITY: A DESCRIPTIVE STUDY

F. Ara¹, F. Saleh¹, A H. Hoque¹, S. Alam²

¹Dept of Community Nutrition, Bangladesh Institute of Health Sciences (BIHS), Bangladesh

²Plan International, Bangladesh

Background and objectives: Improper complementary feeding (CF) practice is one of the main reasons for malnutrition among Bangladeshi children aged less than two years. In this context, the study assessed the CF practices of mothers in four selected slums (Tejgoan, Rayerbazar, Beribad, and Jafrabad) of Dhaka city using the guidelines of the World Health Organization (WHO).

Methods: This descriptive study included 120 mother-child pairs from the four conveniently selected slums. A questionnaire, developed following the guidelines of WHO for CF practices, was used for collecting data.

Results: The mean (\pm SD) age of the children was 14.68 \pm 5.55 months. Twenty-seven (23%) mothers were exclusively breastfeeding (EBF) their children. Only 15 (16%) non-EBF mothers started CF at the recommended time, i.e. at 6 months. At 6-8 months of age, 2 (40%) of the EBF and 12 (67%) of the non-EBF mothers gave complementary foods twice a day to their children. In both the groups of 9-11 months of age, about 70% mothers gave complementary foods twice a day to their children. The frequency of CF was acceptable (3 times a day) in 13 (81%) of the EBF and 32 (56%) of the non-EBF children at 12-23 months of age. Complementary foods given by 24 (89%) of the EBF and 86 (93%) of the non-EBF mothers to their children were not adequate in energy. Feeding with psychosocial care practices was not perfect in both the groups.

Conclusions: The findings showed that, according to the WHO guidelines, the CF practices among mothers of children aged less than two years were very poor in the selected slums of Dhaka city. These findings indicate that there is a considerable gap between the recommendations of WHO and the energy intake among this group of children.

Key words: complementary feeding, WHO guideline.

PO1008

DAIRY PRODUCT CONSUMPTION AND THE NUTRITIONAL STATUS OF PRESCHOOL CHILDREN IN ACCRA, GHANA

M.O. Mensah¹, G.E. Otoo¹

¹Department of Nutrition and Food Science, University of Ghana, Legon

Background and objectives: Poor diet quality is associated with the high rate of malnutrition among young children worldwide. Dairy foods are nutrient and energy dense and hence have the potential to improve the diet quality and reduce the rate of malnutrition. Consumption of dairy products in Ghana is far from optimum and the level of intake of preschoolers is unknown. The main objective of this study was to determine the association between dairy consumption and the nutritional status of preschool children. **Method:** A total of 106 caregivers with preschool children between the ages of 2 to 5 years were selected from nurseries and crèches in the Accra. A semi-structured questionnaire was used to collect household socio-demographic characteristics; dietary data was collected using 24-hour dietary recall and a semi-quantitative food frequency questionnaire. Anthropometric measurements of the children were taken and WHO Anthro software was used to identify wasting, underweight and stunting; WHZ \leq -2SD, WAZ \leq -2SD and HAZ \leq -2SD, respectively. Children identified as wasted, stunted and underweight were classified as malnourished. The relationship between dairy consumption and nutritional status was assessed using Chi-square analysis.

Results: Out of the 106 children, 9 children were underweight, 6 children were stunted and 4 children were wasted. Thirteen children were classified as malnourished. The consumption of dairy products by the preschoolers was low, about a serving/day. Among the four dairy foods (milk, cheese, yoghurt and ice cream), milk was commonly consumed. While no significant associations were found between cheese, yoghurt and ice cream consumption and nutritional status of the preschooler, lower frequency of milk consumption was significantly associated with the increased risk of malnutrition among preschoolers ($p=0.004$).

Conclusion: Milk intake is essential during preschool age. Efforts to encourage frequent milk consumption can reduce the risk of malnutrition in Ghanaian preschoolers.

Key words: Dairy, Preschoolers, Nutritional status

PO1009

EFFECTIVENESS OF FOLIFER SUPPLEMENTATION ALONE VS SUPPLEMENTATION IN COMBINATION TO NUTRITION EDUCATION ON BIRTH OUTCOMES OF RURAL WOMEN, INDIA

S. Upadhyay^{1,2}, S. Kumar², A. Sharma²

¹Dept of Nutrition & Dietetics, Lovely Professional University, Punjab, India

²Indira Gandhi National Open University, New Delhi, India

Background and Objectives: This research aimed to find out the awareness of pregnant women regarding folifer tablets, effectiveness of supplementation alone vs supplementation in combination to nutrition education. **Methodology:** The study was conducted on 190 pregnant women. This was a prospective, observational study. Pregnant anemic women were enrolled at 6 to 10 weeks of gestation and followed to 6 weeks postpartum. The subjects were divided into two groups viz group I received only folifer supplementation and group II received supplementation in combination of counselling. A blood sample was obtained at enrolment, II and III trimester to determine hemoglobin levels. The Hemoglobin was measured by cyanmethemoglobin method, height and weight data was collected as per standard procedures.

Results: Mean BMI of the subjects at the time of enrollment was 21.2 kg/m² (\pm 9.04). Poor status of weight gain during pregnancy was found. Hemoglobin status data revealed that majority of the subjects were mild anemic (43%) throughout the pregnancy. Percentage of the subjects who were taking the folifer tablets was 61%. It was found that women in group II had significant higher value of Hb than group I. Bivariate data established a positive correlation in between the maternal weight and birth weight, maternal Hemoglobin status and

birth outcome, hemoglobin status, maternal nutritional intake and birth out come. Multivariate analysis after adjustment for education, pregnancy history, iron supplementation, and height showed that drinking more than three cups of tea per day before pregnancy, consumption of clay or dirt during pregnancy and never consuming eggs or consuming eggs less than twice a week during pregnancy were significantly associated with anemia.

Conclusions: A high prevalence of anemia, poor compliance with folifer supplementation and effectiveness of supplementation in combination with nutrition education was found.

Key words: anemia, pregnancy, supplementation, birth outcomes.

PO1010

THE INFLUENCE OF DIETARY FATTY ACIDS INTAKE DURING PREGNANCY ON THE COMPOSITION OF MATURE BREAST MILK

R Y. Nishimura¹, P. Barbieri¹, G S F. Castro², A. Jordao Junior², G C S. Perdoni¹, D S. Sartorelli¹

¹Department of Social Medicine, University of Sao Paulo, Brazil

²Department of Internal Medicine, University of Sao Paulo, Brazil

Background and objectives: Little is known about the relationship between maternal dietary intake during pregnancy and the fatty acids content of breast milk. The aim of the present study was to evaluate the influence of the food intake in different periods of pregnancy in the content of fatty acids of mature breast milk.

Methods: Prospective study conducted among 45 pregnant women, aged 18-35 years, who delivered at term, and were exclusively or predominantly breastfeeding their babies. Food intake during pregnancy was evaluated by 3 food recalls (24hR), one in each trimester of pregnancy, and by 2 24hR at the post-partum period. Samples of mature breast milk were collected between 5-14th weeks of lactation, and the fatty acid composition of the milk was determined by gas chromatography. Linear regression models, adjusted by post-partum BMI, were used to verify the association between maternal dietary fatty acids in each trimester of pregnancy and the content of fatty acids on human milk. Furthermore, β 1 and confidence intervals (95% CI) were de-attenuated.

Results: A positive association between EPA [β = 1.87 (95% IC: 0.54, 3.28)] and DHA [β = 0.46 (95% IC 0.21, 0.71)] content of the maternal diet from the third trimester of pregnancy, respectively, and n-3/n-6 dietary ratio [β = 0.09 (95% IC 0.02, 0.17)] on the second and third trimesters and at the post-partum period with the amount of these fatty acids on mature breast milk were found.

Conclusions: DHA and EPA content of the maternal diet during late pregnancy might influence the content of these fatty acids on mature breast milk. Moreover, the data showed a positive association between dietary ratio of n-3/n-6 fatty acids on late pregnancy and post-partum period on fatty acid composition of breast milk. Funding: FAPESP (2010/12320), FAEPA.

Key words: breast milk, pregnancy, fatty acids intake.

PO1012

STUDY ON DIET AND BODY WEIGHT IN SCHOOL CHILDREN AGED 7-14 YEARS FROM THE SOUTH REGION OF BULGARIA (THE EPODE METHODOLOGY)

T. Handjieva-Darlenska¹, J. Staykova², M. Kubateva³, S. Handjiev⁴

¹Department of Pharmacology And Toxicology, Medical Faculty, Medical University, Sofia, Bulgaria

²Regional Health Inspectorate, Kardzhali, Bulgaria

³Regional Health Inspectorate, Smolijan, Bulgaria

⁴Bulgarian Association for the Study of Obesity and Related Diseases (BASORD), Bulgaria

Background and objectives: There is not enough data on the dietary habits of school-age children in the South region of Bulgaria. Thereafter, the aim of our study was to examine the diet and different anthropometric parameters in school children from Kardzhali and Smolijan.

Methods: A total of 9266 school children (7-14 years old) were enrolled in the study. Their weight, height and body mass index were measured. The diet was monitored using different tools.

Results: The results showed an increase of overweight and obesity among the studied population. The diet and nutrition intake did not cover the dietary guidelines and requirements. Every third student did not regularly have a breakfast. It was established that the consumption of yoghurt and dairy products was very low, whereas the consumption of sugar and confectionery was high.

Conclusions: Our data justify the application of educational activities and tools for improvement of the diet and physical activity in school children.

Key words: diet, body weight, obesity, school children.

PO1013**EVALUATION OF DIET AND PHYSICAL ACTIVITY IN SCHOOL-AGE POPULATION IN BULGARIA (THE EPHE PROJECT)**

T. Handjieva-Darlenska^{1,2}, *M. Blajeva*², *S. Handjiev*²

¹Department of Pharmacology And Toxicology, Medical Faculty, Medical University, Sofia, Bulgaria

²Bulgarian Association for the Study of Obesity and Related Diseases (BASORD), Sofia, Bulgaria

Background and objectives: “Healthy kids Bulgaria” is a program for prevention of health inequities in children. The program started officially in 2013 year supported by the EPO-DE methodology. The aim of the program is to evaluate dietary, physical activity habits as well as sleep and water consumption in children.

Methods: A total number of 125 families (children and parents) participated in the program. They were from two schools from two municipalities in Sofia. During a period of one year different activities on promotion of healthy diet and increased physical activity were organized. On a competitive principle 30 children were chosen to attend a 1-week camp on a Black sea coast. The mean age of children was 10 years. Before and after the camp they filled in questionnaires on sleep, diet, physical activity and behavioral-related knowledge. During their stay children had a five-time menu (breakfast, lunch, dinner and two middle-breakfasts) based on healthy balanced diet according to the national nutritional guidelines for their age. Children had two times per day (in the morning and in the afternoon) different physical activities. Cooking classes and lectures were given each day to the children.

Results: At the end of the 1-week camp school-age children gained knowledge on and were used to a healthy balanced diet comprising 5-a-day fruit and vegetables, fish, meat, dairy products, oats and different grains, wholemeal bread.

Conclusion: Different programs focusing on a healthy lifestyle including diet and physical activity are needed in school-age children for prevention of health inequities.

Key words: health inequities, children, diet, physical activity.

PO1014**“BECAUSE MOST MOTHERS ARE HUSTLERS”: CHALLENGES OF AN URBAN POOR BREASTFEEDING MOTHER IN NAIROBI SLUMS**

E. Kimani-Murage^{1,2}, *F. Wekesah*¹, *M. Wanjohi*¹, *P. Muriuki*¹, *C. Kyobutungi*¹, *S. Norris*², *N. Madise*³, *P. Griffiths*⁴

¹African Population And Health Research Center (APHRC), Nairobi Kenya

²University of the Witwatersrand, Johannesburg, South Africa

³University of Southampton, Southampton, UK

⁴Loughborough University, Loughborough, UK

Background and objectives: Poor breastfeeding practices are widely documented in Kenya. This is particularly prevalent in the urban slums, where most urban residents live. Only two percent of infants in Nairobi slums are exclusively breastfed for the six months, while 15 percent of children are not breastfed beyond one year. The aim of this study is to establish the local contexts and norms, and other factors which contribute to infant and young child feeding practices in Nairobi slums.

Methods: In-depth interviews, focus group discussions and key informant interviews were conducted in April 2012 with women, community health workers, community leaders, health care professionals, and traditional birth attendants. Interviews were recorded and transcribed verbatim; and coded and analyzed thematically in NVIVO.

Results: Lack of appropriate knowledge, hence misconceptions regarding breastfeeding influence breastfeeding practices among urban poor women. Other factors include socio-economic, socio-cultural, and medical. Women were said to often be the sole breadwinners working, regarded as hustlers. In the cash-based economy, where labor is mainly casual, maternity leave does not apply, hence women resume work shortly after delivery. Exclusive breastfeeding for six months was therefore considered impossible. Lack of food and poor diet were said to seriously affect the breastfeeding practices. Body image was seen as a key factor influencing breastfeeding behaviors as breastfeeding was associated with accelerated aging. This was particularly associated with the young mothers, who were reported to often engage in transactional sex, given few options for livelihood. Top on the list also were socio-cultural beliefs such as “chira” (curse) associated with breastfeeding; and perceived medical factors, including sore breasts and other illnesses such as HIV.

Conclusions: Interventions to promote optimal breastfeeding practices in these resource-constrained settings should aim at breaking the knowledge gap, empowerment of women and social protection measures for breastfeeding women.

Key Words: breastfeeding practices, slums, Kenya.

PO1015**DIFFERENTIALS IN RISK OF HIGH BLOOD PRESSURE IN UNDERNOURISHED AND OVER-NOURISHED ADOLESCENTS IN URBAN INDIA***S. Rao¹, A Kanade¹, J. Sarode¹, P. Apte¹*¹Agharkar Research Institute, India

Background and objectives: Developing countries like India passing through nutritional transition experience double burden of undernutrition and overnutrition. We attempt to examine risks for high blood pressure associated with both forms of malnutrition which coexist in India.

Methods: Adolescents (9-16 yr) from schools catering to lower socio economic class (LSE; 943 boys, 1000 girls) and affluent high socio economic class (HSE; 867 boys, 1042 girls) were measured in a cross sectional study for weight, height, sitting height, body fat, skinfolds and blood pressure.

Results: High prevalence of overweight in adolescents from HSE class compared to that in LSE (24.1% vs 2.2 % in boys and 20.8% vs 3.9% in girls; $p < 0.01$ for both) conferred risk for high systolic blood pressure (HSBP) while high prevalence of stunting in LSE class (20.8% in boys and 11.8% in girls) seemed to confer risk for high diastolic blood pressure (HDBP) as skeletal growth (leg height ratio) showed significant inverse association with blood pressure levels. In LSE class, prevalence of HDBP was significantly higher than prevalence of HSBP in each quartile of BMI (also for body fat and skinfolds). Further, increase in systolic blood pressure with per unit increase of BMI, was higher in LSE class (1.99 mmHg in boys and 1.03 mmHg in girls) compared to that in HSE class (0.91 mmHg in boys and 0.52 mmHg in girls) and this was also true for diastolic blood pressure.

Conclusions: Implications of increase in BMI are more serious for undernourished children than better nourished children. Preventive strategies are required for reducing obesity among urban affluent adolescents and for reducing stunting in poor sections of the population for achieving better adult health.

Key words: blood pressure, adolescents, India, social class.

PO1016**REPRODUCIBILITY OF SEMI-QUANTITATIVE FOOD FREQUENCY QUESTIONNAIRE MODIFIED FOR MEASUREMENT OF DIOXINS AND RELATED COMPOUNDS IN DIET***J. Zajac¹, E. Kolarzyk¹, A. Potocki¹*¹Jagiellonian University Medical College, Hygiene And Dietetics Dept, Poland

Background and objectives: Questionnaires are popularly used for assessing intake of different nutrients and toxic substances. Different methods used during food processing may influence on presence and concentration of toxic substances in food. The aim was checking the reproducibility of semi-quantitative Food Frequency Questionnaire (FFQ) that includes food processing methods for products that may contain dioxins and related compounds and assessing intake of these compounds with diet.

Methods: modified FFQ was conducted two times in two weeks interval (FFQ1 and FFQ2) on the same coke-plant workers group. The correlation was compared using Pearson's correlation for portion sizes and frequency. Using published values of dioxins and related compounds expressed in pg of Toxic Equivalents (TEQ) per kg of body weight per day for food products an average intake of dioxins from both FFQs was calculated and compared.

Results: The portion sizes declared during FFQ2 were lower in comparison to the first FFQ while the frequencies declared during FFQ2 were higher. Correlation coefficient for more than 50% of products asked about in questionnaire was above 0.90 (60% - FFQ1, 55% - FFQ2). The average correlation coefficient for the most important products (meat prepared in different way) was 0.89. An average intake of dioxins calculated according to FFQ1 was 2.13 pg TEQ/kg bw/day and was comparable with uptake calculated on basis of FFQ2 - 1.94 pg TEQ/kg bw/day.

Conclusions: The reproducibility of answers in first and second FFQ was high, that allows to use modified FFQ as a useful tool. An average intake of dioxins did not exceed the levels of Tolerable Daily Intake appointed by WHO ranging from 1 to 4 pg TEQ/kg bw/day. The main sources of toxins in presented group were cold meats and fish.

Key words: semi-quantitative Food Frequency Questionnaire, diet, dioxins intake.

PO1017**VITAMIN D INTAKE AND FOOD SOURCES OF THE VITAMIN IN A REPRESENTATIVE SPANISH SAMPLE AGED 7-16 YEARS**

A. Aparicio¹, L.G. González-Rodríguez¹, T.K. Villalobos¹, L. Pecharromán¹

¹Departamento de Nutrición, Facultad de Farmacia, Universidad Complutense de Madrid, Spain

Background and objectives: Few foods are a natural source of vitamin D and these are not normally consumed, being the most common bluefish and yolk, although meat also provides significant amounts of the vitamin. Bluefish consumption should be increased taking into account that it is below than recommended (3 servings/week). Therefore, the aim of the present study is to analyze the intake and sources of vitamin D in schoolchildren aged 7-16 years.

Methods: A representative sample of the Spanish population aged 7-16 years (n = 1976) selected from ten provinces (Burgos, Cáceres, Córdoba, Guadalajara, Lugo, Madrid, Salamanca, Tarragona, Valencia and Vizcaya) was studied. Dietary data were obtained by using a 3-day food record. Vitamin D intake and the sources of the vitamin were calculated using DIAL software (1).

Results: Vitamin D intake (1.63 (0.96-3.35) µg/day) was lower than recommended intake (RI) in 85.4% of study participants and it was influenced by age (OR= 0.935; IC: 0.889-0.983; p < 0.01). The main sources of vitamin D were eggs (27.6%), followed by cereals (25.76%), fish (20.86%) and dairy products (12.76%). The main food group that determined vitamin D recommended intakes (RI) was fish (r=0.734; p < 0.001). Additionally, an increase of one fish serving decreased a 72.5% the odds of not covering vitamin D RI (OR= 0.275; IC: 0.222-0.340; p < 0.001).

Conclusions: Vitamin D intake is lower than the recommended intake in a high percentage of the studied participants. Having into account that in the average diet of Spanish children and adolescents, the contribution of vitamin D is mainly determined by fish, an increase in the consumption of this food group would be desirable, especially in 53.6% of children who do not take the minimum amount recommended. Young children merit special attention.

Key words: calcium, dairy products, insufficient intake, representative sample, children, adolescents.

PO1018**MAGNESIUM INTAKE AND ODDS OF DEPRESSION IN INSTITUTIONALIZED ELDERLY PEOPLE WITHOUT ANTIDEPRESSANT TREATMENT**

A. Aparicio¹, J.M. Perea¹, L. Pecharromán¹, E. Aguilar¹, R.M. Ortega¹

¹Departamento de Nutrición, Facultad de Farmacia, Universidad Complutense de Madrid, Spain

Background and objectives: Several studies conducted in animals with magnesium depletion have found that the deficiency of this mineral produces anxiety and depressive-like behaviors and that it has anxiolytic-like activity when it is administered. However, scarce human studies show inconsistent results. The aim of the present work is to analyze the relationship between magnesium intake and affective capacity in institutionalized elderly people without antidepressant treatment.

Methods: This cross-sectional study included 157 institutionalized elderly people from the Madrid region (Spain) (65-90 years of age) whose diets were recorded using a precise weighing method over seven consecutive days. Energy and magnesium intake were calculated using DIAL software (1). The participants's affective capacity was assessed using the Geriatric Depression Scale (GDS). Subjects were grouped into non-depressed (GDS≤5) and depressed (GDS>5).

Results: Magnesium intake was 240.1±44.5 mg/day and a 97.5% had intakes below that recommended. The mean GDS score was 5.25±3.57, with 44.4% of the participants with depression. Magnesium intake was higher in the non-depressed (249.1±41.6 mg/day) compared with the depressed group (228.8±46.8 mg/day) (p < 0.01). Additionally, participants with higher intakes of magnesium had a 2% less odds of suffering depression than those with lower intakes (OR= 0.989, IC: 0.982-0.997; p < 0.05). GDS score and magnesium intake were inversely related. Therefore; an increase in 1 mg of magnesium intake decreased the GDS score by 0.018 units.

Conclusions: Magnesium intake is associated with a lower odd of depression. (1) Ortega RM, López-Sobaler AM, Andrés P, Requejo AM, Aparicio A, Molinero LM. Programa DIAL para valoración de dietas y cálculos de alimentación. Departamento de Nutrición (UCM) y Alce Ingeniería, S.A. Madrid. <http://www.alceingenieria.net/nutricion.htm>, 2004.

Key words: depression, GDS, magnesium intake; elderly.

PO1019**EFFECTS OF IRON AND N-3 FATTY ACID SUPPLEMENTATION ON SPONTANEOUS MOTOR ACTIVITY AND ADHD-RELATED BEHAVIOUR IN SOUTH AFRICAN CHILDREN**

C M. Smuts¹, J. Baumgartner^{1,2}, J. Greeff¹, J. Kvalsvig³, L. Malan¹, M B. Zimmermann²

¹Centre of Excellence in Nutrition, North-West University, Potchefstroom, South Africa

²Laboratory of Human Nutrition, Institute of Food, Nutrition and Health, ETH Zürich, Switzerland

³Department of Psychology, University of KwaZulu-Natal, Durban, South Africa

Background and objectives: Iron deficiency is common during childhood, while children with low consumption of fish and high intake of oils rich in n-6 fatty acids (FAs) are at risk of poor n-3 FA status. Both, iron and n-3 FAs were shown to affect cognition and behaviour. The aim of this study is to investigate the effects of iron and n-3 FA supplementation on spontaneous motor activity and ADHD-related behaviour in iron-deficient (ID) children.

Methods: In a 2x2 trial, children (n=321, aged 6-11 y) received 4/wk for 8.5 months supplements containing: 1) iron (50 mg)+DHA/EPA (420/80 mg); 2) iron+placebo; 3) placebo+DHA/EPA; or 4) placebo+placebo. Physical activity was recorded in a subsample (n=105) at baseline, midpoint and endpoint during three different time periods, namely morning class time (08h00–10h30), break time (10h30–11h00) and after-break class time (11h00–12h00). Classroom behaviour of children was assessed by Conners' Teacher Rating Scales (CTRS) at baseline and endpoint.

Results: DHA/EPA supplementation decreased morning class time activity at endpoint ($p = 0.024$). At baseline, better iron status was positively associated with activity at break time. Subjects in the group receiving both Fe and DHA/EPA showed an improvement from baseline to endpoint on the cognitive problems/inattention subscale ($p = 0.002$) of the CTRS. At endpoint, morning class time activity was positively associated with CTRS subscale scores (higher scores indicate worse behaviour).

Conclusions: These findings suggest that n-3 FA supplementation may influence ADHD-related behaviour during class time. Furthermore, the accelerometer might be a useful tool for assessing both classroom and break time activity behaviour in school children.

Key words: n-3 fatty acids, behaviour, children.

PO1020**SKIM MILK FORTIFIED WITH BUTTERMILK AFFECTS THE PLASMA PHOSPHOLIPID AND FATTY ACID COMPOSITION IN HEALTHY SUBJECTS**

P. Castro-Gómez¹, I. Guillén-Guillén², M. Hernández-Cabria³, L M. Rodríguez-Alcalá¹, M V. Calvo¹, O. López-Cediel¹, J R. Iglesias-Barcia³, F J. López-Román², J. Fontecha¹

¹Instituto de Investigación en Ciencias de la Alimentación, (CIAL, CSIC-UAM), Bioactividad y Análisis de los Alimentos, Madrid, Spain

²Cátedra de Fisiología del Ejercicio, Departamento de Ciencias de la Salud, Universidad Católica San Antonio de Murcia, Guadalupe, Murcia, Spain

³Cooperación Alimentaria Peñasanta SA, Granda, Asturias, Spain

Background and objectives: Milk phospholipids (PLs) are mainly present in milk fat globule membranes of buttermilk. The PLs of milk are attracting renewed scientific interest not only for its nutritional and technological value, but for the biological activities and their potential human health benefits. In recent years, there is considerable evidence that PLs are highly involved in cell metabolism due to its lipophilic and hydrophilic character and are linked to the age-related disease (cognitive ability, dementia), the inflammatory responses and chemotherapeutic activity on some types of cancer. However, to date, there are very limited data available on the PLs bioavailability after human intake of an enriched skim milk with buttermilk.

Methods: A prospective cohort study to determine the buttermilk lipid compounds absorption at different doses has been performed. Thirty healthy subjects were randomly assigned in two experimental groups to receive 200 ml or 400 ml intake of skim milk fortified with buttermilk. Blood samples were taken before and at 1, 2, 3, 4 and 5 hours following intake of the dairy product. Lipids from plasma were extracted by Folch method and thoroughly monitored by GC-MS and HPLC-ELSD techniques.

Results: Chromatographic methods have been carried out for the analysis of plasma lipid fractions. Triacylglycerides, free fatty acids, cholesterol and PLs as well as FAMES have been qualitative and quantitatively determined. The dietary supplementation with buttermilk induced changes of the plasma lipid profile either in the lipid classes as in the PLs profile and FAME composition.

Conclusions: Whether the beneficial effects of buttermilk supplementation may be explained by a remodelling the proportions of the plasma lipids into PLs and triglycerides, needs to be further investigated.

Key words: buttermilk, diet, phospholipids, triglycerides, plasma.

PROMOTING INCREASED KNOWLEDGE OF MATERNAL HEALTH AND NUTRITION THROUGH THE EGYPT SMART PROJECT: BASELINE AND TRAINING RESULTS

A. Abdelmegeid^{1,2}, S. Yassin¹, F. Salah¹, A. Brasington², R. Galloway³

¹Maternal And Child Health Integrated Program (MCHIP)-Smart Project/Save The Children, Cairo, Egypt

²Maternal and Child Health Integrated Program (MCHIP)/Save the Children, Washington, D.C., USA

³Maternal and Child Health Integrated Program (MCHIP)/Program for Appropriate Technology in Health (PATH), Washington, D.C., USA

Background and objectives: From 2003 to 2004, Save the Children used positive deviance (PD) methodology, which identifies and promotes healthy practices used by a few families, to improve maternal health and nutrition in Upper Egypt. As a result of this program, infants of participating mothers were two-times heavier at birth than infants of non-participating mothers. The United States Agency for International Development (USAID)-funded Maternal and Child Health Integrated Program (MCHIP) is currently implementing the Smart project in Egypt and has conducted a baseline survey and trained community health volunteers (CHWs) for the scale-up of this PD intervention to two million people in six governorates.

Methods: A baseline survey about health and nutrition knowledge and practices and the use of services was conducted with 12152 respondents in Upper and Lower Egypt. The Smart project trained 1200 CHWs, supported by local non-governmental organizations (NGOs), over a ten-day period. Pre- and post-training testing evaluated the change in CHW knowledge.

Results: The baseline study found that 99% of women received antenatal care (ANC) with 27% using public sector facilities and 73% using private sector facilities. Awareness of optimal health and nutrition practices and danger signs was limited in women and CHWs. Nearly half (49%) of women did not have information about the health risks for women and children during the pregnancy, delivery, and postnatal periods. Training made a significant difference to CHW knowledge with an increase in knowledge about optimal care and practices from 27.9% to 65.9%.

Conclusions: Baseline results showed high use of ANC services, but knowledge about optimal health and nutrition practices and danger signs was low in women and CHWs. Training of CHWs significantly improved their knowledge. Implementation of Smart over the next year will determine if this knowledge is transferred to mothers and their families.

Key words: positive deviance, maternal, nutrition, community.

PO1022

A COMPARISON OF CALCIUM AND PHOSPHORUS INTAKES IN RURAL GAMBIAN CHILDREN BETWEEN 1995-2008: AN EFFECT OF THE NUTRITION TRANSITION?

L M A. Jarjou¹, G R. Goldberg², A. Prentice^{1,2}

¹MRC Keneba, Gambia

²MRC Human Nutrition Research, Cambridge UK

Background and objectives: Stunting and poor growth are common in developing countries like The Gambia. Our previous studies have shown that calcium intakes of rural Gambian children are particularly low and may contribute to their poor growth. Anecdotal observations suggest that calcium intake is declining due to changes in staple foods and their accompaniments. The objective of this study is to compare anthropometric measures and calcium intakes between two cohorts of pre-pubertal children aged 8-12 years, from the same rural villages of The Gambia, separated by 13 years.

Methods: Data from 80 boys and 80 girls in 1995 (1995 cohort) and from 70 boys and 61 girls in 2008 (2008 cohort) were included. Calcium and phosphorus intakes were assessed by 2-day weighed dietary intake and using cohort-specific Gambian food composition information. Weights and heights were measured. Data presented are mean±SD.

Results: Boys in the 2008 cohort were shorter (1.29±0.08 m vs 1.32±0.07 m, $p = 0.009$) than their 1995 counterparts but not the girls (1.32±0.08 m vs 1.32±0.08 m). There were no differences in weight (Boys: 25.0±4.1 kg vs 25.5±3.6 kg; Girls: 25.5±4.2 kg vs 25.0±4.4 kg). In both sexes, there were lower intakes ($p < 0.0001$) of calcium (Boys: 256±99 mg/d vs 355±160 mg/d; Girls: 252±122 mg/d vs 321±118 mg/d) and phosphorus (Boys: 558±174 mg/d vs 863±307 mg/d; Girls: 491±143 mg/d vs 807±312 mg/d) in the 2008 cohort compared with the 1995 cohort.

Conclusion: This comparative study suggests that there has been a decline in calcium and phosphorus intakes in pre-pubertal rural Gambian boys and girls, possibly reflecting changes in diet and lifestyle due to the transition towards a Western diet and lifestyle. The long term health impacts of such secular changes in mineral intakes on bone growth and development warrant further exploration.

Key Words: children, Gambia, growth, calcium, nutrition transition

UNBALANCED NUTRITIONAL PROFILE IN BABY FOODS ALTERS PLASMATIC CYTOKINES AND SPLEEN CELLS POPULATIONS IN MICE MODEL

E. Sánchez Samper¹, C. Gómez Gallego¹, P. Andreu Miguel¹, M.J. Bernal Cava², G. Ros Berrueto¹

¹Food Science and Nutrition, University of Murcia, Spain

²Global Technology Center for Infant Nutrition, Hero Group, Murcia, Spain

Background and objectives: Obesity is a low-grade inflammatory state characterized by increased inflammatory markers. Inflammatory cytokines can be produced by different cell types, including macrophages and lymphocytes. The aim of our study was to characterize the impact of two different types of homogenized baby foods on the spleen cell populations and in serum cytokines levels using C57BL/6J mice.

Methods: A total of 36 weaned mice were randomly assigned to three different 12-week intervention groups as follows: Group A was fed on baby food containing 67 kcal for 100 g of food, 3.6% proteins, 7.8% carbohydrates, 0.115% sodium, 2.7% fat and a balanced fatty acids profile, which proportion of saturated/monounsaturated/polyunsaturated fatty acids (S/M/P) was 1:2:1. Group B was fed on baby food containing 87 kcal for 100 g of food, 4.2% proteins, 11.1% carbohydrates, 0.150% sodium, 2.9 % fat and an unbalanced fatty acids profile, which proportion of S/M/P was 1:2:0.5. Group C was fed on rodent chow. The spleen lymphocyte and macrophage populations and serum cytokines were analyzed by flow cytometry.

Results: Body mass index (BMI) was significantly higher in groups A and B ($p < 0.002$) compared to group C, without significant differences between them. The percentage of macrophages was only significantly higher in group B compared to group C ($p = 0.004$). Statistical differences were not found in the lymphocyte Th (CD4+), Tc (CD8+), B and cells Natural Killer populations. Higher levels of IL-6 and IL-10 were correlated to unbalanced fatty acids profile ($r=0.358$, p -value = 0.044; $r=0.471$, p -value = 0.007, respectively)

Conclusions: Our results suggest that the intake of homogenized baby food with inadequate nutritional profile might produce changes in immune system markers which could be related with problems associated with overweight. Such an effect should be further studied in human infants.

Key words: cytokines, leucocytes, baby food, animal model.

PO1024

THE RELATION BETWEEN SELF-PERCEIVED FOOD ENVIRONMENT AND FRUIT AND VEGETABLE INTAKE BY PREGNANT WOMEN

D C C. Zuccolotto^{1,2}, D S. Sartorelli²

¹Post-Graduation In Community Health, University of Sao Paulo, Brazil

²Department of Social Medicine, University of Sao Paulo, Brazil

Background and objectives: Environmental factors associated with eating behavior have received attention in the context of public health by directly affecting the health of individuals. The purpose of the present study was to evaluate the relationship between self-perceived food environment, and the adequate consumption of fruits and vegetables in pregnant women.

Methods: A cross-sectional study was conducted among 282 adult pregnant women. Fruit and vegetable intake during pregnancy was assessed by a food frequency questionnaire, and 2 dietary recalls. The multiple source method approach was applied to estimate usual fruit and vegetable intake. Self-perceived food environment was assessed by a structured questionnaire. For the present analysis, we examined the association of self-perceived food environment and the adequate intake of fruit and vegetable (400 g/daily) in logistic regression models [OR (95% CI)], adjusted by maternal age, socioeconomic class, and educational level.

Results: The mean (SD) age of participants was 28 (5) years old, and 35% reported adequate intake of fruit and vegetable during pregnancy. No association between self-perceived food environment and adequate fruit and vegetable intake was found. However, a higher meal frequency was associated with a better chance of daily adequate intake of fruit and vegetable [OR 2.01 (95% CI 1.03, 3.91) $p = 0.04$]. Moreover, the habit of buying fruit and vegetable in specialized food market was associated with the daily intake of > 400 g of fruit and vegetable [OR 1.68 (IC95% 1.01, 2.80) $p = 0.05$].

Conclusions: Our data suggests no association between self-perceived food environment and the adequate intake of fruit and vegetable among pregnant women. Funding: FAPESP (2011/03558-7), FAEPA.

Key words: food environment, pregnancy, fruit and vegetable intake.

PO1025**ASSOCIATION BETWEEN PERINATAL FACTORS AND COMPONENTS OF THE METABOLIC SYNDROME AND INSULIN RESISTANCE IN CHILDREN OF PUENTE ALTO, SANTIAGO, CHILE**

F. Mardones¹, M. Pacheco¹, A. Dominguez¹, L. Villarroel¹, J.G. Eriksson², P. Arnaiz¹, S. Barja¹, O. Castillo¹, M. Farias¹

¹Pontificia Universidad Catolica de Chile, Chile

²University of Helsinki, Finland

Background and objectives: we have previously studied the association of prenatal growth with metabolic syndrome (MS) components, including insulin resistance (IR), in about two thousand Chilean low-income urban school-age children (J Devel Orig Health Dis. 2012; 3(4): 237-244). We aim to ascertain with a higher sample size the influence of the above mentioned variables.

Methods: retrospective cohort study linking information on MS and IR in school-age, with perinatal records. 3325 children were enrolled in schools in the district of Puente Alto (Santiago, Chile) during 2009-2011. Anthropometry and blood pressure (BP) were assessed. A blood sample for determination of glycemia, insulinemia (quimioluminescence) and blood lipids was taken; HOMA was calculated and a national standard was applied to select HOMA-IR cases. Cook et al standard was used to define MS. We used Pearson correlation, chi-square test and logistic regression step-by-step. Linear and quadratic associations were tested with Poisson regression.

Results: 3290 children had complete information at birth (98.9%) 52.01% women; aged 11.4 + 1 years. The prevalence of MS and IR was 7.26% and 25.47%, respectively. Logistic regression analysis showed an inverse association between birth length (BL), gestational age and birth weight (BW) with most dependent variables studied. However BW showed a direct association with the majority of the dependent variables studied. The waist circumference > 90th percentile, BP > 90th percentile and triglycerides > 110 mg/dl were associated with U-shaped BW, BL and ponderal index, respectively.

Conclusions: In this new study we could demonstrate a higher number of U-shaped associations with perinatal variables. New studies with higher sample sizes would permit to show this kind of associations and improve our understanding of the early origins of metabolic diseases.

Key Words: prenatal growth, insulin resistance, metabolic syndrome, retrospective cohort, child.

PO1026**GLUCOSE-INDUCED NEURONAL ACTIVATION DURING COGNITIVE TASK PERFORMANCE IN OLDER ADULTS DEPENDS ON GLYCEMIC-INDICATORS AND BLOOD CHOLESTEROL LEVELS: AN FMRI STUDY**

W Y. Yuen^{1,2}, L A. Meusel¹, N D. Anderson^{1,3}, E. Tchistakova^{4,5}, B J. MacIntosh^{4,5}, C E. Greenwood^{1,2}

¹Rotman Research Institute, Baycrest Centre, Toronto, ON, Canada

²Department of Nutritional Sciences, Faculty of Medicine, University of Toronto, Toronto, ON, Canada

³Departments of Psychology and Psychiatry, University of Toronto, Toronto, ON, Canada

⁴HSF Centre for Stroke Recovery, Sunnybrook Research Institute, Toronto, ON, Canada

⁵Department of Medical Biophysics, Faculty of Medicine, University of Toronto, Toronto, ON, Canada

Background and objectives: Glucose ingestion by older adults enhances long-term and less consistently working memory; less is known about the neural mechanism(s) underlying these cognitive changes. We used blood oxygenation level dependent functional magnetic resonance imaging (BOLD fMRI) to test the hypotheses that glucose ingestion increases 1) cognitive performance and 2) neuronally-mediated BOLD activity in older adults, and that 3) glucose-induced alterations in task-related BOLD signaling are dependent on metabolic/vascular indicators.

Methods: Within-subject cross-over design in 13 healthy hypertensive older adults. Day 1: Collect fasting blood sample, health information, and administer neuropsychological battery to characterize cognitive function and exclude dementia. Day 2/3: Participants are counterbalanced to either a glucose (60 g) or placebo drink. Following drink ingestion, participants are scanned in a 3.0 Tesla MRI scanner during the encoding phase of a wordlist learning task and a 2-back working memory task.

Results: Cognition: There was a trend towards a greater primacy effect during a wordlist immediate/delayed recall for glucose sessions compared to placebo ($p = 0.08$), but no drink effect on 2-back task accuracy nor reaction time. fMRI: During encoding of primacy words (first 5 words in wordlist), dorso-medial prefrontal activation was stronger in the glucose compared to placebo condition even after adjusting for glucose-induced changes in cerebrovascular reactivity (CVR) (p adjusted < 0.05). In the 2-back task, there was a trend towards greater activation in pre- and post-central gyri in the glucose compared to placebo condition after adjusting for CVR (p adjusted < 0.1). Glucose-induced activations correlated negatively with HbA1c, total cholesterol, and LDL-cholesterol levels (all p < 0.05) for the wordlist task and fasting insulin for the 2-back task (p < 0.05).

Conclusions: Glucose ingestion appears to alter both episodic learning and neural activation patterns in older adults. The extent of glucose-induced alteration within regions mentioned may be associated with healthier biological blood profiles. (CIHR, NSERC, OGS)

Key words: fMRI, aging, glucose, memory, cognition.

PO1028

CRITICAL PATHWAYS AFFECTING MATERNAL ANEMIA: A ROAD MAP FOR INTEGRATED PROGRAMMING FOR NUTRITION, HEALTH AND AGRICULTURE

M. Antal¹, M. Griffiths¹, T. Schaetzel¹

¹The Manoff Group, USA

Background and objectives: Maternal anemia is a significant global public health problem. In the developing world 40% of non-pregnant women and 49% of pregnant women are anemic. Although proven and cost effective solutions are known, current single sector strategies to tackle anemia are insufficient. Our objective was to identify how the health, nutrition and agriculture actors can contribute to reduce maternal anemia.

Methods: A review of literature and research about maternal anemia globally, specifically considering barriers and motivators for maternal anemia-related behaviors, provided the foundation to develop a multisectoral framework.

Results: The resulting framework helps sectors identify the role of each sector. The foundation of the framework is the basic physiological factors of anemia control: adequate iron status and pregnancy considerations. The framework delineates the type of interventions within each sector's mandate to support 1) improved iron intake, such as consumption of iron rich foods, 2) reducing iron loss, such as deworming and malaria control, 3) improving iron stores, such as the practice of family planning and 4) iron folic acid supplementation to address expanded blood volume while pregnant. The framework also includes the specific behaviors women and their families can perform and outlines the role of each sector to ensure that those behaviors happen. This framework can be adjusted by country based on specific situations around malaria incidence, antenatal care programs and the agriculture context. It provides guidance for programmers and policy makers to think and act in an intersectoral way.

Conclusions: Using the framework for planning facilitates visualizing and identifying the multiple approaches that must be in place to successfully tackle the burden that anemia places on women of reproductive age, especially pregnant and immediate postpartum women.

Key words: Maternal anemia, multisectoral approach, agriculture, health.

PO1029

INCREASE IN SALT CONSUMPTION IN CHILDHOOD IN THE NETHERLANDS; DUTCH NATIONAL FOOD CONSUMPTION SURVEY 2007-2010

C. Van Rossum¹, E. Buurma-Rethans¹, J. Verkaik-Kloosterman¹, M. Hendrikse¹, M. Ocké¹

¹National Institute For Public Health And The Environment (RIVM), Bilthoven, The Netherlands

Background and objectives: High salt intake is associated with a higher blood pressure and subsequently to cardiovascular diseases. Children with elevated blood pressure often become adults with elevated blood pressure. Insight in the salt consumption in children can be used to support nutrition policy in order to improve public health. The aim of this study is to get insight in the salt consumption and its sources in childhood in the Netherlands. Method: In 2007 to 2010, a Dutch National Food Consumption Survey was conducted. Two non-consecutive 24-hour dietary recalls were collected by dietitians with the software EPIC-Soft[®]. In addition, information about discretionary use of salt was collected. Data on children aged 7-18 years (n=1713) in combination with the Dutch food composition database from 2011 were used to estimate the habitual salt intake among children using SPADE. In addition the intake of salt per kJ and the intake by its sources were calculated.

Results: The habitual total intake of salt was far above the Dutch recommended maximum intake (6 g/day) for most of the children; median intake was 8.2 g/day for boys and 6.7 g/day for girls. The habitual intake of salt increased with age with more than 40%; 6.0 g/day for 7-8 year-olds to 8 g/day for 14-18 year-olds. This was partly explained by increased energy intake. Main sources were discretionary use of table salt, bread, processed meat and cheese. The contribution of sauces and soups increased with age.

Conclusions: In childhood, salt intake increases with age to adult levels. This can not fully be explained by the increase in energy intake by age. At all ages, most children exceed the recommended maximum intake levels. Food reformulation and improving dietary habits in childhood, might result in lower salt intake later in life.

Key words: sodium, monitoring, children, fortified foods.

PO1030**VISUALIZING THE IMPACT OF SELECTED BEHAVIORS ON NUTRITIONAL STATUS AND THE EFFECTIVENESS OF APPROACHES TO PROMOTING POSITIVE BEHAVIORS**

S. Lamstein¹, B. Colaiezzi¹, P. Koniz-Booher², K. Beall³, T. Williams², M. Anson², A. Spray⁴

¹The SPRING Project / JSI, Boston, USA

²The SPRING Project / JSI, Arlington, USA

³The SPRING Project / The Manoff Group, Arlington, USA

⁴The SPRING Project / Save the Children, Arlington, USA

Background and objectives: Optimal nutrition during the first 1000 days (pregnancy to age two) is critical to the prevention of stunting and anemia. Demand for evidence-based programming compels nutritionists to assess the evidence supporting maternal, infant, and young child nutrition practices that are promoted to prevent and reduce stunting and anemia as well as the effectiveness of social and behavior change communication (SBCC) on those practices. The SPRING Project aimed to develop an interactive web-based tool to present this complex body of evidence.

Methods: SPRING conducted a systematic literature review to consolidate the evidence on the effectiveness of SBCC approaches. At the same time, SPRING collected seminal literature recommended by experts in the field on the effect of commonly promoted nutrition practices (e.g., maternal diet, breastfeeding, complementary feeding, prevention and control of micronutrient deficiencies, and water, sanitation and hygiene) on nutritional status. Using data visualization software, SPRING then created a visual representation of these relationships.

Results: The result of these efforts is a visually appealing and user-friendly interface that succinctly synthesizes the evidence linking SBCC approaches to the adoption of high-impact nutrition practices known to protect against stunting and anemia.

Conclusions: Web-based, interactive displays of evidence improve accessibility of information, making them an important complement to traditional, report-style presentations. The display of our findings in this way draws attention to the research gaps and aids policy makers and program implementers in targeting priority nutrition practices and identifying and selecting appropriate evidence-based SBCC approaches to improving nutrition practices.

Key words: social change, behavior change, communications.

PO1031**WAIST CIRCUMFERENCE AND ITS RELATIONSHIP WITH BIOCHEMICAL PARAMETERS IN BRAZILIAN STUDENTS**

G. Possa¹, C. Boscaini², D. Benini³

¹Pediatric Department, Federal University of São Paulo, São Paulo, Brazil

²Cardiology Institute of Rio Grande do Sul, Porto Alegre, Brazil

³Universidade do Vale do Rio dos Sinos, São Leopoldo, Brazil

Background and objectives: The measurement of waist circumference has been considered an important tool for identifying children at higher risk of developing metabolic and cardiovascular complications. Thus, the aim of this study was to evaluate the relationship between waist circumference and biochemical parameters in Brazilian students.

Methods: Cross-sectional study with 588 students (mean age of 8.61 ± 1.36 y) of public and private schools in Garibaldi, Brazil. Socioeconomic data, waist circumference (WC) and biochemical evaluation (triglycerides, total cholesterol, low-density lipoprotein cholesterol (LDL-c), high-density lipoprotein cholesterol (HDL-c), plasma glucose and insulin) were evaluated. Central obesity was defined as WC higher than the 90th percentile. Insulin resistance was calculated by means of the homeostasis model assessment of insulin resistance (HOMA-IR) and 2.5 was adopted as cut-off value.

Results: Of the total sample, 51.4% were male. The prevalence of central obesity was 10.5% (boys 10.0% and girls 11.0%). Regarding the metabolic profile, it was found that girls presented significantly higher concentrations of triglycerides, insulin and HOMA-IR and lower concentration of HDL-c. However, boys had significantly higher concentrations of plasma. Adolescents with WC higher than the 90th percentile presented higher prevalence of hypercholesterolemia (49.2% vs 39.6%), hypertriglyceridemia (39.0% vs 8.0%), hyperinsulinemia (10.2% vs 0.6%), insulin resistance (27.1% vs 2.3%) and inadequate levels of HDL-c (53.4% vs 32.4%).

Conclusions: WC was significantly associated with higher concentrations of triglycerides, insulin and HOMA-IR and lower concentration of HDL-c, confirming the importance of WC for identifying children at risk for the development of metabolic disorders.

Key words: Waist Circumference, abdominal obesity, child, nutritional and metabolic diseases.

PO1032**A RANDOMIZED CONTROLLED TRIAL INDICATES BENEFITS OF CELL PHONE BASED PEER COUNSELING TO SUPPORT EXCLUSIVE BREASTFEEDING IN KENYA**

D. Sellen¹, S. Mbugua², A. Webb Girard³, S. Kalungu², C. Sarange², W. Lou⁴, W. Duan⁴, C-L. Dennis⁵, L. Nommsen-Rivers⁶, B. Aidam⁷, E. Kamau-Mbuthia²

⁵Faculty of Nursing, University of Toronto and Women's College Research Institute, Toronto, Canada

⁶Division of Neonatology, Cincinnati Children's Hospital, Cincinnati, OH, USA

⁷World Vision International, Washington DC, USA

Background and objectives: In Kenya, median duration of exclusive breastfeeding (EBF) is < 1 month despite high breastfeeding (BF) initiation (98%). Cell phone use is high despite widespread poverty, allowing health innovation to support the 10th Step of the Baby Friendly Hospital Initiative. We tested the effect of breastfeeding support from trained peer leaders via cell phone and peer groups on EBF at 3 months.

Methods: We randomized at third trimester low-income women attending antenatal care at a large hospital to (i) continuous cell phone based peer support (CPS), (ii) monthly peer support group (PSG) or (iii) standard of care by existing facility-based support (SOC). TPLs supported both pregnant and post-partum women randomized to CPS and PSG from late pregnancy (32-26 weeks) to 3 months postpartum. We compared EBF estimated by maternal 7 day recall of infant foods at 3 months age by intervention group.

Results: Participant flow was adequate for power (753 women enrolled, 81% of eligible; 504 infants completed, including twins, 66.6%). Both interventions were associated with a higher proportion of EBF (CPS: 89.5%, PSG: 82.6%, SOC: 78.2%, $p = 0.022$). Pairwise comparisons indicated EBF rates with CPS higher than with SOC ($p = 0.006$) and marginally significantly higher than with more logistically difficult and costly PSG ($p = 0.071$).

Conclusions: Cell phone based counseling may be as effective in supporting EBF as peer support group approaches in this setting, and more effective than current standard of care.

Key Words: breastfeeding, peer support, mHealth

⁵Division of Neonatology, Cincinnati Children's Hospital, USA World Vision International, Washington DC, USA

⁶World Vision International, Washington DC, USA

⁷Departments of Anthropology, Nutritional Sciences and Dalla Lana School of Public Health, University of Toronto, Ontario, Canada

Background and objectives: In Kenya, cell phone (CP) use is high and presents new opportunities to support breastfeeding. We examined data from a randomized intervention trial showing CP based support (CPS) increases the prevalence of exclusive breastfeeding (EBF) to identify threats to the validity of findings and evaluate quality of intervention delivery.

Methods: We randomized at third trimester low-income women attending antenatal care (ANC) at a large hospital to (i) continuous cell phone based peer support (CPS) or (ii) monthly peer support group (PSG) or (iii) standard care by existing facility-based support (SOC=control). We analyzed participant flow and process indicators to assess the quality of delivery of CPS and PSG interventions and potential biases at enrolment and through dropout.

Results: There was no difference in dropout by baseline CP access ($p = 0.119$) or intervention allocation ($p = 0.673$).

Among participants with CP, women allocated to each group shared many characteristics, except hours worked outside the home (4.7, 4.0, 3.6 h for CPS, PSG, SOC; $p = 0.036$), and unemployment (40.4%, 54.3%, 56.1% for CPS, PSG, SOC; $p = 0.023$). Among women without CP, there was no difference in baseline indicators by intervention allocation except those allocated to PSG reported less frequent prior prenatal care (2.4 vs 2.7 times; $p = 0.039$).

Conclusions: Indications that cell phone based counseling is potentially as or more effective in supporting EBF than other approaches are unlikely to be attributable to poor quality of delivery of alternative intervention, unanticipated bias at allocation or differential dropout.

Key Words: breastfeeding, peer support, mHealth

⁶World Vision International, Washington DC, USA

⁷Departments of Anthropology, Nutritional Sciences and Dalla Lana School of Public Health, University of Toronto, Canada

Background and objectives: In Kenya, cell phone (CP) use is high and allows health innovation to support exclusive breastfeeding (EBF). We examined data from a randomized

intervention trial showing CP based support (CPS) increases the prevalence of EBF to identify any associations with infant medication, illness and growth.

Methods: We randomized at third trimester low-income women attending antenatal care (ANC) at a large hospital to (i) continuous cell phone based peer support (CPS), (ii) monthly peer support group (PSG) or (iii) standard of care by existing facility-based support (SOC=control). TPLs supported both pregnant and post-partum women randomized to CPS and PSG from late pregnancy to 3 months postpartum. We compared indicators of infant care, illness and growth at 3 months age by intervention group.

Results: Mothers allocated to CPS were not significantly less likely to give medicine, vitamins or minerals (37.3% vs 47.4% and 46.4% for PSG, SOC; $p = 0.132$), report any infant illness (21.6% vs 29.5%, 30.7% for PSG, SOC; $p=0.137$) or diarrhea (11.1% vs 12.7%, 10.6% for PSG, SOC; $p=0.814$), or return to work by 3 months postpartum (61.7 cm vs 61.4 cm, 61.4 cm for PSG, SOC; $p=0.418$). CPS infants did not differ in mean length or weight (6.26 kg vs 6.09 kg, 6.18 kg for PSG, SOC; $p = 0.262$).

Conclusions: Cell phone based peer support is not associated with large differences in infant medication, illness and growth at 3 months postpartum.

Key Words: breastfeeding, peer support, morbidity, growth

³Centre for Family Welfare, Faculty of Public Health, University of Indonesia, Depok, Indonesia

⁴UNICEF Indonesia, Jakarta, Indonesia

Background and objectives: Around 4 out of 10 Indonesian children under-five are stunted. Effective interventions to address undernutrition are known. It relates to improved

young child and maternal nutrition and enhancement of hygiene practices. The study aims to provide baseline information regarding the nutritional status of young children and pregnant women and its key determinants to provide further guidance to nutrition programme and foster a multisectoral and integrated approach to reduce undernutrition.

Methods: A cross-sectional study involved children 0-35 months of age (n=2023) and pregnant women (n=463) randomly selected in three districts with different living conditions. A standardized questionnaire was used to collect data on socio-demographics and potential determinants of nutritional status. Child weight and length/height was measured while mid-upper arm circumference (MUAC) was assessed among women. Hemoglobin was measured with Hemocue in all women and sub-sample of children (n=670).

Results: Among children, stunting rate was 30%, wasting 9%, underweight 21%, anemia 59%. About a third of pregnant women were undernourished and 45% anemic. Only 41% of children 0-23 months were fed as per the WHO recommendations. The situation was worst among children 6-11 months old (22%). Better child feeding practices was associated with a lower proportion of stunting (30% vs 24%, $p < 0.01$) and of anemia (71% vs 59%, $p < 0.01$). Also, stunting tended to be associated with worm infestation, educational level of the caregivers, household access to a healthy environment and its socioeconomic level. Similar associations were observed among women.

Conclusions: The nutritional status of children and pregnant women is of concern. Results reiterate the existence of poor child feeding practices, particularly among children 6-11 months. The involvement of other sectors but health is also imperative.

Key words: stunting, children, women, nutrition, feeding practices The study was carried out with the financial assistance of the European Union and UNICEF.

PO1036

RATIO OF MICRONUTRIENT INTAKE FROM ANIMAL TO NON-ANIMAL SOURCE FOODS AND LINEAR GROWTH OF 1-5 YEARS OLD CHILDREN IN INDONESIA

S. Muslimatun¹, L.A. Wiradnyani¹

¹SEAMEO RECFON, University of Indonesia, Jakarta, Indonesia

Background and objectives: Many <5 years old children in Indonesia experienced linear growth retardation. Poor diets leading to inadequate intake of micronutrients is among prominent causes of linear growth retardation. Foods from animal sources are of better quality than from plant sources in supplying micronutrient and protein because of higher content

and better bioavailability. This study aimed to investigate the ratio of micronutrient intake from animal to non-animal source foods in relation to linear growth of children 1-5 years old.

Methods: The one-year longitudinal study was conducted in periurban area of Bandung City among 4 groups of children: 12-23 mo (n=57), 24-35 mo (n=56), 36-47 mo (n=58) and 48-59 mo (n=56). Children had measurement of anthropometry (body weight and length/height) and dietary intake (2 repeated 24-hour recall) every 16 weeks. General characteristics and other observations were collected at baseline and endline.

Results: Almost all but one child had animal source foods intake; the most frequently consumed were milk (83.7% including breastmilk), eggs (58.6%) and meat/fish/poultry (49.3%). Milk, particularly in the form of liquid and/or powder, had high contribution to the micronutrient intake. Ratio of micronutrient intake from animal to non-animal source foods differs significantly across age group but not across observation. The median ratio of animal to non-animal source foods for vitamin A, calcium, iron, and zinc were 5.8, 1.6, 0.6, and 2.3, respectively and intake of micronutrient above the median tended to be associated with higher height-for-age z-score at endline.

Conclusions: The study reemphasizes the importance of animal source foods, including milk, in children linear growth. The precise ratio of micronutrient intake from animal to non-animal source foods to benefit linear growth warrant further exploration.

Key words: micronutrient, ratio animal to non-animal, children. Acknowledgement: The study received financial support from Sari Husada and Nutricia of Indonesia.

PO1037

EATING HABITS CONCERNING FATS IN DIET OF POLISH AND AMERICAN MEDICAL COLLEGE STUDENTS, COMPARISON

J. Zajac¹, A. Ostachowska-G \pm sior¹

¹Jagiellonian University Medical College, Hygiene And Dietetics Dept, Krakow, Poland

Background and objectives: The long-term ingestion of a fat-rich diet causes severe health problems. Studying on medical college gives a basic dietetics knowledge and during studies eating patterns are evolving, unfortunately often not in positive relationship. The aim is the comparison of eating habits among Polish (P) and American (A) medical students on the fourth year.

Methods: The brief Block Screening Questionnaire was conducted. 172 students (96 P: 74 women, 22 men, and 76 A: 32 women, 44 men) assessed eating frequency of products containing saturated fats. Methods used in study had a self-scoring format thus chosen frequency was exchanged into points that

summed up classified the diets into 3 categories: high fat intake; elevated intake; proper intake. S statistical significance was checked using t-Student test. For all students body mass index (BMI) was calculated.

Results: Polish women had the highest percentage of underweight, while the highest percentage of overweight and obesity had American men (P: women-34% of underweight and 1% of overweight and obesity; men: 14% and 32%; A: women-16% and 6%; men: 0% and 39%). There were no differences between average eating frequency among students but in case of particular products statistically important differences were noticed. Polish students ate more often ($p < 0.05$) butter, sausages, full-fat milk and sweet, greasy cakes. High fat intake was noticed for Polish men, whereas proper intake was found among American women (P: women-3% of too high fat intake, 34% of slightly elevated and 64% of proper fat intake; men-36%, 45% and 18%; A: women-6%, 22% and 72%; men-9%, 39% and 52%).

Conclusions: Uptake of fats for majority is placed within proper range, but especially for Polish men too high. There is a positive correlation between high BMI value and high points score.

Key words: food frequency questionnaire, medical students, eating patterns.

PO1038

COMPARISON OF EATING HABITS CONCERNING FRUITS, VEGETABLES AND FOOD FIBER IN DIET OF POLISH AND AMERICAN MEDICAL COLLEGE STUDENTS

J. Zajac¹, A. Ostachowska-G \pm sior¹

¹Jagiellonian University Medical College, Hygiene And Dietetics Dept, Krakow, Poland

Background and objectives: The physicochemical and biological properties of dietary fiber have important implications in human health. Food fiber should be consumed with everyday portion of fruits, vegetables and grain products. The aim is the comparison of eating habits between Polish(P) and American(A) medical students on the fourth year.

Methods: The Block Screening Questionnaire was used for assessing eating frequency of products containing food fiber among 172 students (96 P: 74 women, 22 men; 76 A: 32 women, 44 men). Method used in study had a self-scoring format, thus, chosen frequency was exchanged into points that summed up classified the diets into 3 categories: low intake of food fiber; moderate intake that could be enriched; desirable intake. Statistical significance was checked using t-Student test. For all body mass index (BMI) was calculated.

Results: For majority BMI value was in normal range, though Polish women had the highest prevalence of underweight, while American men had the highest prevalence of overweight and obesity had (P: women-34% of underweight and 1% of overweight and obesity; men: 14% and 32%; A: women-16% and 6%; men: 0% and 39%). Differences between average eating frequency between nations were not significant but for particular products statistically important ($p < 0.05$) differences between nations were found. Americans significantly ate more often fruits and vegetables in contrast to legume plants chosen by Polish students. The desirable score of questionnaire had Polish women but low intake was common (P: women-46% with low intake, 53% with moderate and 1% with desirable intake; men-68%, 32% and 0%; A: women-78%, 22% and 0%; men-82%, 18% and 0%).

Conclusions: Uptake of fiber-rich products for majority can be classified as low, almost nobody achieved desirable food fiber intake. There is a correlation between underweight of Polish women and low uptake of food fiber.

Key words: questionnaire, students, eating patterns.

PO1039

STUNTING AND IRON DEFICIENCY ARE ASSOCIATED WITH LOW PRESCHOOL DEVELOPMENT SCORES IN A RURAL INDIAN COMMUNITY

M M. Black¹, S. Fernandez-Rao², N. Balakrishna², K M. Hurley³, K V. Radhakrishna², P. Ravinder², N. Tilton¹, K. Harding, G. Reinhart, K M. Nair²

¹Pediatrics, University of Maryland School of Medicine, Baltimore, MD, 21201, USA

²National Institute of Nutrition, Indian Council of Medical Research, Hyderabad, India

³International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, 21205, US

Background and objectives: Stunting and anemia are common problems among young children in low-income countries. The objective is to examine how stunting, anemia, and iron deficiency relate to preschoolers' development in a low-income, rural setting.

Methods: Enrolled 328 preschoolers age 27-59 mo. (mean=37.2, SD=6.3) from Anganwadi Centers in rural India. Measured anthropometry and calculated stunting (HAZ <-2SD), wasting (WHZ<-2), and underweight (WAZ<-2) using WHO standards. Venous blood used to measure biomarkers for iron deficiency (ID) (serum transferrin receptor (sTfR)>2.5 mg/L and ferritin<12 μ g/l), anemia (hemoglobin (Hb)<11 g/dl), and inflammation (C reactive protein (CRP)>10 mg/l). Child development (fine motor, receptive /expressive language)

ge, and visual reception) measured with Mullen Scales of Early Learning, and household assets measured by maternal report. Multiple linear regression (MLR) equations, adjusted by age, household assets, inflammation, and clustering of Anganwadi Centers, used to estimate how stunting, ID, and anemia relate to child development.

Results: 39% of the preschoolers were stunted, 19% wasted, and 44% underweight; 66% had ID (based on sTfR 62% and/or ferritin 41%), 49% were anemic. In MLR analyses, stunting and anemia were significantly negatively associated with all child development measures: e.g., receptive language: stunting ($\hat{\alpha}=-0.20$; CI: -6.90, -2.05), anemia ($\hat{\alpha}=-0.14$; CI: -5.31, -0.56). Adding ID measures to the models, sTfR was significantly negatively associated with fine motor ($\hat{\alpha}=-0.14$; CI: -7.93, -0.55), receptive language ($\hat{\alpha}=-0.14$; CI: -6.04, -0.55), expressive language ($\hat{\alpha}=-0.14$; CI: -5.14, -0.70) and visual reception ($\hat{\alpha}=-0.12$; CI: -5.94, -0.09); anemia was reduced to non-significance.

Conclusions: Stunting was associated with low preschool development, emphasizing the importance of adequate nutrition early in life. STfR, an early biomarker of ID, was a more sensitive indicator of low developmental scores than anemia, suggesting a need to ensure adequate iron intake early in life.

Key Words: iron deficiency, child development, preschool, stunting. Support: Mathile Institute & Micronutrient Initiative.

PO1040

NUTRITIONAL STATUS AT BIRTH AND BLOOD PRESSURE IN CHILEAN YOUNG ADULTS: IS THERE AN AMPLIFICATION WITH AGE?

P. Bustos¹, H. Amigo¹, C. Vargas¹

¹Department of Nutrition, Faculty of Medicine, University of Chile, Chile

Background and objectives: There is an association between birth weight (BW) and chronic diseases and this association increases with the increment of body mass index (BMI). Nevertheless it is not known if this effect changes with age. The Objective of this study was to assess if there is an amplification of the effect between BW and blood pressure in a follow up of adults.

Methods: Cohort study in the Valparaiso Region of Chile. Information of BW was get from birth registers in the Hospital of Limache city and they were evaluated at age of 22 to 28 (first survey, n=1234) and 32 to 38 years (second survey, n=782). Multiple linear models were fit to see the effect of BW and systolic (SBP) and diastolic blood pressure (DBP) in each evaluation, adjusting by sex and BMI in adult age. The second model considered the ponderation effect of attrition.

Results: Mean BP was 114.5/72.1 mmHg in the first and 120.3/74.8 mmHg in the second evaluation. In the first as-

essment there was a significant decrease of SBP for each Kg of increment of BW ($\beta=-3.073$, CI -4.884 to -1.263, $p=0.001$). In the second evaluation, was a similar effect ($\beta=-2.825$, CI=-4.427 to -1.223, $p=0.001$). An inverse effect was also observed with DBP in the second evaluation ($\beta=-1.326$, CI=-2.567 to -0.086, $p=0.036$). These effects were found only when sex and BMI of adult were considered in the model. In this period there was an increment of BMI of 2.7 points.

Conclusion: There was an inverse association between BW and BP in the two assessments, but there wasn't an amplification of the effect in the follow up of 10 years.

Key words: Cohort study, blood pressure, birth weight

PO1041

POST-PARTUM HIGH-DOSE VITAMIN A SUPPLEMENTATION TO IMPROVE VITAMIN A STATUS OF MOTHER AND INFANT: THE ROLE OF TIMING AND INFLAMMATION

T.T. Nga¹, M.A. Dijkhuizen², N.S. Tu¹, H. Friis², J. Berger³, L.T. Hop¹, F.T. Wieringa³

¹National Institute of Nutrition, Ministry of Health, Hanoi, Vietnam

²Department of nutrition, exercise and sports, Copenhagen University, Copenhagen, Denmark

³Institut de Recherche Pour Le Développement (IRD), UMR204-NutriPass, IRD-UM2-UM1, Montpellier, France

Background and objectives: Vitamin A deficiency is responsible for almost 0.6 million child deaths/year. Improving vitamin A status of lactating mothers after delivery seems an obvious strategy to improve vitamin A status of mother and infant. Maternal high-dose vitamin A supplementation soon after delivery was recommended but recently cancelled by WHO as the efficacy was unclear. The present study investigated effects of inflammation and timing of the maternal high-dose vitamin A supplementation post-partum on vitamin A status in mothers and newborns. **Methods.** In a randomized, double-blinded placebo-controlled trial, 400 pregnant women were randomly assigned at 28–32 weeks gestational age, to receive 200000 IU vitamin A within 1 week after delivery (WK1) or 6 weeks post-partum (WK6). Vitamin A in breastmilk and plasma, and inflammation (CRP and AGP) were measured at several time points during the first 6 months post-partum. **Results.** Retinol concentrations during pregnancy and 6 months post-partum were strongly correlated ($r=0.53$, $p < 0.001$). Prevalence of vitamin A deficiency in mothers 6 months post-partum was low (4.3% and 2.2% for WK1 and WK6, respectively), but high in infants (46.2% and 42.4% deficient and marginal status,

respectively). Breastmilk vitamin A concentrations were deficient in 5% of the women first week post-partum, but increased to 28% of the women 6 months post-partum and tended to be higher in the WK1 compared to the WK6 group (24% and 32%, respectively, $p < 0.10$). Inflammation, retinol and hemoglobin concentrations in mothers, and mother-infant retinol concentrations were related ($p < 0.01$ for all).

Conclusions: Lactation caused depletion of vitamin A stores in mothers, resulting in a high prevalence of vitamin A deficiency in infants 6 months post-partum. Inflammation was not only an important determinant of plasma retinol concentrations, but delivery-induced inflammation may also result in reduced effectiveness of the post-partum high-dose vitamin A supplement.

Key words: vitamin A, post-partum, inflammation.

PO1042

MATERNAL MILK CALCIUM CONSUMPTION IMPROVES BIRTH SIZE IN RURAL INDIA

A. Ganpule-Rao¹, S. Rao¹, C S. Yajnik², C H D. Fall³

¹Agharkar Research Institute, Pune, India

²Diabetes Unit, KEM Hospital and Research Centre, Pune, Maharashtra, India

³MRC Epidemiology Resource Centre, University of Southampton, Southampton General Hospital, Southampton, UK

Background and objectives: Studies in single generation highlight role of dairy calcium in modulation of body composition and obesity. There are hardly any intergenerational studies on this asset of dairy calcium. Pune maternal nutrition study (PMNS) investigated the influence of maternal size and nutrition in pregnancy on fetal growth. During current analysis we specifically studied the association of maternal calcium consumption with birth size.

Methods: PMNS was conducted in six villages near Pune. Nutritional status (anthropometry, dietary intakes-recall, FFQ) measured in 797 pregnant women and birth size data on 633 full term newborns is analyzed.

Results: Mothers were short (151.9 ± 5.1 cm) and underweight (41.7 ± 5.1 kg) and had low energy, protein and calcium intakes at 18wks of gestation (1763.1 ± 504.5 Kcal, 45.5 ± 14.3 g, 720.0 ± 298.1 mg, respectively). Primary sources of calcium were cereals, pulses (60%) while ~10-15% was from GLV and milk. At birth mean weight (BW) and length were low (2665 g, 47.8 cm). Mothers having milk calcium (milkCa) intake in the highest tertile (32 - 220 mg/d) had lower suprailliac skinfold thickness, fat mass and higher lean mass and gave birth to children with larger birth size (BW 2595 vs. 2660 g, length 47.3 vs 47.9 cm, $p = 0.05$ both) than mothers in lowest milkCa

tertile (0 - 2 mg/d). These effects were stronger in undernourished mothers (Pre-pregnancy BMI < 25 kg/m²) At 18wks, in spite of having body fat above median ($> 26\%$) mothers consuming low milkCa (0 - 2 mg/d) gave birth to babies with smaller size in comparison to mothers consuming high milkCa (BW 2570 vs 2748 g, length 47.5 vs 48.6 cm), perhaps due to fact that mothers with low milkCa consumption could not spare the body fat for fetal growth.

Conclusions: In view of our findings milk can be a simple and easy solution for improving birth size in rural undernourished mothers.

Key words: fetal growth, birth size, dairy, calcium, India.

PO1043

IMPACT OF NUTRITION EDUCATION ON PREGNANCY WEIGHT GAIN AND BIRTH OUTCOME

K. Jahan^{1,2}, S K. Roy^{1,2}, S. Israt^{1,2}, K. Ferdouse^{1,2}, S B. Salam^{1,2}

¹Bangladesh Breastfeeding Foundation (BBF), Bangladesh

²Nutrition Foundation of Bangladesh (NFB), Bangladesh

Background and objectives: Pregnancy weight gain and birth weight of newborn mortality in Bangladesh. We have analyzed the effect of nutrition counseling during the third trimester of pregnancy on weight gain, birth out come and breastfeeding.

Methods: The study was conducted in Maternal Care and Health Training Institute (MCHTI), Azimpur, and Mariestopes clinic, Bashbari, Dhaka. Monthly nutrition education was given to 155g pregnant women for last 3 months until delivery while the similar number of women selected randomly were given routine service. Body weight was measured monthly and within 24 hours after delivery. Breastfeeding practice was observed for 1 month after delivery.

Results: Body weight at the end of intervention was 59% higher in the intervention group compared to the comparison group (8.60 vs 5.38 kg, $p = 0.011$). The mean birth weight of babies born to the intervention group was 19% (0.49 kg) more than babies born to comparison group (2.98 kg vs 2.49 kg, $p < 0.001$). In the intervention group, 2.7% babies were LBW compared to 44.7% in the comparison group ($p < 0.001$). Birth weight was positively associated with intervention, initial body weight of pregnant women, total weight gain during pregnancy and frequency of intake of khichuri ($p < 0.001$). Initiation of breast-feeding within 1 hour of birth was 86% in the intervention group compared to 56.7% in the control group ($p < 0.001$).

Conclusions: The showed 59% more weight gain, 94% reduction in low birth weight and 54% increase in early initiation of breastfeeding compared to the comparison group.

PO1045**NUTRITIONAL PROBLEMS RELATED TO CALCIUM INTAKE IN CHILDREN WITH LACTOSE INTOLERANCE**

A. I. Jiménez Ortega¹, A. Aparicio², L. Pecharromán², E. Aguilar², R. M. Ortega²

¹Pediatric Gastroenterology, Hospital San Rafael, Madrid, Spain

²Department of Nutrition, Faculty of Pharmacy, Complutense University of Madrid, Spain

Background and objectives: Lactose intolerance (LI) supposes some limitations on dairy consumption which could condition a lower calcium intake. The objective of this study is to analyze this hypothesis.

Methods: A Spanish sample from 5 Spanish cities (A Coruña, Barcelona, Madrid, Sevilla and Valencia) was studied and it included 505 children (259 males) aged 8-13 years. Dietary data were obtained by using a 3-day food record. A sanitary questionnaire was applied in order to know diseases of the participants, including those that suffered from LI.

Results: Those children with LI (1.39%) had a lower dairy consumption (1.42±0.85 servings/day) in comparison to those without LI (2.59±0.94 servings/day) ($p < 0.001$), although their consumption is correctly focused on cheese and yogurt consumption (1.06±0.69 vs 0.90±0.85 servings/day in children without LI, NS). No significant differences were observed in the consumption of other food groups between children with or without LI. However the lower milk consumption observed in children with LI in comparison to those without LI (0.37±0.61 vs 1.19±0.57 servings/day, respectively) conditions a lower calcium intake (635.1±213.8 vs 941.3±221.7 mg/day, respectively) ($p < 0.001$). Calcium recommended intake (RI) contribution was lower in the LI group (58.3±25.5%) in comparison to those without the disease (85.6±28.0%) ($p < 0.05$). 74.1% of healthy children and 100% of children with LI had calcium intakes below those recommended by Department of Nutrition (2011) (and 54.4% and 84.9% had calcium intakes below the EAR, respectively) (IOM, 2010).

Conclusions: Children with LI need specific guidelines regarding the consumption of dairy that they should consume (cheese, yogurt, milk without lactose, etc.) and regarding the consumption of calcium enriched food or calcium supplements, in order to cover the RI of the mineral, because a high percentage of these children has inadequate intakes.

Key words: children, calcium, dairy, lactose intolerance

PO1046**INTAKE OF VITAMIN K AS MODULATOR OF INSULIN RESISTANCE IN A GROUP OF SPANISH SCHOOLCHILDREN**

A. I. Jiménez Ortega¹, A. M. López-Sobaler², L. G. González-Rodríguez², R. M. Ortega²

¹Pediatric Gastroenterology, Hospital San Rafael, Madrid, Spain

²Department of Nutrition, Faculty of Pharmacy, Complutense University of Madrid, Spain

Background and objectives: Vitamin K is involved in blood coagulation and bone maintenance, but can also supposes a benefit in glucose metabolism. Therefore, the aim of this study is to assess vitamin K intake and analyze their association with indicators of insulin resistance in schoolchildren.

Methods: 573 children (264 boys and 309 girls) of 8-13 years were studied. Dietary intake data was obtained using 3-day food records. Insulin resistance was estimated by the homeostasis model assessment (HOMA-IR): insulin (mU/ml) x glucose (mmol/l)/22.5.

Results: Considering the dietary reference intakes (DRI) of the Institute of Medicine (2001) (55 and 60 mcg/day in children of 8 years and older, respectively), the intake of vitamin K obtained (103.3±49.3 mcg/day) represents a 172.3±82.1% of the DRI, but 17.6% of schoolchildren failed to meet the DRI. Regarding the involvement of vitamin K in glucose metabolism is observed that schoolchildren with vitamin K intake above 1 mcg/kg/day have a significantly lower value of HOMA-IR (1.22±0.85) than those schoolchildren who have a lower intake of vitamin K (4.4%) (2.18±1.25) ($p < 0.001$). Using the logistic regression analysis and considering the influence of gender and age, it is observed that the risk of having a value of HOMA-IR higher to the P75 (1.63) is lower when the intake of vitamin K is 1 mcg/kg/day or higher (OR=0.997 (0.995-0.999), $p < 0.05$).

Conclusions: The 17.6% of the schoolchildren have intakes of vitamin K lower than the DRI, moreover, those with lower intake of vitamin K have higher values of HOMA-IR. Therefore, future studies should focus on the analysis of whether a higher consumption of the vitamin may help in some cases of insulin resistance.

Key words: children, vitamin K, insulin resistance

Acknowledgements: Study supported by the Health Research Fund Social Security (FISS) (Project: PI060318).

PO1047**CAN COMPLEMENTARY FEEDING BEHAVIOR CHANGE INTERVENTIONS ACHIEVE IMPACT AT SCALE?***C S. Fabrizio^{1,2}, M.J. van Liere², G H. Pelto³*¹Independent Consultant, Stanley, Hong Kong²Global Alliance for Improved Nutrition (GAIN), Geneva, Switzerland³Division of Nutritional Sciences, Cornell University, Ithaca, NY, USA

Background and objectives: The WHO Global Strategy on Infant and Young Child Feeding (2003) emphasizes that providing sound and culture-specific nutrition counseling to mothers of young children will help ensure that local foods are prepared and fed safely in the home. Complementary feeding behavior change communication has been identified as an effective intervention to improve infant and young child nutrition (Bhutta et al., 2008). Our objective in this study was to examine evidence concerning impact, cost-effectiveness, scalability and sustainability of behaviour change interventions (BCI) to improve infant feeding practices and growth.

Methods: We conducted a literature review to identify components associated with BCI's impact on nutritional status. We reviewed efficacy and effectiveness intervention trials published since 1999, by searching PubMed, EBSCO, Popline, Google Scholar and relevant review articles. Studies were included if they reported on the development and components of the intervention and provided data on the impact for children aged six to 24 months, in developing countries, using the outcomes of anthropometric change, nutritional intake, or change in targeted behaviors.

Results: Most programs utilized formative research to create clear and practical messages to enable behavior change. They combined multiple approaches such as counseling and social support. A few innovative programs utilized adult learning techniques while others mirrored commercial marketing techniques with social marketing. Many of the interventions aimed for sustainability through integration with the health system; however, they faced challenges where health systems were weak and health workers lacked capacity. Most studies reviewed programs of limited size and rarely reported cost-effectiveness or scalability potential.

Conclusions: There is evidence for impact of BCI on growth and infant feeding practices under program conditions. There is very limited reported evidence for cost-effectiveness, sustainability or bringing these programs to scale.

Key words: infant and young child nutrition, behavior change interventions, complementary feeding, scale-up.

PO1048**LIFE COURSE STAGES AND TRANSITIONS ASSOCIATED WITH WEIGHT GAIN IN OBESE MEN***H H. Van Der Spuy¹, H M. de Klerk¹, H M. Vogel², F.A.M. Wenhold³*¹Department of Consumer Science, Faculty of Natural and Agricultural Sciences, University of Pretoria, Pretoria, Gauteng, South Africa²Department of Psychology of Education, College of Education, University of South Africa (UNISA), South Africa³Department of Human Nutrition, Faculty of Health Sciences, University of Pretoria, South Africa

Background and objectives: Since complex human behaviour is at the root of obesity, it should also be studied on a micro-level, taking social context and specific relationships with food and roles of others across the life course into account. This study aimed to explore and describe in the obese man stages, transitions and the role of others in the life course, directing food trajectories and the experience of the self.

Methods: A qualitative, phenomenological approach was used, combining symbolic interactionism and life course perspectives to create a holistic view of obesity. Fourteen obese white South African men retrospectively described experiences of being obese through three individual, in-depth, unstructured interviews. ATLAS ti was used for data analyses by using codes and creating families and networks. Themes were identified and described.

Results: Three themes emerged: the meaning of food, the sadness of obesity, and coping with obesity. The obese man's eating habits were shaped by others, like his mother (childhood and adolescence), and his spouse, friends and work colleagues in young adulthood (around 30). Indulgence in eating was for the anticipated pleasure it brought. Transitions like marriage and career changes influenced food and weight trajectories with negative consequences for their self-experience. Overweight bodies gave rise to distressing physical constraints and emotional experiences of sadness. Regardless of numerous coping strategies, participants were not totally able to handle their plight. It actually deteriorated and impacted negatively on well-being.

Conclusions: Interaction with significant others during specific life stages is important in the development of food trajectories. Childhood is the stage at which the obese man learned food behaviour and attached meaning to food.

Key words: obese men, life course, trajectories, significant others, self.

PO1049**LEVEL OF ANEMIA AMONG ADOLESCENT GIRLS IN TRIBAL INDIA***R. Rani, J. B Singh, S. Sharma*

Institute of Health Management Research, India

Background and objectives: India is the second most populous country in the world with 22.5 percent, adolescents. Adolescent girls need micronutrients to meet the body's increased demand for iron especially during menstruation. Pregnant adolescents who are underweight or stunted are more likely to experience obstructed labor and other complications. Anemia weakens women's ability to survive childbirth, makes them more susceptible to infections.

Methods: A cross sectional survey for anemia detection was conducted with a sample size of 709 adolescent girls from three blocks of Udaipur. Levels of anemia were defined as mild, moderate and severe. Reference values for anemia detection were taken as per Indian standards. Hemoglobin (Hb) level in g/dl as per RCH-II: Normal-Above 12 g, Mild-10.0-11.99 g, Moderate-8.0-9.99 g, Severe-below 8.0 g.

Results: Collectively from three blocks, 79% of adolescents found anemic (mild anemic - 48%, moderate and severe anemic-31%). The mean value of Hb for three blocks is 10.6 with 1.47 standard deviation, which indicates adolescents suffering from anemia. Out of three blocks, comparatively Jhadol block had higher anemia as it had only 9% girls with normal Hb and 49% adolescents moderately and severely anemic.

Conclusions: Anemia is highly prevalent in adolescent girls, especially girls who belong to tribal area. Strategies to reduce anemia of the adolescent girls are need of the hour in both the government and interventions supported by development agencies.

Key words: anemia, adolescent girls, India.

PO1050**A LONGITUDINAL STUDY OF IRON STATUS FROM PREGNANCY TO POSTPARTUM PERIODS***Y. Watanabe¹, K. Uenishi¹, H. Ishida¹, H. Yoshikata²*¹Kagawa Nutrition University, Sakado, Saitama, Japan²Yoshikata Ladies Clinic, Yokohama, Kanagawa, Japan

Background and objectives: Iron deficiency anemia often occurs during pregnancy. However, pregnant women may possibly occur the hydremia because physiological blood is diluted due to an increase in circulating plasma volume and thus hemoglobin (Hb) concentration and hematocrit (Ht) level are

relatively decreased. Therefore, it is very important for pregnant women to discriminate between iron deficiency anemia and hydremia.

Methods: 103 Japanese women (aged 31.7 ± 3.7 years) at 5-12 weeks of pregnancy were recruited from an antenatal clinic in Yokohama between November 2010 and March 2011. Collected data included anthropometry and obstetric measurements, with or without administration of iron, and blood samples at the first trimester, second trimester, last trimester, delivery and the first postpartum month.

Results: Maternal red blood cell count, Hb concentration, Ht level and serum iron concentration were significantly decreased at the second trimester, last trimester and delivery compared to the first trimester. However, in the first postpartum month, they were recovered to the same levels as the first trimester. Ferritin concentration was significantly decreased during pregnancy, and did not recover in the first postpartum month. The prevalence of maternal anemia (Hb < 11 g/dl, Ht < 33% (WHO)) was 4.9% at the first trimester, 41.7% at the second trimester and 53.4% at the last trimester. However, MCV and MCH fell within the criterions (MCV: 79.0-100.0 fL, MCH: 26.3-34.3 pg) in most of the subjects. In this study, low-birth-weight baby and preterm baby were only three and one, respectively. Therefore, it was suggested that not only women with iron deficiency anemia but also a number of women with hydremia, due to a physiological blood dilution, were estimated as maternal anemia.

Conclusions: There was the possibility to overestimate maternal anemia because of a physiological blood dilution.

Key words: pregnancy, iron deficiency anemia, physiological blood dilution.

PO1051**MEDITERRANEAN DIET ADHERENCE AND RISK OF FRACTURES IN OLDER PERSONS: RESULTS FROM THE THREE-CITY STUDY***C. Feart¹, S. Lorrain¹, V. Ginder Coupez², C. Samieri¹, L. Letenneur¹, D. Paineau², P. Barberger-Gateau¹*¹INSERM U897, Univ Bordeaux Segalen, Epidemiologie-Biostatistique, F-33076 Bordeaux Cedex, France²Danone Research, Centre Daniel Carasso, Global Nutrition Department, F-91767 Palaiseau Cedex, France

Background and objectives: The Mediterranean diet (MeDi) has well-known health benefits on the risk of mortality and several age-related diseases. However, the potential effect of a Mediterranean-type diet on the risk of fractures is unclear. The aim was to investigate prospectively the relationship between adherence to the MeDi and the risk of fractures in older persons.

Methods: The study sample consisted of 1482 subjects, aged 67 years and over, enrolled in the Three-City study in 2001-2002. The outcome of interest was incidence of self-reported hip, vertebral and wrist fractures. Over 8 years of follow-up, 155 individuals reported a fracture at any of the three sites. Adherence to a Mediterranean-type diet was assessed at baseline by the MeDi score, a 10-point Mediterranean-diet scale, based on food frequency questionnaire and a 24 h recall. Multivariate Cox regression were performed to estimate risk of fractures according to MeDi adherence.

Results: In analyses adjusted for age, gender, physical activity, energy intake, education, marital status, BMI, self-reported osteoporosis, osteoporosis treatment and calcium and/or vitamin D supplements, each additional unit of MeDi score was associated with a non-significant increased risk of fracture (HR=1.10, IC95% 0.-,99-1.-,21). Among MeDi components, a high consumption of fruits (>2 servings/day) and a low consumption of yoghurts (<1 serving/day) were significantly associated with a doubled risk of fracture of the hip (HR=1.95, IC95% 1.04-3.-,66) and the wrist (HR=1.98, IC95% 1.-,22-3.-,21), respectively. An inverse U-shaped association between alcohol intake and risk of fracture at any site was observed (HR high vs moderate=0.61, p for trend 0.03).

Conclusions: A diet closer to the MeDi is not associated with a decreased risk of fractures. This dietary pattern, characterized by a low consumption of dairy products and a high consumption of fruits, may not be considered as universal healthy dietary pattern.

Key words: Mediterranean diet, fracture, aging.

PO1052

ADEQUACY OF FOLATE INTAKE DURING PREGNANCY: THE ROLE OF FLOUR FORTIFICATION AND DIETARY SUPPLEMENT

L. Crivellenti¹, P. Barbieri¹, D. Sartorelli¹

¹Department of Social Medicine, University of Sao Paulo, Brazil

Background and objectives: The folate during pregnancy plays a relevant role in preventing some adverse effects on maternal and fetal health. The aim of the present study was estimate the adequacy of folate intake contained naturally in foods, and the role of the flour fortification on the adequacy of the nutrient among pregnant women. Additionally, the dose of folic acid supplement recommended internationally was simulated to evaluate if the nutritional requirements during pregnancy would be achieved.

Methods: Prospective study conducted among 82 adult pregnant in Ribeirao Preto, Brazil. Food intake was assessed by 3 dietary recalls during pregnancy and the adequacy of the

nutrient was evaluated by the Estimated Average Requirement (EAR) as the cutoff point. The planning approach for the homogenous groups was used to simulate the effect of the dose of folic acid supplement.

Results: It was found that 100% and 94% of pregnant women reported inadequate dietary intakes of dietetic folate and folic acid, from fortification, respectively (EAR < 520 µg). Considering a dose of 0.4 mg/day of the folic acid supplement, it was observed that 99% of pregnant women had their nutritional requirements achieved.

Conclusions: High proportion of pregnant women had diets with inadequate folate content, and the fortification of wheat and corn flour had little impact in improving the availability of this vitamin. The dose of folic acid supplement recommended by international organizations, added to the content of dietary folate, was adequate for the pregnant women evaluated. Funding: FAPESP (2011/03781-8), FAEPA.

Key words: pregnancy, food intake, folic acid, dietary supplements.

DIET QUALITY DIFFERENCES IN URBAN AND RURAL ADOLESCENTS AND SOCIOECONOMIC ASSOCIATED FACTORS. A TUNISIAN STUDY

H. Aounallah-Skhiri^{1,2}, J. El Ati^{3,2}, P. Traissac⁴, S. Eymard-Duvernay⁴, H. Ben Romdhane⁵, M. Hsairi^{1,2}, F. Delpeuch⁴, B. Bernard⁴

¹National Institute of Public Health, Tunis, Tunisia

²LR12SPO5: Nutritional Surveillance and epidemiology in Tunisia

³National Institute of Nutrition and Food Technology (INNTA), Tunis, Tunisia

⁴Institut de Recherche pour le Développement (IRD), UMR 204 NUTRIPASS, IRD-UM2-UM1, Montpellier, France

⁵Epidemiology and prevention of CVD research laboratory, Faculty of Medicine, Tunis, Tunisia

Background and objectives: Diet quality (DQ) is an important determinant of adolescent's health and should be assessed regularly in order to identify nutritional problems. The aim of this study is to assess DQ of Tunisian adolescents in urban and rural areas and identify socioeconomic associated factors.

Methods: Cross-sectional study (2005) concerned a clustered random sample (1019 adolescents, 15-19 y). Dietary intake assessed by a validated semi-quantitative frequency questionnaire (134 items). DQ estimated by Diet Quality Index International (DQI-I) global (/100) and component scores. Socioeconomic characteristics of the parents, lifestyle behaviour and

anthropometric measurements (weight, height) were recorded. The DQ scores examined according to socioeconomic factors. Adjusted relationships performed using logistic regression (good DQI-I (>60/100) vs poor).

Results: DQI-I was higher among urban (58.2(0.4)) vs rural adolescents (56.6(0.5), $p = 0.014$) but not different by gender in both areas. The variety, adequacy and balance sub-scores were higher in urban area. Inversely, the moderation sub-score was higher in rural area ($p = 0.0002$). The frequency of good DQ was higher in urban (40.7%) vs rural area (31.5%; $p = 0.049$). Contrarily to urban area, in rural area, the DQI-I was higher when the education level of the mother was secondary or more: 59.1(1.3) vs 56.4(0.5), $p = 0.039$; among adolescents of middle economic level households: 58.8(0.7) vs 57.3(1.7) for higher and 55.9(0.6) for lower, $p = 0.0004$; adolescents were at school (57.3(0.6)) vs others: (55.7(0.6), $p = 0.019$). After adjustment on BMI, perceived stress, low physical activity and sport's practice, DQI-I was higher for those having a working mother in urban area (OR:1.8(1.0-3.2), $p = 0.045$) and adolescents of middle economic level households vs low level in rural area (OR:2.0(1.2-3.3), $p = 0.006$).

Conclusion: Tunisian adolescents had a moderate DQ but higher in urban vs rural area. Dietary strategy for improving DQ should consider the socioeconomic context in urban and rural areas.

Key words: diet quality, socioeconomic factors, adolescents, Tunisia.

PO1054

METABOLOMIC STUDY OF THE EFFECT OF ANTIMETHANOGENIC TREATMENT ON RUMEN METABOLISM AT EARLY LIFE OF GOAT KIDS

L. Abecia¹, G. Martínez¹, A I. Martín-García¹, C J. Newbold², D R. Yañez-Ruiz¹

¹Instituto de Nutrición Animal, Estación Experimental del Zaidín-CSIC, Armilla, Granada, Spain

²IBERS, Aberystwyth University, UK

Background and objectives: The aim of this work was to study whether intervention with an antimethanogenesis compound (bromochloromethane, BCM) in early life of kids has an impact on rumen metabolism later in life.

Methods: Eighteen doe goats giving birth to two kids were used. Nine does were treated with BCM (D+) from birth of kids to 8 weeks. The other 9 does were not treated (D-). One kid per mother in both groups was treated with BCM (k+) while the other was untreated (k-), resulting in four experimental groups: D+/k+, D+/k-, D-/k+ and D-/k-. Rumen samples were collected from kids at weaning (8 weeks), a month after (when the treatment ceased) and 3 months later. Extracted samples were split for analysis on GC/MS and LC/MS/MS platforms.

Results: Valerate and acetate increased with time in all k- after weaning. In contrast, the time-dependent increase in valerate was less steep in k+ group after weaning. Treatment of does had an effect on phospholipase activity in kids after weaning. The most apparent effects of the maternal treatment of pre-wean kid rumen content was observed in medium chain fatty acids (MCFA C6-C14), which were greatly elevated in D+ kids. This effect for C9 and C11 MCFA, was mainly driven by the large increase in MCFA levels in kids from D+/k- group. Although MCFA would be mainly derived from maternal milk before weaning, many of these MCFA differences persisted 4 months after wean. Most of the differences did not match between D+ and D-, possibly suggesting additive effects of the doe and kid treatment on the global metabolic profile of ruminal content.

Conclusions: Our results suggest that a modulation of the rumen microbial colonization at early life, including the influence of the mother, caused differential metabolic profile that persisted after weaning, regardless of the post-wean treatment.

Key words: bromochloromethane, early life, metabolism, offspring, rumen.

PO1055

EFFECT OF ANTIMETHANOGENESIS TREATMENT ON RUMEN METABOLIC PROFILE OF LACTATING GOATS.

L. Abecia¹, G. Martínez¹, A I. Martín-García¹, C J. Newbold², D R. Yañez-Ruiz¹

¹Animal Nutrition Institute, Estación Experimental del Zaidín-CSIC

²IBERS, Aberystwyth University, UK

Background and objectives: Bromochloromethane (BCM) is one of the most effective methanogenesis inhibitors when fed to ruminants as reduces methane production by interfering with the cobamide-dependent methyl transferase step of methanogenesis. Our group has recently reported the effectiveness of using BCM in dairy goats on rumen fermentation and methane emissions. However, the effects on the rumen metabolism as a whole have not been investigated yet. The aim of this study was to study the effect of treating goats with an antimethanogenic compound (BCM) on changes on rumen metabolism.

Methods: Eighteen goats giving birth to two kids were used. Nine goats were treated with BCM (G+) after kids were born and over 8 weeks. The other 9 goats were not treated (G-). Rumen samples were collected at weaning. The extracted samples were split for analysis on GC/MS and LC/MS/MS platforms.

Results: Rumen content was a very metabolite-rich sample (473 named biochemical). The experimental treatment affec-

ted levels of amino acid, lipid and carbohydrate metabolites. Levulinate, a keto acid from complex carbohydrates, N-acetylmethionine, derived from protein breakdown or amino acid acetylation, pyridoxate, a B6 metabolite, and indoleacetate, a tryptophan metabolite, were lower in G+. Benzoic acid, generated from metabolism of phenylalanine and polyphenols, was also lower with BCM. Another phenylalanine product, phenethylamine, was elevated in rumen content of G+ animals. By contrary, ciliatine, which can serve as a source of nitrogen, carbon and phosphorous when degraded by bacteria, was elevated with the BCM treatment. Glycolysis intermediates were lower in BCM treated animals. Guanosine and cytosine, were higher and urate was lower in G+ goats. Palmitoyl ethanolamide was lower and oleic ethanolamide trended to be lower in animals fed BCM. GABA was elevated with BCM.

Conclusions: The inhibition of methanogenesis by BCM involves a substantial shift in different metabolic pathways in the rumen.

Key words: bromochloromethane, metabolism, rumen.

PO1056

HELMINTH INFECTIONS AND MICRONUTRIENTS IN SCHOOLCHILDREN: A SYSTEMATIC REVIEW AND META-ANALYSIS

B. de Gier^{1,2}, M. Campos Ponce², M. van de Bor¹, C M. Doak², K. Polman^{2,3}

¹Department of Health Sciences, section Health and Life Sciences, VU University Amsterdam, The Netherlands

²Department of Health Sciences, section Infectious Diseases, VU University Amsterdam, The Netherlands

³Department of Biomedical Sciences, unit Medical Helminthology, Institute of Tropical Medicine, Antwerp, Belgium

Background and objectives: Helminth infections and micronutrient deficiencies are both highly prevalent in developing countries. Neither condition typically causes overt disease but they do lead to indirect morbidity and impaired physical and cognitive development. We aimed to systematically review current evidence on the relationship of helminth infections with micronutrient status in schoolchildren worldwide.

Methods: We included both observational studies and RCTs. We used random effects meta-analysis 1) to estimate cross-sectional associations between helminths and micronutrient status; 2) to estimate anthelmintic treatment effects on micronutrient status, and 3) to estimate effects of micronutrient supplementation on helminth (re)infection.

Results: Meta-analyses of observational studies showed a significant association between helminth infections and serum retinol (SMD (standardized mean difference) -0.30 [-0.48;-0.13]) but not serum ferritin (SMD 0.00 [-0.7;0.7]). Conversely, meta-analyses of anthelmintic RCT studies did show a positive effect on ferritin (SMD 0.14 [0.08;0.20]) but not on retinol (SMD 0.04 [-0.06;0.14]). We did not find enough studies to pool data on other micronutrients besides ferritin and retinol. When evaluating helminth (re)infection rates in micronutrient supplementation studies, only multi-micronutrient interventions showed a modest protective effect (OR 0.77 [0.61; 0.97]).

Conclusions: We found significant associations between helminth infections and micronutrient status in schoolchildren. Our results showed distinct associations with either serum retinol or serum ferritin. More evidence is needed to further unravel the interrelationship between helminth infections and micronutrient status.

Key words: helminth, micronutrient, children.

PO1057

TRENDS OF COMPLEMENTARY FEEDING INDICATORS IN CHILDREN AGED 6-23 MONTHS IN TANZANIA FROM 2004-50 TO 2010

R. Victor¹, S. Baines², K. Agho³, M. Dibley⁴

¹Community Health and Nutrition Department, Tanzania Food And Nutrition Centre, Tanzania

²School of Health Sciences, Faculty of Health, University of Newcastle, NSW 2308, Australia

³School of Medicine, University of Western Sydney, NSW, Australia

⁴Sydney School of Public Health, University of Sydney, NSW, Australia

Background and objectives: Sub-optimal complementary feeding practices are associated with poor nutrition status and contribute to high mortality rates among young children in many developing countries. The aim of this study was to determine trends in complementary feeding indicators among children aged 6-23 months in Tanzania from 2004-05 to 2010.

Methods: The study was a secondary analysis of cross-sectional data from the 2004-05 and 2010 Tanzania Demographic and Health Surveys. These surveys used a multi-stage cluster sample of 10312 in 2004-05 and 10300 in 2010 from eight geographic zones in Tanzania. The sample consisted of 4755 infants aged 6-23 months in both surveys. All statistical analyses were performed using Stata 10.0. Differences in prevalence estimates in complementary feeding indicators were expressed as percentages comparing between the two surveys periods using a chi-square to test the significance of differences at $p < 0.05$.

Results: The percentage of children aged between 6-8 months who received soft, semi-solid or solid foods increased significantly from 77% in 2004-05 to 92% in 2010. The prevalence of minimum dietary diversity was low (40%) in 2004-05 and remained unchanged (38%) in 2010. Similarly, the prevalence of minimum meal frequency decreased significantly from 45% in 2004-05 to 34% in 2010 ($p < 0.001$). The prevalence of minimum acceptable diet decreased significantly from 19% in 2004-05 to 14% in 2010.

Conclusion: Tanzania has made significant progress in increasing the proportion of infants aged 6-8 months who receive soft, semi-solid or solid foods as determined by the 2004-05 and 2010 surveys but minimum dietary diversity, minimum meal frequency and minimum acceptable diet fall short of WHO recommendations. Findings from this study should help public health researchers and policy makers to reflect, plan and evaluate actions needed to support and encourage appropriate complementary feeding practices.

Key words: complementary feeding; dietary diversity; meal frequency; acceptable diet.

PO1058

MATERNAL WORKING CHARACTERISTIC IS ASSOCIATED WITH CHILD UNDERWEIGHT IN URBAN MIDDLE-CLASS FAMILIES OF INDONESIA

A. Roshita¹, A. Page³, L. Schubert², M. Whittaker²

¹SEAMEO RECFON University of Indonesia, Indonesia

²School of Population Health, University of Queensland, Australia

³School of Science and Health, University of Western Sydney, Australia

Background and objectives: Children undernutrition is seen alongside the rise of middle class communities and increased women's participation in the workforce. Few studies explored the relationship between maternal employment and child malnutrition amongst the emerging middle class in developing countries. This study aims to assess whether maternal employment characteristics and having a non-maternal caregiver were associated with child underweight in an urban area of Indonesia.

Methods: The study was designed as a case-control study involving 288 (109 cases and 179 controls) children aged 12-36 months. Cases were mild to moderately underweight children, while controls were normal weight children. The data collection methods consisted of anthropometry measurements and structured interviews pertaining to socio-demographic characteristics of the families, maternal employment characteristics and availability of caregivers, feeding practices, child

illnesses in the preceding 2 weeks and support for mothers and caregivers.

Results: Mothers working outside the home for less than 20 hours per week (informal work) was associated with 6.04 higher odds (CI = 1.20–30.57, $p = 0.030$) of their children being underweight, compared to mothers working outside the home for more than 40 hours per week (formal work), adjusted for child care arrangement and child characteristics, suggesting that mothers with secure income and a formal occupation conferred an advantage for child nutritional status. Having non-maternal caregiver was not significantly associated with child underweight.

Conclusions: The mechanism of positive impact of formal working mothers on child nutrition in Indonesian urban middle class communities may be through the stable care arrangement in the absence of mother and the increased women's income spent on child resources. Nutrition and child health policy responses should be directed to provision of alternative high standard child care arrangements for dual-working parents in Indonesia and other developing countries.

Key words: child care practices, women employment, child underweight, Indonesia.

PO1059

TRENDS OF BREASTFEEDING INDICATORS IN TANZANIA FROM 1999 TO 2010

R. Victor¹, S. Baines², K. Agho³, M. Dibley⁴

¹Community Health and Nutrition Department, Tanzania Food And Nutrition Centre, Tanzania

²School of Health Sciences, Faculty of Health, University of Newcastle, NSW 2308, Australia

³School of Medicine, University of Western Sydney, NSW, Australia

⁴Sydney School of Public Health, University of Sydney, NSW, Australia

Background and objectives: Optimal breastfeeding practices are important to protect against child mortality, and morbidity, and promote optimal growth and development of young child in low- and middle-income countries. Our aim was to examine trends in breastfeeding indicators among children aged 0-23 months in Tanzania between 1999 and 2010.

Methods: The sample included 7603 children aged 0-23 months from Tanzania Demographic and Health Survey data from 1999 to 2010. We examined trends in breastfeeding indicators, which were defined using 2008 World Health Organisation recommended methods. Differences in prevalence estimates in breastfeeding feeding indicators were expressed

as percentages comparing between the three surveys periods using a chi-square to test the significance of differences at $p < 0.05$.

Results: Only 59.0 % of mothers initiated breastfeeding within the first hour of birth in 2004/5 and this was reduced to 46.1% in 2010. Prevalence of exclusive breastfeeding in infants aged 0-5 months was 31.8%, 41.3% and 49.9% in 1999, 2004/5 and 2010, respectively. The proportion of infants (0-5 months) who were “predominantly breastfed” declined significantly from 59.8% in 1999 to 16.8% in 2010. More than 91.0% of mothers breastfed up to 1 year in all surveys but the proportion decreased to 57.2% , 55.5% and 51.1% in 1999, 2004/5 and 2010, respectively, for children at 2 years of age.

Conclusions: Tanzania made significant improvements, regarding exclusive breastfeeding for six months and continued breastfeeding up to 1 year, from 1999 to 2010. There was a significant decline in early initiation of breastfeeding within one hour after birth and continued breastfeeding up to two years from 2004/5 to 2010. These findings highlight the need for effective nutritional programs to promote early initiation of breastfeeding and continued breastfeeding of infants up to two years.

Key words: early initiation of breastfeeding, exclusive breastfeeding, predominant breastfeeding, continued breastfeeding, Tanzania.

PO1060

A STUDY OF DIETARY AWARENESS OF MOTHERS AND THEIR INFANTS

*N. Takagi*¹

¹Toyama College, Japan

Background and objectives: In recent year, the number of people affected lifestyle-related disease has been increasing in Japan. It is thought that provide adequate dietary education is necessary from childhood to prevent lifestyle-related disease. The purpose of this study is to built up a brand-new program for nutritional education in childhood, we surveyed some questionnaires for mothers.

Methods: The participants in this survey were 19 mothers in Toyama city, Japan. We surveyed mothers of children who go to kindergarden. (n=19)

Results: About 80 per cent of mothers and about 90 per cent of their infants surveyed stated that they enjoy a meal. In Japan, before eating you say ‘gitadakimasu’ and after you have finished you say ‘ggochisosama’. Dining manners observed about 80 per cent of mothers and their infants. They can learn dining manners ‘hitadakimasu’ and ‘ggochisosama’ in the home.

Conclusions: 0 per cent of mothers surveyed that they do not know nutrient requirement necessary for family. Though, about 60 per cent of mothers surveyed stated that they think intake necessary nutrients in a day.

Key words: dietary education, lifestyle-related disease, dietary awareness.

PO1061

EFFECTS OF QUERCETIN SUPPLEMENTATION AND EXERCISE ON MITOCHONDRIAL BIOGENESIS IN RAT MUSCLE

*R. A. Casuso*¹, *E. Martínez-lópez*², *F. Hita-Contreras*¹, *R. Martínez-Romero*⁴, *A. Cañuelo*⁴, *A. Martínez-Amat*¹

¹Department of Health Sciences, University of Jaén, Spain

²Department of Music, Plastic Expression and Body Language, University of Jaén, Spain

³Department of Experimental Biology, University of Jaén, Spain

Background and objectives: Quercetin increase muscle fatigue resistance by inducing muscle mitochondrial biogenesis as observed after 7 days of 12.5 mg/kg to 25 mg/kg supplementation in mice. But no ergogenic effects were found after 6-wk quercetin ingestion in both sedentary and exercised rats. Thus, the aim of the present study was to test if chronic quercetin intake is able to enhance mitochondrial biogenesis in sedentary and exercised rats.

Methods: Male Wistar rats were randomly allocated into quercetin exercised (n = 9), quercetin sedentary (n = 8), no-quercetin exercised (n = 8), no-quercetin sedentary (n = 8). Treadmill exercise training took place 5 days a week for 6 weeks. Quercetin groups were supplemented (25 mg/kg of quercetin) via gavage on alternate days. All rats were anesthetized with pentobarbital and were bled by cannulation of the aorta 48h after the last exercise. Muscle was immediately collected and stored in liquid nitrogen. Gene expression of different genes (peroxisome proliferator-activated receptor coactivator 1, PGC-1 α ; NAD(+)-dependent histone deacetylases, SIRT-1) was quantitatively assessed by real-time PCR using α -actin as the normalizing gene. Mitochondrial content was estimated as the ratio between copy numbers of mtDNA vs nuclear DNA (α actin).

Results: Both exercise ($p < 0.05$) and quercetin ($p < 0.001$) supplementation increased PGC-1 α mRNA levels. Quercetin supplementation during exercise abolished ($p < 0.001$) the quercetin induced increase ($p < 0.001$) in SIRT1 mRNA expression. Moreover, the combination of exercise and quercetin supplementation caused lower ($p < 0.05$) mtDNA content when compared to exercise alone.

Conclusions: Quercetin supplementation do not alter skeletal muscle mitochondrial DNA content in sedentary rats. However, the combination of training and quercetin supplementation compromise exercise induced SIRT1 mRNA expression and possibly compromised mitochondrial DNA content.

Key words: quercetin, exercise, mitochondrial biogenesis.

PO1062

EFFECTS OF QUERCETIN SUPPLEMENTATION AND EXERCISE ON PGC-1 ALPHA AND SIRT1 IN RAT BRAIN

R. A. Casuso¹, E. Martínez-lópez², F. Hita-Contreras¹, R. Martínez-Romero³, A. Cañuelo³, A. Martínez-Amat¹

¹Department of Health Sciences, University of Jaén, Spain

²Department of Music, Plastic Expression and Body Language, University of Jaén, Spain

³Department of Experimental Biology, University of Jaén, Spain

Background and objectives: Quercetin is thought to increase brain mitochondrial biogenesis as observed after 7 days of 12.5 mg/kg to 25 mg/kg supplementation in mice. This effect was associated with an increased running time to fatigue. However, in a previous study, we found no ergogenic effect of quercetin neither in sedentary nor in exercised following 6-wk of quercetin intake. Thus, the aim of the present study was to test the hypothesis that long-term quercetin supplementation will not increase PGC-1 α or SIRT1 in the brain of neither sedentary nor exercised rats.

Methods: Male Wistar rats were randomly allocated into quercetin exercised (n = 9), quercetin sedentary (n = 8), no-quercetin exercised (n = 8), no-quercetin sedentary (n = 8). Treadmill exercise training took place 5 days a week for 6 weeks. Quercetin groups were supplemented (25 mg/kg of quercetin) via gavage on alternate days. All rats were anesthetized with pentobarbital and were bled by cannulation of the aorta 48h after the last exercise. Muscle was immediately collected and stored in liquid nitrogen. Gene expression of different genes (peroxisome proliferator-activated receptor coactivator 1, PGC-1; NAD(+)-dependent histone deacetylases, SIRT1) was quantitatively assessed by real-time PCR using α -actin as the normalizing gene.

Results: The exercised groups showed a quercetin-induced 98% decrease (p = 0.003) in PGC-1 α and a 194% decrease (p < 0.01) in SIRT1. Quercetin supplementation during exercise inhibits the expression of exercise-induced SIRT1 and PGC-1 α in the brain.

Conclusions: Long-term quercetin intake is able to enhance mRNA levels of some genes related to mitochondrial biogenesis

in brain, as previously described. However combination of exercise and quercetin compromise these gene-related adaptations.

Key words: quercetin, exercise, brain; PGC-1 α ; SIRT1.

PO1063

FAT MASS INDEX (FMI), LEAN MASS INDEX (LMI) AND APPENDICULAR MUSCLE MASS INDEX (AMMI) IN PROFESSIONAL FUTSAL PLAYERS.

D. Zomeño¹, A. Lizzárraga^{1,2}, I. Palma¹, A. Farran¹, D. Medina³, D. Florit³, F. Drobnic³

¹Department of Nutrition & Food Science, University of Barcelona, Grup de Recerca en Nutrició Aplicada. Campus de l'Alimentació, (Torribera), Santa Coloma de Gramenet, Barcelona,, Spain

²Ciències Fisiològiques II. Facultat de Medicina (UB) Bellvitge, Barcelona, Spain

³Fútbol Club Barcelona. Medical Department, Barcelona, Spain

Background and objectives: Futsal (FS) is a relatively new sport and there are no many studies about anthropometry and body composition of futsal players. This sport demands great mobility and players undergo a lot of changes along the match (accelerations and shorts sprints are performed). In this discipline is necessary to have an adequate strength. It seems interesting to determinate the amount of muscle and its distribution along the body through the valoration of different indexes, which have not found a wide application yet. The aim of this study was to determine the values of Fat Mass Index (FMI), Lean Mass Index (LMI) and Appendicular Muscle Mass Index (AMMI) in professional male futsal players.

Methods: Twelve professional male futsal players were included, and all of them agreed to participate in this study. After being subjected to whole body densitometry by dual X-ray absorptiometry, fat and lean body mass together with other parameters, FMI [fat (kg)/height (m)²], LMI [lean (kg)/height (m)²] and AMMI [arms and legs musculature (kg)/height (m)²] were calculated. Diet was recorded using 3-day records and nutrient intake was estimated using these data. The results were compared with the reference values from the NHANES and with the ones published by Schutz et al 2002.

Results: Considering FMI (mean: 3.69 kg/m²), all of them had normal values, lower than the average for young men (4 kg/m²). LMI's mean was 19.41 kg/m², higher than P50 18.9 kg/m². And finally AMMI's mean was 9.64 kg/m², supposing high values the ones over 9 kg/m².

Conclusions: We proposed the use of height-normalized indexes: LMI, FMI and AMMI in futsal players to avoid the

ambiguities that would be generated when these components are reported as percentages of body weight and/or by absolute weight.

Key words: futsal, anthropometry, muscle, body composition.

PO1064

ACCEPTABILITY OF SALADS IN SCHOOL MEALS CONSUMED IN REAL CONDITIONS IN THE MUNICIPALITY OF MURCIA, SPAIN

A. Rodríguez-Tadeo¹, B. Patiño Villena², M J. Periago Caston¹, Ed. Gonzalez Martínez-Lacuesta², G. Ros Bermejo¹

¹Research Group Nutrition and Food Science, Faculty of Veterinary Medicine, University of Murcia, Spain

²Municipal Health Services, Department of Social Welfare and Health, City of Murcia, Spain

Background and objectives: Hedonic evaluation of vegetables in school meals is limited, but necessary to optimize the consumption and contribute to improving of dining services. SENSOCOLE is a sensory evaluation project in school canteens, which has explored user's preferences. The aim of this study is to evaluate user's preferences for salads served at school cafeterias and the real consumption.

Methods: Descriptive study of hedonic acceptance of food (7-point scale) by 8-12 y school cafeteria users. Participated 10 schools of Murcia City during a week, 5 in spring and 5 in autumn season of 2012; 515 salads were evaluated. School menu included a salad as garnish; the amount served and the remains of salads were weighed to estimate real consumption. Statistical differences were fixed at $p < 0.05$.

Results: 18% of the salads were not consumed; 86% included only fresh vegetables and 14% other components: tuna, egg or nuts. The overall hedonic grading of the salads was 5.14 (median 5), no difference with that included other components and only 16% had negative evaluations. Difference was observed in autumn 5.36 (median 6) and the spring rate of salads 4.71 (median 5) ($p < 0.05$). 66% of users leaving more than half of the quantity served in spring and 49% in autumn. The same trend was observed with second cycle users 5.31 (median 6) than the third 4.93 (median 5) ($p < 0.05$). No differences by sex had observed. The average consumption is 23.84 ± 19.83 grams, which represents a third of the recommendation for fresh vegetables in school meals. No differences by school year and sex. Differences between seasons, being higher in autumn (26.81 ± 21.6) compared to spring consumption (17.27 ± 13.04) ($p < 0.05$).

Conclusions: Salads are highly valued but its consumption is low, indicating the need for sensory and nutritional education with vegetables in the school environment.

Key words: hedonic assessment, vegetable preference, school meal, Murcia.

Background and objectives: To the best of our knowledge, the NEPAD registry is the only registry in the world with exclusively pediatric data. The objective was to analyze the results of the NEPAD (Spanish Pediatric Home Enteral Nutrition) registry.

Methods: Recompilation and analysis of the data from January 2003 to January 2013.

Results: 1314 children (51.3% males), 1440 episodes, from 28 hospitals were included. The median age of Home Enteral Nutrition (HEN) was 1.37 years (y) (IQR: 0.5-5.2). Diseases were classified into eleven groups, being neurological disorders the most frequent (31%). 90% of the children received tube feeding support. The first enteral access was nasogastric tube (NGT) in 52.7% of the cases followed by gastrostomy (G, 35.7%). Overall, a cyclic administration method was used in 62.7% of the cases, 8.4% received continuous infusion and 28.9% only bolus feeding. 71.6% used peristaltic pumps. The type of diet provided by tube was only enteral formula in 76% of the patients. The most common formula (43%) was paediatric polymeric. Only 32 patients (2.5%) received parenteral nutrition simultaneously. Nutritional support had concluded in 65% of episodes. The median duration was 0.4 y (IQR 0.13-

1.5). 35% of the episodes are still open; their median duration is 3.3 y (IQR 1.95-6). Analysis of the data obtained with respect to disease groups revealed highly significant differences.

Conclusions: Numerous chronic diseases benefit from HEN. The modalities vary according to the underlying disease, being the neurologically impaired children the major population. Cyclic infusion is the most frequent administration method. Most patients use peristaltic pumps and complete formula. The main reason for HEN interruption was transition to oral feeding.

Key words: home enteral nutrition; gastrostomy; jejunostomy; enteral tube feeding; enteral registry.

PO1066

USE OF DEUTERIUM OXIDE TO MEASURE BREAST MILK INTAKE AMONG INFANTS BORN TO HIV NEGATIVE AND HIV POSITIVE MOTHERS

E. M. Urio¹, G. Ndossi², N. Range³, S. Tatala⁴

¹Department of Food Science and Nutrition, Tanzania Food And Nutrition Centre, Dar-es-Salaam, Tanzania

²National Health Research Forum, P.O.Box 9653, Dar-es-Salaam, Tanzania

³Muhimbili Medical Research Centre, National Institute for Medical Research, Dar-es-Salaam, Tanzania

⁴Malesta Biomedical Research Centre, P.O. Box 202760, Dar-es-Salaam, Tanzania

Background and objectives: The World Health Organization recommends exclusive breast feeding for the first six months of life and continued breastfeeding up to two years. However, in many societies mothers practice mixed breast feeding. In Tanzania, breast feeding is commonly practiced but only small proportion of infants are exclusively breastfed and there is limited information on the quantity of milk consumed. The objective of this study was to determine breast milk intake among infants born to HIV negative and HIV positive mothers.

Methods: This was a longitudinal study. Eighty five mother-infant pairs attending Reproductive and Child Health Care clinics were recruited and followed up at 6 and 9 months post-delivery. Maternal and infant anthropometric measurements were taken. Breast milk intake was measured using the dose-to-the mother deuterium-oxide technique. Saliva from mother-infant pairs were collected and analyzed for deuterium enrichment by using Fourier Transform Infrared Spectrometry (FTIR) following standard procedures outlined by International Atomic Energy Agency (IAEA).

Results: At three months post-delivery, the mean breast milk intake was 756±185 and 730±196 grams per day for in-

fants born to HIV positive and HIV negative mothers respectively. There was no significant difference in breast milk intake between infants born to HIV positive and those born to HIV negative mothers ($p = 0.56$). Exclusive breast feeding based on isotope technique was 20% at three months and 8.5% at six months post-delivery.

Conclusion: Breast milk intake at three months was within the normal range both among infants born to HIV positive and HIV negative mothers. Only few mothers (20%) at three months and (8.5%) at six months were practicing exclusive breast feeding, majority were practicing mixed breast feeding.

Key words: breast milk intake, HIV negative, HIV positive mothers, exclusive breast-feeding.

PO1067

INFLUENCE OF GINGER AND CINNAMON INTAKE ON INFLAMMATION AND MUSCLE SORENESS INDUCED BY EXERCISE IN IRANIAN FEMALE ATHLETES

R. Ghasvand¹, N. Shokri Mashhadi¹, Gh. Askari¹, A. Feizi¹, L. Darvishi¹, M. Hariri¹

¹Food Security Research Center, Isfahan University of Medical Sciences, Iran

Background and objectives: Ginger rhizomes (rich in gingerols, shogaols, paradols and zingerone) have been used in Asia for the treatment of asthma, diabetes, and pain, and have shown potent anti-inflammatory attributes. Common spices such as Cinnamon (including cinnamic aldehyde and cinnamyl aldehyde) are used in food and many studies have focused on its anti-inflammatory components. Intense exercise can result in an inflammatory response to cell damage and also muscle soreness. The efficacy of dietary ginger and cinnamon as anti-inflammatory agents and their effectiveness in reducing muscle soreness has been investigated in limited studies on humans. Therefore, we have studied the effects of dietary ginger and cinnamon on inflammation and muscle soreness in Iranian female taekwondo players.

Methods: Sixty healthy, trained women, aged 13-25 years, were enrolled in the six weeks investigation and randomly categorized into three groups (cinnamon, ginger or placebo) and received 3 g of ginger, cinnamon or placebo powder each day, depending on the group they belonged to. The IL-6 level and Likert Scale of Muscle Soreness were evaluated at the beginning and the end of the study and compared among the groups.

Results: Forty-nine of the participants completed the six-week intervention. There were no significant changes in the IL-6 cinnamon and ginger group when compared with the placebo group, whereas, there was a significant fall in muscle soreness in the cinnamon group and placebo ($P < 0.1$) and ginger group and placebo ($P < 0.01$).

Conclusions: Administration of ginger and cinnamon in athlete women for six weeks did not show any significant change in the IL-6 level, but showed a decrease in muscle soreness in the cinnamon and ginger groups.

Key words: Athletes, cinnamon, ginger, inflammation, muscle soreness

PO1068

QUERCETIN SUPPLEMENTATION DOES NOT ATTENUATE EXERCISE PERFORMANCE AND BODY COMPOSITION IN YOUNG FEMALE SWIMMERS

R. Ghasvand¹, L. Darvishi¹, M. Hariri¹, H. Khosravi-Boroujeni¹, Gh. Askari¹, P. Rezaee¹

¹Food security Research Center, Isfahan University of Medical Sciences, Iran

Background and objectives: Quercetin is a health-enhancing antioxidant bioflavonoid. This flavonoid occurs in variety of natural fruits and vegetables such as apple, cranberry, onion, broccoli, and teas. Many studies have shown that quercetin has possible positive effects on exercise performance. The aim of this study is the evaluation of effects of quercetin supplementation on VO₂max and exercise performance in female athletes.

Methods: This study was done on 26 young female swimmers. Participants were assigned in to groups and supplemented orally for 8 weeks with either Quercetin (Solaray[®], USA, Inc) or placebo (dextrose). Before and after intervention, athletes performed a continuous graded exercise test (GXT) on an electronically braked cycle ergometer (Lode, The Netherlands) to determine VO₂max and time to exhaustion (TTE).

Results: Participants in the quercetin group consumed higher energy and protein and lower carbohydrates and fats. There was no significant differences in VO₂max, TTE, lactate, and body fat between pre- and post-supplementation neither in the placebo group nor in the quercetin group.

Conclusions: It is concluded that quercetin supplementation (1000 g/day) for 8 weeks in female athletes didn't show any significant association with exercise performance.

Key words: Performance, quercetin, swimmers

PO1069**DIETARY BEHAVIORS AND NUTRITIONAL ASSESSMENT OF YOUNG MALE ISFAHANI WRESTLERS**

L. Darvishi¹, R. Ghiasvand¹, M. Hariri¹, Gh. Askari¹, P. Daneshvar¹, A. Shiranian¹

¹Food Security Research Center, Isfahan University of Medical Sciences, Iran

Background and objectives: Young athletes have more nutritional needs than other adolescents because of physical activity and physical development. Optimal athletic performance results from a combination of factors including training, body composition, and nutrition. Despite the increased interest in nutrition and use of dietary supplements to enhance performance, some athletes might be consuming diets that are less than optimal. In wrestling it is common practice to optimize one's body composition and body weight prior to a competition season. This often includes a change in dietary intake or habits.

Methods: Twenty-eight wrestlers, between the ages of 17 and 25 years, participated in this study. Dietary intakes of micro and macro nutrients were collected by face-to-face interview, structured food frequency questionnaire (FFQ). Dietary intake of energy, carbohydrates, fats and proteins and micronutrients was evaluated.

Results: Mean intakes of energy, carbohydrates, proteins and fat were higher than recommended dietary allowances (RDA). The mean intakes of all vitamins and minerals were higher than the RDAs in these wrestlers, except for vitamin D, biotin, zinc, iodine, chrome and molybdenum.

Conclusions: On the basis of our results, nutritional education should be given to these subjects and their families for promoting healthy eating habits.

Key words: Athletes, dietary behavior, nutritional status, wrestlers

PO1070**EFFECT OF EIGHT WEEKS OF QUERCETIN SUPPLEMENTATION ON EXERCISE PERFORMANCE, MUSCLE DAMAGE AND BODY MUSCLE IN MALE BADMINTON PLAYERS**

L. Darvishi¹, M. Hariri¹, Gh. Askari¹, P. Daneshvar¹, R. Ghiasvand¹

¹Food Security research Center, Isfahan University of Medical Sciences, Iran

Background and objectives: Quercetin is a bioflavonoid which occurs in many food items. Some previous studies on

quercetin showed inconsistent results on exercise performance, muscle damage and body muscle in athletes. The aim of this study was to determine the effects of eight weeks of quercetin supplementation on exercise performance, muscle damage indices and body muscle in badminton players.

Methods: This placebo-controlled, double-blind clinical trial was conducted on 26 badminton players for eight weeks. The subjects were randomly assigned to one of two groups to receive daily quercetin (1000 mg) or placebo (1000 mg dextrose). VO₂ max and time to exhaustion (TTE) for measuring performance and body fat percentage (BFP) were measured before and after intervention. Plasma samples were obtained for the determination of plasma lactate before and after intervention.

Results: Lactate concentration, body fat percentage and VO₂ max did not show any significant difference ($p > 0.05$) after eight weeks of supplementation with placebo and quercetin between two groups and within one group. There was a significant increase in TTE after intervention in the quercetin group ($p < 0.05$) but a significant change was not observed in the placebo group ($p > 0.05$).

Conclusions: The current study shows that intake of quercetin may improve endurance exercise performance but may not reduce the body fat percentage.

Key words: body mass, exercise performance, muscle damage, quercetin.

PO1071**EVALUATION OF QUALITY OF LIFE OF INSTITUTIONALIZED ELDERLY AFTER RECEIVING MODIFIED MILK**

D. Takaara¹, F. Pinheiro Amador dos Santos Pessanha¹, E. Ferriolli¹, M. Saladini Vieira Sales³, A. Saran Netto², M. A. Zanetti², L.C. Roma Junior³, H. Vannucchi¹, K. Pfrimer¹

¹Medical Clinical Department, Medical School of Ribeirão Preto, University of São Paulo, Ribeirão Preto, São Paulo, Brazil

²College of Animal Science and Food Engineering, University of São Paulo, Pirassunga, São Paulo, Brazil

³São Paulo's Agency for Agribusiness Technology, Ribeirão Preto, São Paulo, Brazil

Background and objectives: The inclusion of sunflower oil, vitamin E and selenium in the diet of lactating cows could increase the quality of life for seniors supplemented with modified milk and bring benefits for their health. The objective of this study was to assess the change in quality of life of institutionalized elderly fed for 12 weeks with modified milk.

Methods: Both sex individuals, over 60 years, and that live in a long stay house were recruited. The volunteers were divided into 4 groups corresponding to the type of milk supplemented. Modified milk was obtained by the cows, which were also separated into 4 groups constituting: cows fed with control diet (I); cows fed with control diet plus vitamin E + selenium (II); cows fed with control diet with sunflower oil (III) and cows receiving sunflower oil + vitamin E + selenium (IV). The addition of nutrients to each group enhanced the nutritional value of the milk. Each volunteer received, daily, three milk preparations (250 ml). The evaluation of the quality of life of the elderly was performed by the SF-36, which was applied before the start of the experiment and 12 weeks after supplementation.

Results: A total of 30 individuals were assessed: 9 of group I, 6 of group II, 7 of Group III and 8 of Group IV. A statistical analysis by mixed effects model showed no significant difference in the quality of life in any of the intervention groups, $p = 0.5981$ (I), $p = 0.7606$ (II), $p = 0.8291$ (III) e $p = 0.8953$ (IV).

Conclusions: Performing a preliminary analysis on quality of life, it was not observed any change in the elderly before and after supplementation.

Key words: elderly, milk, quality of life.

PO1072

EATING DISORDERS IN CHILDREN STUDENTS OF A SÃO PAULO PRIVATE SCHOOL ANSWER THE STANDARDIZED QUESTIONNAIRES (EAT-26, BITE AND BES QUESTIONNAIRES)

R. F. Simony¹, E. Migliari¹, F. Arruda¹, T. Melo¹

¹Mackenzie University, Rio de Janeiro, Brazil

Background and objectives: The great importance assigned to body image nowadays influence the identity and relationships of children and adolescents, who are constantly exposed to unrealistic and health-detrimental standards of beauty, often leading to unattainable body image ideals that result in eating disorders, disabilities, feelings of frustration and self-image issues. This study aims to evaluate the presence of eating disorders in preadolescents and adolescents from 6th grade to the last year of high school whose presented risks of developing eating disorders. in a school in the State of São Paulo,

Methods: A transversal study analyzed the answers of 191 schoolchildren, from ages 11 to 18, attending a private school in the State of São Paulo. Each child answered 3 standardized questionnaires, the Eating Attitudes Test (EAT-26), the Bulimic Investigatory Test Edinburgh (BITE) and the Binge Eating Scale (BES).

Results: The results showed a tendency to engage in binge eating among children from 6th to 8th grades. A higher prevalence of anorexia and bulimia was detected in subjects at-

tending high school. Overall, 29.5% of the sample presented risk of developing anorexia, 26,2% risk of developing bulimia nervosa, 5.2% risk of binge eating and 1.1% severe bingeing.

Conclusion: It is possible that globalization contributes negatively by spreading poor eating habits among the population, thus making eating disorders more frequent. More studies focusing on childhood pathological eating behaviors are warranted to devise preventive strategies and to teach better coping skills in the face of social and media influences.

Key words: eating disorders; adolescents; eating behavior.

PO1073

A FORMATIVE ASSESSMENT OF COMPLEMENTARY FOODS AND FEEDING PRACTICES IN THREE REGIONS OF GHANA

S. Armah¹, K. Tano-Debrah¹, S. Ghosh²

¹Department of Nutrition and Food Science, University of Ghana, Accra, Ghana

²Nevin Scrimshaw International Nutrition Foundation, Boston, USA

Background and objectives: Infant and child feeding practices starting from birth are crucial and can impact immediate and long term nutritional status. This study was conducted to understand the major issues associated with complementary feeding, health and food security in the Upper West, Greater Accra, and Central regions of Ghana.

Methods: The study was a qualitative assessment involving one rural, one urban and one peri-urban community. Assessment tools included key informant interviews and focus group discussions. Individual interviews were conducted with mothers with children aged 6-24 months of age, community health workers, regional directors (Nutrition) and District Health Service Directors. Focus group discussions were held with village elders and mothers with children aged 6-24 months. Data were collected on infant feeding practices, food security, health and sanitation, infant and young child nutrition issues, complementary feeding practices and use of specific complementary foods. Responses from study participants were recorded, transcribed and reviewed to identify specific themes. Analysis was done based on themes.

Results: Fifty six respondents participated in the study. Health officials all agreed that the main nutrition problems in infants and children 6-24 months were underweight due to poor feeding practices after 6 months of age. There is no specific complementary feeding program targeting prevention of malnutrition in children aged 6-24 months. Lack of proper hygiene and sanitation were major issues. Mothers reported exclusive breast feeding at least until 6 months of age, with total breast feeding period ranging 18-24 months. At 6 months of

age, the most common complementary food given by mothers in all three regions is koko (fermented maize dough porridge).

Conclusion: Breast feeding until 6 months of age was a common practice. Most complementary foods were cereal-based. Interventions that will promote appropriate complementary feeding practices are needed.

Key words: complementary foods, child feeding practices, nutritional status.

PO1074

DIETARY DIVERSITY AS AN INDEX OF INFANT NUTRITION, HEALTH, AND DEVELOPMENT IN RURAL INDIA

K M. Hurley¹, N. Balakrishna², S. Fernandez-Rao², K V. Radhakrishna², P. Ravinder², N. Tilton³, K B. Harding⁴, G. Reinhart⁵, K M. Nair², M M. Black³

¹Department of International Health, The Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, USA

²National Institute of Nutrition, Indian Council of Medical Research, Hyderabad, India

³Department of Pediatrics, University of Maryland School of Medicine, Baltimore, Maryland, USA

⁴The Micronutrient Initiative, Ottawa, Canada

⁵The Mathile Institute for the Advancement of Human Nutrition, Dayton, Ohio, USA

Background and objectives: Dietary diversity is required during the second half of infancy to meet the high nutrient demands caused by rapid physical and neurological growth. This study examines how caregiver report of infant dietary diversity is related to infant nutrition, health, and developmental status in rural areas of Andhra Pradesh, India.

Methods: A semi-quantitative food frequency questionnaire was developed and administered to 497 caregivers of infants (6-12 month). Dietary diversity was defined as the number of different types of food items consumed per week (scale, 0-28). Infant anthropometry (measured weight and length) and biomarkers for iron deficiency (ID:ferritin <12 µg/L or sTfR >2.5 mg/l) and inflammation (CRP >10 mg/l) were collected. Stunting (HAZ <-2), wasting (WHZ <-2), and underweight (WAZ <-2) were computed using WHO standards. Home stimulation (HOME Inventory), motor, language and visual reception (Mullen Scales of Early Learning) and socio-emotional status (Brief Infant-Toddler Socio-Emotional Assessment) were assessed. Multivariable linear or logistic regression models, adjusting for infant age, home stimulation, household assets, and maternal education were examined.

Results: Among infants 6-8 months, the mean dietary diversity score was 2.8 ± 2.6 (range, 0-15), among infants 9-12 months, it was 6.3 ± 3.3 (range, 0-17). In multivariable regression models, dietary diversity was negatively associated with stunting (OR=0.88; CI: 0.81, 0.96), iron deficiency (sTfR:OR=0.93, CI:0.86,0.99), and inflammation (CRP:OR=0.93; CI: 0.87, 0.99); and positively associated with visual reception (B=0.43; CI: 0.18, 0.68), fine motor (B=0.54; CI: 0.24, 0.84), and expressive language (B=0.56; CI: 0.27, 0.84). Dietary diversity tended to be associated with emotional competence (B=0.13; p = 0.07), but not associated with wasting, underweight, ferritin, gross motor or receptive language.

Conclusion: Caregiver reports of low infant dietary diversity are suggestive of negative health, nutrition, and developmental indicators among a sample of low-income families in rural India, even after adjusting for confounders. Support: Mathile Institute & Micronutrient Initiative

Key words: dietary variety, infant nutrition, development.

PO1075

DIETARY INTAKES AND EATING HABITS OF ELITE ATHLETES IN SERBIA: ARE THEY FOLLOW THE CURRENT SPORTS NUTRITION STANDARDS?

B. Djordjevic¹, I. Baralic², M. Andjelkovic², N. Dikic², T. Antic², M. Vukasinovic-Vesic², V. Blazencic-Mladenovic², M. Popovic², S. Radojevic-Skodric³

¹Sport Medicine Association of Serbia, Belgrade, Serbia

²Institute for Bromatology, Faculty of Pharmacy, University of Belgrade, Belgrade, Serbia

³Institute of Pathology, School of Medicine, University of Belgrade, Serbia

Background and objectives: Adequate nutrition has been recognized as very important factor for good health, conditioning and performance in athletes. Therefore, the purpose of the present study was to assess dietary intakes and eating habits of elite Serbian athletes and to compare them with sports nutrition standards.

Methods: Data were obtained from 58 male athletes between January 2011 and January 2012. Sixteen were soccer players, 12 were basketball players, 13 were kayakers, 8 were judokas and 9 were wrestlers. Participants completed anthropometric measurements and dietary intake, energy expenditure, energy balance, carbohydrate, protein, fat, vitamins and minerals were recorded.

Results: Mean energy and carbohydrate intakes were below recommended values, with 34.5 % of the participants meeting their energy needs. Seventy-two percent of the participants fai-

led to consume the minimum amount of carbohydrates that is required to support training. Fat intake (expressed as % of total calorie intake) of the kayakers was higher than recommended, while the mean protein intake of all participants was within the optimal range (1.2-2.0 g/kg). All the groups of athletes had adequate dietary intake of iron, magnesium, vitamin C and vitamin B12. Only kayakers consumed adequate amount of calcium. Intake of fibers, vitamin B6, vitamin A and vitamin E for all the groups was below the recommended values. All the groups of athletes showed an excess of sodium and insufficient consumption of potassium.

Conclusions: The results of the present study demonstrated that the majority of athletes do not have a good nutritional status for the intake of a carbohydrates, fibers, vitamin B6, vitamin A, vitamin E and potassium. It is therefore suggested that effective dietary intervention measures, including educational programs on proper food selection and eating habits, are needed to improve the nutritional status of the athletes.

Key words: energy intake; micronutrients; nutritional status; athletes.

PO1076

EFFECTS OF ASTAXANTHIN SUPPLEMENTATION ON DNA STABILITY AND PARAOXONASE 1 ACTIVITY IN YOUNG SOCCER PLAYERS

I. Baralic¹, B. Djordjevic², M. Andjelkovic¹, N. Dikic¹, J. Kotur-Stevuljevic³, L. J. Dimitrijevic⁴, T. Antic¹, M. Vukasovic-Vesic¹, S. Radojevic-Skodric⁵

¹Sport Medicine Association of Serbia, Belgrade, Serbia

²Institute for Bromatology, Faculty of Pharmacy, University of Belgrade, Serbia

³Institute for Medical Biochemistry, Faculty of Pharmacy, University of Belgrade, Serbia

⁴Institute of Virology, Vaccines and Sera – Torlak, Belgrade, Serbia

⁵Institute of Pathology, School of Medicine, University of Belgrade, Serbia

Background and objectives: The carotenoid astaxanthin (Asx) is naturally found in variety of aquatic organisms, such as microalgae, crustaceans and fish. Asx possesses antioxidant, free radical-scavenging and anti-inflammatory properties and also reported to afford benefits to human health. Thus, the purpose of the current study was to determine the effect of Asx on oxidative DNA damage and paraoxonase 1 (PON1) activity in young soccer players while following their habitual dietary intake and training program.

Methods: Sixteen players were assigned in a double-blind fashion to Asx and placebo group. Blood samples were obtained before and after 90 days of supplementation. We used comet assay to investigate leukocyte DNA stability. The results were presented as DNA score and percent of cells with medium and high damage. We also determined PON1 activity in serum (using two different substrates: paraoxon and diazoxon), total sulphhydryl groups content (SH) and redox balance.

Results: DNA score and percent of cells with medium and high damage decreased significantly in both groups of soccer players after 90 days of training period ($p < 0.05$). The significant main effect of supplementation ($p < 0.05$) on PON1 activity toward paraoxon was observed. The PON1 activity toward diazoxon increased in Asx group after 90 days ($p < 0.01$), but not in the placebo group. SH groups content rose from pre to post-supplementation period only in Asx group (supplementation and training, $p < 0.05$). Redox balance decreased significantly in response to the regular training, regardless of treatment group (training, $p < 0.001$).

Conclusions: Regular soccer training can have a protective effect against oxidative DNA damage and oxidative stress in young athletes, probably through upregulation of their antioxidant defenses. Asx supplementation had a beneficial effect in improving PON1 activity toward paraoxon and diazoxon, as well as total SH groups content in young soccer players.

Key words: soccer, oxidative stress, DNA damage.

PO1077

ASSOCIATION BETWEEN FAT INTAKE DURING PREGNANCY AND GESTATIONAL DIABETES

P. Barbieri¹, G S. Perdoná¹, L J. Franco¹, D S. Sartorelli¹

¹Department of Social Medicine, University of São Paulo, Brazil

Background and objectives: Few studies have evaluated the association between dietary intake during pregnancy and the occurrence of gestational diabetes. The aim of the present study was to evaluate the quality/quantity of fat intake during pregnancy and to observe whether this is associated with gestational diabetes.

Methods: A cross-sectional study was conducted among 800 healthy adult pregnant women. Food consumption was evaluated by a validated 85-item food frequency questionnaire (FFQ). The FFQ was administered between the 24th to 28th weeks of pregnancy. Gestational diabetes diagnosis was based on the International Association of Diabetes and Pregnancy Study Groups criteria (fasting plasma glucose ≥ 92 mg/dL, or 1-h glucose ≥ 180 mg/dL, or 2-h glucose ≥ 153 mg/dL). For the present analysis we examined the association of energy adjusted tertile of fatty acids intake during pregnancy and the occurrence of gestational diabetes in multiple logistic regres-

sion models [OR (95% CI)], adjusted by maternal age, BMI, and energy intake.

Results: The mean (SD) age of participants was 28 (6) years old, and 19% had gestational diabetes. The mean (SD) saturated, monounsaturated, and polyunsaturated fatty acids intake estimated were 30 (17), 23 (13), and 12 (7) g/daily, respectively. Pregnant women classified in the upper tertile of saturated fat intake were more likely to develop gestational diabetes [OR 1.63 (IC 95% 1.01, 2.64)], when compared with women classified into the lower tertile. No associations between monounsaturated fatty acids intake [OR 1.17 (IC 95% 0.73, 1.87)], and polyunsaturated fatty acids intake during pregnancy [OR 0.88 (IC 95% 0.55, 1.38)] and gestational diabetes were found.

Conclusion: Our data suggest that high intake of saturated fatty acid in early pregnancy is associated with a higher chance of developing of gestational diabetes. Funding: CAPES, CNPq (472221/2010-8).

Key words: gestational diabetes, food intake, fatty acids.

PO1078

PROTEIN INGESTION ENHANCES WHOLE BODY NET PROTEIN BALANCE AFTER PHYSICAL ACTIVITY IN HEALTHY CHILDREN

D. Moore^{1,2}, K. Volterman³, J. Obeid³, E. Offord-Cavin¹, B. Timmons³

¹Nestle Research Centre, Lausanne, Switzerland

²University of Guelph, Guelph, Canada

³McMaster University, Hamilton, Canada

Background and objectives: Physical activity is vital for normal musculoskeletal growth and development. Dietary protein ingestion after physical activity enhances whole body protein balance and can increase gains in lean mass in adults but its effects in children have yet to be investigated. We aimed to determine the impact of graded intakes of dairy protein on whole body protein synthesis (S), breakdown (B), and net balance (NB) over 9 and 24-h recovery periods after physical activity in healthy children.

Methods: Under 24-h dietary control, thirteen (7 males, 6 females) recreationally active children (11±1 y; 39.3±5.9 kg; mean±SD) consumed an oral dose of [15N]glycine prior to performing 45 min of physical activity (3x5 min running; 3x10 min cycling). Immediately after exercise, isoenergetic beverages containing a variable amount of protein (Control, C: 0 g/100 ml; Low Protein, LP: 0.75 g/100 ml; High Protein, HP: 1.5 g/100 ml) were consumed in a randomized, double blind, crossover fashion.

Results: Post-exercise protein intakes were 0.18±0.03 and 0.32±0.07 g/kg for LP and HP, respectively. S and B were significantly greater over 9 h as compared to 24 h with no differ-

ences between conditions. Consistent with the anabolic effects of exercise and feeding, NB was also greater over 9 h as compared to 24 h in all conditions (main effect time, $p < 0.001$). Over the early 9-h recovery period, HP was greater ($p < 0.01$) than LP and C with a trend ($p = 0.075$) towards LP being greater than C. NB was positive over 9 h for all conditions but only over 24 h for HP.

Conclusions: Dietary protein enhances net protein balance in children during recovery from activity; however, larger protein intakes (~0.32 g/kg) are required to maintain a positive protein balance over an entire 24-h period. Strategies to enhance net protein balance, and potentially musculoskeletal growth and development, in children should include the ingestion of high quality protein after physical activity.

Key words: children, protein, exercise, growth, muscle.

PO1079

NET POSTPRANDIAL PROTEIN UTILISATION OF 15N-LABELLED LAMB HYDROLYSATE IN OLDER ADULT HUMANS

S. Henare¹, J. Cui¹, P. Moughan¹

¹Riddet Institute, Massey University, Palmerston North, New Zealand

Background and objectives: Ageing is associated with metabolic and physiologic changes that may contribute to alter dietary protein digestibility and utilisation. In this study we evaluated the postprandial protein utilisation of 15N-labelled lamb hydrolysate in older adult humans.

Methods: Lamb meat was uniformly labelled with 15N in order to differentiate between endogenous and exogenous nitrogen fractions in blood and urine samples. Protein labelling was achieved by feeding lambs a diet formulated with 0.8 % 15N urea (10% enrichment) for 115 days. The final enrichment level of the lamb meat was 0.5 atom % excess. Sixteen healthy older adults (mean age = 71.0 ± 0.3 y) ingested 15N-labelled lamb hydrolysate (320 mmol N) in a balanced meal. Urine and serum were collected for 8 h following ingestion. The 15N-enrichment was determined in the serum amino acids and urea and in the urinary urea and ammonia fractions.

Results: The postprandial distribution of dietary N was 5.8 ± 0.9 % (of the ingested amount) in urinary urea and ammonia, 7.8 ± 0.8 % in body urea and 7.6 ± 0.7 % (of the ingested amount) in serum protein 8 h after the meal. The biological value of the lamb hydrolysate was 86.2 ± 1.5 % considering a true ileal digestibility of 98.4 %. The dietary nitrogen was highly utilized with a net postprandial utilisation of 84.5 ± 1.4 %.

Conclusions: The results demonstrate that the lamb hydrolysate is a dietary protein source that is highly utilised in the older adult human.

Key words: net postprandial protein utilisation (NPPU), hydrolysate The authors acknowledge Meat Biologics Research Limited (MBRL) for funding, Dr D Pacheco, AgResearch, New Zealand, for the ¹⁵N-labelled lamb meat and Dr A Awati, DuPont Industrial Biosciences, The Netherlands, for the true ileal digestibility data for the lamb hydrolysate.

PO1080

PRE-PREGNANCY BODY MASS INDEX AND MATERNAL WEIGHT GAIN ARE INDEPENDENT PREDICTORS OF NEWBORN BIRTH WEIGHT

S. Gowachirapant^{1,2}, P. Winichagoon¹, T. Pongcharoen¹, A. Melse-Boonstra², M.B. Zimmermann²

¹Institute of Nutrition, Mahidol University, Nakhon Pathom, Thailand

²Division of Human Nutrition, Wageningen University, Wageningen, The Netherlands

Background and objectives: Pre-pregnancy maternal weight, gestational weight gain and other maternal factors may influence pregnancy outcomes, especially birth weight, which is a contributing factor toward infant mortality, morbidity and child development. This study aimed to investigate the relationship between maternal characteristics including pre-pregnancy body mass index (BMI, kg/m²), parity, weight gain (kg), gestational age at delivery (wks) and their newborns and birth weight (BW, grams).

Methods: Healthy pregnant Thai women participated in the intervention study at Ramathibodi hospital, Bangkok. They were interviewed for pre-pregnancy weight and parity using a questionnaire. Pre-pregnancy BMI was calculated. Weight of mothers and newborns at delivery and gestational age were obtained from the hospital record.

Results: Three hundred and eighty singleton pregnant women with mean age of 30 years old and median baseline gestational age of 11 weeks were recruited in the study. Two-third of the women had normal pre-pregnancy BMI (BMI 18.5-24.9 kg/m²), while 17% were underweight (BMI <18.5 kg/m²) and 15% were overweight or obese (BMI ≥25 kg/m²). The mean newborns' birth weight was 3.107±451 g and only 7% of the newborns were low birth weight (BW <2500 grams). When comparing the distribution of pregnant women by pre-pregnancy BMI group, about 40% gained weight appropriately. Stepwise multiple regression analysis showed that pre-pregnancy BMI ($\beta=20.37$, $p < 0.001$), parity ($\beta=63.44$, $p = 0.001$), weight gain ($\beta=18.6$, $p < 0.001$) and gestational age at delivery ($\beta=159.18$, $p < 0.001$) were positive predictors of newborns' birth weight.

Conclusions: Maternal characteristics during pregnancy are significant predictors of their babies' birth weight. Our find-

ings suggest that in order to reduce low birth weight, weight counseling prior to pregnancy and weight gain monitoring during pregnancy may be beneficial.

Key words: pre-pregnancy body mass index, weight gain, gestational age, maternal characteristics, birth weight.

PO1081

BREASTFEEDING AT 3 MONTHS IS ASSOCIATED WITH LOWER RISK OF ADIPOSITY AND LIPID METABOLISM ALTERATIONS AT 4 Y OF AGE

I. Ramírez-Silva¹, J. Rivera¹, R. Martorell², A. Stein², U. Ramakrishnan²

¹Center for Research in Nutrition and Health, National Institute of Public Health, Cuernavaca, Morelos, México

²Hubert Department of Global Health, Emory University, Atlanta, Georgia, United States of America

Background and objectives: Evidence of the relationship between breastfeeding and risk of obesity and cardiometabolic alterations later in life is inconclusive. Objective. To evaluate the association between breastfeeding at 3 mo with adiposity and markers of lipid metabolism at age 4 y.

Methods: Study subjects were offspring of women who participated in POSGRAD, a double-blind, randomized, controlled trial in which Mexican women were supplemented with 400 mg/d docosahexaenoic acid (DHA) or placebo from mid-pregnancy to parturition. Breastfeeding status at 3 mo. was classified as exclusive (EBF), predominant (PBF), mixed (MBF) and non-breastfeeding (NBF). Anthropometric measurements and markers of lipid metabolism from non-fasting blood were obtained at 4 y. Analysis. We analyzed the data as a cohort, with adjustment for group assignment. Adjusted means of adiposity and cardiometabolic indicators by type of breastfeeding were estimated using multiple linear regression models adjusted for sex, age, treatment, socioeconomic level and time since last food (for lipid metabolism markers).

Results: Among 593 children, prevalence of breastfeeding was EBF=14.7%, PBF=16.4%, MBF=52.0% and NBF=16.9%. Relative to NBF children, EBF children had lower [means (95%CI)] abdominal circumference [EBF 52.2 (51.4, 53.0) vs NBF 53.5 (52.7, 54.33) cm; $p < 0.05$], sum of subscapular and triceps skinfolds [EBF 14.5 (13.7, 15.3) vs. NBF 15.9 (15.1 vs 16.6) mm; $p < 0.05$], total cholesterol [EBF 155 (149.1, 160.7) vs NBF 165 (159.5, 170.8) mg/dl] and LDL cholesterol [EBF 78.6 (73.4, 83.8) vs NBF 88.2 (83.2, 93.3) mg/dl] at 4 y. PBF children had lower Body Mass Index [PBF 15.0 (14.7, 15.3) vs NBF 15.6 (15.3, 15.9) kg/m²; $p < 0.05$] and triglycerides [PBF 98.7 (88.7, 109.7) vs MBF 111.3 (105.0, 118.0) mg/dl] than the NBF group.

Conclusion: EBF and PBF at 3 mo were associated with lower risk of adiposity and lipid metabolism alterations at 4 y of age.

Key words: breastfeeding, adiposity, lipid metabolism alterations.

PO1082

PREVALENCE AND RISK FACTORS OF ANEMIA IN LACTATING WOMEN IN CHINA

Z. Yang¹, Y. Duan¹, J. Wang¹, S. Yin¹

¹National Institute of Nutrition And Food Safety, Chinese Center For Disease Control And Prevention, China

Background and objectives: World Health Organization recently estimates that over 40% of pregnant women and ~30% of non-pregnant women are anemic globally. The purpose of the study is to identify which subgroups of lactating women had a higher risk of anemia in China.

Methods: Lactating women were recruited for Chinese Human Milk Project in Beijing, Heilongjiang, Yunnan, Gansu and Shandong. Venous blood was collected and hemoglobin was measured by using Hemocue 301 for lactating women from 1 to 11 months postpartum (n=1523).

Results: The prevalence of anemia (defined <120 g/L after adjusting altitude) was 0.9 % in Beijing, 6.3% in Heilongjiang, 9.2% in Yunnan, 45.6% in Gansu and 7.4% in Shandong for these lactating women. The potential risk factors for anemia (16.6%) included the location of residence, prenatal anemia and postpartum duration. Compared to the lactating women living in Shandong, the adjusted odds ratio for anemia was 15.2 [7.3, 31.7] and 0.13 [0.02, 1.07] for those living in Gansu and those living in Beijing, respectively. The prevalence of anemia was similar between those living in Shandong and those living in Heilongjiang and Yunnan. Prenatal anemia was associated with 1.92 [1.23, 3.01] times higher odds of being anemic postpartum. With every 1 month increasing postpartum, lactating women had 0.94 [0.89, 0.99] lower adjusted odds ratio for being anemic.

Conclusion: Lactating women living in Gansu, with prenatal anemia and with shorter postpartum duration had greater risk for anemia.

Key words: anemia, lactating women, China

COMPARISON OF STUDENT'S DIET FOCUSING ON N-6/N-3 POLYUNSATURATED FATTY ACIDS BETWEEN IOWA STATE UNIVERSITY (ISU) AND UNIVERSITY OF HYOGO (UH).

N. Hiramatsu¹, W. White², N. Kiyono¹, R. Farhat², L. Liechty²

¹Nutritional Science, School of Human Science and Environment, University of Hyogo, Japan

²Department of Food Science and Human Nutrition, College of Human Sciences, Iowa State University, Japan

Background and objectives: Omega-3 Polyunsaturated fatty acids (n-3PUFAs) may be beneficial in preventing chronic diseases. Japanese traditionally eat much more fish than meat. However, the Japanese diet has become more westernized in recent years, especially in Japanese youth. The objective of this research was to study the differences in student diets between Iowa State University (ISU) and University of Hyogo (UH), focusing on fat intakes, and specifically n-6 and n-3 PUFAs intakes.

Methods: We analyzed 3 day dietary records of meal and a lifestyle questionnaire (living style, eating habit, and frequency of several food choices etc.). Energy and nutrients intakes were calculated using the Japanese software HealthyMakerPro and by the American software Food Processor, respectively. The nutrient intakes and questionnaire were analyzed using SPSS for Windows.

Results: Daily intakes of energy and nutrients were expressed as values per kg body weight. Intakes of energy, total fat, saturated fatty acids were not different between ISU and UH students. Cholesterol intake in ISU students (2.91 ± 1.78 mg/day/kg) is significantly lower than that in Japanese students (4.90 ± 2.20 mg/day/kg, $p < 0.05$). The intake of n-3 PUFAs in UH students (1.36 ± 0.70 g/day) is significantly higher than in ISU students (0.78 ± 0.51 g/day, $p < 0.05$). There was no significant difference in the intake amount of n-6PUFAs between ISU and UH. The ratio of n-6/n-3PUFAs (10.2) in ISU students is higher than the ratio in UH students (6.1). There was a significant difference between ISU and UH in the frequency of both fish and oily fish intakes ($p < 0.05$).

Conclusions: The diets of Japanese youth are moving closer to that of American youth, but some cultural differences persist (fish intakes frequency) between ISU and UH.

Key words: n-6/n-3PUFAs, dietary intake, fish intake, Japan, USA, college students

PO1084**ANEP IN BANGLADESH: ENABLING INFORMED NUTRITION CHOICES AND GREATER ACCESS TO NUTRITION FOODS***S. Siraj¹, R. Rose²*¹Save The Children In Bangladesh²International Development Enterprises (iDE), Agriculture & Nutrition Extension Project (ANEP) Project Office, Floors 4 & 5, S. S. View, N. Hossain Brother Complex, Police line Road, South Alekanda, Barisal 8200, Bangladesh

Background and objectives: In Asia low income families often suffer from poor access to healthy foods and low ability to make good nutritional choices. The Agriculture and Nutrition Extension Project (ANEP) has been supporting vulnerable families to make healthy food choices in the south of Bangladesh and the Nepal plains since January 2012. The ANEP aims to sustainably raise agricultural productivity, promote effective market linkages and nutritional awareness to improve the nutritional behavior of poor rural and urban households. ANEP is a partnership between International Development Enterprises(iDE), World Fish, CIMMYT, IRRI, Save the Children, CODEC, CEAPRED, and BES and is funded by the European Union(EU).The project seeks to reach 16000 vulnerable households such as those with pregnant-lactating mothers, adolescent girls and children up to 5 years of age directly and 30000 households through value-chain.

Methods: This paper is based on baseline(October'12), formative research (December'12) and program data collected from three rural sub-districts and urban slums of Barisal.

Results: From both baseline and formative research, it was evident that food diversity was lower in urban slums than rural sites. The adolescent in the urban area have scored very poor (99% scored below 20) in nutritional knowledge scoring test. In its first year ANEP delivered some 308 urban nutrition sessions reaching 2500 HHs (with 99% female participation) in Bangladesh. Among the rural beneficiaries 300 demonstrations have been set up across the aquaculture, field crop and vegetable sectors. ANEP has developed and trained over 100 local service providers(LSPs) to make technology services available to small-holder farmers.

Conclusions: The baseline data suggests that using targeted nutrition education in combination with agricultural inputs and rural-urban market linkages delivers synergies which can improve nutrition behaviors amongst the most vulnerable.

Key words: agriculture, nutrition, rural-urban linkages.

PO1085**GESTATIONAL HYPERTENSION; RISK FACTOR; DIETARY INTAKE***F. Jebunnesa¹, H. Chowdhury¹, L. Ali¹*¹Bangladesh Institute of Health Sciences, Dhaka, Bangladesh

Background and objectives: We have previously shown that pregnancy induced hypertension (PIH) is associated with hypertension in a later period after delivery. Diet plays an important role in the development of hypertension, but the association of maternal diet with their future development of hypertension in PIH has not yet been studied. The present study was undertaken to dietary factor(s) is (are) involved in the association between GH and later life hypertension.

Methods: The study design had both a cross-sectional and retrospective component. A total of 140 women (age, 32.4±8.1 y, and BMI 25.1±4.1, kg/m², M±SD) with a previous history of PIH in any pregnancy were included. Clinical and anthropometric parameters were measured by standard techniques, lipids were measured by enzymatic colorimetric method, Systolic blood pressure 130 mmHg or diastolic blood pressure 90 mmHg were taken as cut-off values for hypertension. Dietary intakes were assessed by Food Frequency Questionnaire (24 hr recall methods).

Results: A total of 140 women [age in years 32.4±8.1 y and BMI 25.1±4.1 kg/m², (M±SD)] with a previous history of GH in any pregnancy were included. 49 Subjects (35%) developed hypertension over duration of 5 to 12 yrs. Total energy intake was higher in Htn [kcal, 2175.7±399.6] as compared to non-Htn [1239±483] subjects. The higher energy was contributed mainly by carbohydrate sources from rice (g/day, 582.1±6 vs 239±71.9). On logistic regression analysis, Htn showed a strong positive association with past history of PIH and total energy intake and Carbohydrate intake when the effects of age and BMI were adjusted.

Conclusion: Women with past history of PIH have more chance of developing hypertension and it may have an association with increased energy intake from carbohydrate sources.

Key words: gestational hypertension; risk factor; dietary intake.

PO1086**NUTRITIONAL STATUS ASSOCIATED WITH SOCIO-DEMOGRAPHIC VARIABLES AND FOOD SECURITY AMONG CHILDREN: A STUDY IN DISADVANTAGED RURAL BANGLADESH***A. Quddus¹, S. Bauer²*¹Department of Agricultural Statistics, Bangladesh Agricultural University, Mymensingh, Bangladesh²Institute of Project and Regional Planning, Justus-Liebig University, Giessen, Germany

Background and objectives: Nutritional status of children in hilly, coastal and river-flooded areas remains unreported those are the most vulnerable disadvantaged communities. To develop a national policy for solving the nutritional problem of children in these areas, this study was undertaken to investigate nutritional status of children and its association with their socio-demographic variables and food security status.

Methods: A cross-sectional study was conducted in three different ecological zones, (river flooded, hilly/forest and coastal). Ten percent of the aggregate households in selected fifteen villages were interviewed. Three anthropometric indicators, viz, stunting, underweight and wasting were measured among 156 children aged 24-59 months and BMI was calculated among 246 children aged 60-119 months. Six child-referred questions were used to construct food security scale. Binary logistic regression analyses and Chi-square test were used.

Results: The prevalence of severe underweight, wasted and stunted among children aged 24-59 months were 44.9%, 31.7% and 14.1%, respectively, whereas 17.5% and 47.2% among children aged 60-119 months were severely stunted and underweight, respectively. Underweight was 41% less likely among boys as compared to girls. Children whose family had 3-4 children were 3 times more likely to be underweight than the children whose family had 1-2 children. Three anthropometric measures of child malnutrition were significantly associated with level of mother's education. High proportion of stunted, underweight, wasted children and children having lower values of BMI were food insecure.

Conclusion: Children of the studied population are at high risk of malnutrition. Effective motivational program should be taken to limit 2 children per household and increase female education including nutritional knowledge. Nutrition Rehabilitation Program for the children under 5 years and free nutritious food for school going children during school hour in rural disadvantaged areas of Bangladesh should be formulated and implemented.

Key words: anthropometric, children, nutritional status.

PO1087**A PAST HISTORY OF GESTATIONAL HYPERTENSION IDENTIFIES WOMEN AT RISK FOR HYPERTENSIVE DISEASE AND ASSOCIATED WITH DIET***F. Jebunnesa¹, H. Chowdhury², L. Ali¹*¹Dept of Biochemistry and Cell Biology, Bangladesh Institute of Health Sciences, Bangladesh²Dept of Biostatistics, Bangladesh Institute of Health Sciences, Bangladesh

Background and objectives: We have previously shown that pregnancy induced hypertension (PIH) is associated with hypertension in a later period after delivery. Diet plays an important role in the development of hypertension, but the association of maternal diet with their future development of hypertension in PIH has not yet been studied. The present study was undertaken to study dietary factor(s) involved in the association between gestational hypertension (GH) and later life hypertension.

Methods: The study design had both a cross-sectional and retrospective component. A total of 140 women (age, 32.4±8.1 y, and BMI 25.1±4.1, kg/m², M±SD) with a previous history of PIH in any pregnancy were included. Clinical and anthropometric parameters were measured by standard techniques, lipids were measured by enzymatic colorimetric methods, systolic blood pressure 130 mmHg or diastolic blood pressure 90 mmHg were taken as cut-off values for hypertension. Dietary intakes were assessed by food frequency questionnaire (24 hr recall methods).

Results: A total of 140 women [age 32.4±8.1 y and BMI 25.1±4.1 kg/m² (M±SD)] with a previous history of GH in any pregnancy were included. 49 Subjects (35%) developed hypertension over duration of 5 to 12 y. Total energy intake was higher in hypertensive (Htn) [kcal, 2175.7±399.6] as compared to non-Htn [1239±483] subjects. The higher energy was contributed mainly by carbohydrate sources from rice (g/day, 582.1±6 vs 239±71.9). On logistic regression analysis, Htn showed a strong positive association with past history of PIH and total energy intake and carbohydrate intake when the effects of age and BMI were adjusted.

Conclusion: Women with past history of PIH have more chance of developing hypertension and it may have an association with increased energy intake from carbohydrate sources.

Key Words: gestational hypertension; risk factor; dietary intake.

PO1088**THE EFFECT OF INTERMITTENT ANTENATAL IRON SUPPLEMENTATION ON INFANT OUTCOMES IN RURAL VIETNAM: A CLUSTER RANDOMISED TRIAL**

S. Hanieh¹, T.T. Ha², J.A. Simpson³, G.C. Casey¹, .T. Thuy², N.C. Khuong⁴, D.D. Thoang⁴, S.R. Pasricha¹, T.D. Tran², T. Tuan², T. Dwyer⁵, J. Fisher⁶, B.A. Biggs⁷

⁴Provincial Centre of Preventive Medicine, Ha Nam, Vietnam

⁵Murdoch Childrens Research Institute, Melbourne, Vic, Australia

⁶The Jean Hailes Research Unit, School of Public Health and Preventive Medicine, Monash University, Melbourne, Vic, Australia

⁷Royal Melbourne Hospital, Melbourne, Vic, Australia

Background and objectives: The currently recommended maternal iron-folic acid (IFA) supplementation given daily in pregnancy in developing countries has had limited effectiveness in reducing anemia due to poor compliance and variable availability. We assessed the effect of daily IFA supplementation, compared with intermittent dosing of IFA or multiple micronutrients (MMN) during pregnancy, on maternal and infant outcomes in a rural province of Vietnam.

Methods: A cluster randomised controlled trial was conducted in Hanam Province. Pregnant women less than 16 weeks gestation (n=1258) residing in 104 communes, were randomly assigned to take either daily IFA, twice weekly IFA, or twice weekly MMN.

Results: At baseline, mean hemoglobin was 12.33 g/dl (SD 1.23), with an anemia prevalence of 12.6%. Prevalence of ferritin deficiency (2%), folate deficiency (1.2%) and B12 deficiency (0.2%) were low. More than 90% of women were iodine deficient. There was no difference in birthweight in infants of women receiving daily IFA, compared to twice-weekly IFA (p = 0.27) or twice-weekly MMN (p = 0.11).

Conclusions: A variety of antenatal micronutrient deficiencies are common in this setting, although ferritin, folate and B12 deficiency are not prevalent in early pregnancy. Twice weekly iron-folic acid is an effective alternative to daily iron-folic acid supplementation during pregnancy in rural Vietnam.

Key words: antenatal; iron and micronutrient supplementation; birthweight.

PO1089**MATERNAL VITAMIN D DEFICIENCY AND INFANT OUTCOMES IN RURAL VIETNAM**

S. Hanieh¹, T.T. Ha², J.A. Simpson³, G.C. Casey¹, T.T. Thuy², N.C. Khuong⁴, D.D. Thoang⁴, T. Tuan², T.D. Dwyer⁵, J. Fisher⁶, B.A. Biggs⁷

⁶The Jean Hailes Research Unit, School of Public Health and Preventive Medicine, Monash University, Melbourne, Vic, Australia

⁷Royal Melbourne Hospital, Melbourne, Vic, Australia

Background and objectives: Vitamin D deficiency during pregnancy has been shown to result in significant adverse health outcomes for the mother and infant. Here we describe the prevalence of vitamin D deficiency during pregnancy in a rural setting in Vietnam, and assess the impact of this deficiency on neonatal and infant outcomes during the first 6 months of life.

Methods: Serum 25-hydroxyvitamin D concentrations of 960 pregnant women in Ha Nam province Vietnam, were measured at 32 weeks gestation, and infants were monitored until 6 months of age. Participants were part of a double-blind cluster randomized trial where pregnant women had been randomised to one of three micronutrient regimes.

Results: Eighteen percent (176/960) of women had serum 25-hydroxyvitamin D concentrations less than 50 nmol/L during late pregnancy. A reduced risk of preterm birth with higher maternal 25-hydroxyvitamin D concentration was observed. (Odds Ratio 0.78 per 20 nmol/L increase in vitamin D concentration, 95% CI 0.61 to 0.99).

Conclusions: Low 25-hydroxy vitamin D levels during pregnancy are of concern in rural Vietnam, and are associated with important neonatal and infant health outcomes. Strategies to increase vitamin D levels in pregnant women in this setting should be considered.

Key words: vitamin D; pregnancy; infant health.

PO1090**ANTENATAL AND EARLY INFANT RISK FACTORS FOR IMPAIRED INFANT GROWTH DURING THE FIRST 12 MONTHS OF LIFE IN RURAL VIETNAM**

S. Hanieh¹, T.T. Ha², J.A. Simpson³, G.C. Casey¹, T.T. Thuy¹, N.C. Khuong⁴, D.D. Thoang⁴, T.D. Tran², T.D. Tuan², T. Dwyer⁵, J. Fisher⁶, B.A. Biggs⁷

¹University of Melbourne, Australia

⁶The Jean Hailes Research Unit, School of Public Health and Preventive Medicine, Monash University, Melbourne, Vic, Australia

⁷Royal Melbourne Hospital, Melbourne, Vic, Australia

Background and objectives: Adverse conditions occurring during early life may lead to long-term consequences for a child's future growth and development. We determined which factors occurring during pregnancy and the first six months of life were associated with impaired infant growth at 12 months of age, in rural Vietnam.

Methods: This observational cohort study was conducted in rural Ha Nam province, Vietnam. Participants were infants born of women who had been previously randomised to one of three micronutrient regimes during pregnancy, as part of a double-blind cluster randomized trial. Infant growth and nutritional status during the first 12 months of life were assessed and maternal and early infant factors associated with impaired infant growth were determined. Primary outcomes were height for age z scores, and prevalence of stunting at 12 months of age.

Results: At 12 months of age, 9.2% of infants were stunted, and mean height for age z score was -0.74 (SD 0.97). Multivariate analysis demonstrated factors associated with stunting at 12 months of age were male sex, maternal height less than 145cm, maternal education, and maternal body mass index.

Conclusions: Measures to reduce stunting in childhood should be targeted at increasing female education, and improving maternal nutritional status during pregnancy.

Key words: Growth and development; Pregnancy.

PO1091**THE RELATIONSHIP BETWEEN HOUSEHOLD FOOD SECURITY AND CHILD GROWTH IN BANGLADESH: DOES THE DEPTH OF DEPRIVATION MATTER?**

J. Waid¹, F. Ahmed¹

¹Helen Keller International, Bangladesh

Background and objectives: Standardized perception-based food security measures seek to quantify food insecurity across cultures. In pursuit of this goal, reduced measures focusing only on the most severe indicators, such as going to bed hungry or going for a day and night without food, have been promoted as these elements correlate better across countries. However, no research has yet attempted to relate elements of the various depths of food insecurity to child growth or examine the mechanism through which these affect child growth.

Methods: Seasonal, cross-sectional data from two years of the Food Security and Nutrition Surveillance Project was aggregated (six surveillance rounds), resulting in a data set of 20507 mother and child pairs. The relationship of individual and composite indicators of food insecurity to child feeding and growth was examined using multivariate regression and child feeding practices were tested for mediation between household food insecurity and child growth.

Results: Child feeding practices differed by household food security status as did child growth outcomes. In addition, children in food secure households were found to have better growth outcomes even after accounting for child feeding practices and household dietary diversity. The elements of food insecurity that were not mediated by child feeding practices were the less severe conditions (worrying about obtaining food, eating less preferred food, and eating only rice).

Conclusions: Security is a requirement for mental and physical health. As such, the relationship between food security and the nutritional status of adults and children was not completely captured by examining the relationship between food insecurity and food choices. Furthermore, though useful as a cross country tool, studies within a culture should seek to include "milder" indicators of food insecurity and these have real implications for household well-being.

Key words: food-security, child-growth, well-being, IYCF.

PO1092**FOOD BELIEFS AMONG DIABETIC PREGNANT MOTHERS IN BANGLADESH***K R. Ahmed¹, S. Hossain¹, L. Ali²*

¹Dept of Health Promotion & Health Education, Bangladesh Institute of Health Sciences, Bangladesh

²Dept of Biochemistry and Cell Biology, Bangladesh Institute of Health Sciences, Bangladesh

Background and objectives: Pregnant mothers with diabetes, especially in developing countries, are particularly prone to suffer from dietary imbalances due to superstitions and irrational beliefs and practices. The aim of the study was to explore the existing beliefs and practices related to food intake during pregnancy among a group of Bangladeshi diabetic pregnant mothers.

Methods: One hundred diabetic pregnant mothers (age in yrs, $M \pm SD$, 30 ± 4) were purposively selected from the OPD of BIRDEM (the tertiary care hospital of the Diabetic Association of Bangladesh). Majority of them were literate (96%). An interviewer-administered questionnaire was used to explore the beliefs and practices about the time of intake and the nature of food.

Results: 43% of the pregnant mothers believed that food should not be taken during the 'call for prayer' and 91% of these mothers practiced it. For 'eclipse' the percentage of such kind of belief was much higher (80%) and 90% of these mothers practiced it. With varying proportion for particular fishes 44-58% respondents believed that some fishes should be avoided due to the increased movement of child, fetal malformation and disease. Many of them (93%) actually practiced it. Twenty eight percent had adverse beliefs about duck, 78% about pineapple, 4% about blackberry and 8% had misbeliefs about coconut. The corresponding percentages for practice were 82%, 99%, 75% and 50%, respectively. Mentally and physically abnormal child (like eye spot with pineapple, black skin with blackberry and white eyes with coconut), different kinds of child illness and threat of abortion were among the reasons for misbeliefs about food.

Conclusions: There are a number of nonscientific beliefs and prejudices among diabetic pregnant mother of Bangladesh regarding the intake of food. Educational awareness program should be needed for eliminating misbeliefs during pregnancy.

Key words: beliefs, diabetes, pregnant mother.

PO1093**ASSOCIATION OF TELEVISION VIEWING AND DIETARY BEHAVIOR WITH OVERWEIGHT AND OBESITY IN PRIMARY SCHOOL CHILDREN OF DHAKA CITY***S. Sultana¹, A. Hussain², L. Ali³*

¹Dept of Health Promotion & Health Education, Bangladesh Institute of Health Sciences, Bangladesh

²General Practice & Community Medicine, University of Oslo, Oslo, Norway

³Dept of Biochemistry and Cell Biology, Bangladesh Institute of Health Sciences, Bangladesh

Background and objectives: Childhood obesity is a major risk factor for cardiovascular disease and also increases risk for future diabetes. In a developing country like Bangladesh, televisions have become an important household item, particularly, TV advertisements may have a great impact on dietary behavior on children. The aim of the present study was to assess the possible association between dietary behaviour and television viewing with overweight or obesity in Bangladesh urban primary school children.

Methods: A cross-sectional study was conducted 1200 primary school children. Data were collected from Dhaka City. Participants (age 6-13 years) were randomly collected on the basis of predefined scoring. Subjects were classified as underweight (<90.99%), normal (91-110%), overweight (111-120%) and obese (> 120%), if their weight-for-height values were within the ranges of the recommended median values. Duration of television viewing was categorized as <60 min/day and >60 min/day. Dietary history was taken by specific food frequency questionnaire. Univariate and Multivariate regression models were used as appropriate.

Results: The substantial number of overweight and obesity was found to be 31% in the study subjects. Mean fat intake was significantly higher in overweight and underweight groups ($p = 0.008$) compared to the normal group. About 13.6% overweight and 18% obese children watched television more than 60 minutes. A significant positive correlation ($r = 0.106$, $p = 0.04$) of junk food intake with overweight and obesity and significant correlation ($r = 0.292$, $p = 0.001$) was found between TV viewing with weight for height. In logistic regression analysis, overweight and obesity were associated with TV viewing ($p < 0.001$) and junk food taking ($p = 0.02$) when the effects of other confounders (sex, age, parent's education, parent's income) were adjusted.

Conclusion: A substantial number of children are already overweight and obese and TV viewing and unhealthy food intakes are important contributors of weight gain.

Key words: child obesity, television viewing, diet.

PO1094**DIETARY PATTERN AND FOOD HABITS AMONG ADOLESCENT AND ADULT STUDENT GIRLS IN A CITY OF SOUTH INDIA***S. Omidvar¹, K. Begum¹*¹University of Mysore, India

Background and objectives: The prevalence of obesity and underweight has increased in recent years due to changes in eating habits all over the world. On the other hand eating behavior and dietary factors are as a risk factor in several important diseases such as cancer, coronary heart diseases or obesity. Therefore, we assessed the food habits and dietary pattern of adolescent and adult girls in an urban area from south India and exploring relationships between some factors such as SES, age groups and food behavior.

Methods: A cross-sectional study conducted on 1000 healthy young female students aged 11-28 years. A self administered questionnaire was used to collect information on socio-demographic indicators, food habits and patterns. Body weight and height was measured and BMI computed. All the statistical analyses were performed using SPSS 16.0.

Results: 50.1% of adolescents were underweight. Higher percentage of overweight subjects was adults. Skipping meals was significantly higher among adolescents. Subjects belonged to low SES had higher percentage of underweight while higher proportion of overweight girls belonged to high SES. Adolescents formed highest proportion of meal skippers (53.9% vs 49.1%). 68.7% of subjects consumed fast foods daily or frequently. 53.7% of adolescents and 40.2% of adults had snacks regularly. Adolescents from low SES had higher percentage of daily consuming of fast foods and bakery items. Only 13.7% of subjects use to consume at least one animal product, such as meat or an egg every day.

Conclusions: The results of this study could be used as an important baseline for future monitoring of the dietary pattern, nutritional situation of young females especially adolescents.

Key words: food habits, food pattern, dietary pattern.

PO1095**DOSE-DEPENDENT EFFECTS OF N-3 FATTY ACID ON ERYTHROCYTE MEMBRANE IN CYCLISTS***I. Guillén Guillén¹, J. Contreras¹, D. Barnuevo¹, A. Luque¹, C. Domingo², J. López-Román¹, A. Villegas³*¹Cátedra de Fisiología del Ejercicio, Universidad Católica San Antonio, Murcia, Spain²Departamento de Bioquímica y Biología Molecular, Universidad de Barcelona, Spain³Dirección General de Deportes, Comunidad Autónoma de la Región de Murcia, Spain

Background and objectives: Polyunsaturated fatty acids (PUFA), such as n-3 fatty acid (docosahexaenoic acid –DHA- and eicosapentaenoic acid –EPA-), which are present in cell membrane lipid, are important for many biochemical and physiological functions. Fish oil supplementation increases the relative proportion of the long-chain n-3 PUFA in erythrocyte membrane. The purpose of this study was to establish a dose-response relationship between levels of n-3 fatty acid supplementation (Algatrium®) and changes in erythrocyte membrane. Algatrium® is a nutritional supplement consisting of DHA and EPA, and it has the same structure of natural oil-extracted from fish.

Methods: A randomized, double-blind, placebo-controlled, parallel design dose-response supplementation trial of 4 week duration was undertaken. 59 healthy cyclists were randomly into 5 experimental groups receiving different amounts of DHA and EPA (DHA/EPA: 350/50, 1050/150, 1750/250, 2450/350 mg/d, or placebo). Blood was collected in standard tubes using EDTA as anticoagulant. Fatty acid profiles in erythrocyte membranes were assessed at baseline and after 4 weeks by flame-ionization GC.

Results: DHA and EPA supplementation progressively increased the levels of n-3 in erythrocyte membranes after 4 weeks. There was a strong linear relationship between dose and the changes in DHA incorporation. Total n-6 fatty acids decreased in all groups. Consequence of these changes, the ratio n-6/n-3 experienced a dose-dependent significant decrease in individuals who consumed the experimental product under study (350/50 mg p < 0.023; 1050/150 mg p < 0.0012; 1750/250 mg p < 0.001; 2450/350 mg p < 0.001)

Conclusions: n-3 PUFA consumption produces an increase in these, particularly DHA, in the erythrocyte membrane, being this raise dose-dependent.

Key words: lipids, n-3 PUFA, docosahexaenoic acid

PO1096**INFLUENCE OF BIRTHWEIGHT AND BREASTFEEDING PRACTICES ON BODY ADIPOSITY AND INSULIN RESISTANCE OF ADOLESCENTS IN MALAYSIA**

L H. Foo¹, P S. Teo¹, N F. Abdullah¹, M E. Aziz²

¹Programme of Nutrition, School of Health Sciences, Universiti Sains Malaysia, Health Campus, Kubang Kerian, Kelantan, Malaysia

²Department of Radiology, School of Medical Sciences, Universiti Sains Malaysia, Health Campus, Kubang Kerian, Kelantan, Malaysia

Background and objectives: Few studies have addressed whether there is a relationship between birthweight and infant feeding practices, and body adiposity and insulin resistance during adolescence, especially in adolescents. The aims of the study was to determine the influence of birthweight and breastfeeding practices on adiposity and insulin resistance in 397 adolescents aged 12 to 19 years in Malaysia.

Methods: Information on early growth status and feeding practices was obtained from parental questionnaire. Body adiposity was measured using dual-energy X-ray absorptiometry. Fasting glucose and insulin was measured, and insulin resistance was calculated based on the homeostasis model assessment (HOMA-IR). Analysis of covariance was used to determine the associations between birthweight and feeding practices, and adiposity and insulin resistance, after adjustments for socio-demographic, pubertal status, dietary intakes and lifestyle physical activity and sedentary practices.

Results: Breastfeeding duration was inversely associated with total and regional adiposity. However, subgroup analysis of adolescents with preterm delivery (<37 weeks) showed that birthweight was inversely associated with fasting glucose, insulin and HOMA-IR concentrations, and breastfeeding duration was inversely correlated with adiposity levels. Significant higher fasting glucose, insulin and HOMA-IR concentrations (all $p < 0.05$) were seen among those with low birthweight group compared to those at higher birthweight at preterm birth, after full adjustments for these covariates and body mass index. Additionally, adolescents with longer duration of breastfeeding practices had significantly lower levels of body adiposity (all $p < 0.01$). In contrast, only significant influence of breastfeeding duration on body adiposity levels were found among adolescents borned at full term.

Conclusions: The present findings indicate that intrauterine environment factors determining birthweight may have permanent effects on insulin resistance in preterm delivery, whereas breastfeeding duration practices during infancy, regardless of term delivery status, can exert long-term impacts on body adiposity in adolescence.

Key words: breastfeeding, birthweight, adiposity, insulin resistance, early growth status.

PO1097**A COMPARATIVE STUDY OF IDEAL BODY MASS INDEX AND DIET-RELATED FACTORS OF YOUNG WOMEN IN KOREA AND JAPAN**

K. Mizumoto¹, Y. Takashima¹, H K. Kim¹, K W. Lee², S J. Chung², MS. Cho²

¹Fukuoka Women's University, Japan

²Ewha Woman's University, Korea

Background and objectives: An increase of young lean women (BMI <18.5kg/m²: 29.0%) is one of recent issues in Japan. The idea of that a beautiful woman should be thin has been fixed among young women, and the idea may lead a desire to be thinner for healthy weight. A high rate of young Korean women who strongly desire to be thin was also reported. However, the rate of young lean women in Korea is about half of the Japanese rate (15.0%). This study aims to identify similarities and differences of body images and diet-related factors amongst young Japanese and Korean women.

Methods: A cross-sectional study was conducted at F University in Japan and E university in Korea. The subjects consisted of 168 Japanese and 139 Koreans students. Data was collected through anthropometric measurements and a questionnaire survey. Mann-Whitney's U test and qui-square test were employed for data analysis.

Results: The BMI medians were 19.8(2.3)kg/m² and 19.7(2.5)kg/m² in the Japanese and the Korean students, respectively ($p = 0.106$). The ideal BMI means amongst the Korean students (18.5+1.1kg/m²) was significantly lower than that amongst the Japanese students (19.1+1.1kg/m²) ($p < 0.01$). Of the Korean students, the mean number of skipping breakfast was significantly more frequent ($p < 0.01$) and having dinner with family was significantly less frequent ($p < 0.01$) than within the Japanese students. On the other hand, the Korean students were more frequently having a recommended Korean traditional-meal-combination than the Japanese students (recommended Japanese traditional-meal-combination).

Conclusions: Although the ideal BMI mean amongst the Korea students was significantly lower, the perception was not reflected to their actual BMI. Keeping traditional meal combinations might be a factor of maintaining healthy weight. The reasons for being able to have traditional meal combinations despite of frequent breakfast-skipping and eating without family should be studied soon.

Key words: young women, BMI, diet, comparison study.

PO1098**THE RELATION BETWEEN MATERNAL NUTRITIONAL STATUS WITH BABY BIRTH WEIGHT AND BIRTH LENGTH IN SINT CAROLUS HOSPITAL JULY - SEPTEMBER 2011***C. Kliranayungie¹, E.L. Achadi¹*

¹Departement of Nutrition, University of Indonesia, Depok, West Java, Indonesia

Background and objectives: Both birth weight and birth length show prenatal growth of the baby. Maternal nutritional status, which are maternal height and prepregnancy body mass index as before pregnancy, also maternal iron status in third trimester and weight gain during pregnancy as during pregnancy, have the most important influenced to prenatal growth. This study aimed to determine the relation between maternal nutritional status with baby birth weight and baby birth length by controlling maternal and baby characteristics.

Methods: This cross-sectional study which conducted at Sint Carolus Jakarta Hospital during April 2012 use secondary data from 220 medical records of mothers and babies.

Results: The result shows that 65.9% of babies borned with 3000 g birth weight or more, and 73.6% of babies borned with 48-52 cm birth length, regardless 8.6% of babies borned with birth weight less than 2500 g and 25.9% of babies borned with birth length less than 48 cm. Prediction model of birth weight includes pre-pregnancy body mass index, maternal height, weight gain during pregnancy and maternal age, with maternal height as the most significant factors. Prediction model of birth length includes only maternal height and newborn sex.

Conclusions: Since maternal nutritional status has significant impact of the baby, this factor needs to be prioritized. Unfortunately, there is still a paradigm that this maternal nutritional status only refers to maternal nutritional status during pregnancy. This study supports the significant of maternal nutritional status before pregnancy as important as during pregnancy.

Key words: birth weight, birth length, maternal.

PO1099**EFFECT OF PRENATAL LIPID-BASED NUTRIENT SUPPLEMENTATION ON GESTATIONAL WEIGHT GAIN***H. Lanou^{1,3}, L. Huybregts^{2,3}, D. Roberfroid³, P. Kolsteren^{2,3}*

¹Institut de Recherche en Sciences de la Santé (IRSS)

²Department of Food Safety and Food Quality, Ghent University, Ghent, Belgium

³Child Health and Nutrition Unit, Department of Public Health, Institute of Tropical Medicine, Antwerp, Belgium

Background and objectives: Maternal gestational weight gain is an important predictor of pregnancy outcome. Maternal nutritional interventions to improve pregnancy outcomes rarely assessed the effect of the interventions on maternal weight gain. The objective was to determine the effect of antenatal Lipid-based nutrient based supplementation (LNS) on maternal weight gain.

Methods: Anthropometrical data were collected from 938 pregnant women who participated in a randomized control trial of prenatal LNS supplementation on birth outcome in rural Burkina. The intervention group was given 75 g of an energy dense spread containing one recommended daily allowances (RDA) of 15 micronutrients and providing 1.56 MJ of energy and 14.7 g of protein. The control group was given a tablet containing one RDA of the multiple micronutrients (MMN). Maternal anthropometric measurements were collected during the prenatal visits and at delivery. We used non-linear mixed-effects models to assess the intervention effect on weight gain.

Results: LNS increased total weight gain (+0.5 kg; 95%CI: 0.1, 0.9; $p = 0.011$) and the rate of weight gain (+21.7 g/week; 95%CI: -1.0, 44.6, $p = 0.061$) during pregnancy. The mean rate of weight gain was 206.5 g/week in the LNS and 187 g/week in the MMN group. In the mixed-effect models analysis, LNS increased the weight gain rate (+0.016 kg/week; 95%CI: -0.0004, 0.03; $p = 0.056$). Significant effect modification by maternal hemoglobin concentration at baseline was denoted with mothers. Women of the LNS group with higher baseline hemoglobin (mean+1SD) had significantly higher weight gain (+0.04 kg/week; 95%CI: 0.02, 0.05; $p < 0.001$) compared to those with lower hemoglobin (mean-1SD) concentrations (-0.008 kg/week; 95%CI: -0.03, 0.02; $p = 0.553$).

Conclusions: Prenatal Lipid-based nutrient based supplementation resulted into a significantly higher gestational weight gain. Baseline maternal hemoglobin appeared to modify this effect resulting in higher weight gain effect in mothers with high hemoglobin concentrations at baseline.

Key words: prenatal, lipid-based nutrient supplement, maternal weight gain.

PO1100**BIOELECTRICAL IMPEDANCE VECTOR ANALYSIS (BIVA) AND PHASE ANGLE (PA) IN HEALTHY AND FRAGILE ELDERLY**

F. Lourenço Costa¹, J L S. Marchesi¹, J A O. Carneiro¹, E. Ferriolli¹, K. Pfrimer¹

¹Medical Clinical Department, Medical School of Ribeirão Preto, University of São Paulo, Ribeirão Preto, São Paulo, Brazil

Background and objectives: BIVA is a valuable tool for assessing nutritional status and hydration in the elderly which classifies individuals by athletic, lean, obese and cachectic, while the phase angle (PA) can be used as a indicator of cell mass. BIVA is analyzed by resistance (R) and reactance (Xc) normalized by height, representing a bivariate vector, not requiring regression equations as in bioelectrical impedance (BIA). The aim of the study was to compare and analyze the nutritional status of the elderly, through BIVA and PA, between healthy and fragile groups separated by gender.

Methods: Cross-sectional study involving elderly (over 60 years), divided into two groups: healthy (evaluation clinical-laboratorial) and fragile (reduction in walking speed and manual grip strength, weight loss of 5% per annum, low level of physical activity and self-reported fatigue). The anthropometry and BIA were performed, applying the data in software BIVA 2002[®]. The test Komogorov-Smirnov was used for the normality test and T-test for the evaluation of independent samples.

Results: 12 fragile elderly were evaluated (79.2 ± 6.6 years), 5 males and 7 females, and 20 healthy controls (72.1 ± 3.2 years), 8 male and 12 females. By the classification of BIVA, no healthy volunteer was considered cachectic and no fragile was considered athletic, according to position and length of the vectors in the graph and there was statistically significant difference between the PA means between the female groups, having the fragile group the lowest values, corroborating with the nutritional status changed.

Conclusions: BIVA provides detailed information on the nutritional status of the elderly through the easy monitoring and part of their prognostic power by PA. Therefore, comparative studies of alterations found in the syndrome of frailty in relation to normal aging are of great value.

Key words: bioelectrical impedance, vector analysis, phase angle, elderly.

PO1101**PILOT STUDY IN MATURE SPANISH WOMEN**

M T. Iglesias¹, M L. Garcia²

¹Universidad Francisco de Vitoria, Madrid, Spain

²Clínica Santa Elena

Background and objectives: To examine the nutrient intake in urban native Spanish mature women and its relationship with some analytical variables.

Methods: Participants were 23 volunteer females, that gave their informed consent. Body weight and height were measured with standardized methods. From the 3-d FR, dietary intake was calculated using DIAL[®] program.

Results: Mean intake of protein and fat exceeded the respective Spanish RDA and mean daily intake of carbohydrates and fiber was less than this RDA. This is in agreement with the high consumption of fatty meat and low consumption of fruit and vegetables. Low intakes of folic acid, Ca and Fe, was observed. Serum cholesterol was significantly correlated with LDL-cholesterol and risk factor of atherogenicity. HDL-cholesterol was inversely and significantly correlated with diet polyunsaturated fatty acids and atherogenicity risk factor. Dietary carbohydrates was correlated with serum cholesterol, so probably these are responsible of its increase in serum. We found a lack of correlation of serum vitamin D with dietary vitamin D and was inversely correlated with dietary cholesterol. Dietary cholesterol was correlated with the intake of protein, saturated fatty acids and total fat. Folic acid was correlated with atherogenic risk factors, probably because when folate decreased increased homocysteine responsible of cardiovascular risk.

Conclusions: A dietary imbalance in women was observed. The intake of some nutrients do not meet the established recommendations for Spain people; we found low vitamin D serum levels. Future research is necessary to better understand the optimal vitamin D concentration for promoting health in mature women. The unfavourable lifestyle of the great majority on mature women may have implications during the elderly. It is necessary to promote physical activity to prevent future nutrition related health problems.

PO1103**ASSESSMENT OF YOUNG INFANTS' EXCLUSIVE BREASTFEEDING PRACTICE IN GEOGRAPHICALLY DIVERSE AREAS OF BANGLADESH**

M R R. Talukder¹, A E. Rahman¹, D M E. Huque¹, M. Rahman¹

¹Centre for Child and Adolescent Health, International Centre For Diarrhoeal Disease Research, Bangladesh, 68, Shaheed Tajuddin Ahmed Saroni, Mohakhali, Dhaka, Bangladesh

Background and objectives: Optimum duration of breastfeeding is essential for maintaining proper nutrition and development of children. Recent Bangladesh Demographic Health Survey reported substantial increase in exclusive breastfeeding (EBF) practice of children aged below 6 months. However, we have limited knowledge about EBF practice in geographically diverse areas, which will be useful for sustaining the improvement. We aim to describe geographical diversity (plain, wet and high land) of EBF practice in <6 months infant in Bangladesh.

Methods: We conducted a multi-stage cluster household survey in 14 sub-districts from 5 districts of Bangladesh in 2009-2010. We assessed 790 children aged 0-5 months about their exclusive feeding practice. We used the Google maps for primary categorization of the areas followed by ground verification by field based staffs. We analyzed rate of EBF and contributing factors across plain, wet and high land areas.

Results: The rate of EBF was lower in plain (62%) than that of wet (68%) and high (77%) land areas. In all areas, the proportion of EBF reduced gradually with age. Lower odds of EBF had observed in women of advanced marital age (OR 0.40, 95% CI 0.20, 0.81, $p = 0.01$) in plain land and in women of advanced age in wet (OR 0.52, 95% CI 0.30, 0.90, $p = 0.02$) and high land (OR 0.32, 95% CI 0.12, 0.85, $p = 0.02$). In wet land women who had antenatal check up (OR 1.99, 95% CI 1.02, 3.89, $p = 0.04$) and regular exposure to either print or electronic media (OR 4.62, 95% CI 1.63, 13.05, $p = 0.004$) were more likely to practice EBF.

Conclusions: EBF practice in young infant improved across three geographical areas in Bangladesh where large gap still remains in plain land. Future studies should plan in-depth assessment of both low (plain land) and high (high land) performing areas.

Key words: exclusive breastfeeding, geographical diversity, young infant, Bangladesh.

PO1104**ROLE OF SCHOOL FEEDING PROGRAMME IN MALNUTRITION AMONG UNDER FIVE CHILDREN IN OBOKUN LOCAL GOVERNMENT AREA OF OSUN STATE NIGERIA**

I O. Akinyele¹, W. Ajayi¹

¹Food Basket Foundation International, Nigeria

Background and objectives: The poverty situation in Nigeria has contributed to poor nutritional status of children. This has had an adverse effect on their growth and intellectual development. School feeding programmes have been assumed to affect malnutrition. The aim of this study is to assess the level of effectiveness of school lunch programme as a means of malnutrition control.

Methods: This longitudinal study adopted both qualitative and quantitative methods of data collection. Data collection involved two major aspects which included community baseline and school baseline. School baseline involved the collection of anthropometric data of the pupils such as weight, height, Mid Upper Arm Circumference (MUAC) measurement and Age at the beginning and end of each term in all government primary schools in the Local Government Area between year 2010 and 2011. Data entry and analysis of the quantitative questionnaire was done using the Statistical Package for Social Sciences (SPSS) for windows version 16 and WHO Anthro.

Results: Stunting prevalence at first baseline was 25.5% among 1613 pupils assessed; endline prevalence was 17.9% among 2845 pupils assessed. The second baseline prevalence of stunting was 42.7%, this increased to 49.4 at end line. At first baseline prevalence of underweight was 17.7%; at the endline, it was 14.0%. Second baseline prevalence was 41.7% and endline prevalence was 36.7%. At first baseline, 22.1% were wasted while at endline 20% were wasted. At the second baseline, prevalence of wasted was 23% and end line reported a prevalence of 30%.

Conclusions: The above results suggest that the school lunch programme cannot be said to be a way of improving nutritional status among school children.

Key words: Malnutrition, Stunting, wasting and underweight.

PO1105**INTIMATE PARTNER VIOLENCE AND FEEDING PRACTICES OF CHILDREN ATTENDED IN BASIC HEALTH UNITS OF THE RIO DE JANEIRO CITY, BRAZIL**

R. Mezzavilla¹, G. Vianna¹, M H. Hasselmann¹

¹Rio de Janeiro State University, Brazil

Background and objectives: In Brazil, only 41% of children under six months remain in exclusive breastfeeding. Complementary feeding has been introduced early, around the 4th month. Studies indicate other risk factors for food introduction, features also observed in women who suffer from intimate partner violence (IPV). The aim of this study was to explore the association between IPV and infant feeding practices.

Methods: Cross-sectional study with 339 children in the 4th month of life which attended to 4 basic health units of the Rio de Janeiro city between June 2005 and December 2009. Feeding practices were assessed through a 24-hour recall and were categorized as: Breastfeeding, Exclusive Breastfeeding (EB), Predominant Breastfeeding (PB), Breastfeeding and semi-solid food, Breastfeeding and solid food, Artificial Feeding (AF), AF and semi-solid food, AF and solid food, supply by: powdered milk; fruit juice; porridge; salt food; fruits; and vegetable soup/porridge. IPV was measured using the Portuguese version of the Conflict Tactics Scales(CTS-1) and was analyzed dichotomous. The period investigated referred to four months prior. Prevalence ratios were calculated with a confidence interval of 95%.

Results: Only 18.4% were exclusively breastfed. The prevalence of children in EB was significantly lower (20.9% vs 88.9%) when IPV was positive. Besides, in presence of IPV it was observed a chance of 1.79 times (95% CI 1.04 to 3.08) that the child was not breastfed, 2.17 (95% CI 1.2 to 3.92) to receive artificial milk and semi-solid foods, and 1.92(95% CI 1.36 to 2.71) to receive porridge.

Conclusions: The prevalence of AF and early introduction of semi-solid foods was higher in children whose parents physically hit each other. It is noted the contribution of these results for the development of health promotion actions, both in terms of encouraging the practice of EB, as with regard to IPV.

Key words: Intimate Partner Violence; Feeding Practices; Lactation.

PO1106**FOLLOW UP OF AMBULATORY AND HOME ENTERAL NUTRITION IN A SPANISH TERTIARY CHILDREN HOSPITAL**

R. Berzosa¹, M J. Peláez¹, A. Madrid¹, V. Nava¹, C. Sierra, J. Blasco¹, J. Serrano¹, A. Urda¹, A. Jurado¹

¹Hospital Materno Infantil Carlos Haya, Madrid, Spain

Background and objectives: Nowadays more children need ambulatory and home enteral nutrition support (HEN), sometimes for long periods of time.

Methods: Retrospective data analysis of patients receiving HEN between 2000 and 2012.

Results: 176 patients, 93 male (52.9%) were included. The median age at the initiation of HEN was 3.6 years (IQR 8.2-15.4). The most frequently diseases were congenital heart diseases 38 (26%), neurological and neuromuscular diseases 35 (23.9%), other gastrointestinal tract disorders 35 (23.9%), oncologic diseases 21 (14.3%), oesophageal disorders 12 (8.2%), orofacial anomalies 9 (6.1%), and others 28 (19.1%). EN was delivered via a nasogastric tube in 118 (67.8%), by gastrostomy in 35 (20.1%), orally in 26 (14.9%), and by jejunal access in 1 case. The cyclic feeding was the most frequently route of administration, 90 children (51.1%). Pediatric polymeric formula was administered in 71 (40.3%). The median follow-up time was 108.2 days (IQR 30-138.75).

Conclusions: HEN is an alternative choice to increase the quality of life of these children. The number of these patients is increasing every day. The most used EN way of delivering was by nasogastric tube. The most frequent diseases were congenital heart diseases, however in other publications the most important diseases to start HEN were neurological and gastrointestinal tract disorders. It is important to continue documenting all these patients to reach final conclusions.

PO1107**VITAMIN D, ADIPOSITY AND METABOLIC BIOMARKERS IN CHILEAN CHILDREN**

G. Cediel^{1,2}, C. Corvalan¹, R. Uauy^{1,2}, D. López de Romaña^{2,3}

¹Institute of Nutrition And Food Technology (INTA), Chile

²London School of Hygiene and Tropical Medicine, London, United Kingdom

³Micronutrient Initiative, Ottawa, Ontario, Canada

Background and objectives: Increasing evidence suggests that 25-hydroxyvitamin-D-[VD] concentration is associated with adiposity, and metabolic biomarkers in adults and adolescents. However, there is a lack of information regarding this association in children. We assessed the relationship between VD concentration, adiposity (bioelectrical impedance) and metabolic biomarkers.

Methods: Total-cholesterol, high-density-lipoprotein-cholesterol-[HDL], low-density-lipoprotein-cholesterol-[LDL], triglycerides, glycemia, insulin, HOMA, C-reactive-protein-[CRP], and leptin was determined in a cross-sectional sample of 308 children (7-9 years) who participated in Growth and Obesity Cohort Study in 2011-12 in Chile. The sample was classified in 4 groups according to VD-(ng/ml) and adiposity-(% fat) levels using 'mean' as a cut off: a) High-Adiposity-Low-VD-(HALD), b) High-Adiposity-High-VD-(HAHD), c) Low-Adiposity-Low-VD-(LALD), d) Low-Adiposity-High-VD-(LAHD). An r-Pearson-test was used to evaluate correlation, and two-way-ANOVA to assess interactions between independent variables (adiposity and VD) and comparing the effects between groups.

Results: VD (mean=32.3 ng/ml) was inversely associated with adiposity-($r=-0.12$, $p = 0.03$), BMI-for-age-z-score-($r=-0.09$, $p = 0.04$), subscapular-skinfold-($r=-0.12$, $p = 0.02$), insulin-($r=-0.19$, $p < 0.001$), HOMA-($r=-0.20$, $p < 0.001$) and total-cholesterol-($r=-0.13$, $p = 0.02$). Interactions between adiposity and VD affected glycemia-($p=0.001$) and leptin-($p = 0.04$). VD had an independent effect on insulin-($p = 0.049$), HOMA-($p = 0.01$), total-cholesterol-($p = 0.03$) and LDL-($p = 0.04$); while adiposity had an independent effect on total-cholesterol-($p = 0.03$) LDL-($p = 0.02$), and PCR-($p = 0.0001$). HALD group showed a significant higher concentration of total-cholesterol-(161.1 ± 3.2 ; 149.3 ± 2.6 mg/dl), LDL-(92.7 ± 2.5 ; 82.2 ± 2.1 mg/dl), and CRP-(2.8 ± 0.4 ; 1.2 ± 0.2 mg/l), respectively ($p < 0.05$) than LAHD.

Conclusions: Our data suggests that VD is associated with insulin resistance independent of adiposity, while low VD in conjunction with higher adiposity is associated with risk of dyslipidemia and inflammation early in life.

Key words: vitamin D, metabolic biomarkers, adiposity, children.

PO1108**RAPID WEIGHT GAIN IS AN EARLY RISK FACTOR FOR PRESCHOOL OVERWEIGHT AND OBESITY: A CASE CONTROL STUDY IN SRI LANKA**

A. Satchithanathan¹, K M. Rathnayake¹, A M A S B. Mahamithawa²

¹Department of Applied Nutrition, Faculty of Livestock, Fisheries and Nutrition, Wayamba University of Sri Lanka, Makandura, Sri Lanka

²Nutrition Division, Ministry of Health, Colombo, Sri Lanka

Background and objectives: Rapid weight gain during early childhood is a significant risk factor of adulthood obesity. Our aim was to assess the maternal and child risk factors associated with overweight and obesity among preschool children.

Methods: In this case-control study, from the 1087 preschool children measured, 71 cases and 71 controls of 3-5 years were recruited matching for age, sex and ethnicity. Cases (overweight and obesity) and controls were defined as BMI-for age $>+2SD$ and between $-2SD$ to $+2SD$, respectively (WHO2006 standards). Birth weight and child's weight upto 2 years were collected from child health records. Infant feeding practices, maternal factors and child's dietary and activity pattern were obtained from the mother. Rapid weight gain was defined as an increase in weight-for-age Z score (WHO standards) above 0.67SD from birth to 2 years. Magnitude and mean difference of the variables associated with overweight and obesity were evaluated using logistic regressions and independent samples-t-test, respectively.

Results: Prevalence of obesity and overweight of the study sample was 1.2% and 6.2% respectively. Cases had significantly shorter duration of breastfeeding (19.4, 24.6, $p=0.003$), shorter duration of exclusive breastfeeding (3.7, 5.0, $p=0.001$), long napping hours during preschool age (1.7, 1.1, $p=0.03$) and early initiation of complementary feeding (5.8, 6.5, $p=0.032$), compared to controls. Rapid weight gain (OR=4.113, 95%CI=1.194-14.165), watching television while eating (OR=5.224, 95%CI=1.229-22.368) and maternal obesity (OR=3.544, 95%CI=1.053-11.929) were positively associated with obesity. Child's physical activity (OR=0.156, 95%CI=0.042-0.578), mother with tertiary education (OR=0.075, 95%CI=0.007-0.763) and breastfeeding more than 2years (OR=0.123, 95%CI=0.030-0.499) were negatively associated with obesity.

Conclusion: Rapid weight gain is a predisposing factor for preschool obesity. Children watching television while eating and maternal obesity contribute to obesity, while adequate physical activity during preschool age, extended breastfeeding above 2 years and educated mother protects against obesity.

Key words: Rapid weight gain, preschool, overweight, obesity

PO1109**MINERALS IN FOODS FOR INFANTS AND YOUNG CHILDREN***V. Öhrvik¹, J. Engman¹, B. Kollander¹, B. Sundström¹*¹Science Department, National Food Agency, Sweden

Background and objectives: Adequate intake of minerals during infancy and childhood is important for growth and development. Both deficiencies and high intakes might be harmful, e.g. an excessive intake of manganese might have adverse effects on the nervous system. The Swedish National Food Agency therefore analyzed mineral content in products for infants (0-12 months) and young children (1-3 years).

Methods: 92 products of porridge, gruel, infant formulae, follow-on-formulae, foods for special medical purposes and 'foods for normal consumption' were analyzed as composite samples from different batches available during the sampling period (n=1-3). Products were analyzed 'on sales' basis, i.e. either dry powders or in liquid form. Copper, iron, manganese and zinc were quantified using Inductively Coupled Plasma-Mass Spectrometry after microwave digestion in nitric and hydrochloric acid and followed by dilution with water. The analysis is accredited according to ISO/IEC 17025 by Swedish Board for Accreditation and Conformity Assessment. In addition, the metals arsenic, cadmium and lead were quantified.

Results: Mineral content varied greatly between the products; median (min-max) concentrations in ready-to-eat products were: copper 0.039 mg/100 g (0.002-0.32); iron 0.77 mg/100 g (<0.10 to 6.0); manganese 0.11 mg/100 g (0.02 to 0.89) and zinc 0.55 mg/100 g (0.02-4.7). For manganese and zinc, concentrations did not differ significantly between products fortified with those minerals and non-fortified products, as compared by the Wilcoxon-Mann-Whitney rank-sum test. Some of the products with the highest content of e.g. manganese were non-fortified. For copper and iron fortified products contained significantly higher amounts than non-fortified products.

Conclusions: Mineral content varied from levels below quantification to above the tolerable daily intake in the products. It is therefore advisable to eat a variety of foods from a variety of brands to avoid insufficient and excessive intakes of minerals.

Key words: infant nutrition, zinc, copper, manganese, iron.

PO1110**MATERNAL MILK CONSUMPTION, BIRTH SIZE AND ADULT HEIGHT OF OFFSPRING: A PROSPECTIVE COHORT STUDY WITH 20 YEARS OF FOLLOW-UP***L. Hrolfsdottir¹, D. Rytter², B. Hammer-Bech², T B. Henriksen³, I. Danielsen⁴, L. Steingrimsdottir¹, S. Olsen^{4,5}, T I. Halldorsson^{1,4}*¹Faculty of Food Science and Nutrition, School of Health Sciences, University of Iceland, Reykjavik, Iceland²Department of Public Health, Section for Epidemiology, Aarhus University, Denmark³Department of Pediatrics, Aarhus University Hospital, Skejby, Denmark⁴Center for Fetal Programming, Department of Epidemiology Research, Statens Serum Institute, Copenhagen, Denmark⁵Department of Nutrition, Harvard School of Public Health, Boston, Massachusetts, USA

Background and objectives: Previous studies have suggested that milk consumption during pregnancy may have growth promoting effects on the offspring in utero. Whether this effect tracks beyond the prenatal period remains unclear. We examined whether milk consumption during pregnancy is associated with infant size at birth and offspring's height and growth related biomarkers at ~20 years of age.

Methods: A prospective cohort of 809 Danish pregnant women was recruited in 1988-1989 with offspring follow-up at ~20 years of age (n=685). Milk consumption was assessed at gestational week 30 using a food-frequency questionnaire. Birth weight and birth length were measured according to standard procedures at delivery and converted to gender specific z-scores.

Results: In adjusted models, maternal milk consumption of ≥ 150 millilitre (ml)/d vs < 150 ml/d was associated with 0.32 higher z-scores for birth weight (95% CI 0.06; 0.58) and 0.34 higher z-scores for birth length (95% CI 0.04; 0.64). At follow up, ~20 years later, those offspring whose mothers had consumed ≥ 150 ml milk/d tended to have 0.19 higher z-scores for height ($p = 0.16$), ~8% higher levels of IGF-I ($p = 0.12$), and ~14% higher insulin levels ($p = 0.11$), compared to offspring whose mothers consumed < 150 ml milk/d.

Conclusion: Our findings add to recent observations that maternal milk consumption may have growth promoting effect with respect to weight and length at birth. Furthermore, the results provide some suggestion that this effect may even track into early adult age, although further studies with more statistical power are needed for that purpose.

PO1111**MILK CONSUMPTION THROUGHOUT LIFE IS ASSOCIATED WITH BONE MINERAL DENSITY IN ELDERLY MEN AND WOMEN**

T. Eysteinsdottir¹, T. I. Halldorsson^{1,2}, I. Thorsdottir^{1,2}, G. Sigurdsson^{3,4}, S. Sigurdsson³, T. Harris⁵, L. J. Launer⁵, V. Gudnason³, I. Gunnarsdottir^{1,2}, L. Steingrimsdottir^{1,2}

³Icelandic Heart Association, Kopavogur, Iceland

⁴Faculty of Medicine, School of Health Sciences, University of Iceland and Landspítali National-University Hospital, Reykjavik, Iceland

⁵Laboratory of Epidemiology, Demography, and Biometry, Intramural Research Program, National Institute on Aging, Bethesda, USA

Background and objectives: The role of lifelong milk consumption for bone mineral density (BMD) in old age is not clear. Here we assess the association between hip BMD in old age and milk consumption in adolescence, midlife and current old age.

Methods: Participants of the AGES-Reykjavik Study, age 66-96 years (n=4798) reported retrospective milk intake during adolescence and midlife as well as in current old age, using a validated food frequency questionnaire. BMD of femoral neck and trochanteric area was measured by volumetric quantitative computed tomography (QCT). Association was assessed using linear regression models, and difference in BMD in relation to milk intake portrayed as gender specific Z-scores.

Results: Men with current milk consumption of \geq once/day compared with $<$ once/week had Z-scores 0.9 higher on average for femoral neck (95% Confidence Interval -0.01, 0.20). For midlife consumption the difference was 0.21 Z-scores (95% CI 0.04, 0.38), and for consumption during adolescence the difference was 0.15 Z-scores (95% CI -0.16, 0.45). Results were comparable for femoral neck and trochanter, and for men and women, though associations were generally slightly stronger for men.

Conclusions: Our data suggest that milk intake during midlife has the strongest association with hip BMD in old age, and is stronger for men than women.

PO1112**USE OF DIFFERENT FORTIFIED FOODS, AT THE HOUSEHOLD LEVEL, DISTRIBUTED BY A FOOD ASSISTANCE PROGRAM IN BURKINA FASO**

T. Traore¹, C. Kabore¹, O. Bruyeron²

¹GRET, NUTRIFASO Program, Ouagadougou, Burkina Faso

²GRET, Paris, France

Background and objectives: Food assistance is a strategy generally implemented by international institutions to prevent acute malnutrition among vulnerable groups. The aim of the study is to compare the benefits of 2 different fortified foods distributed, during one year, to 6-23-month-old children mothers as part of WFP food assistance program.

Methods: The study was a cross-sectional survey through questionnaires and observations of the use (preparation, consumption, intrafamily distribution, beneficiaries' satisfaction level, etc) of 2 fortified foods (a lipid-based ready-to-use supplementary food Plumpy'Doz[®] and a locally processed fortified infant flour). 150 beneficiaries of each product (total of 300 beneficiaries) were selected from the list established the day of survey in 11 health centers. Furthermore, focus groups with each product beneficiaries and interviews of each health center responsible were organized.

Results: The nature and the quality of complementary foods distributed were well appreciated by the beneficiaries of the two groups. However, the frequency of distribution (monthly) and the ration size of Plumpy'Doz[®] were considered insufficient by the beneficiaries (81%). A preference for fortified infant flours was identified among the beneficiaries who already used the two food products (91%). Plumpy'Doz[®] was significantly shared at the household level and all family members were generally concerned by this phenomenon. Indeed, 57% of beneficiaries in Plumpy'Doz[®] group had exhausted their stock in less than 10 days, compared to only 5% of beneficiaries in the fortified infant flour group. The food assistance program encouraged beneficiaries to go regularly to the health centres (98% in the Plumpy'Doz[®] group and 100% in the fortified infant flour group).

Conclusions: This evaluation suggested the necessity to give priority to the distribution of fortified infant flour produced locally to vulnerable groups, when logistic conditions allow it. Acknowledgments: WFP funded the study.

Key words: food assistance; complementary foods; ready-to-use supplementary food, household level.

PO1113**PHYSICAL ACTIVITY PERFORMED AT EVENING TIME ALTERS CIRCADIAN RHYTHMICITY TOWARDS A LESS HEALTHY PATTERN**

P. Rubio-Sastre¹, P. Gómez-Abellán¹, A. Martínez-Nicolas¹, J.A. Madrid¹, M. Garaulet¹

¹Department of Physiology, Faculty of Biology, University of Murcia, Murcia, Spain

Background and objectives: Physical activity is one of the most important external synchronizer of our circadian system. However, to our knowledge there is no studies demonstrating which time of the day is the most adequate to perform physical activity to improve circadian system health. One of the better markers to evaluate and diagnose circadian disorders is skin temperature. For this purpose we studied the influence of physical activity at different times of the day on circadian rhythmicity in healthy women, by measuring Wrist skin Temperature (WT).

Methods: The study was conducted in 16 normal-weight women (Age: 23±4; BMI: 23.2±2.9 kg/m²). WT was measured every 10 min during three consecutive weeks. The participants performed controlled physical activity (45 minutes of continuous running) during 7 days in the morning (09:00 h) and night (21:00 h) in two different weeks and results were compared with a no exercise week (control week). Rhythmic parameters were obtained using an integrated package for temporal series analysis "Circadianware®".

Results: We found better WT rhythms when physical activity was performed in the morning than in the evening; as observed in the temperature curves (more flattened and irregular in the evening). Indeed, during the evening, the WT pattern was characterized by a higher temperature (morning: 28.08±1.68 vs. evening: 29.04±0.87; P=0.024), a less pronounced postprandial secondary peak (morning: 1.04±0.59 vs. evening: 0.41±0.47; P=0.001) and a phase delay (time of maximum temperature (morning: 04:51±01:11 vs. evening: 06:35±02:14; P=0.009). These results suggest that performing physical activity during the evening induce chronodisruption in our circadian system.

Conclusion: Physical activity trainers and clinician should recommend people to perform physical activity during the morning when possible, instead of the evening.

Key words: physical activity, circadian rhythm, evening, morning, wrist temperature.

PO1115**INFLUENCE OF DIETARY PHYTOSTEROIDS IN THE ANTIOXIDANT CAPACITY IN ELITE AND SUB-ELITE SOCCER PLAYERS.**

L. Gravina¹, F. Ruiz³, I. Bidaurrazaga¹, J. Zabala¹, A. Badiola¹, C. Granados¹, JA. Lekue⁴, J. Irazusta³, S.M. Gil¹

²Department of Nursing, School of Nursing, University of the Basque Country, Spain

³Department of Physiology, Faculty of Medicine and Dentistry, University of the Basque Country, Spain

⁴Medical Services, Athletic Club de Bilbao, Basque Country, Spain

Background and objectives: Playing a soccer match can produce hematological changes, oxidative stress and muscle damage in soccer players. Phytosteroids are phytochemical compounds with an ability to reduce blood cholesterol levels and inflammation, but their effect in athletes are still unknown. The aim of this study was to assess the influence of dietary phytosteroids in the total antioxidant status (TAS), as well as, the activity of superoxide dismutase (SOD), glutathione peroxidase (GPx), and glutathione reductase (GR) in female soccer players.

Methods: Team A (from 1st division) and Team B (from 2nd division Spanish league) participated in this study. We studied two soccer matches per each team. Both teams registered their diet intake for 8 days to analyze phytosteroids intake (phytosterols, β -sitosterol, campesterol, stigmasterol). Blood samples were obtained at rest to analyze TAS, SOD, GR and GPx activity. T-student for independent variables and Pearson's correlation were used to analyse the data (by SPSS, v.16). The significance level was set at P<0.05.

Results: Team A presented higher TAS (0.8 ± 0.2 vs 0.5 ± 0.2; p < 0.001) and GPx activity (84 ± 11 vs 68 ± 12; p < 0.001) than Team B. Moreover, Team A showed a higher intake of phytosterols (58 ± 38 vs 38 ± 27; p < 0.001) and β -sitosterol (38 ± 22 vs 18 ± 15; p < 0.001) than Team B. We found that GPx activity is significantly correlated to phytosterols intake (r=0.410; p < 0.001) and β -sitosterol intake (r=0.425; p < 0.001).

Conclusions: There are differences between elite and sub-elite team in the dietary phytosteroids consumption. Moreover, elite team presented better antioxidant capacity than sub-elite team at rest. The correlations found seem to predict that specific phytosteroids may enhance the GPx activity in soccer players which could reduce oxidative stress.

Key words: phytosteroids, soccer, antioxidants.

PO1116**DIET AND ACADEMIC PERFORMANCE AMONG NORWEGIAN ADOLESCENTS***T.H. Stea¹, M.K. Torstveit¹*

¹Department of Public Health, Sport and Nutrition, Faculty of Health and Sport Sciences, University of Agder, Norway

Background and objectives: While healthy diet is generally assumed to be important for good school performance, there has been little research on this topic among adolescents. This cross-sectional study examined the association between diet and academic performance among adolescents in Norway.

Methods: The study included 2451 out of 2653 eligible students, 15-17 years old, from 17 different high schools in the southern part of Norway (participation rate= 92.4%). The students filled in a questionnaire with food frequency questions of selected healthy (e.g. fruits and berries, vegetables, juice) and unhealthy food items (e.g. sweets, soft drinks and potato chips), questions of meal frequency, and questions regarding school grades. Logistic regression models were adjusted for sex, BMI and parental education.

Results: Regular intake of breakfast (OR: 1.92 (1.50-2.45), $p = 0.001$) and lunch (OR: 1.39 (1.50-1.76), $P=0.006$) was significant associated with increased odds of high academic grades. A high intake of healthy foods, such as vegetables (OR: 1.33 (1.01-1.74), $p = 0.044$), fruits and berries (OR: 1.49 (1.14-1.93), $p = 0.003$), was also significantly associated with increased odds of high academic grades. At the same time, a high intake of sugar-sweetened soft drinks (OR: 0.50 (0.39-0.65), $p = 0.001$), diet soft drinks (OR: 0.67 (0.45-0.99), $p = 0.044$) and salted snacks (OR: 0.59 (0.42-0.85), $p = 0.004$) was significantly associated with decreased odds of high academic grades.

Conclusions: These findings show that having a regular meal pattern and healthy food intake is associated with increased odds of high academic grades in Norwegian adolescents.

Key Words: diet, meal pattern, academic performance, adolescents.

PO1117**SHIFTING PARADIGMS OF CHILDHOOD HUNGER, MALNOURISHMENT, AND OBESITY: A HISTORICAL POLICY ANALYSIS OF SCHOOL-BASED NUTRITION IN THE UNITED STATES***C. Tran¹*

¹University of Washington, USA

Background and objectives: In 1946, the United States enacted the National School Lunch Act (NSLA) in response to the rising number of malnourished American children. NSLA created the National School Lunch Program (NSLP) to provide free or low-cost school meals to qualified students. Research played a major role in the enactment, expansion, and evolution of school nutrition. Although the NSLP is permanently authorized, it undergoes reauthorization every five years to adapt policy to population needs and trends. The paper examines the role of research in advancing and informing school nutrition policy overtime and provide context to complex policies.

Methods: The paper organizes the research and legislative history of NSLP in three major time periods across 1946-2010. The analysis uses a modified policy streams model from John W. Kingdon (1984) as a framework to explain policies development when three "streams" (problem, policy, and politics) converge to create what is called a policy window. An addition, this model includes research as a fourth stream to explore how research influences policy. These windows provide groups and individuals, known as "policy entrepreneurs," with opportunities to change policies.

Results: Historical analysis of each time period highlights policy changes in each of the four streams, providing important details of how research was used by policy entrepreneurs to shape school nutrition policy. Across each period, hunger emerged as a primary policy target, while social and political climates encouraged major policy shifts: malnourishment motivated policy enactment in 1946, poverty drove policy expansion in 1966, and rising rates in childhood obesity influenced programmatic quality improvement in 2010.

Conclusions: Nutrition science is a developing and diverse field that historically and presently influences the school nutrition policy agenda. Alignment is needed between applied nutrition science and school nutrition policy.

Key words: school nutrition, policy streams model, policy development, periodization, United States.

PO1118**EFFECT OF A 12-WEEK RESISTANCE EXERCISE INTERVENTION ON CIRCULATING TOTAL IGF-I IN ELDERLY PEOPLE: RELATIONSHIPS WITH DIETARY INTAKE AND LEAN BODY MASS**

I. Thorsdottir¹, A. Arnarson¹, O G. Geirsdottir¹, A. Ramel¹, K. Briem², P V. Jonsson³

¹Unit For Nutrition Research, Faculty of Food Science And Nutrition, University of Iceland And Landspítali-University Hospital, Reykjavik, Iceland

²Department of Physical Therapy, Faculty of Medicine, University of Iceland, Reykjavik, Iceland

³Department of Geriatrics and Icelandic Gerontological Research Center, Landspítali - University Hospital & Faculty of Medicine, University of Iceland, Reykjavik, Iceland

Background and objectives: Insulin-like growth factor-I (IGF-1) is a hormone that is associated with preservation of muscle mass. Levels of IGF-I decline with age, which is thought to make elderly people more susceptible to developing sarcopenia, the age-related decrease in muscle mass. Resistance training is considered an effective strategy to maintain and increase muscle mass in elderly people. However, the effect of resistance training on levels of IGF-I is unclear, with previous studies giving conflicting results. The aim of the current study was to investigate the effect of progressive resistance training on levels of total serum IGF-I in 208 elderly Icelandic volunteers (65-91 years old).

Methods: Participants exercised three times per week and followed an exercise program designed to increase muscle mass and strength of all major muscle groups. Fasting serum total IGF-I was measured at the start and at the end of the study.

Results: Despite significant gains in lean body mass (2%) and strength (11%), levels of total IGF-1 decreased significantly during the study period (-5.4%, $p < 0.001$). However, there was considerable inter-individual variability, as IGF-I decreased in 59% of participants and increased in 39%. The change in IGF-I was inversely correlated with baseline protein intake (g/kg) and change in lean body mass, even after controlling for the effect of baseline IGF-I levels, gender, and/or energy intake.

Conclusion: 12-week resistance training causes an overall decrease in total serum IGF-I concentration in elderly people.

Key words: IGF-I, exercise, resistance training, lean body mass, elderly.

PO1119**CHANGED DIET IN INFANCY AND ASSOCIATION WITH BMI AT 6 YEARS: TWO PROSPECTIVE POPULATION BASED STUDIES 1995-2002 AND 2005-2012**

B. Thorisdottir¹, I. Gunnarsdottir¹, A V. Thorisdottir¹, G I. Palsson², T I. Halldorsson¹, I. Thorsdottir¹

¹Unit For Nutrition Research, Faculty of Food Science And Nutrition, University of Iceland And Landspítali-University Hospital, Iceland

²Children´s Hospital, Landspítali-University Hospital, Reykjavik, Iceland

Background and objectives: Our former study showed a high protein intake in infancy associated with higher body mass index (BMI) at 6-years (6-y) in boys. Icelandic infant dietary recommendations were revised 2003, emphasizing prolonged breastfeeding and limited cow's milk, preferring formula instead of cow's milk. The objective was to assess the effects of the revision on infants' protein intake and possible long-term effects on BMI at 6-y.

Methods: Two prospective randomly selected nationwide infant cohorts, investigated prior to and after the revision of the infant dietary recommendations were recruited and studied until 12 months and again at 6 years. Subjects were 90 and 170 children born in 1995-6 and 2005, respectively. Dietary intake at 9 and 12 months was assessed by weighed food-records. Height and weight from birth to 12 months and at 6 years were measured.

Results: The main milk product consumed at ages 9 and 12 months shifted from cow's milk in the former cohort to formula with lower protein content in the latter. Protein intake was significantly lower in the latter cohort, 11.9% energy (E%) vs 14.4E% ($p < 0.0001$) at 9 months and 14.6E% vs 15.6E% ($p = 0.02$) at 12 months. Despite similar average BMI, fewer children were overweight (including obese) in the latter cohort, 12% vs 21% ($p = 0.045$). Cow's milk and protein intake at 12 months were found to be positive predictors of BMI at 6-y.

Conclusion: Emphasis made in the revised infant dietary recommendations from 2003 resulted in lower intake of cow's milk and subsequent lower protein intake in the latter half of the first year. Changes in infant diet on the population level might have contributed to the downwards trend in BMI at 6-y and lower overweight prevalence in the latter cohort than the former.

Key words: infant, proteins, BMI, overweight, child.

PO1120**PROTEIN SOURCES IN INFANCY AS PREDICTORS FOR BODY MASS INDEX AND IGF-1 CONCENTRATION AT THE AGE OF 6 YEARS**

B. Thorisdottir¹, I. Gunnarsdottir¹, G.I. Palsson², T.I. Hall-dorsson¹, I. Thorsdottir¹

¹Unit For Nutrition Research, Faculty of Food Science And Nutrition, University of Iceland And Landspítali-University Hospital, Iceland

²Children's Hospital, Landspítali-University Hospital, Reykjavik, Iceland

Background and objectives: High protein intake in infancy has been associated with growth and higher body mass index (BMI) in childhood. It has been suggested that animal protein has a stronger association with growth than vegetable protein has and that the effects are mediated via insulin-like growth factor 1 (IGF-1). The objective of this study was to investigate the association between total protein intake as well as protein from various dietary sources at the age of 12 months and BMI and IGF-1 at 6 years.

Methods: Subjects were 137 children studied from birth to 6 years of age. Dietary intake at 12 months was assessed by three day weighed food records. Information about height and weight during the first year of life and at 18 months and 6 years was gathered. IGF-1 was measured at 6 years of age.

Results: Children in the highest quartile of animal protein intake at 12 months (consuming >11.9E% as animal protein) had higher BMI at 12 months (0.7 (0.0, 1.3) kg/m²), 18 months (0.7 (0.1, 1.3) kg/m²) and 6 years (0.8 (0.2, 1.4) kg/m²) than children in the lowest quartile (<7.7E% from animal protein). Dairy protein intake at 12 months was a positive predictor of IGF-1 at 6 years for girls (5.4 (2.5, 8.2) µg/l), independent of current height or weight.

Conclusions: Our study supports the hypothesis that the association between high intake of total protein and higher BMI in childhood is rather related to high intake of protein from animal sources than vegetable sources. Furthermore, the study suggests that high protein intake from animal sources, especially dairy, at 12 months predicts increased IGF-1 concentration at the age of 6 years in girls.

Key words: animal protein, infant, BMI, insulin-like growth factor 1, child.

PO1121**ENERGY INTAKE AND EXPENDITURE AND BASAL METABOLISM IN PREGNANT ADOLESCENTS FROM NITERÓI, RIO DE JANEIRO, BRAZIL**

E. Sally¹, V. Wahrlich¹, L. Anjos¹, B. Silva¹

¹Laboratório de Avaliação Nutricional e Funcional, Departamento de Nutrição Social, Universidade Federal Fluminense, Brazil

Background and objectives: Adolescence is marked by rapid complex biological, psychological and social changes in a growing subject. Pregnancy during adolescence is an additional challenge due to inadequate dietary patterns observed in this period of the lifecycle. Prenatal dietary assessment during pregnancy is important for screening and determination of energy requirements to provide healthy gestational body mass gain. The objectives of this study were to assess energy intake (EI), energy expenditure (EE) and to identify underreporting of EI based on its ratio to measured basal metabolic rate (BMR).

Methods: A total of 43 low-income pregnant adolescents (13-19 year of age) recruited from municipal primary care units of Niterói, Rio de Janeiro, Brazil, participated in this cross-sectional study. The distribution of girls by trimester was: first (7), second (22) and third (14). EI and EE were assessed by 24-hour dietary and physical activity recalls. EE was computed from MET codes described in the Compendium of Physical Activities. BMR was measured by indirect calorimetry (M) and also estimated by the FAO/WHO recommended equations (Schofield - SCH). Goldberg's index (EI/BMR) of 1.35 was used to assess EI underreporting.

Results: Mean (SD) EI and M BMR were 2423.5 (736.6) and 1291.5 (200.4) kcal/day. BMR estimated by SCH was significantly higher 1465.5 (157.7) kcal/day. EI underreporting was 16.3 and 34.9% for M and SCH BMR, respectively. EE was 1874.7 (404.4) kcal/day. The adolescents performed sedentary low intensity activities most of the day.

Conclusions: The data indicate that both the EI and EE varied widely among pregnant adolescents. The use of FAO/WHO predicted BMR can lead to overestimation of energy needs of Niteroian pregnant adolescents.

Key words: Energy intake, Brazil, Basal metabolism, Pregnancy in adolescence

⁵Paediatrics Departments, University of Granada, Granada, Spain

Background and objectives: the immune system during pregnancy is the result of a mixture of signals and responses from both the maternal and the fetal-placental immune systems. The aim of this study was to evaluate possible lymphocyte subset changes during the pregnancy period.

Methods: two hundred and forty-five pregnant women (aged 18-45 y) were recruited. The percentage of lymphocyte subsets CD3+ (T cells), CD4+ (helper T cells), CD8+ (cytotoxic T cells), CD3-CD16+CD56+ (NK) and CD19+ (B lymphocytes) was measured at 24th, 34th of gestation, at delivery and 24 weeks after delivery. The CD4+/CD8+ ratio was calculated. Changes over time were analyzed with repeated measures ANOVA, with repeated factor, pregnancy weeks. Post hoc comparisons were performed with Bonferroni (or Paired T test) between time points.

Results: A significant effect of the pregnancy weeks was observed on CD3+, CD8+, CD3-CD16+CD56+ cell percentages and the CD4+/CD8+ ratio ($p < 0.05$, except for CD3+ [$p < 0.001$]). CD3+ and CD8+ cell percentages showed a significant decrease at 24 weeks after delivery compared to 34th week. In addition, CD3+ showed also a decrease at delivery in comparison with 34th week. Moreover, NK cell percentage and CD4+/CD8+ ratio showed significantly higher values at 24 weeks after delivery in comparison with these values at 34th week ($p < 0.05$). CD4+ and CD19+ cell percentages remained unmodified during the whole follow-up.

Conclusions: During this follow-up, the lymphocyte pattern was different especially between 34th weeks of pregnancy and 24 weeks after delivery. However, it is necessary to further study some confusion factors, such as BMI and age to elucidate other possible changes of the immunocompetent cells during pregnancy and 6 months after delivery.

Key words: pregnancy, lymphocyte subsets, follow-up. These results are part of the PREOBE study, funded by Consejería de Innovación, Ciencia y Empresa de la Junta de Andalucía. (PO6-CTS-02341). Spain.

PO1123

FACTORS INFLUENCING DIETARY INTAKE AND NUTRITIONAL STATUS OF PRE-SCHOOL CHILDREN RESIDING IN THE SOUTHERN TOWNSHIP OF GAUTENG, SOUTH AFRICA

T. Nyathela¹, W. Oldewage-Theron²

¹Centre of Sustainable Livelihoods, Vaal University of Technology, South Africa

Background and objectives: This study was carried out in the previously disadvantaged township of Southern Gauteng, South Africa. The purpose of the study was to evaluate the factors influencing the dietary intake and nutritional status of pre-school children dwelling in Southern township of Pretoria.

Methods: This was a cross-sectional study conducted on 100 purposively selected pre-school children aged 1 to 6 years. The measurements included: Socio-demographic questionnaire, 24-hour recall, anthropometric measurements (Height, weight and Mid Upper Arm Circumference -MUAC-). Initially Caregivers/ parents assisted with the completion of socio-demographic and 24-hour recall questionnaires. Statistical Package for Social Sciences (SPSS) was used to analyze socio-demographic data, South African Medical Research Council FoodFinder® program was used to analyze dietary intake, WHO Growth standards (2007) was used to analyze anthropometric measurements (height and weight), and UNCEF colour coded child MUAC tape was used to analyze MUAC.

Results: Socio-demographic results reported that 94 % of the caregivers were young women between the age of 20 and 35 years (69%). Majority (82%) of the caregivers had medium to high level education ranging from standard 8 to 10. Eighty four percent of the caregivers were unemployed with the monthly household income of less than R2500. Dietary intake results indicated that children consumed mainly carbohydrates-rich food and did not meet 100% of the Daily Recommended Intake (DRI) in the majority of the nutrients. Stunting (19.9%), wasting (16.7%) and underweight (3.2%) were prevalence, on the other hand MUAC reported that 4% were moderately malnourished.

Conclusion: Poor social background is still a main factor influencing negatively on the dietary intake and the nutritional status of the pre-school children. Prevalence of malnutrition can be eradicated through various sustainable nutrition programmes.

Key words: Social background, dietary intake, nutritional status, pre-school children.

PO1124**DETERMINATION OF NUTRITIONAL STATUS OF TRAINED WRESTLERS IN AYDIN WRESTLING TRAINING CENTER***F. Tamer¹, N. Ersoy¹, A. Çakmak¹, N. Uçar¹*¹Hacettepe University, Ankara, Turkey

Background and objectives: Wrestling is a sport of strength, endurance, balance, speed and intelligence. Nutrition is very important for wrestling athletes because it is being done according to weight categories. Because they compete in different weight categories, changes in their body weights occur largely. Well-nutrition in wrestlers is crucial because it provides adequate energy and balanced nutrients to increase athletic performance, to manage weight control and replace lost fluids. This study is conducted to evaluate the nutritional status of wrestlers who are exposed to body weight changes.

Methods: 36 wrestlers participated in this study (11-17 years old). General nutrition habits, anthropometric measurements were evaluated with a questionnaire. Individual food records during 3 days was evaluated by the program Nutrition Information System (BEBIS 6.1). For statistical analyses, SPSS 15.0 statistical package program was used.

Results: The mean values of age is 13.6 ± 1.5 years, the average height is 150 ± 10 cm and the average weight is 49.5 ± 16 kg. None of the participants use ergogenic aids. 16.7% use sports and/or energy drink, 16.6% of them use 1-2 times in a week, 83.4% of them use 1 in a month. While 88.9% of participants body weight change before and after the sports season, 11.1% do not change. 68.8% of participants who lose weight have fatigue, 3.1% of them have attention deficit, 12.5% have speed fall and 15.6% of them lose muscle strength.

Conclusions: Concentration and attention is important in every sport game. One of the most important factor is adequate and balanced nutrition. In studies, morbidity and disability rates in well nourished athletes are determined to be less than the malnourished athletes. Protection of body weight is required for the maintenance of health.

PO1126**CONSUMPTION OF FRUITS AND VEGETABLES AMONG ROMANIAN SCHOOL CHILDREN***L M. Lotrean¹, I. Tutui²*¹Department of Hygiene, University of Medicine And Pharmacy, Cluj-Napoca, Romania²Medisprof, Cluj-Napoca, Romania

Background and objectives: The healthy nutrition guidelines proposed by international research institutes and World

Health Organization recommend a daily intake of fruits and vegetables of a minimum 400 g, representing 5 servings/day (each serving having around 80 g). Moreover, the recommendations underline the importance of consuming both fruits and vegetables daily, preferably at least 2 portions of fruits and 3 portions of vegetables per day. The present study aims to identify the individual and familial factors which influence fruits and vegetables consumption among Romanian children.

Methods: A cross-sectional study by means of anonymous questionnaires was performed among 361 school children aged 11-14 from Cluj-Napoca, Romania (April-May 2011).

Results: The recommendations regarding fruits and vegetable intake were respected by 44.6% 9.1% of the children, respectively. Knowledge regarding the recommended number of daily servings and higher self-efficacy in eating fruits and vegetables every day were positively associated with higher consumption of fruits and vegetables. Fruits preference also influenced positively the consumption of fruits. The familial factor associated with vegetables intake was the perceived behavior of mother, while fruits intake was higher among children who declared higher fruits availability at home.

Conclusions: Nutrition interventions addressing the determinants of fruits and vegetables intake identified by this study should be developed for Romanian children.

Key words: fruits and vegetables; Romania; health promotion.

PO1127**PREVALENCE OVER ONE YEAR OF ABNORMAL VITAMIN B12 AND BLOOD LIPIDS RELATED BIOMARKER VALUES IN SPANISH INSTITUTIONALIZED ELDERLY***G. Palacios^{1,2}, U. Albers¹, R. Pedrero-Chamizo¹, F.J. Fuentes¹, A. Melendez¹, K. Pietrzik³, M. Gonzalez-Gross^{1,2}*¹Department of Health And Human Performance, Faculty of Physical Activity And Sport Sciences, Technical University of Madrid, Madrid, Spain²CIBER: CB12/03/30038 Fisiopatología de la Obesidad y la Nutrición, CIBERobn, Instituto de Salud Carlos III (ISCIII), Spain³Department of Nutrition and Food Technology, Rheinische Friedrich-Wilhelms Universität, Bonn, Germany

Background and objectives: To follow-up vitamin B12 and lipids status is essential in elderly since they are closely related to non-communicable diseases risk factors. Objective: To analyze the evolution of biomarkers associated to vitamin B12 and blood lipids and to quantify the prevalence of abnormal

values for each biomarker, over one year, in institutionalized elderly.

Methods: Sixty subjects, mean age (\pm SD) 84 ± 7 years (68% women), were recruited from three old people's homes in the region of Madrid (Spain). Blood samples were obtained four times over a year (at month 1, 5, 9 and 13). To study biomarker mean concentrations evolution along the follow-up period, a mixed model statistics was applied by using SPSS software (v.19.0). Statistical significance was defined as $P < 0.05$.

Results: Concerning biomarkers related to vitamin B12 status, prevalence of abnormal values at month 1 and 13 were as follows: serum total homocysteine (63%/68%), serum folate (69%/47%), serum holotranscobalamin (33%/24%), serum cobalamin (10%/12%) and RBC folate (3%/10%). In spite of these prevalence variations, only mean serum cobalamin (299 vs 273 pmol/L) decreased and mean serum folate increased (14.9 vs 16.3 nmol/L) (both $p \leq 0.05$). For biomarkers related to lipids, the prevalences of value out of reference range were for total-cholesterol (30%/38%), HDL (13%/22%), LDL (33%/38%), triglycerides (10%/20%) and lipoprotein A (52%/53%).

PO1128

INFLUENCE OF VITAMIN D SUPPLEMENTATION ON VITAMIN D STATUS AND BONE MASS DURING LACTATION- DOUBLE BLINDED RANDOMIZED CONTROL TRIAL

J. Czech-Kowalska¹, J. Latka-Grot¹, D. Bulsiewicz¹, M. Jaworski², P. Pludowski², B. Chazan³, B. Pawlus³, G. Wygledowska⁴, A. Zochowska⁵, M. Kornacka⁶, E. Kryskiewicz², E. Karczmarewicz², A. Pleskaczynska¹, A. Dobrzanska¹

⁴Department of Neonatology, Miedzyleski Specialistic Hospital, Warsaw, Poland

⁵Department of Neonatology, Public Hospital, Otwock, Poland

⁶Department of Neonatology, Warsaw Medical University, Hospital of Anna Mazowiecka, Warsaw, Poland

Background and objectives: Optimal vitamin D intake for lactating women remains controversial. We hypothesized that

1200IU/d (vs. 400IU/d) of vitamin D during breastfeeding will enhance maternal vitamin D status and bone mass.

Methods: 174 healthy mothers after term, delivery were randomized to receive vitamin D3: 1200IU/d (800 IU/d + 400IU/d from multivitamins) or 400IU/d (placebo + 400 IU/d from multivitamins) during 6 months of lactation. Serum 25-hydroxyvitamin D (S-25-OHD), parathormone (PTH) and densitometry (DXA, Lunar Prodigy) were performed after delivery (V0), 3 (V1) and 6 months later (V2). Serum and urinary calcium were assessed at V1 and V2.

Results: 137 women (1200IU/d (n=70), 400IU/d (n=67)) completed the study. Baseline S-25-OHD and anthropometric measurements were similar among groups. Median S-25-OHD increased from 13.65 ng/ml to 25.7ng/ml ($p < 0.0001$) and from 16.1 ng/ml to 24.5 ng/ml ($p < 0.0001$) in the study groups, respectively. S-25-OHD was higher in 1200 IU/d group at V1 (25.7ng/ml vs 24.5ng/ml; $p = 0.049$) and V2 (25.6 ng/ml vs. 23.1 ng/ml; $p = 0.008$), respectively. Vitamin D deficiency (S-25-OHD < 20 ng/ml) rate was similar in both groups at V0 (71.4% vs. 64.2%, $p = 0.005$) but lower in 1200IU/d group at V1 (8.57% vs 23.9%, $p = 0.009$) and at V2 (14.3% vs 28.4%, $p = 0.028$). S-25-OHD > 30 ng/ml was not significantly different by group at any time point. PTH decrease from 28.6 pg/ml to 22.1 pg/ml ($p < 0.0001$) and from 30.4 pg/ml to 23.3 pg/ml ($p < 0.0001$) between V0 and V1 in study groups, respectively. There were no differences between groups in PTH, calcemia, calciuria, fish consumption, UVB exposure, bone mass nor decrease of bone mass at any time points.

Conclusions: Vitamin D supplementation at a dose 1200IU/d is sufficient to maintain S-25-OHD > 20 ng/ml among majority of lactating women but not effective in achieving S-25-OHD > 30 ng/ml and reducing bone mass loss during lactation.

Key words: vitamin D deficiency, lactation, bone mass. Clinical Trials: NCT01506557; Financial support: Nutricia Foundation.

PO1129**THE VALUE OF THE SUBJECTIVE MNA ITEMS IN THE MNA TOTAL SCORE IN ELDERLY NURSING HOME RESIDENTS**

R. Serrano Urrea¹, M J. García Meseguer¹, R M. Iglesias Llopart², L L. Arenas Tébar³, F. Cervera Burriel⁴, C. Vico García⁵

¹University of Castilla-La Mancha, Spain

²General Hospital, Health Service of Castilla-La Mancha, Tomelloso, Ciudad Real, Spain

³Núñez de Balboa Nursing Home, Health Service of Castilla-La Mancha, Albacete, Spain

⁴Faustino Cervera Burriel. Health Service of Castilla-La Mancha. Motilla del Palancar, Cuenca, Spain

Background and objectives: The prevalence of malnutrition in institutionalised elderly people is generally high and it is essential to know the nutritional status in order to establish action policies. The Mini Nutritional Assessment (MNA) is a useful screening tool to detect malnutrition among elderly people. The MNA classifies individuals as “malnourished”, “at risk of malnutrition” and “well nourished” and it consists of eighteen items structured in four parts: anthropometric assessment, global assessment, dietary assessment and self assessment. The impact of each item or set of items on the total score allows us to know the value of them as indicators of the nutritional status. The objective of this survey was to study the value of the two subjective MNA items (“self-view of nutritional status” (SNS) and “self-view of health status” (SHS)) as indicators of the nutritional status according to the MNA total score.

Methods: A Cross-sectional study was conducted on a sample of 895 residents, aged 65 or older, living in 34 nursing homes located the province of in Albacete (Spain). Correlations between the subjective MNA items and MNA total score were assessed by Spearman’s correlation. Stepwise multiple linear regression analysis was used to assess the MNA items as predictors of the nutritional status by the MNA.

Results: Positive significant correlations between the SNS and SHS with the full MNA were found, $r=0.39$ ($p < 0.001$) and $r=0.49$ ($p < 0.001$), respectively. When two questions were considered together the correlation coefficient was $r=0.58$ ($p < 0.001$). The stepwise linear regression showed that eight questions (among the eighteen MNA items) were able to explain 91% of the MNA variability and the two subjective questions were within them.

Conclusion: The subjective MNA items can be the first indicators of the nutritional status in a rapid screening in elderly institutionalized population.

Key words: Mini Nutritional Assessment (MNA), elderly, nursing home.

PO1130**ENVIRONMENTAL FACTORS ASSOCIATED WITH OVERWEIGHT IN BRAZILIAN PRESCHOOL CHILDREN.**

J A. Silveira¹, M. Cocetti¹, F A. Colugnati², J A. Taddei¹

¹Departament of Pediatrics, Universidade Federal de São Paulo, São Paulo, São Paulo, Brazil

²Division of Nephrology, Universidade Federal de Juiz de Fora, Juiz de Fora, Minas Gerais, Brazil

Background and objectives: In Brazil, there were an increase of overweight among under-five years old children in the last three demographic and health surveys (DHS) conducted in 1989, 1996 and 2006. Such improvement in the overweight prevalence was due to a 2.5-fold increase among preschool children in the same period, since there was a decline in the overweight among infants. Therefore, our aim was to identify and quantify environmental factors associated to the overweight among Brazilian preschool children.

Methods: Data was from the latest Brazilian Demographic and Health Survey-2006/07. We selected children between 23-60 months ($n=2908$), living in the same house with their mothers. Overweight was defined using the WHO Growth Charts 2006 as weight-for-height z-score $<+2$ SD. Multivariate models were used to estimate the prevalence ratio and their respective 95% confidence interval (PR[95%CI]) of environmental factors associated with overweight.

Results: Prevalence of overweight among preschool children was 8.0%. We observed higher overweight prevalence among the richest Brazilian regions (10.6%), families with high purchasing power (9.9%), with more than two TVs at home (10.5%). Among those children born with more than 3.5 kg and having up to one brother the prevalence of overweight at survey was 10.4% and 9.7%. From those variables significantly associated with overweight in the bivariate analysis, the independent factors associated in the final fitted model were: living in the richest Brazilian regions (1.53 [1.16-2.02]), families with high purchasing power (1.51 [1.10-2.08]), birth weight higher than 3.5 kg (1.53 [1.17-2.00]) and having up to one brother (1.70 [1.23-2.35]).

Conclusion: We identified that overweight among preschool children in Brazil is associated with factors related to region’s or family’s wealth. Acknowledgement: Silveira JA receives a scholarship from Fundação de Amparo à Pesquisa do Estado de São Paulo.

Key words: Infants; Overweight; Surveys.

PO1131**EXCLUSIVE BREASTFEEDING FOR 4 VERSUS 6 MONTHS AND GROWTH IN EARLY CHILDHOOD**

O H. Jonsdottir¹, R E. Kleinman², J C. Wells³, M S. Fewtrell³, P L. Hibberd⁴, G. Gunnlaugsson⁵, I. Thorsdottir¹

³Childhood Nutrition Research Centre, UCL Institute of Child Health, London, UK

⁴Division of Global Health, Massachusetts General Hospital for Children, Harvard Medical School, Boston, USA

⁵Directorate of Health and Reykjavik University, Iceland

Background and objectives: Studies are inconsistent about whether duration of exclusive breastfeeding is protective of overweight and obesity later in life. Existing evidence on this relationship is based on observational studies with a risk of bias from confounding variables. The aim of the study was to investigate the effect of duration of exclusive breastfeeding on weight gain and the risk of being overweight in later infancy and early childhood.

Methods: A total of 119 mother-infant pairs were randomized to either receive complementary foods from the age of 4 months in addition to breast milk (CF), or to be exclusively breastfed to 6 months (EBF). Each infant's weight, length and head circumference were measured at birth, 6 weeks, 3, 4, 5 and 6 months of age. In the follow-up, the children's weight, length and head circumference were measured at 8, 10, 12 and 18 months and infant's weight and height at 29–38 months. All anthropometric measurements were converted to z scores using the WHO Child Growth Standards.

Results: A difference was seen between groups in gain in length from 4-18 months of age, where infants in the CF group (-0.17 ± 0.84) had significantly greater gain in length compared with the EBF group (-0.51 ± 0.84 ; $p = 0.05$). However, no difference was seen in the prevalence between groups in risk of being overweight or those who were overweight at 18 months and 29-38 months of age.

Conclusions: The differences in length seen between the two groups in later infancy to 18 months of age remain to be explained and may be a result of differences in dietary intake between groups. Exclusive breastfeeding for 4 or 6 months does not seem to affect risk of being overweight or the prevalence of those who were overweight or obese in early childhood.

Key Words: Breastfeeding, complementary feeding, growth.

PO1133**EUROPEAN ADOLESCENTS CONSUMING BREAKFAST REGULARLY HAVE HIGHER PLASMA 25-HYDROXYVITAMIN D CONCENTRATIONS AND LESS BODY FAT PERCENTAGE THAN BREAKFAST SKIPPERS.**

Background and objectives: Breakfast skipping is an unhealthy behaviour that often occurs during adolescence and could have negative consequences on nutrient status and global health. As low 25-hydroxyvitamin D [25(OH)D] concentrations have been identified in European adolescents of the HELENA study, the aim of the present work was to find out whether there is an association between breakfast consumption and vitamin D status and body composition in adolescents.

Methods: From a subsample of 1006 adolescents (470 males; 46.8%) of the HELENA Cross Sectional Study with an age range of 12.5 to 17.49 years fasting blood samples were taken. Plasma 25(OH)D was analyzed by ELISA. Body mass index (BMI) was calculated from weight and height, and body fat percentage by means of the Slaughter formula. Breakfast consumption was obtained from a validated questionnaire. Descriptive statistics and ANOVA test controlling by age and sex were performed using SPSS 19.0. The level of significance was set at $p < 0.05$.

Results: There were 30.5% of adolescents who slightly, moderately or strongly agreed to skip breakfast. The results showed that the prevalence of eating breakfast almost everyday was lower in girls (43.0%) than in boys (55.5%). Adolescents consuming breakfast almost every day had significantly higher levels of 25(OH)D (61.43 ± 1.26 nmol/l) than those skipping breakfast (55.67 ± 1.25 nmol/l), after controlling by age and sex ($p < 0.01$). Moreover, those skipping breakfast and having low vitamin D status presented significantly higher body fat percentage and BMI (25.45 ± 0.77 and 22.16 ± 0.29 , respectively) than breakfast consumers with higher vitamin D status (22.41 ± 0.51 and 20.76 ± 0.19 , respectively) ($p < 0.01$) after controlling by age and sex.

Conclusions: Adolescents eating breakfast almost every day had higher vitamin D levels and lower percentage of body fat and BMI than those adolescents not regularly eating breakfast.

Key words: Breakfast, vitamin D, fat mass, adolescence.

PO1134

PRENATAL LIPID-BASED NUTRIENT SUPPLEMENTS INCREASE CORD LEPTIN CONCENTRATION IN PREGNANT WOMEN FROM RURAL BURKINA FASO

L. Huybregts¹, D. Roberfroid², H. Lanou³, P. Kolsteren², J. Van Camp¹

¹Department of Food Safety and Food Quality, Ghent University, Belgium

²Department of Public Health, Institute of Tropical Medicine, Belgium

³Department of Biomedical sciences and Public Health, Institut de Recherche en Sciences de la santé, Burkina Faso

Background and objectives: In developing countries, prenatal lipid-based nutrient supplements were shown to increase birth size, however the mechanism of this effect remains unknown. Cord blood hormone concentrations are strongly associated with birth size. Therefore, we hypothesize that lipid-based nutrient supplements increase birth size through a change in the endocrine regulation of fetal development. The aim of the study was to test the effect of daily prenatal lipid-based nutrient supplements (LNS) on cord blood hormone concentrations.

Methods: Umbilical cord blood samples were collected from 197 pregnant women participating in a randomized controlled trial assessing the effect of LNS on birth size in rural Burkina Faso. Insulin-like growth factors I and II, their binding proteins IGFBP-1 and IGFBP-3, leptin, cortisol and insulin were quantified in cord sera using immunoassays.

Results: LNS was associated with higher cord blood leptin mainly in primigravidae (+57%; $p = 0.02$) and in women from the highest tertile of body mass index at study inclusion (+41%; $p = 0.02$). We did not find any significant LNS effects on other cord hormone concentrations. The observed increase in cord leptin was associated with a significantly higher birth weight. Cord sera from Small-for-Gestational Age newborns had significantly lower median Insulin-Like Growth Factor I (-9 $\mu\text{g/L}$; $p = 0.003$), Insulin-Like Growth Factor II (-79 $\mu\text{g/L}$; $p = 0.003$), IGFBP-3 (-0.7 $\mu\text{g/L}$; $p = 0.007$) and leptin (-1.0 $\mu\text{g/L}$; $p = 0.016$) concentrations, but higher median cortisol ($+18$ $\mu\text{g/L}$; $p = 0.037$) concentrations compared to normally grown newborns.

Conclusions: Prenatal lipid-based nutrient supplementation resulted in increased cord leptin concentrations in primigravidae and mothers with higher body mass index at study inclusion. The elevated leptin levels could point towards a higher neonatal fat mass.

Key words: Intrauterine growth retardation - lipid-based nutrient supplements - endocrine regulation - pregnancy.

PO1135**EFFICACY OF DAILY AND INTERMITTENT SUPPLEMENTATION WITH MICRONUTRIENT POWDERS DURING 6 AND 12 MONTHS ON ANEMIA IN PERUVIAN INFANTS**

N. Zavaleta¹, D. Loza¹, P. Egoavil¹, J. Sanchez¹, R. Mosqueira¹, K. Harding², L M. Neufeld²

¹Instituto de Investigación Nutricional, Lima, Peru

²Micronutrient Initiative, Canada

Background and objectives: Anemia is highly prevalent in infants in developing countries. The aim of this study is to compare the impact of different dosing and duration schemes for micronutrient powders on anemia, and micronutrient status.

Methods: We supplemented a group of 400 infants, 6-11 months old, living in Cajamarca, in the northern highlands of Peru, with micronutrient powders containing iron, zinc, vitamin A, vitamin C and folic acid. Children were randomly assigned to 4 supplementation groups: a) 6 months daily supplementation; b) 6 months intermittent; c) 12 months daily and; d) 12 months intermittent supplementation. Supplements were provided monthly at the baby well visit. Hemoglobin and micronutrient status were measured at entry and at 6 and 12 months supplementation

Results: We found baseline anemia 72.9%, 70.7%, 73.4% and 75.8%, respectively ($p = 0.885$). At 12 months anemia was reduced to 21.1%, 30.4%, 6.4% and 8.4%, respectively ($p = 0.000$). Initial mean hemoglobin values were 116.6, 117.1, 117.0, and 115.6 g/L, respectively. At 12 months mean hemoglobin values were 127.4, 126.0, 131.0 and 129.9 g/L.

Conclusions: The results suggest that supplementation schemes with micronutrient powders for one year were more efficacious in reducing anemia than supplements for 6 months.

Key words: anemia, infants, micronutrient powders. Supported by Micronutrient Initiative, Canada.

PO1136**NUTRITIONAL CARE IN PATIENTS WITH PARKINSON'S DISEASE LEVODOPA DRUG USERS**

A I. Cruz Perez¹, F J. Montanaro Mesquita¹, M A. Macho Fische¹

¹Secretaria de Estado Da Saude de São Paulo, Brazil

Background and objectives: Parkinson is a chronic/degenerative disorder of Central Nervous System that attacks mainly the Motor System, causing tremor, muscle rigidity, slowing of movement and postural abnormalities. This disease is developed when the dopaminergic neurons of the substantia

nigra degenerate/decrease their capacity to produce dopamine neurotransmitter. This absence is responsible for the loss control movements. The most effective drug treatment is Levodopa to relieve symptoms/controls evolution of disease and propitiates better way of living. Levodopa is precursor to dopamine. It is absorbed in proximal small intestine. Some factors, such as the reduction of motility, gastric emptying, constipation, and mainly, the ingestion of food rich in protein near the time of taking the drug, reduce its absorption/invalidate its effect, so the amino acids from protein food compete for the same absorption site as Levodopa in intestine. The aim of this work is to guide the carriers Parkinson's disease who use Levodopa, so that they have an appropriate nourishment in order to the drug reach its desirable therapeutic effects.

Methods: Application of semi/opened questionnaire to carriers of Parkinson's disease to evaluate the nutritional state, analyze the interaction drug/nutrient, and perform further individual nutritional orientation at home, with the delivery and explanation of the Guide of Nutritional Orientation to carriers of Parkinson's disease and users of Levodopa drug.

Results: Among 16 participants between 47 and 80 years old, 100% consume protein food (meat, chicken, fish, milk and its derivatives). The carriers who suffer with constipation are 68.8% and 92.9% do not have the care of taking the Levodopa drug according to the recommendation. All participants, with energetic density varied from 1600/2400kcal/day, were oriented individually in food rich in fiber and suggestions of times of meals and protein amount according to the medicament. Conclusion. Nutritional orientation become primordial once interaction drug/nutrient.

Key words: Parkinson. Interaction drug/nutrient.

PO1137**NUTRITIONAL AND BEHAVIORAL PROFILE OF OBESE ADOLESCENTS IN TREATMENT BY LOW AND VERY LOW CALORIE DIETS**

¹Clínica Da Obesidade, Santos, Brazil

²Universidade Federal da Bahia, Salvador de Bahia, Brazil

Background and objectives: Obesity constitutes an important health problem in adulthood, as in childhood and adolescence worldwide, representing a major challenge to health. Obesity treatment in inpatient seeks to promote better quality of life of individuals through the implementation of healthy habits, with accompanying interdisciplinary team. This study aims to identify the behavioral and nutritional profile of adolescents in inpatient and feeding low and very low calorie diets.

Methods: It is a cross-sectional study, secondary base developed in an obesity clinic in the city of Camaçari, Bahia, Brazil. The collection of secondary data in medical records was performed in January 2013, where information was obtained demographic, clinical, anthropometric, and behavioral habits of life. The percentile for body mass index (BMI), age and sex, was used to define the anthropometric status of adolescents. Descriptive analysis was performed using SPSS statistical software.

Results: It was evaluated the records of 15 adolescents between 11 and 19 years. It was observed that 53.3% of participants were female and severe obesity was present in 66.7% of them. Most patients had cases of obesity in the family (93.3%). Of the patients, 73.3% had some comorbidity and 60% said they did not sleep well. Of those who were followed before admission by any nutritionist (86.7%), the majority responded that it not followed the guidelines of the professional (61.5%) and 81.3% reported some type of food aversion. Regarding the behavioral aspects, 40% of adolescents reported waking at night to eat, grazing behavior was present in 40% of them and 73.3% said they eat quickly during meals.

Conclusion: Important data were described to the profile of obese adolescent, stressing the need of a deeper study to understanding and rationale for new practices and treatments.

Key words: obesity, adolescents, nutritional profile, behavior.

PO1138

POSTPARTUM WEIGHT RETENTION AND NUTRITIONAL STATUS IN ADULT WOMEN ADMITTED AT HEALTH CARE UNITS IN RIO DE JANEIRO/ BRAZIL.

C V. Silva¹, M H. Hasselmann¹, I C. Joia¹

¹Institute Nutrition, State University of Rio de Janeiro, Brazil (UERJ) & Veiga de Almeida University, Brazil

Background and objectives: The objective of this study was to investigate postpartum weight retention and nutritional status in adult women admitted at four health care units in Rio de Janeiro, Brazil.

Methods: Post-partum nutritional status was calculated by body mass index (BMI) (OMS, 1995). Weight retention was calculated by subtracting the reported pre-pregnancy weight from the measured weight at each interview at the periods <1.6 and 12 months. Statistical analyses used means and a 95% confidence interval for weight retention and chi-square for categorical variables.

Results: Mean weight retention was 4.1 and 0.85 kg for underweight; 3.6 and 3.2 kg for adequate weight; 1.6 and 1.5 kg for overweight and 1.7 and 2.0 kg for obese woman at 6 and 12 months postpartum, respectively. Prevalence of overweight

and obesity was 32.9%, 46.3% and 45.2% before pregnancy, at 6 and 12 months post-partum respectively ($p < 0.005$). At 12 months post-partum, 23.1% of women gained ≥ 2 kg; 28% of adequate pre-pregnancy woman became overweight and 28.2% of overweight pre-pregnancy woman change nutritional status to obesity.

Conclusions: These findings highlight the importance of monitoring nutritional status during pregnancy and post-partum to promote women health.

Key words: post-partum weight, woman health; Maternal Nutrition.

PO1139

THRESHOLD SALT TASTE SENSIBILITY IN TEENS: RELATION TO BLOOD PRESSURE AND NUTRITIONAL STATUS

V. Kirsten^{1,2}, M B. Wagner¹, K. Sparrenberger¹

¹Universidade Federal Do Rio Grande Do Sul – Ufrgs, Brazil

²Universidade Federal de Santa Maria – UFSM, Brazil

Background and objectives: The aim was to evaluate the sensitivity thresholds salt taste (STST) in adolescents and its relation to blood pressure and nutritional status.

Methods: We conducted a cross-sectional study and the blood pressure was measured by a digital device and nutritional status by anthropometry and bioelectrical impedance. To determine the STST, were used 9 solutions of different concentrations of sodium chloride, per dropper tip of the tongue. The solutions (mmol/l) were fed increasing concentrations. Subjects were classified into normal STST (n-STST: < 30 mmol/l) and increased (i-STST: > 30 mmol/l). We evaluated 421 adolescents (55.6% female) with a mean of 15.8 ± 0.91 years.

Results: The median (P25-P75) of STST was 30 (30-60) mmol/L and 36.1% had i-STST. The prevalence of high blood pressure was 12.6% (95% CI: 9.6 to 16.1), 25.5% (95% CI: 21.38 to 29.93) of excess weight. Groups of i-STST and n-STST were compared between adolescents with high blood pressure and there was no statistically significant difference between groups ($p = 0.676$). When comparing the mean systolic (SBP) and diastolic (DBP) blood pressure between the same groups, after adjustment for sex, age, physical inactivity and body mass index (BMI), only DBP showed a statistically significant effect ($p < 0.0001$) with a difference of 2.1 mmHg (95% CI: 0.1 to 4.1) between the groups. The effect of i-STST on BMI after adjustment for sex, age and physical inactivity was not significant ($p = 0.177$).

Conclusions: No relationship was observed between i-STST and BMI and SBP, DBP only with adolescents evaluated.

Key words: Taste Thresholds. Sodium Chloride. Blood Pressure. Nutritional Status. Adolescents.

PO1140**EARLY INTRODUCTION OF ULTRA-PROCESSED FOODS IN THE FEEDING OF CHILDREN UNDER TWO YEARS**

A M. Rinaldi¹, J P O. Souza¹, C M. Azeredo¹, L A. Pereira²

¹School of Medicine, Federal University of Uberlândia, Brazil

²School of Maths, Federal University of Uberlândia, Brazil

Background and objectives: Dietary habits established in early life affect the nutritional status in all cycles of development. In recent decades, there was a change in eating patterns of children, with a decline in the consumption of cereals, fruits and vegetables and increased consumption of foods high in sugar, fat and sodium. The aim of this study is to evaluate the age of introduction of foods classified according to the type of processing in children under two years.

Methods: Cross-sectional study with 285 children enrolled in 34 Primary Health Care Centers in Uberlândia, Minas Gerais, Brazil. The food consumption was assessed by food frequency questionnaire (FFQ). Foods were classified according to the type of industrial processing, proposed by Monteiro et al (2010), in group 1: unprocessed or minimally processed foods, group 2: processed culinary and food industry ingredients, group 3: ultra-processed food products. The median age of food introduction was calculated by survival analysis, performed in statistical software R.

Results: A total of 285 children (55% boys) participated of study. The median age was seven months and most of children belonged to low income household. For Group 1 foods: rice, beans, meat, fruits and vegetables and Group 2: pasta, oil and salt the median age of introduction was 6 months. For sugar (group 2) and specific foods to children, formulas and milks ready for consumption (group 3) the median age was seven months. For sugary drinks, snacks, noodles, chocolates and candies the median age of introduction was 12 months.

Conclusions: There is incorrect introduction of foods such as milk and infant formula to replace breast milk and early introduction of sugar and other foods ultra-processed, such sugary drinks, snacks, instant noodles, chocolates. The consumption of these foods increases the risk of obesity and other chronic diseases related to nutrition.

Key words: children, ultra-processed foods, food processing.

PO1141**THE EFFICACY OF MULTIPLE MICRO NUTRIENTS SPRINKLE TO IMPROVE IRON STATUS OF ADOLESCENT GIRLS IN ISLAMIC RELIGIOUS SCHOOL - TANGERANG, INDONESIA**

M. Sitompul¹, H. Ridwan², F. Jalal³, S.A. Marliyati², R. Damanik², S. Sommerset⁴

¹School of Nutrition, Health Polytechnic Jakarta, Indonesia

²Department of Public Nutrition - Faculty of Human Ecology, Bogor Agriculture University, Indonesia

³Faculty of Medicine - University of Andalas, Padang, Indonesia

⁴School of Public Health - Griffith University, Logan Campus, Meadowbrook, Queensland, Australia

Background and objectives: Anemia is one of nutrition problems in adolescent school girls and the highest prevalence in Indonesia was found in Tangerang which was 46 – 61%. This research aimed to formulate multiple micro nutrients sprinkle (MMS) and to investigate their efficacy to improve Hb, SF and STfR levels of adolescent girls.

Methods: A randomized, double blind, placebo-control trial were conducted for 150 anemic adolescent girls, grade 9 – 12, aged 14 to 18 years old in five Islamic Religious School in Tangerang. All selected subjects were randomly allocated into 4 groups. Each group received MMS twice a week for 16 weeks containing 30 mg (Fe30 group), 25 mg (Fe25 group) and 20 mg (Fe20 group) elemental iron plus vitamins and other minerals and placebo group, respectively. One-way ANOVA and ANCOVA were applied to analyze difference in variables tested.

Results: There were no difference among the groups in compliance, nutrient intake, the changes of AGP, IL-6 and hepcidin ($p > 0.05$). A significant difference was found in the changes of Hb, SF, STfR and body iron ($p < 0.05$). After controlling with confounding variables, the changes of Hb, SF and STfR was not related to potential determinants ($p > 0.05$). The prevalence of anemia decreased into 59.4 % and 35.1% for Fe20 and control groups, respectively.

Conclusions: MMS was effectively improve Hb, SF and STfR levels and decrease the prevalence of anemia in adolescent girls and MMS contained 20 mg of elemental iron was the best to increase the iron store in anemic adolescent girls.

Key words: efficacy, multiple micro nutrients sprinkle, adolescent girls, iron status We thank to Ministry of Health, Ministry of National Education and Indonesian Danone Institute who supported grant for this research and we also thank to Fortitech Malaysia who produce sprinkle for this research.

PO3298**RANDOMIZED DOUBLE-BLIND CROSS-OVER STUDY OF A NUTRITIONAL SUPPLEMENT SPECIFIC FOR PATIENTS WITH NEURODEGENERATIVE DISEASES OVER INFLAMMATORY AND CARDIOVASCULAR RISK BIOMARKERS**

C E. Garcia-Rodriguez¹, M D. Mesa¹, M V. Martin¹, M C. Rico¹, L. Campaña¹, M. Perez-Rodríguez², A J. Perez de la Cruz³, A. Gil¹

¹Department of Biochemistry And Molecular Biology II, Institute of Nutrition And Food Technology

²VEGENAT, S.A. Research and Development Department, Pueblonuevo del Guadiana, Badajoz, Spain

³Clinical Nutrition and Dietetic Unit, University Hospital Virgen de las Nieves, Granada, Spain

Background and Objectives: An adequate nutrition could be useful in the improvement of patients with neurodegenerative diseases. The aim of this study was to assess the effects of a specific supplement for patients with neurodegenerative diseases (Supressi®) over inflammatory and cardiovascular risk biomarkers, compared with a nonspecific diet (T-Diet Plus High Protein®) when administered as enteral nutrition for three months.

Methods: 98 patients with neurodegenerative diseases were randomly divided into two groups A (n=51) and B (n=47). Subjects in group A were supplemented Supressi® for three months and a nonspecific product (T-Diet Plus High Protein®) during the next three months. Patients in group B received initially the nonspecific diet during the first three months followed by the experimental product other three months. Plasma levels of inflammatory and cardiovascular risk biomarkers were determined at baseline and after three and six months by immunoassay, with MILLiplex™ kits using the Luminex200® system based on the xMap™ technology. We examined the effect of the diets with t test for paired samples ($p < 0.050$).

Results: After receiving Supressi® for three months, there was an increase of the hormone leptin. Administration of T-Diet Plus High Protein® during three months leads to an increase of resistin along with a significant decrease in monocyte chemotactic protein (MCP)-1. Furthermore, a tendency to decrease ($p = 0.065$) was observed for soluble intercellular adhesion molecule (sICAM)-1, after ingestion of control diet.

Conclusions: The new supplement maintains plasma levels of inflammatory and cardiovascular risk biomarkers similarly to the nonspecific diet, while increases the hormone leptin involved in the regulation of food intake and energy balance, what may indicate a better nutritional status in these patients with high risk of malnutrition.

Key words: neurodegenerative diseases; nutrition; supplement.

PO3309**NUTRITIONAL STATUS OF WOMEN CONSULTANTING THE HEALTH CENTRES OF ERRACHIDIA DISTRICT IN THE SOUTH-WEST OF MOROCCO**

B. El Bouhali¹, A. Bidi¹, M. Benlyas¹, L. Hajji¹, I. Nasri²

¹Team of Nutritional Physiology and Endocrine Pharmacology, Faculty of Science and Technique, University Moulay Ismail, Errachidia, Morocco

²Laboratory of Biochemistry, Environment & Agro-alimentary URAC36, Faculty of Science and Technique, University Hassan II, Mohammedia, Morocco

Background and objectives: Nutritional status is indicator of global well-being. The aim of this study was to evaluate the nutritional status of women and analysis of household dietary diversity close to socio-economic status

Methods: Information was collected by questionnaire. The number of housewives was 168 with an average age of 27.48 ± 6.2 frequenting the health centres of Errachidia. Pregnant women 78%, nursing 15% and consultants 7%. Age was divided into 4 classes: 17-24, 25-32, 33-40 and 41-49. The food questionnaires were done by 24h dietary recall.

Results: The study population is mostly literate, 79.3% of women are literate to 20.7% illiterate women. The distribution of participants according to age groups show that women in the age group [25-32] represent the highest (43%) followed by [17-24] (36%) which shows the youthfulness of the studied sample. The quantitative estimation of vitamins A, D, E by women indicates excess consumption of vitamin E (≥ 15 mg/day) and low consumption of vitamins A and D (≤ 300 µg/day and 10 µg/day, respectively) regardless of level of education. Surveyed have inadequate intakes of some micronutrients such as iodine, calcium, zinc and copper; in this case the level of education has no statistically significant effect on the intake of some nutrients like calcium (≥ 2.5 g/day) among illiterate women. Food availabilities showed that 67% of women have a contribution in excess Kcal (≥ 2800 kcal/d) and 40% have a normal setting range between 2200 to 2800 Kcal/day. Iron deficiency anemia seems to be especially important for pregnant women (80%).

Conclusion: Food consumption is one of several factors that have contributed to improving the nutritional status observed in south-west Morocco. Among these factors, it is worth mentioning the improvement of socio-economic status and education.

Key words: Housewives, 24h recall, food availability, demographic, socioeconomic.

PO3310**INTERVAL EXERCISE IMPROVES EXERCISE TOLERANCE IN COPD PATIENTS WITH NO ALTERATIONS IN ABDOMINAL FAT DEPOSITION**

I. Giannopoulou¹, I. Koutsikos², S. Spetsioti^{1,3}, M. Vasilopoulou^{1,3}, S. Ntalapera¹, S. Spyridaki¹, I. Vogiatzis^{1,3,4}

¹Physical Education & Sports Science Dept, University of Athens, Athens, Greece

²Nuclear Medicine Dept, 401 General Military Hospital of Athens, Athens, Greece

³1st Respiratory Medicine Dept, University of Athens, Athens, Greece

⁴Clinical Exercise & Health Sciences Institute, University of the West of Scotland, Paisley, Renfrewshire, UK

Background and objectives: Abdominal obesity is an important contributor to the respiratory problems and health of chronic obstructive pulmonary disorder patients (COPD). Interval exercise has been shown to improve the exercise capacity of COPD patients. However, no studies have investigated whether interval exercise affects the abdominal fat of the patients. The purpose of this study was to investigate the effect of interval exercise on abdominal obesity in COPD patients and whether its change is related to improvements in exercise capacity.

Methods: Ten overweight COPD patients (FEV1=49.57±14.13, BMI=27.49±5.71 kg/m²) participated in a 12-week program of interval exercise (30 sec: 100% work rate max (WRmax), 30 sec: active recovery) on a cycle ergometer for 40 minutes, 3 times/week. Pre and post intervention patients completed pulmonary function tests, a 6-min walk test, a VO₂peak test and dual energy absorptiometry (DEXA).

Results: Patients had a high level of abdominal fat deposition with a mean abdominal -gluteal fat ratio of 1.09±0.12. Interval training improved exercise capacity with improvements in the 6 min walk (pre: 37±77, post: 414±35 meters, P=0.049) and the WRmax test (pre: 72±37, post: 94±33 watts, P=0.004). No significant changes in body weight and composition were found. Abdominal fat (pre: 40.58±9.96, post: 41.0±9.77%, P>0.05), gluteal fat (pre: 37.66±9.72, post: 38.23±9.16%, P>0.05) and the ratio of the two depots did not significantly change (P>0.05). No significant correlations were found between changes in fat deposition and exercise capacity. **Conclusions:** In COPD patients interval exercise training does not alter the body weight and abdominal fat deposition despite the significant improvements in exercise capacity. As with other clinical populations, it is possible that the addition of a diet program is necessary in order to reduce the body weight and abdominal obesity and possibly lead to greater improvements in these patients.

Key words: Abdominal fat, interval exercise, COPD.

PO3311**ENGAGING FATHERS AND GRANDMOTHERS TO IMPROVE MATERNAL DIETS AND INFANT AND YOUNG CHILD FEEDING PRACTICES IN WESTERN PROVINCE, KENYA**

F. Thuita¹, M. Altrena², S. Martin³

¹School of Public Health, University of Nairobi, Kenya

²Counterpart International, Washington DC, USA

³Cornell University, Div Nutritional Sciences, Ithaca, New York, USA

Background and objectives: Community programs seeking to improve the wellbeing of women and children typically target mothers with young children while grandmothers and fathers are often perceived as obstacles to change. These household members are however important influencers of mothers' infant feeding practices though they are usually perceived as maintaining cultural norms and practices, thereby providing negative social support for adoption of new practices. The purpose of the formative assessment was to generate information for use in the design of culturally relevant interventions for engagement of fathers and grandmothers to support optimal maternal, infant and young child feeding practices in a rural area in Kenya.

Methods: We conducted formative research on maternal nutrition and infant young child feeding practices and the role of mothers, grandmothers and fathers in the household and the community. We conducted 18 focus group discussions with mothers, fathers, and grandmothers and 28 key informant interviews with community leaders, health workers, religious leaders, and community health workers.

Results: Grandmothers and fathers have a positive influence on the complementary feeding practices of young children if they are engaged in culturally-relevant ways. Sub-optimal practices are influenced by cultural beliefs, food availability and knowledge levels. Diets of infants and young children are low in energy and lack variety. Feeding frequency is low and preparation and feeding methods predispose to contamination of foods. Responsive feeding is rare but forced feeding is common.

Conclusion: The family and community roles of fathers and grandmothers put them in key influential positions to positively impact infant feeding practices by supporting mothers, providing a variety of foods and encouraging mothers to practice what they have learned from health workers.

Acknowledgement: Study conducted through support provided by USAID to PATH's IYCN Project.

Key words: Fathers, grandmothers, maternal, child, nutrition.

PO3312**FLUID INTAKE IN CHILDREN AND ADOLESCENTS OF DEVELOPED CITIES IN CHINA**

S. Du¹, W. Xiaojun¹, X. Hu¹, Q. Zhang¹, L X. Lu¹, J.M. Gao¹, S.R. Zou¹, J.W. Fan¹, X.H. Li¹, G. Ma¹

¹National Institute For Nutrition And Food Safety, Chinese Center For Diseases Control And Prevention, China

Background and objectives: Body hydration is essential for adequate physical and mental function, especially in children. This study is to investigate fluid intake and describe the daily consumption of plain water and beverages of children and adolescents in the four cities of China.

Methods: A total of 5914 primary, middle school and high school students were selected from Beijing, Shanghai, Chengdu and Guangzhou using multi-stage random sampling method and 5868 subjects completed the survey. The information on the amounts and types of daily drinking water was recorded for seven consecutive days using a quantitative measurement.

Results: The average daily total drinking water of subjects was (1089-1540) ml, with significant difference among the four cities ($F=114.28$, $P<0.05$). The average daily drinking water was significantly higher in boys [(1157-1575) ml] than girls [(1026-1498) ml] ($F=78.89$; $AP<0.05$). The difference among different ages was statistically significant ($F=91.53$, $P<0.05$) with ascending order in 7-10, 11-13 and 14-17 years old [(953-1483) ml, (1134-1551) ml and (1170-1557) ml]. The average daily consumption of plain water of subjects was (744; 484) ml (68.3% of total drinking water) with statistically significant difference among the Guangzhou, Beijing, Shanghai and Chengdu [$F=113.74$, $P<0.05$]. The average daily consumption of beverages was (345-1287)ml (31.7% of total drinking water). The consumption of beverages of high school students (356; 309) ml and middle school students (360-1301)ml were higher than primary school students (328-1263)ml ($F=8.37$, $P<0.05$).

Conclusion: The daily consumption of total drinking water, including plain water and beverages is different in children and adolescents among different cities and is different in gender. The Major drinking water of primary and middle school students in four cities of China was plain water.

Key words: Children and adolescents, total drinking water intake, beverages, fluid intake.

PO3313**NUTRITIONAL STATUS OF ELDERLY PEOPLE LIVING AT HOME IN SIDI-BEL-ABBES (WEST ALGERIA)**

M B. Khaled¹, M. Norredine², B. Merrakchi³, S. Belbraouet⁴

¹Departement of biology, Faculty of Natural and Life Sciences, Djilali Liabes University of Sidi-Bel-Abbès, Algeria

²Departement of biology, Faculty of Natural and Life Sciences, Djilali Liabes University of Sidi-Bel-Abbès, Algeria

³Department of General Medicine of Sidi Lahcen Health Center (Sidi-bel-Abbes), Algeria

⁴University of Moncton, Ecole des Sciences des Aliments de Nutrition et des Etudes Familiales Moncton, Canada

Background and objectives: The aim of the study was to assess the nutritional status of a cohort of elderly people living independently at home.

Methods: 314 elderly individuals were selected during general medicine examinations. The collection of nutritional data concerned the measurement of some anthropometric parameters (body weight, height, BMI, brachial and calf circumferences), the Mini Nutritional Assessment (MNA) and serum albumin.

Results: The average age was 72.92 ± 6.26 years with a feminine predominance (59.55%). The BMI was 25.63 ± 4.43 kg.m⁻² and serum albumin 36.45 ± 5.77 g.L⁻¹. 61% of the investigated population were affected by chronic diseases such as: diabetes (39%). Using the MNA as a mean of screening; 46.18% of individuals presented a risk of malnutrition and 4.78% were undernourished. However, when the BMI and serum albumin were used; 14.01% and 42.35% have been considered as undernourished respectively.

Conclusions: The MNA seems to be a more sensitive tool rather than the other screening parameters (BMI and serum albumin) in the assessment of nutritional risk.

Key words: Elderly, nutritional status, anthropometric parameters, Mini Nutritional Assessment, albumin.

PO3314**EFFECT OF FOOD-BASED SUPPLEMENT PRIOR TO AND DURING PREGNANCY ON BIRTH WEIGHT AND PREMATURITY IN RURAL VIETNAM (VINA-VAC STUDY)**

N. Tu¹, J.C. King², D. Dean², H. Dirren²

¹Vietnam Nutrition Association (VINUTAS), Hanoi, Vietnam

²Children's Hospital Oakland Research Institute (CHORI), Oakland, California, US

Background and objectives: Poor maternal nutrition is linked to both prematurity and fetal growth retardation, which are major causes of death in newborns. VINA-VAC research was set up to study the effect of consuming a micronutrient-rich food supplement on pregnant outcomes. Study's main goal is to determine the impact of maternal nutrition at conception on birth weight and prematurity.

Methods: The study is an unmasked, cluster, randomized trial. A total of 450 women from 29 rural communes are being recruited when they register to marry. They are randomly assigned to one of three interventions: I) food supplement 5 days/week from marriage to term (~18 months); II) food supplement 5 days/week from 16 wks gestation to term (~5 months); or III) routine prenatal care. The primary outcome is birth weight and the secondary outcome is the prevalence of prematurity. Other outcomes include maternal micronutrient status (iron, zinc, folic acid, vitamins A and B12), the incidence of infections; infant growth and infections from 0-6 months. of age are also assessed. Maternal data and information are measured at recruitment, 16, and 34 weeks gestation. Infant anthropometric status is measured at birth, 1, 3, and 6 months. Infant gestational age is assessed at birth to determine the prevalence of pre-term deliveries, and the mother's activity or physical work during pregnancy is also determined.

Results: This study will be the first to compare a food-based supplement consumed prior to conception to term with one given only during pregnancy. Although it is recognized by many that pregnancy may be too narrow a window to improve maternal nutritional health, it is typical for micronutrient supplements to only be given from the time of enrolling for prenatal care to term.

Conclusion: Thus, the results will have world-wide implications as to when maternal supplementation should be initiated during pregnancy.

Key words: Food-based supplement, pregnant outcomes

PO3315**NUTRITION EDUCATION FOR ADOLESCENTS: AN INTERVENTIONAL APPROACH TO CREATE AWARENESS ON "EAT RIGHT AND PLAY WITH MIGHT"**

D.R. Rao¹, D.A. Kumar²

¹National Institute of Nutrition (ICMR), Hyderabad, India

Background and objectives: Adolescents are most important group of population and the adolescent phase is very critical in the lifecycle. They are also vulnerable to adopt faulty eating habits due to peer pressure, which coupled with lack of physical activity result in overweight and obesity among adolescents. Therefore, a study was conducted to impart education on Nutrition and Physical activity through Participatory Approach.

Methods: Five hundred students from different schools were recruited in the study. Informed consent was obtained from the study subjects and from the principals/teachers of the participating schools. Intervention on adolescent nutrition, growth, development and nutrition, food groups and balanced diet, importance of micronutrients and also the importance of the physical activity was given. Interactive lecture on "Eat right and play with might" was given along with participatory approaches which entailed student activities like computer-aided presentations on these topics. A questionnaire on the dietary behavior and physical activity was administered to all the students before and after the intervention.

Results: About 70% of the students knew the importance of the breakfast and consumed it regularly including different food groups. Most of them were aware of the importance of different food groups. Although they knew ill-effects of carbonated beverages, 50% of them consumed frequently. Since physical education was regular in all the schools, the students participated in the physical activity without realizing the benefits of the same.

Conclusions: An integrated approach on nutrition education combining interactive lecture methods and participatory approaches engaging students was proved to be effective in imparting nutrition knowledge and creating awareness about the importance of physical activity.

Key words: Adolescents, nutrition education, physical activity, participatory approach.

PO3316**THE IMPACT OF PRELACTEAL FEEDING ON BREASTFEEDING DURATION AMONG MOTHERS IN KUWAIT**

M. Dashti¹, S. Jane², C. Edwards³, M. Al-Sughayer⁴

¹Nutrition and Medical Catering Unit, Jaber al-Ahmed Armed forces hospital, Kuwait

²School of Public Health, Curtin University, Perth, Australia

³Human Nutrition Section, Division of Developmental Medicine, University of Glasgow, Glasgow, UK

⁴Department of Biological sciences, Faculty of Science, Kuwait University, Kuwait

Background and objectives: The WHO recommends that infants should be exclusively breastfed for the first six months of life. The use of prelacteal feeds is common among Middle-Eastern countries meaning that few infants are truly exclusively breastfed from birth. **Methods:** This longitudinal study of infant feeding patterns among women in Kuwait recruited subjects within 48 hours of delivery over the period of October 2007 to September 2008. All participants, whether still breastfeeding or formula feeding, were followed up by telephone interview at 6, 12, 18 and 26 weeks postpartum to determine the duration of breastfeeding and the age of introducing solid foods. The multivariate Cox's proportional hazards model was used to estimate the effects of independent variables on the risk of cessation of breast-feeding.

Results: In total, 85% percent of women left the hospital breastfeeding, with 55% partially breastfeeding and only 30% fully breastfeeding. Less than 1% of women initiated infant-to-breast contact within 60 mins as recommended in the WHO/UNICEF 10 Steps to Successful Breastfeeding, with 76% of women first putting their baby to the breast 6 hours or more after birth, leading to high rates of prelacteal feeding (81.8%) and/or in-hospital formula supplementation. As a consequence only 10.5% of infants left hospital having been exclusively breastfed since birth and no infant was fully or exclusively breastfed to 6 months. Delayed initiation of breastfeeding (>6 hr after birth) was a strong predictor for the early cessation of breastfeeding.

Conclusion: This study has shown that the majority of newborns do not benefit from exclusive breastfeeding as a consequence of the delayed initiation of breastfeeding and the associated high use of prelacteal feeds and supplementary formula whilst in hospital. Interventions are needed to raise awareness of both women and health professionals about the importance of early infant to breast contact to establish effective breastfeeding.

Key words: Breastfeeding, infantas, newborns, prelacteal feeding.

PO3317**NUTRITIONAL INTERVENTION FOR SPANISH ELITE MALE WHEELCHAIR BASKETBALL PLAYERS**

L. Grams¹, A. Ferrero¹, M. Francisco¹, G. Garrido¹

¹Faculty of Physical Activity And Sport Sciences, Technical University Madrid, Spain

Background and objectives: The Spanish wheelchair national team shows high performance level. Hence, optimal nutrition is required. There are only a few studies available describing nutrition practice in wheelchair basketball (Goosey-Tolfrey 2010). We have offered the team nutritional advice for the upcoming European Championship which is taken place in Frankfurt (Germany). The purpose of this study was to analyse diet composition, with and without nutritional advice, during the precompetitive phase.

Methods: Energy intake (EI) of 14 Spanish elite wheelchair basketballers age 30.2 ± 5.8 yrs and weight 75.4 ± 13.7 kg was analysed. Diet composition was estimated by food weighing (Mettler-Toledo 1g accuracy) for a 3-day period, both in May and June 2013. Dial Alce[®] was used to determine nutrient composition. During these dates, athletes completed a 24h activity questionnaire. Between both periods, we provided individual written reports, including nutritional modifications, to optimise their diet composition. Individual feedback have been given before the second evaluation.

Results: EI was 2543 ± 391 Kcal/d. Energy distribution was low in carbohydrates ($44 \pm 7\%$) and high in lipids ($37 \pm 5\%$) and proteins ($21 \pm 7\%$) compared to ACSM recommendations for athletes. Cholesterol intake (521 mg/d) and fat saturated distributed energy (14%) were also higher than recommended (7%). Conversely, fibre intake was lower (22 ± 8 g/d) than adequate (FNB 2006). Therefore, our intervention focused on reducing fat intake and increasing carbohydrates and fibre. Our results demonstrated an improved energy distribution, as well as an increase in fibre intake and a reduction in cholesterol intake, in the second evaluation. **Conclusion:** In order to reach ACSM guidelines, more nutritional advice is needed to optimize performance for these athletes.

Goosey-Tolfrey L. (2010). Nutritional practice of competitive British wheelchair games players. APAQ.

PO3318**POTENTIALS AND BARRIERS TO EXCLUSIVE BREASTFEEDING AMONG WOMEN IN AN URBAN LOW-RESOURCE SETTING IN NAIROBI, KENYA: A QUALITATIVE STUDY**

S. Ochola¹, L. Demetre², R. Nduati³

¹Department of Food, Nutrition and Dietetics, Kenyatta University, Nairobi, Kenya

²Division of Human Nutrition, University of Stellenbosch, Cape Town, South Africa

³Department of Paediatrics, Faculty of Health Sciences, University of Nairobi, Kenya

Background and objectives: The practice of exclusive breastfeeding (EBF) remains poor despite demonstrated health benefits to the child. Improving the practice requires an understanding of the social context of infant feeding practices. This study investigated the factors influencing the uptake of EBF.

Methods: A randomized controlled trial in which villages in Kibera slum, Nairobi Kenya were randomly assigned to two breastfeeding counseling groups and a control group that received no counseling. The study participants, 34-36 weeks pregnant, HIV-negative women, attending antenatal clinic, were assigned to study groups and followed up at home until 6 months postpartum. At the end of the 6 months, 2 focus group discussions were conducted separately in each of the study groups; for mothers exclusively breastfeeding to 6 months and those who did not to gain a better understanding of the maternal rationale for the feeding method chosen.

Results: Data was analyzed based on pre-identified themes. The practice of EBF was poor. There were no major differences in the barriers to EBF by study groups. The common barriers were: mothers being away for long periods of time; expressing breast milk was considered tedious and culturally unacceptable for some communities; pressure from relatives to introduce complementary feeding; babies need water to quench their thirst; breast milk is inadequate to nourish the baby and EBF was perceived to make the mother unhealthy. Factors encouraging EBF among those who received breastfeeding counseling were: infants' faster growth; fewer episodes of maternal breast health problems because of the acquired new skills of latching the baby to the breast; spousal support and the continued support offered by research team.

Conclusions: The uptake of EBF is influenced by societal perceptions. The promotion of EBF should address factors involved in decision making of choice of infant feeding.

Key words: Exclusive breastfeeding, potentials, barriers, Kenya

PO3319**DIETETIC EDUCATION TOOL IN PAEDIATRIC PATIENTS IN HEMODIALYSIS**

S. Arroyo Parisi², N. Bueno², C. Vezzani¹, S. Blasi¹

¹Hospital de Pediatria 'Prof. Dr.J.P.Garrahan', Buenos Aires, Argentina

²Escuela de Nutrición, Universidad ISALUD, Buenos Aires, Argentina

Background and objectives: Chronic kidney diseases is the main cause of pediatric morbidity and mortality due to malnutrition, cardiovascular alterations and complication in the metabolism of calcium and phosphorus. Critical nutrients are proteins, phosphorus and sodium, and the nutrition approach require adherence to treatment and patient education. The objective was to evaluate the use of an educational tool designed to promote adherence to dietetic plan.

Methods: The aim of this longitudinal descriptive study is the implementation of educational nutrition materials in twenty pediatrics patients under hemodialysis treatment in our center. Interactive education tool allows a practical reminder of basic renal nutrition guidelines. Previous and post knowledge test about phosphorus content, protein and sodium in foods as measured by self-administered questionnaire, in the other hand, patient's know-how about dietetic plan as measured by dietary recall of 24hs; both, before and after intervention (dietary phosphorus intake was evaluated depending on the degree of serum phosphorus) The cut-off points of reference were the DRIs and protocol used in the institution.

Results: Knowledge about nutrition renal topics showed a significant increase, 90.3 %, versus 72.8 % before intervention. The adequacy of intake of phosphorus improved in 25% of cases, 10% for proteins, and 60% for sodium. Post laboratory values showed decreased serum phosphorus in 55% of the cases

The therapeutic education is essential in patient's motivation to promote the self care and the adherence to the dietetic treatment.

Conclusions: We found a favorable response to the intervention. The use of the instrument represents a effective educational tool and allows an active learning and skills development in everyday practice.

Key words: Renal Chronic Disease; nutrition education.

PO3320**RELATIONSHIP BETWEEN SERUM FOLATE STATUS AND BLOOD CADMIUM CONCENTRATIONS IN PREGNANT WOMEN: MOTHERS AND CHILDREN'S ENVIRONMENTAL HEALTH (MOCEH)**

H. Kim¹, J. Won¹, E-H. Ha², H. Park², M. Ha³, Y. Kim⁴, Y-C. Hong⁵, N. Chang¹

¹Department of Nutritional Science and Food Management, Ewha Womans University, Seoul, South Korea

²Department of Preventive Medicine, College of Medicine, Ewha Womans University, Seoul, South Korea

³Department of Preventive Medicine, Dankook University College of Medicine, Cheonan, South Korea

⁴Department of Occupational and Environmental Medicine, University of Ulsan College of Medicine, Ulsan, South Korea

⁵Department of Preventive Medicine, Seoul National University College of Medicine, Seoul, South Korea

Background and objectives: Cadmium has toxic effects on the body, including on the nervous system and reproductive outcomes. It is possible that folate, which is involved in sulfur-containing amino acid metabolism, participates in the lead detoxification process. We evaluated the relationship between maternal serum folate status and blood cadmium in pregnant Korean women.

Methods: The nutritional status of folate and blood cadmium concentration was measured in pregnant Korean women who participated in a multicenter prospective study between 2006 and 2010. We analyzed existing blood mercury data based on serum folate status at two gestational time points (mid and late pregnancy; n=1281 and 890, respectively).

Results: Serum folate concentrations in pregnant women were negatively associated with blood cadmium concentrations at late pregnancy but not at mid pregnancy (P trend 0.0028 and 0.7205, respectively). A general linear model developed after adjusting for age, prepregnancy body mass index, education status, gestational age at blood collection, and urinary cotinine concentrations indicated a significant negative association between the two at late pregnancy.

Conclusions: These results warrant future studies to explore the mechanisms responsible for the beneficial role of folate status against blood cadmium concentrations at late pregnancy in pregnant women.

Key words: Folate, cadmium, pregnant women.

PO3321**INFLUENCE OF DIETARY NITRATE SUPPLEMENTATION ON THE PHYSICAL PERFORMANCE AND THE AUTONOMIC NERVOUS SYSTEM ACTIVITY IN HEALTHY PEOPLE – PRELIMINARY STUDY**

L. Štulrajterová, P. Stejskal

¹Department of Health Promotion, Faculty of Sports Studies, Masaryk University, Brno, Czech Republic

Background and objectives: Neural regulation of the cardiovascular system is ensured by the basic principle of the concept of sympathovagal balance. It is not known whether the ANS activity is changed under the conditions of increased efficiency of oxygen utilization in the working muscles by nitrate supplementation.

Methods: The subjects (5 M; 5 W; 20-30 y.) will be tested in eight occasions. Subjects will perform a ramp incremental exercise test for determination of the peak VO₂ and respiratory threshold. Subjects will receive 6 days of dietary supplementation with beetroot juice and placebo in two separate periods. In the 4th day they pass two 6 minutes degrees of exercise in moderate intensity, each 5th and 6th day one degree of medium and one of high intensity to determine pulmonary VO₂ dynamics. Degrees will be separated by 25 minutes of passive recovery. The break between the supplementation periods will last for 12-15 days. The supplementation of beetroot juice or placebo will be used two hours before testing. The ANS activity will be monitored in all investigative days every morning in orthoclinostatic conditions by SA HRV. Before the first exercise bout, body pressure will be measured and venous blood samples will be collected for subsequent determination of plasma nitrite.

Results: If the expected results will be achieved (increase on plasma concentration of NO₂⁻, decrease of VO₂.kg⁻¹.W⁻¹ in submaximal load, increases in exercise tolerance during high intensity, the ANS activity without the changes), the project will be extended to the patients who are limited by the poor eNOS expression.

Conclusions: Beneficial effect of physical rehabilitation after extensive myocardial damage and dysfunction is closely dependent on the bioavailability of NO.

Key words: Nitrate supplementation, exercise tolerance, ANS activity.

PO3322**FLUID INTAKE AND NUTRITION STATUS IN CHILDREN AND ADOLESCENTS OF DEVELOPED CITIES IN CHINA**

Q. Zhang¹, W. Xiaojun¹, X. Hu¹, S. Du¹, L. Lu², J. Gao³, S. Zou⁴, J. Fan⁵, G. Ma¹

¹Chinese Center For Disease Control And Prevention, China

²Xicheng District Center for Diseases Control and Prevention, Beijing, China

³Huairou District Center for Diseases Control and Prevention, Beijing, China

⁴Shanghai Center for Diseases Control and Prevention, China

⁵Guangdong Province District Center for Diseases Control and Prevention, China

Background and objectives: Suitable water consumption are important for health and leaning ability in children and adolescents. To assess total fluid intake and its association with obesity, a cross-sectional survey were carried out in four developed cities of China in September to October, 2011.

Methods: By multi-stage random sampling method, 5868 secondary and primary school students (aged 8.0-17.9 yrs) were recruited from urban and rural area of Beijing, Shanghai, Guangzhou and Chengdu. The amounts and types of daily fluid intake was recorded by subjects for seven consecutive days using a quantitative cup. Their height and weight were measured by investigators.

Results: The average daily total fluid intake of subjects was 1089ml, including 744ml (68.3%) drinking water and 345ml (31.7%) beverages. Total fluid intakes were higher in boys (1157ml) than in girls (1026ml, $P < 0.0001$), with the most for students in high school (1185ml), in secondary school (1141ml), and finally in primary school (1000ml, $P < 0.0001$). Their total fluid intakes were statistically significantly higher in urban (1185ml) than in rural (991ml), and varied among four cities(all $P < 0.0001$). Obese children and adolescents had the highest total fluid intake (1270ml), including both plain water (894 ml) and beverages (376ml); followed by overweight students (1202ml, 830ml, and 371ml, respectively) and normal subjects (1067ml, 726ml, and 341ml, respectively); and the least was underweight subjects (1010ml, 681ml and 329ml, respectively, all $P < 0.0001$). After adjusting for age, gender, city, living area and physical activity level, the difference on total fluid intake and plain water was still significant among various nutrition status subjects.

Conclusions: Major of fluid intake of children and adolescents came from drinking water, instead of beverage in developed cities of China. The fluid intake varied with gender, age, living area, city and nutrition status.

Key words: Total fluid intake, plain water, beverage, obesity.

PO3323**ANALYSIS OF DIETARY HABITS IN JUNIOR REPRESENTATION IN SPORT GYMNASTICS**

I. Hrnčirikova¹, K. Katerina¹, L. Stulrajterova¹, M. Kumstat¹

¹Faculty of Sports Studies, Masaryk University, Czech Republic

Background and objectives: In sport gymnastics, good quality performance and trainings require supply of macronutrients and micronutrients. In a junior category, the demand for quality nutrients is even higher. Currently, diet in inseparable part of training programs of sporting children. Composition of dietary regime became crucial, as it must contain balanced amount of basic nutrients, vitamins, and minerals, along with supplementary plans and individual forms of supplements. All must correspond with training seasons and present requirements. The demands in juniors for quality and quantity of nutrients are, of course, bigger than the ones of adults. Insufficient, even temporary absence of nutritive supplies may result in damage to health, in better scenario the outcome is merely inferior performance or training.

Methods and results: We carried out a research into 33 members of gymnastic teams. There were 13 boys and 20 girls. The average age was 15 years. The average age of boys was 15,5 yrs, the average age of girls was 14,5 yrs. The average height/weight ratio of boys was 170 cm/62 kg. The average height/weight ratio of girls was 155cm/48 kg. We applied a method of dietary habits analysis through 24 hour recall, a standard questionnaire for dietary habits in sporting and non-sporting population, in a four days course; i.e. 3 working days and one weekend day. Furthermore, we analyzed the body posture by bio-electric impedance and they passed through Cortex machine.

Conclusion: The average energetic intake was 7000 kJ a day, consisting of 250 g of carbohydrates, 60 g of fat and 60 g of proteins a day. It was irregular, they suffer from vitamins and mineral insufficiency and rather monotonous. The absence of basic nutrients is apparent. Their long-term insufficiency will result in weariness, worse sports performance, injury, decrease in cognitive functions and development.

Key words: Sport gymnastics, adolescents, nutrition.

PO3324

INTERVENTION TO IMPLEMENT HEALTHIER EATING HABIT IN SCHOLAR CHILDREN

A-Z. Herlinda¹, G. Lopez-Moreno¹

¹University of Guanajuato, México

Background and objectives: According with WHO the traditional diets based in vegetable foods now has been change for high-fat diet and high-calories diet, also beef food products. The food eating, no one alone for prevent metabolic diseases exist other factors such as culture, age, sex and familiar eating habits. We implemented an intervention on scholar children of one school in Celaya, Guanajuato, Mexico; based in nutritional education and adherence to the nutritional guide along three months.

Methods and results: We found that some anthropometric measures such as arm circumference ($p=0.03$), Body Mass Index (BMI) in Z-score ($p=0.04$) were significantly different after that our intervention. We found that the index scores about daily intake of fruits increase ($p<0.03$) after our intervention, furthermore index scores about daily intake of white bread ($p<0.03$), flour tortilla ($p<0.03$), beef ($p<0.03$), fish meal ($p<0.01$) and candies ($p=0.01$) were low down after our intervention. However we didn't find different results in the index scores about daily intake of corn tortilla, soda beverage, milk, fried food and sugar. For other hand we found that the BMI had inverse association with the born weight ($\hat{\alpha}-0.42$, $p<0.05$), the exercise minutes had both a positive association with basal BMI in Z-score ($\hat{\alpha} 0.46$, $p<0.04$) and negative association with soda beverage ($\hat{\alpha} -0.48$, $p<0.05$); in this topic the final index score about intake of soda beverage was negatively associated with time in front of the television ($\hat{\alpha}-0.55$, $p<0.3$).

Conclusion: Our educational intervention applied in school children along three months promoted changes on their food intake, however we found that some many food rooted in the familiar and ethnic culture such as soda beverage, corn tortilla, milk ad cheese didn't show any change. So it is necessary one intervention into familiar and scholar nuclei for changing them.

Key words: Nutritional Intervention, scholar children and intake

T3. Public Health Nutrition and Environment**PO889****ULTRASOUND MEASUREMENT OF BONE AGE IN CHILDREN: AN EPIDEMIOLOGICAL APPROACH**

L M. Prieto Parra¹, K. Moenne², J. Kain¹, G. Weisstaub¹, M.L. Garmendia¹, V. Mericq³, C. Corvalán¹

¹Institute of Nutrition and Food Technology, University of Chile, Chile

²Las Condes Clinic, Santiago, Chile

³Maternal and Infant Research Institute, University of Chile, Chile

Background and objectives: Bone age is traditionally measured using hand x-rays, however, there is also the possibility of using a method that does not generate radiation and has a reasonable cost as it is ultrasound (US). However, the accuracy of US measurements may be impaired by adiposity. The objective of this study is to validate the bone age US measurements with a computational method for reading hand x-rays (BoneXpert®-BE-).

Methods: This is a cross sectional study within the Chilean Growth and Obesity Cohort Study (GOCS). The subsample was 194 low socioeconomic status children (54.1% female) with a mean age of 6.9 years (82.3 months) in 2009. We were performed anthropometric measures, left hand x-rays and US measurements of left wrist with BoneAge®. We used Spearman and intraclass correlations (ICC) to compare US and X-rays measurements and we evaluated potential interactions by nutritional status. We calculated adjusted US measurements using an equation developed for obese (BMI >2 SD) and non-obese (BMI < 2 SD) children based on linear regression models adjusted for gender, chronological age, BMI Z score. It was stratified by nutritional status.

Results: Mean bone age according to BE was 87.9 months and 25% of the sample had obesity. Correlation between US and BE was 0.59, but it decreased to 0.52 in obese children. The ICC was 0.41, but it was lower in obese vs non obese children (0.16 vs 0.46). When we adjusted US bone age, correlations with BE improved ($r=0.71$ and $ICC=0.70$), and there were no further differences by nutritional status.

Conclusions: Ultrasound is a noninvasive method useful in the assessment of bone age in epidemiological studies, particu-

larly if this equation is used to adjust the US measurements in order to compare with X-rays values.

Key words: bone age, ultrasound, adiposity.

PO1142**BIRTH WEIGHT AND OBESITY IN 7-14-Y-OLD SCHOOLCHILDREN OF FLORIANOPOLIS CITY - SOUTH OF BRAZIL**

C E. Rossi¹, F A. Guedes de Vasconcelos²

¹Universidade Federal Da Fronteira Sul, Santa Catarina, Brazil

²Universidade Federal de Santa Catarina, Santa Catarina, Brazil

Background and objectives: The first stages of human developing, especially the intra-uterine cycle and the first years of life have been associated to obesity. Birth weight, gestational age and catch-up growth have being indicated like factors that influence later weight, height and body composition. We investigated the influence of birth weight in the overweight and obesity status of 7-14-y-old children and adolescents matriculates in public and private schools in Florianopolis (south of Brazil).

Methods: A cross-sectional study was developed with a probabilistic sample. A total of 2, 696 scholars (857 children 7-9-y-old and 1, 839 adolescents 10-14-y-old) was investigated, being analyzed biological (age, gender, birth weight, gestational age, weight, height, subscapular and triceps skinfolds thickness of scholars, age and parental weight and height) and socioeconomic variables (type of school, family income, mother's and father's schooling). Overweight defined as a Body Mass Index (BMI) equal or above the 85th percentile of Must et al. (1991) and obesity defined for this condition plus the triceps and subscapular skinfolds thickness equal or above the 90th percentile of Johnson et al. (1981) were the outcome variables.

Results: Birth weight and birth weight/gestational age were the explanation variables, and the socioeconomic variables and the parental BMI were the control variables. Analyses of multivariable Poisson regression were made, with estimative of prevalence ratios (PR) and confidence intervals (95%). The prevalence of overweight was 31.5% in 7-9-y-old (children) and 21% in 10-14-y-old (adolescents) and the obesity prevalence was 10.9% in children and 6% in adolescents. Male adolescents that have being born with high birth weight (HBW) demonstrated overweight (PR = 1, 14; CI 95% = 1, 02-1, 27; p = 0, 03).

Conclusions: Birth weight and birth weight for gestational age were not significant associated to obesity. It was just observed association with overweight in the male adolescents that were born with HBW.

Key words: birth weight, obesity, children.

PO1143

PREPARATION AND EVALUATION OF SALAD OIL BLENDS RICH IN OMEGA-3 AND -6 FATTY ACIDS

M. Mostafa¹, A. Bakr², M. El-Habashy¹, M. Aldin¹

¹Department of Food Science and Technology, Faculty of Agriculture University of Minufiya, Shebin El-Kom, Egypt

²Department of Hotels studies, Faculty of Tourism and Hotels, University of Minufiya, Shebin El-Kom, Egypt

Background and objectives: Egyptian people are consuming more saturated fatty acids which raised blood LDL cholesterol causing the risk of heart disease and stroke. This study aimed to increase the intake of omega-3 and-6 fatty acids through preparing vegetable oil blends with health claims to maintain low LDL Cholesterol level.

Methods: Blending of five oils: Flaxseed (F), Corn (C), Sunflower (SF), Soybean (SB) and Wheat Germ (WG) oils were used to formulate three blends of Salad (S) oils rich in n-3 and n-6 fatty acids. Besides, their chemical and fatty acids composition were analyzed. In addition, 36 male albinos' rats feeding experiment over two months period was carried out. Data including body weight, triglyceride level, total cholesterol and LDL cholesterol were collected and analyzed statistically for significance using CoStat version 6.311 and Duncan's multiple range tests.

Results: the highest value of n-3 to n-6 fatty acids (FAS) ratio was found in F oil and blend 3S (15%F+15%SB+19%SF+50%C+1%WGoils W/W). Triglycerides level was relatively higher in the plasma of the rats feeding on diet containing the free n-3 FA oil than those having oil blends (3S, 2S) with different omega 3 and omega - 6 FA ratios. Using diet containing oil blend 3S instead of control caused a marked decrease both total cholesterol and LDL cholesterol. The taste of omega sponge cake was accepted by panelists.

Conclusions: the feeding blend No 3S (rich in omega -3 and -6) was effectively reduced the total cholesterol and LDL cholesterol and would be beneficial in reducing health problem and encourage should be made to broaden the use of Salad Oil blends.

Key Words: Biological Evaluation, Blending Oils, OMEGA-3&6

PO1144

EATING HABITS, LIFESTYLE AND OBESITY: STUDY OF A GROUP OF WOMEN FROM BOUMERDES CITY-ALGERIA

B. Ouzruat¹, H. Kerbal

¹Information and Training of Health-Promotion, Association of Boumerdes, Algeria

²Directorate of Health and Population of the district of Boumerdes, Algeria

Background and objectives: the paper consists in presenting the main findings of a survey conducted in 2011 which targeted a group of women through six health centers Boumerdes city (Algeria), in order to determine the prevalence of overweight and obesity among those surveyed, understand the relationship between overweight, obesity, eating behavior and lifestyle, assess the prevalence of chronic diseases they might suffer and finally evaluating the level of consciousness with regard to the relationship between overweight, obesity and chronic diseases

Methods: The survey targeted 786 women, non-pregnant and non-lactating, aged between 18-70 years. The questionnaire contains qualitative variables (lifestyle, eating habits, and education) and quantitative variables (weight, height), 3.

Results: 44.9% of respondents are aged 40 to 49 years with an average age of 41 years. 2/3 of these women are educated, 37.7% with a university degree and 10% are illiterate. They are workers in 64.8% of cases and married in 70% of cases. Poor eating habits are observed and taking Consumption of fast food is found in 41.8% of cases and more than 5 times per month; The household budget determines the nature of the meal. Physical inactivity is observed; only 7.2% of women are overweight or obese exercise sport against 10.3% with normal weight. 51% of respondents spend an average of 2 hours per day watching television. 64.3% of normal weight women and 72% of overweight and obese women take a nap less than 1 hour per day. 33.2% reported having at least one chronic disease. 92.3% are aware of the risks of obesity to health;

Conclusions: Obesity and overweight pose a serious public health problem, in view of the nature of chronic diseases that are generated and the high cost of their care. Nutrition education and physical activity are essential for their reduction.

Key words: obesity, overweight, chronic diseases.

PO1145**COMPARISON OF ENERGY INTAKE AND RESTING METABOLIC RATE AND THEIR RELATION TO ANTHROPOMETRIC AND SOCIODEMOGRAPHIC FACTORS AMONG IRANIAN WOMEN**

M. Shaneshin¹, S. Rabiei¹

¹National Nutrition and Food Technology Research Institute, Shahid Beheshti University of Medical Sciences and Health Services, Theran, Iran

Background and objectives: This study assesses the accuracy of energy intake (EI) reporting and its relation to anthropometric characteristics and sociodemographic factors. In addition, we attempt to identify foods for which under- or over-reporting is more prevalent.

Methods: EI was assessed for 187 women using a semi-quantitative 168-item food frequency questionnaire (FFQ). Resting metabolic rate (RMR) was measured with an indirect calorimeter. We calculated the EI/RMR ratio to assess the accuracy of EI reporting. This study defined under-reporters as those with an EI/RMR < 1.34 and over-reporters as those with an EI/RMR > 2.4. We measured anthropometric characteristics and collected sociodemographic information. The chi-square test, ANOVA and multiple linear regressions were used for statistical analyses.

Results: Among participants, the under-reporting rate was 35.5% and the over-reporting rate was 7.5%. The EI/RMR ratio was significantly higher for younger women compared to older women ($P < 0.04$). Under-reporters had higher weight, waist circumference (WC), body mass index (BMI) and resting metabolism compared to accurate reporters ($P < 0.05$). Resting metabolism was significantly lower among over-reporters than accurate reporters. After adjusting for energy, the consumption of fish, high-fat dairy products, hydrogenated oil, sweets and coffee was lower, whereas consumption of unsaturated oils, tea, salt and yellow vegetables was higher among under-reporters compared to accurate reporters.

Conclusions: Under-reporting of EI is more frequent than over-reporting among Iranian women. Among various factors that may affect the accuracy of EI reporting, age and anthropometric characteristics might have a significant effect.

Key words: Anthropometric, energy intake, energy reporting, sociodemographic factor.

PO1146**CHANGES IN PROTEIN- ENERGY STATUS OF HOSPITALIZED CHILDREN DURING THEIR STAY AT MOFID CHILDREN'S HOSPITAL, TEHRAN, IRAN.**

M. Beheshti Beglar¹, N. Shahidi², F. Imanzadeh³, M. Hedayati⁴

¹Department of Nutrition, Mofid Childre's Hospital, Tehran, Iran

²Department of Human Nutrition, Shahid Beheshti University of Medical sciences, Tehran, Iran

³Department of Pediatric Gastroenterology, Mofid Children's Hospital, Tehran, Iran

⁴Prevention & Treatment of Obesity Research Center, Research Institute For Endocrine Sciences, Tehran, Iran

Background and objectives: Malnutrition is a common finding in hospitalized children and leads to increased mortality, mental and physical growth retardation and increased costs. The aim of the present study was to assess the nutritional status of the pediatric patients on admission and discharge and some relevant factors.

Methods: 224 children (2-6 years old) who were consecutively admitted to mofid children's hospital, underwent objective and subjective assessments on admission and discharge. Objective assessments consisted of weight, height, mid upper arm circumference and triceps skinfold thickness measurements plus determining the energy and macronutrients intake and plasma albumin and prealbumin levels. Subjective assessments was done using Subjective Global Nutritional Assessment tool.

Results: According to objective (weight for height) and subjective methods, the prevalence of malnutrition on admission was 44.3% and 58.9% respectively. During hospital stay, the mean amount of all anthropometric parameters decreased significantly. This reduction was significantly greater in febrile patients, patients with normal baseline nutritional status and surgery patients. The mean energy, carbohydrate and fat intake, in spite of increasing during hospital stay, were below the recommended intakes (DRI). The mean energy, protein and fat intake were significantly related with patient's satisfaction with hospital food service. The mean plasma albumin and prealbumin concentrations were also below the normal ranges on admission and discharge. Malnutrition was diagnosed by physician only in 6.95% of patients affected and only 0.9% of children were referred to a dietitian.

Conclusions: The prevalence of malnutrition is high among hospitalized children and the nutritional status of them deteriorates during their stay. The situation may be improved by using appropriate screening tools with giving special attention to surgery patients, referring the patients at risk of malnutrition for in time interventions and enhancing the hospital food service quality.

Key words: Children, Hospital, Malnutrition.

PO1147**ASSESSMENT OF NUTRITIONAL STATUS AND QUALITY OF LIFE OF WOMEN IN IBADAN NIGERIA**

A. Okekunle¹, I. Akinyele¹, O. Akpa²

¹Department of Human Nutrition, University of Ibadan, Nigeria

²Department of Epidemiology and Medical Statistics, University of Ibadan, Nigeria

Background and objectives: The well-being of women is vital to their reproductive roles. Of the several factors that affect women's health, nutrition and Quality of Life (QoL) have been reported to be among the most crucial. The relationship between nutritional status and QoL of women is not adequately researched in Nigeria, particularly in relation to the different domains of QoL. This study was designed to examine the relationship between Body Mass Index (BMI) and QoL in apparently healthy Women of Reproductive Age (WRA) in Ibadan, Nigeria.

Methods: The study was a descriptive cross-sectional survey involving 285 non-pregnant and non-lactating WRA selected by a multi-stage random sampling. Interviewer-administered, semi-structured questionnaires were used to obtain information on demography, anthropometric measurements were taken using a stadiometer to measure height, weighing scale to measure weight and BMI(kg/m²) was classified according to World Health Organization (WHO) cut-off points. WHO-QoL BREF questionnaire was used to assess QoL in four domains (Physical Health (PH), Psychological Health (PSH), Environment (EN) and Social Relationships (SR)) scored using WHO-QoL standard on a scale of 0 to 100. Descriptive statistic and Pearson's correlation test were performed at $p < 0.05$.

Results: Mean age of respondents was 29.3 ± 8.3 years and 61.8% of the women were from urban areas. Mean BMI of respondents was 24.0 ± 5.2 kg/m². Mean score of respondents for PH, PSH, EN, and SR domains of QoL were 70.1 ± 30.4 , 67.0 ± 13.3 , 66.4 ± 18.7 , and 57.3 ± 15.9 respectively. Mean overall QoL score was 65.2 ± 11.4 . Overall mean QoL score revealed no significant relationship with mean BMI; however, EN domain score of QoL negatively correlated with BMI ($r = -0.1$, $p = 0.017$).

Conclusions: The environmental components of QoL are more likely to be associated with nutrition. However, further studies are required to clarify this finding.

Key words: Nutrition, Quality of Life, Women, Nigeria.

PO1148**FACTORS ASSOCIATED WITH RECOVERY AMONG ETHIOPIAN MALNOURISHED HIV PATIENTS (PRE ART AND ART) THAT RECEIVED FOOD BY PRESCRIPTION**

S. Ghosh¹, D. Suri², E. Bontrager¹, J. Coates¹, B. Rogers¹, Y. Kidane¹, K. Sadler³

¹Friedman School of Nutrition Science and Policy, Tufts University, Boston, USA

²Friedman School of Nutrition Science and Policy, Tufts University, Boston, USA

³Valid International, Oxford, United Kingdom

Background and Objectives: To examine factors associated with recovery in treatment versus control groups in a program that provided RUTF supplement to malnourished HIV+ adults with MAM or SAM (BMI ≤ 18.5) also receiving standard ART care on nutritional status.

Methods: RUTF was provided to subjects with MAM or SAM and that were pre ART or ART for up to 6 months at 15 health centers and hospitals ($n = 1956$), with 8 matched comparison health facilities ($n = 639$). Longitudinal nutritional and HIV status data were collected. Recovery was defined as having a BMI ≥ 18.5 recorded for 2 or more consecutive visits.

Results: Factors associated with recovery, regardless of treatment group, included being treated at a health center instead of a hospital (OR=0.5, $p = 0.045$) and being female (OR=1.4, $p = 0.013$). Among participants in the treatment group who followed protocol (i.e. attended all prescribed sessions until discharge), factors associated with recovery included being on ART < 6 months (OR=2.1, $p = 0.033$), a CD4 count 200 to 350 (OR=1.77, $p = 0.004$) or having some (OR=1.7, $p = 0.037$) or severe food insecurity (OR=2.92, $p = 0.003$).

Conclusions: Food by Prescription does have the potential to improve prognosis of patients. However, successful uptake of Food by Prescription was associated with recovery with health centers faring better than hospitals. Challenges in administering such a program in a large health facility need to be examined. Individual level factors including ART status, CD4 count and level of food insecurity need further examination.

Key words: HIV, malnutrition, Food by prescription, persistence

PO1149**IMPACT OF HOUSEHOLD HEADS ALCOHOL CONSUMPTION ON DIETARY DIVERSITY AND MORBIDITY IN CHILDREN BELOW FIVE YEARS IN NANDI COUNTY, KENYA**

J. Saina¹, W. Kogi-Makau², S. Mbugua²

¹Kiambu Institute of Science and Technology, Kenya

²University of Nairobi Department of Food Science, Nutrition and Technology, Kenya

Background and objectives: There are many causes of low dietary diversity and disease. Drugs and substance abuse, a serious global problem with adverse effects on national securities and socio-economic development, is a major contributing factor. Objective: To determine the relationship between household heads alcohol consumption, dietary diversity and morbidity in children under five years of age in households in Nandi County.

Methods: The sample consisted of 170 (6-59 months) children of simple random selected households from Nandi. Selected indicators were examined against a set of variables using univariate and multivariate analyses.

Results: There were 82.9% and 17.1% male and female-headed households respectively. Significantly high percentage (37%) of males consumed alcohol than female (12.4%) ($p < .05$). The present research sought to determine the dietary diversity and morbidity among children under five years of age in households. The relationship between alcohol consumption and food diversity was statistically significant ($p < .05$). A High percentage (55.1%) of children from alcohol consuming households was ill compared to those of non-alcohol consuming households (44.9%). Household-heads that consumed 3 or more litres of alcohol per week had the highest number of sick children. Further statistical analyses confirmed that the morbidity level was significantly higher among children from alcohol consuming households than among those from non-alcohol consuming households [$\beta = 0.045$; $p < 0.05$].

Conclusions: This study concludes that household heads alcohol consumption contributes to child negligence and low dietary diversity therefore resulting to poor health and high morbidity.

Key words: Household Heads, Dietary diversity, Morbidity, Alcohol Consumption, Children, below five years

PO1150**BALANCED NUTRITION AT WORK: THE EUROPEAN PROGRAMME FOOD (FIGHTING OBESITY THROUGH OFFER AND DEMAND)**

N. Bertrand¹, N. Renaudin¹

¹Public Affairs Department, Edenred, Brussels, Belgium

Background and objectives: Designated by the WHO as one of the greatest public health challenge of our century, obesity is responsible for 10–13% of deaths in the European region. Companies are an important setting and information channel for promoting health to their employees. The 2005 study Food at Work from the ILO points out that employees who have access to healthy eating increase their productivity by up to 20%. The European programme FOOD promotes healthy eating habits towards employees. The two main objectives of are to improve: 1. nutritional habits of employees by raising their awareness of health issues 2. nutritional quality of the food on offer in restaurants.

Methods: Edenred proposed to Public Health Authorities as well as Nutritionists and Universities to join the project as partners in Belgium, Czech Republic, France, Italy, Spain and Sweden. To meet its objectives, the project followed a five step methodology: 1. Inventory of existing programmes was followed by a quantitative questionnaire (52, 000 employees and 5, 000 restaurants) and a qualitative study (60 interviews in restaurants) 2. Recommendations were made by the partners, subsequent to the results and analysis of the first step 3. Adapted tools were developed and piloted in the restaurants and the companies 4. Pilots were evaluated 5. Following the evaluation, the tools were adapted and best practices disseminated.

Results: The 102 communication tools reached around 4.2 million employees and 352, 000 restaurants. A network of restaurants applying the FOOD recommendations has been created, thus connecting the offer and the demand sides of balanced nutrition.

Conclusions: After the project period, the partners have decided to take advantage of the actions and results of the project and created a long-term programme. The Slovak Republic and Portugal already joined the programme and more countries are expected.

Key words: Nutrition; prevention; lifestyles; PPP; workplace

PO1151

THE VULNERABILITY OF SELECTED FARMERS IN VALENCIA, NEGROS ORIENTAL, PHILIPPINES TO CLIMATE CHANGE: EL NIÑO PHENOMENON AND MALNUTRITION

*J. Pis-An*¹

¹Silliman University; Dumaguete City, Philippines

Background and objectives: The purpose of the study was to examine the vulnerability of farmers in Valencia, Negros Oriental to the effects of climate change, specifically the El Niño phenomenon or Southern Oscillation, which was previously experienced by the Philippines in 2009-2010.

Methods: Knowledge, Attitudes and Practices Survey to determine their behavioural response to determine their vulnerability to the effects of the El Niño. Anthropometric and Dietary assessments are used to identify the nutritional status.

Results: 75 % of the respondents claimed that crop significantly decreased during drought season. Anthropometric assessment showed that the prevalence of Chronic Energy Deficiency Grade 1 among females was 17% and 28.57% for Low Normal. While Male Body mass index result for Chronic Energy Deficiency Grade 1 is 10%, Low Normal 18.33% & and Obese Grade 1 is 31.67%. Dietary assessment of macronutrient intake of carbohydrates, protein and fat is 31.6 % among respondents are below recommended amounts (Recommended Dietary Intake). While micronutrient deficiency are prevalent these are the following : calcium, iron, vitamin A, thiamine, riboflavin, niacin, vitamin C.

Conclusions: Placing the current nutritional status (under relative normal climatic conditions) of the farmers in the context of food security in the area, there are reasons to believe that the status will go for the worse if the extreme climatic conditions like the El Niño phenomenon will once again prevail in the region. As the farmers rely primarily on home grown crops for their food supply, a reduction in farm production due to drought conditions during El Niño is expected to adversely affect their dietary intake. Local government should therefore institute programs to increase food resilience and help communities cope with the onset of adverse climatic conditions.

Key words: malnutrition, children, diet, anthropometry.

PO1152

BARRIERS TO MOTIVATION FOR HEALTHY EATING

*P. Enyan*¹, *J N D. Sasraku*², *Q. Enyan*³

¹University of Ghana, Accra, Ghana

²Pantang Nursing Training College, Accra, Ghana

³Home For Women and Children Foundation, Accra, Ghana

Background and objectives: To gain an insight into children views about food and nutrition.

Methods: Data were collected in focus group discussions; two focus group sessions were undertaken with each school group. A total of 11 post primary schools in Northern Region in Ghana. In all, 106 children aged 11–12-y-old (n=52 boys, n=54 girls).

Results: Focus group transcripts were analyzed using qualitative research methodology. Major barriers to healthy eating were taste, appearance of food, filling power, time/effort, cost, choice/availability, risk, rebellion, and body image/weight concerns. The main difference between sexes was in terms of motivating factors for eating well; girls tended to focus primarily on their appearance whereas boys appeared to be more influenced by sport. There was some mention of balance and variety within the focus group discussions, however, in practice, the children had a tendency to categories foods as either 'good' or 'bad', 'healthy' or 'unhealthy'.

Conclusions: This study has revealed a number of barriers to, and motivations for, healthy eating, which should be taken into account when planning nutrition intervention strategies aimed at children moving into adolescence. While it may be possible to immediately attempt to address some of the barriers identified in this study, for example, in nutrition education initiatives, other barriers (such as the lack of available, attractive and affordable healthy foods in the school canteen) will prove more difficult to tackle without changes at the policy level. Overall, it appears that health promotion specialists have a major challenge ahead in order to encourage this age group to view healthy eating as an attractive and achievable behavior.

Key words: Transcript, Barriers, motivation, Tendency, interventions.

PO1153**SAVING FUEL, COST AND PREVENTING ENVIRONMENTAL POLLUTION THROUGH SOLAR COOKING IN MID-DAY MEAL PROGRAMME**

V. Purushothaman¹, A. Thirumanidevi², G. Jagadeesan³, D. Gayathri³, K. Sobana³, S. Ithayamalar²

¹Department of Community Education and Entrepreneurship Development, Avinashilingam Institute for Home Science and Higher Education for Women, Coimbatore, Tamil Nadu, India

²Department of Food Science and Nutrition, Avinashilingam Institute For Home Science and Higher Education for Women, Coimbatore, Tamil Nadu, India

³Department of Resource Management, Avinashilingam Institute for Home Science and Higher Education for Women, Coimbatore, Tamil Nadu, India

Background and objectives: Noon Meal Programme aims to improve the nutritional status of children, school enrollments, attendance and reduce dropout rates. Increasing fuel cost and emission of carbon monoxide (when wood is used as a fuel) while cooking have remained as unsolved problems in mid-day meal cooking. Objective of the study was to see if solar cooking can save fuel, time and reduce pollution in noon meal preparation.

Methods: An Sk23 paraboloid solar cooker was used for the study. Sixty children received solar cooked lunch (aluminium cooking vessel). Another 60 children received solar cooked lunch (pressure cooker). Third group of 60 children served as control. The smoke emission from conventional cooking was estimated. The impact of using solar cooker for noon meal was assessed for fuel conservation, time taken for cooking and carbon monoxide emission. The experiment was conducted for four months and solar intensity, focal point temperature and ambient temperature recorded.

Results: The results of the study indicated that highest ambient temperature was observed during April and May (36°C and 37°C) and the lowest (33°C) was during July. The trend was similar for solar intensity (1075 w/m² and 1094 w/m²) and focal point temperature (142°C). In April, the time taken to cook rice was 2 hours. In June, it took 2 hours 20 minutes. On an average carbon monoxide level was estimated as 122.75 ppm.

Conclusions: considering 220 days in a year for solar cooking, about 0.4 to 0.9 tons of wood per school could be conserved per year through the implementation of solar cooking. Sk23 paraboloid solar cooker is pollution free, reduces the drudgery of cooking, saves fuel and time, and the acceptability and growth promoting quality were good. Hence introduction of solar cooking can be taken up for noon meal cooking.

Key words: Solar, Carbon monoxide, Drudgery, Fuel

PO1154**NUTRITIONAL STATUS AND ITS DETERMINANTS FOR WOMEN LIVING IN FEMALE HEADED HOUSEHOLDS IN ETHIOPIA: A MULTILEVEL ANALYSIS**

K. Ayalew¹, A. Hailemariam²

¹Department of Statistics, University of Gondar, Ethiopia

²Institute of Population Studies, Addis Ababa University, Ethiopia

Background and objectives: Nutritional status is one of the essential components for the welfare of an individual. However, the prevalence of malnutrition is high throughout the world, particularly in sub-Saharan Africa where 30% of its population is undernourished in 2010. It has become one of an important public health problem in countries like Ethiopia. Thus, this study aims to assess the nutritional status and its determinants for women living in female headed households in Ethiopia.

Methods: This study is carried out using data obtained from the 2005 Demographic and Health Survey of Ethiopia. A multilevel analysis was used to determine factors affecting the nutritional status of women living in female headed households.

Results: Among women living in female headed households, 26.6% were undernourished. In the multivariate analysis, age, family size, being engaged in agriculture, living in households with no toilet facility were found to be factors affecting the nutritional status of women living in female headed households. The risk of under nutrition was high among women aged 15-19 (OR=2.17, P-value<0.01) and 40-49 (OR=1.75, P-value<0.1) years. The risk of malnutrition was also high among women having small household size, whose occupation was agriculture, and those living in households with no toilet facility (OR=1.49, P-value<0.05). Rural women having small parity (OR=2.24, P-value<0.1) and Urban poor (OR=1.74, P-value<0.05) and very poor (OR=1.81, P-value<0.1) women were also likely to be undernourished.

Conclusions: Hence based on the findings raise of awareness about the importance of women nutrition, avoidance of childbirth at early and late ages, improvement of environmental sanitation and economic status of women and providing labor saving technology to the women are suggested recommendation.

Key words: nutritional status, malnutrition, female headed households.

PO1155**HAS THE IODINE STATUS, KNOWLEDGE AND PRACTICES OF PREGNANT AUSTRALIAN WOMEN IMPROVED SINCE MANDATORY BREAD FORTIFICATION?**

K. Charlton¹, H. Yeatman¹, E. Brock¹, C. Lucas¹, L. Gemming², G. Ma³

¹School of Health Sciences, University of Wollongong, Wollongong, NSW, Australia

²National Institute for Health Innovation, University of Auckland, New Zealand

³Institute of Clinical Pathology and Medical Research, Westmead Hospital, NSW, Australia

Background and objectives: In order to address the population-level mild iodine deficiency in Australia, a mandatory iodine fortification program of salt used in bread-making was introduced in the country in late 2009. To date, there has been no assessment of the effectiveness of the program.

Methods: A before-after quasi-experimental study was conducted to assess changes in median urinary iodine concentration (MUIC) measurements, according to supplement use, in pregnant women attending a public antenatal clinic in a regional area of New South Wales, Australia in 2008 (n = 139), 2011 (n = 147) and 2012 (n = 114). Knowledge and practices related to iodine nutrition were investigated in the 2012 sample using a self-administered questionnaire and dietary iodine intake evaluated using a validated iodine-specific food frequency questionnaire.

Results: The mild to moderate iodine deficiency that was confirmed pre-fortification (MUIC (IQR) = 87.5 (62, 123.5)) has steadily improved to 145.5ug/L (91, 252) in 2011 and 166 (97, 237) in 2012 (sufficiency $\geq 150\mu\text{g/L}$). However, only those women taking supplements containing iodine had MUIC indicative of sufficiency in both years surveyed post fortification (178ug/L vs. 109 ug/L; $P < 0.001$ (2011) and 202 $\mu\text{g/L}$ vs. 124 $\mu\text{g/L}$; $P < 0.05$ (2012). Despite bread being the vehicle for iodine fortification, dairy foods remained the major contributor to total iodine intake (58 %). Overall knowledge regarding health implications of iodine deficiency and identification of iodine rich food sources was poor.

Conclusions: Iodine status of women has improved since the introduction of mandatory iodine fortification; however supplementation is indicated during pregnancy.

Key words: iodine, fortification, pregnancy, supplementation

PO1156**FROM RESEARCH TO POLICY IN CHRONIC DISEASE PREVENTION: MANDATORY SALT REDUCTION IN SOUTH AFRICA**

K. Charlton¹, K. Steyn², N. Levitt², C. Lombard³

¹School of Health Sciences, University of Wollongong, Australia

²Department of Medicine, University of Cape Town, South Africa

³Medical Research Council of South Africa, Tygerberg, South Africa

Background and objectives: Ischaemic heart disease and stroke are the leading causes of death after HIV in South Africa. Excessive salt intake, a major cause of hypertension, is considered to be a major risk factor for cardiovascular disease in the South African population.

Methods: A systematic series of studies was undertaken to (1) assess main contributors to total salt intake; (2) to develop and consumer test reduced Na variants of these foods; (3) to conduct an 8-week randomised controlled trial to assess the blood pressure-lowering impact of substitution of these foods in African hypertensives.

Results: Bread is the major source of dietary salt intake, providing 25 to 41 % of non-discretionary salt intake in various groups. Other major contributors include margarine and spreads, savoury snacks, processed meats, soup powders and stock cubes. The salt content of bread could be reduced by 32 % without adverse impacts on commercial baking properties or taste. The magnitude of BP reduction found in the RCT (systolic BP = -6, 2 mm Hg (SEM 2.63) (95 % CI: -11.4 to -0.94 mmHg; $P < 0.05$) provided motivation for salt reduction legislation in foods.

Conclusions: As a result of these studies, South Africa is leading the way globally in policy regarding mandatory salt reduction in various food groups. Monitoring and evaluation of the legislation will be required to assess its effectiveness on health outcomes.

Key words: salt reduction, blood pressure, policy, bread

PO1157**PREVALENCE AND DETERMINANTS OF ANEMIA AMONG OLDER SCHOOL CHILDREN IN THE VOLTA REGION OF GHANA.**

N. Ziem¹, G. Egbi², M. Steiner-Asiedu³, M. Armar - Klemesu²

¹Nutrition Consultancy and Advisory Services (Ghana) Limited, Ghana

²Noguchi Memorial Institute for Medical Research, College of Health Sciences, University of Ghana, Legon

³Department of Nutrition and Food Science, University of Ghana, Legon

⁴Noguchi Memorial Institute for Medical Research, College of Health Sciences, University of Ghana, Legon

Background and objectives: Anemia, a critical public health issue resulting from micronutrient deficiencies, infections and infestation confronts a wide range of population groups. Research in Ghana on anemia among school aged children is often neglected. This study aimed to assess the iron status of older school children, assess their dietary intake and screen them for parasitic infections and infestations.

Methods: The study was cross-sectional involving School Children aged 6 to 12 years. 162 of the participants were randomly selected for the study using a simple random sampling. Blood and stool samples were collected and assessed for malaria parasitemia, helminthes, ferritin, and hemoglobin concentrations. Hemoglobin was determined in the field using a Hemocue Hemoglobinometer ((Hemocue AB, Angelhom, Sweden). Serum ferritin and serum transferrin receptor were measured using radioimmunoassay (Alpha Diagnostics Inc) and enzyme-linked immunosorbent assay respectfully. Malaria parasites and helminthes were investigated using Giemsa staining and Standard Kato-Katz techniques respectfully. SPSS (version 16.0) was used for all statistical analyses.

Results: There was high prevalence of anemia (30.8%) and low iron store (71.3%) among the study participants. Girls had higher prevalence of anemia (41.5%) than boys (21.8%). Malaria prevalence was high (67.8%) among the children and evenly distributed across gender; girls (66.2%) and boys (69.2%). Hookworm infestation was only prevalent in boys (18%). The mean energy, iron and vitamin C intake of the children were 982.67±255.91kcal, 18.98±8.84mg and 23.69±6.76mg respectively.

Conclusions: Anemia was high among the children in the region. Further research is needed to determine other factors responsible for the high prevalence of anemia.

Key words: Anemia, malaria, hemoglobin, ferritin, iron.

PO1158**ADJUSTING PLASMA CONCENTRATIONS OF FERRITIN, RETINOL, AND ZINC AFFECT THE PREVALENCE OF MICRONUTRIENT DEFICIENCIES IN CHILDREN BUT NOT IN WOMEN**

S. Wade¹, N. Idohou-Dossou¹, A. Diouf¹, AB. Seydi¹, AT. Guiro¹, MG. Sall², B. Ndiaye³

¹Université Cheikh Anta Diop de Dakar, Dakar, Senegal

²L'Institut de formation et de recherche en Population, Développement et Santé de la Reproduction (IPDSR), UCAD, Dakar, Senegal

³Micronutrient Initiative (MI), Dakar, Senegal

Background and objectives: The nutritional biomarkers plasma ferritin, zinc and retinol concentrations are influenced by subclinical inflammation/infection leading to over or under-estimate the real prevalence of iron deficiency (ID), zinc deficiency (ZD), and vitamin A deficiency (VAD) in populations. The aim of this study was to assess changes in ID, ZD, and VAD prevalence among women 15-49 years, and children 12-59 months old after adjusting for subclinical infection/inflammation.

Methods: Infection/inflammation was assessed by the measurement of plasma C-reactive protein (CRP) and alpha 1-acid-glycoprotein (AGP) by immuno-turbidimetry in 1496 children, and 1082 women recruited during a national representative cross sectional nutritional survey in Senegal. Plasma ferritin, plasma zinc, and plasma retinol concentrations were measured by ELFA, AAS, and HPLC, respectively. Published correction factors were used to remove the influence of infection/inflammation from each biomarker and the prevalence of ID, ZD, and VAD were compared before and after adjustment.

Results: In the children, inflammation decreased the prevalence of ID by 27% (56% vs. 82%; n= 1431; P<0.0001), increased the prevalence of ZD by 7% (50% vs. 43%; n=1148; P<0.0001), and the prevalence of VAD by 7% (24% vs. 17%; n=1418; P<0.0001). In contrast, although acute and chronic infections were detected in 11%, and 10% among the women, respectively, the adjusted prevalence was for ID 39%, for ZD 58%, and for VAD 1.9%, and was not significantly different from the measured one.

Conclusions: Measures of acute phase proteins (CRP and AGP) are needed to estimate the real prevalence of iron, zinc, and vitamin A deficiency in children but not in adolescent and adult women in Senegal.

Key words: micronutrients deficiency, inflammation, children, women, Senegal.

PO1159**CONCURRENT DEFICIENCIES OF IRON, ZINC AND VITAMIN A IN SENEGALESE WOMEN AGED 15-49 YEARS: A NATIONAL STUDY**

N. Idohou-Dossou¹, A. Diouf¹, N. Ba-Lo¹, D. Ndour¹, MH. Faye¹, A T. Guiro¹, M G. Sall², B. Ndiaye³, S. Wade¹

¹Université Cheikh Anta Diop de Dakar, Dakar, Senegal

²Institut de formation et de recherche en Population, Développement et Santé de la Reproduction (IPDSR), Senegal

³Micronutrient Initiative (MI), Dakar, Senegal

Background and objectives: The Senegalese government has launched a national fortification program to prevent iron and vitamin A deficiencies in Senegalese women. However, the extent of concurrent deficiencies in the population remains unknown. This study assessed the baseline concurrent deficiencies of iron, zinc and vitamin A (VA) among Senegalese women aged 15 to 49 years.

Methods: Concurrent deficiencies were analysed in 1082 women under the framework of a national representative cross sectional baseline survey using a stratified two-stage cluster sampling method. Plasma ferritin (PF), plasma zinc (PZ), and plasma retinol (PR) concentrations were measured by ELFA, AAS, and HPLC, respectively. The data were weighted, and adjusted to subclinical inflammation/infection defined by the plasma concentration of C-reactive protein, and alpha-1 acid glycoprotein measured by immuno-turbidimetry.

Results: For the individual measures, 39% and 58% of the women were iron and zinc deficient, respectively. Very few women (1.9%) was VA deficient (PR < 0.7 µmol/L) but low PR values (< 1.05 µmol/L) were found in 14.2% of them. Seventy seven percent (77%) of the women were suffering from at least one micronutrient deficiency. Among them, 46% were deficient in one micronutrient: zinc (30%), iron (13.4%), or had low VA status (2.5%); P<0.0001. Concurrent two micronutrients deficiencies affected 26% of the women (iron and zinc: 17.5%, zinc and low VA status: 5.5%, iron and low VA status: 3.1%; P<0.01). Concurrent three micronutrients deficiencies were found in 5% of the women.

Conclusions: Zinc is the most single micronutrient deficiency among the Senegalese women, but concurrent two micronutrient deficiencies, particularly zinc and iron, were also prevalent. The Senegalese Government should considered zinc during food fortification and/or supplementation program.

Key words: Concurrent micronutrient deficiencies, women, Senegal.

PO1160**CONCURRENT DEFICIENCIES OF IRON, ZINC AND VITAMIN A IN SENEGALESE INFANTS AGED 12-59 MONTHS: A NATIONAL STUDY**

A. Diouf¹, N. Idohou-Dossou¹, N. Ba-Lo¹, M. Sy¹, AD. Diatta¹, M. Fall Bèye¹, L D. Manga¹, A T.Guiron¹, M G. Sall², B. Ndiaye³, S. Wade¹

¹Université Cheikh Anta Diop de Dakar, Dakar, Senegal

²Institut de formation et de recherche en Population, Développement et Santé de la Reproduction (IPDSR), UCAD, Dakar, Senegal

³Micronutrient Initiative (MI), Dakar, Senegal

Background and objectives: Home fortification with micronutrient powders has been suggested by WHO as an alternative to increase iron, zinc and vitamin A intake in children aged 6-23 months. However, the existence of concurrent deficiencies on these micronutrients in children remains largely unknown. The aim of this study was to assess the concurrent deficiencies of iron, zinc and vitamin A (VA) among Senegalese children.

Methods: A national representative cross sectional survey using stratified two-stage cluster sampling method was conducted in Senegal, and 1496 children aged 12-59 months were investigated for iron, zinc, and VA status. Plasma ferritin (PF; n=1431), plasma zinc (PZ; n=1151), and plasma retinol (PR; n=1418) concentrations were measured by ELFA, AAS and HPLC, respectively. The data were weighted, and adjusted to subclinical inflammation/infection defined by plasma the concentration of C-reactive protein, and alpha-1 acid glycoprotein measured by immuno-turbidimetry. The analysis of concurrent deficiencies involved 1135 children.

Results: Using individual measures, 82.4%, 42.8% and 17.1% of the children were iron (FP<12 µg/L), zinc (PZ<65 in the morning and PZ<57 µg/dL in the afternoon), and marginal VA (POR≤0.70µmol/L) deficient, respectively. More than ninety percent (90.7%) of the children were suffering from at least one micronutrient deficiency. Among them, 46.6% were deficient in one micronutrient including iron (39.4%), zinc (5.8%), and marginal VA (1.3%); P<0.001. The prevalence of two micronutrient deficiencies was 27.7% for iron and zinc, 7.7% for iron and VA, and 1.4% for zinc and VA. Concurrent three micronutrient deficiencies affected 7.2% of the children.

Conclusions: Although iron is the main single micronutrient deficiency among the Senegalese children aged 12-59 months, concurrent two micronutrient deficiencies (zinc and iron) were also prevalent and therefore needs particular attention during home fortification.

Key words: Concurrent micronutrient deficiencies, children, Senegal.

PO1161**ANEMIA AND NUTRITIONAL STATUS OF PRE-SCHOOL CHILDREN IN NORTH GAZA, PALESTINE**B. Alzain¹¹Al Quds Open University, North Gaza Branch, Israel

Background and objectives: The most common cause of anemia is deficiency of iron; but it may also be caused by deficiencies of folates, vitamin B12 and protein. Some anemias are not caused by nutritional factors, but by congenital factors and parasitic diseases such as malaria. This study attempted to estimate the prevalence of anemia and investigate nutritional status among pre-school children in three rural communities of North Gaza government area.

Methods: A total of 150 children between the ages of 24 - 62 months were randomly selected over a period of six months and prevalence of anaemia was estimated. The World Health Organization (WHO) age-adjusted cut-off for hemoglobin were used to classify anemia. Under-nutrition (stunting, wasting and underweight) was classified according to the National Centre for Health Statistics standards. Heights, weights and Mid Upper Arm Circumference were measured. Haemoglobin levels of children were estimated by cyanmethaemoglobin method.

Results: The prevalence of anemia was 65.3 % having haemoglobin levels lower than 11g/dl. The percentage of anemic children among male and female children was 35 and 30 respectively and statistical analysis showed that male children were more susceptible to anemia. Malnutrition was patent; 34.0% of the children were stunted, 20.3% wasted and 45.0% underweight. Anaemia was also significantly higher in Jabalia camp than in bait hanon and Bait lahia town pre-school children ($P < 0.001$).

Conclusions: It is concluded that poor anthropometric indices, undernutrition and iron deficiency anemia may be due to lower intake of food than recommended.

Key words: food intake; Haemoglobin; Anthropometrics; Anemia; pre-school children.

PO1162**FOODBORNE DISEASES IN BAMAKO**H. Hami¹, T. Diallo², A. Maïga², A. Mokhtari¹, R. Soulaymani-Bencheikh³, A. Soulaymani¹¹Laboratory of Genetics and Biometry, Faculty of Sciences, Ibn Tofail University, Kenitra, Morocco²Faculty of Medicine, Pharmacy and Odonto-Stomatology, University of Bamako, Bamako, Mali³Moroccan Poison Control Center, Rabat, Morocco

Background and objectives: Foodborne diseases are a serious public health problem, both in developed and developing countries. They are the result of ingestion of food contaminated with microorganisms or chemicals. The present study aims to estimate the magnitude of the problems posed by foodborne diseases and their characteristics in Bamako, Mali's capital.

Methods: A descriptive retrospective analysis of food poisoning cases, notified between 2000 and 2010 by two University Hospitals (CHU) and six Health Reference Centers (HRC) in Bamako, was performed.

Results: During 2000-2010, a total of 573 cases of foodborne diseases were identified, constituting 52% of accidental poisoning cases notified during this period. Of that number, 201 cases (35, 7%) occurred in children under the age of 6 years (among the 563 cases for whom the age is known). The average age of victims was 15 years. According to data recorded, the poisoning symptoms are varied, depending on the type of contaminated food, the type and degree of contamination, the ingested quantity and the delay before treatment. Among the cases for whom the evolution is known, 2 of them died after eating contaminated food. For other cases, the outcome was favorable with or without sequelae.

Conclusions: Foodborne disease will continue to be a matter of major concern around the world in the foreseeable future, despite some important successes at reducing the levels of certain pathogens in foods.

Key words: Food, Poisoning, Epidemiology, Bamako, Mali.

Background and objectives: This study examines the relationship between educational level and the prevalence of obesity among adults in Abeokuta, Ogun State, Nigeria.

Methods: A total of 240 respondents were selected from two different localities i.e rural and urban, with their ages ranging from 20 years and 64 years. The educational level details were obtained based on the personal information given and the prevalence of obesity was determined using the Body Mass Index cut-off (≥ 30 kg/m²) to estimate those obese. The data were analyzed using descriptive and correlative parameters to demonstrate the influence of educational level and its resultant effect on income level on obesity across the sampled population.

Results: The results showed the highest level of among the rural males of lower educational status. Adjustments were made to establish relationship between educational attainments and BMI graphically.

Conclusions: Conclusively, there was strong and direct association between the educational level and the BMI; which further affirmed that educational level determines the income level and obesity mostly among the urban population. Findings of this nature can provide functional insights into some socioeconomic developments that can help to overcome obesity epidemic.

Key words: Educational Level, BMI, Adults, Trends.

PO1165

EFFECTS OF AGE AND ENERGY EXPENDITURE ON OBESITY AMONG ADULTS IN ABEOKUTA, OGUN STATE, NIGERIA

A S. Adekoya¹

¹African Graduate of Nutrition Students' Network (AGSNET) Ithaca, New York, USA

Background and objectives: The purpose of the study was to assess the independent effects of age and energy expenditure on the risks of obesity among adults (20-64 years) in Abeokuta.

Methods: A cross-sectional study with changes in age, changes in work and leisure-time, and physical activities information played roles. In all, 240 adult subjects of which 120 were females and 120 were males with age ranging between 20-64yrs in rural and urban localities in Abeokuta. The cut-off for energy expenditure and BMI were estimated in accordance with the FAO/WHO classifications. The data were analyzed using descriptive and correlative parameters to demonstrate the influence of age on energy expenditure.

Results: Physical activity information determined the energy expenditure, while the BMI determined the risk of obesity among the subjects. The risks of obesity in the rural and urban areas strongly increased with increased age across the gender, while energy expenditure contributed to the risks in the urban population. Statistically, age has a strong and direct association with obesity in both rural and urban settings, while energy expenditure was inverse in its association.

Conclusions: Findings from this study showed that in developing societies, age tends to be a risk factor for obesity, whereas energy expenditure is to be protective. Level of education and economic development are relevant modifiers of the influences exerted by these variables.

Key words: Age, Energy Expenditure, BMI, Rural/Urban.

PO1166

INFANT YOUNG CHILD FEEDING PRACTICE AND THEIR NUTRITIONAL STATUS IN A NATIONAL NUTRITION PROGRAM AREA

S. Sultana¹, A. Hoque¹, F. Saleh¹

¹Department of Community Nutrition, Bangladesh Institute of Health Science, BSMMU Dhaka, Bangladesh

Background and objectives: Appropriate feeding practice during the first two years of life is important for the growth and development of a child. The aim of this study was to assess infant young child feeding practice and their nutritional status in a national nutrition program area.

Methods: This cross-sectional study was conducted in Kapasia under Gazipur district, Bangladesh. In total, 150 children of 0-2 years were selected purposively.

Results: The rates of initiation of breast-feeding within one hour was 67.3%, exclusive breast-feeding and continued breastfeeding were 82.7% and 98% respectively. Starting complementary feeding at appropriate time was 83.1%. Among the respondents 34% was reported of using bottle for child feeding. In responsive feeding practice 45% mother were talking during feeding but 17% were forcing child to eat. Majority (76%) of the caregivers washed their hands properly before offering complementary feeding to their children but mothers did not use variety of foods. In the program area the underweight, stunting and wasting rates (<-2SD) were 22%, 31.7% and 11.6% respectively. Significant association was found between education of mother and exclusive breast feeding ($p<.005$) and between sex of children and stunting ($p<.002$).

Conclusions: In the study area infant young child feeding practices were good and their nutritional status was acceptable and the prevalence of malnutrition was low. Comprehensive policy response is required to address infant young child nutrition in Bangladesh.

Key words: NNP, infant young child feeding practice, nutritional status.

PO1167

BODY CONCERNS VARY BETWEEN ACADEMIC BACKGROUNDS: A COMPARISON OF FEMALE FASHION DESIGN AND DANCE STUDENTS

M. Kagawa¹, H. May², D. Brough³, S. Boughen³, A. Hills⁴

¹Institute of Nutrition Sciences, Kagawa Nutrition University, Saitana, Japan

²Institute of Health and Biomedical Innovation, Queensland University of Technology, Brisbane, Australia

³Institute of Creative Industries, Queensland University of Technology, Brisbane, Australia

⁴Mater Mothers' Hospital, Mater Medical Research Institute, Mater Mothers Hospital, Mater Medical Research Institute, Brisbane, Australia

Background and objectives: While an excessive desire for thinness has been suggested as a potential health risk for young females, an influence of course of study on body image has not been examined extensively. The present study explored lifestyle, body perception and reasons for body concerns among female university students enrolled in fashion design and dance performance, disciplines with a professional focus on aesthetics of the body.

Methods: A self-administered questionnaire was distributed and 81 completed questionnaires were returned. Data of 27 fashion design and 33 dance students with completed gender, age, and current height and weight information were included in the analysis.

Results: Dance students had a shorter and a lighter physique than their design counterparts ($p<0.01$) but both had a comparable body mass index (BMI). There were no differences in eating behavior and effort for weight management but dance students exercise more frequently ($p<0.01$). Similarly, while perceptions toward their current weight and physiques did not differ between the groups, a greater proportion of dance students reported training/education as an influencing variable for body perception compared to design students (72.7% vs 11.1%; $p<0.01$). Compared to dance students, a greater proportion of design students raised having reassurance (81.5% vs 30.3%; $p<0.01$) and attractiveness (81.5% vs 57.6%; $p<0.05$) as reasons for body concern whereas dance students raised sports performance ($p<0.01$), comments from family members and a comparison of a physique with their surroundings (both $p<0.05$) as their reasons for body concerns.

Conclusions: The current findings indicate reasons for body concern differ between females studying different professions, although their eating behavior and body perception were comparable. It may be important to evaluate differences in reasons for body concerns further for future implementation of population-specific approaches to improve body concern of young females.

Key words: Body concern; females; university students; enrolled course.

PO1168**KNOWLEDGE AND USE OF FOOD LABEL INFORMATION AMONG URBAN CONSUMERS IN INDIA***S. Vemula¹, S.M. Gavaravarapu², V. Mendu³, L. Avula⁴*¹Food & Drug Toxicology Research Centre, National Institute of Nutrition, Hyderabad, India²Extension & Training Division, National Institute of Nutrition, Hyderabad, India³Division of Bio-Statistics, National Institute of Nutrition, Hyderabad, India⁴Division of Community Studies, National Institute of Nutrition, Hyderabad, India

Background and objectives: Overweight, obesity and associated diseases are on the rise in India. To discourage consumption of unhealthy foods, Indian food regulations made nutrition labeling mandatory since 2009. A study was conducted with an objective to assess knowledge, perceptions and use of food labels among consumers.

Methods: A cross-sectional study was conducted in two metro-cities of India using both quantitative and qualitative methods. Intercept interviews (n=1832) were conducted at super-market sites by administering structured questionnaires on a stratified random sample of adolescent (10-19 years), adult (20-59 years) and elderly (60 years) consumers. This quantitative information was triangulated with qualitative data from 21 Focus Group Discussions (FGDs).

Results: About 45% of consumers across the age groups buy packed foods once in a week and 12% buy every day. Taste, quality, convenience and ease-of-use were reported to be reasons for buying packed foods. Although 90% of the consumers across the age groups check food labels, majority (81%) of them look only for manufacturing date, expiration/best-before date. Only 1/3rd of the consumers check nutrition information and list of ingredients. Nutrient information on labels was not often checked because most of them felt they either lacked nutrition knowledge or found information too technical to understand. About 60% of the respondents check quality symbols. It was observed that the significantly ($p<0.001$) higher number of respondents with higher education were checking quality symbols and nutrition information in all categories of the prepackaged foods. Women and girls concerned about 'fat' and 'sugar' intake were checking nutrition facts.

Conclusions: The intent of promoting choice of healthy foods through use of food labels is not being completely met. Majority find nutrition information complicated to comprehend; there is perhaps a need to take up educational activities and/or experiment newer forms of nutrition labeling.

Key words: Food-label, consumer-survey, nutrition.

PO1169**NUTRITION GOVERNANCE FOR MATERNAL AND YOUNG CHILD NUTRITION SECURITY IN THE PHILIPPINES***M. Paunlagui¹, P. Gordoncillo², C. Barba³, M.T. Talavera³, W. Carada⁴, A. Bustos³, N. Gordoncillo³, L. Africa³, Z. Torres³*¹Center for Strategic Planning and Policy Studies, College of Public Affairs, University of the Philippines, Los Baños, College, Laguna, Philippines²Department of Agricultural Economics, College of Economics and Management, University of the Philippines, Los Baños, College, Laguna, Philippines³Institute of Human Nutrition and Food, College of Human Ecology, University of the Philippines, Los Baños, College, Laguna, Philippines⁴Institute for Governance and Rural Development, College of Public Affairs, University of the Philippines, Los Baños, College, Laguna, Philippines

Background and objectives: An important dimension of the UNICEF and the European Union's project to improve child survival, growth, and development through nutrition security and life cycle interventions was to assess the functionality and state of multi-sectoral coordination in addressing maternal and young child nutrition security (MYCNS). Specifically, this paper aimed to: 1) assess the functionality of the local nutrition committee (LNC) and the Local Nutrition Action Plan (LNAP); 2) identify gaps across intervention areas and highlight opportunities for possible stakeholders or partnerships to fill these gaps; and 3) to provide the basis for prioritizing the interventions towards MYCNS.

Methods: The study covered 316 municipalities and cities where both primary and secondary data related to the nutrition interventions were collected. Secondary data were generated to characterize the municipal level nutrition attributes while primary data to characterize the stakeholders and the extent of collaboration and functionality of the LNP and LNC were generated through key informant interviews.

Results: The assessment revealed: 1) an indicative relationship between functionality of the LNC and the LNAP; and 2) the positive relationship between LNC functionality LNP sustainability and functionality and sustainability and effectiveness as measured by the extent of malnutrition. Another indicator used in the study is the knowledge and practices (K&P) rating to measure the degree of functionality of the institutions and the level of appreciation by the key service providers on appropriate knowledge and good practices in health and nutrition interventions.

Conclusions: Overall, K&P rating indicates that knowledge does not necessarily translate into good practices. This rating can serve as the basis for prioritizing the services either

by government administrative unit, by service provider, and by component.

Key words: Nutrition Security, Local Nutrition Planning, Knowledge and Practice Rating.

PO1170

PROMOTING HEALTHY EATING HABITS IN GHANA THROUGH THE PRINT AND ELECTRONIC MEDIA

W. Letsa¹

¹The Trust Hospital, Accra, Ghana

Background and objectives: There is lack of knowledge on healthy eating and preventive health practices such as exercise in Ghana. Taking a history on the above theme from patients that reported to me for dietetic care in the hospital revealed the truth behind this assertion. There is therefore the need to put out information that would elicit public interest in the area of gaining knowledge on healthy eating practices. The objectives were to write articles on healthy eating habits in a simple non-technical language for people to read. It was also aimed at getting social groups like churches, corporate organizations, health clubs, and clinics/hospitals to engage the services of dietitians and nutritionists for some basic education to their members.

Methods: I chose a national newspaper where I write articles once a week. The newspaper is called "The Mirror". Contact information is provided for readers to get in touch with me.

Results: On weekly basis readers send me emails seeking further clarifications on their diet. There have also been calls from groups and corporate organizations that needed our services in educating their members on healthy eating habits. Through these articles in the Mirror, other media houses including TV stations and radio stations have interviewed me on various aspects of diet and health. This has been going on for the past three years. The various articles published in the year 2012 will be presented at the ICN conference. The title of the first article published in 2012 was "Just 30 minutes of walking daily will do these" and the last one published in 2012 was "The appointments you should keep in 2013".

Conclusions: The whole nation gets educated on their diet and health. Groups and organizations also engage our services for further education through seminars.

Key words: Mirror, Articles, Healthy, Diet, Knowledge.

PO1171

THE IMPACT OF VARIOUS DOSES OF LIPID-BASED NUTRIENT SUPPLEMENTS (LNS) ON ENERGY INTAKE OF 9 MONTH OLD MALAWIAN INFANTS

J. Hemsworth¹, C. Kumwenda², M. Arimond³, A M. Rehman¹, K. Maleta⁴, J. Phuka⁴, K G. Dewey³, P. Ashorn², E L. Ferguson¹

¹Department of Population Health, London School of Hygiene and Tropical Medicine, London, UK

²Department of International Health, University of Tampere Medical School, University of Tampere, Tampere, Finland

³Program in International and Community Nutrition, University of California (Davis), Davis, California, USA

⁴Division of Community Health, College of Medicine, Blantyre, Malawi

Background and objectives: The causal pathway of undernutrition during infancy is complex. One of the key players is quality/quantity of complementary foods (CF). LNS has been successfully used to treat moderate undernutrition and is now being evaluated for its potential to prevent undernutrition. The impact of LNS on total intake is not well understood. Objective: To assess the impact of various doses of LNS on energy intake from CF of 9 month old infants participating in a larger trial (International Lipid-Based Nutrient Supplement [iLiNS-DOSE trial]) in Mangochi, Malawi.

Methods: Infants were randomly allocated to one of four LNS doses at enrolment (6 months of age) – control, 10g LNS/d, 20g or 40g. In the dietary assessment substudy, two interactive 24-hour dietary recalls per infant were completed 7 days apart at 9 months of age. Energy and nutrient intake estimations were made using a food composition table compiled for Malawian foods. Between group differences were assessed using an unadjusted linear regression model and pair-wise comparisons between groups using post-hoc linear combination tests.

Results: Recalls were collected from 568 infants. Median (25, 75th percentile) energy intake (kcal/d) from CF in each group (control, 10, 20 and 40 LNS g/d) was 345 (247, 464); 396 (309, 532); 409 (300, 548); and 388 (304, 548), respectively; $p=0.003$. Upon post-hoc analysis, all LNS dose groups were significantly different from the control ($p<0.05$), but differences between LNS groups were not significant ($p>0.05$).

Conclusions: LNS (10, 20 or 40 g/d) increased energy intake from CF; the magnitude of increase was not related to the dose of LNS provided. This could have important implications for the cost of potential interventions. Acknowledgement: This work was funded by grant from the Bill & Melinda Gates Foundation to the University of California, Davis.

Key words: undernutrition, infant, LNS, dietary assessment.

PO1172**FOOD LABELING IN INDIA – A STUDY ON CURRENT SCENARIO OF REGULATION, COMPLIANCE BY INDUSTRY AND CONSUMER PERCEPTIONS**

S R M. Gavaravarapu¹, S R. Vemula, V V R. Mendu, L. Avula

¹Extension & Training Division, National Institute of Nutrition, Jamai, Osmania PO, Hyderabad, India

²Food and Drug Toxicology Research Centre, National Institute of Nutrition, Jamai - Osmania PO, Hyderabad, India

³Division of Biostatistics, National Institute of Nutrition, Jamai - Osmania PO, Hyderabad, India

⁴Division of Community Studies, National Institute of Nutrition, Jamai, Osmania PO, Hyderabad, India

Background and objectives: India witnessed ~300% rise in consumption of packed foods in the last two decades. Considering that food labeling is an important population-based approach to promote healthy and informed food choices, Indian food regulations mandate compulsory food labeling. This study aimed to assess the current scenario of labeling in terms of regulations, market compliance, consumer perceptions and use of label information.

Methods: The study was conducted in three phases. Phase-I: A review of food labelling regulations in India vis-à-vis other countries was done through systematic library and internet search. Phase-II: To assess the manufacturer compliance with mandatory labelling requirements, 815 pre-packaged foods encompassing 15 categories were collected from supermarkets. Their labels were assessed using pre-tested proforma. Phase-III: Questionnaires, stakeholder interviews, and focus groups were used to assess use of label information and consumer perceptions.

Results: India's food labeling regulations are on par with those in developed countries, however, there is ambiguity about nutrition and health claims. Market survey revealed food products were ~100% compliant with mandatory labeling; 77% of labels displayed 'instructions-to-use' and 'storage-conditions'. Nutrient declaration was based on nutritive values of raw ingredients, whereas regulation mandates values based on final product analyses. Although 90% consumers claimed to read labels, >80% perceived shelf-life as a concern and checked only 'best-before' or 'expiration' dates. Only 1/5th of them read nutrition/ingredient information. Many found nutrition information too complex. Education and nutrition knowledge were major determinants of label use.

Conclusions: It is time to evolve permitted nutrition and health claims that can be used on labels. The intent of promoting healthy foods through use of food labels is not being completely met. Nutrition education is the key to promote consumer use of label information for food choices. Keywords Labeling, Regulation, India, Consumer perceptions.

PO1173**ALARMING RATE OF ANAEMIA AMONG UNDER TWO YEAR CHILDREN FROM AYEYARWADY DIVISION, MYANMAR**

⁵Research Institute Trisakti University, Indonesia

⁶Research Team Member, Myanmar

⁷University of Culture, Mandalay Region, Myanmar

Background and objectives: Iron deficiency (ID) is most common micronutrient deficiency among young children. ID impairs cognitive performance, behavior and physical growth of these children which often have long term consequences. Although anemia is multifactorial, prevalence of anemia is a practical indicator used to assess ID in low-income setting. Our previous study showed complementary feeding diet for these children cannot meet their requirement for iron, zinc, folate and vitamin B12. Recently, we conducted a survey to estimate the magnitude of anemia and undernutrition problems among under-2-years children from Myanmar.

Methods: A cross-sectional survey was conducted among 489 children of 12-18 months, in Pan-Ta-Naw and Kyaung-Gon townships, Ayeyarwady Division, Myanmar in February, 2013. This was screening phase of a randomized trial comparing food-based and supplement-based nutrition interventions (ClinicalTrials.gov Identifier: NCT01758159). The children were screened for their Hemoglobin (Hb) concentration by Hemocue and anthropometry assessment was done. Screening for malaria infection was also done by rapid immunochromatographic test (ICT) malaria p.f/p.v.

Results: Mean Hb concentration was 9g/dL and 91% of children were anemic (Hb<11g/dL) with 84% mild anemia, 8.8% moderate anemia (Hb<7g/dL) and 0.2% severe anemia (Hb<5g/dL). Prevalence of wasting (WHZ<-2SD) was 12.1%, stunting (HAZ<-2SD) 28.2% and underweight (WAZ<-2SD) 22%; severe wasting (WHZ<-3SD) 1.2%, severe stunting (HAZ<-3SD) 10% and severe underweight (WAZ<-3SD) 7.3% respectively. The prevalence of anemia and undernutrition are similar in two townships. Only one child was detected for malaria infection.

Conclusions: Anemia is a major nutrition problem among under two year old Myanmar children. Malaria infection was not common among the children. Poor complementary feeding practices based on monotonous and cereal-based diet with low bioavailability of iron may contribute to the problem. The study highlights the urgent need for nutrition intervention for the children of vulnerable age group in Myanmar.

Key words: Anemia, Under 2 year children, Myanmar.

PO1174

BEHAVIORAL AND NEUROCOGNITIVE STATUS OF IRON DEFICIENT SCHOOLCHILDREN IN KENITRA NORTH WEST OF MOROCCO

Y. Aboussaleh¹, R. Sbaibi¹, M. El Hioui¹, A. Ahami¹

¹Nutrition and Health laboratory, Ibn Tofail University, Kenitra, Morocco

Background and objectives: This work aims study the problem of iron deficiency and its implication on neurocognitive regulations and their impact on neurocognitive development and schoolchildren performances in Kenitra north west of Morocco. Iron deficiency remains an important public health trouble on a global scale, regional and local levels. The relations between iron deficiency and cognitive performance exist but the biochemical and physiological mechanisms linking it to an altered neurocognitive function are not yet clear.

Methods: We reviewed the studies relating IDA to Neurocognition especially on hippocampus functions alteration and consequently on learning abilities and memory. Then a set of cross sectional observational studies carried out in the city of Kenitra and its region will be presented. A total of 600 pupils were observed in different settings in rural periurban and urban. After validation and adaptation of cognitive tools, extracted batteries were used to assess cognitive status (Raven Progressive matrix, Bell tests, WISC extracts etc..). Iron status was assessed by Hemoglobin and serum ferritin.

Results: The results confirm that anemia is very important in schoolchildren and its prevalence varies from 20 to 30 %. A strong association was found between iron deficiency alone and iron deficiency anemia with a global induced intelligence and visual attention performances.

Conclusions: Scientists rely on the use of new exploration techniques and behavioral neurocognitive (fMRI, EEG evoked potentials) to enlighten in the near future.

Key words: Iron Deficiency, NeuroCognition, Development.

PO1176

THE EFFICACY OF EDUCATION ON NUTRITIONAL AND DENTAL CARIES KNOWLEDGE OF OBESE CHILDREN'S PARENTS

A. Etebarian¹, F. Esfarjani, M. Khalafi

¹Dental School, Shahid Beheshti University of Medical Sciences, Tehran, Iran

²National Nutrition and Food Technology Research Institute, Shahid Beheshti University of Medical Sciences, Tehran, Iran

³National Nutrition and Food Technology Research Institute, Shahid Beheshti University of Medical Sciences, Tehran, Iran

Background and objectives: Obesity, Dental caries and periodontal diseases are among major public health concerns and growing chronic diseases especially in children. The aim of this study was to determine nutritional and dental caries knowledge of obese children's parents. (All parents of 7 year-old obese pupils, BMI \geq 95).

Methods: This semi-experimental study was conducted to investigate the impact of nutritional and dental caries educational program (32 hours) on knowledge of 75 parents who were randomly selected from several Health clinics in Tehran, Iran (2010). A questionnaire was filled for each subject, based on their Demographic data, Nutritional and Dental caries knowledge, considered into three categories: Good, Moderate and Weak. Data were analyzed using SPSS.

Results: 52% of obese children were girls. 85% family size, belonging to 4 households. The highest level of education was academic, 55% and 50% in fathers and mothers respectively. 39% of Fathers were individual employees. 72% of mothers (mean age 35.62 yr), were housewives. Scores of nutritional and dental caries knowledge in three categories (Good, Moderate, Weak) were: (3.6%, 50.9%, 45.5%) before, and (58.2%, 61.8%, 0%) after education, respectively ($p < 0.0001$).

Conclusions: Considering to the results, Education on nutritional and Dental caries knowledge is an effective approach to promote knowledge by using attractive modern technology is highly recommended.

Key words: Nutrition, Dental caries, Knowledge.

PO1177

PROMOTING EDUCATION AND PROFESSIONAL INSERTION OF WOMEN IS KEY FOR REDUCING THE OBESITY GENDER GAP IN NORTH-AFRICA: EVIDENCE FROM TUNISIA

J. El Ati¹, P. Traissac², H. Aounallah-Skhiri³, C. Béji¹, S. Eymard-Duvernay², H. Ben Romdhane⁴, B. Maire², F. Delpeuch²

¹NNTA (National Institute of Nutrition and Food Technology), Tunis, Tunisia

²UMR NUTRIPASS (IRD, UM2, UM1), IRD (Institut de Recherche pour le Développement), Montpellier, France

³INSP (National Institute of Public Health), Tunis, Tunisia

⁴Epidemiology and prevention of CVD research unit, Faculty of Medicine, Tunis, Tunisia

Background and objectives: South Mediterranean countries have experienced a marked increase in prevalence of obesity whose prevention is now a public health challenge in these countries; beyond general obesity reduction policies, the marked environmental, socio-economic and socio-cultural patterning of obesity underlines the need for targeted strategies. In this gender sensitive socio-cultural context, we studied women vs. men differences in corpulence and their environmental and socio-economic modifiers among Tunisian adults.

Methods: Cross-sectional survey (2005): 35-70y. Tunisians. National, 3 level random cluster sample (F: n=2964, M: n=2379). BMI=weight(kg)/height(m)² from measured height and weight, obesity was BMI \geq 30, abdominal obesity waist(cm)/height(cm) ratio \geq 0.6. The gender contrast measure was women vs. men obesity odds-ratio (OR); multivariate models featuring gender x covariate interaction assessed modifying effect of environment (urban vs. rural) or socio-economics (age, marital status, profession, education, economic level).

Results: Obesity was much more prevalent among women vs. men (37.0% vs. 13.3%, OR=3.8[3.1-4.7]) as was abdominal obesity (42.6% vs. 15.6%, OR=4.0[3.3-4.8]). The obesity gender contrast was higher in urban (OR=3.3[1.3-8.7]) than rural areas (OR=2.0[0.7-5.5]). This obesity gender contrast decreased with level of education (none: OR=6.9[2.0-23.3], primary: OR=4.2[1.5-12.3], secondary and more: OR=3.3[1.3-8.6]) and also steeply with professional activity (not working: 3.3[1.3-8.6], employee/worker: 2.3[1.0-5.4], upper/intermediate: 1.4[0.5-4.3]). Analogous results were observed for abdominal obesity.

Conclusions: The large observed overall gender obesity gap was higher in urban areas but much lower among the more educated and even more so among those having more qualified professional activities. Beyond general policies aimed at

prevention of obesity, or nutrition interventions targeted at women as a group especially at risk, these results underline the importance of reducing social role gender differentials for reduction of gender obesity inequities in the long term. This is a challenge for prevention in the changing socio-political context.

Key words: obesity, gender, inequities, socio-economics, Tunisia.

PO1178

FRUIT CONSUMPTION IS ASSOCIATED WITH LOWER RISK OF DEPRESSION IN MID-AGE WOMEN

S. Mhrshahi¹, A. Dobson¹, G. Mishra¹

¹School of Population Health, University of Queensland, Brisbane, Australia

Background and objectives: There is continued interest in the associations between diet and depression and several cross-sectional studies have focused on individual diets or diet patterns to investigate the relationship. A Mediterranean diet pattern, of which fruit and vegetables form a large part, has been implicated as a possible protective factor. We investigated the association between fruit and vegetables and symptoms of depression in the mid-age cohort of the Australian Longitudinal Study on Women's Health.

Methods: A total of 6869 women with a mean age of 52.5 (SD 1.5) years at baseline were followed up at three surveys over 10 years. A score of greater than or equal to 10 on the Center for Epidemiological Studies Depression-10 scale indicated depressive symptoms. Women were classified as chronically depressed if they had a score of greater than or equal to 10 at all surveys. Fruit and vegetable intake was assessed using short questions. Logistic regression, using general estimating equations, was used with adjustment for several factors including smoking, alcohol consumption, BMI, physical activity, marital status, education, total energy and fish intake. Analysis was performed using STATA 11.0.

Results: A total of 430 women (6.3%) were chronically depressed over 10 years. Among these women only 31% consumed two or more pieces of fruit/day at all three surveys compared with 47% in the group showing no depressive symptoms. There was a reduced odds of depression [OR 0.89 (95% CI 0.86-0.93, p<0.001)] among women who ate two or more pieces of fruit/day even after adjustment. There were no consistent associations between the intake of vegetables and depression.

Conclusions: These associations of fruit intake on depression, if replicated in future longitudinal studies, may be useful for dietary based primary preventive strategies for reducing the burden of depression.

Key words: diet, depression, fruit and vegetable intake.

PO1179

ASSOCIATION BETWEEN LACK OF EXCLUSIVE BREASTFEEDING AND DIARRHOEAL MORBIDITY: AN ANALYSIS OF NATIONAL DATA SETS FROM SOUTH ASIA

³Bangladesh Breastfeeding Foundation, Dhaka Bangladesh

⁴Faculty of Medicine, University of Colombo, Colombo, Sri Lanka

⁵Nutrition Health Research and Community Services, Kathmandu, Nepal

⁶Indira Gandhi Government Medical College, Nagpur, India

⁷Children's Hospital, Pakistan Institute of Medical Sciences, Islamabad, Pakistan

⁸Health, Education and Literacy Programme, Karachi, Pakistan

⁹Institute of Home Economics, University of Delhi, New Delhi, India

¹⁰Sydney School of Public Health, University of Sydney, Sydney Australia for the South Asian Infant Feeding Research Network

Background and objectives: Exclusive breastfeeding (EBF) for the first six months and continued breastfeeding for the first two years of life are among the most effective interventions for reducing childhood mortality and morbidity. Although the prevalence of breastfeeding in South Asia is high, the low prevalence of EBF remains a significant factor that threatens the health and survival of infants. This analysis aims to investigate the association between EBF and diarrhoea in infants aged 0-6 months in the South Asian region.

Methods: Public domain data sets from 2005-2007 including Demographic and Health Survey data from Bangladesh, Nepal, Pakistan and National Family Health Survey data from India were used for this analysis. EBF was defined using the WHO definition. The primary outcome variable was the two week prevalence of diarrhoea. Logistic regression was used and factors such as gender, education and age of mother, birth order, urban/rural location, sanitation variables and poverty quintile were included in the final multivariable model. Analysis was performed using STATA 11.0.

Results: A total of 5660 subjects across the four countries were used for this analysis. The overall prevalence of EBF was

45.4%, ranging from 37.1% in Pakistan to 53.1% in Nepal. The overall prevalence of diarrhoea was 12.3%, ranging from 4.6% in Bangladesh to 26.5% in Pakistan. The odds ratio OR (95% CI) for the protective effect of EBF on diarrhoea was 0.66 (0.54-0.82) $p < 0.0001$. Low maternal education and male gender were also associated with diarrhoea. Factors associated with lack of EBF varied across countries.

Conclusions: Improving rates of EBF is likely to reduce diarrhoeal morbidity substantially in South Asia. Because the prevalence and other factors associated with lack of EBF vary across countries in the South Asian region, promotion efforts should be tailored according to the context.

Key words: exclusive breastfeeding, diarrhoea.

Background and objectives: Prospective studies have consistently suggested that nut consumption is inversely related

to fatal and non-fatal coronary heart disease. Limited data are available on the epidemiological associations between nut intake and cardiometabolic risk factors. The aim of our study was to evaluate associations between frequency of nut consumption and prevalence of cardiometabolic risk factors [obesity, metabolic syndrome (MetS), type-2 diabetes, hypertension, and dyslipidemia] in a Mediterranean population at high cardiovascular risk.

Methods: Cross-sectional study of 7, 210 men and women (mean age, 67 y) recruited into the PREDIMED study. MetS was defined by the harmonized ATP III and IDF criteria. Diabetes and hypertension were assessed by clinical diagnosis and dyslipidemia (high triglycerides, low HDL-cholesterol, and hypercholesterolemia) by lipid analyses. Nut consumption was assessed using a validated food frequency questionnaire and categorized as <1, 1-3, and >3 servings/wk. Control of confounding was done with multivariate logistic regression.

Results: Compared to participants consuming <1 serving/wk of nuts, those consuming >3 servings/wk had lower adjusted odds ratios (OR) for obesity (0.61, 95% confidence interval 0.54 to 0.68; P-trend <0.001), MetS (0.74, 0.65 to 0.85; P-trend<0.001), and diabetes (0.87, 0.78 to 0.99; P-trend=0.043). Higher nut consumption was also associated with lower risk of the abdominal obesity MetS criterion (OR 0.68, 0.60 to 0.79; P-trend<0.001). No significant associations were observed for the MetS components high blood pressure, dyslipidemia, or elevated fasting glucose.

Conclusions: Nut consumption was inversely associated with the prevalence of general obesity, central obesity, MetS, and diabetes in subjects at high cardiovascular risk.

Key words: Nut consumption, cardiometabolic risk, obesity, metabolic syndrome. **Acknowledgments:** We thank all the participants of the PREDIMED study.

THE EXTENT AND NATURE OF TELEVISION FOOD ADVERTISING TO CHILDREN IN XI'AN CITY, CHINA

T. Wang¹, Y. Cao¹, L. Zeng¹

¹Department of Epidemiology and Health Statistics, Xi'an Jiaotong University College of Medicine, Xi'an, China

Background and objectives: Childhood obesity is a growing global epidemic while wide sales of energy dense low nutrient food are a gradually prominent factor for it. Television advertising as a public media plays an important role in food propaganda and sales, and children who are without independent judgment will be affected in food cognition and choice. This study aims to explore the extent and nature of food advertising that children are exposed to on television in Xi'an, China.

Methods: Television data for 2 weekdays and 2 weekend days between 6:00 and 22:00 during May and June in 2012 from three television channels which children like most were recorded. Food advertisements were classified as healthy food (nutrient dense, low in energy), unhealthy food (high in undesirable nutrients or energy), or miscellaneous. The persuasive marketing skills were divided into promotional characters and premium offers. The time children watching TV were categorized as peak viewing times and non-peak viewing times.

Results: Of the 5527 advertisements transcribed, 25.49% were for food, among which 58.27% were considered to be unhealthy. More than 50% unhealthy food advertising used persuasive marketing skills. The frequency of advertising was 22 per hour per channel, including six food advertisements and three unhealthy food advertisements. The rate of unhealthy food advertising was higher during children's peak viewing times. Significantly more unhealthy food advertisements were screened on weekends compared with weekdays, children's television channel compared with other television channels, CCTV compared with local television stations.

Conclusions: Children were exposed high levels of television advertising for unhealthy food, with children oriented persuasive marketing skills. The study provided a baseline to this field in Xan and more research need to be done in order to improve children health in future.

Key words: television food advertising; children; obesity.

THE IMPACT OF SMOKING ON DIET IN ISRAEL

E. Mbong^{1,2}, Y. Neumark², R. Goldsmith^{3,4}, S. Bonny⁴, E. Berry²

¹Ministry of Public Health, Yaounde, Cameroon

²Braun School of Public Health and Community Medicine, The Hebrew University of Jerusalem Israel

³Nutrition Department, Ministry of Health, Israel

⁴Robert H. Smith Faculty of Agriculture, Food and Environment, The Hebrew University of Jerusalem-Israel

Background and objectives: Israel, a multi-cultural society, offered the opportunity to study the co-occurrence of unhealthy diet and smoking - both modifiable risk factors for chronic disease.

Methods: The study, a cross-sectional secondary analysis of Israel's national health and nutrition MABAT (1999-2001) adults (25-64 years) survey, compared dietary patterns, diet quality index (DQI) and BMI in relation to smoking status - never smoked, current and past smoking. Chi-squared test tested differences between proportions, ANOVA, differences

between means and binary logistics, associations between categorical variables.

Results: Current smokers read food labels least often and skipped and combined meals most often. They had the highest mean total caloric intake, but the lowest mean fiber and micronutrients intake except for sodium, iron, zinc, vitamins A, E and niacin. They had the lowest mean DQI score in contrast to former smokers who had the highest (54.15 ± 0.55 and 57.17 ± 0.66 respectively, $p=0.002$). Former smokers had significantly better dietary intakes compared to the other two groups. However, past smoker status was associated with a significant 38% increased likelihood of being obese (AOR: 1.38 95% CI 1.06-1.80). Current smoking was not protective of being overweight/heavier or obese (AOR 0.88 95% CI 0.72-1.08 and AOR 0.80 95% CI 0.63-1.01 respectively). Among past smokers, each cigarette smoked daily was associated with a 3% increased likelihood of being overweight/heavier (AOR 1.03 95% CI 1.01-1.04) and a 2% increased likelihood of being obese (AOR: 1.02 95% CI 1.01-1.03). The likelihood of being overweight or obese differed with country of origin suggesting a possible genetic modification of nicotine's action on weight which needs further investigation.

Conclusions: This study adds to growing evidence that smoking is associated with poor dietary choices, and quitting improves eating habits, findings that warrant the integration of dietary counseling in smoking control programs.

Key words: Smoking, diet, obesity.

PO1184

ACCESS TO AND CHOICE OF FOOD IN A STUDENT RESIDENTIAL AREA: THE CASE OF BONAMOUS-SADI, CAMEROON

S. Tabe¹, E N. Mbong^{1,2}, V. Mbi³, S. Bonny⁴

¹Building Bridges Cameroon (BBCAM)

²Ministry of Public Health, Cameroon

³ISEC Higher Institute of Health and Human Services, Annex Yaoundé, Cameroon

⁴Ministry of Public Health, Cote d'Ivoire

Background and objectives: The Universal Declaration on Human Rights recognizes the right to food as a core element of basic living standards. In Cameroon, there is little data on the determinants of access to and choice of food amongst students, the country's future. This study sought to address the above data gap.

Methods: A pilot cross-sectional survey of 150 participants of a student residential area in Yaoundé, Cameroon's most populous city.

Results: Food-related expenditure represented 54.7 % of total monthly household expenditure, 47.6 % of which was

on non-nutritious (junk) food. Non-nutritional factors were as strong a reason for food choice as were nutritional needs (51.3% versus 48.7%). Half (55 %) of participants depended on friends or relatives for food. Non-financial determinants of food choice included taste (55.8%), culinary skills (27.3%), cohabitation (9.1%) and cultural restrictions (7.8%). Two-fifths (42.7%) of participants ate out often at restaurants. Two-thirds (66.0%) of participants acknowledged that this might pose a health risk, 42.4% of who were those who ate out often and 57.6% those who rarely ($p=0.933$). The high price of food was the most commonly (68.0%) cited cause of restricted access to sufficient, safe and nutritious food, followed by insufficient time to cook (23.3%), and lack of storage facilities (4.7%) and land to farm(4.0%). Men and women, and university and non-university graduates differed significantly ($p<0.001$ and 0.040 respectively) on how important the above issues were impediments. One-third (34.7%) of participants relied on untreated water sources for drinking. Though 92.7% reported that environmental hygiene influenced what they ate, only 6.0 % acknowledged engaging often in environmental sanitation practices.

Conclusions: Non-nutritional factors as well as nutritional needs determine access to and choice of food, and need to be taken into consideration in food security initiatives in Cameroon.

Key words: Access to food, students, food choice.

PO1185

MULTILEVEL CORRELATES OF ANTHROPOMETRIC TYPOLOGIES IN COLOMBIA IN 2005

D. Parra^{1,3}, L. Gomez², O. Sarmiento¹, L. Iannotti³, D. Ayala⁴, R. Brownson³

¹Universidad de Los Andes – EpiAndes, Bogotá, Colombia

²Universidad Javeriana, Bogotá, Colombia

³Washington University, St. Louis, USA

⁴Instituto Colombiano de Bienestar Familiar, Colombia

Background and objectives: Overweight and underweight increase the risk of metabolic impairments and chronic disease. The dual burden of malnutrition is also a growing problem in developing nations. The goal of this study was to establish the association of maternal, family and contextual correlates of anthropometric typologies at the household level in Colombia.

Methods: Using 2005-DHS/ENDS data we included household level information from mothers 18-49 yrs. and their children <5yrs. Stunting and overweight was assessed for each child. Mothers were classified according to BMI. We constructed four anthropometric typologies, normal, underweight,

overweight, and dual burden. Selected municipal and state level indicators were included. Hierarchical multinomial models with three levels (states n=33, municipalities n= 226, and families n=9, 138) were carried out. Four separate models were developed using normal anthropometric typology as the reference, an empty model, one including maternal and family characteristics, then adding municipal characteristics, and finally state characteristics.

Results: Most of the variance was explained by maternal and family characteristics versus municipal and state characteristics. Higher levels of municipal living conditions index and royalties were negatively associated with the underweight typology, while higher municipal density was positively associated. Higher municipal living conditions index was positively associated with the prevalence of overweight, while density was negatively associated. Higher municipal royalties was the only contextual variable associated with the dual burden of malnutrition in a negative direction.

Conclusions: Proximal risk factors such as maternal and family characteristics are explaining most of the variance in household anthropometric typologies. Variance components show that municipal and state levels indicators also contribute to explain differences but to a lesser degree than maternal and family characteristics. Findings highlight the fact that Colombia is still in the midst of a nutrition transition where overweight is still more prevalent among higher socioeconomic conditions.

Key words: nutrition-transition, overweight, dual burden, Colombia.

PO1186

MATERNAL AND FAMILIAL CORRELATES OF ANTHROPOMETRIC TYPOLOGIES IN COLOMBIA IN 2010

D. Parra^{1,3}, L. Gomez², O. Sarmiento¹, L. Iannotti³, D. Ayala⁴, R. Brownson³

¹Universidad de Los Andes – EpiAndes, Bogotá, Colombia

²Universidad Javeriana, Bogotá, Colombia

³Washington University, St. Louis, USA

⁴Instituto Colombiano de Bienestar Familiar, Colombia

Background and objectives: Overweight and obesity are a growing problem in developing nations, while prevalence of underweight is decreasing. There is also documentation of a dual burden of malnutrition where both problems coexist at the household level. Both overweight and underweight increase the risk of metabolic impairments and chronic disease. The goal of this paper is to determine the maternal and familial correlates of various anthropometric typologies at the household level in Colombia.

Methods: Using 2010 DHS/ENDS data we included household level information from mothers 18-49 yrs. and their children <5yrs. Each child was classified according to z-score of height for age (HAZ <2 SD) to assess stunting, and mothers according to their BMI distribution. Four final anthropometric typologies at the household level were determined including normal, underweight, overweight, and dual burden households. Multinomial logistic regression models were carried out to examine several maternal and familial correlates of the different anthropometric typologies in 2010.

Results: Maternal and familial indicators were associated with the prevalence of specific anthropometric typologies at the household level, including parity, maternal age, wealth index, female head of household, and area of residence (urban versus rural). Participation in nutrition programs for children younger than 5 was associated with a lower likelihood of overweight and underweight typology. Being an indigenous household was positively correlated with the likelihood of being classified as an overweight, underweight and dual burden household. Food purchase decisions made by the mother were positively correlated with likelihood of underweight and less likelihood of overweight and dual burden. Moderate food insecurity was associated with a higher likelihood of dual burden.

Conclusions: It is necessary to identify the micro and macro determinants of the various anthropometric typologies at the household level to better frame policies and programs targeting potentially modifiable risk factors.

Key words: underweight, overweight, dual-burden, indigenous, Colombia.

PO1187

VITAMIN A SUPPLEMENTATION PROGRAMME IN NIGERIA-CHALLENGES AND PROSPECTS

I. Onimawo¹, I. Alo²

¹University, Ekpoma, Nigeria

²UNICEF

Background and objectives: Vitamin A supplementation has been carried out in Nigeria for over the past twelve years. It is therefore necessary to assess the progress made in vitamin A supplementation and the challenges experienced.

Methods: Reports from various monitors and supervisors were analysed from all over the country. The NDHS (1999, 2003, 2008) were used as secondary sources.

Results: Under-five mortality rate in Nigeria was 200/1000 live birth in 1999 (NDHS 1999) and this informed the need to include vitamin A supplementation as a plus in the national immunization days (NIDs). The NID programme was later change to national immunization plus days (NIPDs). NIPDs were essentially implemented as a WHO led programme and

this led to resistance by the WHO- supported health workers to accommodate input from UNICEF that brought in the VACs as a component of the NIPDs. There were also disparity in the remuneration between health workers supported by WHO and those supported by UNICEF. Some health workers could not administer VACs correctly due to poor training. In some cases political considerations informed the recruitment of adhoc staff who could not administer both the vaccines and VACS. Data management was poorly carried out. Poor micro-plans and supply of enough quantities of VACs, scissors, wipes and tally sheets were also observed.

Conclusions: Despite these challenges, vitamin A coverage for under-five children had risen from initial 27% in 1999 to 75% in 2011. This has also positively affected the under-five mortality by reducing it to 157/1000 live birth (NDHS, 2008)

Key words: Vitamin A supplementation, under-five mortality, data management.

YAKUMO-CHO INHABITANTS MEDICAL EXAMINATION -RESULT OF TASTE AND OLFACTOMETRY

N. Katayama¹, S. Nakata², M. Kato³, M. Kagaya³, K. Kato³, M. Teranishi³, M. Sone³, T. Nakashima³, N. Hamashima⁴, Y. Ito⁴

¹Nagoya Women's University, Food Science and Nutrition, Japan

²Fujita Health University Hospital, Otorhinolaryngology, Japan

³Nagoya University school of medicine, Otorhinolaryngology, Japan

⁴Nagoya University Graduate School of Medicine, Preventive Medicine, Japan

Background and objectives: In Japan, an already aged society, healthy taste and olfaction are a necessary part in the process of creating a safe and fertile living environment for everyone, and of improving the quality of life. Given these circumstances, the objective of this study was to understand the age-related decline in taste and olfactory function in people aged 40-99 years, and identify the odours which are particularly difficult for people of these age groups to distinguish in order to draw attention to the issues that face people and to facilitate the improvement in the quality of life.

Methods: The study included 40 people aged 40-49 years, 74 people aged 50-59 years, 191 people aged 60-69 years, 89 people aged 70-79 years, 15 people aged 80-89 and 1 people aged 90-99 years in Yakumo Town, Hokkaido, Japan. Taste was tested using a "Test paper" (ADVANTEC Toyo Roshi Kaisha,

Ltd., Japan). Odours were tested using a "standard odours by odour stick identification" (Daiichi Yakuhin Sangyo, Japan).

Results: There was possibility of the taste disorder in 20%. In addition, the person with impaired taste had high BMI level. There was possibility of the sense of smell disorder in 7%. The ability to identify domestic gas - an odour that may be considered closely linked to QOL - was lost from the 60-69 years to the 80-89 years age group.

Conclusions: Although "gas" is not an odour that people actively look for in everyday life, considering the dangers posed by gas leaks and explosion, efforts must be made so that people won't forget such an odour. It is necessary to understand more detail of relationship between taste disorder and the BMI. The taste abnormality, connection with the metabolic syndrome is doubted.

Key words: Health examination, Taste, Odour, BMI, Metabolic syndrome.

A RANDOMIZED CONTROLLED FEEDING STUDY WITH PROVITAMIN A RICH CASSAVA IMPROVES TOTAL CAROTENOID INTAKE IN PRIMARY SCHOOL CHILDREN IN KENYA

E F. Talsma¹, I D. Brouwer¹, A M. Mwangi², M B. Zimmermann³, J C M. Verhoeff⁴, A. Melse-Boonstra¹

¹Division of Human Nutrition, Wageningen University, Wageningen, The Netherlands

²Applied Nutrition Programme, Department of Food Technology and Nutrition, University of Nairobi, Nairobi, Kenya

³Human Nutrition Laboratory, Institute of Food, Nutrition and Health, Department of Health Sciences and Technology, Swiss Federal Institute of Technology (ETH), Zürich, Switzerland

⁴London School of Hygiene and Tropical Medicine, MRC International Nutrition Group, London, UK

Background and objectives: Biofortified pro-vitamin A rich cassava could potentially contribute to reduce vitamin A deficiency (VAD) in Africa. Efficacy in improving vitamin A (VA) status in humans has not been proven. We aimed to measure the effect of daily consumption of biofortified cassava on VA intake in children aged 5-13 years in Kenya.

Methods: Children (n=342) with VAD (serum retinol-binding protein concentration (RBP) 4.5 ng/ml, sd 0.75) were randomly allocated to 1) biofortified cassava and placebo capsule; 2) white cassava and placebo capsule; or 3) white cassava and a capsule (1, 400 µg β -carotene). Cassava was cooked and mashed with salt and 4 g /oil per portion; portion size was 325 and 375

g per child depending on age given daily for 6 days/week for 18.5 weeks. Nine different varieties of biofortified cassava were locally grown and harvested daily during intervention. Participants and staff were blinded to capsule contents but not to cassava type. Cassava intake was measured daily and cooked cassava was sampled daily for carotenoid analyses with HPLC.

Results: Complete data were collected for 337 children. Mean duration of intervention was 112 days. At baseline, groups were similar regarding age, sex and RBP. Compliance to cassava feeding was 100% with no differences between groups. Mean cassava intake per day was 365.6 g (sd 24.5) for white cassava and 360.6 g (sd 25.8) for biofortified cassava. Mean carotenoid concentration of biofortified cassava was 394.20 µg (sd 75.3) per 100 g (fresh weight). Daily mean carotenoid intake from biofortified cassava was 200 µg RAE. Conclusions Daily consumption of biofortified cassava improved the vitamin A intake to 50% of the EAR. Acknowledgments The project was realized in the framework of INSTAPA Project, funded by EU: FP7/2007-2013 nr 211484.

Key words: Biofortification, cassava, Vitamin A, Randomized controlled feeding trial, Kenya

PO1190

BIOFORTIFIED CASSAVA WITH PRO-VITAMIN A IS SENSORY AND CULTURALLY ACCEPTABLE FOR CONSUMPTION BY PRIMARY SCHOOL CHILDREN IN KENYA

E F. Talsma¹, B P H. de Kok¹, G N K. Mbera², A M. Mwangi², A. Melse-Boonstra¹, I D. Brouwer¹

¹Division of Human Nutrition, Wageningen University, Division of Human Nutrition, Wageningen, The Netherlands

²Applied Nutrition Programme, Department of Food Technology and Nutrition, University of Nairobi, Nairobi, Kenya

Background and objectives: Biofortification of cassava with pro-vitamin A can potentially reduce vitamin A deficiency in low-income countries. However, little is known about consumer acceptance of this deep yellow variety of cassava compared to the commonly available white varieties. We aimed to determine the sensory and cultural acceptability of the consumption of pro-vitamin A rich cassava in order to identify key factors predicting the intention to consume pro-vitamin A rich cassava by families with school-aged children in Eastern Kenya.

Methods: Sensory acceptability was measured by replicated discrimination tests and paired preference tests among 30 children (7-12 yr) and 30 caretakers (18-45 yr) in three primary

schools. Cultural acceptability was assessed with a questionnaire based on the combined model of The Theory of Planned Behavior and The Health Belief Model in one primary school among 140 caretakers of children aged 6 to 12 years. Multivariate analyses and correlations were used to determine associations between summed scores for model constructs.

Results: Both caretakers and children perceived a significant difference in taste between white and pro-vitamin A rich cassava and preferred pro-vitamin A rich cassava over white cassava because of its soft texture, sweet taste and attractive color. 'Perceived barriers 1' ($\hat{\alpha}=-0.21$, $P=.02$), 'Control beliefs' ($\hat{\alpha}=0.18$, $P=.02$) and 'Cues to action' ($\hat{\alpha}=0.51$, $P<.01$) were the best predictors of intention to consume pro-vitamin A rich cassava. 'Knowledge' was a strong predictor of 'Health behavior identity' ($\hat{\alpha}=0.29$, $P<.01$).

Conclusions: Pro-vitamin A rich cassava is well accepted by school children in our study population. Acknowledgments The project was realized in the framework of INSTAPA Project, funded by the European Union's Seventh Framework Programme [FP7/2007-2013] under grant agreement nr 211484.

Key words: Bio-fortification, Cassava, Pro-vitamin A rich cassava, Acceptability, $\hat{\alpha}$ -carotene.

PO1191

APPETITE TESTING IN HIV-INFECTED AFRICAN ADULTS RECOVERING FROM MALNUTRITION AND GIVEN ANTIRETROVIRAL THERAPY (ART)

A. Rehman¹, M. Chisenga², J. Siame², J. Kidola³, G. Sampson¹, S. Woodd¹, G. Praygod³, J. Koethe⁴, S. Filteau¹

¹Faculty of Epidemiology and Population Health, London School of Hygiene and Tropical Medicine, London, UK

²University Teaching Hospital, Lusaka, Zambia

³National Institute of Medical Research, Mwanza, Tanzania

⁴Vanderbilt University, Nashville, TN, USA

Background and objectives: The NUSTART trial is investigating the appropriateness of a two-stage re-feeding regimen, analogous to that used for severely malnourished children, for malnourished HIV-infected African adults starting ART. We investigated whether, as for children, regain of appetite could indicate when to increase calorie provision for adults in such regimens.

Methods: Malnourished (BMI < 18.5 kg/m²) HIV-infected Zambian (n= 593) and Tanzanian (n=378) adults participating in the NUSTART trial were provided with a low calorie lipid nutrient supplement (LNS) from referral for ART until 2 weeks

after starting ART and a high calorie LNS from weeks 2-6 ART. At weekly visits appetite was measured by short questionnaire and by weight of maize porridge consumed in a standardized test. Appetite questions were combined for analysis using polychoric correlations to generate a standardized score. Linear regression was used to relate appetite and body weight change at three key points, referral, starting ART and trial completion (12 weeks post ART). Cox regression was used to assess the effect of appetite on mortality.

Results: Both measures of appetite showed data clumping in Zambia, suggesting results did not represent appetite accurately. In Tanzanian participants, appetite questionnaire score and weight increased over time but there was little change in the appetite test. In Tanzanian participants, there was weak evidence that lower referral appetite score was associated with lower values of weight change up to starting ART and higher mortality to 12 weeks ART.

Conclusions: There appeared cultural differences between the sites such that the appetite questionnaire and test were of little use in Zambia. In Tanzania the appetite score was a better indicator of changes over time than the appetite test and correlated with weight change. The appetite questionnaire appeared an adequate and cheap way of measuring appetite in Tanzania.

Key words: appetite, malnutrition, HIV, Africa, adults.

PO1192

ARE THE INCREASES IN BREASTFEEDING DURATION EQUAL WITHIN COUNTRIES? THE FUNDAMENTAL CAUSE CONCEPT BEING TESTED ON 50 COUNTRIES.

C. Boccolini¹, F. Carvalhaes², R. Pérez-Escamilla³, P. Boccolini⁴

¹Department of Social Nutrition, Rio de Janeiro State University, Brazil

²Instituto Universitário de Pesquisas do Rio de Janeiro, Rio de Janeiro State University, Brazil

³Department of Chronic Disease Epidemiology, Yale University, USA

⁴Instituto de Estudos em Saúde Coletiva, Rio de Janeiro Federal University, Brazil

Background and objectives: Breastfeeding duration has been increasing in most Countries, but not all the segments of the society experiment those increases in the same rate. We aim to observe what segments of the society has been experiencing the highest increases on breastfeeding duration.

Methods: The outcomes were the increase in the median durations (in months) of Total Breastfeeding (TBF) and Exclusive Breastfeeding (EBF), obtained from secondary data of

Countries that did at least two national representative surveys (from 1986 to 2011) according to Demographic and Health Survey (DHS) methodology. The study population was children under three years of age, categorized according to the following background characteristics: place of residence (rural, urban); household wealth index (lowest, second, middle, fourth, highest); and educational level (no education, primary, secondary or higher). The differences of increase in median duration of TBF and EBF between categories were evaluated with Wilcoxon non-parametric test.

Results: From 86 Countries with DHS surveys, 50 Countries had at least two comparable surveys with data on TBF and EBF duration. The median duration of TBF increase within Countries was higher in the population living in urban areas (62.5%, $p=0.05$, $n=48$), wealthier (52.5%, $p=0.46$, $n=40$) and with highest educational level (68.1%, $p<0.01$, $n=47$). The increase of EBF duration was higher among: urban (58.3%, $p=0.32$, $n=48$), wealthier (48.8%, $p=0.85$, $n=40$) and highest educational level (55.3%, $p=0.04$, $n=47$) population.

Conclusions: The population experienced increases of the duration of TBF and EBF in different rates, giving support to the theory of fundamental social causes, where people who have more resources (eg. knowledge, money, power, prestige) are better able adopt protective health behaviors, such as breastfeeding. The public policies on breastfeeding must focus on closing the gaps between different segments of society.

Key words: Breastfeeding, Social epidemiology, Inequalities, Child nutrition.

PO1193

MILK CONSUMPTION OF COLLEGE STUDENTS

H. Yardimci¹, E. Ciracioglu¹, A. Ozcelik¹, S. Gurel¹

¹Ankara University, Ankara, Turkey

Background and objectives: Milk contains most of the essential nutrients for growth and it consists one of the main food groups which has to be consumed everyday. Milk is the best source of calcium which plays an important part in body functions during lifespan. Aim: The study is planned and conducted to determine the milk consumption of college students who attend Ankara University and live in dorms.

Methods: 190 Turkish and 20 foreigner students participated in the study ($n=210$). Data collection was made by a questionnaire. SPSS was used to evaluate data.

Results: Median age for female (56.7%) and male (43.8%) students is 21 and 22 years, respectively. 42.9% of them regularly drink milk ($n=89$) and 43.8% of the participants stated they made a habit of drinking milk in pre school period and 63.3% of them are encouraged to drink milk by their parents. 37.1% of the participants stated they consume milk for its nu-

tritional value, 33, 3% of them consume it before sleep and 71.9% of them apply no heat on it. Among the students who consume milk, 27.1% of them consume it 3-4 times a week 24, 0% of the subjects twice a month, 21.4% of them 1-2 times a week, 20.3% of them everyday and 7.3% of them 5-6 times a week. 33.3% of the subjects who state they drink milk everyday, consume ≥ 500 mL /day. Mean consumption amount is 280 mL (male: 290 mL, female: 250 mL) which is statistically significant according to gender.

Conclusions: The development of dietary habits that include the frequent intake of milk during childhood and adolescence is likely to lead to higher calcium intake in later years. Recommendations to the public should continue to emphasize increased calcium intake, perhaps most effectively achieved by increasing milk consumption.

Key words: Turkey, Milk Consumption, Students

PO1194

COMPARING PHYSICAL ACTIVITY AND ENERGY EXPENDITURE BETWEEN OBESE AND NON-OBESE PRESCHOOL BOYS OF THE KINDERGARTEN A HANOI IN 2011

N. Dung¹, L. Tuyen²,

¹Department of Nutritional Biochemistry and Metabolism, National Institute of Nutrition, Hanoi, Vietnam

²Department of Nutrition Surveillance and Policy, National Institute of Nutrition, Hanoi, Vietnam

Background and objectives: The physical activity patterns of Vietnamese obese and non-obese preschool boys have been not described. This study aims to compare physical activity (PA), energy expenditure between obese and non-obese preschool boys.

Methods: Body weight and height of 51 children (20 obese, 31 non-obese), mean age of 62.5 years old from the kindergarten A Hanoi were collected. Subjects were asked to wear an accelerometer (Omron Active style Pro HJA-350IT) while awake for 5 consecutive weekdays. The Omron Bi-Link Activity monitor Professional Edition Ver1.0 software was used to generate the measurements of physical activity. Obesity was defined according to WHO 2007 child growth standards.

Results: the number of steps of obese children was 7, 623 steps/day and that of non-obese children was 6, 389 steps/day ($P = 0.049$), physical activity level values were 1.93 and 1.86 respectively ($P = 0.099$). When normalized for body weight, energy expenditure for walking and non-walking (kcal/kg/day) was not different among the two groups: 11.6 vs. 11.7 ($P = 0.959$); 22.3 vs. 24.3 ($P = 0.218$). The quantity of PA among obese children was 74.2 METs•hour/wk and that of non-obese children was 67.9 METs•hour/wk ($P = 0.347$).

Conclusions: some PA parameters are similar among obese and non-obese preschool boys, excessive food intake should be considered as the main cause of obesity in this target group.

Key words: Physical activity, energy expenditure, preschool children.

PO1195

PERCEPTION OF CARDIOVASCULAR HEALTH IN AN ADULT POPULATION

P. Aguilar-Alonso¹, A. Navarro-Cruz², O. Vera-López², R. Avila-Sosa², N. Melgoza-Palma², E. Herrera-Saucedo², S. Cid-Pérez²

¹Posgrado en Ciencias Químicas, Facultad de Ciencias Químicas, Benemérita Universidad Autónoma de Puebla, Puebla, Mexico

²Departamento de Bioquímica y Alimentos, Facultad de Ciencias Químicas, Benemérita Universidad Autónoma de Puebla, Puebla, Mexico

Background and objectives: Cardiovascular epidemiology began in the thirties as a result of the observed changes in the causes of mortality, in the fifties were launched several epidemiological studies to clarify the causes of cardiovascular disease and four years after the start of the Framingham Heart Study the researchers identified that cholesterol and high blood pressure were important cardiovascular risk factors. The aim of this study was to determine the cardiovascular risk using the Framingham Score in people 35-79 years in the town of Nuevo Necaxa, Puebla.

Methods: It was performed a study of health perception in a random sample of people who voluntarily participated in the study through a signed consent. Study subjects were chosen randomly in the busiest areas of town (down town, market, hospital, etc.) They were given a questionnaire that included parameters like: sex, age, total cholesterol, systolic blood pressure and smoking habits. Were collected 221 surveys and the answers were assessed using the Framingham Score.

Results: 78 % of the surveyed population perceived low risk of cardiovascular disease, 20.5% moderate and 1.5% high risk; women considered to have a low risk of cardiovascular disease compared with men, this could be a problem because if perception of people is of healthy or low-risk, little can do in preventive health, which could lead to start the condition of chronic degenerative diseases.

Conclusions: The population doesn't have a good perception of their cardiovascular health, these results do not match the percentage of obesity in adults than in this year increased in Mexico to almost 70%, so people have to be aware of their health and have at least one checkup a year to rule out cardiovascular disease.

Key words: Cardiovascular health, chronic degenerative disease, Framingham

PO1196

BEVERAGES CONSUMPTION: A QUANTITATIVE ANALYSIS ON CHILDREN AND ADOLESCENTS DIET IN BRAZIL

R. Feferbaum¹, L.C. Abreu^{2,3}, C. Leone³, A. Lemos⁴, G. Rodrigues⁴

¹Department of Pediatrics, Faculty of Medicine, University of Sao Paulo, São Paulo, Brazil

²Laboratory of scientific studies design, Faculty of Medicine of ABC, Santo Andre, Sao Paulo, SP, Brazil

³Department of Maternal and Child Health, Faculty of Public Health, University of Sao Paulo, São Paulo, Brazil

⁴Danone Research

Background and objectives: Epidemiological studies are generally designed to evaluate solid food intake; whereas, beverages should also be considered in the nutritional approach, as fluids have a relevant participation on population's diet. The aim of this study was to evaluate the volume of beverages consumed by children and adolescents in Brazil.

Methods: This descriptive study was conducted in 90 census tracts randomly selected, in order to represent socioeconomic diversity, in 5 Brazilian cities. It included 831 participants (3-17 years old), selected according to population proportions per each age group. Liquid intake volume was assessed using a dietary record.

Results: Total volume of liquid intake increased with age, as did the volume of water and carbonated beverages consumed ($p < 0.05$), whereas the intake of milk and dairy products decreased as the age of the participants increased. For study participants aged 3 to 6 years, 7 to 10 years and 11 to 17 years, water intake represented 31%, 33% and 34% of the total volume of liquid intake, respectively; carbonated beverages composed 13%, 17% and 23% of that figure, respectively; and milk and dairy products represented 32%, 24% and 16% of that figure, respectively.

Conclusions: Our findings show a worrisome beverages intake profile in Brazilian children and adolescents, which should encourage healthcare professionals to be more diligent in recording liquid intake and to prescribe water to their patients to ensure healthy hydration, in order to prevent complications in adulthood.

Key words: beverages intake, children, adolescents, water

PO1197

BRAZILIAN CHILDREN AND ADOLESCENTS: WHAT ARE THEY DRINKING?

R. Feferbaum¹, L.C. Abreu^{2,3}, C. Leone³, A. Lemos⁴, G. Rodrigues⁴

¹Department of Pediatrics, Faculty of Medicine, University of Sao Paulo, São Paulo, Brazil

²Laboratory of scientific studies design, Faculty of Medicine of ABC, Santo Andre, Sao Paulo, Brazil

³Department of Maternal and Child Health, Faculty of Public Health, University of Sao Paulo, São Paulo, Brazil

⁴Danone Research

Background and objectives: Obesity is considered an important public health problem and a global epidemic. One of the factors that could impact on this high prevalence is energy from liquids. The purpose of this study was to investigate the quality of beverages consumed by children and adolescents and to determine the proportion of their daily energy intake composed of liquids.

Methods: This descriptive study included 831 individuals and was conducted in 5 cities, considering a random selection of census tracts according to Brazilian Institute of Geography and Statistic. Liquid intake was assessed using a dietary record. Energy intake from liquids was compared with the daily energy requirements recommended for children and adolescents by the Brazilian food regulation authority, the National Health Surveillance Agency (ANVISA).

Results: Energy intake increased significantly with age. Sugar sweetened beverages provided 37%, 46% and 59% of the energy intake of individuals ages 3 to 6 years, 7 to 10 years and 11 to 17 years ($p < 0.05$), respectively; whereas milk and dairy products contributed 52%, 40% and 27% ($p < 0.05$) of the total energy intake for these age groups, respectively. Among 11- to 17-year-olds, sugar sweetened beverages alone contributed an average of 290 kcal/day, which constituted 15% of the recommended daily energy for this age group, exceeding the maximum recommendation of World Health Organization (10%).

Conclusions: This study indicates that a high daily energy intake comes from beverages and when such patterns are associated with a high-energy solid food diet, they may lead to excessive weight gain. Health care professionals and nutrition education programs should encourage water intake, which has no additives or calories, to ensure proper hydration.

Key words: beverages, water, children, adolescents, obesity.

PO1198**ANTHROPOMETRIC, BIOCHEMICAL AND LIFESTYLE COMPARISON OF A POPULATION DIAGNOSED WITH DIABETES MELLITUS TYPE II AND A HEALTHY POPULATION**

A. Navarro-Cruz¹, O. Vera-López¹, P. Aguilar-Alonso², R. Avila-Sosa¹, R. Dávila-Márquez¹, I. Centeno-García¹, R. Ramírez y Ayala², N. Melgoza-Palma¹

¹Facultad de Ciencias Químicas, Benemérita Universidad Autónoma de Puebla, Puebla, Mexico

²Posgrado en Ciencias Químicas, Facultad de Ciencias Químicas, BUAP, Puebla, Mexico

Background and objectives: The prevalence of diabetes in Mexico has increased significantly, to stand as the second leading cause of overall death according to the National Institute of Statistics, Geography and Informatics, though some statistics place it as the leading cause of mortality in the country. The development of type 2 diabetes is linked to lifestyle factors, so it suggests it may be a preventable disease, hence the objective of this study was to compare the lifestyle and anthropometric and biochemical parameters of a healthy adult population versus a population diagnosed with diabetes mellitus type II, in order to evaluate the differences among them.

Methods: Laboratory tests were performed (glucose, cholesterol, triglycerides, urea and creatinine) to 300 patients attending the Public Health Clinic in Atlixco, Puebla. We measured blood pressure and anthropometric measurements were taken. Later they were given a survey of personal and dietetic habits in order to determine any correlation with the disease or health condition. The results were processed with the statistical program R-sigma Babel.

Results: The population consisted of 160 diabetic and 140 non-diabetics. The average age was 52 years. The average BMI was 29.7. No anthropometric differences between populations. Overweight in diabetics was 35.63%, while in non-diabetics was 40%. Obesity was 46.25% in diabetics and 42.14% in non-diabetics. Regarding clinical parameters, there were differences in glucose, triglycerides and urea being higher in diabetics ($p < 0.05$). Blood pressure was high in both groups, with no differences between them. The percentages of people who smoke, drink alcohol, soft drinks and junk foods, as well as those who do not practice physical activity were similar in both groups.

Conclusions: Diabetics are not adequately controlled and non-diabetics have many risk factors for diabetes, if it is not that already are diabetic and are undiagnosed.

Key words: Diabetes, Obesity, Lifestyle.

PO1199**ASSESSMENT OF THE IMPACT OF ORGANIC SCHOOL MEALS TO IMPROVE THE SCHOOL FOOD ENVIRONMENT AND CHILDREN'S AWARENESS OF HEALTHY EATING HABITS**

C. He¹

¹Aalborg University Copenhagen, Copenhagen, Denmark

Background and objectives: The aims of this study were to identify the extent to which public organic food procurement policies might act as a driver for healthy eating among children, to explore potential actions to support the introduction of organic food in public school food serving outlets for school children, and to understand and to increase our understanding of sustainable nutrition among school children.

Methods: Study I & II: These were two cross-sectional studies involving school food coordinators as the research subject and using web based questionnaires distributed in selected public primary and lower secondary schools in Denmark ($n = 179$), Germany ($n = 2050$), Finland ($n = 998$) and Italy ($n = 940$). Study III: An observational study was carried out among 6th grade Danish pupils in two organic schools ($n = 85$) and two non-organic schools ($n = 80$) in two different municipalities located in the Copenhagen Capital region.

Results: Schools with an organic food policy are more likely to adopt a FNP ($P < 0.001$), to build a health promoting school ($P < 0.001$), to promote physical activity and to supply a school canteen ($P < 0.001$). Children in schools with an organic food policy had better expectations of school meals ($P < 0.001$). School children's attitudes had an impact on their intention to consume organic food, independently of whether the school had or not an organic food policy ($P < 0.001$). The organic concept could act as a landmark/characteristic for those engaged in healthier lifestyles.

Conclusions: The results of the thesis suggest that that it is possible to influence pupils' awareness of health and eating habits, through combining modifications of the school lunch with modifications of the whole school food environment.

Key words: School children, organic food procurement policy, school meals, healthy children.

PO1200**SHIFTING OF UNDERNUTRITION TO OVERNUTRITION AND ITS DETERMINANTS IN THE LOW TO MEDIUM INCOME COUNTRIES***A. Mamun¹, J. Finlay²*¹School of Population Health, The University of Queensland, Brisbane, Australia²Harvard School of Public Health, Harvard University, Massachusetts, USA

Background and objectives: The shifting of underweight to overweight among women of child-bearing age in the low-to middle-income countries (LMIC) are relatively less understood. Objectives are to examine the shift away from undernutrition towards overnutrition for LMIC and investigate the potential determinants of this shift using the nationally representative survey data.

Methods: We analysed cross-sectional, representative samples of 540, 290 women aged 20-49 years drawn from the Demographic and Health Surveys (DHS) at two time points in 36 LMIC. Potential determinants of underweight (BMI<18.5) and overweight (BMI≥25) are examined.

Results: In the latest DHS compared to the earliest DHS (mean duration 10 years), the prevalence of underweight significantly declined for one in two countries and the prevalence of overweight significantly increased for 80% of the listed countries. The annual increase of overweight was two folds higher than annual decline of underweight (6.4% vs. 3.3%). Although higher socio-demographic factors are associated with shifting of underweight towards overweight, over time, the risk of the highly educated, wealthy, and urban women being overweight is weakening.

Conclusions: Findings of this study suggest that among women of child-bearing age there was a large shift away from undernutrition to overnutrition for most of the LMIC. Over-time, the contribution of higher education, wealth and urbanization to the being overweight was decreasing in the LMIC.

Key words: undernutrition, overnutrition, women, low to medium income countries.

PO1201**EVALUATION OF NUTRITION REPORTS BASED ON RESEARCH STUDIES IN POPULAR INDIAN NEWSPAPERS***M. Maheshwar¹, G. Subba Rao¹, K. Venkaiah¹, D. Raghunatha Rao¹*¹National Institute of Nutrition, Indian Council of Medical Research (ICMR), Jamai Osmania P.O., Hyderabad, Andhra Pradesh, India

Background and objectives: Newspapers are an important form of Mass media that can play significant role in health promotion, which is crucial for social development. Studies revealed that newspaper reports lacked consistency in presenting nutrition research results to the readers. A study was conducted with a hypothesis “Newspapers often highlight nutrition research findings disproportionately in order to draw reader’s attention”. Objective: To assess presentation of nutrition research findings/ outcomes by newspapers as compared to the original research papers on which they are based.

Methods: Based on the circulation figures, the top six popular newspapers (three from English and three from Telugu) were selected for the study from 1st September 2010 to 28th February 2011. A scale was evolved based on 10 parameters for gauging accuracy of the reports.

Results: A total of 214 reports were identified as based or claimed on nutrition research in all the above six newspapers. Overall, vernacular newspapers published more number of reports (125) on nutrition research compared to English dailies (89). One-fourth of the newspaper reports did not conveyed nutrition research results properly. Few reports were found as contrary to the original findings on which they were based on. Almost one-fifth of the reports have no mention of the source, which denies access to the reader for the original report. Usually, any research or scientific study has its own limitations. But, this vital aspect is missing in the newspapers reports on nutrition research.

Conclusions: With emphasis on short, ‘newsworthy’ pieces, the media often only report the results of single studies, and many stories are chosen simply because the results run contrary to current health recommendations. Nutrition scientists need to help translate their research for consumers.

Key words: Newspapers, Health promotion, Nutrition, Research translation.

PO1202**CAN HYDRATION STATUS IN POPULATIONS BE BETTER ESTIMATED FROM URINE OUTPUT THAN FROM WATER INTAKE?***S. Gibson¹, R.J. Maughan²*¹Sig-Nurture Ltd, Guildford, Surrey, UK²School of Sport, Exercise and Health Sciences, Loughborough University, Loughborough, UK

Background and objectives: Guidelines for adequate water intake are based on observational data rather than empirical estimates of water requirements. However, water losses may provide a better basis for estimating hydration status in populations. We present first results from a study aiming to quantify components of water balance and assess adequacy of water intake. Water balance = (Water intake from diet + metabolic water) – (urine volume (UV) + non-renal water losses (NRWL)).

Methods: Total water intake (TWI) was calculated from 7-day weighed diet records from the UK National Diet and Nutrition Survey of Adults for 2000/2001 (<https://www.esds.ac.uk/>). Metabolic water was calculated from macronutrient intake, assuming complete oxidation. Urinary losses were calculated from 24 h urine collections (n 1328).

Results: Mean TWI was 2.57 L/d (SE 0.03) and 2.11 L/d (SE 0.03) among men and women, respectively; metabolic water contributed 0.33L/d for men and 0.23 L/d for women. Thus total available water (TAW) averaged 2.90 L/d and 2.34 L/d, respectively. Urine volumes (UV) were correlated with water intake in men and women (r 0.50, r 0.52; P<0.0001); mean UV was 1.98 L/d (SE 0.04) among men and 1.80 L/d (SE 0.03) among women. The difference between TAW and UV equals NRWL at zero water balance; mean NRWL was 0.92 L (SE0.04) for men and 0.54 L (SE 0.03) for women, decreasing with age. Average NRWL is usually estimated to be about 1.0-1.3 L/d, so our result may indicate underestimation of intake and/or overestimation of output in the NDNS, or possibly negative water balance.

Conclusions: TWI and UV were higher than those reported in Germany (Manz et al. (2012) *Br J Nutr* 107: 1673-1681) while estimated NRWL were lower. Further investigation of the obligatory urine volume (OUV) may provide an estimate of hypo-hydration risk.

Key words: Water, intake, urine, balance, hydration.

PO1203**EFFECT OF SELECTED DIETARY SUPPLEMENTS ON MICRONUTRIENT STATUS DURING RECOVERY FROM MODERATE ACUTE MALNUTRITION IN YOUNG MALIAN CHILDREN***R.S. Ackatia-Armah^{1,2,3}, C.M. Mc Donald⁴, S. Doumbia⁵, J. Earhardt⁶, J. Peerson³, K.H. Brown^{2,3}*¹Nutrition and Metabolism, Boston University School of Medicine, Boston, MA, USA²Helen Keller International, New York, NY, USA³Program in International and Community Nutrition, University of California, Davis, CA, USA⁴Boston Children's Hospital, Boston, MA, USA⁵Department of Public Health, Faculty of Medicine, University of Bamako, Mali⁶Regional Center for Community Nutrition, University of Indonesia, Jakarta, Indonesia

Background and objectives: Moderate acute malnutrition (MAM) and associated micronutrient (MN) deficiencies are major public health concerns in low-income countries. Iron (Fe) and vitamin A (VA) status indicators were measured before and after 12 weeks of treatment with 1 of 4 dietary supplements in young Malian children aged 6-35 mo with MAM.

Methods: 12 health centers were randomly assigned to provide children with MAM 1 of the following supplements containing ~500 kcal/d and micronutrient (MN) profiles designed to meet or exceed WHO recommendations: 1) lipid-based, ready-to-use supplementary food (Supplementary Plumpy, SP); 2) special corn-soy blend (CSB++); 3) locally processed, fortified food (Misola, MI); or 4) locally milled flours and MN powder (HFM). The type of Fe used in the 4 groups were Fe sulphate, Fe fumarate, electrolytic Fe and NaFeEDTA, respectively. Hemoglobin (Hb) was measured in 1154 children, and plasma ferritin (pF), transferrin receptor (pTfR) and retinol binding protein (pRBP) were measured using a sandwich ELISA technique in a subset of 452 children.

Results: Attendance at weekly/bi-weekly follow-up visits was >85% in all groups. Mean \pm SD change in Hb were 0.96 \pm 2.1, 0.27 \pm 1.7, -0.13 \pm 1.7, 0.60 \pm 2.0 for groups respectively (SP > MI p<0.05, ANOVA). After adjusting for inflammation, mean change in pF were 4.3 \pm 38.6, -7.25 \pm 35.1, -9.7 \pm 26.4, -8.1 \pm 38.5, for the groups respectively (SP > CSB++, MI, p<0.01, ANCOVA) Mean change in pTfR were -4.4 \pm 8.8, -0.2 \pm 8.3, -1.1 \pm 6.4, -2.6 \pm 8.6, for the groups respectively (SP < CSB, MI, HFM; HFM < CSB ++, p<0.05, ANCOVA). By contrast, for VA, mean change in pRBP were 0.05 \pm 0.39, 0.18 \pm 0.49, 0.12 \pm 0.39, 0.08 \pm 0.39, (NS).

Conclusions: SP was more effective than the other dietary regimens in increasing Hb and pF and decreasing pTfR. CSB++ was more effective in increasing RBP.

Key words: Moderate Acute Malnutrition, Iron, Vitamin A Supported by: UNICEF.

PO1204**THE COMPLIANCE OF PACKAGED FOOD PRODUCTS IN INDIA WITH NATIONAL AND INTERNATIONAL NUTRITIONAL LABELLING STANDARDS**

E. Dunford¹, R. Guggilla², A. Ratneswaran³, J. Webster¹, P. Maulik², B. Neal¹

¹The George Institute For Global Health, Sydney, Australia

²The George Institute for Global Health, Hyderabad, India

³Queen Mary University of London, London, UK

Background and objectives: India is experiencing a nutrition transition with the consumption of processed foods rapidly increasing. Nutrition labels are essential if consumers are to understand the healthiness of these products. The Food Safety and Standards Authority of India has recently introduced regulation defining national nutrition labelling requirements and Codex Alimentarius recommends a global standard. Our objective was to quantify the compliance of the nutrition labels on Indian packaged foods with national and global requirements.

Methods: The presence or absence of data for seven required nutrients was recorded for all food products available for sale in branches of three major retail chains and three smaller stores in Hyderabad, India between October and November, 2010.

Results: Data were collected for 4166 packaged products that fell into 14 different food groups. 52% of products displayed nutrient information on energy, protein carbohydrate, sugar and total fat, meeting the minimum requirements of the Food Safety and Standards Authority of India. Only 27% met the minimum criteria defined by Codex which also requires the reporting of saturated fat and sodium. There was significant variation in compliance for major brands, country of manufacture and food group ($p < 0.001$ for all).

Conclusions: The compliance of Indian packaged foods with food labelling requirements is sub-optimal. With the Indian population likely to consume much more packaged food over coming years full and effective food labelling will be essential. The failure of Indian legislation to require labelling of sodium and saturated fat may warrant review.

Key words: Food labelling, processed foods, public health nutrition.

PO1205**ADULTS' CONSUMPTION OF MILK AND DAIRY PRODUCTS IN TURKEY**

A. Uçar¹, M V. Yilmaz¹, E. Energin¹, L S. Akan¹, E.D.Çiracıoğlu¹, N. Yabancı¹, H. Yardımcı¹, F.P.Çakıroğlu¹, A Ö. Özcelik¹, M.S. Sürücüoğlu¹

¹Department of Nutrition and Dietetics, Faculty of Health Sciences, University of Ankara, Ankara, Turkey

Background and objectives: It is known that in Turkey, milk is mostly consumed as yogurt, white cheese and ayran; and drinking milk consumption is lower compared to other dairy products. In this study, it is aimed to identify the milk and some dairy product consumption of adults who live in Ankara, Turkey.

Methods: The study sample consists of 2433 subjects (M:647, F:1786) who agrees to participate among the ones who apply to Family Health Centers in different regions of Ankara. Data collection was made using a questionnaire and data evaluated using SPSS program.

Results: 26.7% of the participants are high school graduates, 73.0% of them are married and 69.3% of them are employed. Milk was consumed regularly by 61.7% (F:60.2%, M:66.0%), yogurt was consumed regularly by 93.7% (F:93.6%, M: 93.8%), cheese was consumed regularly by 95.3% (F:95.5%, M:94.7%), and kefir was consumed regularly by 10.2% (F:10.6%, M:8.8%) of the participants. The most stated reason of not consuming milk (34.4%), yogurt (40.3%) and cheese (69.4%) was the subjects' dislike of taste or smell of the product. The reason of consuming kefir has given as kefir's positive health benefits by 62.0% of the subjects who regularly consume it. The most preferred kind of milk was whole milk (50.1%), yogurt (51.5%) and white cheese (100%) was whole fat. The mean consumption amount of participants who regularly consume milk, yogurt, kefir and cheese were 228.8+114.5 mL, 206.7+80.7g, 194.80+91.7 mL and 34.4+11.9 g; respectively. The mean consumption amount of milk differed significantly according to gender ($p=0.009$).

Conclusions: It is recommended for adults to consume 3 servings of milk and dairy products daily by Dietary Guidelines for Turkey. Regarding the health benefits of milk and dairy products, it's essential to raise the awareness of community about consuming these products.

Key words: Milk, Yogurt, Cheese, Kefir, Turkey.

PO1206**FAMILY-BASED INTERVENTION FOR CHILDHOOD OBESITY: AN EXPERIENCE AMONG TEHRANIAN CHILDREN**

F. Esfarjani¹, M. Khalafi¹, F. Mohammadi¹, A. Mansour¹, R. Roustaei¹, N. Zamani-Nour¹, R. Kelishadi²

¹Department of Food and Nutrition Policy and Planning Research, National Nutrition and Food Technology Research Institute, Faculty of Nutrition Sciences and Food Technology, Shahid Beheshti University, Tehran, Iran

²Department of Pediatrics, Child Growth and Development Research Center, and Faculty of Medicine, Isfahan University of Medical Sciences, Isfahan, Iran

Background and objectives: Treatment of childhood obesity is difficult and successful management may differ in various areas with different cultural backgrounds. The present study was conducted to assess the effect of lifestyle modification family-based intervention in young Iranian children.

Methods: This field trial study was conducted in 2011 among 156 obese children (BMI \geq 95th) in Tehran, Iran. They were randomly assigned to intervention and control groups. At the baseline, anthropometric measurements and biochemical analysis were assessed. The second and third phases consisted of training sessions for parents of intervention group. At the fourth phase there was no training program. In all four phases, questionnaires on demographic characteristics, lifestyle and food frequency were completed by interviewing with mothers and biochemical analysis was repeated at the end of the study.

Results: The mean body mass index was 23.08 (2.9) kg/m². Evaluation of anthropometric indices showed that weight and height increased significantly in both groups, though weight increased more slowly and waist and hip circumferences was decreased during 2nd and 3rd phase in the intervention group. Also, serum triglycerides and cholesterol decreased significantly in intervention group ($p < 0.05$). Analysis of food group consumption showed that in the intervention group, not only consumption of milk, dairy and nuts group increased significantly but also the corresponding figure decreased for bread and cereals, sugar and confectionery ingredients; moreover, the family's oil and fat consumption decreased significantly ($p < 0.05$). Watching TV and playing computer decreased significantly in intervention group; However walking time increased significantly in both groups ($p < 0.05$).

Conclusions: The family-based lifestyle program had limited effects on anthropometric and metabolic outcomes of the obese children. We suggest that if interventions were done in longer periods with teamwork, weight control and lifestyle modification would have been more efficient.

Key words: Obesity, Children, Family-based intervention.

PO1207**CALORIE LABELING OF MENUS: A FEASIBILITY STUDY IN A UNIVERSITY CAFETERIA**

J. Sych¹, C. Mueller¹, M. Fotohinia², C. Brombach¹

¹Institute of Food and Beverage Innovation, Zurich University of Applied Sciences, Waedenswil, Switzerland

²Lausanne Hotel School, Switzerland

Background and objectives: Nutrition is becoming increasingly important in the food service and catering industry due to the high frequency of eating out, a trend which might contribute to chronic illness and obesity. Nutritional labeling has been proposed to encourage healthier menu choices, but there is still no consensus on how it should be implemented. Calorie labeling is now mandatory in the USA for chain restaurants with 20 or more locations, and has stimulated interest in Europe, particularly among international caterers.

Methods: A recent Swiss study at a campus gastronomy restaurant showed that calorie-labeling led to selection of menus with significantly lower energy contents. Indeed further research is needed. The present preliminary study aimed to test calorie-labeling in a university cafeteria. Lunch menus (3) were labelled for three days using a traffic light system, with green, yellow or red corresponding to increasing energy contents. After menu selection, customers completed questionnaires and their reactions were also recorded. The experiment will be repeated and compared with a more complex labeling system recently developed at ZHAW.

Results: In the first testing, a total of 248 students, lecturers and researchers from the university participated. Answers showed 70% of customers took notice of, and 56% found the traffic-light system to be helpful. However, only 17% of customers considered the nutritional data in their menu selection, suggesting a low influence on customers. Further study is required to determine the reasons. Simple adjustments to the labeling system, such as additional nutritional information, might lead to higher influence on customers towards the targeted outcome, i.e. selection of lower calorie menus. Nonetheless, the traffic light system appears to be a good starting point.

Conclusions: Further studies should include stricter control of experimental errors associated with food catering, e.g. data collection, menu preparation, portion size and others.

Key words: food service, food catering, labelling, calories, menu.

PO1208**INFLUENCE OF EARLY EXPOSURE TO VITAMIN D FOR LATER DEVELOPMENT OF TYPE 1 DIABETES - THE D-TECT STUDY**

R. Jacobsen¹, A. Vaag², K. Raymond¹, B. Abrahamsen³, T. Soerensen¹, B. Heitmann¹

¹Institute of Preventive Medicine, Frederiksberg Hospital, Frederiksberg, Denmark

²Department of Clinical Medicine, Orthopedics and Internal Medicine, Rigshospitalet, Copenhagen, Denmark

³Institute of Clinical Research, University of Southern Denmark, Odense, Denmark

Background and objectives: To date, the relationship between vitamin D status during fetal life and long-term health has not been widely examined. Fetal vitamin D levels are similar to maternal levels, as vitamin D travels freely over placenta. The present study examined the influence of maternal intake of extra vitamin D from fortified margarine during pregnancy, for the development of type 1 diabetes (T1D) during child- and adulthood in the offspring.

Methods: In 1961-1985 fortifying margarine with vitamin D was mandatory in Denmark. Fortification supplied 15% of vitamin D intake on average. This well-defined time period provide a natural experiment for comparing the effects of early exposure to vitamin D on the development of diseases later in life amongst exposed and non-exposed adjacent birth cohorts. To find out the incidence of T1D, the data from the Danish National Patient Registry were used. To compare time to debut of T1D in the adjacent birth cohort, Cox regression analyses were conducted. To compare incident rates of T1D in these cohorts, Poisson regression models were run.

Results: Hazards ratios (HR) as well as incident rate ratios (IRR) for T1D among those exposed to extra vitamin D were lower than among non-exposed: HR=0.763 [95 % CI 0.685-0.849], $p < 0.001$; IRR=0.874 [95 % CI 0.787-0.969], $p = 0.01$. Time trends in meteorological conditions and influenza extent in the country were considered.

Conclusions: The present results suggest that ingestion of extra vitamin D from fortified margarine during pregnancy lower the risk of T1D in the offspring. Such results add to our understanding of potential benefits of vitamin D, qualify the ongoing discussion on food fortification, and contribute to future recommendations related to vitamin D.

Key words: Vitamin D, long term effect, T1D.

PO1209**FOOD-RELATED LIFESTYLES AND THEIR ASSOCIATION TO PHYSICAL ACTIVITY IN POLAND**

M. Jezewska-Zychowicz¹

¹Department of Organization and Consumption Economics, Warsaw University of Life Sciences, Poland

Background and objectives: Economic changes altered people's lifestyle. The modern living conditions facilitate unhealthy behaviours concerning food and physical activity. The food-related and physical activity can contribute together to the weight gain. Objective is to investigate the associations between physical activity and Food-Related Lifestyles (FRL) in Poland.
