The statements, opinions and data contained in this publication are solely those of the individual authors and contributors and not of the publisher and the editor(s). The appearance of advertisements in the journal is not a warranty, endorsement, or approval of the products or services advertised or of their effectiveness, quality or safety. The publisher and the editor(s) disclaim responsibility for any injury to persons or property resulting from any ideas, methods, instructions or products referred to in the content or advertisements.

Drug Dosage

The authors and the publisher have exerted every effort to ensure that drug selection and dosage set forth in this text are in accord with current recommendations and practice at the time of publication. However, in view of ongoing research, changes in government regulations, and the constant flow of information relating to drug therapy and drug reactions, the reader is urged to check the package insert for each drug for any change in indications and dosage and for added warnings and precautions. This is particularly important when the recommended agent is a new and/or infrequently employed drug.

Editorial

Dear Participants,

The 20th International Congress of Nutrition (ICN) is organized under the auspices of the International Union of Nutritional Sciences (IUNS) by the Spanish Society of Nutrition (SEÑ). To organize the IUNS 20th ICN at these times of economic and financial crisis has been a big challenge. Notwithstanding, at the same time it offered us the unique opportunity to bridge the multidisciplinary areas of nutritional sciences, particularly basic and applied research activities all around the world. Furthermore, this Congress provided a broad platform to discuss experiences gathered at multinational and global levels in the fields of nutrition research, human nutritional requirements, role of nutrition in the promotion and prevention of chronic non-communicable diseases and nutrition education, as well as in the composition of foods and the role of bioactive food components on health and well-being at different food cultures. Likewise, food safety and consumer protection and food production and environment sustainability are major aspects related to food science and nutrition worldwide that are approached. Therefore, we planned a comprehensive congress under the theme "Joining Cultures through Nutrition" to convey nutrition and healthy lifestyles for everyone in a sustainable environment.

Being conscious of the broad range of professionals working in the different fields of nutritional sciences, the 20th ICN features a 'Track' design of audience segmentation by grouping the related sub-themes and ensuring the inclusion of sessions from scientific knowledge to applications. The main tracks are:

- 1: Advances in Nutrition Research
- 2: Nutrition Through Life Course
- 3: Public Health Nutrition and Environment
- 4: Nutrition and Management of Diseases
- 5: Nutrients and Nutritional Assessment
- 6: Functional Foods and Bioactive Compounds
- 7: Food culture practices and Nutritional Education
- 8: Agriculture, Food Science and Safety

The scientific program comprises 6 plenary lectures, 32 special lectures, 4 debates, 90 parallel symposia, 38 sponsored symposia and 16 Satellite Symposia.

The response to the proposed scientific program was very encouraging. In addition to the invited lectures, we received about 3570 submissions, 96% of which have been accepted. 347 correspond to invited speeches for Paralleled Symposia (30% did not deliver any abstracts), 193 have been selected to be presented as Oral communications and 3223 as e-posters. All submitted abstracts were peer-reviewed by at least two independent reviewers blinded to authors and institutions from the International and Local Scientific Committees. The number of entries in the list of abstract is higher than 17000. An effort has made to assure the involvement of speakers and participant from all continents and countries, including nutrition and food specialists in research, academia and industry as well as policy makers with a gender balance and applicability for all societies.

In the present Supplement of Annals of Nutrition and Metabolism only the abstracts for Parallel Symposia, Oral Communications and Posters are published. In addition, the abstracts corresponding to the International NUTRIMENTHE Conference, which has been held as a Satellite event of the 20th ICN, are also published. The Plenary Lectures and Special Lectures will be published later on in full in a Supplement of Advances in Nutrition available on-line to all 20th ICN participants.

The 20th ICN wish to recognize and thank the importance of the participation of young investigators and nutrition professionals from developing countries. Travel grants, registration fee and accommodation for selected young investigators and other awardees were made possible by contribution from international agencies and foundations and private sectors. A special fee rate for students and participants from low- and middle income countries was offered to encourage their participation.

We would like to express our sincere appreciation to all participants and particularly to invited speakers and national and international experts and delegates whose contributions, participation and interest make this congress a successful forum for sharing and exchanging knowledge in nutritional sciences for the benefit of the whole world.

Prof. Angel Gil

Congress President and Chairman of the Organizing Committee

Prof. J. Alfredo Martinez

President of the Scientific Committee

DISCLAIMER

All abstracts have been printed as received and formatted for uniformity and the Organizing and Scientific committees cannot be claimed responsible of the contents and future applications. All views expressed during the scientific sessions at this Congress are those of the individual authors and do not necessarily reflect the views of any of the Committees or any other individual member of these Committees or the views of any of the official organizing bodies.

Contents

Paralleled Symposia

T1 ADVANCES IN NUTRITION RESEARCH

NPS1-1	Early life nutrition intervention: Effects on long term health and function	1-2
PS1-1	Developments in personalized nutrition: What's next? (Food4me Project) Challenges and opportunities for personalised nutrition business models	2-4
PS2-9	Biomarkers of nutrition for development: An overview BOND	4-6
PS2-17	Immunonutrition in health and disease	6-7
PS3-25	New biomarkers for health claims made on food.....	7-11
PS3-33	OMICS technologies with nutritional perspectives	11-12
PS4-41	Public health genomics in individualized nutrition.....	12-14
PS4-49	Biomarkers of response to dietary interventions.....	14-16
PS5-57	Early programming and nutrition in Latin America	16-19
PS5-65	Metabolic and nutritional aspects of genetic diseases	19-21

T2 NUTRITION THROUGH LIFE COURSE

NPS1-2	Efficacy of lipid-based nutrient supplements for prevention of maternal and infant undernutrition in Africa: Results of the iLiNS Project.....	23-26
PS1-2	Nutrition and lifestyle in adolescents: The HELENA study.....	26
PS2-10	Energy balance and active living.....	26-28
PS2-18	Healthy life style promotion	28-29
PS3-26	Scaling up nutrition to improve infant and young child feeding (IYCF) (Alive & Thrive).....	29-30
PS3-34A	Nutrients and exercise performance – What is the evidence behind recent claims of major benefits?.....	30-32
PS3-34B	Past and current experiences in leveraging multiple program and partner platforms to scale-up nutrition interventions (The SPRING project).....	32-34
PS4-42A	Complimentary feeding and infant health (FAO).....	34-36
PS4-42B	Generating evidence of impact for integrated programs aimed to improve child nutrition during the first 1000 days (IFPRI).....	36-38
PS4-50	Early diet is critical for later development - New research into changing early eating habits (HABEAT and VIVA)	38-40
PS5-58	NUAGE research.....	41-43
PS5-66A	Trace elements and chronic diseases.....	43-44

T3 PUBLIC HEALTH NUTRITION AND ENVIRONMENT

NPS1-3	Nutrition and environmental sustainability (FAO).....	45-46
PS2-11	Global challenges in maternal and child nutrition for today and the future	46-47
PS2-19	Confronting the global epidemic of noncommunicable diseases: Findings from the NHLBI/ UHG Global Network	47-49
PS3-27	Community-based programme to prevent obesity: Lessons and perspectives from 20 years of experience (EPODE International Network)	49
PS3-35	Promoting healthy growth and preventing childhood stunting – a WHO initiative	50-51
PS4-43	Nutrition Profiling (WHO)	51
PS4-51	Nutrition, physical activity and the prevalence of NCDs in the Middle-East and North-Africa.....	51-53
PS5-59	Food insecurity and obesity across the life cycle.....	54-55
PS5-67	Type 2 diabetes in Asia's rapid growth is due to genetic or dietary change?.....	55-58

T4 NUTRITION AND MANAGEMENT OF DISEASES

NPS1-4	Dietary lipids and the risk of common diseases	59-60
PS1-4	Scaling up prevention and treatment of malnutrition	60-62
PS2-12	Food, nutrition, physical activity and cancer – Keeping the evidence current: WCRF/AICR Continuous Update Project (CUP) - (WCRF)	62-64
PS2-20	Tackling obesity in pre-school children: First results from the ToyBox-Study	64-66

PS3-28	Role of dietary macronutrients on weight management. Role of protein and glycemic index in body weight regulation – Lessons from the Diogenes intervention study	66-68
PS3-36	ISCOLE: International Study of Childhood Obesity, Lifestyle and the Environment.....	68-70
PS4-44	Nutrition in inflammatory bowel diseases. From basic to clinical application	70
PS4-52	International Life Sciences Institute (ILSI) Session on Food Allergy	70
PS5-60	Maternal nutritional supplementation of HIV-infected women during lactation: Implications for maternal and infant health in resourcepoor settings	71-72
PS5-68	New insights in obesity, metabolic syndrome and diabetes	72-73
T5 NUTRIENTS AND NUTRITIONAL ASSESSMENT		
NPS1-5	Methods and outcomes of nutritional assessment and health monitoring.....	75-78
PS1-5	The SMILING Project: A South East Asian- European collaborative action to prevent micronutrient deficiencies in women and young children in South-East Asia	78-81
PS2-13	Harmonization of human zinc requirements and country experiences in assessing population zinc status.....	81-82
PS2-21	Assesment of body composition from birth to 2 years	82-84
PS3-37	Findings from 5 birth cohorts from developing countries: The COHORTS collaboration	84-86
PS4-45	Iron and Malaria (FeMal) Project Results	86-88
PS4-53	Strengthening micronutrient nutrition surveillance: WHO and CDC tools and methods	88-89
PS5-61	Micronutrient Fortification. Science and Strategies for Public Health Improvement in Asia	90-93
PS5-69	Evaluation of food fortification and biofortification interventions in developing countries using stable isotopes.....	93-94
T6 FUNCTIONAL FOODS AND BIOACTIVE COMPOUNDS		
NPS1-6	PREVIEW Project.....	95-98
PS1-6	Diversity of physiological functions of amino acids and peptides	98-99
PS2-14	Dietary reference values for DNA damage prevention.....	99-101
PS2-22	The role of nutrition in healthy ageing: Insight from the CHANCES Project.....	101-102
PS3-30	Fibres and the gut immune system(FIBEBIOTICS Project)	102-103
PS3-38	HEALTHGRAIN Forum Symposium - Cereal foods and health - New results and science based nutrition guidelines	103-106
PS4-46	Functional roles of human milk and other selected oligosaccharides	106-107
PS4-54	Functional roles of prebiotic inulin-type fructans.....	108-109
PS5-70	Phytochemicals responsible for the food function, from the chemistry to physiological relevance and human health.....	110-111
T7 FOOD CULTURE AND NUTRITIONAL EDUCATION		
NPS1-7	The role of nutraceuticals in health along with basic nutrition	113-114
PS1-7	Cultural differences in diet and nutrition across Europe. Impact on health.....	114-116
PS1-7 B	Professionalism and Capacity Building in Nutrition – a UK perspective.....	116
PS2-15	Linking food security and nutrition education to improve infant and young child feeding	116-118
PS2-23A	China's nutrition transition: Implications of rapid social and economic change for non-communicable disease risk.....	118-121
PS2-23B	A global partnership to improve nutrition medicine in Vietnam.....	121-122
PS3-31A	Building research capacity in Latin America to address NCDs and obesity.....	122-123
PS3-31B	Traditional, Indigenous and cultural food and nutrition	123-125
PS3-39A	ENLP -Nutrition during times of economic crisis, let's cook something up!.....	126-127
PS3-39B	Capacity development in innovative techniques in food and nutrition research	127-128
PS4-47	Mediterranean diet and disease	128-129
PS4-55	PREDIMED study.....	129-130
PS5-63A	Regulation Versus Innovation (IUFOST).....	130-132
PS5-63B	Food systems for nutrition and health: Growing, shopping, cooking and eating.....	132-134
PS5-71A	The value of nutrition labelling: Has nutrition labelling reduced any chronic diseases? (IUFOST)	134-135
PS5-71B	Urbanization and Food Security.....	135-137

T8 AGRICULTURE, FOOD SCIENCE AND SAFETY

NPS1-8	IMAPP (Intake, Monitoring and Program Planning): Software nutrient intake data....	139-141
PS1-8	Food-based approaches to improve multiple micro-nutrient deficiencies and protein quality.....	141-144
PS2-16	Food composition (FAO).....	144-146
PS2-24	Sugars and health: The controversies continue.....	146-147
PS3-32	Low-calorie sweeteners: Are they safe and can they help with weight management?....	147-148
PS3-40	FESNAD forum.....	148-151
PS4-48	Bellagio report on healthy agriculture, healthy nutrition, healthy people	151-153
PS4-56	Food and nutrition reporting in the media.....	153-154
PS5-64	Feeding workers	154-155
PS5-72	The shift toward a modern industrialized food system, potential implications for nutrition-related chronic diseases and for public policies	155-156

Oral Communications

O001	TUMOR SUPPRESSOR GLYCINE-N METHYLTRANSFERASE REGULATES ONE CARBON TRANSMETHYLATION KINETICS	157
O002	RELATIONSHIP BETWEEN VITAMIN A STATUS OF LACTATING SENEGALESE WOMEN AND THEIR 6 MONTHS OLD INFANTS.....	157
O003	GENOME-WIDE VARIANCE CONTRIBUTION OF GENOTYPE BY ERYTHROCYTE N-3 POLYUNSATURATED FATTY ACIDS INTERACTION TO DIABETES-RELATED TRAITS.....	158
O004	THE METABOLIC RESEARCH ON PRETERM INFANTS WITH NRDS	158
O005	THE EXPRESSION OF TASTE RECEPTOR HTAS2R FAMILY OF DIABETICS	159

T1 ADVANCES IN NUTRITION RESEARCH

NPS1-1 Early life nutrition intervention: Effects on long term health and function

EARLY NUTRITION PROGRAMMING OF ADULT HEALTH: OPPORTUNITIES FOR THE PREVENTION OF OBESITY AND ASSOCIATED DISORDERS

B. Koletzko

Division Metabolic and Nutritional Medicine, Dr. von Hauner Children's Hospital, University of Munich Medical Centre- Klinikum d. University München, Muenchen, Germany

Child growth reflects health and nutrition. In addition to growth faltering, effects of excessive growth on child health get increased attention. Rapid weight gain in the first two years predicts later obesity risk. Breastfeeding protects against rapid weight gain and may reduce obesity risk at school age by about 20%, relative to early formula feeding. We followed the "Early Protein Hypothesis", i.e. the lesser protein supply of breast milk is causative. In a multicentre RCT, term infants were fed isoenergetic formulae with higher or lower protein during infancy. Length was not affected but weight-for-length and BMI were lower at 24 months of age in the lower protein group and similar to a breastfed reference group. There was a persistent effect on lowering later BMI and a marked risk reduction for obesity up to early school age. Based on current evidence, the timing of starting complementary feeding at four or six months does not affect obesity risk, but there are indications for adverse effects of high intakes of energy, protein and sugar with complementary feeds. We conclude that breastfeeding has a modest protective effect against obesity. Infants not breastfed should get formulae with reduced protein contents. The use of cows' milk (rich in protein) as a drink should be avoided during infancy.

Acknowledgments: Supported by the Commission of the European Community, Grant FP7/2007-13 (Early Nutrition Project); European Research Council, Grant 3226059; and German Federal Ministry of Education and Research. Abstract does not necessarily reflect views of the Commission and in no way anticipates the future policy in this area.

Key words: Child growth, nutrition programming, obesity, breastfeeding, complementary feeding

THE SOUTHAMPTON WOMEN'S SURVEY: FROM EPIDEMIOLOGY TO INTERVENTIONS AND POLICY

K. Godfrey, H. Inskip, S. Robinson, C. Cooper

MRC Lifecourse Epidemiology Unit, University of Southampton, UK

Introduction: Observational mother-offspring cohort studies inform our understanding of early life influences on offspring health. Findings can inform the design of new intervention studies. Observational studies can also lead directly to policy changes, but such changes need formal evaluation.

Methods: The Southampton Women's Survey (SWS) is a longitudinal birth cohort with data collected on the mothers before conception. 12,583 women aged 20-34 years were assessed when not pregnant; 3,159 were then followed through pregnancy and the children are followed-up.

Results: Maternal vitamin D insufficiency in pregnancy was associated with markers of impaired bone development and with greater adiposity in the children. Women's educational attainment was strongly related to the quality of their diets before conception, which in turn predicted the quality of the diets of their infants and children. Variations in infant diet were related to body composition at the age of four years. Our findings have led to intervention studies. Firstly, we are conducting a randomised controlled trial of vitamin D supplementation in pregnancy (MAVIDOS). Secondly, in relation to our diet quality findings, we are conducting a complex intervention, in collaboration with local policy makers, in which staff working in centres for women and children in disadvantaged areas are trained to engage in 'healthy conversations' with young women visiting the centres, to enable them to improve their diets and lifestyles (Southampton Initiative for Health). A school intervention to increase science and health literacy (LifeLab) has been developed and will be evaluated in a cluster randomised trial.

Conclusion: The SWS, a large mother-offspring observational cohort study, has led to the development of interventions to improve health of women and their children. These are being evaluated to inform public health policy, locally, nationally, and internationally.

Key words: Maternal nutrition, infant nutrition, vitamin D

LONG-TERM EFFECTS OF EARLY LIFE MICRONUTRIENT INTERVENTIONS IN UNDERNOURISHED SETTINGS

P. Christian

Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, USA

Fetal and postnatal nutritional environments are important predictors of later cardiometabolic and other functional outcomes. Micronutrient deficiencies in early life may have important long term effects; plausible mechanisms and pathways of action have been derived from the existing animal and in vitro models. These relationships have been examined in settings where the burden of micronutrient deficiencies is high and opportunities for follow-ups of birth cohorts and interventions exist. Studies that have examined the effects of prenatal micronutrient intervention effects on outcomes of blood pressure, insulin resistance and obesity have found mixed results. For example, prenatal multiple micronutrient supplementation in randomized trials have found no effect (Mexico), decrease (Nepal) or increase (Bangladesh) for the outcome of blood pressure. In one trial in Nepal, prenatal folic acid supplementation resulted in reduced risk of microalbuminuria and metabolic syndrome, whereas prenatal zinc with iron-folic acid supplementation increased height, and reduced adiposity compared with the placebo. Studies have also observed long term survival benefits for micronutrient interventions in some of these studies. Recently preconceptional multiple micronutrients produced alterations in methylation patterns in genes involved in infection related immune response in a study from the Gambia, which may provide a potential link to the beneficial impact of micronutrients on long term survival. Additionally, preconceptional vitamin A resulted in improved lung volume and prenatal iron-folic acid benefitted neurocognitive function in school age children in rural Nepal. This overview provides an update on the recent literature related to the critical role of micronutrients in long term survival, cardiometabolic health and other functions in low-middle income countries.

Key words: Micronutrients, pregnancy, metabolic syndrome, preconceptional

ANTENATAL DIETARY EXPOSURES AND NUTRITIONAL STATUS ON OFFSPRING HEALTH IN UNDERNOURISHED SETTINGS

S. Moore

MRC International Nutrition Group, London School of Hygiene and Tropical Medicine, London, UK

Inverse associations between size at birth and later risk of cardiovascular disease and/or risk factors are well established and interpreted as showing the long-term effect of environmental exposures operating in early life. Fetal growth restriction in this context is thought to reflect nutritional insufficiency during in utero development. Most published evidence in support of a link between antenatal nutritional exposures and long-term health comes from industrialised countries. However, one might predict the worst case scenario in populations with widespread undernutrition, yet undergoing a nutrition transition away from the traditional diet and lifestyle. Understanding associations between maternal dietary status on offspring health is thus critical, for appropriate targeted nutrition. In this presentation, I will review the evidence linking dietary exposures and nutritional status during pregnancy on offspring health outcomes in undernourished settings.

Key words: antenatal diet, fetal growth, developmental origins, cardiovascular disease

PS1-1 Developments in personalized nutrition: What's next? (Food4me Project) Challenges and opportunities for personalised nutrition business models

EXPLORING FUTURE OPPORTUNITIES AND BARRIERS FOR BUSINESS MODEL CONCEPTS IN PERSONALIZED NUTRITION

J. Goossens¹, A. Ronteltap², H. vanTrijp³

¹Bio-Sense, Aarschot, Belgium

²LEI, Wageningen University and Research Centre, Wageningen, The Netherlands

³Marketing and Consumer Behaviour group, Wageningen University and Research Centre, Wageningen, The Netherlands

Our societies have to find ways to release the pressure on healthcare budgets from the consequences of unhealthy lifestyles and dietary behavior. As the science on the genetic basis and metabolic dynamics that control the relation between food and health progresses, the difficulties of achieving the lasting dietary behavior change where needed still presents a daunting problem and is mainly due to the inherent individual

dimension of food choice and the concept of health. Personalized nutrition is a new approach that may help to overcome this problem by matching dietary advice with health requirements at a more individual level. Food4me has explored the emerging personalized nutrition offerings in the market and the barriers and opportunities as currently perceived from a consumer, industrial as well as societal perspective. This resulted in the development of a personalized nutrition system that describes the characteristics of a personalized nutrition concept and how it is influenced by its environment (societal, technical, commercial, political, legal, ethical, psychological). In order to use this to explore possible novel business model concepts, future scenarios were created to explore how value patterns around nutrition and health could shape future European societies by 2030. With two variables 'logic of healthcare systems' and 'concept of health' defining the scenario space, for scenarios have been created: 'Super Sister', 'My health My Home', 'Me Inc' and 'Nudging World'. They will serve in the next steps of the project as a rich background to design novel business model concepts and to evaluate barriers and opportunities.

Key words: Personalised nutrition, business models, future scenarios.

PERSONALISED NUTRITION INTERVENTION, HOW EFFECTIVE IS PERSONALISED NUTRITION ADVICE?

J. Mathers, C. Celis

Newcastle University, Newcastle, UK

There is ample evidence from observational studies that dietary patterns are associated with many aspects of health but there is limited evidence about which interventions are most effective in achieving sustained changes in eating behaviour. The current "one size fits all" approach to nutrition interventions may be less effective than interventions which are stratified or personalised. In the Food4Me Proof of Principle (PoP) Study we are testing the hypothesis that personalisation of nutrition advice enables participants to make more appropriate, and sustainable, dietary behaviour changes. We are personalising dietary advice based on 3 types of information i.e. current (habitual) diet, phenotype and genotype. Participants in the PoP Study are randomised to one of 4 treatment limbs i.e. Level 0: Conventional (non-personalised) dietary advice; Level 1: Advice based on current dietary pattern; Level 2: Advice based on diet and phenotype (anthropometric characteristics and nutrients and metabolites in blood); Level 3: Advice based on diet, phenotype and a panel of genotypic variants. In addition, participants in Levels 1 – 3 are randomised to more or less intensive intervention. The Food4Me PoP is being undertaken in 7 European countries and we aim to recruit 1280 participants. A novel aspect of this study is that we are using web-based pro-

ocols for participant recruitment, for data collection and for personalised feedback to participants. The latter is based on a set of algorithms which we have developed specifically for the PoP study. The primary outcome from the study is change in dietary intake (eating behaviour) which will be measured at 6 months. We are also recording changes in physical activity, in anthropometry and in blood-based biomarkers of nutrient status and health. We will use the experience of the PoP Study to evaluate and to refine the algorithms which we have developed for providing "automated" feedback.

Key words: Dietary intake, eating behaviour, personalised nutrition, phenotype.

IS IT RIGHT? THE ETHICAL AND LEGAL IMPLICATIONS OF PERSONALISED NUTRITION

Do we know enough for offering personalized nutritional advice?

On the one hand the scientific evidence for personalized nutritional advice is limited, and motivation is not yet well understood. On the other hand, standard population based dietary advice is usually not proven by clinical trials. How can we responsibly go forward in such a situation characterized by limited knowledge and disagreement? How can personal, cultural and scientific perspectives on food and health be integrated? Food is not only nutrition, but it is connected to social contexts, cultural values and identities. Likewise, health may be seen as instrumental in relation to individual life plans. The ethical challenge is how to integrate individual, cultural and scientific perspectives of food as well as health.

How does personalized nutrition affect individual autonomy?

The individualization of health promotion brings to the fore the dilemma of individualization, caused by a conflict between the right to individual freedom and societal interests. Also, a certain amount of trust is necessary, as the consumer has no possibility to entirely verify the scientific basis for personalized nutrition offerings. Trust requires trustworthiness, which cannot be enforced, but must be deserved.

Which urgent ethical and legal matters stand out when personalized nutrition is commercialized?

Consumers often have a positive attitude to the option of receiving personalized nutrition advice based upon genetic testing. However, current direct-to-consumer offerings over the Internet suffer from a questionable level of truthfulness. From an ethical point of view, consumer protection is crucial, and caution must be taken when putting nutrigenomic-based tests and advice services on the market. Current Internet offerings appear to reveal a need to further guarantee legal certainty by ensuring privacy, consumer protection and safety.

Key words: Personalized nutrition, ethics, values, dilemmas, legal issues.

F. Ashour, D. Raiten

Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, USA

During the course of the BOND process several issues were identified that cut-across the range of nutrients being considered, one of them being the impact of inflammation on selection, use and interpretation of nutritional biomarkers. To address this real need, the Inflammation & Nutrition Science for Program/Policy: Interpretation of Research Evidence (INSPIRE) Project was initiated. The project was a response to the

increased needs expressed by the global nutrition community to address the bidirectional relationship between nutrition and inflammation and to identify gaps in knowledge. The core objectives of INSPIRE include – 1) review what is known about the interaction and impact of inflammation (infection or other causes) on selection, use and interpretation of biomarkers; and, 2) develop a set of principles, to be published and posted on Tier 1 of the BOND website, that contains information and guidance to users. More specifically, the information will feed into the deliberations of the BOND Expert Panels on how to account for the impact of inflammation on selection, use and interpretation of biomarkers; and, 3) develop a research agenda. To accomplish these goals, four thematic areas were identified by the Scientific Steering Committee (SSC) and Working Groups (WG) were created to review the literature and develop a prioritized research agenda. The themes were: 1) Overview of the role of nutrition in immune function and the inflammatory response; 2) Evaluation of the impact of nutrition and specific nutrients on immune function/inflammation and vice versa; 3) Translating evidence to practice: approaches to addressing the nutrition and inflammation relationships, and, 4) Methodologies and new technologies. In this presentation, the speaker will discuss a set of principles developed through the INSPIRE process to guide the community on addressing the issues of inflammation as it pertains to the nutritional biomarkers.

Key words: Biomarkers, INSPIRE, nutrition, inflammation.

ROADMAP FOR BOND: A PANEL DISCUSSION OF PHASE 1 AND OPPORTUNITIES FOR PHASE II

I. Darnton-Hill¹, D. Raiten²

¹The Boden Institute of Obesity, Nutrition, Exercise & Eating Disorders, University of Sydney, Sydney Australia

²Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, USA

With the BOND program having completed the first wave of nutrients (iodine, vitamin A, iron, zinc, folate and vitamin B12) and with the launching of the web-based resource, a conversation is needed with the broadly-defined nutrition ‘community’ to get feedback about the utility and future of the BOND. Based on the feedback received so far, and with additional partner support, the scope of the BOND activities for phase II will be developed using a “cluster approach”. This will integrate a more systems biology approach to address issues of public health importance. BOND Phase II will include: 1) Biomarkers in Growth (BIG), intended to focus on biomarkers of linear growth and will address the relevant clusters (including vitamin D, calcium, magnesium and phosphorous) as well as

other functional markers; and, 2) Biomarkers in Neurological Development (BIND), designed to address the role of micronutrients in neurological development and cognitive/behavioral outcomes. The relevant nutrient clusters will include vitamins involved in single-carbon transfer and amino acid metabolism (pyridoxine, riboflavin, thiamine, and with additional work on iron). In this presentation, the speaker will discuss the next steps for BOND, including opportunities for phase II and will deliver a roadmap for its suggested implementation. This will be followed by a panel discussion with the audience, expert panel chairs and the BOND Program staff. It is expected that the work of the expert panels and the input from the community during this discussion will help inform the research agenda, which will also help funding agencies make decisions about new directions in biomarker research and development.

Key words: Biomarkers, BOND, BOND phase I, BOND phase II, growth, micronutrients.

ENDOCRINE ASPECTS OF LINEAR GROWTH AND POTENTIAL BIOMARKERS

M. Haymond

Baylor College of Medicine, University of Houston, USA

The identification of useful biomarkers influencing growth and development as a result of nutrient factors would be of great interest. Such markers would not only provide potential targets for therapeutic interventions in those affected but would expand our understanding of the multiplicity of factors influencing normal growth and development and the identification of underlying unique hormonal, substrate, genetic and/or epigenetic factors influencing the unaffected general population. Currently, the only effective biomarker for linear growth is accurate measurements of a child's length or height. It is upon these measurements and perhaps similar ones of the parents that will identify children at risk who could be targeted for intervention and follow-up. Linear growth is achieved largely in the spine and the epiphyses in the distal femur and proximal tibia and final adult height is largely genetically determined. Auxologic measures are epidemiologically inexpensive to obtain but the precision and accuracy of such measures overtime is not trivial but only from such linear tracking can we obtain critical measures of growth velocities. Linear growth measures paired with measurements of bone age and a limited number of hormone measures have been the traditional mainstay of pediatric endocrinologists. The observed increase in second generation heights upon children migrating to western societies is well documented but poorly understood. These are most likely multifactor and a variety of biomarkers might be considered including markers of inflammation, hormone secretion, environmental stress and pollutants, macro and mi-

cronutrient deficiencies. Timing of the "nutritional" insult(s) and relief from such factors are most likely critical. Thus, evidence of the offending factor(s) at a later time may be difficult to identify. The timing of such events may influence the degree of recovery and ultimately the individual's final adult height.

Key words: Linear growth, auxologic measures, hormones, genetics, epigenetics.

BOND OVERVIEW AND SUMMARY OF EXPERT PANEL REPORTS

D. Raiten, R. Raghavan

Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, USA

The Biomarkers of Nutrition for Development (BOND) program, initiated in 2009 by the Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD) of the National Institutes of Health (NIH)/U.S. Department of Health and Human Services, with support from the Bill and Melinda Gates Foundation, PepsiCo, and the NIH Office of Dietary Supplements and the NIH Division of Nutrition Research Coordination, has three main goals: 1) address the need for discovery, development, and implementation of reliable and valid biomarkers to assess nutrient exposure, status, function, and effect; 2) develop a process to harmonize the decision making about what biomarkers are best for use in the full range of activities represented by the global food and nutrition enterprise; and, 3) use information developed through 1 and 2 to provide evidence-based advice to those involved in food and nutrition-related activities. To achieve these goals and establish a proof of concept for the BOND approach, the phase I of BOND was focused on six "case study" nutrients: iodine, vitamin A, iron, zinc, folate and vitamin B12, chosen by the BOND steering committee for their public health importance and because they represent the range of challenges confronting the user communities. For each nutrient an Expert Panel was constituted and charged with the development of critical reviews. In this opening talk, the speaker will provide an overview of BOND and present the work done to date under the BOND program including the summary of reviews drafted by the expert panel. In addition, the speaker will discuss the key research gaps identified by each panel.

Key words: BOND, biomarkers, micronutrients.

DEMO OF BOND WEBSITE AND QUERY BASED SYSTEM

R. Raghavan, D. Raiten

Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, USA

The implementation of the Biomarkers of Nutrition for Development (BOND) program occurs primarily through a set of translation activities whereby the work of nutrient specific expert panels will be presented on the BOND website (http://www.nichd.nih.gov/global_nutrition/programs/bond/Pages/index.aspx). The schema for BOND website is like an inverted triangle with the content arranged into three tiers, from generic to specific. The top tier, tier 1, provides an overview of the BOND, links to all participating agencies and organizations and addresses general principles and cross-cutting issues related to nutritional assessment and biomarker use and interpretation. Tier 2, provides an overview of the nutrient biology for the six case study nutrients of phase I (iodine, vitamin A, iron, zinc, folate and vitamin B12) and a summary of biomarkers with relative strengths and weaknesses and caveats for their use. Tier 3 houses the Query Based System (QBS) which is designed specifically to respond to individual user needs. The QBS is an interactive online tool that provides users with customized advice derived from the work of the nutrient Expert Panels about appropriate biomarker(s) to meet their needs. The capacity of the BOND website encourages input from the user communities. That input will be used to determine new directions for BOND and related activities. In this presentation, the speaker will provide an overview of the BOND website, its tiered structure and the QBS, and will take the audience through a virtual tour of the website, including QBS.

Key words: BOND, BOND website, Query Based System, QBS and micronutrients.

PS2-17 Immunonutrition in health and disease ADMINISTRATION OF POLYPHENOL-ENRICHED NUTRACEUTICALS TO ELDERLY PEOPLE AND EFFECTS ON THE IMMUNE RESPONSIVENESS

E. Jirillo¹, V. Pugliese², S. Fontana³, T. Magrone¹

¹University of Bari, Department of Basic Medical Sciences, Neuroscience and Sensory Organs, Bari, Italy

²Geriatric Center "Mamma Rosa", Turi, Italy

³Farmalabor S.p.A., Canosa, Italy

Human ageing is characterized by several abnormalities of both innate and adaptive immune responses, thus leading to

an increased frequency of infectious, inflammatory, allergic and autoimmune diseases. In elderly patients, among allergic diseases, asthma is a very common pathological event which complicates the dysfunction of many systems. Among a variety of natural products used to modulate the altered immune response, polyphenols have been shown to exert anti-inflammatory activities in both young and aged persons. Here, special emphasis will be given to the immune-modulating effects of Leucoselect® Phytosome® (a dietary supplement enriched in the flavonoid epigallocatechin) administered to frail elderly patients. Leucoselect® Phytosome® was able to upregulate the T helper (Th)1 response [increase in serum concentrations of interleukin (IL)-2 and interferon- γ]. On the other hand, IL-4 serum levels, as an index of Th2 function, fluctuated within normal ranges. Quite interestingly, in this cohort of frail aged patients from south Italy the balance between inflammation (IL-17) and anti-inflammation (IL-10) was preserved, thus suggesting that the Mediterranean diet might have been involved in the observed effects. In conclusion, these data support the ability of Leucoselect® Phytosome® to induce up-regulation of Th1 responses in frail elderly patients which may be beneficial in those patients affected by chronic allergic disorders.

Key words: Ageing, allergy, inflammation, Leucoselect® Phytosome®, Polyphenols.

PROBIOTICS AS PROTECTIVE AGENTS AGAINST ENTEROBACTERIA

G. Perdigón^{1,2}, N. Castillo¹, C. Maldonado Galdeano^{1,2}, A. de Moreno de LeBlanc¹

¹Cerela-Conicet, San Miguel de Tucumán, Tucumán, Argentina

²Cátedra de Inmunología, Instituto de Microbiología, Facultad de Bioquímica Universidad Nacional de Tucumán, Tucumán, Argentina

Salmonella is one of the major causative agents of foodborne diseases, morbidity and mortality worldwide. Salmonella enterica serovar typhimurium (S. typhimurium) produces in mice an infection with similar pathogenesis and clinical manifestations than S. typhi in humans. Probiotics influence the innate and adaptive immunity and the activity of the intestinal microbiota. This knowledge allowed us to propose the use of probiotic bacteria against Salmonella infection. On this topic, the mechanisms mediating this protection are not yet established. We determine the effect of the oral administration of probiotic bacterium L. casei CRL-431 on the biological and immune mechanisms involved in the prevention and treatment of the S. Typhimurium infection, using BALB/c mice. Oral administration of probiotic to healthy mice, induced activation of gut immune cells in a regulated state. The continuous L. casei

CRL-431 administration (previous and post-infection) protected mice challenged with *S. Typhimurium*. The mechanisms involved were: a) The modulation of innate immune response by increased TLR expression on epithelial and immune cells. b) Epithelial cell activation, evidenced by increases in secretion of IL-6 and MCP-1. c) Increased number of macrophages, dendritic cells and IgA (+) cells in lamina propria of the small intestine, and increased secretion of total S-IgA. d) Reduction of inflammation, with reduced TNF-alpha levels and myeloperoxidase activity, less PMN infiltration in lamina propria and regulation by IL-10. e) Increased phagocytic activity in macrophage isolated from Peyer's patches, spleen and peritoneum, correlated with an increase of IFN-gamma. The results showed that *L. casei* CRL-431 induces biological and immune mechanisms, which confer resistance to *S. typhimurium* infection, showing lesser severity of the infection. The safety of continuous administration of this probiotic strain, allows us to suggest its use as an adjuvant of the mucosal immune system in the prevention, and during *Salmonella* infection.

Key words: *Salmonella* infection, probiotics, mucosal immune system.

GEOGRAPHY AND THE IMMUNOINFLAMMATORY PROCESSES IN OVERWEIGHT AND OBESITY

R. Valdes-Ramos, P. Muñoz-Aguirre, R. Oros-Pantoja, B. E. Martínez Carrillo, A.D. Benítez-Arciniega

Center for Research and Graduate Studies In Health Sciences, Faculty of Medicine, UAEM, Mexico

Cytokines and adipokines regulate various biological processes, including acute phase protein synthesis, and are being used as emerging indicators of the immune or inflammatory response. Their concentrations are altered when homeostasis is interrupted (sepsis, shock, obesity, etc.). There is evidence that hypoxia is a stress factor that affects homeostasis by a reduction of arterial oxygen saturation, however organisms may get used to or compensate these changes with lifelong exposure. Despite the higher prevalence of diabetes and hypertension in populations residing at moderate altitudes (Ö500m), mortality from cardiovascular disease in these populations is lower than in populations residing at sea level. Leon et.al, in Canary Islands, Spain, showed that individuals residing at moderate altitudes have a lower heart rate and lower serum concentrations of total leptin, free leptin, and CD40L. Mazzeo et.al, in Denver, Colorado, exposed healthy women for 12 days to very high altitudes (4300m), showing a significant increase in IL-6. Klausen in Mont Blanc, France evaluated the effect of a very high altitude exposure in ten healthy men; although no effects were observed in IL-1 β , TNF- α and C-reactive protein, a highly significant ($p=0.002$) change was found in IL-6

concentrations compared to sea level values after four days of exposure. We have recently shown that resistin, insulin, adiponectin, IL-2 and IL-8 values are significantly different between overweight and obese adolescents living in moderate altitude or high altitude (2300m) cities in Mexico. Hypoxia caused by different lengths of exposure may be inducing modifications in pro-inflammatory cytokines and obesity associated adipokines, affecting the metabolic effects of chronic disease, thus justifying the difference in morbidity and mortality at different geographical sites.

Key words: Obesity, inflammation, altitude, geography

IMMUNOMODULATOR ROLE OF MOTHER'S MILK

J.R. Mujico, A. Marcos

Immunonutrition Group, Department of Metabolism and Nutrition, Institute of Food Science, Technology and Nutrition (ICTAN-CSIC), Madrid, Spain

Breast milk contains the nutrients necessary to support the development of the infant's immune system as well as other components that defend against infection. This includes various antimicrobial substances, factors that promote immune development, constituents that promote tolerance of the infant immune system, anti-inflammatory components, as well as compounds that promote healthy intestinal microbiota. It is well documented that breast milk provides antimicrobial defence to the infant; however, research on neonatal immune development, tolerance and prevention of the inflammatory response is still needed. Although there have been many modifications in the nutrient composition of infant formula aimed at improving immune function (such as fortifying with probiotics, sIgA, LCPUFA, nucleotides...) they have only begun to provide the immune benefits conferred by human milk.

Key words: Human milk, immune system, inflammation, microbiota.

PS3-25 New biomarkers for health claims made on food

BIOMARKERS OF BENEFIT FOR HEALTH CLAIMS MADE ON FOOD: THIS IS THE CHALLENGE

A. Palou

Universidad de las Islas Baleares & CIBERobn (Ciber de Fisiopatología de la Obesidad y Nutrición), Spain

The identification of robust biomarkers is crucial for assessing the potential effectiveness of health-promoting food-com-

pounds. This is the basis for new/competitive developments in the food-health sector as covered by the harmonized legislation on health claims (HC) made on food in Europe (Regulation EC 1924/2006), probably the most controversial, certainly the most complicated piece of food legislation, including new concepts, science-regulatory unexperienced interactions allowing a number of opportunities but also uncertainties. Obstacles and related-delays, include nutrient profiles, biomarkers, data and/or intellectual property protection, far from being solved by a number of EC/EFSA guidelines or the more recent Regulation No.432/2012 establishing “a list” (the List?) of 222 permitted HC or the particularities of a few claims on reduction of disease risk based or claims based on new science. ‘Biomarkers of Robustness of Metabolic Homeostasis for Nutrigenomics-derived Health Claims Made on Food’ (BIOCLAIMS, Grant agreement no. 244995) is a Collaborative - Large-scale integrating research project funded by the EC. It faces the problem that only a few recognized (EFSA) risk factors are available for HC; that for a number of physiological functions there are no useful biomarkers; and that for other functions there is a need for earlier biomarkers. This lack is the main bottleneck for the consolidation/expansion of the health claims-based added values in the food sector.

Moreover, instead of relying only on disease-oriented biomarkers used in the biomedical world and making derivative biomarkers out of these (“surrogate end points”), a new focus on biomarkers towards maintenance of physiological function and homeostasis integrity is proposed. A nutrigenomic-based biomarker is a set of information consisting mainly of quantitative levels of gene-expression and/or proteins and/or metabolites that can be measured in a reproducible affordable way, expressing a health-benefit, either a reduction of disease-risk or a physiological/nutritional benefit.

Key words: Biomarkers, gene expression, health claims, homeostasis.

COMPARISON OF THREE NON-INVASIVE METHODS, INCLUDING CHALLENGE TESTS, TO MEASURE METABOLIC HEALTH IN MICE USING INDIRECT CALORIMETRY

E. Van Schothorst, L. Duivenvoorde, H. Swarts, J. Keijer
Human and Animal Physiology, Wageningen University, Wageningen, The Netherlands

Indirect calorimetry (InCa) is a non-invasive method that can potentially be used to assess metabolic health. To test this, we compared three InCa-based methods using aged and adult C57BL/6J male mice (72 and 10 weeks old) and assessed the stability of the responses over time. The aged and adult mice differed in adiposity and white adipose tissue mitochondrial density, indicative of a compromised metabolic health of the

aged mice. In method 1, diurnal patterns of respiratory exchange ratio (RER) were followed for 24hrs under standard conditions. In method 2, fasted mice received glucose to test effective switching in substrate oxidation. In method 3, mice were exposed to oxygen restriction (OxR, 14.5 % O₂) to test how effectively animals switch from normal to low oxygen availability. Each method was repeated with at least a 10 week interval to assess response stability. Method 1 was not stable in time. Method 2 did not reveal differences in metabolic health between adult and aged mice. Method 3 appeared most sensitive to detect differences between both groups and in each period. Adult mice maintained reduced oxygen consumption under OxR, while aged mice did not. Thus, the response to OxR is a sensitive and reproducible method to non-invasively measure metabolic health in mice. Molecular analyses showed that OxR affected glucose and lactate metabolic pathways in liver and adipose tissue, supporting the observed differences in oxygen consumption.

Acknowledgements: We thank Inge van der Stelt, Femke Hoevenaars, Elise Hoek, and Davina Derous of Human and Animal Physiology for their helpful contributions. We also would like to thank Dr. Jan Kopecky (Dep. Adipose Tissue Biology, Institute of Physiology, Acad. Sci. Czech Rep, Prague, Czech Republic) for the constructive discussions.

Key words: Hypoxia, indirect calorimetry, challenge test, oxygen restriction, metabolic flexibility.

STRESS CHALLENGES AS TOOLS FOR BIOMARKER IDENTIFICATION

S. Klaus

German Institute of Human Nutrition In Potsdam, Postdam, Germany

The aim of BIOCLAIMS is the development of new “health biomarkers” through assessment of the robustness of the homeostatic mechanisms involved in maintaining optimal health. This is based on the assumption that the ability to maintain homeostasis in a challenged environment is key for healthy ageing. To this end we employ mouse models of different stress challenges using (i) nutritional challenges, and (ii) bioenergetic challenges. (i) Using a high fat diet challenges we could show that short term effects of high fat diet feeding on adipose tissue gene expression are highly predictive of long term effects linked to increased adiposity. We identified Mest (mesoderm specific transcript) as an early marker of fat cell expansion (Voigt et al. Mol Nutr Food Res. 2013, in press), and are now focusing on the identification of markers for adipose tissue health. (ii) We have established a mouse model of healthy aging by ectopic expression of the uncoupling protein UCP1 in skeletal muscle (Keipert et al. Aging Cell. 10: 122, 2011). In this model, a mild mitochondrial uncoupling acts as a constant

bioenergetic stress in skeletal muscle resulting in an increased oxidative stress (Keipert et al. *Am J Physiol Endocrinol Metab.* 304: E495, 2013) and an upregulation of the integrated stress response, albeit without evident muscle pathologies or functional impairments. Using a combined transcriptome and metabolome approach we identified a novel metabolic rescue cycle involving a reprogramming of skeletal muscle glucose metabolism and secretion of an endocrine acting myokine channeling energy from peripheral tissues (liver and white fat) to muscle. We are now aiming to exploit this model for identification of biomarkers for healthy aging to be used in humans.

Acknowledgement: Supported by the European Union's Seventh Framework Program FP7 2007-2013 under grant agreement n° 244995 (BIOCLAIMS Project).

Key words: Nutrition, biomarkers, healthy aging, stress challenge.

PERIPHERAL BLOOD CELLS AS SOURCE OF BIOMARKERS

P. Oliver, C. Picó

University of the Balearic Islands, Palma de Mallorca, Spain

Peripheral blood mononuclear cells (PBMC) constitute an interesting biological material as they can be collected easily and repeatedly with minimum invasion in comparison to sampling of other tissues and reflect expression pattern characteristics of certain pathologies. Thus, the use of PBMC for the development of diagnostic tools is growing and they have also been shown to be useful for nutritional research. Our studies indicate that the expression of key energy metabolism genes in PBMC (studied with omic techniques) changes in response to acute changes in feeding conditions (fasting/refeeding) reflecting changes that occur in other internal organs as liver or adipose tissue. This nutritional regulation in PBMC is altered in diet-induced obese animals, reflecting an insensitivity to feeding conditions, even in the earlier stages with a low degree of overweight. PBMC gene expression is also affected by the intake of different diets and by diet-induced obesity. Hyperlipidic diets produce an alteration in the expression of genes related to energy metabolism, adiposity, inflammation and other pathways related to body weight gain. Interestingly, PBMC altered gene expression can be recovered with weight loss. Macronutrient diet composition also has an impact on PBMC gene expression. We have observed that the intake of isocaloric unbalanced diets (rich in fat or proteins) alter the expression of genes related to several metabolic pathways, including energy metabolism and immune response. Thus, PBMC could be used as a source of biomarkers of adiposity, early homeostatic imbalance related to obesity development, metabolic recovery with weight loss, and intake of unbalanced diets. For these reasons, this set of cells appears as an interesting and useful tool to be

used in nutritional studies that could help to predict and/or prevent the occurrence of obesity.

Acknowledgements: Research funded by the European Union (BIOCLAIMS FP7-244995)

Key words: PBMC, biomarkers, obesity, nutrition .

READING THE PATTERNS OF ENDOGENOUS DAMAGE TO THE PROTEINS

J. Masania, P. Thornalley, N. Rabbani

Warwick Medical School, University of Warwick, Coventry, UK

Proteins in human tissues and body fluids continually undergo spontaneous glycation, oxidation and nitration reactions forming low levels of glycation, oxidation and nitration adduct residues. Examples of glycation adducts are: Nac-fructosyl-lysine – an early-stage glycation adduct, methylglyoxal derived hydroimidazolone MG-H1 – an advanced glycation endproduct (AGE), oxidation methionine sulfoxide and nitration adduct 3-nitrotyrosine. Proteolysis of proteins damaged in this way releases glycation, oxidation and nitration amino acids, also called free adducts, which are excreted in urine. Urinary excretion of free adducts is an estimate of total body glycation, oxidation and nitration damage – also influenced by adduct repair in some cases leading to underestimates and adducts absorbed from digested damaged proteins in ingested foods leading to overestimates. Stable isotopic dilution analysis liquid chromatography-tandem mass spectrometry (LC-MS/MS) is the best methodology for measurement of protein glycation, oxidation and nitration adducts to which other higher throughput methods such as immunoassay and indirect methods are corroborated. For protein adduct residues prior exhaustive enzymatic hydrolysis is required which can be conveniently automated and performed under aseptic conditions. Free adducts are analysed in 3 kDa ultrafiltrate of samples. Steady-state levels of protein damage are influenced by both changes in rates of glycation, oxidation and nitration and rate of protein turnover. If the rate of modification is constant, the extent of modification of proteins is proportional to protein half-life and therefore protein damage levels are surrogate markers of plasma proteomics dynamics. Quantitative measurement of glycation, oxidation and nitration adducts provides information on the level of exposure to potentially damaging protein modifications, protein inactivation in ageing and disease, metabolic control, protein turnover, renal function and other aspects of body function. Multiple protein damage markers combined by machine learning techniques in diagnostic algorithms provide a powerful approach for biomarker development in diet and health relationships.

Key words: Advanced glycation endproduct, glycation, nitration, oxidation, proteins.

THE CARNITINE FAMILY AS BIOMARKERS OF METABOLIC HEALTH IN THE INTERVENTION STUDIES USING OMEGA 3 AND THIAZOLIDINEDIONES

J. Kopecky

Institute of Physiology Academy of Sciences of the Czech Republic, Czech Republic

Background and objectives: Combined interventions are required for a better handling of metabolic diseases associated with obesity. Thus, dietary, lifestyle, and pharmacological interventions should be considered in the therapy of type 2 diabetes. Naturally occurring n-3 long-chain polyunsaturated fatty acids (omega-3) are now regarded as healthy constituents of diets for diabetic patients. These lipids act as hypolipidemics, reduce inflammation, and reduce incidence of cardiac events. In our studies in dietary obese mice, we have found that omega-3 augment the effects of anti-diabetic drugs, namely thiazolidinediones (TZDs). Thus, the combined intervention could exert synergistic effects in prevention as well as reversal of insulin resistance in mice. Since insulin-resistance is often linked to impaired oxidation of lipids in metabolically relevant tissues, and since plasma levels of acylcarnitines with long saturated and monounsaturated even side-chain (C12-C18; AC) correlate with the activity of beta-oxidation in the tissues, we aimed to learn whether the plasma AC levels could serve as a marker of beneficial metabolic effects of omega-3 and TZDs.

Methods: Adult B6 mice were fed for 2 months high-fat diet supplemented or not with omega-3, or TZDs, or omega-3 + TZD. Glucose tolerance, plasma levels of AC, and lipid and glucose metabolism markers (in both fasted and re-fed mice), whole-body energy metabolism and metabolic flexibility (indirect calorimetry), and tissue (liver, muscle) lipid content were characterized.

Results: Changes in plasma levels of AC in response to fasted/refed transition discriminated between the interventions. The additive improvement of glucose homeostasis as well as metabolic flexibility in response to the combined intervention was reflected by changes in the plasma AC levels.

Conclusions: Changes in plasma AC profile, which reflect tissue fatty acid oxidation, could serve as a reliable marker of metabolic health.

Acknowledgement: Supported by EU FP7 project Bio-claims and Czech Science Foundation (13-00871S).

Key words: Biomarkers, carnitine, glucose homeostasis, type 2 diabetes, obesity, lipid catabolism.

THE CHALLENGE OF VALIDATING BIOMARKERS IN HUMANS: THE BIOCLAIMS APPROACH

B. Winklhofer-Roob¹, J. Roob²

¹Human Nutrition & Metabolism Research and Training Center, Institute of Molecular Biosciences, Karl-Franzens University, Graz, Austria

²Clinical Division of Nephrology, Department of Internal Medicine, Medical University, Graz, Austria

A biomarker is a biological indicator of normal biological or pathogenic processes or responses to different kinds of intervention. Almost any measurement reflecting changes in biochemical processes, structures or functions may serve as biomarker, including biomarkers of nutritional/environmental exposure and functional biomarkers (e.g. biomarkers of inflammation, oxidative stress, liver function). The general objective of the FP7-project BIOCLAIMS ("BIOmarkers of robustness of metabolic homeostasis for nutrigenomics-derived health CLAIMS made on food") is to identify, in animal and human studies, candidate biomarkers indicating biochemical changes in response to metabolic challenges. The specific questions include "What are early predictive biomarkers of phenotypic changes occurring later in life?", "Do acute stressors (e.g. high-fat diet, oxygen limitation) reveal underlying mechanisms?", "What are the predictive values in different models under different conditions?", "Are these biomarkers predictive across gender, genotype, and life span?", and "Are these biomarkers sensitive to bioactive food compounds?" Special focus is directed on biomarkers of homeostatic robustness, indicating how well an organism preserves its capacity to regulate and maintain a functionally relevant balance of metabolic processes in response to acute (oral glucose or lipid tolerance tests, fasting, oxygen limitations) or chronic/repeated perturbations (impaired renal function, aging, menstrual cycle, season). To achieve these goals, a wide array of models and methodologies has been selected. They are applied to hundreds of samples in cross-sectional studies for studying associations of new biomarkers with established ones, and as outcome variables for comparing results before and after nutritional interventions. Additional studies provide data for all variables on variability from day to day, between seasons and within menstrual cycle, as well as reference ranges. Validation includes good-laboratory-practice validation of new analytical methods, including estimation of precision, within-run, between-run and between-day coefficients of variation, etc. These results will allow for reliable interpretation of biomarkers in on-going and future human studies.

Key words: Biomarkers, metabolic homeostasis.

BIOMARKERS OF INFLAMMATION: RELATIONSHIP WITH NUTRITION AND WITH HEALTH OUTCOMES

P. Calder

University of Southampton, Southampton, UK

Inflammation is a characteristic feature of many conditions and diseases. Irrespective of the trigger and the locus of activity, inflammation typically involves a common panel of cells and a common set of chemical mediators. It is now recognised that metabolic dysfunctions, like obesity, also include an inflammatory component. Adipose tissue releases a number of inflammatory mediators and circulating concentrations of such mediators increase with body mass index and are higher in obese than normal weight individuals. Furthermore weight loss, either through surgery or through lifestyle change is associated with decreased concentrations of inflammatory mediators in the bloodstream. Within adipose tissue both adipocytes and infiltrating inflammatory cells (mainly macrophages) seem to play roles in synthesis and secretion of inflammatory mediators. Some of these mediators, like TNF, can induce insulin resistance both locally and distally. Food components can influence inflammation in a variety of ways with some acting to promote inflammatory processes and others to dampen inflammatory processes. In general, healthy eating patterns and higher intakes of key components of such patterns are associated with lower inflammation. There is an increase in blood inflammatory markers following consumption of a meal especially one high in fat. This post-prandial inflammatory response is exaggerated with obesity and diabetes and can be modified according to the composition of the meal.

Key words: Adipocytes, inflammation, immune system, metabolic dysfunction.

PS3-33 OMICS technologies with nutritional perspectives

NUTRIEPIGENOMICS AND OBESITY

J.A. Martínez^{1,2}

¹University of Navarra, Pamplona, Spain

²CIBERObn

The 'epigenetic code' represents 'the sum of the alterations to the chromatin template that collectively modulate gene expression patterns. In other words, epigenetics involves the heritable changes in gene expression that occur independently of the underlying DNA nucleotide sequence. These processes include DNA methylation, covalent histone modifications, chromatin folding and regulatory miRNA or polycomb group complexes. Two outstanding features of epigenetic processes are the ability for transgenerational heritability and temporal differentiation from totipotent cells.

Different examples of dynamical changes in DNA methylation patterns and histone architecture due to the restriction or supplementation with different foods and nutrients have been reported. Thus, maternal caloric restriction has been related to methylation status of some genes, while the intake of minerals, methyl donors such as vitamins of the B complex, polyphenols or amino acids, led to DNA methylation changes. Furthermore, alcohol consumption, hypoxia and inflammation have been associated with an epigenetic regulation. Additionally, metabolically important genes (Epigenes) are being identified (POMC, FASN, CLOCK, FNF- α , LEP, AQP9, CD44, etc.) as part of the epigenetic machinery regulation of body weight homeostasis, which may serve for diagnosis and prognosis purposes. In summary, interindividual differences concerning the outcomes of nutritionally-related chronic diseases depend not only on the dietary intake and the subject's DNA sequence, but also on the inherited epigenome and on different nutritional influences that modify the epigenetic marks and are able to affect gene expression and function. This research is part of the CIBERObn program, Madrid.

METABOLOMICS AND NUTRITIONAL APPLICATIONS

L. Brennan

UCD Institute of Food and Health, UCD Dublin, Ireland

Metabolomics is the study of metabolites present in biological samples such as biofluids, tissue/cellular extracts and culture media. Combining metabolomic data with multivariate data analysis tools allows us to study alterations in metabolic pathways following different perturbations. Examples of perturbations can be disease state, drug or nutritional interventions with successful applications in the fields of drug toxicology, biomarker development and nutrition research. In recent years, metabolomics has been used to define the metabolic phenotype (metabotype) of individuals. There is an expectation that assigning individuals to a particular metabotype will provide a prediction for response to interventions such as drug and nutritional treatments thus providing a personalisation to treatment. Examples which have been successful include response to supplementation with vitamin D and treatment with acetaminophen and Fenofibrate therapy.

However, further work is necessary to establish the true potential of metabolomics in personalised health. Metabolomics can also be applied to the discovery of biomarkers of food intake and current approaches and developments in this field will be discussed.

Key words: Metabolomics, metabolic pathways, metabotype, personalised health.

NETWORK BIOLOGY AND SYSTEMS BIOLOGY APPLICATIONS IN NUTRITION

T. Kelder, B. Van Ommen, M. Radonjic

Microbiology and Systems Biology, TNO, Zeist, The Netherlands

Nutrition, in combination with genetics background, represents the major determinant of the individual's health status throughout life. Inadequate dietary patterns, either in a form of undernourishment, scarcity of essential nutrients or excess caloric intake, contribute to failure of systems resilience and consequently development of disease. Understanding of relations between diet, genetics, physiological processes and organ(ism) health is essential for devising nutritional strategies to achieve optimal health benefit.

Current definition of health implements a view of optimally functioning human physiology as the ability to adapt to one's environment. To achieve such optimal function, flexibility should be established and maintained at all levels of systems complexity: at the level of molecular regulation, in various physiological processes, in different organs, etc. To comprehend the organization of systems elements that are required for flexible response to perturbations – and therefore maintenance of health - we are using network biology as a mean for multi-level mapping of systems components and interactions between them. This enables understanding of the processes required for adaptive response in various organs and discovery of (combinations of) “hotspot” nodes that need to be fine-tuned in order to achieve optimal flexibility of the system.

A growing compendium of nutrigenomics and challenge test studies now allows for integrative analysis and reconstruction of “reference networks” as a mean to capture dynamic relations between molecular entities, physiologically relevant marker processes and health benefit endpoints. Our mission is to develop and use such reference networks to address systems flexibility using network properties, as a readout parameter for the health effects of nutrients, for discovery and prioritization of mechanisms, biomarkers and intervention targets and as a guidance for improved, evidence-based dietary interventions.

Key words: Network biology, systems biology, systems flexibility, metabolic health, biomarkers.

PS4-41 Public health genomics in individualized nutrition

PUBLIC HEALTH GENOMICS IN NUTRITIONAL SCIENCES

A. Brand

Institute For Public Health Genomics (IPHG), Maastricht University, Maastricht, The Netherlands

Rapid scientific advances in genomics such as in the light of epigenomics, microbiomics and systems biology supported by new ICT solutions not only contribute to the understanding of disease mechanisms, but also provide the option of new promising applications in human health management during the whole life-course of a person. What was little time ago a vision for a new era of public health, in which advances from the -omic sciences would be integrated into strategies aiming at benefiting population health, is now responding to the very pressing need for the development of effective personalized health-care going even beyond personalized medicine. Nutrigenomics is the field showing not only that nutrients play a central role in the stabilization of the DNA but also that there is a need to understand the complexity of the interaction between nutrition, genomics and other environmental factors as well as their role in the development of diseases. So far, all stakeholders including policy-makers and the private sector are struggling to translate the emerging knowledge into public health. Public Health Genomics (PHG) is the area of public health ensuring that scientific advances in genomics (“from cell...”) triggered by innovative technologies are timely, effectively and responsibly translated into health policies and practice for the benefit of population health (“...to society”). The implementation of PHG requires increased concerted activities. The Institute for Public Health Genomics (IPHG) at Maastricht University aims to fulfil this task in all European Member States by hosting the European Centre for Public Health Genomics (ECPHG) and coordinating the Public Health Genomics European Network (PHGEN). Furthermore, it is actively involved in the FP7 CSA on Personalised Medicine (PerMed) funding bodies, as well as in the European Flagship Pilot ITFoM on the future of medicine that aims to achieve the visionary goal of the “virtual human”.

Key words: Personalized nutrition, Public Health Genomics.

EPIGENETIC MECHANISMS OF BIOACTIVE FOOD COMPONENTS IN CANCER PREVENTION

B. Stefanska

Department of Pharmacology and Therapeutics,
McGill University, Montréal, Québec, Canada

Aberrations in gene expression and protein function observed in a variety of human disorders with cancer at the forefront are caused by both genetic and epigenetic factors. Epigenetics refers to changes in gene expression programming that alter the phenotype without disrupting the underlying DNA sequence. Epigenetic modifications, which include DNA methylation, covalent histone modifications, and regulation by non-coding RNAs, are dynamic and serve as an adaptation mechanism to a wide variety of environmental and social factors including diet. A number of studies provide evidence that natural bioactive compounds found in food and herbs can modulate gene expression by targeting elements of the epigenome, in particular DNA methylation, during different life stages. Increase in DNA methylation within gene promoters of tumor suppressor genes has been linked to their transcriptional silencing and is considered a hallmark of cancer. Resveratrol, a polyphenol present abundantly in grapes and red wine, as well as vitamins D and A reverse DNA promoter hypermethylation of tumor suppressor genes and lead to their re-activation in breast cancer. It robustly reduces cancer cell growth and sensitizes cells to anti-cancer agents. Nutrients that are components of one carbon metabolism such as folate, riboflavin, pyridoxine, cobalamin, choline, betaine, and methionine, affect DNA methylation by regulating levels of S-adenosyl-L-methionine that is the ubiquitous methyl donor. These compounds can potentially reverse DNA promoter hypomethylation in cancer and inactivate genes driving cancer progression and metastasis. Our findings indicate that natural compounds can change the epigenome leading to activation of tumor suppressor genes and suppression of oncogenes and pro-metastatic genes. Since epigenetic abnormalities have been shown to be both causative and contributing factors in different health conditions including cancer, individualized nutrition might play a tremendous role in cancer prevention and therapy.

Key words: Nutritional epigenetics, carcinogenesis, individualized nutrition.

LET'S IMPLEMENT PUBLIC HEALTH GENOMICS AND PERSONALIZED NUTRITION

B. Van Ommen

TNO, Wageningen, The Netherlands

Over the last decade, personalized nutrition has become a buzz word, with promises piling up. Many small and large companies have tried to enter this area, not all successfully. Scientifically and technologically, personalized nutrition is feasible. Yet, the implementation requires more than this. A consumer needs to know all relevant aspects of his/her health status, and needs to have access to information and knowledge that links the personal health status to dietary advice that is pleasant, convenient, varied, etc., within a system that motivates to continue and comply. Well, we are not there yet. However, new areas of implementation emerge that combine information technology, do-it-yourself health assessment ranging from genome to glucose, intelligent algorithms that turn measurements into motivation. Yet, the real breakthrough will not come for personalized nutrition in isolation, but as part of a paradigm shift in health(care) comprising 6 aspects:

- from a reductionist to a systems view on society and health
- from disease management to health promotion;
- from medicine-focus only to include lifestyle, nutrition, psychology;
- from a generic to a personalized approach;
- from the patient as "case" to an empowered person (self-management).
- from passive patient to an optimally participating citizen.

This requires a massive change in our approach on science. I will demonstrate how in Europe, nutrition scientists are taking a lead in this shift by creating the "Nutrition Researchers Cohort", as a significant step in implementing public health genomics and personalized nutrition.

Key words: Epigenomics, nutrigenomics, personalized nutrition.

GENETIC, EPIGENETIC AND NUTRITIONAL INTERACTION IN NEUROLOGICAL DISORDERS

B. Peterlin, A. Maver

Clinical Institute of Medical Genetics, UMCL, Ljubljana, Slovenija

The global burden of disease related to neurology is considerable and projected to rise in the future. Accumulating data from hypothesis free - genomic approaches including exome/genome next generation sequencing, transcriptomics, epigenomics, and other omics approaches are revolutionizing understanding of mechanisms underlying brain diseases. Evidence is

accumulating on mutual interaction among dietary molecules, genes and gene function. Moreover, epigenetic mechanisms, which are influenced by endogenous and exogenous stimuli contribute to plasticity and homeostasis of the central nervous system in health and disease. Bioinformatic tools are promising to integrate these various types of data to better understand nutrition -gene interactions. Consequently, novel approaches to prevention and treatment of neurological disorders can be envisaged.

Key words: Epigenetics, neurological disorders, nutrition.

GENOMICS, MICROBIOMICS AND EPIGENOMICS IN METABOLIC SYNDROME: A CASE STUDY IN PUBLIC HEALTH GENOMICS

A G. Haslberger, E. Aumüller, B. Hippe, M. Remely
Department Nutritional Sciences, University of Vienna, Vienna

Public Health Genomics translates knowledge from molecular biology for the benefit of population health. The understanding of interactions between omic levels needs to be integrated in public health strategies. The metabolic syndrome is a good example for the need to integrate knowledge from sequence based genomic data, epigenetic mechanisms, individual microbiota, and complex gene environment interactions for an understanding of pathogenesis and therapy.

Analysis of the adaptive thermogenesis pathway in obesity suggests that multiple SNPs in genes (ADRB3, UCP1, PPAR γ , Pgc1 α , rXra, c/EBP α , FaBP4, LPL) correlate with obesity. However, for almost all of these genes also an epigenetic regulation, influenced by the environment was demonstrated. Mechanisms between sequence changes and epigenetics need better understanding.

Individual characteristics of microbiota influence the development of low grade inflammation. Changes in patterns and metabolic activities of GI microbiota have been claimed as a cause of obesity. Abundance and changes of Firmicutes: Bacteroidetes, SCFA producing Clostridia and bacterial diversity seem to influence mechanisms underlying obesity and T2D. These changes in GI microbiota can be linked to an altered gene expression and epigenetic regulation, especially methylation of CpGs in promoter region of SCFA receptors, inflammatory mediators (such as IL-6 and TNF- α), and Toll like receptors.

The conclusion of these case study points to the need to respect gene - environment interactions and different omic levels for individualized health prevention and results in concepts for public health genomics.

PS4-49 Biomarkers of response to dietary interventions

ADVANCED IMAGING TECHNIQUES TO STUDY BRAIN DEVELOPMENT IN NUTRITIONAL INTERVENTION

S. Sizonenko

Geneva University Hospital, Geneva, Switzerland

This talk will focus on Magnetic Resonance Imaging (MRI) techniques and how they can be used in nutrition studies of brain development. The advent of non-invasive MRI was a breakthrough to assess the human brain in vivo, greatly expanding the possibilities to investigate brain structure and function. Clinically, neuroradiologists usually interpret scans by visual inspection; however, in order to reveal more subtle features, other techniques have been developed that depend on different acquisition modalities with post-acquisition processing of the scans. Within the broad divisions of macro-, micro-structural, metabolic and functional imaging, a variety of techniques have emerged from magnetic resonance (MR) leading to multimodal assessment of the brain. Therefore, the combination of MRI as a multimodal tool with post-acquisition processing techniques provides powerful technology for the study of the effects of nutrition on brain development. Further it represent an excellent translational tool from animal to human research as the same techniques can be applied. These aspects will be presented and examples of nutrition studies in the early life spectrum that have included MRI will be discussed.

Key words: Magnetic resonance imaging, brain imaging, nutrition

APPLYING STRUCTURAL MAGNETIC RESONANCE BRAIN IMAGING IN NUTRITION STUDIES

K.B. Walhovd

Department of Psychology, University of Oslo, Norway

A number of changes in brain and cognition take place across the lifespan. There are great individual differences. Changes can be influenced by a number of conditions, including nutrition. Brain imaging techniques have been applied to

demonstrate the effect of dietary intake patterns and nutrition interventions on brain structure and function. Biomarkers of nutrient intake and related parameters, e.g. cholesterol, can also be linked to brain imaging data. One example of dietary components studied includes long-chain polyunsaturated fatty acids. In this presentation, imaging related to nutrition, including data using MR imaging and nutrition biomarkers, limitations of these techniques and potential future applications across the lifespan will be discussed. Preliminary data will be presented on MR imaging of longitudinal brain age changes in relation to nutrition, including data on cortical thinning in relation to body mass index (BMI) and blood markers of cholesterol, DHA and vitamin D.

Key words: Biomarkers, brain imaging, magnetic resonance, nutrition.

A CONSIDERATION OF BIOMARKERS TO BE USED FOR EVALUATION OF INFLAMMATION IN HUMAN NUTRITIONAL STUDIES

P C. Calder¹, N. Ahluwalia², R. Albers^{3,4}, N. Bosco⁵, R. Bourdet-Sicard⁶, D. Haller⁷, S T. Holgate¹, L S. Jönsson⁸, M.E. Latulippe⁸, A. Marcos⁹, J. Moreines¹⁰, C. M'Rini¹¹, M. Muller¹², G. Pawelec¹³, R J J. van Neerven¹⁴, B. Watzl¹⁵, J. Zhao¹⁶

¹⁰Pfizer, Madison, New Jersey, USA

Background and objectives: Inflammation is a normal process and there are a number of cells and mediators involved. They are common to all inflammatory diseases and inflammatory responses, and to both high-grade and low-grade inflammation. Despite great advances linking nutrition to inflammatory processes, there is no consensus as to which markers of inflammation best represent low-grade inflammation or differentiate among acute and chronic inflammation or between the initiation, propagation and resolution phases of inflammatory responses.

Methods: To provide state-of-the science guidance, the ILSI Europe Nutrition and Immunity Task Force commissioned an Expert Group on Biomarkers of Inflammation, with the aim

to evaluate the suitability of inflammatory markers in studies evaluating the impact of nutrition. For this project, the Expert Group identified robust and predictive markers, or patterns or clusters of markers, which can be used to assess inflammation in human nutrition studies in the general population.

Results: Guidance for use of markers in nutrition research: There are a number of modifying factors that affect the concentration of an inflammatory marker at a given time; these modifying factors include age, body fatness, physical (in)activity, sex, smoking, genetics and microbiota composition. Probably most informative is measuring concentration changes in response to a challenge. A number of inflammatory challenges reflecting metabolic stress, infection, and tissue damage have been described. However, many of these challenges are poorly standardised. Patterns and clusters may be important as robust biomarkers of inflammation.

Conclusions: The review provides guidance for future studies in the general population, specifically noting that challenge models and cluster analyses seem promising but require rigorous standardisation and testing in prospective cohorts to assess their predictive value. Overall, the guidance contributes to a better understanding of the current limitations and opportunities for assessing inflammation.

Key words: Inflammation, leukocyte, cytokine, chemokine, acute phase.

NEW METABOLOMIC STRATEGIES IN CLINICAL NUTRITION RESEARCH: FROM DIET TO REVEALING DISEASE RISK BIOMARKERS

⁹Institute of Biological Environmental and Rural Sciences, Aberystwyth University, Aberystwyth, UK

Backgrounds and objectives: An important challenge of modern nutrition is to correctly assess metabolic status of subjects after specific diets. Usually, evaluations of human dietary patterns (or its components) have been carried out in small or medium controlled studies; however, on few occasions have been scaled to free-living studies. The Mediterranean diet shows a complex profile (qualitative and quantitative point of view) of bioactive-rich food sources including fruits, wine, nuts, olive oil, etc. The aim was to apply a metabolomic approach to explore the relation between dietary information and metabolic profiles in producing biomarkers that allow the intake of a particular dietary pattern or component to be assessed.

Methods: The PREDIMED study (www.predimed.org) is a parallel-group, single-blind, multicenter, randomized, controlled, 5 y feeding trial assessing the effects of the Mediterranean Diet supplemented with extra-virgin olive oil (MD-EVOO) or mixed nuts (MD-Nut) on the primary prevention of coronary heart disease, compared to a control Low Fat Diet (LFD). Spot urine samples and FFQ data from the participants of the PREDIMED were studied. Urine samples were analyzed by LTQ(Thermo) followed by statistical analysis. Biomarker identifications were achieved combining computational- assisted identification (MZedDB, HMDB, Masstrix, Metlin databases and in-house-database), IT/FT-MS/MS (Thermo) data and in-silico MS/MS experiments (MetFrag).

Results: Differences between dietary patterns of intake were detected. The results reinforce the interest to combine dietary information with metabolic fingerprinting to obtain new food-related metabolome biomarkers. Application of these approaches will allow us to obtain a picture of the complex interactions between diet, health status and urinary metabolome.

Conclusions: This study reveals the interest of metabolic phenotyping strategies in the identification of biomarkers related with clinical parameters.

Key words: Biomarkers nutritional intake, exposure, metabolomic, dietary intervention.

PS5-57 Early programming and nutrition in Latin America

MATERNAL CALCIUM INTAKE AND MODELING OF FETAL BLOOD PRESSURE

J. Belizán

Instituto de Efectividad Clínica, Buenos Aires, Argentina

Our interest in the relationship between calcium intake and blood pressure started from the observation of indigenous women in Guatemala. Those women have a high calcium intake due to the Mayan tradition to treat corn with lime and have a very low incidence of hypertensive disorders of pregnancy. These observations led us to hypothesize that the incidence of one of the most severe forms of hypertension during pregnancy, pre-eclampsia, can be reduced in populations of low calcium intake by calcium supplementation (1). In agreement with this hypothesis, a recent meta-analyses including 11 randomized controlled trials have shown that in communities with low dietary calcium intake, calcium supplementation during pregnancy is associated with a 68 % (from 51% to 79%) reduction in the incidence of pre-eclampsia (2). Our group performed a large, randomized controlled trial of calcium supplementation during pregnancy (3) in a population with low calcium intake, and 7 years later we conducted the follow-up of children born from these mothers (4). This study showed that the offspring of calcium supplemented mothers had a lower incidence of high blood pressure than offspring of mothers receiving placebo, suggesting a role of fetal calcium restriction on the genesis of hypertension in later life. We have shown in Wistar-Kyoto rats that maternal dietary calcium intake during pregnancy has a modeling effect on offspring's blood pressure. Rats exposed in utero to a calcium deficit develop high blood pressure during adulthood (5).

²Universidade de São Paulo - Ribeirão Preto, São Paulo, Brazil

³Hospital Materno-Infantil Ramón Sardá, Buenos Aires, Argentina

⁴Universidade Federal do Maranhão, São Luis, Brazil

Background and objectives: Birth weight and weight gain have been associated with high adult systolic blood pressure (BP) but not with high diastolic BP. Less well known is if the association between weight gain with high PHT or HT changes across the life cycle. The objective of this study is to assess the independent association of body mass index (BMI) measured in three points in the life cycle with adult PHT and HT.

Methods: A prospective cohort of all living born in the city of Ribeirão Preto, Brazil, was assessed at birth (1978/79), school-age (1987/88) and adulthood (2002/04). Data on neonatal variables, socioeconomic position and anthropometry of all three moments as well as adult RF for HT were present for 1143 subjects. Conditional weight analysis was performed to assess the risk of repeated-in-time measurements.

Results: Lower BMI at birth was associated with diastolic HT (RR=3.10; 95%CI 1.08-8.88). Higher BMI gain between birth and school age was associated with adult diastolic PHT & HT (respectively RR=2.78; 95%CI 1.67-4.64 & RR=6.79; 95%CI 1.82-25.46). Higher BMI gain between school age and adulthood was associated with both systolic PHT & HT (respectively RR=2.29; 95%CI 1.57-3.34 & RR=4.68; 95%CI 2.34-9.36) and diastolic PHT & HT (respectively RR=2.37; 95%CI 1.43-3.82 & RR=14.94; 95%CI 3.42-64.67). These effects were significant after adjustments for traditional HT risk factors and possible confounders.

Conclusion: Low BMI at birth, BMI gain between birth and school age, and BMI gain between school age and adulthood are all associated with adult diastolic HT. BMI gain between birth and school age is associated with both adult diastolic PHT and HT, whereas BMI gain between school age and adulthood is associated with systolic and diastolic PHT and HT.

Key words: Cohort, body mass index, hypertension, life course epidemiology.

MATERNAL OBESITY AND NEONATAL INSULIN RESISTANCE IN THE ORIGIN OF METABOLIC SYNDROME IN CHILDHOOD

⁴Dr. Sótero del Río Hospital, National Health Service, Santiago, Chile

Obesity during pregnancy has been recognized as an independent risk factor for maternal and fetal complications, including congenital anomalies, gestational diabetes mellitus, gestational hypertension and preeclampsia, caesarean delivery, macrosomia (birth weight > 4000 g), increased neonatal adiposity and hyperinsulinemia. In addition to perinatal complications associated to maternal obesity, rising epidemiological evidence has suggested the intrauterine programming of whole body insulin resistance (IR) in the offspring of obese pregnant woman, evaluated both at early neonatal stage and at young adulthood. Our cohort data showed association among elevated neonatal anthropometry measurements (birth weight and height) and increased levels of waist circumference and blood pressure in childhood, two components of the metabolic syndrome (MetS). In the other hand, the homeostasis model assessment index of insulin resistance (HOMA-IR) was correlated to the number of MetS components in this population. In order to describe potential mechanisms of relationship between maternal obesity and future development of MetS, we have evaluated modulators of neonatal insulin signaling pathway in human and animal models of maternal obesity. We have found increased levels of neonatal insulin secretion (serum C-peptide) and sub-clinical markers of cellular insulin resistance and endoplasmic reticulum stress (ER-stress) in offsprings of women with maternal weight excess. The ER stress response has been related to IR and diabetes mellitus development in multiple models of obesity. Thus, a mechanistic link could be proposed between maternal obesity, ER stress and IR in fetal tissues as part of the physiopathology route that connects abnormal intrauterine nutrition with elevated risk of MetS in childhood.

¹Pontificia Universidad Católica de Chile, Santiago de Chile, Chile

²Corporation for Infant Nutrition (CONIN), Santiago de Chile, Chile

³Universidad Diego Portales, Santiago de Chile, Chile

Infant malnutrition was highly prevalent in Chile during the first half of the 20th century, reaching 20% in 1970. In order to alleviate hospital overcrowding a corporation (CONIN) was created in 1977 that housed children below 2 years of age once they were stabilized in public hospitals. The residences provided food, child and medical care and nutrition education to the mothers. A cohort from Curicó, a city 180 km south of Santiago is being formed with adults that suffered moderate and severe protein-calorie malnutrition (PCM) in their first 2 years of life and currently are 20-30 years old. 256 charts available were examined and 180 were selected from children moderately and severely malnourished (Gomez classification) during the first two years of life. Weight at birth, gestational age, lactation, weight progression and complete medical records during their residence were available in the charts. Adults were evaluated for socioeconomic level, food intake, insulin resistance and anthropometry. They had 148 days of residence at the center. 40 % were women. The formation of the cohort will allow to assess the effect of early PCM on adults and their progeny.

Key words: Infant malnutrition, cohort, adults, follow-up.

EARLY GROWTH AND BIOLOGICAL MATURATION

S. Cruchet

Institute of Nutrition and Food Technology (INTA), Santiago de Chile, Chile

Increasing evidence indicates that excess adiposity is associated with accelerated skeletal and sexual maturation although results are not always consistent across sexes or ethnic groups. Also, it has been also suggested that some of these relationships would originate in the first years of life. Since 2006 we have followed ~1100 Chilean children (50% girls) from low-middle socioeconomic class in the Growth and Obesity Chilean Cohort Study (GOCS). In these children we have collected detailed anthropometric information from birth to 10y of age and we have also characterized biological maturation with ultrasound bone age, DHEAS concentrations, and Tanner staging. We will present data that shows that obese prepubertal GOCS

children compared to normal counterparts have accelerated maturation, particularly in terms of skeletal maturation. We will also present evidence that linear and ponderal growth during infancy is associated with maturation status in childhood, although magnitude and direction of the associations vary by sex and by type of indicator assessed. Taken altogether, we believe our results suggest that maturation status is a key component for judging the adequacy of growth.

Key words: Early growth, obesity, skeletal maturation, adrenarche.

A NEW STANDARD FOR INSULIN RESISTANCE AND ITS ASSOCIATION WITH THE METABOLIC SYNDROME IN CHILEAN SCHOOL AGE CHILDREN

S. Barja

Department of Pediatrics, Pontificia Universidad Católica de Chile, Santiago de Chile, Chile

Insulin Resistance (RI) has been proposed like the common pathogenic mechanism for the different risk factors that constitute the Metabolic Syndrome (MS). In studies of adult population the estimation of RI by means of Homeostasis Metabolic Assessment index (HOMA) has allowed to find an association to cardiovascular risk and especially to evaluate and follow the development of type 2 Diabetes Mellitus. Generally agreed insulin or HOMA cut-off levels for the pediatric population do not exist. This is due in part because the measurement of insulinemia presents a significant inter and intra-individual variation, and has a high dependency of the used technique. In addition, in children it is influenced by sex, age, pubertal maturation and also by genetic and cultural factors, which makes necessary to have local standards. The objective of this talk is to briefly present the development of a new standard of reference for insulinemia and HOMA, in a Chilean population of children and adolescents*. This reference enables a better clinical interpretation of RI, suggesting cut-off points for identifying children with higher risk according to sex and pubertal maturation. Its relationship to abdominal obesity and the agreement with different criteria for MS are also presented.

*Barja S, Arnaiz P, Domínguez MA, Villarroel L, Cassis B, Castillo O, Salomó G, Fariás M, Goycoolea M, Quiroga T, Mardones F. Normal plasma insulin and HOMA values among Chilean children and adolescents. *Rev Med Chile* 2011; 139: 1444-1452.

Key words: Insulin, insulin resistance, children, metabolic syndrome.

ASSOCIATION OF PRE AND POST NATAL GROWTH WITH METABOLIC SYNDROME COMPONENTS DURING CHILDHOOD

F. Mardones, A. Dominguez, L. Villarroel

Pontificia Universidad Católica de Chile, Santiago de Chile, Chile

Background and objectives: Fast weight gain and linear growth in children in the first two years of life have been recently proven to result in substantial gains in height in schooling in relatively poor countries (Adair LS et al. Lancet 2013; published online). We aimed to assess the relative influence of weight gain and linear growth at 6 and 10-13 years old on metabolic syndrome (MS) components and insulin resistance (IR).

Methods: We used data of 20 public schools (n=1556) from a relatively low income area of Santiago, Chile. Retrospective information on perinatal variables and anthropometry at 6 years old was obtained. Present data on MS and HOMA-IR was also obtained. In order to account for linear growth in height and weight on the MS components, we used the so-called conditional weight gain method. To quantify the odds ratio (OR) of non normal values, logistic regression models were used.

Results: Birth length (BL) was almost significantly associated with waist circumference (WC), decreasing the odds of WC (OR: 0.93 (0.87-1.00)). Birth weight (BW), relative or conditional on BL, also decreased the odds of WC (0.45 (0.35-0.57)). Relative height gain at 6 years old increased the odds of triglycerides (TG) (1.04(1.02-1.06)), IR (1.05(1.03-1.08)) and MS (1.05(1.01-1.09)). Relative weight gain at 6 years old increased the odds of HDL (1.05(1.01-1.09)), TG (1.11(1.07-1.15)), blood pressure (BP) (1.07(1.03-1.12)), IR (1.22(1.17-1.27)) and MS (1.21(1.15-1.28)). Height gain to present examinations increased the odds of glycemia (GLI) (1.08(1.05-1.11)), HDL (1.02(1.001-1.05)) and IR (1.09(1.07-1.11)). Relative weight gain to actual examination increased the odds of HDL (1.05(1.03-1.07)), TG (1.07(1.06-1.09)), BP (1.04(1.02-1.06)), HOMA (1.15(1.13-1.18)) and MS (1.13 (1.10-1.16)). All variables were inversely associated to WC.

Conclusion: Linear excess height gain and relative weight gain increases the risk of having MS at 10-13 years old, and its components, except for WC that performs in the opposite way.

Key words: Childhood, metabolic syndrome, obesity, anthropometry, insulin resistance, blood lipids, blood pressure.

PS5-65 Metabolic and nutritional aspects of genetic diseases

THERAPEUTIC STRATEGIES IN ORGANIC ACIDURIAS

B. Perez, L R. Desviat, M. Ugarte

Centro de Diagnóstico de Enfermedades Moleculares, Centro de Biología Molecular, CIBERER, Universidad Autónoma de Madrid, Madrid, Spain

Propionic (PA) and methylmalonic acidurias (MMA) are the most frequent forms of branched-chain organic acidurias. PA is caused by genetic defects in either alpha or beta subunits of the nuclear encoded mitochondrial protein propionyl-CoA carboxylase (PCC) and four defects involved in B12 transport, synthesis of active cofactor adenosylcobalamin (AdoCbl) and for the apoenzyme methylmalonyl-CoA mutase (MUT) causing MMA. Currently there is no cure for these diseases and therapeutic options include dietary restriction of substrates and carnitin and pharmacological biotin and cobalamin supplementation is part of the usual treatment. Efforts are now being directed towards exploring alternative therapies based on identifying new targets in the context of personalized medicine. The analysis of the mitochondrial dysfunction performed in the primary dermal fibroblasts have revealed the presence of high doses of ROS species and subsequent release of apoptosis pathway and also mitochondrial bioenergetic impairment and fission of the mitochondrial reticulum. Multiple combinations of conventional and novel pharmacological and nutritional interventions to improve the oxygen consumption which increase energy metabolism and to ROS scavenger in specific tissues organs will be necessary. In fact, the vitamin B12 and others antioxidants ameliorate the ROS content in patients-derived fibroblast. Additionally, we have obtained promising results on antisense therapy to rescue and modulate the splicing process caused by deep intronic mutations and we have also generated a proof-of-concept to use read-through drugs to translate transcripts bearing nonsense changes. Finally, we have detected some pharmacological chaperones, small compounds which are able to increase the activity of the some destabilizing mutant forms of adenosylcobalamin transferase protein affected in MMA cblB. In summary, the knowledge gained from the comprehensive study of the genetic and functional basis of these diseases has enabled us to generate proof-of-principles to use genetic and pharmacological drugs as possible therapeutic interventions for PA and MMA.

Key words: Adenosylcobalamin, propionic aciduria, methylmalonic aciduria, vitamin B12.

NUTRITIONAL ASPECTS OF PHENYLKETONURIA AND METHYLMALONIC ACIDEMIA

V. Cornejo, E. Raimann, J.F. Cabello, G. Castro, V. Hamilton, C. Arias, A. Valiente, K. Betta, M. Colombo

Laboratory of Genetic and Metabolic Diseases,
Institute of Nutrition and Food Technology (INTA),
University of Chile, Santiago, Chile

Phenylketonuria (PKU) and Methylmalonic Acidemia (MMA) are inborn errors of metabolism with an autosomal recessive inheritance. In a 95% of PKU cases is due to the absence or deficiency of the enzyme phenylalanine hydroxylase. If not diagnosed and treated during the neonatal period, there is a progressive deterioration of the central nervous system (CNS) causing severe mental retardation (MR). The hydroxylase gene is in chromosome 12q22-q24.1. There are more than 600 mutations described. Treatment consists on a phenylalanine (Phe) restricted diet, based on special formulas free of Phe. MR is prevented if the Phe levels are maintained below 8.0 mg/dl, through life time. Because this is a very strict diet during school age and adolescence, the adherence to treatment diminishes considerably. For this reason new alternatives of treatment have been developed, such as the use of neutral amino acids (LNAA), glycomacropeptides (GMP) and tetrahydropterin (BH4). This last one has been very effective in variant mutations. MMA is due to the deficit of the enzyme methylmalonyl CoA or a defect in its cofactors: cblA, cblB, cblC all dependent of vitamin B12. Clinical presentation consists of hyperammonemia, metabolic acidosis, progressive CNS dysfunction leading to coma and death. Treatment in the acute phase requires a rapid removal of methylmalonic acid and ammonia by extracorporeal methods. During the chronic phase a special diet is indicated, restricted in the amino acids methionine, threonine, valine and isoleucine (MTVI). Tolerance for intact protein is low. Patients must be supplemented with special formula free of MTVI, L-carnitine (100 mg/kg/day) and B12 (10 mg/day oral or 1 mg/day intramuscular). It is important to point at the fact that an early and well controlled treatment permits normal growth and development.

Key words: Inborn errors of metabolism, methylmalonic acidemia, phenylketonuria.

OMEGA-3 FATTY ACIDS AND INBORN ERRORS OF METABOLISM

M. Gil-Campos¹, P. Sanjurjo-Crespo²

¹Department of Pediatrics, University Reina Sofia Hospital, Maimonides Institute For Biomedical Research (IMIBIC), Córdoba, Spain

²Division of Metabolism, Hospital de Cruces and Basque University, School of Medicine, Bilbao, Spain

N-3 polyunsaturated fatty acids have multiple functions under investigation in metabolic inborn errors. In premature infants and neonates, functions in visual and neurological development have been shown; however, their effects are still being studied on certain chronic neurological diseases, inflammatory and metabolic disorders. Docosahexaenoic acid (DHA) is a n-3 polyunsaturated fatty acid with multiple functions conferred under study. The DHA requirements are not fixed but recommendations must be based on inputs that mimic the composition of breastfeeding, and in older children and pregnant or in lactation, ensure to intake a similar quantity as the intake of oily fish at least twice a week. It is essential to recognize the need for supplementation of DHA in some diseases that restricted diets or may induce altered metabolism resulting in deficit, and to found scientific evidence on its effects. The aim of this review is to examine the effects of long chain polyunsaturated fatty acids supplementation in preventing cognitive impairment or retarding its progress, and nutritional deficits, in children with inborn errors of metabolism. All double-blind, placebo-controlled, randomized trials, and other studies in which supplements of omega-3 were administered in children with inborn errors, or studies that evaluate omega-3 fatty acids status in plasma in these pathologies, were analyzed. Few randomized controlled trials fulfilled the inclusion criteria for this specialized review but there is evidence that, in several inborn errors in children, there is a deficit in omega-3 fatty acids, and supplementation may improve function, or prevent the progression of impairment. Nonetheless, further investigations are needed on this issue.

Key words: Amino acid metabolism, children, docosahexaenoic acid, omega-3 fatty acids, peroxisomal disorders, urea cycle disorders.

STRATEGIES FOR SEARCHING GENETIC CAUSES OF NUTRITION-RELATED EXTREME METABOLIC PHENOTYPES

J.L. Santos¹, V. Cortés¹, S. Zanlungo², J.F. Miquel²

The arrival of novel genetic technologies offers an unprecedented capacity for the analysis of the human genome and for the understanding both rare and common human diseases. In the last years, the combination of exome/genome sequencing, analysis of the genome-wide landscape of insertions-deletions, linkage analysis, and the application of -omics disciplines (notably metabolomics) have been used as a powerful weapon to disentangle genetic causes of metabolic diseases. As an example of the application of these technologies, a syndrome characterized by epilepsy and neurological impairment was linked to mutations in the enzyme Branched-Chain Ketoacid Deshydrogenase Kinase (Novarino et al. *Science* 2012; 338: 394-397), opening the possibility of a personalized treatment based on the dietary supplementation of branched-chain amino acids. A number of genetic strategies have been used in the discovery of new genetic mutations causing metabolic diseases in Chile. We show the identification of mutations in Chilean families with multiple affected cases of early-onset cholesterol gallstone disease through whole-exome sequencing. Through a genome-wide analysis of genetic markers, we identified a nonsense mutation in the APOA5 gene in a Chilean consanguineous family with multiple affected cases of severe hypertriglyceridemia. Using a targeted-sequencing approach, we have also found mutations involved in the Lecithin: Cholesterol Acyltransferase deficiency characterized by very-low plasma HDL-cholesterol levels, congenital generalized lipodystrophy causing diabetes and extreme leanness, bile acid inborn errors such as cerebrotendinous xantomathosis, Niemann-Pick Type B disease and monogenic forms of diabetes and obesity. The combination of cutting-edge genomic, metabolomic and molecular technologies constitutes a powerful weapon to find causes of genetic disorders, with potential application in common multifactorial nutrition-related diseases. The identification of genetic causes of rare metabolic conditions leads to accurate molecular diagnoses and, in some cases, to personalized nutritional or pharmacological treatments.

Key words: Metabolic diseases, genetics, diabetes, obesity, lipid disorders.

T2 NUTRITION THROUGH LIFE COURSE

**NPS1-2 Efficacy of lipid-based nutrient supplements for prevention of maternal and infant undernutrition in Africa: Results of the iLiNS Project
INTRODUCTION TO THE INTERNATIONAL LIPID-BASED NUTRIENT SUPPLEMENTS (ILINS) PROJECT**

K. Dewey¹, P. Ashorn²

¹Department of Nutrition, University of California, Davis, USA

²Department of International Health, School of Medicine, University of Tampere, Tampere, Finland

Tackling undernutrition, including micronutrient deficiencies, is a high priority and potentially high-return development investment. Infants, young children and pregnant and lactating women in lower income countries are most vulnerable due to their high nutrient requirements and limited access to nutrient-rich foods. For these groups, innovative and low-cost approaches are needed to fill gaps in essential nutrients. The goal of the iLiNS Project is to provide information on the use of lipid-based nutrient supplements (LNS) to reduce undernutrition. LNS are a family of products designed to deliver nutrients to vulnerable groups. In addition to providing multiple micronutrients, LNS also provide energy, protein, and essential fatty acids. Drawing on the positive experience with LNS for the treatment of acute malnutrition, the iLiNS Project focuses on developing LNS products for prevention of undernutrition, particularly child stunting, and evaluating their impact. The iLiNS Project includes four randomized controlled efficacy trials in Malawi, Ghana, and Burkina Faso, designed to answer key questions about the efficacy of “small-quantity” LNS (generally 20 g/d, ~118 kcal/d). The trial LNS products were developed to be mixed with and enrich locally available foods, and not to replace them. Two of the trials (iLiNS-DOSE and iLiNS-ZINC) targeted children beginning at 6 or 9 months of age, respectively, following them to 18 months of age. Two other trials (iLiNS-DYAD) are evaluating the impact of LNS developed especially for and given to women during pregnancy and the first 6 mo of lactation, as well as child-LNS provided to their children from 6 to 18 months. The iLiNS Project also extends beyond efficacy trials to explore a range of socioecon-

omic issues, including cost-effectiveness, willingness to pay for the LNS products, and possible product delivery systems.

EFFICACY OF REDUCED-COST LNS FORMULATIONS FOR INFANTS AND YOUNG CHILDREN IN MALAWI: THE ILINS-DOSE TRIAL

K. Maleta¹, J. Phuka¹, K. Dewey², U. Ashorn³, S. Vosti⁴, P. Ashorn³

¹Department of Community Health, College of Medicine, University of Malawi, Blantyre, Malawi

²Department of Nutrition, University of California, Davis, Davis, USA

³Dept. of International Health, School of Medicine, University of Tampere, Tampere, Finland

⁴Department of Agricultural and Resource Economics, University of California, Davis, Davis, USA

Background and objectives: Complementation of infant diet with lipid-based nutrient supplements (LNS) has been suggested to improve growth and reduce morbidity. The daily quantity and the milk content of LNS affect its cost. The iLiNS Project developed different formulations of lipid-based nutrient supplements (10, 20 or 40g/d, with and without milk powder) for infants and children, to enrich complementary food with essential fatty acids, high quality protein and micronutrients. To evaluate the efficacy and safety of various formulations of LNS in infants and children.

Methods: Randomized single blind controlled trial enrolling six month old infants. Infants were randomized to one of six groups to receive daily 10, 20, or 40 g of LNS containing milk powder, 20 or 40 g of milk-free LNS, or no supplement until 18 mo of age. The daily ration contained approximately 1 RDA of micronutrients and 56 to 243 kcal of energy. The food supplements were delivered at home at 2 week intervals. Participants underwent a morbidity evaluation weekly, a limited development assessment 4-weekly, anthropometric evaluation at 26-week intervals and laboratory analyses at enrollment and at

18 mo. Growth and complete developmental assessments were done at 18 months.

Results: In total 1932 infants were enrolled of whom 1556 completed follow up at 18 months. During the follow-up period 81 children died while 295 dropped out for various reasons. The effects of the intervention on length, changes in anthropometric indices, anaemia and incidence of adverse events will be presented.

Conclusion: The effect of various doses of LNS in comparison to no supplementation will be discussed.

Acknowledgement: Bill & Melinda Gates Foundation

Key words: Lipid-based nutrient supplements, child growth, efficacy.

SMALL-QUANTITY LIPID-BASED NUTRIENT SUPPLEMENTS TOGETHER WITH MALARIA AND DIARRHEA TREATMENT IMPROVE GROWTH AND NEUROBEHAVIORAL DEVELOPMENT IN YOUNG BURKINABE CHILDREN

S. Hess¹, S. Abbeddou¹, E. Yakes², J. Somé^{1,3}, E. Prado¹, Z. Ouédraogo³, R. Guissou³, S. Vosti⁴, J.B. Ouédraogo³, K. Brown¹

¹Program in International and Community Nutrition, Department of Nutrition, University of California, Davis, USA

²Nutrition Program, Department of Individual, Family and Community Education, University of New Mexico, Albuquerque, USA

³Institut de Recherche en Sciences de la Santé, Bobo-Dioulasso, Burkina Faso

⁴Department of Agricultural and Resource Economics, University of California, Davis, USA

Background and objectives: Supplementing young children's diets with small-quantity lipid-based nutrient supplements (SQ-LNS) is a promising strategy to prevent growth restriction and improve development, but the optimal amount of zinc to include in these products is uncertain. We assessed zinc-related functional responses among young Burkinabe children who received micronutrient products (SQ-LNS containing 0, 5 or 10 mg of zinc and 5 mg zinc or placebo tablets) provided with or between meals.

Methods: In a partially masked, placebo-controlled, randomized trial, 34 communities were assigned to immediate (II) or delayed intervention (DI). 2469 eligible II children were randomly assigned to receive 20g LNS/d with varying contents of zinc along with zinc or placebo tablets, and treatment of malaria and diarrhea from 9-18 months of age. Children in DI (n=797) received neither SQ-LNS nor morbidity treatment.

Length, weight and mid-upper arm circumference (MUAC) were measured at 9 and 18 months in all children. Motor, language, and personal-social development was assessed at 18 months in a randomly selected subgroup (n=747 II; n=376 DI).

Results: Reported compliance was 95% for SQ-LNS and tablets. Length, weight, MUAC, and developmental scores were significantly greater at 18 months in children who received SQ-LNS and morbidity treatment (p<0.001) compared to children in DI. Stunting prevalence at 18 months was 39% in children in DI and significantly reduced to 24 – 33% in children in the II groups (p<0.0001). There was no difference in growth, stunting prevalence or development among the four II groups, which are still blinded.

Conclusions: Providing 20g of LNS daily with or without zinc along with malaria and diarrhea treatment significantly improved growth and motor, language, and personal-social development and reduced stunting prevalence in young Burkinabe children.

Acknowledgement: Funded by the Bill & Melinda Gates Foundation.

Key words: lipid-based nutrient supplement, LNS, growth, stunting, neurobehavioral development.

EFFICACY OF LNS PRODUCTS FOR PREGNANT AND LACTATING WOMEN: PREGNANCY OUTCOMES FROM THE ILINS-DYAD STUDIES IN GHANA AND MALAWI

S. Adu-Afarwuah¹, A. Lartey¹, H. Okronipa¹, K. Maleta², P. Ashorn³, U. Ashorn³, J. Phuka², S. Vosti⁴, K. Dewey⁴

¹University of Ghana, Legon, Ghana

²University of Malawi, Republic of Malawi

³University of Tampere, Tampere, Finland

⁴University of California, Davis, USA

Background and objectives: Nutrient deficiencies are common among pregnant women in low-income countries. The iLiNS Project developed small-quantity lipid-based nutrient supplements (LNS, 20 g/d, ~118 kcal) for pregnant and lactating women, to enrich local diets with essential fatty acids, high-quality protein and micronutrients. To examine the effects of LNS, multiple micronutrient (MMN) tablets, and iron-folic acid (IFA) tablets on pregnancy outcomes in Ghana and Malawi.

Methods: Randomized, partially double-blind, controlled trial enrolling pregnant women < 20 wk gestation) attending ante-natal clinics. In all, 1320 women in Ghana and 1391 in Malawi were randomized to one of three treatments daily: (a) IFA (60 mg Fe, 400 mcg folic acid); (b) MMN containing 1-2 RDA of 18 micronutrients including 20 mg Fe, and (c) LNS with similar micronutrient content as MMN, plus Ca, P, K,

Mg. Baseline data were collected at enrollment. Women were visited biweekly until delivery. Blood and urine samples were collected at enrollment and at 36 wk gestation. Birth weight was measured within 48 h after delivery; other measurements (length, head circumference) were generally performed within 48 h in Ghana and within 14 days in Malawi.

Results: Mean gestational age at enrollment was 16 wk in both sites. In total, 1294 women in Ghana and 1302 women in Malawi were followed through delivery (or termination of pregnancy). Attrition was mainly due to permanent relocation from the study site. Pregnancy outcome data are currently being analyzed. The effects of the intervention on birth weight and length, duration of pregnancy and maternal anemia will be presented.

Conclusion: The effect of LNS in comparison to MMN and IFA on pregnancy outcomes will be discussed.

Acknowledgement: Bill & Melinda Gates Foundation and the U.S. Agency for International Development's FANTA project, managed by FHI 360.

Key words: Lipid-based nutrient supplements, multiple micronutrients, pregnancy outcomes.

WILLINGNESS-TO-PAY FOR LNS PRODUCTS AND COST-EFFECTIVENESS ESTIMATES FOR THE ILINS PROJECT SITES

S. Vosti, K. Adams, J. Humber, T. Phiri, E. Ayifah, R. Guissou, P. Ashorn, A. Lartey, K. Maneta, J B. Ouedraogo, K. Dewey

Department of Agricultural and Resource Economics, UC Davis, Davis, California, USA

Background and Objectives: Households' perceived benefits, i.e., their stated willingness-to-pay (WTP), from consuming small-quantity lipid-based nutrient supplements (LNS) influence the economic viability of retail outlets for them, and, alongside comprehensive estimates of the products' cost-effectiveness (CE), can help guide public policy action when WTP falls short of LNS costs. This presentation will provide preliminary evidence on WTP and CE estimates for LNS products tested in the context of the International Lipid-Based Nutrient Supplements (iLiNS) Project in Malawi, Ghana and Burkina Faso.

Methods: Field-based contingent valuation methods provide estimates of WTP for LNS for pregnant/lactating women (LNS-P&L) and for children 6-24 mo of age (LNS-child). Experimental auctions provide incentive-compatible estimates of WTP for LNS-P&L (Ghana). Estimates of LNS production, transportation, distribution and household consumption costs are taken from iLiNS Project sites. CE estimates will be reported for birth outcomes (Malawi and Ghana), and for linear growth (Burkina Faso and Malawi-DOSE).

Results: Hypothetical WTP at baseline for LNS-child (one 20g sachet) was approximately US\$0.39 (Ghana), US\$0.23 (Burkina Faso) and US\$0.20 (Malawi-DOSE). Hypothetical WTP at baseline for LNS-P&L (one 20g sachet) was approximately US\$0.56 (Ghana) and US\$0.17 (Malawi-DYAD). Experimental WTP for LNS-P&L was approximately US\$0.25 per 20g sachet (Ghana). Several household characteristics that could be used for programmatic targeting, e.g., number of children under five years of age, were associated with WTP. CE results are still in progress.

Conclusions: Hypothetical WTP is greater than zero for most respondents in all study areas and average WTP is above expected average national production costs for all LNS products; hence, LNS products may be commercially viable. However, significant proportions of respondents reported WTP below expected average production costs, especially in Malawi, signaling the need for alternative mechanisms for reaching resource-poor households.

Acknowledgement: Funded by the Bill & Melinda Gates Foundation.

Key words: Willingness-to-Pay; LNS Products; Cost-Effectiveness.

THE BREASTFEEDING, ANTIRETROVIRALS, AND NUTRITION (BAN) STUDY IN MALAWI: USE OF QUALITATIVE METHODS TO GUIDE STUDY DESIGN AND EVALUATION OF A RANDOMIZED CONTROLLED TRIAL

M. Bentley¹, A. Corneli², M. Parker³, C. Chasela^{3,4}, D. Kayira³, A. Moses³, M. Tembo³, C. van der Horst⁵, D. Jamieson⁶, L. Adair¹

¹Department of Nutrition, Carolina Population Center, University of North Carolina, Chapel Hill, USA

²FHI3601, Durham, USA

³PATH, Seattle, USA

⁴Division of Epidemiology and Biostatistics, School of Public Health, University of Witwatersrand, Parktown, South Africa

⁵Division of Infectious Diseases, School of Medicine, University of North Carolina, Chapel Hill, USA

⁶U.S. Centers for Disease Control and Prevention, Atlanta, USA

Background and objectives: Qualitative research can be used to ensure that study interventions are culturally appropriate and that they have been implemented as expected. To use qualitative methods to inform the design and evaluate the implementation of the Breastfeeding, Antiretrovirals, and Nutrition (BAN) study.

Methods: In-depth interviews with HIV-infected mothers, health providers and community leaders (n=73); focus group discussions with pregnant women, fathers, and grandmothers (n=12); home observation visits, including 24h dietary recalls (n=35); and taste tests of maternal nutritional supplements (n=52) guided study design. In-depth interviews with women who had completed the BAN study (n=45) assessed the acceptance and feasibility of exclusive breastfeeding for 6 months and of using lipid-based nutrient supplements (LNS) as a breastmilk replacement in 24-48 week infants.

Results: Based on formative research, the original BAN study design was modified in several ways: a pictorial guide was developed for the consent process, the amount of blood drawn from infants was kept to a minimum, the period of weaning was lengthened from a few days to 4 weeks, a nutritional supplement for weaned infants was added, and a nutritional supplement for lactating mothers was selected. Interviews after the study indicated that exclusive breastfeeding and early weaning were feasible and women felt supported by study nurses. LNS was accepted as a breastmilk replacement and incorporated into usual infant diets.

Conclusions: Qualitative research conducted before and after the BAN study proved beneficial in assuring the cultural acceptance of study procedures and allowed researchers to assess the success of study implementation.

Key words: Antiretrovirals, breastfeeding, infants, nutrition, weaning.

PS1-2 Nutrition and lifestyle in adolescents: The HELENA study

VITAMIN STATUS IN ADOLESCENTS: IS THERE A NEED FOR INTERVENTION?

M. González-Gross, J. Valtueña

Universidad Politécnica de Madrid, Madrid, Spain

Research in recent years has shown that vitamin biological activities are much broader than expected, specifically during childhood and adolescence, in the setting of risk factors. In the frame of the HELENA study, selected B-vitamins and antioxidant vitamins have been analysed. Mean concentrations were: Retinol: 356.4 ± 107.9 ng/mL; α -tocopherol: 9.9 ± 2.1 μ g/mL; vitamin C: 10.3 ± 3.3 mg/L; and β -carotene: 245.6 ± 169.6 ng/mL. 25% had β -carotene deficiency and less than 5% for α -tocopherol deficiency. Females showed higher α -tocopherol and vitamin C values compared with males and 17-year-old boys had higher retinol levels than the same-aged girls ($p = 0.018$). Retinol serum concentrations increased significantly according to age in both gender, but girls had also significantly increasing β -carotene levels by age. Almost 80% of the sample had suboptimal 25-hydroxyvitamin D [25(OH)D] levels (39% had

insufficient, 27% deficient and 15% severely deficient levels). Vitamin D concentrations increased with age ($p < 0.01$) and tended to decrease according to BMI. Following the current cut-off for adults, 2% of the adolescents had low cobalamin and 5% had low holo-transcobalamin concentrations. Approximately 35% of the subjects had plasma folate insufficiency with levels < 13.6 nmol/L and 15% PF deficiency with levels < 10.2 nmol/L. 27% of the adolescents could have insufficient RBC folate levels (< 566 nmol/L). Five percent had PLP concentrations < 20 nmol/L and 20% < 30 nmol/L. Moreover, 5% had high tHcy. THcy increased ($P < .001$) and PF ($P < .001$) concentrations decreased across age categories. 71% of the females had RBC folate concentrations below the cut-off of 906 nmol/L (400 ng/mL) that is the protective level set against folate-dependent neural tube defects. Our results indicate that vitamin D deficiency is highly prevalent condition in European adolescents and should be a matter of concern for public health authorities. Followed by β -carotene, folate and vitamin B6 concentrations.

Key words: Cobalamin, folate, homocysteine, neural defects, vitamin D.

PS2-10 Energy balance and active living

PERSPECTIVE ON THE INFLUENCE OF PHYSICAL ACTIVITY ON HUMAN APPETITE AND ENERGY BALANCE

J. Blundel

University of Leeds, Leeds, UK

The effect of physical activity (PA) on energy balance (EB) goes beyond the measurement of energy expended (EE) in exercise or daily activities (sometimes referred to as NEAT). This is because PA influences not only EE but also has an impact of energy intake (EI). Does sedentariness downregulate EI to prevent a positive energy balance? and does PA upregulate EI to prevent a negative energy balance? Logic suggests that a sedentary lifestyle promotes weight gain. Although not all large scale surveys or cross cultural studies have supported this concept, it seems likely that when people change from an active to a sedentary lifestyle, eating habits are not adjusted therefore favouring a positive EB and tendency for weight gain. The effect of raising PA EE through exercise is also intensively under investigation. One classic view is that when PA EE is increased then compensation occurs (decrease in non-exercise EE or increase in EI) to prevent any change in EB. In intervention studies in which exercise is both mandatory and supervised a weight loss is normally observed. However, the individual variability is very large with some people losing large amounts of weight and others (approximately 15%) gaining weight. The important fact is that the weight lost is almost entirely fat tissue whereas the weight gained is lean tissue (fat-free mass).

This indicates that body weight itself is a very poor indicator of the response to PA and should not be given importance. More significant is the change in body composition. Moreover, following PA (even in those people who gain weight) there are significant health benefits including reductions in blood pressure and heart rate, plasma insulin, waist circumference (and therefore visceral fat) and increases in cardiovascular fitness.

Key words: Appetite, body composition, physical activity, energy balance, exercise.

COMPLEXITY OF METHODOLOGIES FOR STUDYING ENERGY BALANCE

D. Allison

University of Alabama at Birmingham, Birmingham, USA

The study of energy balance can involve many difficult and specific questions. These questions may relate to whether energy compensation occurs under a particular set of circumstances, whether some circumstances cause differential energy compensation to a perturbation than other circumstances, precise measurement of the amount of compensation that occurs, or the behavioral, biological, or energetic mechanisms through which any compensation occurs. Methodology will need to vary as a function of the question asked. Pertinent factors will include sample size consideration, selection of appropriate control conditions, and especially measurement issues. Theoretical and empirical aspects will be discussed and examples provided.

Key words: Energy balance, energy compensation.

PHYSICAL ACTIVITY: IMPACT ON MORTALITY AND MORBIDITY

S. Blair

Department of Exercise Science, University of South Carolina, Columbia, South Carolina, USA

Sedentary habits are highly prevalent in most countries of the world. In the U.S. approximately 25-35% of adults are inactive, meaning that they have sedentary jobs, no regular physical activity program, and are generally sedentary around the house and yard. Given that sedentary and unfit individuals are at approximately two-fold higher risk for many health conditions than those who are moderately active and fit, the population attributable risk (PAR) of inactivity is high. In the Aerobics Cen-

ter Longitudinal Study (ACLS) the PAR for low fitness in more than 50,000 women and men followed for many years is 16-17% of deaths. This is far higher than other putative risk factors for mortality. For example, obesity accounts for 2-3% of deaths in this cohort. Another example from the ACLS is that in 3,293 obese men (BMI ≥ 30.0), 27% of the deaths might have been avoided if none of the men had prevalent cardiovascular disease at baseline whereas 44% of the deaths might have been avoided if none of the men had been unfit. The independent relative risks for death are comparable for prevalent cardiovascular disease (RR=2.4) and for low fitness (RR=2.3). Over the past few decades we have largely engineered the need for physical activity at home, on the job, and during leisure-time out of the daily lives of most people in industrialized societies. To address the major public health problem of physical inactivity we will need to consider and evaluate societal, environmental, and individual approaches to making physical activity more common for more people more of the time.

Key words: Exercise, inactivity, physical activity, sedentarism, cardiovascular disease

PERSPECTIVE ON THE INFLUENCE OF DIET/FOOD CONSUMPTION ON ENERGY BALANCE

G. Varela-Moreiras

University CEU San Pablo, Madrid, Spain

Energy balance refers to the integrated effects of diet, physical activity, and genetics on growth and body weight over an individual's lifetime. Energy density is a relatively new concept that has been identified as an important factor in body weight control in adults and in children and adolescents. Environmental changes over the past two decades have increased sedentary behaviors, decreased physical activity, and increased consumption of more energy dense foods and larger portion sizes. Although an imbalance in energy consumption and expenditure are required to promote inappropriate weight gain, the relative contributions of each remain not well characterized, mainly due to the lack of appropriate methodology to evaluate energy balance or lacking of updated data for many countries. An important gap in knowledge concerns the role of diet composition in energy balance. Moreover, since diet is increasingly being more complex and not well known. The role of macronutrients in energy balance will be discussed. Moreover, some nutrients have been proposed to have bioactive attributes that may differentially impact energy balance (e.g. dietary resistant starch or some amino acids). Studies addressing the impact of diets varying in levels of protein, carbohydrate, fat, phytochemicals, or ethanol on appetite, food selection and intake, and energy expenditure will be evaluated, but also studies assessing life-stage, racial/ethnic, and gender-related factors underlying response to diet composition, including studies in

children, adolescents, and adults of various ages. Finally, a picture of food consumption (availability) evolution, both globally and for different regions of the world, along with the drivers largely responsible for these observed consumption trends are also attempted, mainly how may be affecting energy balance maintenance.

Key words: Energy balance, energy density, diet, nutrients, physical activity

PS2-18 Healthy life style promotion LIFESTYLE INTERVENTIONS ON WEIGHT LOSS AND CARDIOMETABOLIC RISK FACTORS

B. Goodpaster

University of Pittsburgh, Pittsburgh, USA

Obesity and low physical activity have both been implicated in insulin resistance and type 2 diabetes mellitus as well as impaired muscle function with normal aging. Evaluating the potential of weight loss and exercise interventions to improve cardiometabolic risk is clearly relevant to the prevention or treatment of diabetes and cardiovascular diseases and age-related dysfunction. This presentation provides an overview and critical evaluation of the effects of weight loss and exercise interventions on skeletal muscle metabolism, along with implications for insulin resistance, obesity, type 2 diabetes and aging. The available literature strongly suggests that insulin resistance and impaired energy metabolism associated with obesity, type 2 diabetes and aging is not an irreversible lesion. However, it is unclear whether weight loss is sufficient to improve or normalize this, or whether increased physical activity is requisite or additive in its effect. In summary, studies of diet and exercise training have advanced our understanding of the links among obesity, physical fitness, insulin resistance, obesity, type 2 diabetes and aging. Nevertheless, additional inquiry is necessary to establish the significance and clinical relevance of those perturbations, which could lead to targeted therapies for a myriad of conditions and diseases.

Key words: Obesity, diabetes, aging, weight loss, exercise

COMBINED EFFECT OF EXERCISE AND DIET ON FAT MASS AND LEPTIN RESISTANCE

J A L. Calbet, I. Pérez-Suárez, J. Calle-Herrero, J G. Ponce-Gonzalez

University of Las Palmas de Gran Canaria, Las Palmas, Spain

Obesity should be treated by reducing energy intake and/or increasing energy expenditure to achieve a negative energy balance. One of these interventions alone produces only a moderate loss in mean weight (2-3 kg or less); while dieting in combination with exercise for 3-12 months reduces body weight by an average of 1.1 kg more than simply dieting. A more pronounced reduction in body mass can be achieved much more rapidly (i.e., within 3-10 days) by combining severe caloric restriction, with extensive daily exercise. The latter approach sustained during 30 weeks has led to fat mass losses comparable to bariatric surgery. Leptin is a hormone produced by the adipocytes that regulates appetite, basal metabolic rate and muscle fat oxidation. Plasma leptin concentration is proportional to fat mass. However, with severe energy deficit, plasma leptin concentration is remarkably decreased, far beyond the reduction in fat mass. Moreover, we have observed a progressive increase of leptin plasma concentration after a short period of a severe energy deficit (~6000 Kcal/day) as soon as the energy intake was increased, despite a persistent negative energy balance. This could indicate some degree of leptin resistance or just an elevation of leptin concentration in response to reduced physical activity. In fact, plasma leptin concentration increases after bed rest even without significant increases in fat mass. Skeletal muscle leptin receptors (LPR) show great plasticity. LPR are reduced in skeletal muscles of obese, while are increased by chronic overload in the dominant arm of tennis players. Under severe energy deficit, the expression of LPR is reduced in skeletal muscle, but this effect is blunted by exercise. Thus, the combination of exercise with diet, not only allows a faster and greater loss of fat mass, but also tends to preserve skeletal muscle leptin sensitivity to a greater degree.

Key words: Exercise, fat mass, leptin, obesity

GENE HEALTHY LIFESTYLE INTERACTIONS IN TYPE 2 DIABETES

P W. Franks

Genetic & Molecular Epidemiology Unit, Clinical Research Center, Skåne University Hospital, Lund University, Malmö, Sweden

Obesity and type 2 diabetes are major global health concerns owing to their rapidly increasing prevalences and the se-

vere burden they impose on affected individuals and healthcare systems. These diseases share behavioral and genetic determinants, with obesity frequently preceding the onset of diabetes. Genome-wide association studies (GWASs) have motivated a major transition in the way single nucleotide polymorphisms (SNPs) that predispose to obesity, diabetes and many other complex traits are discovered. For almost all common complex diseases, the number of confirmed genetic risk variants has increased manifold in the past three years. Until 2006, only a handful of SNPs had been equivocally associated with type 2 diabetes or common obesity. Today, the identities of >60 independent diabetes or obesity predisposing loci are known, most of which were discovered using GWASs. These discoveries have rejuvenated interest in the role of genetics in personalized medicine. However, the successful translation of this information into the clinical setting is predicated on two assumptions; i) the level of risk conveyed by a genetic variant is clinically meaningful, and ii) if so, genetic risk can be offset through clinical intervention. Few studies have evaluated these points. Moreover, if gene variants exist that exert their effects in the presence of certain environmental conditions/lifestyle behaviors and not in others, many risk variants may be undetectable when using conventional gene-discovery approaches. Thus, novel approaches accounting for lifestyle-dependent effects may uncover new risk variants, indicate ways in which genetic risk can be ameliorated, and identify the most susceptible subgroups of the population in which early intervention may be appropriate.

In my talk I will define the concept of interaction as used in population genetic research; I will overview the evolutionary background to why gene variants might act in lifestyle-dependent ways (i.e. interact with diet and exercise) to influence disease risk; I will provide examples of interaction effects from experimental and observational studies; and I will outline some of the factors that inhibit the detection, interpretation and clinical translation of interaction effects.

Key words: Genes, gene variants, GWAs, obesity, type 2 diabetes, SNPs

**PS3-26 Scaling up nutrition to improve infant and young child feeding (IYCF) (Alive & Thrive)
MOTIVATING FRONTLINE WORKERS TO DELIVER IMPROVED INFANT AND YOUNG CHILD NUTRITION SERVICES: A CROSS-COUNTRY PERSPECTIVE**

P. Menon, P. Tyagi, D. Ali, K. Saha, P. Nguyen, M. Ruel, R. Rawat

International Food Policy Research Institute, Washington, USA

Background and objectives: Frontline health workers (FHW), paid or volunteer, are the first, and often only, point of contact with health care systems for millions of people.

They deliver lifesaving interventions, including counseling to change health behaviors. Although limited knowledge, skills, incentives, supervision, and time can lead to inadequate infant and young child feeding (IYCF) services, little is known about nutrition-related skills, motivations and capacities of FHWs worldwide. Our objective was to document FHW technical knowledge about IYCF practices, study IYCF-related activities and assess factors associated with FHW motivation.

Methods: We used data from surveys of 5 types of FHWs and 3 supervisor-level staff from 3 countries - Bangladesh, Ethiopia, and Viet Nam. Data were gathered on FHW knowledge about nutrition, training exposure, and perceptions about supervision and job motivation. We developed scales to measure motivation and conducted regression analysis to identify major predictors of motivation.

Results: FHW knowledge was good for breastfeeding, but gaps existed in knowledge about complementary feeding. Training exposure in IYCF across the 3 countries was variable, with greater exposure to training about breastfeeding in Ethiopia than the other two countries. FHWs uniformly noted high levels of intrinsic motivators, like feeling valued by the community, but high work pressure and extrinsic motivators like financial remuneration and training could affect performance. FHWs seem well connected with and well supported by supervisory systems in all three countries. Regression results demonstrate that supportive supervision and training are associated with higher scores on motivation scales for all three countries.

Conclusion: Our results signal important gaps in IYCF knowledge of FHWs in all three contexts, and suggest that establishing solid training programs and supervision systems are important to build capacity and maintain FHW motivation.

ALTERNATIVES TO RANDOMIZED CONTROL DESIGNS: EVALUATION OF A MASS MEDIA CAMPAIGN WHERE TELEVISION IS UNIVERSAL, LESSONS FROM VIET NAM

N. Franklin¹, S. Alayón²

¹Global Health, Population, Nutrition Group, FHI 360, Washington, USA

²Department of Health and Nutrition, Save the Children, Washington, USA

In 2009, when Alive & Thrive began operating in Viet Nam, the exclusive breastfeeding rate nationally was 17%. In addition to providing counseling on infant and young child feeding to pregnant women and new mothers, a nationwide mass media

campaign promoted six months of exclusive breastfeeding. The campaign focused on television, viewership of which is near universal, and targeted women's knowledge of breastfeeding, prevalent misconceptions, and social norms. Without the possibility for a control group, this posed a challenge to designing an evaluation to determine the extent to which such a campaign could influence breastfeeding behaviors.

Rather than a single design, evaluators opted to implement multiple approaches to the evaluation to build evidence for the plausibility that changes were attributable to the campaign. These approaches included: 1. Trend analysis, using annual national nutrition data, comparing the slope of breastfeeding trends before, during and after the campaign; 2. Trend analysis of behaviors, knowledge, misconceptions and beliefs about social norms through repeated household surveys implemented during the airing of the campaign and comparing these trends among women who reported exposure to the campaign and those who did not; 3. A constructed cohort design, which uses post-campaign data to predict the likelihood of exposure among women surveyed before the campaign, to proxy an "unexposed" comparison group at baseline. 4. Using the natural geographical variation in exposure to the campaign to compare breastfeeding behaviors in high and low exposure areas. Lessons learned to date from the implementation of these four approaches will be shared. Results of three rounds of household surveys will be presented focusing on defining various exposure categories and comparing breastfeeding knowledge, misconceptions, beliefs about social norms and ultimately behaviors across these categories.

Acknowledgement: Funded by Gates Foundation to Alive & Thrive, managed by FHI 360.

EVIDENCE LINKING HANDWASHING TO IMPROVED CHILD FEEDING OUTCOME

L. Unicomb¹, F. Nizame¹, D. Biswas¹, P. Ghosh¹, S. Roy², T. Sanghvi², S. Luby^{1,3}

¹International Centre For Diarrhoeal Disease Research, Bangladesh

²Alive and Thrive, Bangladesh

³Infectious Diseases and Geographic Medicine, Center for Innovation and Global Health Stanford University, Stanford, USA

Background and objectives: Handwashing with soap can prevent childhood infections; reduced infections and improved complementary feeding can reduce malnutrition. We describe formative research to link handwashing with soap to complementary feeding and an intervention trial.

Methods: A formative study on perceptions, practices, barriers and motivators, among households across three districts

in Bangladesh, with a child 6-23 months of age given complementary food included video data collection, motivational exercises, indepth interviews, and focus group discussions. An intervention trial of an integrated handwashing and complementary feeding included qualitative studies and baseline-endline surveys among up to 450 households.

Results: Distant location of soap and water from the child feeding place was a common barrier to handwashing with soap before child feeding; commonly water only was used. Limited knowledge of the link between handwashing with soap around food events and childhood disease prevention was detected. Facilities that brought soap and water together, located near the kitchen was a motivator and reminder for handwashing with soap. By the trial end, 65% of participants were observed washing hands with soap at key times, 75% reported that they intended to adopt and continue, 83% followed complementary feeding recommendations, the main motivators being child health and convenience. Trial target handwashing practice was associated with intervention component exposure, handwashing facility near the kitchen and perceived link between disease and handwashing. Acceptable complementary feeding was associated with wealth, older child age and intervention component exposure.

Conclusions: The integrated handwashing and improved complementary feeding intervention was acceptable and feasible. Handwashing facilities location increase convenience and facilitate handwashing. Increasing knowledge on complementary feeding and links between handwashing and disease prevention were incorporated into a national media campaign to motivate behavior change.

Acknowledgement: Funding was provided by the Gates Foundation through Alive & Thrive, managed by FHI 360.

Key words: Complementary feeding, handwashing

PS3-34A Nutrients and exercise performance – What is the evidence behind recent claims of major benefits?

REVISITING THE ERGOGENIC PROPERTIES OF L-CARNITINE

F. Stephens

School of Life Sciences, University of Nottingham Medical School, Nottingham, UK

More than 95% of the body's carnitine is found in skeletal muscle where it translocates fatty acids into the mitochondrial matrix for β -oxidation via carnitine palmitoyltransferase 1 (CPT1), and buffers excess acetyl-CoA from the pyruvate dehydrogenase complex (PDC) during high glycolytic flux as a via carnitine acetyltransferase. Not surprisingly oral L-carnitine feeding has been advocated as an ergogenic aid. However, scientific interest in L-carnitine as an ergogenic aid declined

during the 1990s when it became apparent that oral (2-6 g per day for 1 day to 4 months) or intravenous (up to 5 g) administration of L-carnitine alone does not increase muscle carnitine content or alter fuel utilisation during exercise. We have recently demonstrated that insulin stimulates muscle carnitine uptake, and that 12-24 weeks of L-carnitine feeding in combination with a carbohydrate beverage in order to stimulate insulin release (1.4 g L-carnitine + 80 g carbohydrate twice daily) can increase the muscle carnitine store by 20-30% and have some remarkable effects upon fuel utilisation compared to carbohydrate feeding alone. For example, the increase in muscle carnitine content in these studies resulted in reduction in muscle glycogen utilisation, and an increase in whole-body fat oxidation and energy expenditure during low intensity exercise (cycling at 50% VO₂max), which is consistent with the premise that carnitine availability is limiting to CPT1. On the other hand, during high intensity exercise (cycling at 80% VO₂max) an increase muscle carnitine content results in greater buffering of acetyl groups and a better matching of glycolytic flux to mitochondrial ATP production, as evidenced by increased muscle PDC activation and reduced muscle lactate accumulation. Manipulating both of these metabolic roles of carnitine will have implications for exercise performance.

Key words: Carnitine, skeletal muscle, exercise, fat oxidation, carbohydrate oxidation.

DOES PROTEIN SUPPLEMENTATION AUGMENT MUSCLE MASS AND STRENGTH?

L. van Loon

Maastricht University, Maastricht, The Netherlands

Dietary protein consumption following a bout of endurance or resistance type exercise stimulates muscle protein synthesis, inhibits protein breakdown and, as such, stimulates net muscle protein accretion during post-exercise recovery. Protein ingestion during and/or immediately after exercise is believed to facilitate the skeletal muscle adaptive response to each exercise session, resulting in more effective muscle reconditioning. A few basic guidelines can be defined with regard to the preferred type and amount of dietary protein and the timing by which protein should be ingested. Whey protein appears to be most effective protein source to augment post-exercise muscle protein synthesis rates. The latter is likely attributed to its rapid digestion and absorption kinetics and specific amino acid composition. Ingestion of ~20 g of a high quality dietary protein during and/or immediately after exercise is sufficient to maximize post-exercise muscle protein synthesis rates. Additional ingestion of large amounts of carbohydrate does not further augment post-exercise muscle protein synthesis rates when ample amounts of dietary protein are already ingested. Dietary protein should be ingested during and/or immediately after

cessation of exercise to allow muscle protein synthesis rates to reach maximal levels. Future research should focus on the impact of the timing of protein provision throughout the day on the adaptive response to more prolonged exercise training.

Key words: exercise, nutrition, protein, muscle, strength

DIETARY NITRATE SUPPLEMENTATION AND EXERCISE PERFORMANCE

J. Lundberg

Karolinska Institutet, Stockholm, Sweden

Inorganic nitrate (NO₃⁻) is abundant in our everyday diet and traditionally this anion has been associated with negative health effects most notable gastric cancer (Tannenbaum Nature 1985). Nitrate is also an oxidation product of nitric oxide (NO) generated endogenously, and as such it has been regarded as completely inert (Moncada NEJM 1993). Research ndsly atroviothe(p)-

that RONS scavenging may delay fatigue during submaximal prolonged exercise but fail at high contraction intensities. In humans, N-acetylcysteine (NAC) delays muscle fatigue during submaximal exercise, but not at high intensities. However, the majority of studies in humans with antioxidant vitamins have shown no ergogenic effect during prolonged exercise. Most studies have shown that antioxidant supplementation attenuates exercise-induced oxidative stress. Several animal and human studies (but not all) indicate that regular ingestion of antioxidants may reduce the benefits of training for health and performance. This is likely due to the antioxidant inhibition of critical signaling events, like AMPK, JNK and CaMKII phosphorylation, necessary to induce the gene expression program necessary for the training structural adaptations. In addition, chronic antioxidant supplementation during training may blunt the enhancement of endogenous antioxidant systems, in part due to blunted NF-kappaB activation, increasing the vulnerability against the exhaustive nature of competitions. Ingestion of antioxidants before sprint exercise may decrease the glycolytic rate and attenuate the drop in intracellular pH, ameliorating muscle efficiency. This may reduce RONS-mediated oxidative damage, as reflected by reduced protein carbonylation in muscle and plasma. Although sprint performance depends on fast twitch (Type II) muscle fibers, which are more sensitive to RONS, exercise sprint performance is not improved by antioxidant supplementation. Well-trained athletes have increased antioxidant capacity, i.e., they should be less prone to exercise-induced oxidative stress. It remains to be determined if acute antioxidant supplementation may be more ergogenic in some populations at higher risk of increased exercise-induced oxidative stress.

Key words: Antioxidants, exercise, oxidative stress

PS3-34B Past and current experiences in leveraging multiple program and partner platforms to scale-up nutrition interventions (The SPRING project)

LEARNING FROM PAST SUCCESSES IN SCALING-UP INTEGRATED NUTRITION PROGRAMS TO INFORM FUTURE EFFORTS: DESIGN AND DELIVERY CONSIDERATIONS

C. Winger

The SPRING Project, JSI Research & Training Institute, Inc., Rosslyn, USA

There have only been a handful of success stories in achieving large scale coverage, impact and sustained reductions in undernutrition through integrated nutrition programs. Notable successes in changing key infant feeding practices have been achieved under the LINKAGES Project in Bolivia, Ghana

and Madagascar and under the Essential System for Health in Ethiopia (ESHE) Project. Additional successes in integrated nutrition programming are emerging under current USAID-funded projects, both globally and at the country level, in Nepal, Ethiopia and Bangladesh.

Many more success stories exist on scaling-up single intervention programs, such as vitamin A supplementation and breastfeeding, and with interventions delivered through the social services sector. The Strengthening Partnerships Results and Innovations in Nutrition Globally (SPRING) USAID-funded project will present a retrospective and current review of USAID investments in nutrition, including infant and young child feeding (e.g. Wellstart, LINKAGES, IYCN projects), micronutrients (OMNI, MOST, A2Z projects), nutrition and HIV (PEPFAR) and the Food for Peace program.

SPRING will present how USAID has leveraged multiple platforms for scale-up and outline promising directions for the future. More recently, USAID has prioritized leveraging agriculture programs to improve nutrition through its Feed the Future initiative. SPRING, with the support of USAID, conducted a series of Agriculture-Nutrition Global Learning Evidence Exchange (AgN- GLEE) workshops that identified and shared practical emerging best practices in linking agriculture and nutrition. Key elements of success identified through the AgN- GLEE will be highlighted. With a view toward on-going efforts in nutrition scale-up, including USAID's Feed the Future and Global Health Initiatives and within the Scaling Up Nutrition movement, SPRING will outline key steps to be considered for current and future nutrition scale-up projects, including to document achievements, measures of success that go beyond coverage and impact to include dimensions of quality, capacity building and sustainability.

Key words: Capacity building, nutrition, integration, scale-up, sustainability.

USING LESSONS LEARNED FROM EARLIER NUTRITION EFFORTS IN NEPAL TO DESIGN A MULTI-PLATFORM NATIONAL SCALE INTEGRATED NUTRITION PROJECT

P. Pandey Rana¹, H. Koirala², K. Dearden¹, L. Borja¹

¹Suaahara Project, Helen Keller International, Kathmandu, Nepal

²USAID/Nepal, Kathmandu, Nepal

Nepal is committed to addressing chronic malnutrition through the development of the Multisectoral Nutrition Plan for Accelerating Reduction of Maternal and Child Undernutrition. The USAID-funded Suaahara project is designed to support this initiative by addressing undernutrition in women and children under-two years in 20 targeted districts (250,000 households). In partnership with Government of Nepal, particu-

larly health, agriculture, water and local development sectors, Suaahara focuses on improving health and nutrition behaviors through promotion of Essential Nutrition Actions (ENA), especially Infant and Young Child Feeding (IYCF), as well as addressing availability and access to food, hygiene, quality health care, child spacing and socio-cultural factors. It also aims to strengthen nutrition policies and programs.

Learning from a range of interventions in Nepal, Suaahara's strategy drew from Saving Newborn Lives a SCI initiative; USAID-HKI's Action Against Malnutrition through Agriculture (AAMA) and the DFID-funded Support to Safe Motherhood Program where JHU/CCP strengthened localized approaches to reach marginalized populations.

Suaahara implements behavior change at all levels to create demand for improved ENA+ policies and practices, strengthens nutrition counseling in national programs and works closely with district-level actors and community structures to build linkages across sectors. In districts that are severely food insecure, Suaahara is implementing an enhanced homestead food production model for households with pregnant women and children under two. Families receive support from village model farms, a model adapted from AAMA project that has successfully mainstreamed the ENA framework into agriculture production and created strong links with community health workers. Suaahara also promotes hygiene and sanitation behaviors through inter-personal communication in schools, events, and mass media and is expanding UNICEF's successful Community Led Total Sanitation (CLTS) approach to improve access to and use of latrines.

Key words: ENA, Behavior change, integration

SCALING-UP NUTRITION USING SYNERGY BETWEEN HEALTH AND AGRICULTURE PLATFORMS IN BANGLADESH

E. Williams¹, Y. Arafat², A. Guyon³, T. Williams³

¹The SPRING Project, Helen Keller International, Gulshan, Dhaka, Bangladesh

²SPRING/Bangladesh, Save the Children, Gulshan, Dhaka, Bangladesh

³The SPRING Project, JSI Research & Training Institute, Inc., Rosslyn, VA, United States

The USAID-funded SPRING Project is a five year integrated nutrition program, which aligns with the Government of the People's Republic in Bangladesh's Health, Population and Nutrition Sector Development Program as well as the US Government's Global Health and Feed the Future Initiatives. Using the 1000-day approach, the goal of SPRING/Bangladesh is to improve the nutritional status of pregnant and lactating women and children under the age of 2 in Barisal and Khulna divisions.

In an effort to scale-up nutrition, SPRING has synergized Bangladesh's existing health and agriculture platforms by building on the experience of implementing partners and carrying out several qualitative research activities. First, SPRING undertook a "Pathways to change" exercise to identify the determinants of undernutrition among rural populations in Bangladesh. Second, SPRING reviewed the existing knowledge base including UNICEF's conceptual framework on malnutrition, Helen Keller International (HKI) and John Snow, Inc.'s (JSI) experiences with implementing essential nutrition actions (ENA), and the LINKAGES Project's experience using multiple contacts in Madagascar. Third, current health, agriculture and nutrition interventions in SPRING targeted sub-districts were mapped. Fourth, SPRING adapted existing materials including the JSI/HKI/CORE ENA trilogy, Alive & Thrive's infant and young child feeding and advocacy materials, WASH+ "tippy taps" model to improve hygiene practices, and the farmer field school methodology used by the Regional Fisheries and Livestock Development Component.

This approach has allowed SPRING to identify existing resources and determine strategic partnerships. Within one year of implementation, SPRING formalized 11 partnerships across the agriculture and health sectors with government directorates and non-governmental projects funded by diverse donors including the Bill & Melinda Gates Foundation, DANIDA and USAID. SPRING's investment in a broad strategic review of existing knowledge, practices and partnerships has allowed for improvements in project efficiency, reach, sustainability and comprehensiveness.

Key words: Nutrition, hygiene, agriculture, Bangladesh

BUILDING CAPACITY ACROSS MULTIPLE SYSTEMS TO ENHANCE NUTRITION OUTCOMES: THE ENGINE PROJECT'S APPROACH TO CAPACITY BUILDING IN ETHIOPIA

H. Fekadu

The ENGINE Project, Save The Children, Addis Ababa, Ethiopia

The USAID-funded ENGINE project is a five year integrated nutrition program, which builds upon the Government of Ethiopia's existing initiatives and renewed commitment to nutrition as well as the US Government's Global Health and Feed the Future Initiatives. ENGINE supports the revision and implementation of the new National Nutrition Program and works on a number of inter-related fronts to build capacity at different levels. This includes strengthening multi-sectoral coordination, building capacity at the policy and implementation levels, strengthening pre-service education and training, supporting large-scale behavior change communication for nutrition, linking nutrition, livelihoods and food security interventions, and integrating health and nutrition with private-

public partnerships. For example, ENGINE has increased the capacity of agriculture-focused projects to integrate nutrition into their existing portfolio using an agriculture-to-nutrition pathway as an innovative approach to reveal the untapped potential of such projects to implement nutrition sensitive interventions at multiple levels. To operationalize coordination efforts, ENGINE launched a multi-sector nutrition technical working group as a forum to engage agriculture and nutrition partners in using this pathway as a practical framework to synergize and build on existing efforts to enhance nutritional outcomes in a shared zone of influence. Through this multi-partner and multi-platform approach, it is estimated that over the period from 2011 to 2016 the ENGINE project will reach about 2.7 million households with improved support to high impact nutrition interventions.

Key words: Multi-sector coordination, capacity building, nutrition.

PS4-42A Complimentary feeding and infant health (FAO)

BENEFITS OF LONGER BREASTFEEDING

M.B. Krawinkel

Justus Liebig University Giessen, Giessen, Germany

The evidence is well established that breastfeeding results in a reduction of certain health risks. Debate has arisen, however, about the optimal duration of exclusive breastfeeding. The general recommendation is to breastfeed newborn babies for 6 months exclusively and then to introduce complementary foods and continue breastfeeding. In industrialized countries, earlier introduction of complementary foods is recommended for preventing food allergy. There are data suggesting such a risk reduction and therefore the argument must be taken seriously.

Considering the evidence about earlier introduction of complementary foods, it remains unclear how long the children have been exclusively and partially breastfed. It may well be that children who are breastfed exclusively for 3 months or less benefit from an introduction of complementary foods as long as they still receive partial breastfeeding. If this is true, it remains the first priority to advocate and advise for longer breastfeeding. Only if this fails, the mothers may be advised to introduce complementary foods at a time when they still breastfeed.

Key words: Breastfeeding recommendation, prevention, food allergy.

INTRODUCTION OF SOLIDS AND SEMI-SOLID FOODS: CRITICAL NUTRIENT AND ENERGY DENSITY

A. Lartey

University of Ghana, Accra, Republic of Ghana

In developing countries, the growth of infants is usually adequate during the first 6 months when exclusive breast feeding is practiced. However growth faltering sets in the second half of infancy when complementary feeding is introduced. Traditional complementary foods given to top up breastmilk are often low in energy and nutrient densities. Thus meeting the energy and micronutrient needs even when these foods are consumed in addition to breastmilk is a challenge. Additionally being entirely of plant source, these diets have low nutrient bioavailabilities. It is critical to examine options by which diets based on traditional foods for infants can be augmented. Intervention studies employing the use of fortified foods, home-fortification of local foods and their impact on child growth and micronutrient status are examined. Although these products are efficacious and relatively cheap, their use in national programs in developing countries is limited. These interventions have the potential to fill the gap while efforts are made to promote other food based strategies such as dietary diversification.

Key words: Complementary feeding, micronutrient deficiency, fortification, infants

NUTRITION EDUCATION AND INFANT FEEDING

E. Muehlhoff

Food and Agriculture Organization of the United Nations (FAO), Rome, Italy

Promoting agriculture and food-based solutions to alleviate hunger and malnutrition is a major aim of The Food and Agriculture Organization (FAO). Interventions which focus on optimal nutrition during the first two years of life are recognized as essential in order to capitalize on the window of opportunity for preventing stunting and building healthy and productive future lives. FAO has been promoting improved complementary feeding for children 6-23 months by empowering rural families to enrich young children's diets using local foods. FAO uses practical hands-on learning approaches that aim at behaviour change in complementary feeding. The trials of improved practices (TIPs) method is used to provide a comprehensive assessment of current dietary practices and to test feasible culturally acceptable solutions and behaviours with mothers, fathers and other caregivers in a real home environment. Using community-based multi-sectoral approaches families learn how to: 1) grow different nutritious foods; 2) store, process and prepa-

re foods to preserve nutrient content; 3) vary complementary foods based on taste, seasonal availability and price; 4) introduce nutritious complementary food in a timely manner, feed age appropriate quantities of complementary foods to children and continue breastfeeding; and 5) practice basic hygiene and sanitation. None of these actions are intuitive and frequently require learning of new knowledge and practical hands-on skills. Recognising that good eating habits are learnt during the early years, good complementary feeding can form a basis for lifelong healthy eating patterns and may prevent the onset of diet-related diseases in the future. FAO is currently exploring how these improvements in complementary feeding are most readily adopted on a larger scale and how health and agricultural extension workers and community nutrition promoters can be trained to assist in scaling up the process.

Key words: Complementary feeding, nutrition education, TIPS.

HEALTH RISKS ASSOCIATED WITH INFANT FEEDING PRACTICES

I. Jordan

Justus Liebig University Giessen, Giessen, Germany

Poor nutritional status in early infancy is associated with growth faltering and increased risk for morbidity. Main causes for undernutrition are a diet poor in quality and quantity, poor feeding practices and poor hygiene conditions, as well as insufficient access to health services. Breastmilk is considered to be the best diet for an infant below 6 months even in countries heavily affected by HIV/Aids. The initiation of breastfeeding within few hours after birth is considered the first step to prevent childhood malnutrition. The initiation is also related to successful exclusive breastfeeding for 6 months.

WHO recommends to introduce complementary food to healthy children at the age of 6 months. At the age of 9-12 months the children might be introduced to the family food stepwise – and in addition to breastmilk which should be given for the first two years of life.

In cross sectional baseline surveys on infant feeding in Malawi and Cambodia breastfeeding and complementary feeding behaviour as well as growth and markers of inflammation were assessed in a total of about 2.000 children between 3 and 23 months of age. The risk estimations indicate that exclusive breastfeeding as well as adequate complementary feeding practices are associated with better growth and health. Microbial contamination of infant feeds through inappropriate food processing, lack of safe drinking water and poor food storing are important determinants for food safety. They need to be addressed in any programme aiming at improved infant feeding practices. However, such programmes should emphasize on affordable ways for improving dietary diversity and meal

frequency which can be followed by families, irrespective of their economic means. The research was conducted within the IMCF Project of FAO which is funded by the Federal Ministry of Food, Agriculture and Consumer Protection of Germany.

Key words: Breast feeding, complementary feeding, feeding practices, health risks.

ASSESSMENT OF INFANT AND YOUNG CHILDREN FEEDING PRACTICES IN ZANZIBAR USING THE PROCESS FOR THE PROMOTION OF CHILD FEEDING (ProPAN) TOOL

J. Kinabo¹, P.Mamiro¹, A. Mwanri¹, N. Bundala¹, J. Msuya¹, J. Ntwenya¹, K. Kulwa¹, A. Nombo², R. Mzimhiri², E. Macha³, J. Picado⁴, E. Chang⁵

³UNICEF, Tanzania

⁴Freelance Consultant, Nicaragua

⁵UNICEF, New York

Abstract

Malnutrition in Zanzibar has remained a great challenge despite the success achieved in reduction of other childhood diseases like malaria and helminths infestation.

A study was carried out to understand and identify the current feeding practices among families with children below two years of age using the ProPAN tool in Unguja island in Zanzibar. Consultative research methods based on the ProPAN procedure were used to collect information from caregivers on current infant and young child feeding practices and factors such as environment and culture that promote or act as barriers to ideal feeding practices. Breastfeeding was a common practice (97%). Pre-lacteal feeding was practiced by 21% of mothers. Mothers (53%) reported inadequate support from health workers and family members to initiate breastfeeding. There was early initiation of complementary feeding (2 – 6 months). Energy and protein supply was adequate but key micronutrients such as iron, zinc and vitamin A were inadequate in the diets consumed by children aged 11-23 months despite diverse varieties of locally available foods in Zanzibar. Mothers/caregivers lack knowledge on child feeding and recipe formulation. There is need to strengthen IYCF education in the antenatal clinic regime and or establish community centres where women will be given information about child care and feeding. Fundamentally, the problem is not only on lack of awareness and limited information on child feeding, it is also about the limited skills for food preparation and feeding. Fruits and vegetables are seldom fed to infants and children below two years of age. Thus, dietary inadequacies, inadequate care practices,

irresponsive feeding, use of pre-lacteals, early introduction of complementary foods and low rate of exclusive breastfeeding were common among caregivers. Most of the caregivers are not aware of the existing opportunities to improve IYCF due to limited knowledge on infant nutrient requirements and limited skills on food preparation and feeding using locally available resources.

Key words: ProPAN, infant feeding practices, Zanzibar.

PS4-42B Generating evidence of impact for integrated programs aimed to improve child nutrition during the first 1000 days (IFPRI)

THE USE OF AN INTEGRATED RESEARCH APPROACH TO EVALUATE HELEN KELLER INTERNATIONAL'S ENHANCED-HOMESTEAD FOOD PRODUCTION PROGRAM IN BURKINA FASO

D. Olney¹, A. Dillon²

¹International Food Policy Research Institute, Washington, USA

²Michigan State University, Ontario, Canada

In Burkina Faso, Helen Keller International (HKI) implemented an enhanced-homestead food production (E-HFP) program with the objectives of improving women's agricultural production of nutrient-rich foods as well children's nutritional status. This program was expected to achieve these objectives through a set of production and nutrition interventions through three primary program impact pathways which revolved around increasing production of nutrient-rich foods, increasing income through the sale of surplus foods and improving maternal knowledge of optimal health and nutrition-related practices. The International Food Policy Research Institute (IFPRI) worked with HKI to use an integrated research approach to evaluate the impact of the E-HFP program. This integrated approach included a rigorous impact evaluation, two rounds of process evaluation and gender-specific qualitative research. It is envisioned that the results from the impact evaluation, process evaluations and gender-specific qualitative research will be used to inform HKI's future E-HFP programs in Burkina Faso as well as elsewhere by emphasizing the importance of using a program theory framework in the design of the program and evaluation and using an integrated research approach for the evaluation of the program. Furthermore, it is expected that this type of partnership and integrated research approach can be used as an example of how program implementers and researchers can work together to improve program design, implementation and utilization to optimize the potential for impact, to generate the necessary rigorous evidence

to attribute impact to programs, and to explain how and why impacts were achieved or were not achieved.

Key words: Homestead food production, integrated research approach, impact evaluation, process evaluation.

USING A PROGRAM IMPACT PATHWAY (PIP) ANALYSIS TO TRACE EARLY IMPACT IN THE ALIVE & THRIVE INITIATIVE IN BANGLADESH

R. Rawat, K. Saha, A. Khaled, M. Ruel, P. Menon

International Food Policy Research Institute (IFPRI), Washington DC, USA

Background and objectives: In Bangladesh, the Alive & Thrive (A&T) initiative aims to improve infant and young child feeding (IYCF) practices of mothers through intensive counseling by trained frontline health workers (FHWs) who follow a schedule of routine home visits, and through a nationwide mass-media campaign focusing on six key IYCF messages.

To describe the development and use of theory-driven process evaluation methods, within the context of a cluster randomized impact evaluation design of a BCC intervention in Bangladesh, to trace critical program processes using a program impact pathway (PIP) model to help explain how early impacts are being achieved.

Methods: The following steps were taken as part of the overall evaluation approach:

1) developing PIPs; 2) identifying domains and research questions within each PIP; 3) linking data collection activities with implementation timelines; and 4) linking data collection to PIPs utilizing mixed methods, collection at multiple levels, and using multiple data sources. We map data (qualitative and survey-based) collected between 2010-2013, against five broad domains in the PIP: 1) training and management, 2) service delivery, 3) exposure and coverage, 4) service utilization, and 5) behavioral impact.

Results: IYCF training of FHWs was thorough, and knowledge among these FHWs significantly improved. Household reach by trained FHWs was high, and contacts more frequent, compared to households exposed to the mass-media campaign alone. Differences in exposure to specific IYCF messages can be traced to the source - either FHWs or mass media alone. Maternal IYCF knowledge and practices improved across the program, but improvements were greater in areas where households were exposed to both trained FHWs and mass media.

Conclusions: Use of theory-driven process evaluation methods allows evaluators and programmers to trace key processes that help explain how programs may be achieving impact, and to identify factors that might hamper or enable greater impact.

Key words: Infant feeding, nutrition intervention evaluation.

ADDING VALUE TO EVALUATION: ANSWERING “WHY” AND “HOW” ALONG WITH “DID OR DIDN’T”

J. Garrett

International Food Policy Research Institute, Washington, USA

The experiences in Burkina Faso, Burundi and Bangladesh that are part of this panel, as well as those from other countries, show how to design evaluations that determine not only whether a program “did or didn’t” work but also “why” and “how.” Designing evaluations to answer these questions requires a high level of phrasing, integration, and complexity, along with analytical rigor. Elements of process and “impact” evaluations and of qualitative and quantitative methods are common – and necessary to answer the questions that are of greatest utility to policy makers and development practitioners. Such integrated approaches are thus more appealing to these key audiences, who are the ones actually making decisions about how to design, implement, and operate programs to be more effective. Integrated evaluations tend to focus on how to improve the design and operation of all points along the impact pathway, since a weakness at any point affects the final outcome. The results, therefore, highlight the need for good management and institutional capacity in ways that standard impact analyses do not. Importantly, these analyses then also provide decision-makers, technicians and managers with actionable information they can use now to change and improve programs, a focus that has been somewhat lost with recent impact evaluations. These country experiences examined also provide important lessons for how to increase the impact of results, by, for example, incorporating users from the beginning to identify needs, adopting a range of communication strategies to get information in usable form to specific audiences, and by strengthening leadership and management capacities.

Key words: Management, institutional capacity, program evaluation.

THE EVALUATION OF TUBARAMURE IN BURUNDI: AN INTEGRATED FOOD AID PROGRAM

J. Leroy, D. Olney

International Food Policy Research Institute (IFPRI), Washington, USA

The objective of the Tubaramure program, which uses the Preventing Malnutrition in children under 2 years of Age approach (PM2A), is to improve the health and nutritional status of pregnant and lactating women and children under 2 years of age. The program is implemented in two provinces in eastern Burundi suffering from extremely high levels of malnutrition. It provides mothers during pregnancy and children up to the age of 2 years with a package of health and nutrition interventions designed to address the underlying determinants of malnutrition (inadequate food, health, and care). This package includes individual and family food rations, the required use of preventive health services, and the required participation of beneficiaries in behavior change communication activities focused on improving health- and nutrition-related behaviors. In order to generate scientifically sound and programmatically relevant evidence on the impact of this integrated program, a comprehensive evaluation based on Tubaramure’s program theory is used. First, a cluster randomized controlled design is used to evaluate the program’s effectiveness. Communities were randomly assigned to one of the 3 treatment arms (varying the timing of duration of treatment) and a control arm. Second, in-depth process evaluation focusing on the delivery and utilization of the programs’ 3 components provides information used by the program implementer to improve operations; the findings are also invaluable in the correct interpretation of the impact results. Finally, an Activity Based Costing approach is used to estimate the cost of all program activities, to estimate the programs’ cost-effectiveness and to compare cost-effectiveness across treatment arms. The presentation will show how the comprehensive evaluation approach has provided results and insights we would not have obtained with a classic “Does it work?” evaluation design. We will also present common challenges in conducting these comprehensive evaluations and discuss how they can be overcome.

Key words: Children, malnutrition, nutrition intervention programs.

DATA FOR DELIVERY

S K. Baker

Helen Keller International, New York, USA

In the implementation community there can be resistance to investing in robust program evaluation based on a perception that it is an academic exercise. However, if we are going to

be serious about making progress in tackling undernutrition we need to be serious about measuring that progress. No one would question a business spending resources to make sure it understands its profit and loss – I would argue our bottom line is even more important – it is measured in terms of lives saved and futures secured. Program evaluation is too often conducted as an audit with a good or bad outcome at the end of a project. We need to change the dynamic to design evaluations that identify key levers in the program impact pathway that can be used as proxies for impact when programs are scaled up. Evaluation methods need to capture not just impact by explain the elements of success or failure to enable course correction. This is particularly important in integrated programs where the program impact pathways are very complex and there are potentially multiple benefits. Purposeful teaming up of implementers with researchers creates a win-win environment, however there are challenges in making it successful including aligning research needs and program roll-out, engaging stakeholders in research design to facilitate uptake of results, ensuring timely analysis and reporting of results, management of conflicts of interest and ownership of intellectual property. Both parties must listen to and respect other points of views. The implementer needs to have an institutional commitment to using results to improve programs. The researcher needs to have an institutional commitment to generate data to serve programs. The presentation will draw on lessons-learned in partnership between Helen Keller International and the International Food Policy Research Institute in Burkina Faso.

Key words: Children, nutrition intervention programs, malnutrition, nutrition, research, integrated programs.

the British Avon Longitudinal Study of Parents and Children (ALSPAC), the French EDEN study, the Portuguese Generation XXI Birth Cohort, and the Greek EUROPREVALL study. Two outcomes variables were considered: Food variety of healthy foods and fruit and vegetable (F&V) intake. Both variables were assessed by FFQ in the child up to 4 years in all cohorts and in the mother in ALSPAC and EDEN only. Breastfeeding duration and timing of complementary feeding were assessed by questionnaire. Logistic regression analysis was performed in parallel in each cohort and adjusted for likely confounders. Most children consumed less than five portions of F&V and had a less varied diet than recommended. Variety was measured on a scale of 0 to 5; 2-year-olds scored 2.3 to 2.9 and 4-year-olds 3.2 to 4.1 with Portuguese children the highest. We found longer breastfeeding duration in Portugal and earlier introduction to complementary foods in the UK. Longer breastfeeding duration was quite consistently related to higher F&V intake across the cohorts. Breastfeeding for <3 months or not all was associated with lower variety of healthy foods. Timing of complementary feeding was consistently associated with both outcomes in the UK but not in the other cohorts. Maternal diet, in the UK and France, was strongly associated with F&V eating and dietary variety in the children but breastfeeding associations were independent of it. The consistent relationship we have found across countries between breastfeeding duration and childhood diet suggests that efforts to promote breastfeeding may be beneficial to long term diet. This collaboration has shown that working across cohorts in different countries can increase confidence in research findings.

Children's consumption of vegetables falls below recommendations across Europe. This might be due to attributes of the food (bitter taste, low energy density), characteristics of the child (fussy eating, neophobia), or parenting practices (vegetables offered infrequently). In a series of systematic studies involving infants from weaning age to 36m, partners in Denmark, France, Greece, Netherlands, Portugal and the UK set out to test the effects of early taste exposure, different forms of learning strategies (including repeated exposure, flavour-flavour learning and flavour-nutrient learning), and sensory manipulations on learning to like and to consume vegetables.

Results across studies from both HabEat and VIVA projects demonstrated that early, varied and repeated exposure is the most effective technique for promoting vegetable intake in infants and young children. At weaning, early exposure to the taste of vegetables is most effective where vegetables are rarely offered as a first food. This is confirmed when vegetables are added to milk just before weaning. Across studies between 7 and 15 exposures were used to familiarise with novel vegetables in different forms, but changes in intake were significant at around 5 exposures. Adding seasoning, offering dips, increasing energy (with oil or maltodextrin) or pairing with an existing liked flavour are strategies used to improve intake of vegetables. However, the consistent finding across countries and projects suggests that repeated exposure and familiarization to the novel vegetable is most successful in promoting preference from weaning to early childhood.

The first year of life may be optimal for the introduction of a variety of vegetables into the habitual diet because novel food acceptance is a more difficult task after 2 years when neophobia begins. Since infants tend to eat foods they prefer, offering vegetables as a first food, offering often and providing variety will increase liking and therefore intake.

Recent research indicates that weaning is a critical period for increasing children's acceptance, liking and consumption of new foods as they grow up. The aim of TASTE study was to investigate the effectiveness of an intervention providing guidance to parents in the early repeated exposure of their infants to a variety of vegetables on later intake and liking of fruits and vegetables by children. A community sample of mothers of 4-6 month old infants in UK (n=97), Portugal (n=97) and Greece (n=89) were randomised to either an intervention group, who were given guidance on introducing a variety of vegetables as first weaning foods, or a control group who received no such guidance. Intervention was delivered shortly before initiation of complementary feeding by mothers. Infants' liking and consumption of unfamiliar vegetable followed by an unfamiliar fruit was assessed at 'taste tests', one- and six-months post-intervention (randomly selected subgroup of infants). Additional questionnaires were completed by mothers at one-, six- and nine-month post-intervention follow-ups. TASTE intervention was successful in increasing intake and liking of an unfamiliar vegetable one month post-intervention in the UK [Intake (g): 32.3 vs.16.3, P=0.012; liking rating by mother: 6.7 vs. 4.3, P<0.001; liking rating by researcher: 6.7 vs. 4.6, P<0.001 in intervention vs. control group]. No effect was found for intake or liking six months post-intervention in any of the three countries. Results from Greece showed positive intervention effect on the variety of vegetables consumed by infants at all post-intervention follow-ups.

TASTE study was effective in increasing vegetable consumption in the short term in UK, and variety of vegetables consumed by infants in Greece. Future research should incorporate longer follow-ups in order to investigate long-term effects on liking and consumption.

⁴Københavns Universitet, Copenhagen, Denmark

Young children's vegetable consumption is below the recommended intake across Europe. After the age of two years, neophobia and pickiness begin to impact eating behavior. Efforts to increase vegetable consumption at this age range is therefore particularly challenging. In a series of studies aimed at three- to six-year-olds, different strategies were applied with the aim to increase children's vegetable consumption, including mere exposure in combination with sensory variation in Denmark and the Netherlands, imitation of a role model in the Netherlands and Greece, freedom of choice in Greece, Denmark and the Netherlands, and participation in vegetable preparation in the Netherlands. Most studies were executed in nurseries or in the first years of primary school.

Results showed that offering vegetables at school can contribute to children's daily intake of vegetables, in particular in countries where vegetables are predominantly consumed at dinner time. However, achieving an increase in vegetable intake was difficult. Preliminary results show that mere exposure works at this age, although multiple factors influence the success of mere exposure. Imitation of a role model such as a teacher or a popular (TV) character showed some, although limited, promise. Participation in cooking did not lead to an increased vegetable intake at dinner time. In all studies aimed at this age range, large variation in eating patterns was observed. A considerable group of non-eaters were unresponsive to the tested strategies and alternative strategies might be necessary

for this particular group of children. Acknowledgements: European Community's Seventh Framework Program (FP7/ 2007-2013) n°FP7-245012-HabEat.

CALORIC COMPENSATION AND EATING IN THE ABSENCE OF HUNGER IN EARLY CHILDHOOD: IMPACT OF PARENTAL FEEDING PRACTICES

S. Nicklaus¹, E. Remy¹, V. Boggio², S. Issanchou¹

¹CNRS, UMR6265, INRA, UMR1324, Université de Bourgogne, Centre des Sciences du Goût et de l'Alimentation, Dijon, France

²CHU, Dijon, France

The aims were to measure caloric compensation (CC) and eating in the absence of hunger (EAH) in 2 to 6 year-old French children in a realistic context and to link these measurements with individual characteristics and parental feeding practices. Three identical lunches were offered to 236 children in school canteens. Food intake was measured at individual level. First lunch was a control session. For CC situation, thirty minutes before the second lunch children were offered a preload (137 kcal). For EAH situation, ten minutes after the third lunch children were exposed to palatable foods (430 kcal). Six types of parental feeding practices were measured by questionnaires. Parents were clustered in two groups based on their feeding practices. On average children partially compensated the preload and ate in the absence of hunger about a quarter of the energy that they had consumed during their lunch. These measurements were not correlated with each other. EAH and CC did not vary with age or adiposity. EAH was higher in boys than in girls. Parents who used feeding practices such as food as reward, emotional regulation, pressure, and child control more often had children who ate more in absence of hunger than parents who used restriction for weight and monitoring more often. No link was found between CC and parental feeding practices. This study provides evidence that CC and EAH are two distinct eating behaviours. CC may be mostly driven by homeostatic factors while EAH may be influenced by external factors such as parental feeding practices. Results may be used to develop interventions to educate parents to provide an eating environment likely to prevent development of overweight.

Background and objectives: The proportion of elderly in Europe is expected to increase to approximately 30% in 2050. Specific individual dietary components may reduce risk of disease and improve quality of life of the elderly. When combined these dietary components may modulate many processes that are involved in ageing and so it is likely that a whole diet approach might have greater impact on age-related decline than individual components. The aim of this intervention is to study the effects of a whole diet on health and quality of life in people aged 65 years and older.

Methods: The NU-AGE study is a randomized trial. The intervention comprises a period of one year in 1250 apparently healthy, independently living European subjects aged 65 to 80 years. The elderly are randomised into either the diet group or the control group. Participants in the control group received no dietary advice. Participants in the diet group received dietary advice aimed at meeting the nutritional requirement of the ageing population, foods and a vitamin D supplement. Special attention was paid to nutrients that may be inadequate or limiting in diets of elderly people.

Conclusions: The NU-AGE study is the first dietary intervention study investigating the effect of a whole diet and providing targeted nutritional recommendations for optimal health and quality of life in apparently healthy European elderly men and women. Results of this intervention will provide evidence on the effect of a whole diet on the prevention of age related decline at the cellular, organ, and whole body level.

Acknowledgments: This project is supported by the European Union's Seventh Framework Program under grant agreement no. 266486 ('NU-AGE: New dietary strategies addressing the specific needs of the elderly population for healthy ageing in Europe').

The microbiota associated with the human body is now intensively studied as an environmental risk factor for disease, and a modulator of health. The development of culture-independent methods for microbiota analysis has allowed identification of alterations in the microbiota associated with the extremes of life, with functional gastrointestinal diseases, with endocrine disease, with antibiotic therapy, and with habitual diet, and evidence is accumulating for linkages other conditions and syndromes. In a baseline analysis of the faecal microbiota composition of 161 older persons, we previously reported a core microbiota and aggregate composition that was distinct from younger persons (Claesson et al., PNAS 2011). We also identified significant inter-individual variation at phylum level, the reasons for which were then unclear. To investigate further, we analyzed the microbiota composition of 178 elderly subjects, none receiving antibiotics, and for whom we had collected dietary intake information. The data revealed distinct microbiota composition groups. Clustering of subjects was also distinguishable by analysis of faecal metabolites and shot-gun metagenomic data. Major separations in the microbiota correlated with selected clinical measurements. Novel constellations of microbiota subtypes were identified. Correlations in the data between diet, microbiota and health status suggest a causative axis (Claesson et al., Nature 2012). However, distinction between cause and consequence requires a large-scale intervention and prospective analysis of subjects for microbiota-related pathophysiology. The NuAge project combines multinational participation to take account of ethnic and geographical factors, with a defined nutritional intervention of a well characterized cohort at baseline, to identify diet-microbiota-health causative linkages. Available data from the NuAge project will be presented, in conjunction with NuAge partners.

Ageing is characterized by a progressive, generalized impairment of biological functions resulting in an increased vulnerability to environmental challenge and a higher risk of disease and death. Variations in the biological functions and processes during ageing do not appear in isolation, but instead are embedded in a large network of physiological and genetic interactions. Within these reasons, understanding the physiology of ageing is of tremendous importance to allow populations to grow old, prevent or delay the onset of disease and maintain a high quality of life. Metabonomics is a well-established systems approach to characterize metabolic phenotypes, which result from a coordinated physiological response to various intrinsic and extrinsic parameters like the environment, including diet and lifestyle, genetics, the human microbiome, and drugs. Clinical ageing research: By combining metabonomics and lipidomics we report recent efforts in characterizing the metabolic phenotype of longevity and aging in a well characterized human cohort comprising centenarians, elderly and young individuals. Our results underpin profound differences in the longevity phenotype with activation of specific lipid mediator mechanisms. Preclinical ageing research: As caloric restriction (CR) is has been shown to be to date the most potent dietary means of modulating and possibly slowing the ageing process, we report a comprehensive metabolic phenotyping across several strains of mice to determine the effects of moderate CR. We revealed tissue-specific panels of biomarkers that are commonly affected by CR. Moreover, metabonomics was applied to blood plasma in multiple mouse strains to evaluate early CR-associated metabolic regulations, which may translate into long-term benefits for longevity. Identification of pathways activated by caloric restriction could facilitate the development

of nutritional interventions and dietary programs mimicking the health benefits of CR.

Key words: Ageing, caloric restriction, elderly, lipids, metabonomics.

SOCIO-ECONOMIC DETERMINANTS OF DIET QUALITY AND HEALTH OF THE EU ELDERLY

⁴Department of Food Economics and Marketing, University of Reading, UK

⁵Department of International Development, University of Oxford, UK

To better understand how to effect dietary change for healthy ageing, we investigate the determinants of food choices, diet quality and health of the EU elderly. A literature review indicates that although many factors are thought to be at work, their relative importance and interactions remain poorly understood. Thus, we investigate empirically the determinants of diet quality of older people in four EU countries (Finland, Italy, Sweden and the UK) using secondary cross-sectional datasets. A modified Diet Quality Index measuring nutritional quality is regressed on the same socio-economic and demographic factors in the four countries. We show that diet quality among the EU elderly is both low on average and heterogeneous, with differences in observable socio-demographic variables explaining only a small but significant fraction of the heterogeneity. There is little support for the proposition that poor diet quality is driven by a lack of economic resources among the EU elderly. However, education, not living alone, and being a female are characteristics that are positively associated with diet quality after controlling for other socio-demographic factors. Regional differences in diet quality are evident, while the relationship of age and retirement status to diet quality is weak, hence suggesting that food preferences and habits are largely set in the latter part of life. The framework of analysis is then extended to investigate the full continuum of relationships from the socio-economic status of elderly individuals to their dietary choices and health status. The results establish that the causal relationship between diet quality and health is bi-directional: diet quality influences health but health influences diet quality. Although intuitive, this result implies that feedback mechanisms in the relationship between diet quality and health should be consi-

dered carefully when analysing the benefits from promoting healthy eating to the elderly.

Key words: Ageing, diet quality, elderly, food preferences, health.

PS5-66A Trace elements and chronic diseases MICRONUTRIENTS DEFICIENCY AND OBESITY

J. Rosado

Universidad Autonoma de Queretaro, Santiago de Querétaro, Querétaro de Arteaga, Mexico

Recent studies have demonstrated that the risk of obesity might be increased when individuals have micronutrient deficiencies. Specific micronutrient deficiencies involved include Zinc, Iron, Vitamin E and Vitamin C. Deficiency of these micronutrients is common in populations in Mexico and other Latin American countries. Possible mechanisms for these associations involving Leptin and perhaps other hormones are reviewed, they may explain the role of these micronutrients on fat deposition and fat metabolism. In a prospective study with 136 obese Mexican women micronutrient supplementation of a milk formula product increased the effectiveness of an energy restricted diet to reduce body weight and body fat. In other studies in women in China micronutrients addition to calcium supplements increased body weight loss and decreased blood lipids. These and other investigations suggest that some micronutrient deficiencies increase fat deposition and that in populations with a high incidence of micronutrient deficiencies, micronutrient supplementation is effective to increase fat losses in obese individuals. The precise role of micronutrients deficiency on obesity and fat homeostasis remains to be elucidated.

Key words: Micronutrients deficiency, obesity iron, vitamin E, vitamin C, zinc.

IRON AND INFLAMMATION IN TYPE-2 DIABETES

M. Arredondo¹, M. Andrews¹, N. Soto², I. Acevedo¹, V. Candia¹

¹Micronutrient laboratory, INTA, Universidad de Chile, Santiago, Chile

²Hospital Arriarán, SSMC, Santiago, Chile

Type 2 Diabetes mellitus (T2D) is a disease associated with inflammation and oxidative stress. Iron (Fe) is one of the major catalysts for the occurrence of free radicals and oxidative stress. The pancreatic beta-cells are the primary affected in the advanced DM2, they present minor antioxidant activity and

therefore they are more sensitive to substrates such as oxidants and oxidation catalysts.

T2D patients present increased iron storage (measured as ferritin, transferrin receptor and total body iron) and altered levels of oxidative stress parameters (heme oxygenase activity, SOD, GSH and TBARS). The same behavior is observed by sons of T2D patients. This characteristic may contribute in the future to a greater susceptibility to develop T2D.

We have shown that 2DM patients and their sons share a microsatellite polymorphism in the HO1 gene, characterized by a high frequency of the SM genotype, which is a risk factor for T2D development. T2D and obesity share a pro-inflammatory profile (altered expression of TNF- α , IL6 and TLR2) and an increased expression of hepcidin, a regulator of iron nutrition.

High levels of ferritin, heme oxygenase activity and elevated expression of hepcidin and TLR2 mRNA are a risk factor for 2DM development. Low levels of TLR4 and mTOR mRNA are a protective factor for T2D and obesity.

Key words: Ferritin, hepcidin, inflammation, diabetes mellitus, obesity.

ZINC, INFLAMMATION AND TYPE 2 DIABETES

O.P. Garcia

Universidad Autonoma de Queretaro, Santiago de Querétaro, Querétaro de Arteaga, Mexico

Zinc(Zn) is an essential trace element that has been related in the last years with chronic disease, such as diabetes. Zn is known to favor the interaction between insulin and its receptor, facilitate glucose transport through membranes and increase insulin function in peripheral tissues. Diabetes has been associated with low Zn concentration possible due to an impaired active transport of Zn in the kidney. Zn deficiency increases the expression of IL6, IL1, IL8 and TNF- α , increasing the risk of cardiovascular disease observed in diabetes. IL6, in turn, affects methalothionein homeostasis, thus affecting further Zn metabolism. Also, increased proinflammatory cytokines in diabetes may play an important role in Zn metabolism through the regulation of Zn transporters, particularly, ZnT8 and ZiP14. The effect of zinc supplementation on inflammation in diabetic patients needs to be further explored.

Key words: Cytokines, diabetes, glucose transport, insulin, methalothionein, zinc.

ZINC AS A COADJUVANT IN TYPE-2 DIABETES TREATMENT

M. Ruz

Department of Nutrition, Faculty of Medicine, University of Chile, Santiago, Chile

Type-2 diabetes is a chronic condition responsible for long-term severe dysfunction of several organs, including kidneys, heart, blood vessels, and eyes. This condition is highly prevalent in populations having high overweight/obesity rates. While there is a number of pharmacologic products in the market to treat the most prominent features of this disease (insulin resistance and impaired insulin secretion), interventions directed to preserving the integrity and function of β -cell in the long-term are less available. The use of some nutrients with important cellular protective roles that may lead to a preservation of β -cell has not fully tested. Given its insulin mimetic action, as well as its role as regulator of oxidative stress, inflammation, apoptosis, and insulin secretion, zinc is an interesting candidate to become a co-adjuvant to diabetes therapy. It is reviewed the available information on the use of zinc as part of diabetes therapy. According to two meta analyses recently published, zinc supplementation may have beneficial effects on glycemic control, as indicated by a modest but significant reduction of fasting glucose and a trend to decreased HbA1c. Nevertheless, among the studies considered the vast majority lasted for 6 months or less, suggesting the importance of conducting long duration studies given the characteristics of type-2 diabetes as a chronic disease.

Acknowledgement: Funded by the National Commission for Scientific and Technological Research (CONICYT), Fondecyt Research Project 1120323.

Key words: Type 2 diabetes, zincpancreas, insulin.

TRADITIONAL FOOD SYSTEMS OF INDIGENOUS PEOPLES

H. Kuhnlein

Centre For Indigenous Peoples' Nutrition and Environment (CINE), McGill University, Montréal, Québec, Canada

Indigenous Peoples who have cultural homelands in rural areas have knowledge of vast biodiversities that have developed within their heritage regions to provide food resources for food and nutrition security. Despite formidable environmental and cultural challenges to the use of this wealth of knowledge, Indigenous Peoples are aware that their original diets and local foods can provide cultural expression, self-identity, health and well-being. Research has given recognition to the vast array of unique food species and subspecies/varieties/cultivars within food systems of Indigenous Peoples and the nutritional contributions they make. With focus on 12 cultures in defined ecosystems in different parts of the world, participatory research with communities and interdisciplinary scholars was used to document the local food resources and how they have been culturally used. This knowledge was then applied at the community level to develop methods, processes and activities to mobilize leaders and communities to encourage interventions and policies that improve health and well-being. Central to Indigenous Peoples using their food resources is attention to environmental integrity and sustainability.

Knowledge on traditional wildlife animal and plant harvests and agriculture based in traditional crops must be promoted within communities and transmitted to youth to ensure future provisioning. This benefits from advocacy to create activities that build local cultural pride, and the development of cross-sectoral government planning and action. Keeping Indigenous Peoples' food systems vital not only ensures their continuing contribution to community well-being, but also creates the imperative for cultural and ecosystem protection and sustainability. Lessons learned with Indigenous Peoples' food systems contribute important knowledge on how and why to address

challenges to maintaining ecosystem integrity for environmental sustainability, and for the food and nutrition security of the entire planet.

Key words: Indigenous peoples, food systems, sustainability.

FOOD-NATURAL RESOURCES NEXUS IN THE MEDITERRANEAN REGION: EXPLORING THE ENVIRONMENTAL FOOTPRINTS OF THE CURRENT DIETARY PATTERNS

C. Lacirignola, R. Capone, H. El Bilali, P H. Debs, G. Cardone

Mediterranean Agronomic Institute of Bari, International Centre for Advanced Mediterranean Agronomic Studies (CIHEAM), Italy

Environmental degradation - whose primary driving forces are population, consumption and technology - has reached in the Mediterranean proportions that require immediate action. Unsustainable food consumption patterns are putting increasing stress on ecosystems and human social systems. Food consumption patterns are important drivers of land degradation, declining soil fertility, unsustainable water use, marine environment degradation, climate change, biodiversity loss, etc. The paper aims at exploring the environmental footprints of the current Mediterranean consumption and production patterns with a particular focus on the current dietary patterns. The work is mainly based on secondary data from different sources e.g. FAOSTAT, the World Development Indicators, the Water Footprint Network (WFN), the Global Footprint Network. The analysis regards 21 Northern, Southern and Eastern Mediterranean countries. The paper describes the main environmental challenges in the Mediterranean region e.g. water scarcity, land degradation, climate change and biodiversity loss. It provides an overview of the ecological, carbon and water footprints of the current regional consumption patterns as well as national virtual water balances. The paper characterizes the Mediterranean dietary patterns using Food Balance Sheets data. The WF of food supply is calculated for Bosnia, Egypt, Italy, Morocco and Turkey and the contribution of vegetal- and animal-based food product groups is highlighted. The paper compares the WF of the current Italian diet with that of the proposed Mediterranean one. It also analyses fertilizer consumption and

nitrogen fertilizers use trends. High resource use intensity is exacerbated by food waste implying the loss of large amounts of precious resources and inputs such as water, land, energy and fertilisers. The transition to more sustainable diets and food consumption patterns in the Mediterranean – implying an increased adherence to the traditional Mediterranean diet – and the reduction of food losses and waste can contribute to easing pressure on the scarce resources of the region.

Key words: dietary patterns, environmental footprints, natural resources, Mediterranean region.

PS2-11 Global challenges in maternal and child nutrition for today and the future

NUTRITION-SENSITIVE INTERVENTIONS AND PROGRAMS: HOW CAN THEY HELP ACCELERATE PROGRESS IN IMPROVING MATERNAL AND CHILD NUTRITION?

M. Ruel, H. Alderman

International Food Policy Research Institute (IFPRI), Washington, USA

Accelerating progress in improving nutrition will require effective and large-scale nutrition-sensitive programs that address key underlying causes of undernutrition and enhance the coverage and effectiveness of nutrition-specific interventions. We reviewed programs in four sectors - agriculture, social safety nets (SSNs), early child development (ECD) and classroom education. Targeted agricultural programs support livelihoods, food security and diet diversity, but evidence of their impact on child nutritional status is inconclusive, with the exception of vitamin A from biofortification of orange sweet potatoes; poor-quality evaluations prevent firm conclusions on nutritional impact. SSNs are a powerful poverty reduction tool but pooled estimates show no overall impact on nutrition outcomes; although some cash transfers have improved nutrition among younger and poorer children exposed for longer durations, the lack of overall impact is attributed to weaknesses in nutrition goals and inputs and in service delivery (supply). Combining ECD and nutrition interventions can have additive or synergistic impacts on child development and nutrition outcomes. Thus, programs combining ECD and nutrition inputs could lead to significant gains in cost, program efficiency and nutrition and development outcomes. Parental schooling is a strong determinant of nutrition outcomes, but school curriculum seldom includes nutrition training and when it does, evaluations of impacts on knowledge acquisition and future parental skills are lacking. Many of the programs reviewed were not originally designed to improve nutrition, yet they have great potential to do so. Ways to enhance the nutrition-sensitivity of programs include: improve targeting; use conditionalities if feasible;

strengthen nutrition goals and incorporate well-designed and implemented nutrition-sensitive actions; and focus on optimizing women's nutrition, time allocation, physical and mental health, and social status and empowerment. Nutrition-sensitive programs can play a pivotal role in invigorating nutrition-specific interventions and creating a stimulating environment for young children to grow and develop to their full potential.

Key words: Agriculture, early child development, nutrition-sensitive programs, schooling, social safety nets.

THE POLITICS OF REDUCING MALNUTRITION: BUILDING COMMITMENT AND ACCELERATING IMPACT

S. Gillespie¹, L. Haddad², V. Mannar³, P. Menon¹, N. Nisbett²

¹International Food Policy Research Institute, Washington, USA

²Institute of Development Studies, University of Sussex, Brighton, UK

³Micronutrient Initiative, Canada

Political discourse on the challenge of malnutrition has ramped up markedly in recent years, at both national and international levels. The Scaling Up Nutrition (SUN) movement has both driven, and been driven by, this developing momentum. While knowledge of the critical factors and processes for effectively operationalizing and scaling up nutrition-specific and nutrition-sensitive interventions is increasing, we know less about the politics of reducing malnutrition. How can political and policy processes and “enabling environments” be cultivated, sustained and ultimately translated into nutritional impact on the ground? In our review of the limited but growing evidence base we use a six cell framework to structure our discussion of the ways in which three domains (knowledge and evidence, politics and governance, and capacity and resources) are pivotal for a) creating and sustaining political momentum, and b) translating it into nutritional impact in high-burden countries. We show how political calculations lie behind effective coordination between sectors, between national and subnational levels, private sector engagement, resource mobilization, and state accountability to its citizens – all hugely important for nutrition-relevant action. Political commitment can be proactively built—there is no need to wait for it -- but converting such commitment to impact requires a different set of strategies and skills. It will simply not be possible to accelerate and sustain progress without national and global support to a long-term process of strengthening systemic and organizational capacities, and to nurturing and strengthening leadership in high-burden countries. The private sector has significant positive potential but there remains a lack of trust and a lack of

evidence, both of which need to be addressed. Finally, we argue that operational research on delivery, implementation and upscaling of interventions, and more contextual analyses on how to shape and sustain enabling environments, is essential as the focus shifts toward action.

Key words: Malnutrition, nutrition policies.

PS2-19 Confronting the global epidemic of non-communicable diseases: Findings from the NHLBI/UHG Global Network

THE NIH NHLBI/UHG CENTERS OF EXCELLENCE: A MODEL FOR INTERNATIONAL RESEARCH COLLABORATION

C. Rabadan-Diehl

National Heart, Lung, and Blood Institute/NIH,
Bethesda, USA

Chronic non-communicable diseases (NCDs) account for 63% of deaths around the world. In 2008, 80% of NCD-related deaths occurred in low and middle income countries. Cardiovascular disease (CVD) comprises 30% of global mortality, followed by cancer, COPD and diabetes. Unhealthy diet has been identified as a risk factor to the four disease categories, providing an opportunity to develop common approaches to NCD prevention. Accumulation of risk for NCDs begins during prenatal development and continues through early life, childhood, adolescence, and adulthood. In June 2009, The National Heart, Lung and Blood Institute (NHLBI) and UnitedHealth Group (UHG), established a network of eleven Centers of Excellence (COE) across the globe. The Centers are located in developing countries and have strong partnerships with institutions around the world. The goals of this program are to enable research capacity building, train future chronic cardiovascular and pulmonary disease investigators and conduct research, programs and measures to prevent or treat chronic cardiovascular and pulmonary diseases. The COEs are leveraging their expertise and infrastructures built on the areas of maternal/child health and infectious diseases, to develop and carry out the NCD agenda. The COEs are key players in the area of nutrition and are linked to Birth Cohorts like the Matlab cohort in Bangladesh and the Consortium of Health Oriented Research in Transitional Societies (COHORTS) in Brazil, Guatemala, India, Philippines and South Africa. The COEs are also in close communication with local, state and national governments and policy makers.

The COE program has received international attention and it is considered a unique and innovative model of research collaborations at the global level. The COE program is designed to serve as a platform to develop research-based evidence for strategies that can be implemented not only in developing

countries, but that can also inform research agendas across the world.

Key words: Child health, Infectious diseases, Research collaboration, The National Heart, Lung and Blood Institute.

PRIMARY PREVENTION OF NUTRITION-RELATED CHRONIC DISEASES: INNOVATIVE INTERVENTIONS IN LATIN AMERICA

M. Ramirez-Zea

INCAP Comprehensive Center for the Prevention of Chronic Diseases (CIIPEC), Institute of Nutrition of Central America and Panama, Panama

Nutrition-related chronic diseases (NRCDD), such as cardiovascular diseases, diabetes, and some types of cancer, are the main cause of mortality and morbidity across all Latin American countries, even exceeding the prevalence of many developed countries. Even worse, age at onset of NRCDD risk factors and death is declining, due to early and rapid changes in lifestyle patterns. Population-based innovative strategies for preventing NRCDD risk factors in developing countries are scarce. The INCAP Comprehensive Center for the Prevention of Chronic Diseases (CIIPEC) has recently led few intervention studies on NRCDD prevention in Latin America. We have developed a culturally appropriate, community-based intervention to improve cardiovascular health in elementary school-age Guatemalan children through the promotion of healthful eating behaviors and physical activity, as well as the prevention of tobacco use and alcohol consumption. We have also evaluated the effectiveness of an affordable and sustainable primary health care intervention, based on mobile health (mHealth) technology, to reduce blood pressure and prevent progression from pre-hypertensive status to hypertension in individuals at poor urban clinics in three Latin American countries (Argentina, Guatemala, and Peru). Another two projects have assessed intervention models to determine how well primary health care (PHC) workers can correctly identify and refer subjects at high risk of cardiovascular diseases in Guatemala, and to improve adherence to treatment and healthy lifestyles in diabetic and/or hypertensive patients who assist to PHC facilities in Costa Rica and Southern Mexico. Main preliminary results of those studies will be presented in this session.

Acknowledgements: This work was supported by the National Heart, Lung and Blood Institute (NHLBI, HHS-N268200900028C) and the UnitedHealth Group Chronic Disease Initiative.

Key words: Nutrition, chronic diseases, intervention, Latin America.

CHINA RURAL HEALTH INITIATIVE – SODIUM REDUCTION STUDY: A CLUSTER RANDOMIZED TRIAL ON A COMMUNITY-BASED DIETARY SODIUM REDUCTION PROGRAM

L. L. Yan¹, N. Li¹, W. Niu², H. Chu³, J. Zhang¹, Z. Hao¹, D. Labarthe⁴, X. Feng⁵, J. Shi⁶, J. Zhang⁷, R. Zhang⁸, Y. Zhang⁹, Z. Li⁵, B. Zhou⁶, Z. Li⁵, J. Sun¹⁰

⁸Xian Jiaotong University, Xian, China

⁹Ningxia Medical University, Yinchuan, China

¹⁰Hebei Province Center for Disease Prevention and Control, Shijiazhuang, China

Background and objectives: Cardiovascular diseases are the leading cause of death in rural China with high blood pressure being a major determinant of risk. Excess intake of dietary sodium, a modifiable risk factor for high blood pressure, is widespread with most added as salt during the cooking or preservation of food in the home. The aim of this study is to determine the effects of a multi-faceted community-based sodium reduction program on sodium and blood pressure.

Methods: The China Rural Health Initiative is a large-scale, cluster-randomized, trial done in five Northern Chinese provinces. Two counties have been selected from each province and 12 townships enrolled in each county making a total of 120 clusters. One village from each township was selected for participation in the study. Randomization was stratified by county with 60 villages receiving the intervention and 60 continuing with usual practices. The sodium reduction program comprises community health education and a food supply strategy designed to promote the use of salt substitute through the village convenience stores. Subsidization of the price of salt-substitute is provided to 30 intervention villages. The primary outcomes for the study is dietary sodium intake levels estimated from assays of 24-hour urine samples and blood pressure.

Results: The trial randomized 120 villages in April 2011 and the intervention was implemented from May 2011 to October 2012. All data have been collected and are currently being cleaned and analyzed. We expect to have trial results to share by August 2013.

Conclusions: This sodium reduction study is a major new initiative designed to identify a nutrition-based, practical, scalable strategy for vascular disease prevention in rural China. If proved effective, this sodium reduction program will provide an evidencebase for policy and programs in China and potentially other countries and substantial health gains when scaled up.

Key words: Sodium reduction, cardiovascular disease, health education, salt substitute, community-based program.

BASELINE CHARACTERISTICS OF A SCHOOL BASED INTERVENTION TO PROMOTE HEALTHY DIET IN SOUSSE, TUNISIA

H. Ghannem¹, J. Maatoug¹, I. Harrabi¹, M. Belkacem¹, S. Hmad¹, R. Ghammam¹, S. Slama²

¹Chronic Disease Prevention Research Center of Sousse, Tunisia

²Department of Community medicine, Primary care and emergency, Geneva University Hospitals, Switzerland

Background and objectives: In this study, we will focus on diet habits among schoolchildren. This is a component of a community based intervention to promote healthy lifestyles in school settings. It consists on a school based intervention with the aim to improve knowledge, attitudes and behaviors concerning healthy diet. The study design, implementation and baseline results are presented.

Methods: The study design was a quasi experimental design, intervention with pre post assessment and control group. The study concerned pupils of colleges of Sousse aged 11 to 16 years old in 7th and 9th grade. The pre-assessment concerned a random sample of schoolchildren. The proportional and stratified sample was composed of 4003 schoolchildren with 1929 and 2074 respectively in intervention and control groups. We used chi square test to compare prevalences with 0.05 as level of significance.

Results: Sex ratio was respectively 1 in the intervention group and 0.87 in control group. The mean age of the study population was 13.48±1.29 and 13.24±1.25 respectively in intervention and control groups. The proportion of schoolchildren who knew that it's recommended to eat at least 5 fruits and vegetables daily was 35.6% in intervention group and 23.6% in control group. Concerning eating habits, the schoolchildren reported frequency (number of days per week) of consuming various foods and beverages included respectively in the intervention and control group: vegetables 3.9 days/week and 4.81 days/week, fruits 5.41 days/week and 5.7 days/week, high fat food 2.49 days/week and 2.48 days/week, sweetened beverage 3.84 days/week and 3.3 days/week, sweets 4.33 days/week and 4.57 days/week.

Conclusion: Integrated and sustainable interventions to promote healthy diet in this region are needed to prevent obesity and non communicable diseases early in childhood. Acknowledgment: This project is funded by UnitedHealth Group. The intervention is cofunded by Geneva University Hospitals

Key words: Diet intervention, lifestyles, prevention, schools.

PS3-27 Community-based programme to prevent obesity: Lessons and perspectives from 20 years of experience (EPODE International Network)

EFFECT OF VITAMIN B12 AND N-3 POLYUNSATURATED FATTY ACIDS ON PLASMA HOMOCYSTEINE, AND OTHER CARDIOVASCULAR RISK FACTORS: A RANDOMIZED CONTROLLED TRIAL

T. Huang³, K.L. Li^{1,2}, M. Asimi^{1,2}, Q. Chen^{1,2}, D. Li^{1,2}

¹Zhejiang University, China

²APCNS Centre of Nutrition and Food Safety

³Johns Hopkins Bloomberg School of Public Health, USA

Background and objectives: Vitamin B12 and n-3 polyunsaturated fatty acids (PUFA) decrease blood homocysteine (Hcy) concentration. However, the combined effect of these nutrients on Hcy and ferritin, and C-reactive protein is limited and inconclusive. The objective was to examine the synergistic effect of vitamin B12 in combination of n-3 PUFA on plasma Hcy, ferritin, and other biochemical markers.

Methods: In a randomized controlled trial, thirty eligible subjects were randomly divided into three groups, and assigned to receive 1000 µg of vitamin B12, 2g fish oil, or 1000 µg vitamin B12 and 2g fish oil respectively for 8 weeks. Plasma phospholipid (PL) fatty acids and biochemical markers were determined.

Results: Plasma PL 20:5n-3, 22:6n-3 and n-3 PUFA were increased after 4 and 8 week supplementation of fish oil, and vitamin B12+fish oil. Plasma concentrations of triacylglycerol, uric acid, and ferritin were significantly decreased after 4 and 8 week supplementation of fish oil, and vitamin B12+fish oil. In all groups, significant changes in plasma Hcy were observed during the study period. Vitamin B12, fish oil, and vitamin B12+fish oil supplementation lowered plasma Hcy concentrations by 22%, 19%, and 39%, respectively. **Conclusions:** Combination of vitamin B12 and fish oil have synergistic effect on lowering plasma concentrations of Hcy and ferritin.

Key words: Homocysteine, fish oil, vitamin B12.

COMMUNITY-BASED PROGRAMMES TO PREVENT OBESITY

J. M. Borys⁴, H. Ruault du Plessis⁴, T. Huang¹, B. Swinburn², J. Seidell³, A. Barriguete⁴

¹University of Nebraska Medical Center College of Public Health, Nebraska, USA

²The University of Auckland, Auckland, New Zealand

³VU University of Amsterdam, Amsterdam, The Netherlands

⁴EPODE International Network, Brussels, Belgium

Childhood obesity is one of the main public health challenges of the 21st century. Preventive efforts should include community-based interventions (CBIs) using social marketing campaigns targeting families, children and key stakeholders within the community and the broader environment of the child. Indeed, childhood obesity is a complex issue and needs a complex system with a multi stakeholder involvement at all levels to foster healthier lifestyles in a sustainable way. The EPODE methodology contributes to this approach.

With now 20 years of experience, this methodology is now implemented in more than 300 towns in 8 countries (France, Belgium, Spain, Greece, The Netherlands, South Australia, Mexico and Romania) and concerns more than 20 million people. The added value of the methodology is based on a strong scientific input, institutional and political endorsement, evidence-based and social marketing techniques, sustainable resources, brand dynamics and evaluation.

At child level the prevalence of overweight and obesity in children aged 5 to 12 is monitored. In the 8 French pilot towns, the prevalence of children overweight including obesity decreased by 10% between 2005 and 2009 ($p < 0.0001$). In Belgium pilot towns, the prevalence of children overweight significantly decreased by 22% between 2008 and 2010 ($p < 0.04$) in comparison with control towns.

The EPODE International Network (EIN) is a non-governmental organization which has been created to support Community-Based Programmes (CBPs) aimed at preventing obesity. Today, 29 CBPs are member of this network (10 in Europe, 13 in America and 6 in Asia-Pacific region).

Key words: Prevention, obesity, social marketing, nutrition, diet, lifestyle, community-based programme, sustainability.

PS3-35 Promoting healthy growth and preventing childhood stunting – a WHO initiative

PROMOTING HEALTHY GROWTH AND PREVENTING CHILDHOOD STUNTING

A. Onyango¹, E. Borghi¹, M.C. Casanovas¹, M. de Onis¹

¹World Health Organization, Geneva, Switzerland

Linear growth faltering, increased susceptibility to infection and impaired neurobehavioral function are characteristically associated with an increased risk that children fail to achieve their developmental potential. These are features of stunted growth and stunted development, both outcomes of biological (e.g., nutritional deficiencies and infections) and psychosocial deprivations that restrict physiological growth and intellectual development. The period from conception through the first 2-3 postnatal years is highly sensitive because it is programmed for rapid growth and developmental processes which if disrupted carry potential long-term effects on physical growth and the brain's structural and functional capacity. Stunting serves as a composite measure of the degree of physical and developmental wellbeing and has concurrent, short-term and long-term health and economic consequences. The risk of stunting is affected by interdependent influences rooted in the political economy, health and health care, education, society and culture, agriculture and food systems, water and sanitation, and the environment. Therefore, the interventions required to prevent stunting are anchored in many different sectors. This reality is acknowledged by the multiplicity of actors attempting to address stunting. What poses some challenge is establishing a common agenda within which different sectors recognize their roles and how each can contribute synergistically to stunting prevention.

Through the project Promoting healthy growth and preventing childhood stunting the World Health Organization is seeking to collaborate with governments and other agencies to shift programmatic focus towards considering nutrition as a long-term development investment. The presentation will describe the efforts being undertaken towards setting and implementing stunting reduction agendas, with emphasis on strengthening the weakest components of infant and young child feeding and the assessment of associated linear growth.

Acknowledgement: The project is supported by funds from the Bill and Melinda Gates Foundation

Key words: stunting, child growth, multisectoral interventions.

PROMISING INTERVENTIONS AND RESEARCH AREAS IN COMPLEMENTARY FEEDING AND HEALTHY GROWTH PROMOTION

K.F. Michaelsen

Department of Nutrition, Exercise and Sports, University of Copenhagen, Frederiksberg, Denmark

Stunted growth and development is caused by a broad range of factors as outlined in the WHO conceptual framework on childhood stunting. This presentation will focus on promising interventions and research within complementary feeding and healthy growth promotion. Especially in low-income countries optimal breastfeeding practices have an important impact on growth, development and survival and it is important that breastfeeding is continued during the complementary feeding period. Animal source foods (ASF) are effective in promoting linear growth and development as they have high micronutrient content, high protein quality, no anti-nutrients, high energy density and high n-3 fatty acids content. ASF e.g. milk and meat are often expensive and not available, but affordable, sustainable and locally available sources like small dried fish have shown promising effects and should be promoted. However, there is a need to determine the amount of ASF needed to make an impact. It is recognized that appropriate consistency of complementary foods is important but a better understanding of the interaction between acceptability, taste preferences, texture and regulation of satiety during the transition to family food is likely to also have long term effects on feeding habits. The growth pattern during the complementary feeding period is complex and strongly influenced by diet. Breastfed infants have a different growth pattern, regarded as a more optimal pattern, compared to non-breastfed infants. There are differences in linear growth patterns, gain in fat and lean mass and hormonal regulation of growth. Furthermore, new data suggest that the composition of intestinal microbiota, which is strongly influenced by diet, has an impact on both over- and undernutrition. Although much is known about how to optimize growth through complementary feeding, there is still a need for research to better understand the mechanisms behind the effect of diet on growth.

Key words: Breastfeeding, Animal source foods, body composition, microbiota.

MONITORING CHILD GROWTH AND INFANT AND YOUNG CHILD FEEDING PRACTICES

M. de Onis

World Health Organization, Geneva, Switzerland

In May 2012 the World Health Organization (WHO) adopted a resolution on maternal, infant and young child nutrition including six global targets to reduce the high burden of disease associated with malnutrition, particularly during the critical period from conception to 24 months of age. Four of the targets (i.e., stunting, wasting, overweight and low birth weight) are related to child growth and all six will require improved infant and young child feeding practices for their achievement. The Comprehensive Implementation Plan (2012-2025) on Maternal, Infant and Young Child Nutrition adopted with the resolution, will require the development of an accountability framework and the strengthening of existing surveillance systems to monitor adherence to commitments and the degree to which targets are achieved. Currently many countries have national child growth monitoring programs and/or nutrition surveillance systems but most of them are weak (e.g. do not use standardized, state-of-the-art methodologies) and only a few include indicators of infant and young child feeding practices (IYCF) — despite the existence of a comprehensive set of IYCF indicators. The presentation will describe standardized methods of data collection, analysis and interpretation that provide valid and reliable information to feed into decision making processes to address child malnutrition. Similarly, it will discuss the standardized collection of comprehensive data on IYCF practices based on the experience and lessons learned from the incorporation of the WHO-IYCF indicators into Vietnam's National Nutrition Surveillance System. The data have been used in developing provincial plans for nutrition and advocacy for extension of maternity leave. Capacity building at all levels will also be critical to ensure high quality data and appropriate use and interpretation of information for planning, advocacy and monitoring of trends.

Key words: Child growth, child feeding practices, child nutrition, maternal nutrition.

PS4-43 Nutrition Profiling (WHO)

IS IT POSSIBLE TO DEVELOP A GLOBAL NUTRIENT PROFILE MODEL?

M. Rayner

British Heart Foundation Health Promotion Research Group, Department of Public Health, University of Oxford, UK

Nutrient profiling is 'The science of classifying or ranking foods according to their nutritional composition for reasons related to preventing disease and promoting health'. This presentation will: (i) briefly outline the principles of nutrient profiling; (ii) briefly describe the uses of nutrient profiling; (iii) briefly discuss the development and validation of nutrient profile models; (iv) describe some results of comparing different models used, or which potentially could be used, for regulating the marketing of foods to children; (v) discuss whether a single nutrient profile model for all applications and for all countries is possible; (vi) discuss the process of achieving a more consistent approach to nutrient profiling.

Key words: ?Nutrient profiling, food marketing, food labelling.

PS4-51 Nutrition, physical activity and the prevalence of NCDs in the Middle-East and North-Africa

NUTRITION AS A RISK FACTOR OF CARDIOVASCULAR DISEASES IN COUNTRIES OF THE MIDDLE EAST

N. Hwalla

Faculty of Agricultural and Food Sciences, American University of Beirut, Lebanon

New evidence is pointing out to pre and post natal nutrition as playing a pivotal role in the development of non-communicable diseases (NCDs). Recent epidemiological, observational and experimental studies suggest that suboptimal feeding patterns and practices during the first two years of infancy could be key determinants of adult disease. Under and over nutrition during critical periods (in utero/infancy) has been shown to be associated with metabolic 'programming', possibly increasing the risk of adult obesity, cardiovascular diseases (CVD), type II diabetes, hypertension, and metabolic syndrome. Recent research studies revealed that infants introduced to solid foods before 4 months had a six-fold increase in odds of obesity at three years of age. In addition, excessive food intakes during infancy have been associated with the risk of obesity and CVD risk factors in adulthood. In the Middle East region, eviden-

ce shows that current complementary feeding practices fall below global recommendations. The majority of the Kuwaiti (54%) and Lebanese (52.6%) infants receive solid foods before 4 months. In the Kingdom of Saudi Arabia (KSA), 81.5% of infants receive complementary foods between 4 and 6 months of age, whereas in Iraq and the United Arab Emirates (UAE) the figures are 78.6% and 70%; respectively. In parallel to faulty feeding patterns, the rates of CVD in countries of the Middle East have been increasing rapidly and currently account for 25 to 45% of total mortality with the highest mortality rates being recorded in the Arab countries of this region (Iraq, Syria, Lebanon, Jordan, and the Palestinian territories). Hence, enhancing infant/young child feeding practices may contribute to reduced morbidities and mortalities from NCDs, ultimately decreasing the region's high burden of these diseases.

Key words: Infant nutrition, complementary feeding, non-communicable diseases, cardiovascular diseases, Middle East.

NUTRITION AND NCDs IN NORTH AFRICA

N. Mokhtar, T. Beecic

International Atomic Energy Agency, Vienna, Austria

Countries of North Africa have experienced significant demographic, social and economic changes over the past decades that have greatly influenced the nutrition and health patterns of their populations. Not different from the rest of developing world, these societies are faced with rapidly growing population and urbanization, changes in food availability and cost and lifestyle changes resulting in nutrition transition that has shifted once traditional to a modern diet. While undernutrition still exists as a problem, particularly in the younger population, overweight and obesity are increasing at alarming rates and have reached dramatic levels. In 2008, the prevalence of overweight among adults was estimated to be 45.5% in Algeria, 46.8% in Morocco, 53.7% in Tunisia, 61.9% in Libya and 67.9% in Egypt with higher rates among women in all countries. High levels of overweight/obesity, going hand-in-hand with adverse changes in dietary patterns and physical inactivity are important contributors to high epidemiology of non-communicable diseases. In 2008, the prevalence of raised cholesterol in the region ranged from 33% to 39%, raised blood pressure 35-43% and raised blood glucose 6-12%. Proportionally, non-communicable diseases were estimated to account for the greatest percentage of all deaths, ranging from 63% in Algeria to 82% in Egypt, with cardiovascular diseases as single largest NCD. With the growing burden of overweight, countries are challenged to implement effective nutritional policies and action plans to combat this malnutrition form. Although some nutrition policies already exist, they are often not supported

by a clear strategic plan of implementation. Strong political commitment, structured policy frameworks, health expertise, adequate budget allocation and institutional capacity building should be pillars when developing and monitoring the implementation and sustainability of future nutrition programmes.

Key words: Nutrition, non-communicable diseases, obesity, undernutrition.

PHYSICAL ACTIVITY AND LIFESTYLE HABITS OF ARAB ADOLESCENTS: PRELIMINARY FINDINGS FROM THE ARAB TEENS LIFESTYLE STUDY

H. Al-Hazzaa

Pediatric Exercise Physiology Laboratory, College of Education, King Saud University, Riyadh, Saudi Arabia

Background and objectives: The dramatic lifestyle transformation experienced by major Arab cities can have a considerable negative health impact. Therefore, the objective of the Arab Teens Lifestyle Study (ATLS) was to investigate the lifestyle habits of Arab adolescents living in major urban cities. Materials and

Methods: About 9800 young participants were randomly selected from 12 participating cities in the Arab countries, including Riyadh, Jeddah, and Al-khobar (Saudi Arabia), Dubai (UAE), Kuwait, Bahrain, Amman (Jordan), Mosel (Iraq), Muscat (Oman), Doha (Qatar), Tunisia (Tunisia) and Kenitra (Morocco). Measurements included anthropometry, physical activity (PA), sedentary behaviors (SB), sleep duration (SD) and dietary habits (DH).

Results: The findings from the first patch of data, representing 8 cities; Riyadh, Jeddah, Al-khobar, Dubai, Kuwait, Amman, Mosel and Muscat, are presented. Adolescent obesity ranged from 5.2% in Mosel to about 24% in Kuwait. Obesity plus overweight prevalence ranged from 15.2% in Muscat to 48.7% in Kuwait. Participants from the Arabian Gulf (GCC) countries, except Muscat, have higher obesity and overweight levels than those from Amman or Mosel. PA-related energy expenditure (MET-min/week) was the lowest in teens from GCC cities. In addition, girls were significantly less active than boys in all participating cities. Time spent on daily SB ranged from 3.3 hours in Mosel to 7.5 hours in Kuwait. The proportion of youth sleeping for less than 7 hours/day ranged from 27-81%. Only 18-48% of the sample eats daily breakfast and about 10-60% have daily vegetables or fruit. Consumption of fast foods or sugar-sweetened drinks 3 times or more/week ranged from 30-54% and 65-85%, respectively.

Conclusion: Arab adolescents demonstrated some similarities and differences in their lifestyles. The ATLS provide invaluable baseline data for public health providers and policy

make to be utilized in health promotion and disease prevention.

Key words: Arab adolescents, physical activity, dietary habits, sedentary behaviors.

BUILDING RESEARCH CAPACITY IN NUTRITION TO PREVENT NCDs IN THE MIDDLE-EAST AND NORTH-AFRICA

I. Elmadfa², A. Meyer¹

¹Institute of Nutritional Sciences, University of Vienna, Vienna, Austria

²IUNS President

Non-communicable diseases are the most common death cause worldwide especially in low and middle-income countries where limited health care resources make them a particular burden. Without counteractive actions, the WHO expects the strongest increments (almost 25 %) in the African and the Eastern Mediterranean Region. The high prevalence of overweight and obesity in many countries of the region is a major causative factor of NCDs like diabetes mellitus type 2. At the same time, micronutrient malnutrition (hidden hunger) occurs frequently. The effects of nutrition on NCDs are currently the field of intense research worldwide, offering a promising and less expensive approach to prevention through weight reduction and improved diet quality. Building research capacity in nutrition in the MENA region is therefore of great importance. Indeed, the development of effective intervention programs requires knowledge about the specific nutritional problems of the region that can only be gained from well-designed nutritional surveys. A priority in this regard is the development of the necessary tools such as regional food composition databases, food intake protocols, and calculation programs. These tools can also serve to evaluate the efficacy of fortification programs aimed at improved micronutrient supply that are currently widely applied. An emerging research field is the influence of genetic variance on metabolism, requirements, and health effects of nutrients that can account for ethnic differences in disease pattern. Molecular markers can also be used as indicators of NCD prevalence and risk. Institutional capacity building in nutrition in the MENA countries needs further development, both in education and research. This recommendation must be pronounced although scientific research generally suffers from the political instability in the region that is also a cause for aggravating of nutritional issues and may present an obstacle to international cooperation.

Key words: Eastern Mediterranean, North Africa, NCD, nutrition, capacity building.

THE PALESTINIAN MICRONUTRIENT SURVEY (PMS) - FIRST REPRESENTATIVE NATIONAL NUTRITIONAL STUDY

I. Elmadfa¹, A. Abu-Rub², A. Skeek², N. Rizkallah³, K. Ben-Abdallah³

¹Institute of Nutritional Sciences, University of Vienna, Vienna, Austria

²Nutrition Unit, Palestinian Ministry of Health, Ramallah & Gaza, Palestinian Territories

³UNICEF, Jerusalem, Israel

Background and objectives: Selective micronutrient deficiencies especially anemia are of public health concern in the occupied Palestinian Territories. The prevalence of anemia is high in Palestine, despite the flour fortification program with iron, zinc, vitamins A, D, B1, B2, B6, B12, folic acid, and niacin, which was implemented in 2006. Most affected are children <5 y, schoolchildren (6-16 y), and pregnant women (59 %, 30 %, and 34 % on average, respectively) with people in the Gaza-Strip more affected than the West-Bank. Reports categorized most cases of the diagnosed anemia as moderate or mild. Our aim was to assess and characterize the prevalent anemia and explore its causes. A representative national nutritional survey (n=6.000) was planned and conducted as a cooperation project between UNICEF and the Palestinian Ministry of Health and the University of Vienna with financial support from the European Union.

Methods: In a randomized cross sectional survey in the regions (Gaza-Strip and West-Bank), children of both genders aged <5, 6-14 and 15-18 years in different school types (UN-RWA, Government, private), pregnant (22-24 weeks of gestation) and lactating women were considered. Intake including the use of supplements (interview) and the status of Fe, Zn, folic acid, vitamins B12, A, E and D are to be assessed using standard/validated assays. The erythrometric parameters (Hb, MCV, MCH, MCHC), CRP and anthropometric measurements will be analyzed. The fieldwork has just begun and will last 3-4 months.

Results and conclusions: Data of this project are important to explain the potential causes of anemia and inform about the efficiency of the ongoing flour fortification program in Palestine. This study can also be seen as an example for a systematic and science-based capacity development in the Middle-East and North-Africa-Region.

Key words: Micronutrient status, anemia prevalence, flour fortification, cooperation project UNICEF-Palestine.

PS5-59 Food insecurity and obesity across the life cycle

HOUSEHOLD FOOD INSECURITY AND OBESITY ACROSS THE LIFE CYCLE: CONCEPTUAL FRAMEWORK AND BIOLOGICAL PLAUSIBILITY

R. Perez-Escamilla

Yale School of Public Health, New Haven, USA

Global epidemiological evidence indicates that Household Food Insecurity (HFI) and obesity co-exist at least in some population sub groups. Thus, it is crucial to understand if this is a spurious or a causal relationship. Research in animal models and humans indicate that there are diet related and stress related pathways that may help understand how HFI affects obesity risk. Also epigenetic mechanisms may help understand how HFI affects offspring obesity risk through its effect on parental obesity. HFI in the context of countries undergoing or being at the post phase of the nutrition transition may lead to higher consumption of lower cost highly energy dense diets of low nutritional value. HFI may lead to disordered eating patterns as economic resources to acquire food become depleted during the month. These maladaptive eating patterns may be associated with monthly cyclical fluctuations in body weight and fat regulation hormones (e.g., insulin) that promote the cumulative retention of body fat over time. HFI is a major stressor that can increase the levels of stress hormones, such as cortisol, that promote fat deposition. In addition HFI has been consistently associated with depression, a condition that may significantly reduce physical activity levels. Parental obesity has been linked to an increased risk of obesity in the offspring via epigenetic mechanisms that may be triggered during the pre- and peri- conception periods, gestation and early infancy. Thus, children's obesity risk related to HFI may also be affected indirectly by the influence of HFI on parental body fat accumulation. In conclusion, there are clear direct and indirect biologically plausible pathways supporting the hypothesis that HFI is likely to affect obesity risk of humans across the life cycle.

HOUSEHOLD FOOD INSECURITY AND EXCESSIVE WEIGHT AMONG BRAZILIAN SUBJECTS: A LIFE-COURSE APPROACH

G. Kac¹, M. Maia¹, A. da Sila², R. Pérez-Escamilla³

¹Rio de Janeiro Federal University, Brazil

²Departamento de Saude Publica, Universidade Federal do Maranhao, Brazil

³Office of Community Health, Yale School of Public Health, USA

Household food insecurity (HFI) may increase obesity risk but results are not consistent across the life course and between developed/underdeveloped settings. The objective of this paper is to review findings from previous analyses in Brazil among adult women, female adolescents and children under five. Data were derived from the 2006-07 Brazilian Demographic and Health Survey. Associations between HFI, measured using the Brazilian Food Insecurity Scale, with excess weight/obesity were investigated through Poisson regression models. Whereas severe HFI was associated with obesity risk among adult women [PR: 1.49; 95% CI: 1.17±1.90], moderate HFI was associated with excess weight among female adolescents [PR: 1.96; 95% CI: 1.18±3.27]. There was no association between HFI and obesity among children of both genders. It is possible that the nutrition transition process in Brazil may be shaping the differential deleterious effect of HFI on body fat accumulation across the life-course, being the association evident among female adolescents and adult women but not yet among children.

Key words: Adolescents, children, food insecurity, women

FOOD SECURITY AND OBESITY RISK THROUGHOUT LIFE CYCLE STAGES IN MEXICO

T. Shamah Levy, J.A. Rivera Dommarco, V. Mundo Rosas, L. Cuevas Nasu, C. Morales Ruan

National Public Health Institute, Mexico

Background and objectives: Food security situation in Mexico suggest a complex and contrasting scenario. National Health and Nutrition Survey 2012 (ENSANUT 2012) reported that almost one in every three households suffer food insecurity (FI) in moderate or severe degree. This work objective is to describe the Food Security magnitude in Mexico from the feeding access and consumption perspective and its relation with overweight and obesity throughout the different life cycle stages (children, teenagers and adults), using (ENSANUT 2012) information.

Methods: Data for this analysis comes from ENSANUT 2012 . Food Insecurity status was measured using the last harmonized version of ELCSA (Latin American and Caribbean

Food Insecurity Scale Overweight and Obesity: In children and teenagers was determined by the z-score for the Body Mass Index (BMI=kg/m²) for Age indicator using the WHO Growth Reference. . In adults categories proposed by the WHO .

Results: In children under five years old no association was found between FI and overweight, however, wasting (<-2Z Weight/Age) was 2.17 times greater when the household was in severe FI condition (p=0.027). Stunting was also associated to households with moderate (p=0.019) and severe (p<0.001) FI. In the women between 20 and 59 years group the risk of suffer obesity increased 2.5 times when their household was in severe FI in contrast with an 1.3 times increase in overweight and obesity for the same group but in a household with food security conditions.

Conclusions: In Mexico, food insecurity increases not only the malnutrition risk in children but also contributes in important way in the incidence of overweight and obesity in other population groups.

Key words: Children, food insecurity, overweight, obesity, life cycle, Mexico.

HOUSEHOLD FOOD INSECURITY AND OBESITY RISK ACROSS THE LIFE COURSE: USA

E. Frongillo

University of South Carolina, Columbia, USA

Household food insecurity (HFI) is experienced when there is uncertainty about future food availability and access, insufficiency in the amount and kind of food required for healthy life, or the need to use socially unacceptable ways to acquire food. Hunger and malnutrition (i.e., undernutrition or obesity) are possible, although not necessary, consequences of HFI. Other closely linked consequences besides hunger are part of the experience of food insecurity: 1) worry and anxiety, 2) feelings of alienation and deprivation, and 3) distress and adverse changes in family and social interactions. These three closely linked consequences represent non-nutritional mechanisms leading to poor physical and mental health. Some behaviors potentially resulting from experiences of food insecurity are reductions in investments, risk avoidance, and survival strategies. Food needs compete with other needs, and trade-offs involving food are sometimes made to ensure long-term livelihood. Therefore, there are several potential mechanisms through which HFI may lead to obesity. In the USA, studies have reported substantial variability in the association of HFI with obesity. This variability can be understood using four perspectives. First, household and individual circumstances determine the relative importance of nutritional and non-nutritional mechanisms. Second, severity of HFI matters; severe HFI leads to weight deficit, but moderate HFI leads to weight excess. Third, the association of HFI with obesity reflects developmental changes as children pro-

gress through adolescence to adulthood. Fourth, individuals have different experiences with different consequences across the life course. HFI is a form of material deprivation. Since material deprivation leads to poor outcomes in many domains, obesity is an expected consequence of HFI for some subpopulations and at some ages.

Key words: Food insecurity, weight, obesity

PS5-67 Type 2 diabetes in Asia's rapid growth is due to genetic or dietary change?

EFFECTS OF NUTRITION, LIFESTYLE AND GENETIC FACTORS ON METABOLIC ABNORMALITIES AMONG CHINESE

X. Lin, L. Sun, X. Ye, H. Li, G. Zong, L. Lu, W. Gan, J. Zhu

Key Laboratory of Nutrition and Metabolism, Institute for Nutritional Sciences, Shanghai Institutes for Biological Sciences, Chinese Academy of Sciences, Shanghai, Republic of China

Background and objectives: With a dramatic nutrition transition in last few decades, China is facing the challenge of an epidemic of obesity-related diseases like metabolic syndrome (MetS) and type 2 diabetes (T2D). However, few studies have systematically investigated roles of genetic variants and diet/lifestyle factors in the pathogenesis of metabolic diseases among Chinese. Thus, a population-based prospective study was conducted.

Methods: Baseline data included 3,289 men and women aged 50-70 years from Beijing and Shanghai, China and 2,198 of them participated in the 6-year follow-up study.

Results: Our baseline data showed significant north-south and urban-rural differences for the prevalence of MetS and T2D, even at given adipose levels. Multiple environmental and genetic variants, obese phenotype, inflammatory biomarkers and adipokines were found to be significantly associated with the risks of MetS and T2D. Among these factors, circulating of 25(OH)D and erythrocyte docosahexaenoic acid was inversely, while plasma ferritin was positively associated with the risk of MetS. However the levels of 25(OH)D, ferritin and n-3 polyunsaturated fatty acids were modified by genes variants in related metabolic pathway(s). Ethnic differences on genotypes (FTO, CDKAL1 and GRK5), phenotype (C-reactive protein), and sources of trans-fatty acids were also observed between Chinese and Caucasians. In our follow-up study, multiple nutrient biomarkers were confirmed to predict the development of MetS and T2D, independent of established risk factors. For instance, plasma ferritin was independently associated with 60% increased risk of developing MetS (relative risk [RR] 1.60; 95% confidence interval [CI] 1.16-2.20), while erythrocyte trans-fatty acid trans-18:1 was associated with reduced diabetes incidence

(RR 0.59; 95% CI 0.45-0.79) by comparing extreme tertiles in multivariate models (all $P < 0.01$ for linear trend).

Conclusions: Our studies provided important insights regarding the complicated relationships of gene-nutrition and gene-phenotype with metabolic abnormalities in Chinese population.

Key words: Nutrition, genetic, metabolic abnormalities, China.

ASIANS ARE MUCH MORE VULNERABLE TO DIETARY CHANGE DUE TO LOWER INSULIN SECRETION

K. Tanaka¹, Y. Seino²

¹Kyoto Women's University, Kyoto, Japan

²International Diabetes Federation Western Pacific Region

The increasing number of patients with diabetes is a worldwide serious problem, which is most eminent in Asia. Now, one third of diabetic patients are in Asia. According to International Diabetes Federation (IDF), the prevalence of diabetes in Western Pacific Region is 8.0%, with the number of patients being 132.2 million, which is expected to increase to 187.9 million in 2030. Clinical evidences suggest that Asians are much more susceptible to developing diabetes. Impaired insulin secretion and increased insulin resistance are both responsible for . In Caucasians, the importance of insulin resistance is advocated, whereas insulin secretory capacity is much lower in Asians than in Caucasians. Higher insulin secretion is associated with increased fat deposition and obesity. In contrast, in those with lower insulin secretion, hyperglycemia would be prolonged since lipid synthesis and fat deposition is not much enough. Thus, Asians are at higher risk of developing diabetes even at slightly increased body mass index (BMI). These ethnic differences might be explained by the different life styles, especially the different dietary tradition. The meat and the dairy product consumption, and the carbohydrate consumption have been large in Caucasians and Asians, respectively. Now that the Asian dietary habit is rapidly westernized, pancreatic beta-cell in Asians is likely to be unable to adapt to the new circumstance.

Thus the current research question is if type 2 diabetes in Asia and rapid growth is due to genetic or dietary change is both yes. Many Asians, with genetically lower insulin secretory activity and susceptibility to developing diabetes, have developed diabetes triggered by the dietary change.

Key words: Dietary habits, insulin resistance, type 2 diabetes.

OVERWEIGHT AND DIABETES IN INDIA

A. Kurpad¹, T. Thomas², K. Sankar¹

¹St John's Medical College, Bangalore, India

²St John's Research Institute, Bangalore, India

In the past two decades, the prevalence of diabetes has doubled in both urban and rural areas in India. The increase in the rural population is noteworthy as it is large in India. In general the change can be attributed to economic growth and urbanization resulting in changes in behaviour and lifestyle. The prevalence of overweight/obesity in Indian adults has increased, and is greater in women than men. The notion that overweight and diabetes are brought on by unhealthy lifestyles is intuitive. Surveys have documented a gradual decrease in the daily consumption of cereals and pulses, with relatively little change in the calories consumed, indicating substitution with other sources of energy such as fats. Factors driving such consumption patterns can be deduced from the fact that the greatest increases in area under cultivation and production over the last 50 years has been for sugar cane and oil seeds. Food price stability is also of concern; prices of sugar, edible oils and milk and dairy products have been more stable compared to vegetables and pulses over the last decade. In contrast to food intake, information on physical activity from India is scant. Access to open spaces or parks for leisure-time physical activity is poor in Indian cities, and the walkability of Indian cities is extremely poor. The use of non-motorised modes like cycling and walking is risky, since these modes have to share the same right of way with motorized modes. As the use of virtual modes for social interactions catches up in India in the information age, physical activity levels are likely to decrease further. Given the low priority accorded to chronic diseases in general by central and state governments, advocacy focussed towards securing political commitment and adequate policy and funding support is vital.

Key words: Obesity, diabetes, India

EFFECT OF VITAMIN B12 AND N-3 POLYUNSATURATED FATTY ACIDS ON PLASMA HOMOCYSTEINE, AND OTHER CARDIOVASCULAR RISK FACTORS: RANDOMIZED CONTROLLED TRIAL

T. Huang^{1,2,3}, K. Li^{1,2}, M. Asimi^{1,2}, Q. Chen^{1,2}, D. Li^{1,2}

¹Department of Food Science and Nutrition, Zhejiang University, Hangzhou, China

²APCNS Centre of Nutrition and Food Safety, Hangzhou, China

³Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, USA

Background and objectives: Vitamin B12 and n-3 polyunsaturated fatty acids (PUFA) decrease blood homocysteine (Hcy) concentration. However, the combined effect of these nutrients on Hcy and ferritin, and C-reactive protein is limited and inconclusive. The objective was to examine the synergistic effect of vitamin B12 in combination of n-3 PUFA on plasma Hcy, ferritin, and other biochemical markers.

Methods: In a randomized controlled trial, thirty eligible subjects were randomly divided into three groups, and assigned to receive 1000 µg of vitamin B12, 2g fish oil, or 1000 µg vitamin B12 and 2g fish oil respectively for 8 weeks. Plasma phospholipid (PL) fatty acids and biochemical markers were determined.

Results: Plasma PL 20:5n-3, 22:6n-3 and n-3 PUFA were increased after 4 and 8 week supplementation of fish oil, and vitamin B12+fish oil. Plasma concentrations of triacylglycerol, uric acid, and ferritin were significantly decreased after 4 and 8 week supplementation of fish oil, and vitamin B12+fish oil. In all groups, significant changes in plasma Hcy were observed during the study period. Vitamin B12, fish oil, and vitamin B12+fish oil supplementation lowered plasma Hcy concentrations by 22%, 19%, and 39%, respectively.

Conclusions: Combination of vitamin B12 and fish oil have synergistic effect on lowering plasma concentrations of Hcy and ferritin.

Key words: Homocysteine, fish oil, vitamin B12

INSULIN RESISTANCE IN GLUCOSE TOLERANT OBESE ADOLESCENTS ARE ASSOCIATED WITH INCREASED LEVEL OF PLASMA HSCRP AND URIC ACID

⁵AKPER Muhammadiyah, Makassar, Indonesia

⁶STIKES FAMIKA, Makassar, Indonesia

⁷Syekh Yusuf Hospital, Sungguminasa, Indonesia

⁸Bhayangkara Nursery School, Makassar, Indonesia

Background and objectives: The increasing prevalence of insulin resistance and obesity has also affected adolescent. This study aimed to compare the level of insulin resistance and metabolic disorder indicators between obese and non-obese male adolescent.

Methods: Thirty nine male Indonesian adolescent students with no family history of type 2 diabetes were enrolled in this study. They were classified as obese, overweight, and normal weight according to International criteria. After a 12-h overnight fast, blood vein was taken for measurement of fasting blood glucose, insulin, hsCRP, uric acid, and antioxidant status (AOS) and OGTT was performed.

Results: Of 39 subjects 9 were obese, 16 were overweight and 14 were normal weight. Obese subjects were clearly insulin resistant compare to overweight and normal weight subjects evidenced by higher insulin level with value of 14.177 ± 6.921 , 6.55 ± 4.72 , and 4.48 ± 4.51 respectively ($p < 0.001$) and higher HOMA-IR i.e., 2.66 ± 1.464 , 1.193 ± 0.891 , and 0.607 ± 0.347 respectively ($p < 0.001$). Interestingly, these were associated with significant higher level of hsCRP and uric acid in obese subjects. Level of hsCRP in obese, overweight, and normal weight subjects were 2.32 ± 2.23 , 1.10 ± 0.43 , and 0.56 ± 0.40 respectively ($p < 0.003$). Whereas uric acid level for obese, overweight, and normal weight subjects were 7.406 ± 1.3025 , 6.878 ± 1.1959 , and 5.704 ± 1.0406 respectively ($p < 0.001$). The values of 2 h-pp blood glucose level during OGTT in obese, overweight, and normal weight subjects were 96.90 ± 17.38 , 98.92 ± 17.49 , and 90.65 ± 14.46 respectively ($p < 0.433$). Similarly, insignificant difference of AOS was observed between obese, overweight, and normal weight subjects with value of 1.98 ± 0.34 , 1.96 ± 0.33 , and 1.99 ± 0.35 respectively ($p = 1.232$).

Conclusions: There was a clear association between high IMT with insulin resistance markers and increased plasma uric acid level and are moreover associated with increased level of

plasma hsCRP in male adolescents with normal glucose tolerance.

Key words: Adolescents, obesity, insulin resistance, hsCRP, uric acid.

GLOBAL DIETARY WHOLE GRAIN RECOMMENDATIONS: A HARMONISED OR MULTIFARIOUS MESSAGE?

F. Thielecke¹, A. Nugent², T. Siong³, C. Seal⁴

¹Cereal Partners Worldwide, Lausanne, Switzerland

²UCD Institute of Food and Health, UCD, Belfield, Dublin, Ireland

³TES NutriHealth Strategic Consultancy, Malaysia

⁴Human Nutrition Research Centre, School of Agriculture, Food and Rural Development, Newcastle University, Newcastle upon Tyne NE1 7RU, UK

Background and objectives: Dietary recommendations for whole grain intake exist in a number of countries worldwide, however, the nature and wording of these recommendations have not been characterized to date.

Methods: Using a combination of literature searches and direct enquiry, this research reviewed current whole grain recommendations around the globe to assess presence/absence, rationale and diversity in emphasis and wording.

Results: The level of emphasis placed on dietary whole grain intake is hugely variable globally. For some countries, clearly defined dietary recommendations for whole grain intake exist which are supported by policy and health promotion campaigns. In these instances, quantitative recommendations may co-exist whereby a numerical value is ascribed providing a benchmark or 'target' for population intakes. However, this value can vary between countries and is sometimes related to a gram intake (e.g. 48g/d) or number of servings per day (e.g. 3 x 16 servings). In other countries, whole grain-specific dietary recommendations may be deemed as secondary, whereby they usually form part of broader guidelines on carbohydrate and/or fibre intakes or even general healthy eating guidelines. Where this occurs, the recommendations are typically less prescriptive and may be more difficult to disentangle from the primary recommendation. This can make the impact of any public health campaigns difficult to assess. Finally, in some regions, dietary recommendations for whole grain intake do not exist at all.

Conclusion: This review critiques the evidence regarding dietary recommendations for whole grain intake worldwide. The results indicate that there is a lack of a harmonized message which may result in potential confusion for the consumer, lessen the impact of public health messages and pose barriers to trade for the food industry.

Key words: Dietary whole grain recommendations.

T4 NUTRITION AND MANGEMENT OF DISEASES

NPS1-4 Dietary lipids and the risk of common diseases

BENEFICIAL EFFECTS OF DIETARY PHOSPHOLIPIDS ON METABOLIC SYNDROME

T. Yanagita¹, B. Shirouchi², K. Nagao³

¹Nishikyushu University, Kanzaki, Japan

²Kyushu University, Furuoka, Japan

³Saga University, Saga, Japan

Background and objectives: Metabolic syndrome (MS) is associated with obesity, disorder of lipid metabolism, diabetes, and increased risk of developing cardiovascular disease. Recent evidence showed that the quality of food components is important modulators in terms of risks with metabolic syndrome. In addition, growing evidence showed that dietary phospholipids have beneficial effects on health compared with dietary triacylglycerols (TAG). We evaluated the physiological functions and molecular actions of bioactive phospholipids, phosphatidylinositol (PI) and phosphatidylcholine (PC), in the development of fatty liver and inflammation of experimental animal models.

Results: Intake of purified soybean PI (2%) suppressed the accumulation of body fats and alleviated metabolic syndrome through the transcriptional regulation of lipid and glucose metabolism in Zucker (fa/fa) rats. Additionally, when rats were fed semisynthetic diets that contained either 5% corn oil + 2% Egg-PC, or 5% corn oil + 2% DHA-PC, DHA-PC diet DHA-PC diet significantly decreased omental WAT weight, and markedly alleviated hepatomegaly and hepatic lipid accumulation in obese OLETF rats. These effects were attributable to the suppression of fatty acid synthesis and the enhancement of fatty acid beta-oxidation in the liver.

Conclusions: These results indicate that dietary phospholipids would be useful to prevent or alleviate metabolic syndrome.

Key words: Phospholipids, metabolic syndrome, lipid metabolism, DHA-Phospholipid, phosphatidylinositol.

POSTPRANDIAL METABOLISM OF DOCOSAPENTAENOIC ACID (DPA, 22:5N-3) AND EICOSAPENTAENOIC ACID (EPA, 20:5N-3) IN HUMANS

A. Sinclair¹, K. Linderborg², D. Cameron-Smith³

¹Deakin University, Melbourne, Australia

²University of Turku, Turku, Finland

³University of Auckland, Auckland, New Zealand

Background and objectives: The study of the metabolism of docosapentaenoic acid (DPA, 22:5n-3) in humans has been limited by the unavailability of pure DPA and the fact that DPA is found in combination with eicosapentaenoic acid (EPA, 20:5n-3) and docosahexaenoic acid (DHA, 22:6n-3) in natural products.

Methods: Pure DPA and EPA were incorporated in meals served to healthy female volunteers in a double blind cross over study. Mass spectrometric methods were used to study the chylomicron lipidomics.

Results: Plasma chylomicronemia was significantly reduced after the meal containing DPA compared with the meal containing EPA or olive oil only. Both EPA and DPA were incorporated into chylomicron TAGs, while there was less incorporation into chylomicron phospholipids. Lipidomic analysis of the chylomicron TAGs revealed the dynamic nature of chylomicron TAGs. The main TAG species that EPA and DPA were incorporated into were EPA/18:1/18:1, DPA/18:1/16:0 and DPA/18:1/18:1. There was very limited conversion of DPA and EPA to DHA and no retroconversion of DPA to EPA during the 5 hour postprandial period.

Conclusions: EPA and DPA showed different metabolic fates, and DPA hindered the digestion, ingestion or incorporation into chylomicrons of the olive oil present in the meal.

Key words: Chylomicrons, EPA, digestion, DHA, omega-3, fatty acids.

SIGNIFICANCE OF PHOSPHATIDYLCHOLINE HYDROPEROXIDE IN THE PATHOGENICITY OF ATHEROSCLEROSIS

T. Miyazawa

Tohoku University, Tohoku, Japan

The accumulation of phosphatidylcholine hydroperoxide (PCOOH), a primary oxidation product of phosphatidylcholine (PC), in blood plasma and tissues has been observed in various pathological conditions, including atherosclerosis. To estimate the atherogenicity, the effect of PCOOH on THP-1 monocytic cell adherence to immobilized vascular endothelial cell adhesion molecules were evaluated. THP-1 cell adhesion to intracellular adhesion molecule-1 (ICAM-1) was dose dependently increased by presence of PCOOH. Unoxidized PC, sn-2 truncated PCs, and other hydroperoxide compounds did not affect the adhesion. In the PCOOH-treated cells, obvious protruding F-actin-rich membrane structures were formed, and lymphocyte function-associated antigen-1 (LFA-1) was localized to the protruding structures. Cytochalasin D, an actin polymerization inhibitor, suppressed the PCOOH-induced cell adhesion to ICAM-1 and the membrane protrusions. Next the involvement of Rho-family GTPases in PCOOH-induced THP-1 cell adhesion to ICAM-1 was investigated. Isoprenoid depletion by fluvastatin and geranylgeranyltransferase inhibition by GGTI-286 suppressed PCOOH-induced cell adhesion to ICAM-1 and F-actin-rich membrane protrusion formation. Pull-down assays demonstrated the activation of Rac1 and Rac2 in PCOOH-treated cells. Pan-Rho-family GTPase inhibitor Clostridium difficile toxin B, Rac-specific inhibitor NSC23776, and RNA interference of the Rac isoforms suppressed the cell adhesion. These findings indicate the involvement of Rac GTPase activation in PCOOH-induced cell adhesion to ICAM-1 via actin reorganization. The results indicate that PCOOH evokes monocyte adherence to the arterial wall in the initiation of atherosclerosis. Dietary ascorbic acid, tocopherols, carotenoids and polyphenols prevents the increase of plasma PCOOH in humans.

Key words: Oxidized phospholipid, atherosclerosis, monocytes, PCOOH, tocopherols.

LIPASE-CATALYZED PRODUCTION OF STRUCTURED LIPIDS AS HUMAN MILK FAT ANALOGS

C.C. Akoh

Department of Food Science & Technology, University of Georgia, Athens, USA

Most of the energy that the infant needs for nutrition come from fats. The aim of producing infant formula fat analogs is

to produce lipids that mimic the breast milk fatty acid composition. Our goal was to explore the use of lipases to produce lipids that mimic human milk fat (HMF) for infant nutrition. HMF analogs were enzymatically prepared using different substrates and esterification methods. The acidolysis and interesterification reactions were catalyzed by sn-1,3 specific and non-specific lipases. The products were structured lipids (SLs) with potential as infant formula fat analogs or as nutraceutical lipids for normal free-living humans and pregnant women. The SLs have high sn-2 palmitic acid content and comparable fatty acid composition to HMF. Physiologically important fatty acids such as stearidonic (SDA), eicopentaenoic (EPA), docosahexaenoic (DHA), gamma-linolenic (GLA), arachidonic (ALA), and oleic acids were important components of the HMF analogs fatty acids profile. Both DHA and ARA are important in brain development and cognitive functions of the infant. The use of HMF analogs compared to vegetable oil blends in infant formula formulations should provide better regiospecific fatty acids and enhance calcium absorption. This enhanced absorption is due to the difference in the positional distribution of palmitic acid in the triacylglycerols.

Key words: Enzymes, human milk fat, infant formula, structured lipid.

PS1-4 Scaling up prevention and treatment of malnutrition

SCALING-UP PREVENTION OF STUNTING

T. Ahmed, M. Hossain, J. Chisti, M. Mahfuz, M. Islam, I. Hossain

CDDR,B Centre for Nutrition and Food Security, Mohakhali, Dhaka, Bangladesh

With more than 175 million under-five children stunted, stunting or chronic malnutrition is the most common manifestation of childhood malnutrition. Asia alone accounts for 63% of the global burden of stunting. Stunting not only blunts cognitive potentials of children, 14.5% of all under-five deaths in developing countries can be attributed to this condition. Globally stunting is dropping at a rate of 1.8% per year. Clearly this is not enough to control the situation in which more than one-third of children worldwide suffer from this condition. The causes of stunting are multifactorial. These include prenatal causes (maternal malnutrition, anemia, hypertensive disease of pregnancy), low birth weight, postnatal causes (inappropriate feeding, repeated infections, zinc deficiency, enteropathy etc), and environmental toxins such as aflatoxin. Although food insecurity is a major underlying factor, lack of awareness regarding infant feeding is important. These determinants of stunting should therefore be the focus of programs for preventing stunting. Given the huge burden of stunting, it is imperative

also to implement programs that reverse stunting in young children.

There are examples of national programs that have successfully reduced stunting. The Progressa program in Mexico was able to improve height through a combination of conditional cash transfer and food supplementation. In a micronutrient powder supplementation program in a cyclone affected population in Bangladesh, children who consumed at least 75% of the micronutrient powder sachets had a significantly lower prevalence of stunting than those who did not. A very successful program was that run by CARE in Bangladesh that combined direct nutrition-specific interventions, such as child feeding, with nutrition-sensitive or indirect interventions that empower women, like involving women in income generating activities. This program reduced stunting by 4.5% points over less than 4 years. What we need now is focus and resources for scaling up such programs to control stunting.

Key words: Food insecurity, food supplementation, infant feeding, stunting.

SCALING-UP TREATMENT OF SEVERE ACUTE MALNUTRITION: CHALLENGES

M P. Allie

Medecins Sans Frontieres

Severe acute malnutrition [SAM] affects approximately 25 million children under age 5 each year. Effective treatment in the form of ready-to-use therapeutic food [RUTF] has been available for more than 10 years, yet only 10% of children who need treatment are receiving it. What are the obstacles and how might they be negotiated? Discussion The sheer numbers of SAM-affected children and the pressure their care exerts on fragile health systems in parts of Sub-Saharan Africa and South Asia are a major barrier. SAM prevention via programs that combine routine vaccination services, promotion of breastfeeding, prevention and early detection of common infectious diseases and dietary supplementation beyond 6 month of age, are key to reducing the caseload of children who require SAM treatment. Unsurprisingly, when SAM prevention efforts are comprehensive, stunting prevalence decreases as well.

Secondly, SAM treatment protocols must be simplified. The majority of national protocols rely on determination of weight-for-height to identify wasted children. This approach is cumbersome and non-intuitive. Middle-upper arm circumference [MUAC] more accurately identifies children at highest risk for malnutrition-related mortality and is far easier to implement. MUAC gain parallels weight gain, thus is also a useful measure of nutritional recovery. If SAM treatment is to be incorporated into integrated pediatric healthcare, using MUAC offers a much better chance of success.

Lastly, there are major knowledge gaps in the medical scien-

ce upon which treatment of the severely ill malnourished child depends. If hospital mortality rates for these children are to decline, better evidence must guide the management of fluids, electrolytes, transfusion and antibiotic prescription.

A malnourished child is, above all, a child whose health is compromised. The care and management of these children belongs squarely with medical professionals until healthy growth patterns are established.

Key words: Severe acute malnutrition, ready-to-use therapeutic food, Middle-upper arm circumference.

RESEARCH TO IMPROVE INFANT NUTRITION IN AFRICA

A. Lartey

University of Ghana, Ghana

Undernutrition is the underlying cause of death for 3.1 million children under five years annually. The recent Lancet series reported population attributable deaths for African children with diarrhea to 38% from underweight, 46% to stunting and 34% to wasting as underlying causes. Micronutrient deficiencies are also widespread, with about 41%, 39%, 24% and 16% of African children under five years being vitamin A, iodine, zinc and iron deficient respectively. Interventions involving the promotion of optimal breastfeeding practices, early introduction of safe and nutritionally adequate complementary foods, diversification of local diets and improving care practices as well as disease prevention continue to remain effective means to address undernutrition. However, adverse prevailing conditions such as HIV-AIDS, household food insecurity and poverty are issues to grapple with. These must be specifically dealt with as they compromise child growth and development. Report of adverse effect of iron supplementation to children in malaria endemic areas has virtually brought interventions for the management of iron to a halt in many countries in sub-Saharan Africa. The paper reviews research interventions with the potential to address undernutrition in Africa. Priority research must focus on how effective research interventions can be incorporated into country programs and scaled up for maximum effect.

Key words: Child undernutrition, micronutrient deficiency, nutrition interventions, sub-Sahara Africa.

SCALING UP NUTRITION: WINDOWS OF OPPORTUNITY

S. Fan

International Food Policy Research Institute, Washington, USA

The triple burden of malnutrition is increasingly a big challenge. Global hunger remains persistent as nearly 870 million people worldwide are undernourished. Micronutrient deficiencies, also known as “hidden hunger” affects more than 2 billion people. In addition, obesity or overnutrition now co-exists with undernutrition. The cost of malnutrition can be very high. In India, for example, the economic cost of micronutrient deficiencies amounts to about 2.5 percent of GDP. For poor and vulnerable groups in developing countries to lead healthy and productive lives, good nutrition is key. Agriculture and food systems play a critical role in improving nutrition. For example, biofortification—plant breeding to enhance the nutrient content of food crops—is a promising strategy to combat micronutrient deficiencies in developing countries. Policymakers must also work together to maximize synergies and minimize risks that lie at the intersection of agriculture and nutrition. National agricultural strategies and investment plans need to be designed using a nutrition lens in order to take advantage of the pathways through which agriculture can help to improve nutrition. To increase the availability, affordability, quality, and acceptability of nutrient-rich foods, nutrition-sensitive value chains should be explored. Similarly, the design and implementation of nutrition interventions should also incorporate agriculture and food. While challenges to cross-sectoral collaboration may exist, coordinated actions to harness opportunities must be pursued. Specifically, windows of opportunity for policy change must be exploited. This presentation will discuss what it means to leverage agriculture for better nutrition outcomes and highlight the windows of opportunity which exist to scale up nutrition.

Key words: Malnutrition, micronutrient deficiencies, biofortification, windows of opportunity.

PS2-12 Food, nutrition, physical activity and cancer – Keeping the evidence current: WCRF/AICR Continuous Update Project (CUP) - (WCRF)

EVIDENCE BASED RECOMMENDATIONS FOR PREVENTION OF CANCER AND OTHER CHRONIC DISEASES - THE 2007 AND 2009 WCRF/AICR REPORTS

M. Wiseman

WCRF International, London, UK

The remarkable variation in cancer incidence around the world and its plasticity, when populations migrate or over time within countries, demonstrates a strong environmental component to cancer patterns. Both epidemiologic and laboratory evidence point to food, nutrition and physical activity as key environmental determinants of cancer risk. To better explore their role in cancer, WCRF/AICR commissioned an expert report (Food, Nutrition, Physical Activity, and the Prevention of Cancer: a Global Perspective) using the most rigorous systematic approaches. Published in 2007 this report is the most authoritative review of this area. In order to translate these findings into practice WCRF also commissioned a unique and rigorous review of the evidence for effective policies and actions. The findings were published in 2009 in Policy and Action for Cancer Prevention. Recognising the ongoing accumulation of evidence, WCRF has commissioned from Imperial College London a continuous update of the evidence, which is judged by an independent expert panel (the WCRF/AICR Continuous Update Project).

Key words: Cancer, environment, epidemiology, food, nutrition, physical activity.

THE WCRF/AICR CONTINUOUS UPDATE PROJECT – AIMS AND PROCESS

T. Norat

Imperial College London, London, UK

Introduction: The 2007 World Cancer Research Fund/American Institute for Cancer Research (WCRF/AICR) report Food, Nutrition, Physical Activity and the Prevention of Cancer: a Global Perspective was based on systematic literature reviews (SLRs) conducted in nine different centres. WCRF/AICR has commissioned a team at Imperial College London (ICL) to update the evidence on a continuous basis.

Methods: Having first combined the databases for the 17 cancers reviewed for the 2007 Expert Report into one database, the ICL team conducts SLRs on food, nutrition physical activity and cancer, according to peer-reviewed protocols. The results of the SLRs are judged by a panel of experts who draw

conclusions and where necessary, give advice on whether current WCRF/AICR recommendations need amendment. The database is currently being updated through a rolling programme. A complete updated database is expected by 2015.

Results: The database is kept up-to-date for cancers of the breast, prostate, colorectal, pancreas, endometrium, ovary, kidney, bladder, liver, gallbladder, and oesophagus and updates of stomach and lung cancer are on-going. SLRs for breast, colorectal, prostate, ovary, endometrium and breast cancer survival have been evaluated by the Expert Panel and further updated SLRs will be published on other cancers. Once the SLRs for all the cancers have been updated, the database will be made publicly available, and the 2007 Expert Report recommendations reviewed.

Conclusion: The CUP will provide a unique resource synthesising epidemiological and other evidence on food, nutrition, physical activity and cancer, to facilitate related research, and underpin advice to public and policy-makers.

Key words: Cancer, nutrition, physical activity, obesity.

THE WCRF/AICR CONTINUOUS UPDATE PROJECT – SYSTEMATIC REVIEWS ON NUTRITION, WEIGHT, PHYSICAL ACTIVITY AND HEALTH OUTCOMES IN CANCER SURVIVORS

A. McTiernan

Fred Hutchinson Cancer Research Center, Seattle, Washington, USA

The number of cancer survivors has greatly increased in recent decades. There are currently an estimated 28 million people living with cancer globally. This is partly because the general prevalence of cancer continues to rise, within a world population that is also rising. In addition, screening programmes for common cancers are identifying many more cases, usually at relatively early stages. Also for some cancers, treatment is increasingly successful and so cancer survivors are living long enough to develop new primary cancers or other chronic diseases. In 2007 when WCRF/AICR published its Second Expert Report 'Food, Nutrition, Physical Activity, and the Prevention of Cancer: a Global Perspective', evidence on the associations of nutrition, weight, and physical activity with cancer survivorship was not sufficiently developed for the Expert Panel to draw firm conclusions. The Expert Panel report stated that cancer survivors should follow the recommendations for prevention of cancer on diet, healthy weight and physical activity, with the guidance of their treating physicians and other medical providers. The research on nutrition, weight, and physical activity in cancer survivorship has been expanding over recent years. WCRF/AICR has developed a new protocol as part of the Continuous Update Project to capture and review

the evidence, which includes that from randomised controlled trials and follow-up studies. The key outcomes are total and breast cancer mortality, and second primary breast cancer. The Continuous Update Project expert panel will use newly developed criteria specific for cancer survivorship for judging the evidence, as a basis for developing nutrition, weight, and physical activity recommendations for women who have had breast cancer, to reduce mortality and risk of further primary cancers.

Key words: Cancer, environment, epidemiology, food, nutrition, physical activity, survivors.

THE WCRF/AICR CONTINUOUS UPDATE PROJECT: SYSTEMATIC REVIEW OF MECHANISTIC STUDIES IN RELATION TO FOOD, NUTRITION, PHYSICAL ACTIVITY AND CANCER

M. Wiseman

WCRF International, London, UK

The remarkable variation in cancer incidence around the world and its plasticity, when populations migrate or over time within countries, demonstrates a strong environmental component to cancer patterns. Both epidemiologic and laboratory evidence point to food, nutrition and physical activity as key environmental determinants of cancer risk. To better explore their role in cancer, WCRF/AICR commissioned an expert report (Food, Nutrition, Physical Activity, and the Prevention of Cancer: a Global Perspective) using the most rigorous systematic approaches. Published in 2007 this report is the most authoritative review of this area. In order to translate these findings into practice WCRF also commissioned a unique and rigorous review of the evidence for effective policies and actions. The findings were published in 2009 in Policy and Action for Cancer Prevention. Recognising the ongoing accumulation of evidence, WCRF has commissioned from Imperial College London a continuous update of the evidence, which is judged by an independent expert panel (the WCRF/AICR Continuous Update Project).

Key words: Cancer, environment, epidemiology, food, nutrition, physical activity.

WCRF CONTINUOUS UPDATE PROJECT (CUP) AND FUTURE IMPLICATIONS

A. Jackson

Southampton General Hospital (MP 113),
Southampton, UK

In 2007 WCRF/AICR published the most comprehensive review of the world literature which demonstrated that diet, nutrition and physical inactivity cause cancer in specific sites. It was estimated that these factors account for at least 30% of cancers. In 2009 a systematic review of the evidence to support policy actions to prevent cancer was published. Since 2007 there has been an ongoing literature review to maintain the database on cancer causation up-to-date with a programme of continuous review for all cancer sites. Updates so far been completed for: breast, colorectal, pancreas, endometrial, ovary, with a review for breast cancer survivors. These are published as they are completed and mostly confirm or strengthen recommendations from 2007. There is clear evidence that individual susceptibility to cancer is in part determined by genetic factors, but a large part of the variability in risk can be related to differences in the personal metabolic phenotype. Incorporation of robust mechanistic understanding will strengthen the conclusions drawn from the epidemiological evidence and lead to new research directions and is now the subject of a new major systematic review. While much remains to be understood about how food, nutrition and physical activity influence cancer risk, progression and outcome, enough is already known to implement public health policies that will be effective in reducing the burden not only of cancer but also of other chronic diseases.

Key words: Cancer, environment, epidemiology, food, genetic factors, nutrition, physical activity, survivors.

PS2-20Tackling obesity in pre-school children: First results from the ToyBox-Study

EARLY PREVENTION OF CHILDHOOD OBESITY: REVIEW OF THE LITERATURE AND THE FIRST RESULTS OF THE TOYBOX-STUDY

Y. Manios¹, O. Androutsos¹, C. Katsarou¹, I. de Bourdeaudhuij², B. Koletzko³, L. Moreno⁴, C. Summerbell⁵, V. Iotova⁶, P. Socha⁷, T. Lobstein⁸, On behalf of the ToyBox-study group

⁷Children's Memorial Health Institute, Warsaw, Poland

⁸International Association for the Study of Obesity, London, UK

Background and objectives: To provide an overview of the literature on school-based obesity prevention programmes and introduce ToyBox-study by presenting key-methodological issues and preliminary results.

Methods: Recent reviews and meta-analyses have shown that studies of high methodological quality were more likely to report positive, long-term outcomes, and that a) the use of certain behavioural models, b) targeting children's physical and social environment at home and school, c) involvement of appropriate role models, d) implementation of recreational experiential learning with total class participation and e) duration of at least six months, should guide the development of ToyBox-study. Four key-behaviours were identified to be associated with early childhood obesity: snacking and drinking habits, physical activity and sedentary behaviour. ToyBox-study was implemented in six European countries during 2012-2013. Baseline and follow-up measurements were performed, and process and cost-effectiveness were assessed during implementation.

Results: At baseline (May-June 2012), more than 8,700 preschool children, their teachers and their families entered the study in Belgium, Bulgaria, Germany, Greece, Poland and Spain. The prevalence of overweight and obesity was found to be 10.8% and 4.1% respectively (IOTF-criteria), with higher prevalence of obesity in South- and East-Europe compared to CentralEurope, and in families with low socioeconomic-status.

Conclusions: These findings, in line with previous studies in older children and adults, indicate that the prevalence of obesity is differently distributed among regions and socioeconomic groups, reflecting not only cultural and lifestyle diffe-

rences, but also differences related to barriers and facilitators of health behaviours. Understanding these parameters when designing and implementing intervention programmes is critical to their success.

Acknowledgements: The ToyBox-study is funded by the 7th Framework Programme of the European Commission (grant 245200).

Key words: Childhood obesity, intervention, prevention, ToyBox-study.

PRE-SCHOOL CHILDREN'S PHYSICAL ACTIVITY AND SEDENTARY BEHAVIOURS

I. de Bourdeaudhuij¹, G. Cardon¹, M. de Craemer¹, E. de Decker¹, L. Moreno², B. Koletzko³, V. Iotova⁴, Z. Kulaga⁵, T. Lobstein⁶, O. Androustos⁷, Y. Manios⁷, on behalf of the Toy-Box-Study Group

⁵Children's Memorial Health Institute, Warsaw, Poland

⁶International Association for the Study of Obesity, IASO, London, UK

⁷Harokopio University, Athens, Greece

Background and objectives: This study aims at investigating physical activity and sedentary behaviours in a large sample of European pre-school children.

Methods: The ToyBox-study is a cluster-randomized intervention with a pre- and post-test design targeting pre-school children, their parents and their teachers. Parent questionnaires were gathered at baseline from 8709 preschool children (2 to 5 year olds) out of six European-countries: Belgium, Bulgaria, Germany, Greece, Poland and Spain.

Results: About 33% of parents report that their pre-school child is a member of a sports club, from 12% in Spain to 48% in Germany. Most popular sports were swimming (28%), pre-school gymnastics (22%) and dance (11%). About 37% of pre-school children walk to school, while 52% are brought by car: but only 16% were walkers in Belgium and 55% were walkers in Spain. About 25% of the pre-schoolers have a TV in their bedroom, ranging from 69% in Bulgaria to 6% in Germany, while 14% have a computer in their bedroom, ranging from 44% in Bulgaria to 2% in Germany. At weekdays, only 2% of German children watch more than 2 hours per day of TV, while highest levels were found in Bulgaria (10%) and Greece (14%). Weekend, numbers are much larger: 36% of Greek and Bulgarian children watch over 2 hours TV per day, followed by Spain

(30%), Poland (28%) and Belgium (26%). Only 7% of German children watch more than 2 hours/day of TV at weekends.

Conclusions: Results show large differences in physical activity and sedentary habits in pre-school children across European countries. Interventions should be tailored to country and cultural characteristics.

Acknowledgement: The ToyBox-study is funded by the Seventh Framework Programme (CORDIS FP7) of the European Commission under grant agreement n° 245200.

Key words: Physical activity, sedentary behaviour, TV viewing, computer use, ToyBox.

PRE-SCHOOL CHILDREN'S FOOD INTAKE AND SNACKING HABITS AND THEIR DETERMINANTS

⁶International Association for the Study of Obesity, IASO, UK

⁷Harokopio University, Athens, Greece

Background and objectives: This study aims at describing food intake and snacking habits in a large sample of European pre-school children.

Methods: The ToyBox-study is a cluster-randomized intervention with a pre- and post-test design targeting pre-school children, their parents and their teachers. Parent questionnaires were gathered at baseline from 8466 preschool children (2 to 5 year olds) in six European-countries: Belgium, Bulgaria, Germany, Greece, Poland and Spain.

Results: Water is the most frequently consumed beverage (90%) overall and in each country. For other beverages, in Bulgaria, Greece and Spain fresh home-made fruit juice is largely consumed (around 10%) after water, whereas in Belgium light beverages (13%) and in Germany fruit juice (pre-packed/bottled) (15%) are more often consumed. Around 18% of the parents state their child can drink soft drinks or pre-packed juices whenever he/she asks, ranging from 7% in Greece to 18% in Poland. 75% of the parents report that their child likes to eat fruits or vegetables as a snack ranging from 43% in Spain to 86% in Germany, and 67% reported to be pleased with my child's snacking behaviour (52% in Poland to 76% in Belgium). Fruit and vegetables followed by milk (plain) are the most

commonly reported daily consumed snacks (82% and 74% respectively). Fruit and vegetable consumption as snacks varies from 74% in Greece to 89% in Germany. Consumption of milk (plain) varies from 48% in Bulgaria to 88% in Spain.

Conclusions: Variations in parental attitudes and food intake and snacking habits of pre-school children across European countries should be considered when developing intervention programs at European level.

Acknowledgement: The ToyBox-study is funded by the Seventh Framework Programme (CORDIS FP7) of the European Commission under grant agreement n° 245200.

Key words: Food intake, snacking, pre-school, children, ToyBox.

DEVELOPMENT AND IMPLEMENTATION OF THE TOYBOX INTERVENTION

B. Koletzko¹, J. Birnbaum¹, C. Geyer¹, A. Payr¹, K. Duvinage¹, I. de Bourdeaudhuij², V. Iotova³, L. Moreno⁴, T. Lobstein⁵, Y. Manios⁶, P. Socha⁷

⁴University of Zaragoza, Zaragoza, Spain

⁵International Association for the Study of Obesity, London, UK

⁶Harokopio University, Athens, Greece

⁷Children's Memorial Health Institute, Warsaw, Poland

Objectives: Overweight in early childhood is an increasing public health problem and needs effective preventive intervention. ToyBox is an innovative and evidence based obesity prevention intervention scheme for children aged 4-6 years.

Methods: The development of the ToyBox intervention is guided by a stepwise process following an intervention mapping protocol. This includes the systematic assessment of children's energy balance-related behaviours and their determinants, educational strategies and behaviour models by doing systematic reviews, secondary data analyses and focus group research, as well as adoption of established successful models for prevention in this setting. A review of policies, legislation, regulations and existing health promotion activities also guided the intervention development. After identifying objectives and determinants, effective methods and strategies are designated and operationalized into practical tools. Finally a plan for the implementation was drafted. The intervention was implemented in kindergarten settings in six European countries with children from different sociodemographic backgrounds. Teachers performed the developed activities with setting their

priorities on different behaviours. Parents were addressed via targeted materials.

Results: A feasible and attractive intervention programme was developed with different tools directed towards children, teachers and parents addressing four key behaviours and implemented in six European countries.

Conclusion: Developing an international intervention program is a complex process that should follow a systematic approach. It requires effort and time to develop strategies and methods addressing different conditions in participant countries. During implementation, close communication with partners is needed.

Acknowledgement: The ToyBox-study is funded by the Seventh Framework Programme (CORDIS FP7) of the European Commission under grant agreement n° 245200.

PS3-28 Role of dietary macronutrients on weight management. Role of protein and glycemic index in body weight regulation – Lessons from the Diogenes intervention study

BENEFITS AND MECHANISMS OF MODERATELY MIGHT PROTEIN AND HIGH FIBER INTAKE IN BODY WEIGHT LOSS AND MAINTENANCE

J.A. Martínez Hernández^{1,2}

¹University of Navarra, Pamplona, Spain

²CIBEROBN

Overweight and obesity management have been mainly focused on reducing food intake or increasing energy expenditure (or both) by following different dietary or behavioural strategies. Thus, very low calories diets (VLCD), low energy programmes (LED), low 'carb' or low fat energy-restricted or 'at libitum' strategies have been prescribed in order to induce body fat losses. In recent years, the role of the macronutrient distribution in slimming dietary approaches is receiving much attention. Indeed, foods with a low glycaemic index and moderately high protein dietary patterns have been shown effective in weight reduction. The mechanisms that have been claimed to explain such body weight lowering are reduced appetite, increased thermogenesis and lower energy efficiency. Interestingly, a combination of high protein (30% E) and fiber intake (low GI) as designed in the DIOGENES project have produced healthy associated benefits not only on body fat deposition, but also on the lipid profile and inflammatory markers in both adults and children. It can be concluded that the amount and distribution of specific macronutrients within hypocaloric diets may be important in designing weight loss programs, but

it is envisaged that the nutrient quality (specific carbohydrates, fatty acids and amino acids) will have an impact on tackling the obesity burden. This research is part of the DIOGENES project (EU Contract no. FP6-513946).

²Section for Epidemiology, Department of Public Health, Aarhus University, Århus, Denmark

³Danish Cancer Society, Research Center, Baandrup, Denmark

⁴NUTRIM School for Nutrition, Toxicology and Metabolism, University of Maastrich, Maastricht, The Netherlands

⁵Department of Nutrition, Exercise and Sports (NEXS), Faculty of Science, University of Copenhagen, Copenhagen, Denmark

Background and objectives: Physiological evidence indicates that high protein diet may increase satiety, thermogenic response and decrease subsequent caloric intake. Thus diet high in protein might prevent weight gain and weight-regain following weight loss. Clinical trials, including the Diet, Obesity and Genes trial (DiOGenes), show such effect. Large-scale, long-term, observational cohort studies suggest the opposite effect i.e. higher protein diets may increase body weight. Discrepancy between trials and cohort studies could be that individuals recruited for trials are a subset of the population in cohort studies important for the effect of protein. The aim of this study is to investigate explanations of the discrepancy by analyzing different subsets on participants in a cohort study.

Methods: Subsets (n=1872) of the Diet, Cancer and Health (DCH) cohort (n=57.055) comparable with the DiOGenes trial (n=548) was selected based on inclusion criteria of DiOGenes, matching DCH-participants with DiOGenes-participants on exposure and different possible effect-modifiers and finally analyzed similar to the DiOGenes trial. **Results:** When matching on intake of protein, carbohydrates, glycemic index and on body fat % a high protein intake was associated with better weight maintenance compared with low protein intake indicating similar effect as the DiOGenes trial. However, the association of protein on weight change did depend on matching criteria and the statistical analysis.

Conclusions: The association between dietary protein intake and subsequent body weight changes appears to depend on the selection characteristics of the participants and the statistical analysis, which may reconcile the otherwise contrasting evidence from physiological and clinical human experiments and large-scale cohort studies.

Key words: Protein, weight control, study design, opposing evidence.

CAN WE PREDICT WEIGHT LOSS AND WEIGHT MAINTENANCE SUCCESS USING THE GENOMICS AND METABOLICS TECHNOLOGIES: THE DIOGENES STUDY

W H M. Saris

Nutrition and Toxicology Research Institute NUTRIM, University of Maastricht, Maastricht, The Netherlands

In recent years significant progress have been achieved in the elucidation of how nutrition influence energy homeostasis using the genomic/metabolomics tools. No topic can so vividly illustrate this progress as the role of energy balance in body weight regulation. DIOGENES (full title “Diet, Obesity and Genes”) is one of the largest multi-centre weight loss and maintenance dietary RCT on obesity sponsored by the European Union (FP6-2005-513946). This dietary intervention trial across 8 centres in Europe consisted of an 8-week weight loss (LCD) phase (minimal 8 kg loss) and a 6-month weight maintenance phase, where subjects were allocated to five different diets varying in protein content and glycemic index. Measurements of candidate genes, GWAS, adipose tissue transcriptomics and plasma proteomics and metabolomics were executed or planned. This information will be linked to phenotypical data from the weight loss and weight maintenance period in order to predict outcome success from baseline measurements. Some examples will be presented about the candidate genes, adipose tissue transcriptomics and the metabolomics profiles in relation to weight loss and maintenance success. In general predic-

tion of the weight loss success based on the baseline metabolomic profile was better in the morbid obese subgroup (>40 BMI) compare to the obese group (27 – 40 BMI). The combination of ~10 clinical parameters & metabolites measured by NMR and lipidomics and phenotypical data predict weight loss in morbid obese individuals with a performance of ~60%. Analysis of the candidate gene variants or GWAS did not reveal any significant effect. Most probably the lack of power or the very well controlled negative energy balance using a LCD, leaving little room for metabolic variation can explain these negative results.

Key words: Prediction weight change, Protein, Glycemic index, Genomics, Metabolomics.

PS3-36 ISCOLE: International Study of Childhood Obesity, Lifestyle and the Environment

BACKGROUND, RATIONALE AND STUDY DESIGN OF THE INTERNATIONAL STUDY OF CHILDHOOD OBESITY, LIFESTYLE AND THE ENVIRONMENT

P. Katzmarzyk, T. Church

Pennington Biomedical Research Center, Pennington, USA

The primary aim of the International Study of Childhood Obesity, Lifestyle and the Environment (ISCOLE) is to determine the relationship between lifestyle characteristics and obesity in children, and to investigate the influence of behavioural settings and physical, social and policy environments on the observed relationships within and between countries. The targeted sample includes 6000 10-year old children from twelve countries in all major regions of the world (Asia, Africa, Europe, South America, North America, and Oceania). The protocol includes procedures to collect data at the individual level (lifestyle, diet and physical activity questionnaires, accelerometry), family and neighborhood level (parental questionnaires and Geographic Information System (GIS) analyses), and the school environment (school administrator questionnaire and school audit tool). A standard protocol has been developed for implementation in all regions of the world. Quality control is addressed through the training and certification of personnel, active monitoring of remote data entry, and site visits. A rigorous system of training and certification of personnel has been developed and implemented, including web-based training modules and regional in-person training meetings. Unique features of the ISCOLE study include the global representation of study sites with a range of low to high income countries at different stages of nutritional transition, robust, standardized training and data collection methods, and the multi-level nature of data being collected, including individual, family, neighborhood, and school levels. The results of this study will provide a robust examination of the correlates of body weight

and obesity in children. The results will also provide new information to inform the development of lifestyle, environmental, and policy interventions to address childhood obesity that can be culturally adapted for implementation around the world. ISCOLE represents an international collaboration among all world regions, and represents a global effort to increase research capacity and infrastructure in childhood obesity.

Key words: Childhood obesity, diet, lifestyle, physical activity.

ISCOLE – PORTUGAL: PRELIMINARY DATA ANALYSIS LINKING WEIGHT STATUS AND THE ENVIRONMENT

J. Maia, D. Santos, T. Gomes, F. Santos, R. Chaves, M. Souza, A. Borges, S. Pereira

Faculty of Sport, University of Porto, Porto, Portugal

The primary aims of this presentation are fourfold: (i) present the organizational structure and implementation of ISCOLE in Portugal; (ii) show how schools, parents and children reacted to the study challenges; (iii) illustrate how the data collection was completed to achieve milestones, and (iv) demonstrate how parents, children, physical education teachers, and schools' directors were provided with feed-back reports. Further, preliminary data analysis will be presented concerning the prevalence of overweight and obesity, and their dependence of environmental conditions, namely school settings and family surroundings, using a multilevel approach. Finally, we will offer a first overview of CINE WIZARD, a user-friendly software that is being developed to analyze and graphically display several capabilities of dealing with the complexities of physical activity patterns and their eventual links to obesity in children.

Key words: Childhood obesity, diet, lifestyle, physical activity.

THE INTERNATIONAL STUDY OF CHILDHOOD OBESITY, LIFESTYLE AND THE ENVIRONMENT: PRELIMINARY RESULTS FROM KENYA

V. Onywera¹, J. Wachira¹, S. Muthuri², M. Tremblay²

¹Department of Recreation Management and Exercise Science, Kenyatta University, Nairobi, Kenya

²Healthy Active Living and Obesity Research Group, Children's Hospital of Eastern Ontario Research Institute, Ontario, Canada

Childhood obesity is now a major public health challenge globally. The problem is currently on a rapid increase in developing countries, including Kenya and the problem is thought to be exacerbated by the emergence of western lifestyles which increases sedentarism and access to nutrient-poor, energy dense foods. Kenya was one of the countries that participated in the International Study of Childhood Obesity, Lifestyle and the Environment (ISCOLE). This presentation is guided by the following broad objectives:

1. To describe Kenya and the Kenyan ISCOLE sample.
2. To describe the challenges, lessons and possibilities of conducting a study in a developing country.
3. To describe the school results feedback mechanism (report) and show how capacity building took place through the ISCOLE.
4. To present some statistics of body composition (underweight, normal weight, overweight and obesity) in relation to gender, environment and socio-economic status.
5. To describe on-going advocacy to address childhood overweight and sedentary lifestyle in Kenya. In conclusion, it is envisaged that Kenya, a country going through the physical activity and nutrition transition, will draw significant public health lessons from the ISCOLE study.

Key words: Kenya, childhood, obesity, physical activity.

INTERNATIONAL STUDY OF CHILDHOOD OBESITY, LIFESTYLE AND THE ENVIRONMENT (ISCOLE): METHODS AND PRELIMINARY RESULTS FROM COLOMBIA

O. Sarmiento¹, A. Ramirez¹, S. Gonzalez¹, R. Gamez²

¹Universidad de Los Andes, Bogotá, Colombia

²Instituto Distrital de Recreación y Deporte de Bogotá, Bogotá, Colombia

The increasing prevalence of overweight and obesity in children and adolescents in middle income countries is a public health concern. The objective of this study was to determine the factors associated with childhood obesity in Bogotá, Colombia as part of the International Study of Childhood Obesi-

ty, Lifestyle and the Environment (ISCOLE). A cross-sectional school-based multilevel study was conducted in the year 2012. Twenty schools were randomly selected from a sampling frame stratified by socioeconomic status and private vs. public status. The study included 905 10-year-old children with a response rate of 75.5%. Data collection included characteristics of the children (lifestyle, diet and physical activity questionnaires, and accelerometry), family, neighborhood and school environment. An ancillary study to assess reproducibility and validity of the ISCOLE Food Frequency Questionnaire (FFQ) was conducted in a subsample of 128 children with a response rate of 89.1%. Children, parents, and teachers received feedback reports regarding nutrition status and physical activity. In addition, a course of healthy habits was given to children after finishing data collection.

Key words: Children, obesity, nutrition, physical activity.

METHODS OF MEASURING OVERWEIGHT AND OBESITY, AMONG 6-9 YEARS SCHOOL CHILDREN IN ALAIN CITY, UAE

S. Washi¹, A. Al Dhahiri¹, C. Platat¹, H. Ali¹, E. Masuadi², A. Jarar¹, F. Helou¹, I. Tewfik³

¹Department of Nutrition & Health, United Arab Emirates University, AlAin, UAE

²Department of Statistics, United Arab Emirates University, AlAin, United Arab Emirates

³School of Biosciences, University of Westminster, London, UK

Childhood overweight and obesity is now becoming a major clinical and public health concern contributing to increasing morbidity and mortality rates for several chronic diseases. Obesity has been attributed to unhealthy lifestyle behavior, resulting from unbalanced diet, sedentary lifestyle and inconsistent knowledge, attitude and behavior. Our study aimed to test several anthropometric methods used to determine overweight and obesity among 6-9 years school children in a pilot cluster-randomized intervention study designed to address childhood obesity and its related risk factors. Methods used were weight and height; body mass index; biceps and triceps skinfold thickness; MUAC; waist and hip and waist-hip circumference ratio. The visibility and accuracy of these methods were discussed. The classification of overweight and obesity based on weight and height and body mass index (BMI) for school children was highlighted. Results indicated that out of the 1073 children participated in the study pre-intervention, the majority (71.8%) had normal body mass index (BMI). An equal percentage of children were classified as underweight (7.4%) and overweight (7.4%), while 13.5% were categorized as obese. At baseline, the average weight for all children participating in this study was 24.0 kg while the average height was 1.21 m. Mean BMI was

16.2 kg/m². Anthropometric assessment indicates that the average measurements for biceps, triceps skin fold thickness and mid-upper arm circumference at baseline were 6 mm; 10.6 mm; and 17.2 mm respectively. Average waist and hip circumference measurements for all children pre-intervention were 54cm and 64cm respectively. No significant differences were found in those measurements pre and post intervention. Never the less, this pilot school-based intervention proved effective and can be deployed to combat obesity at larger scale or community level. Behavior modification, environmental factors and supportive public health nutrition policy are pivotal factors in managing obesity effectively.

Key words: Anthropometry, obesity, school children, UAE.

PS4-44 Nutrition in inflammatory bowel diseases. From basic to clinical application

ARTIFICIAL NUTRITION IN INFLAMMATORY BOWEL DISEASE: NUTRITIONAL THERAPY AND BEYOND?

E. Cabré

Hospital Universitari Germans Trias I Pujol, Barcelona, Spain

Since the pioneer trial by O'Moráin et al. in 1984 comparing steroids and an elemental diet in active Crohn's disease the possibility that enteral nutrition could be used as primary treatment (i.e. able, per se, to induce remission) in this disease has been a matter of debate. Four meta-analyses of the RCTs comparing enteral nutrition vs. corticosteroids in active Crohn's disease agree that steroids are better than enteral nutrition in inducing remission, but also indicate that, as a whole, enteral nutrition is able to induce clinical remission in about 50%-60% of patients, a remission rate substantially higher than that obtained with placebo in active Crohn's disease, which hardly achieves 30%. Therefore, this suggests that enteral nutrition (or, at least, some enteral formulas) would have a primary therapeutic effect in active Crohn's disease (or, at least, in some subset of patients). This could be particularly relevant in paediatric patients as suggested by two meta-analyses of data from exclusively paediatric trials which conclude that in these patients enteral nutrition is as effective as steroids in inducing remission. The wide range of remission rates obtained in different trials indicate that not every enteral diet is equally effective in inducing and/or maintaining remission. However, the mechanisms whereby enteral nutrition would have these effects remain obscure. To date, the amount and/or the type of dietary fat appears as a major candidate to account for the therapeutic effect of enteral nutrition in Crohn's disease. Experimental and clinical studies suggests that diets with very low fat content may be particularly useful. Also, diets with a substantial amount of

fat as either olive oil or MCT could be effective. Omega-3 fatty acids have been scarcely evaluated in this setting.

Key words: Crohn's disease, inflammatory bowel disease, enteral nutrition, olive oil, omega-3 fatty acids ulcerative colitis.

PS4-52 International Life Sciences Institute (ILSI) Session on Food Allergy

FOOD ALLERGY RELATED PROBLEMS AND THEIR SCIENTIFIC SOLUTION

Introduction to ILSI's Food Allergy Programmes

D. Bánáti

International Life Sciences Institute (ILSI) - ILSI Europe, Brussels, Belgium

Operational management of allergens still suffers from the lack of an agreed set of reference values defining a tolerable level of risk. Food allergy is of growing importance to public health, affecting consumers' quality of life (mainly children) and impacting health service resources. The symptoms range from a tingling sensation in the mouth to life-threatening anaphylactic shock. An agreed set of tolerable levels of risk is still missing. Minimising the risk from allergenic foods is a shared responsibility of all the stakeholders involved (patients, clinicians, food manufacturers, retailers, caterers and regulators).

This ICN session will provide an overview of the global effort that has been undertaken to review new low-dose challenge data and tools to analyse these data and apply them to quantitative risk assessment. ILSI Europe together with ILSI North America and ILSI Japan organized a Workshop on "Food Allergy: From Thresholds to Action Levels", in September 2012, to share the work of global experts and to foster a consensus over the feasibility of defining reference values.

The ILSI North America Technical Committee on Food and Chemical Safety supported the Food Allergy Resource and Research Program's (FARRP) approach to focus on probabilistic risk assessment for establishing thresholds and commissioned a peanut data set that FARRP researched and published in 2010. This research led to further opportunities for data acquisition by the TNO (Netherlands), ILSI Europe, and the Allergen Bureau of Australia (VITAL).

Recent research on the consumer's perspective on living with food allergies will be presented. An overview of scientific approaches to evaluating novel proteins expressed in biotech products and the development of reliable and accurate methodologies for characterizing the allergenic potential of novel proteins will also be discussed.

PS5-60 Maternal nutritional supplementation of HIV-infected women during lactation: Implications for maternal and infant health in resource-poor settings

EFFECTS OF MATERNAL NUTRITION SUPPLEMENTATION AND ANTI-RETROVIRALS ON NUTRITIONAL STATUS AND BREASTMILK COMPOSITION OF HIV-INFECTED WOMEN IN THE BAN STUDY

L. Adair

University of North Carolina at Chapel Hill, Chapel Hill, USA

The Breastfeeding, Anti-retrovirals, and Nutrition (BAN) study was designed to (1) evaluate the safety and efficacy of maternal or infant ARV regimens, taken for up to 28 weeks during exclusive breastfeeding, in reducing mother-to-child postpartum transmission of HIV; (2) evaluate the efficacy of a high-calorie, micronutrient-fortified lipid-based nutritional supplement (LNS) for preventing excess maternal weight loss and micronutrient deficiencies during exclusive breastfeeding. At delivery, 2,369 HIV-infected Malawian mothers and their infants were randomized to a 28-week intervention using a 2-arm (LNS vs. no LNS) by 3-arm (maternal, infant, or no ARV) factorial design. Women exclusively breastfed for 24 weeks and weaned by 28 weeks, after which no maternal LNS or ARVs were provided. The LNS provided RDA levels of micronutrients and about 700 kcal per day. Weight change from 0-28 weeks was tested using bivariate analysis. Longitudinal models were used to examine the effects of the interventions on weight from 0-28 weeks. In a subsample of 537 mother-infant pairs, micronutrient concentrations were measured in maternal plasma, breast milk, and infant plasma at 2 or 6 weeks, and 24 weeks. Analyses included measures of iron status, vitamin A status, folate and B vitamins. A higher percentage of weight loss from 2-28 weeks was observed in women randomized to receive ARVs, but this adverse effect was mitigated by supplementation with LNS. Similarly maternal plasma folate was reduced by ARVs, but a positive effect of LNS on folate mitigated this effect. Maternal supplement also reduced the risk of maternal tissue iron depletion related to ARVs. Maternal breast milk B-vitamin levels were enhanced by LNS. More attention needs to be paid to maternal nutritional status of lactating women taking ARVs in accordance with current WHO breastfeeding recommendations for HIV-infected mothers.

Key words: HIV, maternal nutrition, micronutrients, LNS.

GROWTH AND MICRONUTRIENT STATUS OF HIV-EXPOSED INFANTS IN THE BREASTFEEDING, ANTIRETROVIRALS, AND NUTRITION STUDY DURING THE FIRST YEAR OF LIFE

V. Flax^{1,2,3,4}

¹University of North Carolina at Chapel Hill, Chapel Hill, USA

²UNC Project

³USDA-ARS Western Human Nutrition Research Center, USA

⁴US Centers for Disease Control, USA

Background and objectives: HIV-infected women typically have poor nutritional and micronutrient status, which negatively impacts the growth and health of their infants during and following breastfeeding. Our aims were to evaluate how micronutrient-fortified maternal lipid-based nutrient supplements (LNS) and maternal/infant antiretrovirals (ARV) affect infant growth and micronutrient status from 0-24 weeks and to describe growth when LNS was used as a breastmilk replacement from 24-48 weeks.

Methods: Malawian mother-infant pairs were randomized to: maternal ARV+maternal LNS, maternal ARV, infant ARV+maternal LNS, infant ARV, maternal LNS, or control. Mothers were counseled to exclusively breastfeed to 24 weeks then wean from 24-28 weeks. Infants were given LNS from 24-48 weeks. Longitudinal models estimated the effect of study interventions on anthropometry from 0-24 weeks (n=2121) and 24-48 weeks (n=1619). Logistic regression was used to calculate the odds of deficiency in plasma micronutrients at 24 weeks (n=519).

Results: From 0-24 weeks, maternal LNS had no effect on infant growth, while maternal or infant ARV had a small negative effect on weight and BMI. The proportion of infants who were underweight (2 and 24 weeks, 6%; 48 weeks, 12%) or stunted (2 weeks, 13%; 24 weeks, 16%; 48 weeks, 34%) increased, but remained lower than for infants in the Malawi Demographic and Health Survey (all p<0.01). Following weaning, assignment to the maternal LNS arm was associated with greater length (p<0.05); fever and diarrhea were associated with lower weight and BMI (all p<0.001). Study interventions were not associated with anemia, iron deficiency, or folate, B12, or selenium deficiency at 24 weeks.

Conclusions: Supplementation of healthy HIV-infected mothers during lactation had a modest post-intervention effect on infant length, but no effect on infant micronutrient status. LNS provided to weaned HIV-exposed infants may prevent more severe growth faltering.

Key words: Infant, growth, HIV-exposed, lipid-based nutrient supplements.

MEETING THE NUTRITIONAL NEEDS OF HIV-INFECTED WOMEN AND INFANTS IN RESOURCE-POOR SETTINGS: PROGRAM AND POLICY IMPLICATIONS

E. Piwoz

Bill & Melinda Gates Foundation, USA

In 2011, UNAIDS and its partners put forward a bold vision: “By 2015 children everywhere can be born free of HIV and their mothers remain alive”. Achieving an AIDS-free generation requires significant investments in scale up of HIV-testing and counseling, increased access to family planning, expansion of antiretroviral (ARV) therapy to improve maternal health and lower risk of mother-to-child transmission, and supportive interventions to maximize the health impacts of these investments. WHO guidelines to prevent HIV infections in children propose two options, maternal AZT prophylaxis during pregnancy followed by infant prophylaxis during breastfeeding (‘option A’) or maternal triple ARV prophylaxis during pregnancy and breastfeeding, with infant ARV prophylaxis for the first 6 weeks only (“option B”). Some countries, such as Malawi, are implementing a modified version of the second alternative, ‘option B+’, which places all HIV-positive pregnant and breastfeeding women on ARV treatment for life. This approach will undoubtedly save many women’s lives and prevent infant infections but data presented in this session suggest that these potent medications alter nutritional status in unexpected ways and that complementary nutritional interventions will be needed. Particular attention needs to be paid to potential ARV and micronutrient interactions in light of findings that breast milk B-vitamins and maternal folate levels were significantly lower in women with prolonged ARV use. Micronutrient-fortified lipid based nutritional supplements (LNS) mitigated the effects of ARV exposure on these outcomes, and also prevented weight loss among HIV-infected women. LNS formulated as a replacement food for infants weaned from breast milk after 6 months was acceptable and protected them from significant growth faltering. These findings strongly support the need to make nutrition a vital component of HIV prevention and treatment policies and programs for success in achieving an AIDS-free generation.

Key words: Maternal nutrition, HIV, ARV treatment.

PS5-68 New insights in obesity, metabolic syndrome and diabetes

GENETIC SUSCEPTIBILITY TO OBESITY AND METABOLIC SYNDROME IN CHILDHOOD

C M. Aguilera, J. Olza, A. Ruperez, A. Gil

Department of Biochemistry and Molecular Biology II, School of Pharmacy, Institute of Nutrition and Food Technology, Centre for Biomedical Research, University of Granada, Granada, Spain

Obesity is one of the major public health problems worldwide. It is a chronic, complex, and multifactorial-origin disease characterised by body fat excess mainly due to an imbalance between dietary intake and energy expenditure. One of the major complications of obesity is metabolic syndrome, which comprises anthropometrical, clinical, and metabolic dysfunctions that predispose the affected individual to the development of type 2 diabetes mellitus and cardiovascular diseases. It is hypothesised that the variability in the susceptibility to obesity-mediated metabolic complications involves both environmental and genetic factors. Whereas advances in the knowledge of the variations in the human genome have led to the identification of susceptibility genes that contribute to obesity and related disorders, relatively few studies have specifically focused on the interactions between obesity and genetic polymorphisms and the development of metabolic complications. Despite these limited efforts, an increasing amount of evidence suggests that the effects of some gene variants on metabolic traits are modified by or present only in the setting of obesity. Furthermore, some of these loci may have larger effects on metabolic phenotypes in the presence of certain dietary or lifestyle factors. In the present manuscript, we reviewed the genes and their variants that have been evidenced to play a role in obesity-associated metabolic complications through genetic association studies, including candidate gene and genome-wide association approaches in adults and children.

Key words: Genes, gene variants, metabolic syndrome, obesity, single-nucleotide polymorphisms.

CIRCADIAN RHYTHMS, FOOD TIMING AND OBESITY

M. Garaulet

Department of Physiology, University of Murcia, Murcia, Spain

Recent studies link energy regulation to the circadian clock at the behavioural, physiological and molecular levels, emphasizing that the timing of food intake itself may have a significant role in obesity. In this regards, there is emerging literature

in animals demonstrating a relationship between the timing of feeding and weight regulation. Unusual feeding time can produce a disruption of the circadian system which might produce unhealthy consequences in humans. In a longitudinal study, we recently showed that the timing of the main meal was predictive of the weight loss during a 20-week dietary intervention and that this effect was independent from total 24-h caloric intake. The importance of caloric distribution across the day on weight loss therapy was supported by a recent 12-week experimental study showing that subjects assigned to high caloric intake during breakfast lost significantly more weight than those assigned to high caloric intake during the dinner.

Furthermore, one of the most influential discoveries relevant for this area of research in the last years is the presence of an active circadian clock in adipose tissue. New data suggest that there is a temporal component in the regulation of adipose tissue functions. In fact, studies performed by microarrays have shown that a substantial percentage of active genes expressed in adipose tissue follow a daily rhythmic pattern. Thus, a specific temporal order in the daily patterns of these genes appears to be crucial for adipose tissue to exclusively either accumulate fat or to mobilize fat at the proper time. Taking into account that feeding is the source of energy for adipose tissue, the time of feeding, particularly for high-energy content meals, may be decisive, and changes in this timing could have metabolic consequences for the development of obesity and for weight loss.

Key words: Circadian clock, circadian rhythms, chronobiology food timing, obesity.

RECENT ADVANCES IN NUTRITIONAL SCIENCES: GENE THERAPY FOR DIABESITY AND THE GENETIC BASIS OF POSTPRANDIAL METABOLISM

R A. Bastarrachea

Department of Genetics, Texas Biomedical Research Institute, San Antonio, Texas, USA

Background and objectives: Here we present two projects: Project A transferred genes involved in islet regeneration to the baboon's pancreas through ultrasound-targeted microbubble destruction (UTMD) therapy. Project B was designed to study whole genome expression analysis before and after a well-defined meal to characterize normal variation in postprandial metabolism.

Methods: Project A-We developed an innovative methodology for gene-based therapy delivered towards a specific tissue or organ, using UTMD technology. These microbubbles work as a noninvasive delivery system that can target specific anatomical sites. Project B-We obtained fasting and post-prandium biopsies of muscle and adipose tissue in the same subject two weeks apart. Each subject provided synchronous measures of

gene expression in vivo in two tissues related to obesity and diabetes pathophysiology.

Results: Project A-We targeted plasmids encoding the cyclin D2/CDK4/GLP-1 genes to the baboon pancreas. We obtained in vivo β -cell regeneration and normalization of blood sugar, insulin, and C-peptide without administering viruses. Project B-We examined 17,128 gene transcripts detectable above background in every subject in at least one tissue type. 78.6% were detectably expressed in two tissues.

Conclusions: Project A-Gene therapy is frequently highlighted as one of the most promising technologies of the 21st century. Results related to enhancing the regenerative capacity of the pancreas acquired from this study are highly innovative and have the potential to be translated to humans. Project B-We have standardized a family-based study for collecting postprandial phenotypes and biopsies. This expression profiling is expected to find genes contributing to the metabolic flexibility of individuals. The genetic response following the consumption of a defined meal at the level of the specific tissues involved (adipose tissue and muscle), will produce new insights into the genetic architecture of individual variation in metabolism of carbohydrates, lipids and proteins.

Key words: Gene therapy, whole genome profiling expression, UTMD, postprandial metabolism.

T5 NUTRIENTS AND NUTRITIONAL ASSESSMENT

NPS1-5 Methods and outcomes of nutritional assessment and health monitoring USING BIOMARKERS FOR THE VALIDATION OF NUTRIENT REFERENCE INTAKE VALUES AND TO VERIFY INTAKE DATA IN NUTRITION SURVEYS

I. Elmadfa^{1,2}, A. Meyer¹

¹Institute of Nutritional Sciences, University of Vienna, Vienna, Austria

²President of IUNS

The determination of nutrient requirements and the derivation of reference intake values for different population groups have been a central area of interest in the nutritional sciences research and development. Over the decades, reference values have been issued for an increasing number of nutrients at the national, regional and international level. Nevertheless, uncertainties still remain about the adequate supply of certain nutrients. This is especially true for potential at-risk population groups such as infants, children, elderly, and pregnant and lactating women. The situation is further complicated by recent discoveries of additional health-promoting functions of certain nutrients beyond mere nutrition. Generally, reference intake values should be based upon the intake of healthy individuals corroborated by status levels. This calls for valid, i.e. specific and sensitive biomarkers. The importance of biomarkers for the setting of reference intake values has been emphasized in the Austrian Nutrition Report 2012 where among others status of folate, vitamin D, and iron was better, that of vitamin B6, B12, and zinc was lower than would have been expected from the intake levels compared to recommended amounts. Functional biomarkers such as enzyme activities often allow an earlier detection of inadequate status than plasma levels. More recently, immune functions are being discovered as sensitive tools as well. However, most nutrients have many functions in the body so that a single biomarker might not adequately reflect status. Another aspect to consider is that normal ranges (cut-offs) of many biomarkers in humans are still not exactly known (plasma levels of 25-OH vitamin D, essential fatty acids in structural lipids). Additionally, genetic and epigenetic influences on absorption, metabolism and storage of nutrients

and levels/activities of functional biomarkers add to inter-individual variation. New biomarkers may open the way to a more personalised nutrition.

Key words: Nutritional assessment, nutritional status, biomarkers, reference intake levels.

IODINE STATUS

P. Emmett¹, S. Bath², C. Steer¹, J. Golding¹, M. Rayman²

¹University of Bristol, Bristol, UK

²University of Surrey, Guildford, UK

Worldwide, iodine deficiency is one of the most important preventable causes of poor brain development. In some industrialized countries (e.g. The Netherlands) iodine deficiency has been eradicated mainly by the introduction of iodised-salt. However in the UK in the 1930s the iodine content of milk increased due to changes in the dairy-farming industry and iodine deficiency disappeared without the introduction of iodised-salt. By the 1960s the UK was thought to be iodine sufficient and the iodine status of the population has not been monitored since then. In the last few years some UK studies have found mild-to-moderate iodine deficiency in a sample of pregnant women and in teenage school-girls and this has started to raise concerns.

The period of great vulnerability to iodine deficiency is at the time of fast brain development, in utero. Severe deficiency of iodine during pregnancy is well-known to result in cretinism and mental retardation but little is known about the effect of mild-to-moderate deficiency. Urinary iodine concentration, measured in a spot urine sample, is a reasonably good population biomarker of iodine status.

The concurrent measurement of creatinine levels to correct for dilution of urine can overcome some of the limitations of this method, especially in studies of subjects of similar age and sex. Food frequency questionnaires can be used to assess diet at a population level but must be designed to capture the intake of the nutrient concerned and to cover likely food sources in the population under study. Results from a UK cohort study of pregnant women and the neurodevelopment of their offspring at age 7-9 years will be discussed. This will be used to illustrate the importance of ongoing monitoring of the diet and health of the population even after a problem has been thought to be eradicated.

Acknowledgement: EC Seventh Framework Program n°FP7-212652-Nutrimenthe.

Key words: Iodine deficiency, nutritional assessment, health monitoring.

PLASMA LEVELS OF FATTY ACID-BINDING PROTEIN (FABP) ASSOCIATED WITH THE ANTIOXIDANT STATUS AND INFLAMMATORY MARKER IN KOREAN CHILDREN

E. Park^{1,2}, E.S. Lyu², J.H. Park¹

¹Department of Food and Nutrition, Kyungnam University, Changwon, Korea

²Department of Food and Nutrition, Pukyong National University, Busan, Korea

Background and objectives: Adipocyte fatty acid-binding protein (A-FABP) has been reported to be increased in obese and to be related to metabolic syndrome. The purpose of this study was to investigate the relationship between plasma level of A-FABP and lipid profiles, insulin resistance, antioxidant, and inflammatory parameter in Korean children aged 9-10 years.

Methods: One hundred seventeen healthy children (66 boys, 51 girls) were evaluated with respect to anthropometric measurement, lipid profiles, A-FABP, leptin, glucose, insulin, C-peptide, free fatty acid, lipid soluble vitamins, total antioxidant capacity, lipid peroxidation, antioxidant enzyme activities, and C-reactive protein. Insulin resistance was estimated by the homeostasis model assessment (HOMA).

Results: It is found that the A-FABP was positively correlated with BMI, waist circumference, plasma level of total-cholesterol, triglyceride, activity of alanine transaminase, C-peptide, leptin, and C-reactive protein, while it was negatively correlated with the plasma level of HDL cholesterol, alpha-tocopherol, lycopene, and beta-carotene. The overweight subjects (n = 15) had higher concentrations of A-FABP compared to the children with healthy weight (n = 79) or at risk of overweight (n = 23). Subjects within the highest tertiles of A-FABP levels had correspondingly poor metabolic risk profiles (BMI, waist circumference, systolic blood pressure, triglycerides, total cholesterol, LDL cholesterol, HDL cholesterol, fasting insulin, C-peptide, HOMA), higher level of leptin and C-reactive protein, and lower levels of alpha-tocopherol, lycopene, and beta-carotene compared with those in the mid or lowest A-FABP tertiles.

Conclusion: These results suggest that the plasma A-FABP level might be closely related with not only metabolic risk profiles, but deteriorated antioxidant and inflammatory markers in children.

Key words: Adipocyte fatty acid-binding protein, metabolic risk profile, antioxidant status, C-reactive protein, children.

EVALUATION OF THE STATUS OF WATER SOLUBLE VITAMINS IN AUSTRIAN PREGNANT WOMEN

P. Rust, I. Elmadfa

Department of Nutritional Sciences, University of Vienna, Vienna, Austria

Background and objectives: Micronutrient requirements during pregnancy increase due to fetal growth and development as well as maternal changes. Several micronutrients play a critical role in development; other can influence inflammation, and oxidative stress. Therefore, the objective of this survey was to evaluate micronutrient status during pregnancy.

Methods: Blood samples of 113 Austrian pregnant women (3rd trimester, 18-43 y) were analyzed. Plasma folate and vitamin B12 concentrations were examined by radioimmunoassay, plasma vitamin B6 and aspartate-aminotransferase in erythrocytes were detected by HPLC and photometrically.

Results: Mean plasma folate concentration was 26.68 [22.99; 30.37] nmol/l. 77.1% of pregnant women reached the reference value of >13.4 nmol/l, 2.9% had a bad supply (<6.8 nmol/l). Average folate intake was 253.72 [227.06; 280.38] µg/d. The satisfying blood levels result from multivitamin supplements, which include without limitations 0.75-0.80 mg folic acid. Because high doses of folic acid are suggested to mask anemia caused by vitamin B12, cobalamin concentrations were measured: mean plasma concentration was 152.09 [141.28; 162.91] pmol/l; 34.3 % showed slightly and 18.6% clearly decreased levels. Although, average intake meets recommendations (4.47 [3.19; 5.75] µg/d) 46.2 % of pregnant women were undersupplied. In all women a marked deficiency of vitamin B6 was observed: mean plasma level was 6.82 [5.86; 7.78] nmol/l; average-EAST 1.88. Mean vitamin B6 intake (0.20 [0.18; 0.22] mg/MJ) was below recommendations.

Conclusions: Estimated folate requirement increases during pregnancy and can barely be reached through food consumption. Therefore, supplementation is recommended to prevent neural tube defect, as well as pathological changes in the placenta, and spontaneous abortion. As results show monitoring of vitamin B6 and B12 levels is also important to protect pregnant women from deficiency outcomes.

REVISION OF CHINESE IODINE DRIS AND SOME ISSUES OF USI

W.Q. Zhang, W. Chen, M. Li, X.L. Ren, Q. Zhang

Department of Nutrition and Food Safety, School of Public Health, Tianjin Medical University, Tianjin, China

The iodine nutrition has greatly improved in China since the Universal Salt Iodization (USI) was introduced and officially launched in 1996. Based on the current iodine status in both China and the world, iodine excess has become an emerging issue which needs to be solved. Further studies are needed to develop specific and accurate iodine intake levels for different populations. During the 2nd revision of Chinese DRIs in 2013, the UL of iodine of adults was decreased from 1000 µg/day to 600 µg/day based on an RCT trial on 256 Chinese euthyroid adults in 2012. However, there is still a dearth of data. So, we reviewed the reports of iodine EAR and RNI from different countries by means of evidence-based nutrition, RNI for Chinese adult was revised based on these data with adjustment by weight. In addition, the iodine RNI for pregnant and lactation women was also revised. Because of the complicated geographical environment, most regions in China are iodine deficiency, whereas 11/30 provinces are high iodine where nearly 30 million people are exposed to iodine excess because high iodine content in drinking water. Many studies found that excessive iodine intake is harmful to health, suggested that the safe range of iodine may be relatively narrow. After the revision of DRIs, emerging issues of USI has drawn great attention. Although the median UIC in school-aged children is typically considered to represent the iodine status of most population, recent studies suggest median UIC may not be an appropriate proxy for iodine status among pregnant women. Pregnant women and their offspring are particularly vulnerable to iodine deficiency. It is of great importance to develop safe and suitable iodine intake level for the vulnerable populations. Therefore, iodine supplementation policy should be continually carried out to control iodine deficiency and avoiding excess as well.

INDICATORS OF A HEALTHY AGING AND AGE RELATED FRAILITY

H. Boeing

German Institute of Human Nutrition, Postdam, Rehbrücke, Germany

Large scale epidemiological research might become a very valuable resource for studying aging. It is therefore the question which methods should be applied in such study populations to promote research into the elderly.

Indicators of a healthy aging can be divided into indicators describing mental or physical performance. For the estimate of mental performance respective cognitive decline, the Mini-Mental-State-Examination (MMSE) is widely been used. The test can be conducted in about 10 minutes. Physical status and its decline with aging are reflected in the concept of frailty. Frailty is a syndrome with decreased reserves and resistance to stressors. A high index of frailty is associated with increased disability, co-morbidity and risk of mortality. Frailty is composed of shrinking of muscle mass, weakness, poor endurance, slowness, and low physical activity. These aspects can be evaluated by a battery of tests and questions and the degree of frailty in each individual can be assessed by a score value.

There are several proposals for measuring each of the aspects: Shrinking of muscle mass by questions on weight change and applying multi-frequency bio impedance analysis, weakness by hand craft, endurance by Health Survey questions (SF), slowness by walking speed, and physical activity by accelerometry. Particularly useful for evaluation of frailty status in the future could be the new generation of actimeters measuring movements in 3 dimensions with high frequency. These devices might not only record physical activity in detail but the raw data can be used for pattern recognition analysis estimating walking speed under natural condition and gait characteristics including impairments. The application of specific measurement tools for aging and age related frailty in existing frameworks of longitudinal studies will facilitate research into healthy aging in the next future.

Key words: Cognition, nutritional assessment, health monitoring, Mini-Mental-State-Examination.

NUTRITIONAL STATUS ASSESSMENT, A CONTINUOUS CHALLENGE

I. Elmadfa^{1,2}, A. Meyer¹

¹Institute of Nutritional Sciences, University of Vienna, Vienna, Austria

²UNS President

Optimal supply of essential nutrients is the basis for health and wellbeing. Although obesity prevalence is increasing alarmingly worldwide, malnutrition is common not only in low-income countries. In fact, insufficient intake of certain micronutrients and overconsumption of macronutrients often occurs in obese persons contributing to diseases associated with excessive bodyweight. In turn, undernutrition exists in many parts of the World, especially in vulnerable population groups. Good knowledge of the nutritional situation of the target population is essential for the development of effective solutions to malnutrition calling for reliable assessment methods. While biochemical analysis certainly provides the best picture of an individual's actual status, the necessary equipment, trained staff and expenses present a limiting factor especially in large field trials where dietary assessment is generally preferred despite its many weaknesses. Rapid turnover or tight control of nutrient concentrations in blood limits their sensitivity as biomarkers as in the case of many trace elements. The existence of different forms of a micronutrient in the body adds further complexity. Functional biomarkers such as enzyme activities mirror long-term status better, but are subject to confounding factors. Moreover, markers like hemoglobin and homocysteine levels are influenced by several micronutrients, i.e. not specific for only one, therefore using a combination of biomarkers is advisable. Considering the role of many nutrients for immune functions, there has been increasing interest in using these latter as nutritional biomarkers (e.g. for Cu or Zn). Another option comes in the form of molecular biomarkers such as mRNA transcripts e.g. for Se status. Finally, a question concerns the setting of reference values and cut-off points. Recent advances in genetic research have revealed the impact of genes on nutrient status and requirements resulting in a wide inter-ethnic and interindividual variance of certain biomarkers due to polymorphisms.

Key words: Nutritional assessment, nutritional status, biomarkers, micronutrients.

PS1-5 The SMILING Project: A South East Asian-European collaborative action to prevent micronutrient deficiencies in women and young children in South-East Asia

FOOD FORTIFICATION IN FIVE SOUTHEAST ASIAN COUNTRIES: THE SMILING PROJECT

P. Winichagoon¹, J. Berger², F. Wieringa², E. Wasantwisut¹, C. Chamnan³, M. Chea⁴, Siti Muslimatun⁵, S. Kounnavong⁶, L. Bach Mai⁷, for SMILING consortium

⁵Regional Center for Food and Nutrition, The Southeast Asian Ministers of Education Organization, University of Indonesia, Jakarta, Indonesia

⁶National Institute of Public Health, Vientiane, Laos PDR

⁷National Institute of Nutrition, Hanoi, Vietnam

Background: Food fortification is one of nutrition interventions considered by all SEA SMILING countries.

Method: A 3d-workshop on Food fortification was organized to compile information related to food fortification, namely, target groups, food vehicles, fortificants and existence of specific policy and implementation; strengths and weaknesses of the policy and programs were identified. A 2d advocacy meeting resulted in recommendations on further actions to improve effectiveness of food fortification programs.

Results: Common to all countries is the mandatory iodization of salt, although it was stopped and being revived in Vietnam. Additional mandatory fortification exists in Indonesia and Thailand. Indonesia has iron & zinc fortification of wheat flour, multiple fortified complementary foods, and vitamin A fortification of cooking oil. Thailand has iodization of fish/soy sauce and vitamin A fortification of sweetened condensed milk. Four countries (except Laos) have voluntary fortification of condiments, staples and complementary foods as a public health strategy. All countries have implemented food-based strategies as one of the nutrition programs, such as food-based dietary guidelines, food security for nutrition, nutrition education communication. However, they are not necessarily specific to micronutrient deficiencies. The meeting recommended that food fortification will be an important intervention. There should be a national level food fortification committee which

may be a subcommittee of the national nutrition committee, or an independent one if the national nutrition committee does not exist. A functional and active secretariat to the national food fortification committee is essential to coordinate the multi-sectoral efforts as well as partnering with academic, non-government and international organizations. Food fortification should be advocated to the current ASEAN committee on food security to support the exchange of knowledge, expertise, resources in laboratory (crucial for quality assurance) and capacity building.

Conclusion: Food fortification is an important intervention to alleviate micronutrient deficiencies in children and women in SEA SMILING countries. Key challenges in scaling up as a national program include establishing a functional national food fortification committee to formulate and oversee a comprehensive program, a monitoring system for quality assurance and capacity building. Harmonizing efforts in food fortification among ASEAN countries will benefit the countries within and beyond SEA SMILING countries.

THE SMILING PROJECT: A NORTH-SOUTH-SOUTH COLLABORATIVE ACTION TO PREVENT MICRONUTRIENT DEFICIENCIES IN WOMEN AND YOUNG CHILDREN IN SOUTH-EAST ASIA

J. Berger

Institute of Research for Development (IRD), France

Background and objectives: Micronutrient deficiencies prevent a third of the world's children from reaching their intellectual and physical potential. Because of their enormous impact on health, and human and economic development, micronutrient interventions are recognized among the most urgently needed and the most cost-effective interventions. The objective of the SMILING project 'Sustainable Micronutrient Interventions to Control Deficiencies and Improve Nutritional status and General Health in Asia' is to support the transfer of state-of-the-art knowledge in nutrition to public and private stakeholders, and policy-makers. It aims at improving the micronutrient status of women of childbearing age and young children on a large scale.

Methods: SMILING is a transnational collaboration of eleven research institutions and implementation agencies in five South-East Asia (SEA) countries - Cambodia, Indonesia, Lao's PDR, Thailand and Vietnam, with five European research organizations. SMILING has been built around a strong project consortium that works on a constant and pro-active exchange of data and analyses between partners and allows for the differences in contexts and development stages of the countries, a strong North-South-South collaboration and co-learning. SMILING is applying innovative tools that support nutrition policy making and programming.

Results: The Major expected outcomes are (i) to identify appropriate, efficient, and sustainable interventions adapted to each target countries; (ii) to develop a road map for decision makers and donors for integration of these priorities interventions into the national policy plans; and (iii) to raise awareness on the magnitude of micronutrient deficiencies and advocate for their prevention among the civil society, communities, non-governmental and international organizations, public and private sectors.

Conclusion: Main results will be presented during the symposium Project funded by the European Commission in the 7th Framework Programme for Research and Technological Development (GA 2896 16). Web site: www.nutrition-smiling.eu

Key words: South-East-Asia, micronutrient deficiencies, large-scale strategies, policy.

SEA COUNTRY SITUATIONS FOR MICRONUTRIENTS: PRIORITY PROBLEMS AND NATIONAL/SPECIFIC PROGRAMS

⁷NIN - National Institute of Nutrition, Ministry of Health, Hanoi, Vietnam

⁸VU - Institute of Health Sciences, University of Amsterdam, Amsterdam, The Netherlands

⁹IRD - Nutripass, Institut de Recherche pour le Développement, Montpellier, France

Background and objectives: The success of interventions to control micronutrient deficiencies rely on a combination of the biological efficacy of enhancing nutrient intake and the effectiveness to reach target groups. The objective of the review was to compile information on nutritional status and micronutrient intervention efforts in the five 'SMILING' countries, and hereby identify priority problems to be targeted.

Methods: SMILING partners in Cambodia, Laos PDR, Indonesia, Thailand and Vietnam systematically compiled available national and sub-national information on nutritional status in children and women in reproductive age (WRA), along with information on national and sub-national interventions specifically targeting micronutrient deficiencies.

Results: Information on micronutrient status in the SMILING countries varied widely. Recent data are available in some countries while others are decade old or lacking. Information on growth (stunting, wasting) is more consistently available. Except Thailand, the SMILING countries implement vitamin A supplementation for under-five children, and all countries have programmes for supplements containing iron-folic acid (IFA) for pregnant women, with variable coverage. Multimicronutrient (MMN) interventions to children or WRA have not been adopted nationally by any countries, but are implemented in selected pilot sites in a few. Micronutrient interventions specifically reaching WRA before pregnancy are recognized as beneficial but national programmes are lacking. Food fortification programmes are rapidly developing, and it may be implemented either mandatory or voluntarily. There is a growing attention that sustainable solutions rely on improving diets eg through agriculture production.

Conclusion: Stunting and micronutrient deficiencies existed in all SMILING-countries, with varying severity. Programmes to address these problems have been implemented, but impact may not be carefully evaluated. National surveys should be carried out to more consistently contribute to evaluate performance of national priority programmes. Food-based strategies may include scaling-up food fortification, along with incorporating nutrition objective in agriculture.

Key words: Micronutrient deficiency, children, women, Asia.

STATE-OF-THE-ART OF INTERVENTIONS TO CONTROL MICRONUTRIENT DEFICIENCIES IN CHILDREN AND WOMEN

⁸MU - Institute of Nutrition, Mahidol University, Bangkok, Thailand

⁹IRD - Nutripass, Institut de Recherche pour le Développement, Montpellier, France

Background and objectives: The objective of the review of the State-of-the-art of interventions to control micronutrient deficiencies was to support the understanding of micronutrient status in the light of national efforts to control micronutrient deficiencies in the five 'SMILING' countries. The present knowledge about the efficacy and effectiveness of interventions targeting children and women in reproductive age (WRA) was reviewed.

Methods: For children under five, a systematic review of published systematic reviews and meta-analysis of the efficacy and effectiveness of interventions was conducted through a search strategy in PubMed. For WRA, an expert review was compiled assessing potential interventions to improve micronutrient status in WRA, and when possible, impact was quantified.

Results: The review on children found vitamin A supplementation reduced vitamin A deficiencies and MMN supplementation increased serum vitamin A. Iron supplementation as well as MMN supplementation/food fortification were protective against anemia. Zinc and MMN tended to show protective associations with faltered linear growth, while no systematic reviews supported a protective association between vitamin

A or iron on child growth. For WRA, evidence shows that supplementation programs need to be started before 12 weeks of pregnancy to be effective. It is unclear whether MMN render more benefits than Iron-Folic-Acid (IFA) only. Interventions enhancing intake before conception are more effective than targeting pregnant women, and when suitable food vehicles are available, fortification is more effective than supplementation.

Conclusion: The systematic reviews found inconclusive results regarding the effectiveness of single nutrient supplementation on micronutrient status and child growth, while positive impact of multimicronutrient (MMN) supplementation or fortification on growth were more consistent. Increasing micronutrient intake of women before conception, either through supplementation or fortification, could be an effective tool to reduce severe anemia in pregnancy and improve birth outcomes, but research on effective interventions is needed

Key words: Micronutrients, children, women.

PS2-13 Harmonization of human zinc requirements and country experiences in assessing population zinc status

HARMONIZATION OF ESTIMATES OF HUMAN ZINC REQUIREMENTS, INCLUDING SAFE UPPER INTAKE LEVELS

K. Brown

University of California, Davis, USA

Several expert committees and international advisory groups have published estimates of human zinc requirements, but these estimates lack consistency because they are based on different conceptual frameworks and/or statistical techniques and they rely on diverse sources of empirical information. This lack of uniformity in estimated requirements undermines their usefulness for developing dietary recommendations and assessing dietary adequacy. The US Institute of Medicine (IOM) and the International Zinc Nutrition Consultative Group (IZiNCG) employed a similar factorial method to estimate zinc requirements; but their respective estimates of adult (and derived child) physiological and dietary requirements differ because they did not use the same data sources, they contained several minor errors in transcribing or interpreting published data, they employed different statistical modeling procedures and assumptions concerning adult body weight, and the IOM did not consider zinc bioavailability in the estimates of dietary requirements. A meeting convened to resolve these discrepancies has resulted in newly harmonized estimates of adult physiological requirements that are intermediate to those previously published by IOM and IZiNCG. Consensus was also achieved on the importance of including estimates of zinc bioavailability in the derivation of dietary requirements. In addition, new

information on adverse effects of zinc supplementation on indicators of copper status among children suggests that the current IOM and IZiNCG estimates of safe upper intake levels may be lower than necessary for this age group. These collective sets of results argue for the need to review, update and harmonize current global estimates of human zinc requirements.

Key words: Zinc, requirements, dietary intake.

RECOMMENDATIONS FOR ASSESSING ZINC STATUS AND POPULATION RISK OF ZINC DEFICIENCY

C. Hotz

Nutridemics, Toronto, Canada

While the consequences of zinc deficiency have been quantified with respect to the global burden of disease, information on the prevalence of zinc deficiency in at-risk countries using direct indicators of zinc status is still limited. One reason may be the lack of clear global consensus on recommended zinc status indicators. Methods to assess zinc status have been reviewed extensively in recent years by the United Nations and other international organizations or initiatives. Collectively, conclusions drawn thus far have been consistent. The distribution of serum or plasma zinc concentration is currently the best available indicator for assessing zinc status in populations. Serum zinc is responsive to zinc intakes, declining with zinc restriction and increasing in response to supplemental sources of zinc; reference data for interpreting serum zinc are also available. The limitations of serum zinc are not unique to zinc, and include lack of specificity for reflecting zinc status under some conditions (e.g. inflammation), and lack of response with mildly low or high zinc intakes due to homeostatic control. Nonetheless, additional indicators that are both sensitive and specific to zinc status should still be identified. Until greater consensus and advocacy for the use of existing or new indicators is achieved, indirect indicators have been proposed to estimate the relative risk of zinc deficiency at national level. The prevalence of inadequate zinc intake based on national food supplies and population weighted theoretical zinc requirements, combined with the prevalence of stunting among children <5 years of age, has been proposed, and widely utilized. Following recent updates and methodological improvements, a 'best-estimate' model suggests that 17% of the global population is at risk of inadequate zinc intakes, while the composite index identified 32 countries as being at high risk. Assessment of population zinc status in those high-risk countries using direct indicators is recommended.

Key words: Zinc deficiency, indicators, requirements, status, supplements.

NATIONAL EXPERIENCE IN ASSESSING THE RISK OF ZINC DEFICIENCY: CAMEROON

R. Engle-Stone¹, A O. Ndjebayi², M. Nankap², D W. Killilea³, K H. Brown^{1,2}

¹Program In International and Community Nutrition, University of California, Davis, USA

²Helen Keller International, New York, USA

³Children's Hospital Oakland Research Institute, Oakland, USA

Prior to initiating a mass fortification program including zinc, this study aimed to assess zinc status and risk of zinc deficiency among Cameroonian preschool children and women of reproductive age. This was a nationally-representative, multi-stage cluster survey. We randomly selected 30 clusters in each of 3 zones (North, South, and Cities) and 10 households (HH) per cluster, each with a child 12-59 mo and a woman 15-49 y (n = 1002 HH). IZiNCG recommendations for blood collection and processing procedures for zinc measurement were followed. Plasma zinc concentration (PZC) was measured by ICP-AES, and plasma C-reactive protein (CRP) and α 1-acid-glycoprotein (AGP) were measured by ELISA. PZC was adjusted mathematically for the presence of elevated acute phase proteins (CRP > 5 mg/L and/or AGP > 1 g/L). Adjusted mean PZC was 54.7 μ g/dL among children (95% CI: 53.6 – 55.8 μ g/dL, n = 812) and 53.4 μ g/dL among women (95% CI: 52.1 – 54.7 μ g/dL, n = 853). Low PZC was present in 69.1% of children (adjusted plasma zinc < 65 μ g/dL in AM samples and < 57 μ g/dL in PM samples) and 76.9% of women (adjusted plasma zinc < 70 μ g/dL for AM fasting samples, < 66 μ g/dL for other AM samples, < 59 μ g/dL for PM samples, and < 50 μ g/dL for pregnant women). Mean PZC was lower in the North than in the South and the Cities and was positively related to SES among both children and women. Stunted children (n = 240) had lower adjusted PZC than did non-stunted children (n = 507) (52.6 vs. 56.1 μ g/dL, p < 0.001). The prevalence of low PZC and risk of zinc deficiency are high among both women and children in Cameroon. Programs to improve zinc nutrition, including food fortification, are needed.

Key words: Zinc, deficiency, Africa.

PREVALENCE OF ZINC DEFICIENCY IN MEXICAN CHILDREN AND WOMEN OF CHILDBEARING AGE

S. Villalpando, J. Rivera, V. de la Cruz, A. García

Centre for Nutrition and Health Research, National Institute of Public Health, Mexico

Background and objectives: Describe the prevalence of zinc deficiency (ZD) among Mexican children and childbearing

age women from the National Health and Nutrition Survey 2006 (ENSANUT-2006).

Methods: Serum Zn concentrations were determined in 3,964 children 1-11 y, and 2,421 women 12-49 y from ENSANUT-2006. ICP atomic emission spectroscopy was used for determinations. The IZiNCG cut off was used to define ZD. Analyses were adjusted for survey design.

Results: Prevalences of ZD were: 26.3% in 1-4 y, 26.9% in 5-11 y and 33.8% in women 12-49 y. No significant differences were observed in prevalences by sex, geographic region and ethnicity in all ages. Higher prevalences of ZD were observed in children 1-11y from rural areas (28.1 vs 25.9%), those belonging to the lower socioeconomic (SES) tertile (28.2 vs 23.6%), non beneficiaries of a Federal fortified (including zinc) milk distribution program (Liconsa) (29 vs 19%; p=0.05) and preschoolers non beneficiaries of Oportunidades (26.9 vs 23.3%). A higher prevalence was found in urban women (35.8 vs 29.2%) and those belonging to the lowest SES tertile (36.5 vs 31.7%). Results from the 2012 national survey, currently in the process of determination, will be presented.

Conclusions: The prevalence of ZD in Mexican children and women is a public health problem. There is a need to extend the distribution of micronutrient containing foods or preparations in children <5y and from the poorest areas. This is supported by two efficacy studies of fortified food which demonstrated a reduction of ZD prevalence.

Key words: Zinc deficiency, children, women, nutrition surveys.

PS2-21 Assessment of body composition from birth to 2 years

BODY COMPOSITION MEASUREMENT TECHNIQUES IN INFANTS

K. Ellis

Baylor College of Medicine, University of Houston, USA

A number of techniques have been developed for body composition assessment in adults. Some of these methods can be extended to the measurement of infants. An overview of these methods will be presented, along with their limitations and advantages. Measurements of changes in body water, protein, bone mineral, and fat will be presented from birth to two years of age. The impact of pre-term birth, along with catch up growth, will be compared will reference curves developed for full-term healthy infants.

Key words: Body composition, infancy, growth, pre-term, full-term.

STANDARDIZATION OF BODY COMPOSITION ASSESSMENT FROM BIRTH TO TWO YEARS OF AGE – AN INTERNATIONAL INITIATIVE

L. Davidsson

Kuwait Institute for Scientific Research, Food and Nutrition Program, Kuwait

There is now strong evidence that growth from conception to 2 years of age represents a critical “window of opportunity” in terms of later risk of ill health and is central to the concept of the developmental origins of adult disease (DOHaD). However, the assessment of growth during this crucial period of early vulnerability is largely based on anthropometric measurements such as body weight, with insufficient attention to the “quality of growth” and the relative partitioning of nutrients to fat free mass or fat mass although infants of similar weight, height or even weight for height can vary substantially in body composition. In order to better understand the associations between growth during early life and later health status, there is an urgent need to better capture the dynamic nature of growth during early life. However, the reliable measurement of body composition during early life represents a technically challenging area.

The International Atomic Energy Agency (IAEA) initiated a review of body composition assessment techniques recently as the basis for efforts toward the standardization of body composition assessment from birth to 2 years of age. A document was developed by an international group of experts to provide practical information on the assessment of body composition from birth up to 2 years of age, using techniques with the highest potential for standardization globally; stable isotope dilution for total body water (TBW) assessment, dual energy X ray absorptiometry (DXA) and air displacement plethysmography (ADP). In addition, the importance of standardization of anthropometric measurements is highlighted in this book as basic measurements of body weight and length are crucial for accurate body composition assessment. The document will be available 2013.

Key words: Body composition, TBW, DXA, ADP.

PS3-29 Vitamin A supplementation for children 6-59 months of age: Revisiting program strategies and priorities

DELIVERING VITAMIN A SUPPLEMENTATION AT 6-MONTHS OF AGE: AN OPPORTUNITY TO IMPROVE CHILD SURVIVAL

R.Kupka¹, J. Nielsen², C. Nyhus-Dhillon³, J. Blankenship⁴, M. Haskell⁵, K. Brown^{2,5}

²Helen Keller International (HKI) Headquarters, New York, USA

³HKI Tanzania Country Office, Dar es Salaam, Tanzania

⁴HKI Africa Regional Office, Nairobi, Kenya

⁵Program in International and Community Nutrition and Department of Nutrition, University of California, Davis, USA

Vitamin A deficiency (VAD) is a major contributor to child mortality, and high-dose vitamin A supplementation (VAS) of children aged 6-59 months reduces child mortality by 11-24%. Globally, an estimated 66% of children living in areas with VAD receive the recommended two annual VAS dosages, most often through twice-yearly supplementation events. However, these events were not designed to reach children at exactly 6 months of age and as a result, they only reach an estimated 8.3% of children during their sixth month. The remainder is not reached through a supplementation event until later infancy, or during a measles vaccination visit at 9 months. We estimate that the systematic introduction of a 6-month VAS contact, optimally within the routine immunization schedule, could reduce infant mortality by an additional 2.3% as compared to twice-yearly VAS events. Modeling exercises using maximum hepatic vitamin A levels demonstrate that VAS at 6 months is safe even in the presence of a second VAS dose one month later and food fortification programs delivering vitamin A. In addition to the mortality benefits, VAS at 6-months could also serve as a platform to strengthen routine immunization programs and other nutrition interventions, such as promotion of high-quality and safe complementary foods. Revisions of vaccination cards could be linked to revisions related to the introduction of pentavalent vaccines and therefore increase feasibility. We therefore conclude that a 6-month VAS visit in the routine immunization schedule is an effective, safe, and feasible approach to reduce infant mortality rates.

Key words: Children, Vitamin A deficiency, supplementation.

VITAMIN A SUPPLEMENTATION FOR CHILDREN 6-59 MONTHS OF AGE: REVISITING PROGRAM STRATEGIES AND PRIORITIES

S. Baker¹, N. Kakrania², J. Blankenship¹, R. Gupta², T. Mkumbwa¹, A. Greig³, L. Neufeld³

¹Helen Keller International, New York, USA

²UNICEF

³Micronutrient Initiative

The objectives of this symposium are to:

- Review the current global prevalence of vitamin A deficiency (VAD)

- Describe efforts to strengthen vitamin A supplementation (VAS) program implementation in contexts where VAD remains a significant public health problem

- Introduce recent efforts to support governments in the phase out of supplementation programs when VAD is no longer a public health problem. Moderator: Shawn Baker, Regional Director for Africa, Helen Keller International (HKI) Panel: Nita Kakrania, Nutrition Specialist, UNICEF Roland Kupka, Nutritionist, West and Central Africa Regional Office, UNICEF Jessica Blankenship, Regional Micronutrient Advisor, HKI East and Southern Africa Temina Mkumbwa, Nutrition Program Officer, HKI Tanzania Alison Greig, Senior Technical Advisor, Child Survival, Micronutrient Initiative Lynnette Neufeld, Director Technical Services, Micronutrient Initiative Topics for Presentations

1) Introduction: Shawn Baker (10 min) Continuing relevance of VAS and contributions to reducing U5M

2) Vitamin A Supplementation Programs – Revisiting the Strategy: Nita Kakrania) Current priorities of global VAS strategies including building national ownership.

3) Program Implementation examples:

- o Monitoring for equity: Use of monitoring data and post event assessments to inform programme strategy and ensure equity: Jessica Blankenship

- o Delivering vitamin A supplementation at 6-months of age: An opportunity to improve child survival: Roland Kupka)

- o Mobilizing religious leadership to increase coverage of VAS in Tanzania: Temina Mkumbwa

- o Integration of VAS into the Health System: Alison Greig

4) Evidence base to inform countries when phase-out of VAS may be appropriate: Lynnette Neufeld

Key words: Children, vitamin A supplementation, vitamin A deficiency.

PS3-37 Findings from 5 birth cohorts from developing countries: The COHORTS collaboration HISTORY OF THE COHORTS COLLABORATION AND METHODOLOGICAL CONSIDERATIONS

C. Fall

MRC Lifecourse Epidemiology Unit, University of Southampton, Southampton, UK

The COHORTS collaboration (Consortium of Health-Orientated Research in Transitioning Societies) was formed in 2005 and brings together five population-based prospective birth cohorts from low- and middle income countries (LMICs). These include the 1982 Pelotas Birth Cohort Study (Brazil), the Institute of Nutrition of Central America and Panama Nutrition Trial Cohort (INTC, Guatemala), the New Delhi Birth Cohort Study (India), the Cebu Longitudinal Health and Nutrition Survey cohort (CLHNS, Philippines) and the Birth-to-Twenty cohort (Bt20, Soweto-Johannesburg, South Africa). All studies recruited mothers before/during pregnancy, recorded birth weight and serial weight and height data in the children, and have followed the children up into adult life.

COHORTS combines data from approximately 11,000 individuals from populations with a high prevalence of maternal and child under-nutrition, in order to produce high-quality scientific evidence on the early-life determinants ('programming') of adult health. Analyses examine associations of early-life exposures (birth size, linear growth and weight gain during childhood, infant feeding and childhood social environment) with adult outcomes relating to human capital (height, attained education, income, next-generation birth weight) and chronic disease risk (body composition, blood pressure, plasma glucose and lipids). Conditional growth modelling is used to identify critical periods in childhood when growth predicts adult outcomes. 'Trade-offs' between different outcomes is examined. The large sample size enhances statistical power and has led to high-impact findings with strong public health relevance for LMICs. The different patterns of confounding in COHORTS data, compared with high-income countries, enable conclusions concerning early-life programming of relevance to all populations. In the development of analysis strategies to overcome the difficulties of combining data collected at different ages and using different methods, COHORTS has been a unique platform for capacity-building in epidemiology among the study teams. The collaboration's work is funded by the Wellcome Trust and the Bill and Melinda Gates Foundation.

Key words: COHORTS, children, chronic disease, risk, growth, mothers.

GROWTH FROM BIRTH TO ADULTHOOD IN FIVE LOW- AND MIDDLE-INCOME COUNTRIES – COHORTS

A D. Stein, E A. Lundeen

Emory University, Atlanta, USA

Background and objectives: Growth failure remains a persistent challenge in many countries, and understanding the of patterns of growth failure is critical to the development of appropriate interventions. Most studies have been cross-sectional or have focused on children through age 5 y. We therefore characterized patterns of linear growth in the COHORTS study participants.

Methods: We analyzed data on lengths (or heights, as appropriate) at birth (not available for the cohorts from Brazil or South Africa), 12 mo, 24 mo, mid childhood (48 mo except 102 mo in Philippines) and adulthood for 5292 individuals. Lengths and heights were converted to Z-scores (HAZ).

Results: Mean HAZ were <0 at birth in the three cohorts with data and decreased sharply through age 24 mo in all cohorts. Mean HAZ at 24 mo ranged from -0.64 (Brazil) to -2.89 (Guatemala). Between 24 mo and mid-childhood HAZ increased by 0.45 – 0.49 SD in Guatemala, Philippines and South Africa and was unchanged in Brazil and India. Between mid-childhood and adulthood, mean HAZ increased further (range 0.07 SD (South Africa) – 0.86 SD (India)) but remained <0 (mean adult HAZ range -0.34 (Brazil) to -1.82 (Philippines)). Stunting (HAZ <-2.0) prevalence followed the same pattern, increasing through 24 mo (range 13.3% (Brazil) to 81.2% (Guatemala)) and decreasing between 24 mo and adulthood (range 3.2% (Brazil) to 41.1% (Philippines)). The proportion of children stunted at 24 mo who were no longer stunted as adults ranged from 21.4% (South Africa) to 82.0% (Brazil).

Conclusions: Patterns of growth failure and recovery vary across countries. The period from birth through 24 mo is critical. There is some growth recovery after this period among children who are stunted at 24 mo. Identifying the determinants of this recovery might provide opportunities to mitigate stunting among children for whom early preventive interventions were ineffective.

Key words: Adults, COHORTS, children, growth, low-middle income countries.

INTERGENERATIONAL EFFECTS ON GROWTH

R. Martorel, O. Addo

Hubert Department of Global Health, Rollins School of Public Health, Emory University, Atlanta, USA

We examine intergenerational relationships between size and growth across generations. In one set of analyses, we explore how maternal height influences birthweight and growth of her children. This is followed by other analyses that examine how birthweight and growth of the mother as a child influences birthweight of her children. We were particularly interested the relative importance of the predictive variables. The COHORTS collaboration uses data from birth cohorts from Brazil, Guatemala, India, the Philippines and South Africa. The first analysis relates height of the mothers of these cohorts to birth weight and conditional height measures of the cohorts. Maternal height was related to birth weight and to conditional height at all periods examined: 0-2y, 2y –mid childhood and mid-childhood to adult. The strongest relationships however, were with conditional growth from 0-2y and with mid-childhood to adult height. Independent of confounding factors, short maternal stature was an important predictor of stunting at 2 y of age. The second analysis is novel. It uses conditional growth measures but it disentangles linear growth from weight gain. Birthweight of the mother is a strong predictor of birthweight of her offspring. Only her linear growth from birth to 2 y predicts birthweight of her children. Weight gain independent of linear growth is unrelated to birthweight until the last period we examined: mid childhood to adult. This may point out to the importance of intrauterine growth, linear growth during the first 2 years and gains in relative weight during adolescence and prior to conception.

Key words: Intergenerational influences, linear growth, birthweight.

LONG TERM EFFECTS OF LINEAR GROWTH VS. WEIGHT GAIN ON ADULT HUMAN CAPITAL AND HEALTH

L. Adair

University of North Carolina at Chapel Hill, USA

The debate around the long term risks of rapid early-life weight gain has not differentiated the relative importance of linear growth and relative weight gain. We explored how birth weight, linear growth, and weight gain disproportionate to linear growth related to adult height, body composition, blood pressure, plasma glucose, attained schooling; and assessed whether growth after age 2 years related differently to these adult outcomes among those who were stunted or not stunted at age 2.

The COHORTS collaboration analyzed pooled data from >8000 participants in birth cohorts from Brazil, Guatemala, India, the Philippines and South Africa. Linear growth and relative weight gain from 0-2yr, 2 yr to mid-childhood and mid-childhood to adulthood were represented by residuals derived from regressing current size on all prior size measures. These uncorrelated variables represent faster or slower than expected growth during each interval. Taller adult stature and more attained schooling were significantly related to higher birth weight and faster 0-2 year linear growth. Higher BMI, blood pressure, and fat and lean mass were related to faster relative weight gain: associations were weak from 0-2 years and strengthened with age. Faster mid-childhood relative weight gain predicted larger increases in adult BP, fat mass, % body fat, and risk of hypertension and overweight among non-stunted individuals, but to significantly elevated odds of impaired fasting glucose or diabetes and to less attained schooling only in those who were stunted at age 2.

Faster mid-childhood linear growth was more strongly related to adult height in those who were previously stunted. Results reinforce the benefits of linear growth in the first 2 years for human capital, and the risks excess relative weight gain after age 2 for obesity and related chronic disease risks.

Key words: Developmental origins of adult health, linear growth, weight gain, human capital, chronic diseases.

LESSONS LEARNED FROM COHORTS AND THE POST 2015 GLOBAL AGENDA

C. Victora¹, R. Martorell²

¹Universidade Federal de Pelotas, Pelotas, Brasil

²Hubert Department of Global Health, Rollins School of Public Health, Emory University, Atlanta, USA

Recent findings from analyses of the long-term consequences of early growth patterns in low and middle-income countries, which were presented earlier in this session, have important consequences for policy, practice and research. In terms of policy, nutritional recommendations in many countries are based on promoting rapid weight gain for children with low weight for age, regardless of how old they are, while research findings suggest that rapid increases in weight (above and beyond the rate of linear growth) do not contribute to human capital and also increase the risk of non-communicable diseases later in life. Growth monitoring and feeding programs (including school feeding) should be reexamined critically to ensure that these are not contributing to the child obesity epidemic. The practical implications of these findings include the need to incorporate measurement of child length/height in routine screening and growth monitoring activities; this will raise a se-

ries of challenges regarding availability of equipment and training health workers, but our recent results show that assessing anthropometric status based on weight only is insufficient and may lead to incorrect conclusions. Finally, further research is needed to understand how health and nutrition interventions can promote optimal linear growth without increasing BMI above what would be desirable.

Key words: Developmental origins of adult health and disease, linear growth, weight gain, growth monitoring, optimal growth.

PS4-45 Iron and Malaria (FeMal) Project Results OVERVIEW OF THE IRON AND MALARIA PROJECT

D. Raiten

Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD), National Institutes of Health (NIH), USA

Background and objectives: Historical concerns have been reinforced by recent studies suggesting that iron supplementation during early childhood increases the risk of severe morbidity and mortality from malaria and other infections. As many of these effects have been reported in individual who were not iron deficient prior to supplementation, questions have been raised about not only safety but also assessment of iron status and the utility of “universal” supplementation programs particularly in the context of malaria and other infections. To address these concerns a project was launched by the NICHD in collaboration with the Bill and Melinda Gates Foundation in November 2007.

Methods: The project was designed to address three core elements: 1) mechanisms to explain adverse effects of iron, 2) biomarkers and 3) an evaluation of existing interventions. As a first step, a Technical Working Group (TWG) was formed to evaluate available evidence and identify an initial research agenda. Subsequently, a Research Review Committee (RRC) was constituted to provide additional scientific oversight including evaluation of a grant portfolio, and identification of new research opportunities.

Results: A Technical Report drafted by the TWG was completed in 2009 and an Executive Summary published in 2011. Ten new grants have been funded to addressing aspects of the three core focal points. Based on suggestions by the RRC three additional projects were initiated: 1) Biomarkers Reflecting Inflammation and Nutrition Determinants of Anemia (BRINDA) Project; 2) Harmonization of soluble transferrin receptor (sTfR) assay; and 3) Inflammation and Nutritional Science for Programs/Policies and Interpretation of Research Evidence (INSPIRE) project.

Conclusion: The Iron and Malaria project has established a model for how to 1) translate existing knowledge to support

program/policy, and 2) actualize a research agenda to address high priority knowledge gaps. The results of these efforts will be presented in this session.

Acknowledgements: BMGF; NIH (NICHD, ODS, DNRC)

Key words: Biomarkers, iron, malaria.

SOLUBLE TRANSFERRIN RECEPTOR (STFR) COMMUTABILITY STUDY

H W. Vesper¹, S J. Thorpe², Y I. Rahmani¹, C M. Pfeiffer¹

¹Division of Laboratory Sciences, Centers for Disease Control and Prevention, USA

²Biotherapeutics Group, National Institute for Biological Standards and Control, UK

A 2004 Joint WHO/CDC Technical Consultation recommended the use of serum ferritin and sTfR as the best approach to assess the iron status of populations. This requires laboratory measurements of sTfR to be accurate over time and across studies, otherwise iron status and changes in status cannot be determined reliably. Currently, different tests for sTfR performed on the same sample give highly variable results. One step to overcome this problem is to use a common calibrator or material to verify measurement accuracy. In 2009, WHO/NIBSC (National Institute for Biological Standards and Control) released a new Reference Reagent for sTfR (07/202), recombinant rsTfR, intended to standardise immunoassays for sTfR.

Clinical sTfR tests are optimized for measuring patient samples. The WHO/NIBSC material differs from patient samples in its overall composition. Studies involving other analytes of interest have shown that laboratory tests are often accurate when testing patient samples but show a measurement bias with materials that are modified like the rsTfR. Materials that show such effects are considered “non-commutable” and cannot be used as a common calibrator or to assess the accuracy of an assay (trueness control). The goal of this commutability study is to assess the suitability of the WHO/NIBSC material for use as calibrator or trueness control with routine clinical tests.

The study design follows protocols established by the Clinical and Laboratory Standards Institute. Six participants were enrolled, including major assay manufacturers. The WHO/NIBSC material and 20 single-donor patient samples are analyzed by each participant. Commutability is assessed by comparing data from patient samples with data from the WHO/NIBSC material. The patient samples cover an approximate sTfR concentration range of 1.65-5.40 mg/L. Results from this study will be presented.

Key words: Soluble transferrin receptor, reference material, commutability.

BIOMARKERS REFLECTING INFLAMMATION AND NUTRITION DETERMINANTS OF ANEMIA (BRINDA): PROJECT OVERVIEW

P S. Suchdev¹, S. Namaste², G J. Aaron³

¹Centers For Disease Control and Prevention (CDC), USA

²Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD), USA

³Global Alliance for Improved Nutrition (GAIN)

Background and objectives: Identification of the relative contribution of nutritional and other risk factors for anemia is needed to develop programs that address the multi-factorial etiology of anemia. Furthermore, in countries with high anemia burden, the relationship between inflammation, infection and nutrient biomarkers, as well as potential methods for adjusting biomarker data to account for this association need to be explored. This necessitates a better understanding of the determinants of anemia and the effects of inflammation on nutrition biomarkers among high risk groups in different settings.

Methods: The Centers for Disease Control and Prevention (CDC), Global Alliance for Improved Nutrition (GAIN), and Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD) formed a collaborative research group called Biomarkers Reflecting Inflammation and Nutrition Determinants of Anemia (BRINDA). We identified data from nationally and regionally representative surveys that included preschool children (PSC, 6-59 mo), school-age children (SAC, 5-14 yr) and women of reproductive age (WRA, 15-49 yr) that at minimum measured hemoglobin, inflammation (C-reactive protein and/or alpha1-acid glycoprotein), and iron status.

Results: Of 22 datasets identified, 3 did not meet the inclusion criteria, and currently permission has been received for 15, which include all 6 WHO geographic regions. Datasets represent 27,925 PSC, 7,906 SAC, and 25,384 WRA. Research topics to be addressed include: 1) impact of inflammation on anemia, iron and vitamin A biomarkers, as well as approaches to adjust for the effects of inflammation; and 2) risk factors and their relative contribution to anemia. Individual country and aggregated analyses will be performed.

Conclusions: BRINDA results will inform guidelines on the measurement and interpretation of anemia and other micronutrients in populations with high levels of inflammation.

Findings will also guide the development of a research agenda for future longitudinal studies.

Acknowledgements: Supported by NICHD, CDC, GAIN and the BMGF.

Key words: Biomarkers, inflammation, micronutrients.

THE IRON AND MALARIA PROJECT: PROGRESS REPORT ON FUNDED GRANTS

A. Prentice

London School of Hygiene & Tropical Medicine,
London, UK

Background and objectives: The project was initiated to address concerns about the safety and effectiveness of iron interventions particularly in areas of endemic malaria, included two solicitations published by NICHD that resulted in 10 funded grants to address three core areas: 1) mechanisms to explain adverse effects of iron; 2) biomarkers to assess iron particularly in the context of infection; and 3) an evaluation of currently available interventions.

Methods: Four of the studies were primarily lab-based mechanistic studies covering such issues as the impact of interactions between malaria and iron on iron regulatory proteins (e.g. hepcidin), impact of iron on stages of the malaria life cycle (e.g. erythrocyte versus hepatic stages), and comparative impact of iron on malaria versus co-infections. Five clinical studies have explored issues including the impact of iron interventions on such outcomes as placental malaria, malaria incidence, cognition and birth outcomes. Several studies focused on mechanistic aspects in clinical populations including impact of iron on gut microflora, impact of timing of interventions on response to treatment and the role of non-transferrin bound iron in malaria pathophysiology.

Results: Presentation will report on the completed results on: 1) role of hepcidin and macrophage function in malaria infection; 2) relationship between host iron levels and growth and development of erythrocytic stage of the malaria parasite (*P falciparum*) in vitro; and 3) a trial in Ghana to assess malaria incidence in children receiving powdered encapsulated Fe added to complementary foods.

Conclusion: Safety of iron interventions remains an open question under defined conditions of use. Iron homeostasis is impacted by the malaria parasite but functional implications remain unclear. Young erythrocytes are more susceptible to plasmodial infection so iron designed to reconstitute erythroid mass should be given with malaria prophylaxis.

Acknowledgements: Supported by the BMGF, NICHD and ODS.

Key words: Iron biomarkers, iron interventions, malaria.

PS4-53 Strengthening micronutrient nutrition surveillance: WHO and CDC tools and methods

THE UPGRADE AND EXPANSION OF THE VITAMIN AND MINERAL NUTRITION INFORMATION SYSTEM (VMNIS)

L M. De-Regi, J P. Peña-Rosas, L M. Rogers, G. Rob

World Health Organization, Geneva, Switzerland

Since its establishment in 1991 by the World Health Organization, the Vitamin and Mineral Nutrition Information System (VMNIS) remains the primary surveillance system for monitoring anaemia, vitamin A and iodine status in populations and is used to develop global and regional estimates of deficiency. In 2009, an external evaluation of the epidemiological aspects of this surveillance system and the public health informatics features of the database guided a VMNIS upgrade and expansion. It now includes a flexible data entry platform that captures more survey characteristics and methodologies on multiple biomarkers, and features an interactive dissemination website. Better quality assurance procedures for data entry and survey search were also established.

The VMNIS now provides tools and resources to support efforts by Member States and their partners for assessing the vitamin and mineral nutritional status of populations. A section on “indicators” includes compilations of current WHO recommendations on cut-offs for defining vitamin and mineral status in populations as well as their severity. These cut-offs are essential for identifying populations at risk of deficiency and in need of interventions. The “Global laboratory directory for micronutrients assessment” identifies laboratories with capacity to analyze biomarkers of micronutrients for large surveys. This directory is not exhaustive and is not intended to prescribe, qualify or endorse any of the included laboratories. A section on “monitoring and evaluation” includes resources that can be useful for conducting surveillance related to vitamin and mineral nutrition. Examples of these tools are the eCatalogue of indicators for micronutrient programmes and manuals for micronutrient surveillance. The VMNIS is now available in the six WHO languages.

Key words: Surveillance, micronutrient, information system.

NUTRITION SURVEY TOOLKIT AND 2ND EDITION OF THE MICRONUTRIENT SURVEY MANUAL TO IMPROVE THE DESIGN AND QUALITY OF MICRONUTRIENT SURVEYS

K. Tripp, K. Sullivan, T. Duque

Centres for Disease Control and Prevention, Atlanta, Georgia, USA

Key words: Survey, micronutrients, toolkit, manual Periodic cross-sectional surveys of the vitamin and mineral status and coverage of interventions within the population are an important component of micronutrient programs. Carrying out such surveys can be enhanced by the availability of tools and materials for planning, organizing, training, implementing, and reporting of results. The U.S. Centers for Disease Control and Prevention (CDC) developed a nutrition survey toolkit, containing resources that can be used in micronutrient surveys. This toolkit is available online and for download at www.micronutrient.org/nutritiontoolkit. It was developed to provide a publicly accessible compilation of qualitative and quantitative survey tools such as sample size calculators, lists of equipment and supplies, budget templates, step by step specimen collection procedures, training materials, templates of various data collection forms, survey report outlines. A search function enables the user to easily identify the tools needed for a specific task. This toolkit serves as a companion to a manual for designing and implementing micronutrient surveys. The manual "Indicators and Methods for Cross-Sectional Surveys of Vitamin and Mineral Status of Populations", was developed by the CDC, Micronutrient Initiative, World Health Organization and UNICEF. The manual provides practical information on how to plan and execute a cross-sectional survey and comprehensive help on all steps of survey implementation, including working with stakeholders, survey planning, calculating sample sizes, selecting indicators, and analysing survey data. The 2nd edition has been revised and expanded and includes new sections on the assessment of zinc and folate status. The toolkit and manual are based on field experience, expert group discussions, documents from various organizations, and journal articles relevant to the assessment of vitamin and mineral status in populations. Together, they can help survey managers improve the validity and efficiency of cross-sectional surveys of vitamin and mineral deficiency.

Key words: Nutrition surveys, micronutrients, minerals, vitamins.

CONTINUOUS HOUSEHOLD SURVEYS TO PRODUCE HIGH QUALITY, LOW COST, AND TIMELY NUTRITION SURVEILLANCE DATA

M. Jefferds, R. Flores-Ayala

International Micronutrient Malnutrition Prevention and Control Program, US Centers for Disease Control and Prevention, Atlanta, Georgia, USA

Monitoring and evaluation systems are needed to effectively implement programs. Some countries collect nationally representative, high quality data on priority nutrition indicators through large-scale periodic surveys, such as Demographic and Health Surveys (DHS) or Multiple Indicator Cluster Surveys (MICS). These surveys are important for the breadth and quality of the information produced, but are expensive and do not provide timely information related to program processes and outcomes. Ministry of Health management information systems are an important source of information, but generally are unable to provide the extent of information found in household surveys, and may have limitations related to data quality or representativeness.

Continuous household surveys as a surveillance system method can provide representative, high quality, and timely process and impact data for nutrition programs. The design of the system includes continuous cross-sectional household surveys used to develop annual nationally representative estimates. Depending on the needs of the country, the data can be representative of other geographic areas or include non-nutrition components. Ideally the system is institutionalized within the government agency, which may lower costs. Data collection is carried out by a small and highly trained team that works part-time every month collecting data in the field.

A government laboratory manages the biological data, as needed, and the epidemiology or statistical unit carries out data management, analysis and report publication. These roles are built into the work plans of government staff and result in a continual and stable level of work for these employees.

With annually representative data, the system provides timely access to key nutrition indicators. CDC and partners have supported the development of these types of nutrition surveillance systems in Nicaragua, Guatemala, and Uganda, and the presentation will describe these experiences and lessons learned.

Key words: Surveillance, continuous household surveys, indicators.

PS5-61 Micronutrient Fortification. Science and Strategies for Public Health Improvement in Asia
MICRONUTRIENTS AND FOOD FORTIFICATION – STRATEGIC AND PRACTICAL ISSUES

G. Smith

ILSI Southeast Asia Region

We have just celebrated the 100th anniversary of the “discovery” of vitamins (Funk, 1912) and tremendous progress has been made in understanding the consequences of vitamin and mineral deficiencies and in addressing the issues. Fortification of food with micronutrients has proved a useful approach to reduce inadequate intakes over large populations. Nevertheless, implementation has often been slow and issues remain. The iodization of salt to prevent iodine deficiency has been a good example. As recently as 1990, only a few countries in Europe, plus Australia, Canada and the USA were completely iodine sufficient. A global program to iodize salt has resulted in a dramatic reduction in iodine deficiency. However, some countries in Asia are still not iodizing salt.

Although fortification is simple in principle, several practical and strategic issues often receive insufficient attention to achieve effective results. Actual levels of deficiency are often not well established for a given country. Intake data of foods to be fortified may not be adequate to assess the risk of excess nutrient consumption or sufficiency of the nutrients for each age group. There must be effective interaction between the public health, academic and industry sectors to address the various concerns. Fortification needs to be placed within the framework of all strategies to address micronutrient deficiencies, including dietary diversification, biofortification, supplementation and education. Careful implementation and continuous monitoring of results are important aspects. Additional complications include variation of intake and requirements, dietary inhibitors of bioavailability, increased requirements in pregnancy, special requirements for children and cost considerations.

Both mandatory and voluntary fortification policies are in effect globally, together covering most countries in the world. The advantages and disadvantages of these approaches will be reviewed and contrasted. Risk-benefit concepts may need to be incorporated in strategic plans.

Key words: Biofortification, food fortification, micronutrients.

GAIN's GLOBAL STRATEGY ON FOOD FORTIFICATION TO IMPROVE PUBLIC HEALTH - ASIA HIGHLIGHTS

R. Moench-Pfanner¹, A. Laillou²

¹Global Alliance for Improved Nutrition, Singapore

²Program Delivery, Global Alliance for Improved Nutrition

Despite the economic growth and the reduction of certain micronutrient deficiencies (Iron, vitamin A) in the region, some micronutrients such as zinc, vitamin D and folate for example are still a concern. In addition, significant parts of the population are at the borderline of developing micronutrient deficiencies (for example in Vietnam, over 25% of children and women had a ferritin concentration <30µg/l that indicates low iron stores, and more than half of children had a marginal or deficient vitamin A status); therefore preventive strategies need to be implemented. This is even more important since during moments of economic crisis, populations with lower purchasing power consume, as widely documented, mainly staple foods, and hence, these foods need to provide a critical amount of micronutrients to prevent large population segments from developing or worsening their micronutrient status. In Indonesia, a recent study showed that in TTS only 25% of households could afford meeting nutrient requirements. The potential contribution of large-scale fortification of staple foods and condiments toward filling the micronutrient intake gap cannot be ignored.

The benefits of fortifying staple foods and certain condiments are based on the fact that those foods are commonly and widely eaten by most of the population. A recent consumption data from Vietnam showed that rice, flavoring powders, fish/soya sauces and vegetable oil were consumed daily in significant amounts by over 65% of the women and 40% of the young children (6-59 months), making those foods suitable vehicles for fortification. For example, fortifying vegetable oil on a large-scale in Malaysia and Indonesia can reach millions of people globally (as they are the global leaders in vegetable oil export). Knowing that the UL cannot be approached, vegetable oil fortification with vitamin A and D has the potential to become a global public health intervention strategy. In addition, to ensure adequate fortification, it is essential to develop tools which evaluate micronutrient concentrations. GAIN has assessed with its partner's rapid test kits for different food vehicles and they offer a viable solution for field monitoring.

In summary, the Global Alliance for Improved Nutrition (GAIN), is implementing several food fortification programs in the Asia region that are attempted to be rolled out at large scale and nation-wide but also pilot studies towards fortification of rice. Through our GAIN premix facility we were able to reduce the cost of fortification without jeopardizing the quality of the micronutrient. In Indonesia, this consolidated procurement approach has allowed a 14% decrease of the unit price of vitamin A.

Key words: Fortification, rice, vitamin A, vitamin D.

IRON-FORTIFIED SOY SAUCE IN CHINA – AN ASSESSMENT OF 10 YEARS OF POLICY AND BUSINESS DEVELOPMENT

J. Huo¹, J. Sun¹, J. Chen²

¹Institute of Nutrition and Food Safety, Chinese Centre for Disease Control and Prevention, Beijing China

²ILSI Focal Point China, Beijing, China

Iron deficiency (ID) and ID anemia (IDA) remains to be one of the major malnutrition issues in China. Iron-fortified soy sauce was identified as one of the key measures in controlling ID and IDA in China, because soy sauce is widely used in China. NaFeEDTA was selected as the fortificant, because of its high bioavailability (more than twice as ferrous sulphate in humans) and stability, and also no effects on the organoleptic characteristics of soy sauce. Therapeutic studies in anemic school children showed full recovery of blood hemoglobin to normal level after 3-month intervention used 5 mg Fe (as NaFeEDTA) in 5 ml of soy sauce per day. In a 18-month population-based double blind controlled intervention trial, iron-fortified soy sauce group (2-4 mg additional Fe per day) showed significant reduction of IDA prevalence than the control group in all age and gender groups. Based on the research achievements and regulatory approval, two phases of GAIN projects on the voluntary application of NaFeEDTA fortified soy sauce in the control of IDA in China were carried out. In the first phase, more than 20 soy sauce companies joined the project as designated iron fortified soy sauce producers. The application was launched in 7 provinces in a government supported “two wheels turning at same time” model, i.e. local public health professionals as one wheel and soy sauce producers as another wheel. All types of health education activities were conducted in collaboration with mass media. Within 3 years, 50 millions of residents regularly use iron fortified soy sauce and an average of 30% reduction of anemia rate were seen at the sentinel sites. The second phase started in 2010 is aiming at developing effective scaling up business model in selected provinces. The project is challenged by how to convince consumers to use fortified soy sauce regularly through proper public health education.

Key words: Iron fortification, soy sauce, iron deficiency, anemia.

IRON-FORTIFIED FISH SAUCE: EVALUATING AND ADOPTING A SUCCESSFUL MODEL IN VIETNAM

T. Pham Van, H. Le Thi

National Institute of Nutrition, Hanoi, Vietnam

Iron deficiency and iron deficiency anemia remains one of the biggest problems in Vietnam. Iron-fortified fish sauce (IFFS) was identified as one of the strategies in controlling ID and IDA, because fish sauce is a condiment and widely used by more than 80 percent of the population. NaFeEDTA was selected as the fortificant, because of its high bioavailability (more than twice as ferrous sulphate in humans), stability and also acceptability by consumers. The Efficacy study in anemic working women showed significant improvement of blood hemoglobin and serum ferritin after a 6-month intervention using 10 mg Fe (as NaFeEDTA) in 10 ml of fish sauce served with a meal based on noodles or rice every day and 6 d/wk. In an Effectiveness study, an 18-month population-based double blind controlled intervention trial, the iron-fortified fish sauce group (11 villages) showed significant reduction of IDA prevalence than the control group (10 villages) in women of reproductive age.

Based on the research achievements and support from GAIN, projects on the voluntary application of NaFeEDTA fortified fish sauce (4mg iron as NaFeEDTA per 10ml fish sauce) in the control of IDA in Vietnam were carried out. In this phase, more than 10 soy sauce companies joined the project as designated iron-fortified fish sauce producers. The application was launched in 16 provinces, with local public health professionals and fish sauce producers working together to provide the iron-fortified fish sauce to consumers in the provinces. All types of health education activities were conducted in collaboration with mass media. District and commune health officers play an important role in communication and education to change the behavior of consumers. Within 6 months, prevalence of residents regularly using iron-fortified fish sauce increased significantly as compared with the beginning and in women aged 20-49 years, with 60 percent coverage of IFFS, the prevalence of anemia significantly reduced on average by 30 percent at the sentinel sites. Improvement in hemoglobin and anemia rates was not significantly different between the 2 groups of women aged 20-35 years and 36-49 years, and between the two groups of workers and farmer women. This phase, started in 2008, was aiming at developing an effective business model in selected provinces. The project is very challenging because we should convince consumers to use iron-fortified fish sauce regularly through proper public health education.

Key words: NaFeEDTA, iron fortification, fish sauce, Vietnam.

CAMBODIA IRON-FORTIFIED FISH SAUCE: PROGRESS & DEVELOPMENT

T. Chan

Reproductive and Child Health Alliance (RACHA),
Cambodia

High prevalence of Iron Deficiency Anemia among children and women is a major public health issue in Cambodia. In response to this, the Reproductive and Child Health Alliance (RACHA) funded by USAID, in collaboration with GTZ and International Life Science Institute (ILSI) Japan has undertaken a four-year product incubation of iron fortification of fish sauce and soy sauce (IFFS/SS) including efficacy study and market trial in selected areas. Results showed that consumption of IFFS significantly reduced anemia and improved iron status among anemic people.

RACHA in collaboration with the National Sub-committee for Food Fortification implemented the IFFS/SS and Vitamin A Fortification of Vegetable Oil Project in Cambodia, supported by Global Alliance for Improved Nutrition (GAIN), ILSI and USAID. This project is now being scaled up nationwide both in rural and urban areas, aiming at reducing the prevalence of anemia and vitamin A deficiencies by 30 percent and fortifying at least 42,000 MT/year of FS and SS, and 32,000 MT/year of vegetable oil. RACHA had a long process of influencing government policy and regulation on iron fortification. In 2012, the Proclamation (Prakas) for the official label/logo to be used for iron-fortified fish sauce and soy sauce products nationwide, and the Prakas for production and consumption of IFFS/SS were approved by the Senior Minister of Planning and Chairman of the National Council for Nutrition (NCC).

The social marketing strategy and advocacy plan have been finalized and implemented; the IEC materials for local and national campaign were reviewed; and a TV Spot on advantages of IFFS/SS as part of the education campaign has been broadcasted. Recently, a National Workshop on this fortification project has been convened, as multi-sector collaboration is vital to the success of this new project in addressing anemia in the country.

Key words: Iron fortification, fish sauce, iron deficiency, anemia.

IRON FORTIFIED RICE - LESSONS LEARNT, OPPORTUNITIES AND CHALLENGES

M V. Capanzana, I. Angeles-Agdeppa, E. Saises

Food and Nutrition Research Institute, Taguig City,
Philippines

Background and objectives: With the persistent high rate of iron deficiency anemia (IDA), the Philippine government had passed the Food Fortification Law in 2000 which stipu-

lates the mandatory fortification of staples like rice with iron. This presentation aims to share experiences on iron rice fortification, technology generation and product development, barriers, challenges encountered and opportunities for implementation.

Methods: A document review from previous FNRI publications and current government and private sector programs was done to gather inputs on iron-fortified rice. The effects of fortification both in efficacy and effectiveness trials were extracted from the reports and the documented challenges and barriers of implementation and identified opportunities on how the program could best be implemented were evaluated.

Results: Evidences showed that the iron premix rice (IPR) fortified with micronized dispersible ferric pyrophosphate (MDFP) using extrusion technology has a stable colour, moisture, and iron contents during the 10 months storage period. Efficacy trial among school-aged children revealed significant decline in anemia rate from 100% to 33%. Small-scale and large-scale market trial revealed also a significant decline in anemia rate among consumers. Acceptability test revealed that the iron fortified rice (IFR) was rated as "like moderately" to "like very much". A local ordinance to sell iron-fortified rice and intensive social marketing activities resulted to increased knowledge and improved practice encouraged families to buy iron-fortified rice. Reluctance of rice dealers to sell IFR and product adulteration were among the challenges.

Conclusion: Strong political support and intensive social marketing activities are crucial in commercializing IFR. Keeping the cost affordable and maintaining the commitments of partners from the government and private sectors were the key factors for providing a continuous supply of iron-fortified rice.

Key words: Iron, rice, fortification.

RICE FORTIFIED WITH VITAMINS AND MINERALS USING EXTRUSION TECHNOLOGIES IS HIGHLY ACCEPTABLE IN VIETNAM AND CAMBODIA

L T. Hop¹, T K. Van¹, K. Burja², T T. Nga¹, K. Kong², J. Berger³, M. Gardner⁴, M A. Dijkhuizen⁵, L D. Tuyen¹, F. Wieringa³

¹National Institute of Nutrition, Ministry of Health, Hanoi, Vietnam

²World Food Program, Cambodia

³UMR-204 NutriPass Prevention of Malnutrition, Institut de Recherche pour le Développement, France

⁴PATH Cambodia

⁵Department of Human Nutrition, Copenhagen University, Denmark

Background and objectives: Rice fortified with micronutrients has the potential to improve the daily intake of micro-

nutrients in populations which are at a high risk for micronutrient deficiency. However, rice fortified with micronutrients has to be acceptable in terms of organoleptic qualities before introduction can be considered. Few data exist on the acceptability of fortified rice in SE Asia. This study aimed to assess the acceptability of 2 types of fortified rice (cold and hot extruded) in Vietnam and Cambodia, 2 large rice consuming countries in SE Asia.

Methods: Sensory testing in Vietnamese women of reproductive age (n=430) and in adults (n=200) and schoolchildren (n=600) in Cambodia. In addition, consumption patterns in Cambodian school children (n=1700) were followed for 1 month.

Results. Most adults (>70%) corrected identified the fortified rice on taste and smell out of a choice of 3 (P<0.01). Fortified rice was found to be highly acceptable in both countries. In Cambodia, school children consuming fortified rice had higher intake than when consuming normal rice (P<0.05).

Conclusion: This study shows that fortified rice is highly acceptable in SE Asia, and holds great promise to improve the micronutrient status of vulnerable groups.

Key words: Fortified rice, acceptability, organoleptic qualities.

PS5-69 Evaluation of food fortification and bio-fortification interventions in developing countries using stable isotopes

EFFICACY OF VITAMIN A IN FORTIFIED EXTRUDED RICE IN SCHOOL CHILDREN IN SOUTHERN THAILAND

¹Institute of Nutrition, Mahidol University, Salaya, Thailand

²Dept. Food Science and Nutrition, Prince of Songkla University, Pattani campus, Thailand

³Department of Nutritional Sciences, University of Wisconsin-Madison, Madison, USA

⁴Laboratory for Human Nutrition, Institute of Food, Nutrition and Health, ETH Zurich, Switzerland

Rice is widely consumed in Asia and is a promising vehicle for food fortification to prevent vitamin A (VA) deficiency in at-risk populations. Artificial rice grains were triple fortified with VA, zinc and iron using hot extrusion technology and the product showed good vitamin A stability. The aim of the study was to evaluate the impact of this multi-fortified rice to improve vitamin A status in school children in Southern Thailand. VA pool size was determined by paired stable isotope dilution technique with labeled ¹³C₂-retinyl acetate at the beginning

and end of 2 month feeding period. Fifty school children with serum retinol concentration > 0.7 μmol/L were randomized to receive either triple fortified rice (n = 25) or natural rice (n = 25) for 2 months served as the daily school meal. The fortified rice (mixed with natural rice at a ratio of 1:50) provided an additional 890 μg VA/d for 5 d/wk. Total body reserves of vitamin A (TBR of VA) increased significantly (p<0.05) in the intervention group after 2 months feeding. The control group showed no change in the TBR of VA. In conclusion, VA fortification of rice using hot extrusion is efficacious to improve VA status in at-risk populations.

Key words: Vitamin A fortification, rice, vitamin A status, vitamin A liver stores, stable isotopes.

VITAMIN A INTAKE IN BREASTFED BABIES FROM MOTHERS CONSUMING DAILY VITAMIN A FORTIFIED OIL DURING SIX MONTHS

A. El Hamdouchi¹, K. Ekari¹, N. Mokhtar¹, E. Rjimati², N. El haloui¹, H. Aguenau¹

¹Joint Unit of Diet and Nutrition, CNESTEN-Ibn Tofail University, URAC39, Rabat, Morocco

²Ministry of Health, Rabat, Morocco

Background and objectives: To evaluate the impact of daily consumption of vitamin A fortified oil on vitamin A status in milk and serum in lactating women during 6 months post-partum. Study design: it's a longitudinal randomized controlled and double blinded trial.

Methods: mother-infant pairs were recruited at 2-3 weeks post-partum, from a local hospital in Morocco. Baseline data were taken from the mothers and their babies. Women were split into two groups and were all supplemented with a capsule of vitamin A dose and received each week, a supply of vit A Fortified soya Oil for the test group (FO) and None Fortified soya Oil for the control group (NFO). Blood samples were taken at baseline, 3 months and 6 months while human milk samples were taken each month. Human milk retinol and retinol in serum concentrations were measured by HPLC. The quantity of human milk intake was also determined in a subgroup of 32 mothers using the deuterium technique dose to the mother.

Results: At 6 month, the mean of serum retinol rises in both groups and the difference was highly significant in the FO group (p<0, 0001). Between 4 and 6 months, there was a decline in mean human milk vitamin A concentrations under 1.05μmol/L in NFO group. However the increase observed in the FO group was maintained above 1.05 μmol/l, even at 6 months post-partum (p<0.0001). For the human milk intake assessed by the deuterium technique, the results show a decline in breastfeeding practices of babies from 33.3 % at 3 months to 13.3% at six months

Conclusion: Supplementation and fortification seems to be more effective for maintaining a significant level of vitamin A in human milk; 2-For successful programs, the promotion of breastfeeding practices is necessary.

Key words: Lactating women, vitamin A supplementation, fortified oil, breastfeeding, deuterium technique.

USE OF DEUTERATED RETINOL DILUTION TECHNIQUE TO ASSESS TOTAL BODY VITAMIN A STORES IN MEXICAN PRESCHOOLERS CONSUMING VITAMIN A FORTIFIED MILK

H. Astiazarán-García¹, V. Lopez-Teros^{1,2}, L. Quihui-Costa¹, J. Esparza-Romero¹, M E. Valencia^{2,1}, M H. Green³, G. Tang⁴, M I. Grijalva-Haro¹, R O. Mendez-Estrada¹, B I. Pacheco-Moreno¹, O. Tortoledo-Ortiz¹

³Pennsylvania State University, USA

⁴Tufts University, USA

In Mexico, as in many other developing countries Vitamin A deficiency (VAD) continues to be a major nutritional problem. Among Mexican preschoolers, milk is a well-accepted vehicle and thus can be used for the administration of micronutrients (vitamin A [VA]). The aim of the study was to investigate the efficacy of daily intake of 250 mL of VA-fortified milk (0.68 $\mu\text{mol/d}$) for 3 months on total body-VA stores, in marginally VA deficient preschool children (serum retinol concentration >0.35 and <1.05 $\mu\text{mol/L}$), who did not receive food assistance. The study design was a randomized clinical controlled trial. Twenty-seven marginally VAD preschoolers, were randomly assigned based on screening outcome variables to either the intervention ($n=14$) or control group ($n=13$). The study protocol was completed by all children in the control group and 11 preschoolers from the intervention group (79%). Deuterated retinol dilution (DRD) technique was used to estimate total body VA (TBVA) pool size before and after the intervention. After 3 months of fortified milk intake, median changes in serum retinol concentration for the intervention and control group were 0.13 nmol/L vs. -0.21 nmol/L, respectively ($P=0.009$); median changes in TBVA stores were 0.06 mmol vs. 0.01 mmol, respectively ($P=0.006$) and estimated median changes in liver VA concentration were 0.09 nmol/g vs. 0.01 nmol/g ($P=0.002$), respectively. The daily intake of vitamin A-fortified milk significantly increased total body VA stores, liver VA stores and serum retinol concentration, additionally milk was well accepted among preschoolers, indicating that it may be an effective means to fight VAD in young Mexican children. Special thanks to Liconsal for providing the micronutrient fortified powdered

milk for this study and the International Atomic Energy Agency for the funding provided (contract no. 15198). Full study information available at: *J Nutr* 2013;143:221-6

Key words: Vitamin A, isotopes, milk.

MULTIPLE MEAL STUDIES TO EVALUATE HUMAN IRON ABSORPTION FROM TYPICAL RWANDAN MEALS BASED ON BEANS

J.B. Gahutu¹, I. Egli², N. Petry², E. Boy³, R. Hurrell²

¹Department of Medical Biology, Faculty of Medicine, National University of Rwanda, Butare, Rwanda

²Laboratory of Human Nutrition, Institute of Food Science and Nutrition, Swiss Federal Institute of Technology, Zurich, Switzerland

³HarvestPlus, Washington DC, USA

Phytic acid and polyphenol compounds inhibit iron absorption, hindering food-based prevention of iron-deficiency anemia. Multiple meal studies reflect long term iron bioavailability more closely than single meal studies. Three multiple meal iron absorption studies were carried out with extrinsically labeled common beans fed with rice and potatoes in Rwandese women (20 per study). Iron absorption was measured as erythrocyte incorporation of stable iron isotopes. Study 1 comparing iron absorption from high and low polyphenol beans, similar in phytic acid and iron, did not show any significant difference ($p>0.05$) in mean fractional iron absorption from high polyphenol beans (7.0%) and low polyphenol beans (7.4%). Study 2 compared iron absorption from high and regular iron beans (9.1 or 5.2 mg Fe/100 g bean) with similar polyphenol levels and phytic acid: iron molar ratio. Mean fractional iron absorption from the high iron beans (3.8%) was 40% lower ($P<0.001$) than from the regular iron beans (6.3%) resulting in equal amounts of iron absorbed ($p>0.05$). Study 3 investigated phytic acid influence. The mean fractional iron absorption from the control bean meal with native phytic acid concentration was significantly higher than from the biofortified bean meal with native phytic acid concentration ($P<0.001$) leading to only a marginally higher amount of iron absorbed per test meal from the biofortified beans (66 μg (19%); $P<0.05$). Participants absorbed 37% more iron from the biofortified beans than from the control beans after partial dephytinization ($P<0.005$) and 51% more iron after dephytinization to low phytic acid ($P<0.0001$). In conclusion, in multiple meals phytic acid limited iron bioavailability from biofortified beans in marginally iron deficient female subjects. In the presence of high phytate, polyphenols did not exert any further inhibition.

Acknowledgements: The studies were supported by HarvestPlus/CIAT and the International Atomic Energy Agency.

Key words: Beans, iron absorption, polyphenols, phytate.

T6 FUNCTIONAL FOODS AND BIOACTIVE COMPOUNDS

NPS1-6 PREVIEW Project

THE ROLE OF DIET IN THE PREVENTION OF TYPE-2 DIABETES (STATE-OF-THE ART)

J. Brand-Miller

University of Sydney, Sydney, Australia

Three well-designed long term studies (the Diabetes Prevention Program, the Finnish Diabetes Prevention Study and the Chinese Da Qing study) reached the same conclusion: a low fat, high fibre diet and exercise intervention is highly effective in delaying or preventing the transition from impaired glucose tolerance to diabetes. The critical element in each study was achievement of weight loss (5-7% of body weight) followed by prevention of weight re-gain. It can therefore be argued that sustained weight loss and weight loss maintenance is the key to diabetes prevention, rather than a specific diet composition. In recent years, alternate dietary approaches, including high protein, low glycaemic index, and Mediterranean-style diets, have produced faster weight loss and better weight loss maintenance than traditional low-fat, high-carbohydrate diets. Indeed, the Diogenes study found that official dietary recommendations (low fat, high fibre) were associated with greater weight re-gain while a combination of a high protein and low GI diet prevented weight re-gain over 26 weeks. These alternate diets may be effective because they are more filling but also because they reduce postprandial glycaemia and insulinaemia, and thus the burden on the beta-cell. Some food patterns and specific foods (rice, white bread, soft drinks) characterised by hyperglycaemia are also associated with higher risk of adiposity and/or type 2 diabetes. The recent rise in gestational diabetes and type 2 diabetes in the young may be traced to food patterns that exaggerate postprandial glycaemia and insulinaemia superimposed on the physiological insulin resistance of pregnancy and puberty. It is likely that there are more efficient ways than just a low fat, high fibre diet to prevent diabetes in predisposed individuals.

Key words: Diabetes, diet, carbohydrate, glycemic index, protein.

PHYSICAL ACTIVITY AND THE PREVENTION OF DIABETES: PREVIEWING THE EVIDENCE

G. Stratton

A-STEM Research Centre, College of Engineering, Swansea University, Swansea, UK

Regular physical activity has a range of psychological and physiological benefits. Whilst improvements in glucose control in diabetes and overweight are well reported, the relative benefits of different exercise training interventions on glucose control are less clear. In addition the effect of physical activity on the psychological health in has further uncertainties. It is possible that the degree of compliance to physical activity programmes interacts with intensity and duration. Therefore effective behavioural approaches to maintaining a sufficient level of physical activity are key to successful delivery of programmes. Consequently the construction and delivery of physical activity programmes and their effect on health are critical factors in the prevention of diabetes and the management of overweight. Thus the objective of this presentation will be to outline the current literature and guidance on the effects of physical activity programmes on the prevention of diabetes and maintenance of healthy weight.

Key words: Diabetes, physical activity, body weight.

PREVIEW: PREVENTION OF DIABETES THROUGH LIFESTYLE INTERVENTION AND POPULATION STUDIES IN EUROPE AND AROUND THE WORLD

A. Raben¹, M. Fogelholm², E. Feskens³, M. Westerterp-Plantenga⁴, W. Schlicht⁵, J. Brand-Miller⁶

⁵Department of Sport and Exercise Science, Division I: Exercise and Health Science. University of Stuttgart, Stuttgart, Germany

⁶Boden Institute of Obesity, Nutrition, Exercise & Eating Disorders, University of Sydney, Sydney, Australia

Background and objectives: PREVIEW is a new 5-y EU project (2013-2017) under the FP7, KBBE programme. The primary goal is to identify the most efficient lifestyle pattern for the prevention of type-2 diabetes in a population of pre-diabetic overweight or obese individuals.

Methods: The project comprises two distinct lines of evidence, both embracing European and overseas countries:

1) A multicentre, clinical randomized intervention trial (3 years) with a total of 2,500 pre-diabetic participants, including children, adolescents, adults and elderly. The impact of a high-protein, low-glycemic index diet vs. the officially recommended diet in combination with moderate or high intensity physical activity on the incidence of type-2 diabetes will be investigated. The trial will be performed in 8 countries.

2) Large population studies using data from all age groups in European and overseas countries (estimated persons included = 170,000). Modelling strategies will be used. Focus in both lines of evidence will be on specific diet (protein vs. carbohydrates, glycaemic index) and intensity of physical activity, their interaction with the lifestyle factors: habitual stress and sleeping pattern as well as behavioural, environmental, cultural, and socioeconomic variables.

Partners: PREVIEW includes 12 European and 3 overseas partners.

From Europe: Raben, University of Copenhagen (DK), Project Coordinator; Fogelholm, University of Helsinki (FI); Feskens, Wageningen University (NL); Westerterp-Plantenga, Maastricht University (NL); Macdonald, University of Nottingham UK; Martinez, University of Navarra (ES); Handjiev, Medical University Sofia (BU); Stratton, Swansea University

(UK); Schlicht, University of Stuttgart (DE); Meyers Madhus (DK); Lam, NetUnion (CH); Sundvall, National Institute for Health and Welfare (FI); From overseas countries: Brand-Miller, University of Sydney (AUS); Poppitt, University of Auckland (NZ); Tremblay, Laval University (CAN).

The aim of the PREVIEW-intervention trial is to determine the preventative impact of a high-protein and low-GI diet in combination with moderate or high intensity physical activity

on the incidence of Type 2 diabetes (T2D) in pre-diabetic individuals. The trial will be performed in 6 EU countries (Bulgaria, Denmark, Finland, Spain, Netherlands, United Kingdom), Australia, and New Zealand. A total of 2,500 pre-diabetic overweight or obese participants (200 children and adolescents, aged 10–18 y, 800 younger adults, aged 25–45 y, and 1500 older adults, aged 55–70 y) are to be recruited. Adult participants are first treated by a low-calorie diet (LCD) for 8 weeks, with the aim of reaching >8% weight reduction. Children and adolescents are treated separately with a conventional weight-reduction diet, without a specific target for weight loss. If >8% weight reduction is achieved (adults only), participants are randomized into two diet intervention groups and two exercise intervention groups, for a total of 148 weeks. The two interventions diets are: Moderate-protein: protein intake 15% of total energy intake (E%), carbohydrates 55 E%, glycaemic index (GI) >56; High-protein: protein 25 E%, carbohydrates 45 E%, GI <50. Both diets are 30 E% fat, and will incorporate only healthy food items. The two exercise interventions are: Moderate intensity: 60–75% of maximal heart rate; High intensity: 76–90%. This life style intervention is based on behaviour change theories and techniques. Participants are supervised in groups with meeting frequency declining throughout the study.

The primary endpoint is the incidence of type-2 diabetes over 3 years according to diet (high-protein/low-GI versus moderate-protein/medium-GI), adjusted for physical activity. Stress, sleep, and different socio-ecological and behavioural factors will also be assessed. The research described here receives funding from the FP7/2007-2013 programme under grant agreement no. 312057.

Key words: Complex Intervention, physical activity, protein, GI, Type 2 diabete.

THE PREVIEW-POPULATION STUDIES: DESIGN AND METHODS

E. Feskens¹, D. Sluik¹, M. Fogelholm², J. Brand-Miller³, S. Poppitt⁴, A. Tremblay⁵, A. Raben⁶

¹Division of Human Nutrition, Wageningen University, Wageningen, The Netherlands

²Department of Food and Environmental Sciences, University of Helsinki, Helsinki, Finland

³Boden Institute of Obesity, Nutrition, Exercise & Eating Disorders, University of Sydney, Sydney, Australia

⁴The Human Nutrition Unit, University of Auckland, Auckland, New Zealand

⁵Department of Kinesiology, Laval University, Québec, Canada

⁶Department of Nutrition, Exercise and Sports, Faculty of SCIENCE, University of Copenhagen, Copenhagen, Denmark

The overall objective of PREVIEW population studies is to substantiate the findings in the intervention study with data from five longitudinal population studies from Europe, New Zealand and Canada, covering the entire lifespan. It will be evaluated whether protein intake, glycaemic index (GI), and physical activity, are predictive of diabetes and its cardiovascular consequences. This will add insight into the natural history of diabetes, by considering specific dietary and exercise factors. The following epidemiological studies will be analysed:

1. The Netherlands: LifeLines (2006-ongoing), a three-generation population-based study in 165,000 people 4-90+y and NQplus (2011-ongoing), a survey in n=1,750 people 20-70y, repeated 3 times.

2. Finland: Cardiovascular Risk in Young Finns Study (1980-2012), a survey in n=3,596 people 3-18y at baseline, repeated 8 times.

3. New Zealand: NZ Adult Nutrition Survey (2008/09), a cross-sectional survey in n=4,721 people > 15y.

4. Canada: Quebec Family Study (1978-2002), a 3-phase longitudinal study from ~500 families including ~200 families with one obese member. A common database of these five population studies will be generated. Main exposure variables will be dietary components and physical activity. The outcome will be diabetes prevalence or incidence, and blood glucose parameters. Data-analysis will be conducted with meta-analytical techniques, using a random-effects model to consider heterogeneity among cohorts. Population attributable risks will give an estimate on how much of diabetes risk could theoretically be prevented by modifying these factors. Additionally, given that GI, one of the key exposures, is not routinely available in all food tables, a dedicated questionnaire focusing on assessing GI will be developed. It will be applied to the NQPlus cohort to gain insight into the quality of the GI results. The research

described here receives funding from the EU Seventh Framework Programme (FP7/2007-2013) under grant agreement no. 312057.

Key words: Population studies, diabetes, protein, glycaemic index, physical activity.

PS1-6 Diversity of physiological functions of amino acids and peptides

PHYSIOLOGICAL FUNCTION OF SOYBEAN PEPTIDES

H. Hara, S. Nakajima, T. Hira

Research Faculty of Agriculture/Hokkaido University, Sapporo, Japan

Soybean seed includes around 35% protein. The soybean protein isolate (SPI) is well known to be reduced blood cholesterol levels in animals and human. The hydrophobic peptides derived from SPI contributes the anti-atherogenic effects. Recently, we found that an internal peptide in soybean β -conglycinin stimulates release of cholecystokinin (CCK) and suppresses food intake in rats, and also suppresses hunger in healthy human. Cholecystokinin is a gut hormone released from an enteroendocrine I-cells located in the upper small intestinal epithelium, and stimulates exocrine pancreatic secretion, reduces gastric emptying rate and induces satiety via afferent vagal nerve. We showed that dietary proteins and peptides directly stimulate the enteroendocrine cells and release CCK through a G-protein coupled receptor (GPCR) with activating $G_{f\zeta q}$ subunit. We tried to identify the responsible peptides for enhancement of CCK release in soybean protein, and have got a tridecapeptide in β -conglycinin β -subunit (β 51-63). The amino acid sequence of this active peptide is VRIRLLQRFNKRS, that is, the CCK-releasing peptide includes four arginine residues. The soybean peptide strongly stimulates CCK release in rats after an injection into the duodenum, and suppresses food intake after overnight fast. The suppression of food intake completely depends on CCK action, which confirmed by a CCK a-receptor blocker, devazepide. By a double blind crossover study in healthy individuals, a peptide preparation of soybean β -conglycinin hydrolyzed by pineapple-origin protease dose-dependently (1.5-3.0 g) suppresses hunger sensation and induces transient satiety in post-absorptive state with statistical significances compared with a whole soybean peptide preparation. Finally, we have identified a receptor for β 51-63, which is a GPCR, calcium-sensing receptor (CaSR) expressed on the enteroendocrine cell line STC-1, by using a specific antagonist of CaSR and transfection of CaSR in HEK293 cells.

Key words: Soybean protein, cholecystokinin, appetite suppression, calcium-sensing receptor.

AMINO ACID PROFILING AND DATABASE FOR CLINICAL DIAGNOSIS AND PERSONALISED NUTRITION

Y. Noguchi, K. Nagao

Institute for Innovation, Ajinomoto Co.,Inc, Japan

Recent studies show new possibilities of using plasma amino acid profiles as biomarker discovery by generating diagnostic indices through multivariate analysis. Using a rapid and sensitive LC-MS technologies enabling high-throughput amino acid measurement, we have constructed large scale human database containing medical information of more than 20,000 Japanese in total concerning multiple diseases (e.g. cancers, metabolic syndrome, hepatic diseases etc.) and their metabolic profiles. By variable selection and regression analysis, we have developed multivariate diagnostic indices that enable the early detection of multiple cancers and also metabolic disorders from a single blood draw and analysis. In addition, we have analyzed datasets from large database of healthy subjects by correlating blood amino acid profiles and physiological states to expand application of amino acid profile toward health and nutritional management, and then obtained some meaningful relationships between alternation in amino acid profiles and physiological variables. Current our data therefore indicates a potential use of blood amino acid profile for developing multivariate index exclusively associated with a specific physiological state so that single measurement of an amino acid profile could be used as an initial stratification for a multitude of disease and nutritional states, and also subsequent personalization of nutrition and dietary interventions.

Key words: Amino acid, metabolic profile, personalized nutrition.

DIETARY SUPPLEMENTATION WITH SPECIFIC AMINO ACID MIXTURES PROMOTES MITOCHONDRIAL BIOGENESIS: PHYSIOLOGICAL AND PATHOPHYSIOLOGICAL RELEVANCE IN MAMMALS

E. Nisoli¹, G D'Antona², G. Corsetti¹, M. Ragni¹, C. Ruocco¹, A. Fossati¹, L. Tedesco¹, A. Valerio¹

¹Department of Medical Biotechnology and Translational Medicine, University of Milan, Milan, Italy

²Department of Molecular Medicine, University of Pavia, Pavia, Italy

Nutrients are major regulators of biochemistry and physiology in living organisms, and subtle changes in nutrient composition result in genetic or epigenetic control of processes influencing healthspan and survival. Though contentious

yet, calorie restriction (the reduced intake of calories as foods without malnutrition) postpones several age-related diseases, hence extending healthspan and lifespan in many species. The molecular basis of this long known phenomenon are still elusive, albeit evidence seem to converge on the reduction of mitochondria-derived oxidants through the generation of new, more efficient organelles (mitochondrial biogenesis) (Nisoli et al., *Science* 310: 314-317, 2005). Branched-chain amino acids (BCAAs) display healthy effects both in animals and humans (Valerio et al., *Aging* 3: 464-478, 2011). Notably, we reported that unlike other amino acid mixtures, a BCAA-enriched mixture (BCAAem), promoted mitochondrial biogenesis in cultured cardiomyocytes and skeletal myocytes as well as in heart and skeletal muscles of sedentary and trained middle-aged mice. This was accompanied by muscle fiber rejuvenation, improved locomotor activity and coordination, and extension of average lifespan (D'Antona et al., *Cell Metab* 12: 362-372, 2010), suggesting that BCAAem acts as a CR mimetic. We then investigated the BCAAem effects on statin-induced muscle damage in mice. Though known to be rather safe, statin use is associated with an elevated risk of myopathy, ranging in severity from asymptomatic increases in creatine kinase to muscle weakness, aches and fatigue, up to the rare fatal rhabdomyolysis. We found that BCAAem prevented atorvastatin- and rosuvastatin-induced structural and functional deterioration of skeletal muscles in both wild-type and hypercholesterolemic mice (ApoE receptor knockout mice on a high-fat diet). Statin prescription is expected to grow alongside the aging of population. Dietary supplementation with specific amino acid mixtures may be an effective strategy to avoid common adverse effects limiting the adherence to statin therapy in human subjects.

Key words: Amino acids, branched chain amino acids, malnutrition, mitochondria, skeletal muscle.

RECENT ADVANCES IN ARGININE METABOLISM: ROLES AND REGULATION OF THE ARGINASES

S. Morris

University of Pittsburgh School of Medicine, Pittsburgh, USA

Arginine is a semi-essential or conditionally essential amino acid in humans and is a precursor for synthesis of urea, nitric oxide, polyamines, proline, glutamate, creatine, and agmatine. Regulation of its metabolism is quite complex and involves a variety of enzymes, including the arginases. It has become clear that the arginases, which are expressed as two isozymes in mammals, play important roles in regulating many aspects of arginine metabolism in health and disease, including vascular disease, pulmonary disease, infectious disease, immune cell function, and cancer. In some cases, aberrant expression or lo-

calization of the arginases may result in arginine insufficiency, as in sickle cell disease. Therefore, there is growing interest in use of arginine supplementation or arginase inhibitors to treat a variety of conditions. This presentation will highlight recent advances and questions regarding the roles and regulation of the arginases.

Key words: Arginase, nitric oxide, endothelial, macrophage.

PS2-14 Dietary reference values for DNA damage prevention

THE CONCEPT AND RELEVANCE OF DIETARY REFERENCE VALUES FOR DNA DAMAGE PREVENTION

M. Fenech

CSIRO, Nutrigenomics & DNA Damage Diagnostics, Preventative Health Flagship, Adelaide, Australia

Damage to the genome is recognized as a fundamental cause of developmental and degenerative diseases. Several micronutrients play an important role in protecting against DNA damage events generated through endogenous and exogenous factors by acting as cofactors or substrates for enzymes that detoxify genotoxins as well as enzymes involved in DNA repair, methylation, and synthesis. In addition, it is evident that either micronutrient deficiency or micronutrient excess can modify genome stability and that these effects may also depend on nutrient-nutrient and nutrient-gene interaction, which is affected by genotype. These observations have led to the emerging science of genome health nutrigenomics, which is based on the principle that DNA damage is a fundamental cause of disease that can be diagnosed and nutritionally prevented on an individual, genetic subgroup, or population basis. The following topics will be discussed: 1) biomarkers used to study genome damage in humans and their validation, 2) evidence for the association of genome damage with developmental and degenerative disease, 3) current knowledge of micronutrients required for the maintenance of genome stability in humans, 4) the effect of nutrient-nutrient and nutrient-genotype interaction on DNA damage, and 5) strategies to determine dietary reference values of single micronutrients and micronutrient combinations (nutriomes) on the basis of DNA damage prevention. This presentation will also identify important knowledge gaps and future research directions required to shed light on these issues. The ultimate goal is to match the nutriome to the genome to optimize genome maintenance and to prevent pathologic levels of DNA damage.

Key words: Dietary reference values, DNA damage, prevention, micronutrients, nutriomes.

VITAMINS AND DNA DAMAGE PREVENTION

I. Elmadfa^{1,2}, A. Meyer¹

¹Institute of Nutritional Sciences, 1 University of Vienna, Vienna, Austria

²UNS President

The DNA is constantly exposed to noxious agents from endogenous and environmental sources and the resulting damage is a major cause of potentially harmful mutations, cell death, and cancer. Vitamins as antioxidants Insights into DNA oxidation and repair mechanisms have revealed important roles for vitamins. Indeed, many of these micronutrients are potent antioxidants in the organism. Some studies showed inverse correlations between status of alpha-tocopherol and vitamin C, the most important lipid- and water-soluble dietary antioxidants, respectively, with markers of DNA damage. Supplementation with these micronutrients has also shown some protective effects. Prooxidative properties However, by acting as scavengers of reactive molecules, antioxidant vitamins have prooxidant potential as well. Oxidative damage to nucleic acids by high-dose micronutrient supplements as evidenced by 8-oxo-deoxyguanosine formation was reported particularly for vitamin C that is commonly used as an over-the-counter supplement and also added to many foods as a fortificant or an antioxidant. As dietary vitamin C supply is generally adequate, the resulting high intake could be of concern. Vitamins in DNA maintenance and repair Folate and vitamin B12 are essential for the supply of 1-carbon units that are required for nucleic acid synthesis and hence, for DNA maintenance and repair as well as methylation reactions as part of epigenetic mechanisms. More recently, epigenetic regulation of DNA damage detection and repair is being unveiled. Methylation of histones determines the accessibility of the DNA to repair enzymes. Besides, activity of repair enzymes themselves is regulated through methylation. Finally, disturbance of the epigenome resulting in excessive smooth muscle cell proliferation also seems involved in the development of atherosclerotic lesions. Vitamins are protecting factors in the prevention of DNA damage but can at high doses also become potential promoters.

Key words: DNA damage, DNA repair, vitamins, antioxidants, prooxidants.

MINERALS AND DNA DAMAGE PREVENTION

L. Ferguson

The University of Auckland, Auckland, New Zealand

Three main types of dietary recommendations are currently produced by public health agencies: dietary allowances (DRVs), dietary goals, and dietary guidelines. These figures provide national targets for selected macronutrients and mi-

cronutrients, aimed at preventing long-term risks of chronic diseases including coronary heart disease, type II diabetes mellitus and cancer. Minerals identified as necessary in certain amounts for human health are: Calcium, Chromium, Copper, Fluoride, Iodine, Iron, Magnesium, Manganese, Molybdenum, Phosphorus, Potassium, Selenium, Sodium and Zinc. However, recommendations in the national guidelines are aimed at the population, rather than the individual level. The example of our own studies on Selenium has emphasized how individuals with certain genotypes and certain disease states require higher than normal intakes of this mineral, in order to protect against DNA damage. The optimal Selenium intake level is also impacted by lifestyle factors, especially smoking. Similar are found for other minerals, including calcium, magnesium and zinc. There is a strong case for optimizing nutrient requirements at an individual level, as the amount required to optimize DNA repair and reduce DNA damage.

Key words: DNA damage, genomic stability, mutagenesis, selenium.

PHYTONUTRIENTS AND DNA DAMAGE PREVENTION

A. Collins

Department of Nutrition, University of Oslo, Oslo, Norway

The evidence for protective effects of phytochemicals against DNA damage in humans is strong, and comes from several directions. Cross-sectional studies have shown negative correlations between the plasma concentration of phytochemicals (e.g. carotenoids) and DNA base oxidation in peripheral blood mononuclear (PBMN) cells. Supplementation of the diet with fruits or vegetables, or with individual phytochemicals, enhances antioxidant status, as indicated by the resistance of PBMN cell DNA to ex vivo oxidation by H₂O₂ – an effect seen after a single dose as well as after sustained supplementation. Endogenous DNA base oxidation can show a significant decrease,

especially after long term intervention. The antioxidant efficacy of phytochemicals is confirmed in experiments with cells in culture. On the other hand, large-scale, long-term human intervention trials with clinical outcomes (disease incidence or mortality) have shown, overall, no effect of antioxidant supplements, or even a harmful effect. There are also theoretical reasons to doubt the usefulness of antioxidant supplements; reactive oxygen species play an essential role in the inflammatory response and in cell signalling pathways, and suppressing them too far may be counter-productive. Intrinsic antioxidant defences have evolved, that – at least in healthy subjects – keep oxidants in the body within tolerable limits. Phytochemicals, however, have many other potentially important and beneficial roles, such as moderating phase I and II metabolism, and, as has recently been shown, influencing DNA repair capacity.

Key words: Phytochemicals, antioxidants, DNA oxidation, DNA repair.

PS2-22 The role of nutrition in healthy ageing: Insight from the CHANCES Project

NUTRITION AND OSTEOPOROTIC FRACTURES IN THE ELDERLY: INSIGHT FROM THE CHANCES PROJECT

V. Benetou

Department of Hygiene, Epidemiology and Medical Statistics, University of Athens Medical School, Athens, Greece

Bone fractures constitute important causes of morbidity and mortality among the elderly, especially in the developed countries. Furthermore, they represent important causes of long-standing pain and functional impairment, disability and diminished quality of life. A large proportion of bone fractures in the elderly are related to osteoporosis. Hip fractures, although represent less than 20% of all osteoporotic fractures, account for the majority of fracture-related health care expenditure and mortality in men and women over the age of fifty. Osteoporosis and osteoporosis-related fractures result from the interaction between genes and the environment. Nutrition plays an important role during childhood and adolescence for achieving peak bone mass and preventing osteoporosis in later life. However, the contribution of nutritional factors in the prevention of osteoporotic fractures among the elderly is still, largely, unknown. There is limited evidence that specific food groups (e.g fruits and vegetables), macro- and micronutrients (e.g protein, certain B vitamins) and dietary patterns (e.g adherence to Mediterranean diet) can have a beneficial or detrimental contribution in the incidence of osteoporotic fractures.

The Consortium on Health and Ageing: Network of Cohorts in Europe and the United States (CHANCES) provides an important opportunity to investigate the role of individual

dietary factors, as well as, diet as a whole, in relation to hip fracture incidence using harmonized data from a population of elderly individuals from Europe and USA. The final goal of the consortium is to generate the scientific knowledge required for the development of evidence-based recommendations and the implementation of public health interventions for the well-being of the elderly.

Key words: Nutrition, fractures, osteoporosis, elderly, hip fractures.

BIOMARKERS AND NUTRITION

E. Jansen

Centre for Health Protection, National Institute for Public Health and the Environment, Bilthoven, The Netherlands

CHANCES (Consortium on Health and Ageing: Network of Cohorts in Europe and the United States) is a collaborative large-scale integrating project funded by the European Commission (FP7) which aims to produce evidence on ageing-related health characteristics and determinants in Europe. The CHANCES project focuses on four groups of chronic diseases and conditions which are major contributors to the burden of disease in the elderly: cancer, cardiovascular diseases and diabetes, osteoporosis and fractures, cognitive function and psychiatric disorders. In an integrating work-package on Biomarkers (WP9) a set of biomarkers will be identified that can act as a general predictor of health in the elderly, and which correlates with absence or presence of various age-related chronic diseases. In this WP9 an inventory has been made of the biomarkers that have already been measured in the various cohorts. For further analysis we will focus on biomarkers that are thought to be involved in more than one age-related chronic disease. It was decided to focus the measurements on one cohort from Heidelberg (DKFZ) and four cohorts from the HAPIEE study, Prague, Kaunas, Krakow and Novosibirsk. In these cohorts the following biomarkers will be measured in serum samples: the oxidative stress parameters ROM (hydroperoxides), BAP (anti-oxidant status) and TTP (total thiols); the vitamins 25hydroxy-vitamin D, folate and vitamin B12; the electrolytes Na, K, Cl, Ca and Mg and in addition creatinine, uric acid, gamma-glutamyl transferase and high-sensitive C-reactive protein. In total about 13,000 samples will be measured using two (immuno) auto analyzers. In the present study data will be given on the measurements of the mentioned biomarkers and the quality control data. Focus will be put on oxidative stress biomarkers and vitamins. The relation of these biomarkers with aging, nutrition and chronic diseases will be discussed.

Key words: Biomarkers, aging, nutrition, chronic diseases.

25-HYDROXYVITAMIN D LEVELS AND MORTALITY

B. Schöttker, J.M. Ordóñez Mena, H. Brenner

Division of Clinical Epidemiology and Aging Research, German Cancer Research Center, Heidelberg, Germany

Background and objectives: Serum 25-hydroxyvitamin D levels (25(OH)D) have been linked to mortality in several studies but comparisons across European countries are lacking. Objective: It was aimed for an analysis on the association of serum 25-hydroxyvitamin D levels with all-cause, cardiovascular and cancer mortality in cohorts of the Consortium on Health and Ageing (CHANCES).

Methods: 25(OH)D was measured in overall around 25,000 subjects aged 50 and over in 8 population-based cohorts: ESTHER (Germany): n=8,938; TromsØ (Norway): n=4,401; MONICA/KORA-Augsburg (Germany): n=1,267; SENECA (across Europe): n=824; HAPIEE: n=10,000 (n=2,500 in each of the four centers in Czech Republic, Russia, Poland and Lithuania). Adjusted Cox regression models were used to estimate hazard ratios (HR) in each cohort and random-effects meta-analyses to pool results.

Results: As analyses in all cohorts except the ESTHER cohort are ongoing, only results from the ESTHER cohort can be shown now. During 9.5 years of follow-up, 974 study participants died, among whom 228 died of cardiovascular diseases and 338 died of cancer. Comparing bottom and top quintile of 25(OH)D concentrations resulted in HRs for the outcomes all-cause, cardiovascular and cancer mortality of 1.65 (95%CI: 1.34-2.03), 1.70 (95%CI: 1.09-2.64) and 1.12 (95%CI: 0.78-1.62), respectively).

Conclusions: Results from the ESTHER cohort showed a strong association between low 25(OH)D levels and all-cause as well as cardiovascular mortality but no association with cancer mortality. It is now up to analyses in the other CHANCES cohorts to verify these findings and compare results from different European countries.

Acknowledgements: This study was conducted in the context of the German Cancer Aid project number 108250 and 108426 and the CHANCES project funded in the FP7 framework programme of DG-RESEARCH in the European Commission (Grant no. 242244).

Key words: Vitamin D; all-cause mortality, cardiovascular mortality, cancer mortality, cohort studies.

PS3-30 Fibres and the gut immune system(FIBEBIOTICS Project)

FIBRES AND THE GUT IMMUNE SYSTEM (EU FIBEBIOTICS PROJECT)

J. Mes

Food & Biobased Research, Wageningen, The Netherlands

The human gut and immune system is of utmost importance to maintain health. Polysaccharides/fibers are amongst the best studied compounds in relation to support of the gut & immune system. However, for demonstrable health claims, conclusive scientific evidence is needed. The EU FibeBiotics project studies the effect on gut and immune health of non-digestible polysaccharides (NPS) in detail. NPS represent a class of food fibres composed of polymers of carbohydrates (Dp > 10) that is not digested by the upper gastrointestinal tract. NPS can have a complex composition of different types of sugars with variable linkages, resulting in polysaccharides with different length and different degrees of branching. It can be expected that different NPS will have different bioactivity and that source, genetic background, processing and food formulation will have an effect on this bioactivity. Goals of the project are to set up methods and design strategies for efficient characterisation of NPS and improving the understanding on bioactivity using in vitro models based on human cells or blood derived cells, ex vivo analysis based on intestinal biopsies and on in vivo analysis. As one of the possible bioactivities is selective growth promotion of microbiota species or the production of short chain fatty acids (SCFA), also these are studied in vitro and in vivo. This winter season a double blind placebo controlled 6 arms pilot trial was performed, with 40 subjects in each arm. Currently biomarkers are analysed so no results are available yet. The presentation will give an overview on previous studies with NPS, strategies for bioactivity analysis in vitro and in vivo and technologies developed within the consortium that can be of benefit for other groups interested to study the gut and immune effects of food compounds and products.

Key words: Fibre, food formulation, microbiota, short chain fatty acids, intestine.

DETERMINATION OF BETA-GLUCANS IN FOOD AND SAMPLES FROM IN VITRO SYSTEMS

S.H. Knutsen, A. Rieder, S. Grimmer, S. Ballance

Nofima, Norwegian Institute of Food, Fisheries and Aquaculture Research, Norway

Linear 1,3-1,4 or branched 1,3/1,6- linked beta-glucans can all be classified as dietary fibre but are attributed to di-

fferent effects such as immunological modulation and glucose and cholesterol metabolism. The different beta-glucans might be quantified by their unique monosaccharides or oligosaccharides motives. For analysis some spectroscopic approaches (NMR, IR) require purification and isolation of the polysaccharides due to overlapping spectra with other polysaccharides. Specific enzymes are being used to degrade the polysaccharides into oligosaccharides and glucose that can be quantified by colorimetry (Megazyme or GEM assays). In combinations with chromatography these analysis can give sequential information on building blocks. The interaction between cereal beta-glucans and calcofluor can be used with HPLC and fluorescence detection for determination of molecular weight. This approach can be used to analyze complex mixtures such as extracts from bread and fermentation cultures, without the needs of isolation and purification. In a batch mode minute amounts of cereal beta glucans can be quantified in complex samples (Rieder et al., 2012). On the other hand precise selection of enzymes, HPLC-systems and proper correction for the occurrence of free glucose and starch different types of beta glucans in biological material can be determined. We will present some new approaches for the quantification of different types of beta-glucans in fibre ingredients, food and fermentation fluids with fluorescence spectroscopy upon interaction with certain dyes (calcofluor and aniline blue) or HPLC analysis (Rieder et al., 2013) of released oligosaccharides. Rieder, A., Grimmer, S., L. Aachmann, F., Westereng, B., Kolset, S.O., and Knutsen, S.H. (2013). Generic tools to assess genuine carbohydrate specific effects on in vitro immune modulation exemplified by β -glucans. *Carbohydrate Polymers* 92, 2075-2083. Rieder, A., Knutsen, S.H., Ballance, S., Grimmer, S., and Airado-Rodríguez, D. (2012). Cereal β -glucan quantification with calcofluor-application to cell culture supernatants. *Carbohydrate Polymers* 90, 1564-1572.

Key words: β -glucans, bread, HPLC analysis, dietary fibre, food analysis.

DEVELOPMENT OF INTEGRATED IN VITRO GUT MODEL PLATFORMS TO STUDY FIBER FERMENTATION AND GUT IMMUNE EFFECTS

S. Possemiers^{1,2}, I. Pinheiro¹, C. Duysburgh¹, I. Scheirlinck¹, M. Marzorati²

¹ProDigest, Gent, Belgium

²LabMET, Ghent University, Gent, Belgium

The role of foods on human health (e.g. immune function) is becoming more and more apparent. Into a large extent, such effects are mediated through intestinal processes. This is especially the case for dietary fibers, which may have direct immune effects, but for which most effects will result from specific fer-

mentation by the gut bacteria. Given the difficulty of studying such intestinal processes inside the human body, well-designed in vitro simulation technologies offer an essential tool to assess metabolism and bioavailability of actives or modulation of the intestinal microbiome. ProDigest is specialized in the development of in vitro simulation technologies, among which the validated SHIME® (Simulator of the Human Intestinal Microbial Ecosystem) technology, an internationally accepted, representative simulation of the gastrointestinal tract (GIT). However, although the predictive value of this model has been long validated, it does not evaluate the ultimate effects of food ingredients, such as fibers, on the intestinal epithelium and immune system, as it lacks a host biological compartment. Therefore, ProDigest has developed a novel toolbox which allows to evaluate the biological effect of microbiota and metabolites on gut wall functioning and the host immune system. The toolbox consists of the direct coupling of its SHIME technology with human cell culture models, including co-cultures of epithelial cells and immune cells and its so-called Host-Microbiota-Interaction module. This patented technology can be coupled with the SHIME and therefore allows to evaluate the metabolic fate of active ingredients in the intestine, their effect on the complete intestinal environment (e.g. microbiota changes) and the resulting modulation of gut epithelial and immune functioning; and this all in one integrated platform. Being part of the FibeBiotics project, the technology will be described in this presentation, based on proof-of-concept fiber fermentation and immune modulation studies.

Key words: Gastrointestinal tract, SHIME, gut bacteria, prebiotics, immunity.

PS3-38 HEALTHGRAIN Forum Symposium - Cereal foods and health - New results and science based nutrition guidelines

CEREAL FOODS AND COMPONENTS IN OUR DAILY DIETS AND THEIR IMPORTANCE FOR HEALTH

G. Riccardi

Department of Clinical Medicine and Surgery, Federico II University, Naples, Italy

Background and objectives: Cereal foods are the most important component of the human diet; they are major contributors of dietary carbohydrates and, therefore, play an important role in energy and substrate metabolism. The relevant literature has been reviewed to better understand the relationship between cereal food intake and major chronic non communicable diseases (NCD), trying to elucidate potential mechanisms linked to food constituents.

Methods: A PubMed search has been undertaken utilizing as key-words cereals (refined and wholegrain) plus other terms

identifying NCD and associated relevant body functions; both epidemiological and human intervention studies have been included.

Results: Relationships between cereal food consumption and health outcomes have heterogeneous patterns, depending on the type of cereal, on whether cereals are consumed as whole-grain or in refined form, on the amount of fibre, food structure, glycemic index, polyphenol content, micronutrients, etc. Recent research indicates as relevant for health not only the rate of starch accessibility and digestion in the small intestine, but also carbohydrate fermentation in the gut. Prebiotic compounds present in cereal products may influence the composition of intestinal microbiota and promote production of short chain fatty acids in the colon; this may represent one of the relevant mechanisms of the beneficial impact of many cereal foods on energy, glucose and lipid metabolism and intestinal cell proliferation (linked to the risk of cancer).

Conclusions: Epidemiological surveys consistently show an association between cereal consumption (mostly whole-grain) and prevention of several NCD; however, there is a gap between the health benefits shown in observational studies and the elucidation of the mechanisms involved. More research (particularly human intervention studies) is needed to fill this gap and provide solid grounds for more specific guidelines for cereal food consumption at the population level.

Key words: Cereal foods, health benefits, blood glucose regulation, energy metabolism, plasma lipids.

WHOLE-GRAIN AND FIBER INTAKE AND COLORECTAL CANCER; NEW RESULTS FROM THE HELGA AND EPIC COHORTS

A. Olsen¹, C. Kyro¹, G S. Skeie², A. Tjønneland¹

¹Danish Cancer Society Research Center, Danish Cancer Society, Denmark

²Department of Community Medicine, University of Tromsø, Norway

Background and objectives: Recently, World Cancer Research Fund stated that intake of dietary fiber is convincingly related to lower risk of colorectal cancer. When looking into sources of dietary fiber, cereals emerged to be the food group showing the strongest association. The content of dietary fiber constitutes one of the main differences between refined grains and whole grains. The association seen with cereal fiber may consequently partly be assigned as evidence for whole grains. None of the published cohort studies on wholegrain intake and colorectal cancer have been able to evaluate the potential different effects of the main cereals: wheat, rye and oats. Un-detailed baseline information about whole-grain intake makes studies of associations to disease a challenge in most existing

cohorts, using a biomarker to estimate whole-grain intake can overcome this problem.

Methods: In this presentation associations between dietary fiber and whole-grain intake and incidence of colorectal cancer, by use of detailed questionnaire information in a Nordic cohort (HELGA) and by use of the biomarker alkylresorcinols in a European cohort (EPIC) will be shown.

Results: In the HELGA cohort intake of dietary fiber, especially from cereal sources, and whole grains was found associated with lower colorectal cancer incidence. The strongest association was seen for whole grain wheat, with non-significant associations for oats or rye. In the EPIC cohort, whole-grain intake was measured by plasma levels of the phenolic lipids alkylresorcinols that is a validated biomarker for whole-grain wheat and rye intake. Plasma levels of alkylresorcinols were not found related to overall colorectal cancer, but lower incidence of distal colon cancer was seen among those with highest levels.

Conclusions: These studies confirm that whole grains may play a role in colorectal cancer prevention. The results are, however, preliminary and must be interpreted as such.

Key words: Whole grains, dietary fiber, alkylresorcinols, colorectal cancer, epidemiology.

HEALTH BENEFITS OF WHOLE GRAIN WHEAT: INTERVENTION STUDY CLARIFYING UNDERLYING MECHANISMS AND THE ROLE OF POLYPHENOLS BOUND TO DIETARY FIBRE

V. Fogliano, P. Vitaglione

Department of Food Science, University of Naples 'Federico II' Portici, Naples, Italy

Background and objectives: Epidemiological studies associate whole grain (WG) consumption to reduced CVD risk, body weight and abdominal circumference. Data obtained by intervention studies were not conclusive. Evidence from animal and few human studies indicated that prebiotic dietary fibre ameliorates metabolic syndrome. Whole grain, especially wheat and rye, present a large amount of polyphenols (mainly ferulic acid) bound to dietary fibre. This study aims to assess the role of dietary fiber polyphenols on health benefits of WG.

Methods: A commercial WG product, was selected. Eighty healthy overweight subjects were enrolled. Forty volunteers replaced equicaloric portions of specific foods with 68 g WG/day for 8 weeks; the other half did not change their diets. At baseline, and after 4 and 8 weeks, body weight, waist and hip circumferences, bioimpedance analysis and blood, urine and feces collection was measured. Markers linked to bioavailability of ferulic acid and several polyphenols (by HPLC/MS/MS), to inflammatory status (several cytokines by multiplexed immunometric assay), to lipid and glucose metabolism as well as

to the overall nutritional status and appetite, were measured. Metagenomic analysis of feces was run to evaluate the influence of intestinal microflora composition on the health benefit of a WG-enriched diet.

Results: 63 subjects (34 treated with WG and 29 controls) completed the study. Preliminary results indicate different concentration trends for inflammatory cytokines and ferulic acid-related metabolites in blood collected from subjects who consumed WG compared to control subjects over the study period. Data analysis is still ongoing and all final results will be crossed with metagenomic data to ascertain the role of individual microflora on bioavailability of polyphenols bound to WG dietary fiber as well as on health effect.

Conclusions: Consumption of wheat whole grain might improve inflammatory status in overweight subjects:

Key words: Whole grain, ferulic acid, prebiotic, inflammation.

WHOLE GRAIN WHEAT INTAKE – IMPACT ON WEIGHT LOSS, BODY COMPOSITION AND CARDIOMETABOLIC FACTORS – RESULTS FROM INTERVENTION STUDIES

P. Kris-Etherton, K. Harris

Department of Nutritional Sciences, Pennsylvania State University, University Park, USA

Background and objectives: Cardiometabolic syndrome (CMS) is characterized by three of the following criteria, increased visceral adiposity, hypertension, hyperglycemia, hypertriglyceridemia, and low HDL-cholesterol. Weight loss is standard treatment for CMS.

Methods: A literature review was conducted to evaluate whole grain (WG) wheat intake, weight loss and CMS risk factors.

Results: Epidemiologic evidence demonstrates a decreased risk of CMS and type 2 diabetes with WG > 2 servings/day). A systematic review of 21 prospective studies demonstrated that consuming 3-5 sv/d of WG (48-80 g/day) versus consumption rarely lowered risk of type 2 diabetes 21%, and decreased weight gain over ~10 years (1.27 vs. 1.64 kg, P=0.0001). The Health Professionals Study reported that every 40-g/d increment of WG consumption was associated with a reduction of 0.49 kg in body weight over 8 years. In three prospective cohort studies with 120,877 subjects, weight gain was inversely associated with WG intake (-0.37 lb). Intervention studies have not shown consistently that WG enhance weight loss or improve insulin sensitivity; there is some evidence that replacing refined with WG may benefit individuals with insulin resistance/prediabetes. Also, WG decrease body fat % more than refined grains in response to weight loss (-3% vs -2.1%; P = 0.04). Re-

sults from 20 RCTs reported that WG reduced fasting glucose (-0.93 mmol/L), total cholesterol (-0.83 mmol/L) and LDL-C (-0.72 mmol/L). Many studies also have reported a hypotensive effect of WG mediated by improvements in body weight, dyslipidemia, and insulin resistance.

Conclusions: Epidemiologic studies show benefits of WG on CMS, including body weight. Mixed results from clinical studies on body weight might be explained by different methodologies, including type and amount of WG consumed.

Key words: Whole wheat grain intake, risk of cardiometabolic syndrome, weight loss, body composition.

GLOBAL DIETARY WHOLE GRAIN RECOMMENDATIONS: A HARMONISED OR MULTIFARIOUS MESSAGE?

F. Thielecke², A. Nugent¹, T.E. Siong³, C.J. Seal⁴

¹University College Dublin, Institute of Food and Health, Dublin, Ireland

²Cereal Partners Worldwide, Lausanne, Switzerland

³TES NutriHealth Strategic Consultancy, Malaysia

⁴Human Nutrition Research Centre, School of Agriculture, Food and Rural Development, Newcastle University, Newcastle upon Tyne, UK

Background and objectives: Dietary recommendations for whole grain intake exist in a number of countries worldwide, however, the nature and wording of these recommendations have not been characterized to date.

Methods: Using a combination of literature searches and direct enquiry, this research reviewed current whole grain recommendations around the globe to assess presence/absence, rationale and diversity in emphasis and wording.

Results: The level of emphasis placed on dietary whole grain intake is hugely variable globally. For some countries, clearly defined dietary recommendations for whole grain intake exist which are supported by policy and health promotion campaigns. In these instances, quantitative recommendations may co-exist whereby a numerical value is ascribed providing a benchmark or 'target' for population intakes. However, this value can vary between countries and is sometimes related to a gram intake (e.g. 48g/d) or number of servings per day (e.g. 3 x 16 servings). In other countries, whole grain-specific dietary recommendations may be deemed as secondary, whereby they usually form part of broader guidelines on carbohydrate and/or fibre intakes or even general healthy eating guidelines. Where this occurs, the recommendations are typically less prescriptive and may be more difficult to disentangle from the primary recommendation. This can make the impact of any public health campaigns difficult to assess. Finally, in some regions, dietary recommendations for whole grain intake do not exist at all.

Conclusions: This review critiques the evidence regarding dietary recommendations for whole grain intake worldwide. The results indicate that there is a lack of a harmonized message which may result in potential confusion for the consumer, lessen the impact of public health messages and pose barriers to trade for the food industry.

Key words: Diet, whole grain, recommendations.

PS4-46 Functional roles of human milk and other selected oligosaccharides

ISOLATION, CHARACTERIZATION AND FUNCTIONAL ROLES OF HUMAN MILK OLIGOSACCHARIDES

C. Kunz¹, S. Rudloff^{1,2}

¹Institute of Nutritional Sciences, University of Gießen, Gießen, Germany

²Department of Pediatrics, University of Gießen, Gießen, Germany

Since the discovery of human milk oligosaccharides (HMO) more than 60 years ago, research has faced major challenges including (i) the development of methods to identify and characterize these components, (ii) the need to use HMO fractions for functional studies since single HMO were not available, and thus (iii) the low availability of large quantities of single HMO for animal and human studies. In the last 10 years, there has been a tremendous progress in all these areas. Based upon *in vitro* experiments, animal studies and a few association studies in humans, many functions of HMO have been proposed. Recent animal studies support HMO functions shown *in vitro*. Concomitantly with these observations, progress in biotechnology today allows the production of at least some of the major HMO to be potentially added to infant formula. To be able to decide which compound should be used in which concentrations or combinations, studies are needed regarding absorption, metabolism and physiological functions in infants. Strikingly, the pattern of oligosaccharides in human milk depends on the mothers Lewis blood group specificity and secretor/non-secretor status. HMO are mainly characterized by type 1 structures (Gal α 1-3GlcNAc-linkages). Milk of other species including apes and monkeys either contains only or mainly type 2 oligosaccharides (Gal α 1-4GlcNAc-linkages). It seems likely that type I HMO exert specific effects in breast-fed infants. Here, we will focus on the potential of HMO to influence the microbial composition in the gastrointestinal tract, the adhesion of pathogens to the epithelium, and inflammatory processes after intestinal absorption. In addition, an increasing number of publications indicate a link between the blood group and secretor status of an individual and the risk for diseases, such as inflammatory gastrointestinal diseases. Thus, not only the

HMO content but also their pattern may be relevant for the infants' health.

Key words: Gastrointestinal tract, human milk, infant formula, oligosaccharides.

BASIC ASPECTS OF HUMAN MILK OLIGOSACCHARIDES; NEW PRECLINICAL AND EX-VIVO OBSERVATIONS

P. Prieto¹, K. Goehring¹, S. Davis¹, J. Bienenstock², R. Buck¹

¹Abbott Nutrition, Strategic Research Department, Columbus, Ohio, USA

²Department of Pathology and Molecular Medicine, McMaster University, Hamilton, Ontario, Canada

We have previously demonstrated that a soluble human milk glycan (SMG) can be produced in kilogram scale and conducted preclinical, toxicological and clinical studies to demonstrate its safety of use and probe for biological effects. We decided to focus our research on interactions of the most abundant soluble milk glycans with different cellular and tissue systems to identify biological activities that may be consistent with health benefits. We determined concentrations of SMGs in mother's milk, and plasma and urine of breast-fed infants to evaluate the possibility of systemic effects. We also exposed respiratory epithelia and peripheral blood mononuclear cells to SMGs before challenging them with respiratory viruses. We then measured viral load and cytokine profiles to ascertain the ability of these SMGs to protect from infection and modulate immune responses. We also explored topical effects in the gastrointestinal system by assessing the effect of SMGs on cell lines representing different stages of maturation of human intestinal tissue. Furthermore, we measured the effect of fucosylated glycans on *ex vivo* rodent intestine and measured the ability of these carbohydrates to modulate peristaltic movement. We found that the plasma and urine concentration of the most abundant free soluble glycan of human milk, 2'fucosyllactose, in breast-fed infants correlates with the concentration of this carbohydrate in milk of the corresponding mother. We also found that different SMG decrease the viral load of specific respiratory viruses and impact cytokine responses with a marked modulation of IP-10, which is a recognized biomarker of respiratory disease susceptibility and inflammation. In addition, specific SMG emulate differentiation of intestinal cell lines and modulate neurally dependent colon contractions in rodent intestinal explants. These novel findings indicate SMG have the potential to deliver local and systemic health benefits.

Key words: Cytokine, glycans, human milk, oligosaccharides.

THE ROLE OF HUMAN MILK OLIGOSACCHARIDES IN INTESTINAL COLONIZATION

A. Walker

Harvard Medical School, Massachusetts General Hospital, Boston, USA

Human breast milk contains numerous functional components which facilitate the newborn's adjustment to the extrauterine environment. of major importance to the newborn is an appropriate initial colonization of the intestine. Such colonization assures the development of intestinal mucosal and systemic immune function leading to immune homeostasis and preventing the expression of allergic and immune-mediated diseases in later life. Breast milk contains several factors that help to establish a symbiotic relationship between the colonizing bacteria and the host. A major component of breast milk is oligosaccharides which comprise eight percent of the total nutrients and represents a diverse array of oligosaccharides. The oligosaccharides, also known as prebiotics, bypass small intestinal digestion and enter the colon where they are fermented into short chain fatty acids (ascetic, butyric, proprionic, etc.) producing and acidic intrauterine environment. This collective environment favors the proliferation of specific probiotic bacteria, e.g., Bifidobacteria, Bacteroides, and Lactobacillus, which colonize the intestine in large quantities early in postpartum existence and preferentially stimulate appropriate innate and adaptive immune responses. In addition, the breast milk environment stimulates these probiotic bacteria, particularly Bifidobacteria, to activate their specific genes which favor protection from pathogens including specific anti-inflammatory responses. The composition and quantity of oligosaccharides (prebiotics) in breast milk is dynamic with more diverse and larger quantities present in colostrum and breast milk from mothers who delivery preterm infants. Accordingly, breast milk comprehensively contributes to the initial colonization of infant's gut and indirectly helps protect the newborn from insult in the extrauterine environment.

Key words: Human milk, intestine, oligosaccharides, immune system, prebiotics, probiotics.

NONABSORBABLE OLIGOSACCHARIDES: JUST PREBIOTICS?

O. Martínez-Augustín¹, M. Ortega-González², F. Capitán-Cañadas², B. Ocón³, I. Romero-Calvo², A. Zarzuelo⁴, M.D. Suárez¹, F. Sánchez de Medina⁴

¹Department of Biochemistry and Molecular Biology II, CIBERehd, University of Granada, Granada, Spain

³Department of Pharmacology, University of Granada, Granada, Spain

⁴Department of Pharmacology, CIBERehd, University of Granada, Granada, Spain

Prebiotic effects of non absorbable glucids (NAGs) have been widely studied and depend mainly on the fermentation by the colonic microbiota. Nevertheless, before reaching the colon, NAGs go through the small intestine and are in contact with the intestinal epithelium and, in intestinal pathologies, they can even reach other layers of the intestine. On the other hand there is some evidence indicating that prebiotics could be transported by the intestinal epithelium. Little is known about non prebiotic effects of NAGs but it is widely known that carbohydrates interact with different cell types, and NAGs have been reported to bind to specific receptors on cells of the immune system, suggesting that microbiota-independent, immune-modulatory effects play a role as well. In fact, recent research with different cell lines and primary cultures indicate that NAGs interact with different receptors in intestinal epithelial cells, macrophages and lymphocytes regulating signal transduction pathways and the subsequent expression various cytokines. NAG also may exert modulatory actions in germ free mice, supporting that direct effects occur in vivo. Differences among several milk oligosaccharides including oligofructose, inulin, goat's, cow's and human milk have been described. Non-prebiotic effects of NAGs have been related to their beneficial effects on allergy and to a possible role in the intestinal defense. The relevance of these findings will be discussed.

Key words: Prebiotics, intestinal epithelial cells, immune cells, signal transduction pathways, non absorbable glucids.

PS4-54 Functional roles of prebiotic inulin-type fructans

PREBIOTIC MODULATION OF THE HUMAN GUT MICROBIOTA: IS THIS A HEALTH BENEFIT?

R.A. Rastall

Department of Food and Nutritional Sciences, The University of Reading, Reading, UK

It is recognised that the complex microbial ecosystem in the human colon has a profound impact on health. This has led to approaches to improve health via the nutritional manipulation of this ecosystem.

Functional food ingredients have the potential to modulate the colonic microbiota and its metabolic profile to promote health. Traditionally, this has been by the administration of live bacterial supplements, or probiotics. Whilst specific, carefully selected bacterial strains can have health benefits, it is not possible to bring about large changes in the colonic microbiota this way. In 1995 the concept of prebiotics was introduced and several definitions have followed with the most recent one published in 2010. Essentially prebiotics are food ingredients, supplements or components that escape digestion in the small intestine and reach the colon largely intact. They are then selectively fermented by health-positive members of the colonic microbiota. All recognised prebiotics are carbohydrates such as fructo-oligosaccharides, inulin and galacto-oligosaccharides. Many more are being investigated.

Much of the early work on prebiotics focused on increasing the relative populations of bifidobacteria and lactobacilli. These are non-pathogenic species with a range of recognised health-positive attributes including inhibition of intrinsic and extrinsic pathogens, modulation of immunity and vitamin synthesis. The health attributes of these organisms are still being explored in laboratory and human volunteer trials and data are accumulating to support their use in a range of chronic and acute gut disorders. Recent thinking, however, has focussed increasingly on the metabolites produced by the colonic microbiota and the impact of these metabolites on health is being studied. This widening of emphasis is stimulating debate over the definition of prebiotics.

This talk will examine the evolving view of what is meant by a prebiotic, and critically examine how they might act to increase health.

Keywords: Gut microbiota; prebiotics; gut health.

GUT MICROBIOTA IMPACT ON METABOLIC DISORDERS ASSOCIATED WITH OBESITY

N. Delzenne

Université Catholique de Louvain, Louvain-la-Neuve, Belgium

Experimental data in animals, but also observational studies patients, suggest that the composition of the gut microbiota differs in obese versus lean individuals, in diabetic versus non diabetic patients, or patients presenting other diseases associated with obesity or nutritional dysbalance, such as non alcoholic steatohepatitis. Several observation studies in humans allow to point out interesting bacterial targets, such as *Bifidobacterium* spp., which abundance is inversely correlated to obesity and diabetes; *Faecalibacterium prausnitzii*, that could be involved in the control of diabetes-related inflammation, or *Akkermansia muciniphila*, involved in mucus layer regulation, which has been shown to be inversely correlated with obesity. We have recently confirmed, in an intervention study with fructan prebiotics versus placebo in obese women, that, even if the increase in Bifidobacteria remains the major and common signature of the prebiotic approach, a complex modulation of the gut microbial ecology – that can be studied through both bacterial genomic analysis and host fluids metabolomics- occurs upon prebiotic treatment in obese individuals. Some bacterial changes are clearly related to a decrease in inflammation, others the improvement of fat mass and of metabolic alterations. The mechanistic studies suggest that the changes in the gut microbiota occurring upon prebiotics, can be related to an improvement of gut bacterial functions implicated in the regulation of host energy homeostasis. The promotion of gut hormones release, changes in the gut barrier integrity, and/or the release of bacterial-derived metabolites could all participate in the improvement of host health in the particular context of overfeeding and obesity.

Key words: Gut microbiota, obesity, prebiotics, inflammation, gut peptides.

PREBIOTICS IN INFANT NUTRITION

R. Closa-Monasterolo^{1,2}

¹Hospital Universitari Joan XXIII de Tarragona, Tarragona, Spain

²Institut d'Investigació Sanitària Pere Virgili, Universitat Rovira i Virgili, Reus, Tarragona, Spain

Before birth, the gastrointestinal tract is sterile; it occurs immediately after birth that the gastrointestinal tract become colonised by bacteria from the mother and the birthing environment. The developing microbiota and its composition is

thereby influenced by a number of factors such as the type of delivery (caesarean section showing lower numbers of *Bifidobacterium fragilis* and higher counts of *Clostridium difficile* in comparison to vaginally birth), the stage of maturity, antibiotic therapy and feeding practices. Breastfed infants, for instance, have different flora that is mainly composed of *Bifidobacteria* and *Lactobacillus* in comparison with formula-fed infants, displaying a more complex flora with a predominance of *Clostridia*, *Bacteroides* and *Streptococci*. Moreover, it has been observed that breast-fed infants grow and developed differently with reduced incidences of late-onset neonatal infection, necrotizing enterocolitis, infections, allergy and childhood obesity. There is also evidence that infant feeding can influence the risk of metabolic syndrome later in life.

Whereas human milk contains about 8% of total carbohydrates in the form of prebiotic oligosaccharides that selectively favour the growth and residence of lactic acid bacteria in the infant gut, infant milk formulas do not contain such prebiotics unless they are enriched. Meanwhile several studies have examined the impact of prebiotic supplementation with inulin, oligofructose and Orafiti®Synergy1 to infant formula in paediatric populations, feeding improvement in gut flora composition, increased stool frequency and promoting softer stools.

Further benefits of prebiotic supplementation show preventive protection against the development of atopic dermatitis or infections.

One of this studies published recently by Veereman-Wauter and co-workers assesses the effects of an infant formula supplemented with 0.8g/dL Orafiti®Synergy1 in newborns in a randomized controlled trial of 4 weeks. Orafiti®Synergy1 supplemented formula showed similar efficacy as a "GOS:FOS (90:10) supplemented formula in promoting a stool consistency and microflora closer to the breastfed pattern.

This work led to the development of the Bambinol study which addresses tolerance, safety, and efficacy of an Orafiti®Synergy1 supplemented infant formula during the first four months of life.

The Bambinol study was set up in double-blind, randomized, placebo-controlled design with two groups of neonates receiving and infant formula supplemented with 0.8g/dL Orafiti®Synergy1 or an infant formula without prebiotics as control (n=252) for four months. An additional reference group of breast-fed infants (129) was monitored in parallel. Results showed similar growth, milk intake, and fluid balance and biochemical values in the intervention and control groups, demonstrating the safety of Orafiti®Synergy1 supplementation. Additionally, Orafiti®Synergy1 promote a deposition pattern closer to the mother milk with improved stool frequency and consistency versus de control formula. An important finding from this study is that the favourable softer stools were not associated with disturbed water balance. Moreover, a trend of increasing *Bifidobacterium* in faecal flora was seen with Orafiti®Synergy1, without any side effects compared to the standard formula. In conclusion, the study demonstrates that the

supplementation of 0.8g/dL Orafiti®Synergy1 to formula milk during the first four month of life is safe and effective in terms of gut health.

Key words: Inulin, oligofructose, prebiotics, infant formula.

ROLE OF PREBIOTICS IN REGULATING ENERGY INTAKE AND BODY WEIGHT

R A. Reimer

Faculty of Kinesiology, University of Calgary,
Calgary, Alberta, Canada

The human food supply has changed drastically over the past 50-75 years, including reduced dietary fiber content, with an alarming increase in obesity following close behind. In response, there is a growing interest in value-added foods that will help curb the obesity epidemic. The effectiveness of dietary fiber, particularly prebiotic inulin-type fructans, to aid in weight management is supported by convincing data in animal studies and a growing body of evidence from human clinical studies. This presentation will highlight the mechanisms by which prebiotic fiber acts to regulate body weight with a special focus on gut satiety hormones. Furthermore, given the demonstration that the susceptibility to obesity can be programmed early in the course of development, the influence of prebiotic fiber on maternal health during pregnancy and offspring health will also be discussed. The overall goal of this presentation is to highlight the latest evidence for role of prebiotic fibers in body weight management across the lifespan.

Key words: Prebiotic, Energy Intake, Obesity.

PS5-70 Phytochemicals Responsible for the Food Function, from the chemistry to physiological relevance and human health

RED WINE POLYPHENOLS AND HUMAN HEALTH

⁴CIBER Fisiopatología de la Obesidad y la Nutrición, Instituto de Salud Carlos III, Spain

⁵Laboratorio de Investigaciones Biomédicas del Hospital Virgen de la Victoria (Fundación IMABIS), Málaga, Spain

⁶Servicio Endocrinología y Nutrición del Hospital Universitario Virgen de la Victoria, Málaga, Spain

Background and objectives: Epidemiological studies have associated moderate consumption of red wine (RW) to a lower risk of coronary heart disease. The aim of this study was to evaluate RW polyphenols as biomarkers of intake and effect on human health using targeted and untargeted approaches by mass spectrometry (MS) and Nuclear Magnetic Resonance (NMR). The potential prebiotic effect of wine polyphenols on human feces microbiota was evaluated.

Methods: High cardiovascular risk subjects followed three interventions (28 days each) in a randomized crossover clinical trial: dealcoholized-RW (DRW)(272mL/day, polyphenols-control), RW (272mL/day) and Gin (100mL/day, alcohol-control). Urine samples (24h) were collected and analyzed by UPLC-MS/MS, HPLC-q-TOF-MS and 1H-NMR. Multivariate (Orthogonal Partial Least Square: OPLS) and univariate statistical analysis (ANOVA, Friedman and Wilcoxon's signed-rank tests) were used to compare treatments.

Results: Targeted analysis identified up to 21 resveratrol (RV) metabolites [phase II conjugates of RV and dihydroresveratrol (DHR) as microbial metabolites] after RW and DRW consumption. Besides others, glucuronide conjugates of dihydroxyphenylvalerolactone, RV and DHR identified by untargeted HPLC-q-TOF-MS were discriminant by OPLS analysis after both wines compared with gin intake. Endogenous 3-methyl-2-oxovalerate, a branched-chain amino acid (BCAA) metabolite, was highly excreted after RW and DRW intakes..

Considering the microbial composition in feces, Fusobacterias, Enterococcus spp, Bifidobacteria, Blautia Coccoides and Eggertella lenta were significantly increased after DRW and RW comparing with baseline.

Conclusions: The use of multivariate statistical approaches can elucidate new biomarkers in high cardiovascular risk subjects after RW consumption. Presence of metabolites from BCAAs pathway could suggest an increase in the global energetic metabolism. This study showed that RW consumption can significantly modulate the growth of selected gut microbiota in humans, which suggests possible prebiotic benefits associated with the inclusion of RW polyphenols in the diet. This trial was registered at controlled-trials.com as ISRCTN88720134.

Key words: Wine, biomarker, metabolomic, metabolic profiling, LC/MS, NMR.

MULTI-FUNCTION OF GALLATE FOR HUMAN HEALTH

S.J. Chang

National Cheng Kung University, Tainan, Taiwan

Gallic acid (3,4,5-trihydroxybenzoic acid.) is one of phytochemicals and is found in many plants, such as gallnuts, tea leaves, and Toona sinensis leaves. Gallic acid (GA) and its derivatives (gallate) have been regarded to possess anti-oxidant, anti-obesity, anti-atherosclerotic, anti-diabetic, and anti-cancer effects in animal and human studies. GA is part of the structure of other polyphenols, and commonly used in laboratories as standard to measure the concentration of phenolics and polyphenols in plant extracts. GA has two functional groups hydroxyl and carboxylic acid groups. It can yield numerous esters and salts derivatives including digallic acid which is formed by the reaction of two gallic acids such as epigallocatechin gallate (EGCG). EGCG, the major and active compound in green tea, is a powerful antioxidant and has been shown to protect against heart diseases and cancer in numerous studies. Tannins, esters of digallic acids, have shown potential anti-viral, anti-bacterial and anti-parasitic effects. Recent studies indicated that GA, the major compound in the ethanolic extract of Toona sinensis leaves, decreased the hyperglycemia and insulin resistance in the type 2 diabetic mice, and reduced the lipid accumulation in the adipocytes and oleic acid treated hepatocytes, which is beneficial for body fat control and fatty liver. Molecular mechanism underlying was through peroxisome proliferator activated receptor alpha (PPAR γ) due to the increased expressions of PPAR γ and its downstream genes responsible for glucose and lipid metabolism by GA. Protein analysis indicated that GA reduced the expression of proteins responsible for gluconeogenesis and lipogenesis, leading to the reduced hepatic glucose production and lipid accumulation in liver of diabetic mice.

Thus, GA and its derivatives with a variety of biological activities protect human from metabolic disorders, suggesting to be developed into new adjunctive agents for human health.

Key words: Human health, phytochemicals, gallate, oxidative damage, viral infection, metabolic disorder.

GARLIC-DERIVED COMPOUNDS FOR THE PREVENTION OF LIFESTYLE-RELATED DISEASES

T. Seki, K. Watanabe, T. Imai, A. Sato, Y. Kagawa, T. Hoso

Department of Chemistry and Life Science, Nihon University, Fujisawa, Japan

Garlic (*Allium sativum* L.) has long history as food with characteristic flavor and some medicinal properties. Modern scientific research revealed that wide variety of dietary and medicinal functions of garlic such as antimicrobial, antiobesity, antihypertensive, antithrombotic, and anticancer effects. These potent activities are mostly attributed to sulfur compound derived from garlic. Actually, garlic contains great amount of sulfur in comparison with other edible vegetables. The sulfur is usually stored as amino acid including S-allyl-L-cysteine sulfoxide, S-methyl-L-cysteine sulfoxide in the garlic. Characteristic flavor is generated by the reaction of CS-lyase and S-allyl-L-cysteine sulfoxide or S-methyl-L-cysteine sulfoxide, when the cellular structure of garlic is disrupted. Diallyl thiosulfinate (allicin) and allyl methyl thiosulfinate are generated by the enzymatic reaction, and several kinds of sulfides are further generated by the following spontaneous reactions with sulfinates produced by CS-lyase. The sulfides including diallyl trisulfide, diallyl disulfide, allyl methyl trisulfide, diallyl sulfide are more stable than the sulfinates. In the crushed garlic, more than 20 kinds of sulfide compounds could be detected; however, their functions are different from one another; e.g., allicin, allyl methyl trisulfide, and diallyl trisulfide have potent antimicrobial, antithrombotic, and anticancer activity, respectively. Food function of garlic against lifestyle-related diseases including antiobesity, antithrombotic and antileukemic properties of these sulfides, and some of their molecular basis will also be discussed in this paper.

Key words: Cancer, garlic, obesity, thrombosis.

PHYSIOLOGICAL FUNCTIONS OF A FLAVOR COMPONENT FROM SHIITAKE MUSHROOMS

H. Kumagai, M. Akao

Department of Chemistry and Life Science, College of Bioresource Sciences, Nihon University, Japan

Background and objectives: Shiitake mushrooms (*Lentinula edodes*) are appreciated for their specific flavor and often used in Japanese cuisine. The flavor compounds from shiitake mushrooms are cyclic sulfuric compounds, which are formed from lentinic acid by enzymes when they are cut or crushed. Lenthionine is the major component among them characterizing the shiitake flavor. This study presents the physiological functions of lenthionine especially focusing on the inhibitory activity against platelet aggregation and suppressive activity against hepatic injury.

Methods: Lenthionine was orally administered to rats, and its inhibitory effect against platelet aggregation was evaluated *ex vivo*. In order to examine the mechanism of action, platelets were activated by various agonists *in vitro* and the inhibition percent of lenthionine against aggregation was measured. Phosphorylation of proteins, morphological change and activation of platelets were also compared with and without the presence of lenthionine.

The preventive effect of lenthionine against acute hepatic injury was evaluated by using carbon tetrachloride. After the oral administration of lenthionine to mice, hepatic injury was induced by carbon tetrachloride. Then, markers of hepatic injury and activities of detoxification enzymes were determined.

Results:] Platelet aggregation was inhibited by the oral administration of lenthionine and by the addition of lenthionine to the blood samples prior to the induction of aggregation by various agonists. Phosphorylation of β -actinin and polymerization of actin were suppressed by the addition of lenthionine to platelets, which led to the prevention of their morphological change and integrin GP IIb/IIIa activation. Orally-administered lenthionine prevented the progress of hepatic injury inducing phase II detoxification enzymes and suppressing oxidative stress.

Conclusions: These results indicate that lenthionine exerts physiological functions *in vivo* even when it is orally administered, and the mechanism of action of lenthionine is different from that of sulfides from garlic.

Key words: Shiitake flavor, lenthionine, platelet aggregation, hepatic injury.

T7 FOOD CULTURE AND NUTRITIONAL EDUCATION

NPS1-7 The role of nutraceuticals in health along with basic nutrition

GLOBAL NUTRIENT SECURITY AND NUTRIENT BIOAVAILABILITY

H. Lelieveld¹, I. Odriozola-Serrano², G. Oms-Oliu², O. Martin-Belloso²

¹GHI Association, c/o Department Food Science & Technology, Universität Für Bodenkultur, Vienna, Austria

²Department of Food Technology, University of Lleida, Agrotecnio Center, Lleida, Spain

A billion people suffer from hunger, but even if people receive their energy supply, they often do not receive enough essential nutrients. In many cases these nutrients are in the food, but not bioavailable, thus, attention should be paid to making nutrients accessible to the organism. Preservation technologies are being used to obtain safe and stable food, in addition, feasibility of using these technologies to enhance the bioavailability of certain nutrients present in food products is under study. Depending on the food matrix, the presence of antagonistic agents may substantially compromise nutrient bioavailability.

Thereby, an update on the state of the art of processing technologies regarding the effects on nutrient bioavailability on different foods will be presented through the discussion of some of the key aspects that rule the enhancement or decrease of nutrient bioavailability in preserved food. As fruits and vegetables are rich sources of nutrients and other health-related compounds, case studies on various plant foods will be presented to illustrate the ability of thermal and nonthermal food preservation technologies for increasing nutrient accessibility to the organism. Although an improvement of nutrient bioavailability is important for population in general, this is a critical concern for people who do not have a guaranteed food security.

Key words: Food security, nutrient bioavailability, processing technologies.

ANCIENT WISDOM AND NUTRACEUTICALS - INTERNATIONAL PERSPECTIVE

L R. Juneja

Taiyo Kagaku Co., Ltd., Yokkaichi, Mie, Japan

The role of diet in health maintenance and disease prevention has been known for centuries based on experience and epidemiological data. We have explored functionality of green tea and various other botanical by various scientific studies to confirm the health benefits. Many studies on various nutraceuticals based on ancient secrets will be discussed. The relationship between food and health is complex and continuously evolving with recent increased consumer awareness of nutrients and nutraceuticals and their delivery system that has begun to appear in a tremendous increase in the market size

Key words: Botanicals, disease prevention, nutraceuticals.

DRUG-INDUCED NUTRIENT DEPLETION: UNMET CLINICAL NEED OR LABEL WARNING?

M P. Palthur

Indigene Pharmaceuticals, Inc., Hyderabad, India

The depletion of nutrients by drug treatments and iatrogenic nutritional deficiencies is a long-standing problem in the current health care. Although the disease itself is the primary factor in the progression of symptoms, scientific literature with varied level of evidence indicate the role of nutrient depletion in the progression of disease. Furthermore, drug-induced nutrient depletion seems to be understated in the current drug review and approval process as an adverse drug reaction among the cluster of adverse reactions and side-effects on patient safety information sheets. Drug-Induced Nutrient Depletion is complex and appropriate system of comprehensive disease management program is yet to be evolved. This session is inclined to raise debate and call for action on Drug-Induced Nutrient Depletion issues rather than reviewing the published literature. Various options for debate including, nutrition panel review as a component of drug approval are proposed. Furthermore, repurposing of nutraceuticals and the co-existence and integration of nutraceuticals and pharmaceuticals is proposed as a prospective product solution.

Key words: Drugs, health care, nutrient depletion.

MAPPING FRUIT, VEGETABLE AND PHYTONUTRIENT CONSUMPTION GLOBALLY

Y. Lin

Supplement Product Development, Amway Corporation, USA.

Fruits and vegetables are important sources of key nutrients, such as potassium, dietary fiber, folic acid, vitamins A, C and E with recommended intakes. Additionally, they contain naturally occurring phytochemicals, which may have health benefits beyond basic nutrition, despite having no recommended intakes at this time. By utilizing the World Health Survey (WHS) Data and Global Environment Monitoring System (GEMS) Data which maps clusters, new global research will reveal, by global cluster as defined by the World Health Organization, the number of servings of fruit and vegetables consumed, the top fruits and vegetables consumed based on volume intake, and indicate the most concentrated phytonutrient sources among the fruits and vegetables being consumed. These findings will provide the foundation for further research documenting any global phytonutrient shortfalls. The research design mirrors an earlier protocol, which quantified the “phytonutrient gap” or intake shortfalls of nine phytonutrients found predominantly in fruits and vegetables among the US population (published February 2012 in the paper entitled “Phytonutrient Intake by Adults in the United States in Relation to Fruit and Vegetable Consumption” in the Journal of the Academy of Nutrition and Dietetics.

Key words: Fruit, vegetable, phytonutrient consumption

COLLABORATIVE FUNCTIONAL FOOD AND NUTRACEUTICAL RESEARCH OPPORTUNITIES IN CANADA

L. Milligan

Advanced Foods and Materials Canada, Guelph, Ontario, Canada

The research and development landscape in Canada is diverse and complex. There are numerous world-class resources to aid discovery, scale-up, and commercialization of innovative food and health products, and Advanced Foods and Materials (AFM) Canada is the portal to engage with them. Our extensive network across Canada includes Universities, Government research labs, contract development centers, , business enterprises, producer groups, and private and public funding organizations. Evolving into an independent, self-sufficient, non-profit organization from AFMNet (a Network of Centres of Excellence in food research founded in 2003), AFM Canada gains awareness , and facilitates the translation, of laboratory

breakthroughs into commercial success and has managed a portfolio of over \$25 million in multidisciplinary and multi-sectoral R&D funding and has successfully raised an additional \$13 million in leveraged financing from other sources, leading toward the generation of numerous start-up companies, patents, licenses, and the development of highly qualified personnel. AFM Canada is actively managing more than 25 innovative projects, including over \$2.5 million in public and private project funding, producing technologies that will have a positive impact on the well-being of consumers around the world.

Key words: Collaboration, R&D, network, funding, university.

PS1-7 Cultural differences in diet and nutrition across Europe. Impact on health

NUTRITION AND POLITIC – EASTERN COUNTRIES’ EFFECT OF TRANSFORMATION

M. Schlegel-Zawadzka

Department of Human Nutrition, Institute of Public Health, Jagiellonian University Medical College, Krakow, Poland

The transformation from a communist into a capitalist system in East European countries had an influence on their population in many aspects. Among them were dietary habits, consumer preferences and food security. Since early twenty-first century, when several countries joined the European Union, this influence started to increase. Several facts should be mentioned in connection with food nutritional value – the development of new food formulations, application of new technology in food industry, changes in agricultural (animal and plant) production, the introduction of new food packaging for extending the shelf life and increase in food imports, which had not been before. Changes occurred in dietary habits, structure of fat consumption in favour of poultry meat. However, several negative effects can be also observed, such as increased consumption of sugar, sweets, fat and salt, irregular meals, food intake higher than the energy demand. These phenomena are reflected in the increase of the incidence of civilization diseases.

Key words: Politic, food security, civilization diseases

DIET AND HEALTH IN THE MIDDLE OF EUROPE

H. Boeing

German Institute of Human Nutrition, Potsdam-Rehbrücke, Germany

Eating habits in the middle of Europe are influenced by the local production of food. However, with the common European market, these local eating practices were more and more influenced by ideas of a healthy diet originating either from the South or recently from the North of Europe. The most prominent example is the Mediterranean diet index mainly characterized by olive oil, fish, raw vegetables, fruits and less meat and dairy products. Recently, a Nordic healthy diet index was proposed consisting of fish, cabbage, rye bread, oatmeal, apples, pears and root vegetables. Both types of indices have shown to be associated with reduced mortality and chronic disease risk in their regions, but also other populations.

The future diet in the middle of Europe have the change to combine the advantages of both types of indices since most components of the two indices also belong traditionally to the diet in middle Europe or have found acceptance during the last decades. Very interesting is the combination of the fiber component from the Northern diet with the vegetable component from the Southern diet. In the middle of Europe, the intake of fiber rich bread as well as the intake of raw vegetables is a widespread dietary practice, however, with some modification compared to the original indices. Compared to the North, fiber rich wheat products instead of rye products are often been eaten. Compared to the South, not only fruiting and leafy vegetables such as tomatoes and lettuce are eaten, but also root vegetables such as carrots. Despite these differences, inverse risk relation could be observed for particularly these two dietary components in cohort study analyses from Middle Europe.

In conclusion, the diet of the middle of Europe has the change to select the best preventive dietary components, identified either in Northern or Southern Europe, and to combine them in the daily dietary practice, since their consumption is already been introduced in principle for a long time.

Key words: Diet, European Union, Mediterranean diet

IS THE MEDITERRANEAN DIET THE BEST ONE IN EUROPE?

M. Porrini

Department of Food, Environmental and Nutritional Sciences, University of Milan, Milan, Italy

Since the first data from the seven countries study, numerous surveys showed that adherence to a Mediterranean diet (MD) can significantly decrease the risk of mortality from cardiovascular diseases and cancer, as well as the incidence of age associated cognitive decline.

The MD was identified as the traditional dietary pattern from Crete, Greece and southern Italy in the early 1960s, characterized by high consumption of whole grains, legumes, nuts, fruits, vegetables and olive oil and moderate consumption of fish. For decades, researchers have been intrigued by the health benefits of its numerous components, but also by the role of the overall dietary pattern. The rationale is that food items and nutrients may have synergistic or antagonistic effects. Furthermore, the combination of healthy food choice with healthy weight, physical activity, a well ordered life, and a proper dose of sunlight may increase the beneficial effects.

There are other diets associated with a reduced risk of chronic diseases, such as the traditional Okinawan diet and the modern DASH diet (Dietary Approaches to Stop Hypertension), as well as dietary patterns identified by a statistical approach (e.g. factor or cluster analysis), such as the Prudent pattern.

In Europe, considerable differences in food habits exist among different countries, even if a sort of south-north gradient is present from Mediterranean to Western dietary patterns. However, southern countries are moving away from the Mediterranean model, as revealed also by a survey conducted in southern Italy (the Moli-sani project). On the other side, an interesting experience comes from the North Karelia Project, launched in Finland in the 1970s to help reducing the high coronary mortality. The results confirm how the Mediterranean "lesson" may be helpful in improving lifestyle and promoting health.

Key words: Mediterranean diet, dietary pattern, lifestyle

DOES LOCAL DIET LEAD TO MORE SUSTAINABLE DIET?

I. Thorsdottir

School of Health Sciences, University of Iceland, Reykjavik, Iceland

Background and objectives: Growing interest for locally produced healthy foods is linked to actions needed because of climate change. Striving to avoid transporting food long distances is an example of such actions. The vision to go back from the all-a-like global food production to varying cultural foods supports this interest. More knowledge about food, nutrition and health has also led to increased interest in locally produced food. The objective of this paper is to explore whether a local diet leads to a more sustainable diet.

Methods: Sustainable diet can be defined as

-a diet that can be the diet of a population continued over a long time without damage to the environment i.e. based on sustainable use of resources and without harmful pollution,

-a diet that promotes health of the population at all ages and conditions and takes the impact of diet in early life on health later into consideration, -a diet that preserves biodiversity.

Results from several studies on local foods for vulnerable groups (infants, children, adults with metabolic syndrome) will be discussed and evidence for recommending local diet as more sustainable diet.

Results: Investigations show a need for better adherence to the old Nordic recommendation on vitamin D intake. A minority of 7 year-old children (22.4%) were following the vitamin-D intake recommendations during autumn in Iceland. About 65% of the children had sub-optimal vitamin-D blood levels. In the SYSDIET randomized controlled study the dietary quality of a Nordic population with metabolic syndrome was found unsatisfactory. A change to a Healthy Diet including local foods (e.g. rye bread, barley, fish, vegetables, fruit and berries, rapeseed oil) improved the nutritional quality of the intake significantly.

Conclusions: Studies on local diets in the Nordic countries indicate they are more sustainable and promote health in several vulnerable groups in the population.

Key words: Local diets, Nordic diet, sustainability, Vitamin D.

to assess, maintain and enhance the nutrition competence of those who give nutrition advice to the public, including online assessment of nutrition skills leading to AfN Certificate of Nutrition Competence, and Course Certification, which recognises evidence-based and effective nutrition training. Finally, we will provide an overview of AfN's strategic objectives for the next five years; to provide leadership to the international community and share our skills and knowledge in capacity building in the workforce, at both the professional and lower levels, to the benefit of all.

The lecture will be of interest to those involved in capacity building and skill development, in the governance of professional, regulatory or statutory bodies in nutrition, to course leaders in higher and further education, to employers and commissioners of training programmes.

You can find out about AfN's work to support the wider workforce for the protection of the public, on www.associationfornutrition.org.

Key words: Capacity building, nutrition education, leaderships, training.

PS1-7 B Professionalism and Capacity Building in Nutrition – a UK perspective

PROFESSIONALISM AND CAPACITY BUILDING IN NUTRITION – A UK PERSPECTIVE

A. Jackson^{1,2}, L. Milliner¹

¹Association for Nutrition, UK

²Institute of Human Nutrition, University of Southampton, UK

Professor Jackson and Leonie Milliner will update the conference on developments in the UK to regulate the practice of nutrition to build capacity and develop workforce competence in evidence-based nutrition. The lecture will outline the role of the Association for Nutrition (AfN), the Voluntary Regulator for Registered Nutritionists in the United Kingdom, and the Association's work to restructure the register, define competency standards for entry to the nutrition profession, and develop a modern, responsive and internationally-focused course accreditation for higher-education providers. They will outline AfN's work, funded by the UK's Department of Health's Third Sector Investment Programme, and building on AfN's role as the Voluntary Regulator, to set standards, recognise and quality assure the skill and competence of the wider workforce across health and social care. AfN's view is that it is vital everyone who uses or provides nutrition information and advice has the skill, confidence and capacity to do so safely and effectively, supported by sound, evidence-based scientific practice. The lecture will give an overview of UK regulatory developments and provide an update on our work to develop AfN Certification

PS2-15 Linking food security and nutrition education to improve infant and young child feeding AGRICULTURE-NUTRITION LINKAGES: POTENTIALS AND LIMITATIONS FOR IMPROVING YOUNG CHILDREN'S DIETS THROUGH LOCAL FOODS

E. Muehlhoff

Food and Agriculture Organization of the United Nations

Growing attention is being given to the pathways through which agriculture and food systems can play a stronger role in improving nutrition. Aiming toward more nutrition-sensitive agriculture means recognizing the value of diversified food production systems, particularly for smallholders and adding nutritional value to production systems by translating increased income and food availability into more nutritious family diets. Nutrition sensitive agriculture also means recognizing the importance of adequate food and a nutritionally sound diet for women and young children, particularly during the 1000 day period between conception and the first two years of life. FAO has been promoting improved complementary feeding for children 6-23 months by empowering rural families to enrich young children's diets using local foods. A multi-sectoral approach is encouraged to foster linkages between different sectors having an influence on food security, such as agriculture, fisheries, health, rural development and women's affairs. The approach supports a community based process which combines food security and nutrition education activities. Tools such as the Seasonal Food Availability Calendar and Gender

Based activity calendars are used to identify local food resources available throughout the year to better understand problems of food insecurity and malnutrition. Community based nutrition education and hygiene and cooking demonstrations are undertaken with families with young children in order to facilitate adoption of improved feeding and hygiene practices. Preliminary evidence from projects in Afghanistan, Cambodia, Laos, Malawi and Zambia has demonstrated: 1) families' interest in using locally available foods by seasons to improve the nutritional content of young childrens' diets 2) the relevance of introducing such skills and 3) the practical feasibility of using improved recipes in the family setting. The potentials and limitations of this approach are discussed and insights and lessons are offered on upscaling complementary feeding interventions.

Key words: Complementary feeding, food-based approach, nutrition-sensitive agriculture.

EXPERIENCE AND LESSONS FROM TRIALS OF IMPROVED PRACTICES: CONSULTATIVE RESEARCH WITH CAREGIVERS

T. Jeremias

Food and Agriculture Organization, Rome, Italy

Food-based approaches to improve nutrition during the first two years of life are one of the essential strategies to prevent stunting and to contribute to people's health and well-being throughout life. FAO has used Trials of Improved Practices (TIPs) in Afghanistan, Cambodia, East Timor, Laos, Malawi and Zambia to design nutrition education programmes to improve infant and young child feeding in the context of food security projects. TIPs is a consultative process to test improved infant feeding and nutrition practices using locally available resources. During TIPs current infant and young child (children 6-23 months) feeding practices are assessed, improvements are negotiated with the family and subsequently tested in a real environment while information is gathered on their acceptability. In all countries, participants lived in rural agricultural economies with poor market integration, where seasonal variations in food availability are pronounced. TIPs teams were multisectoral and comprised of extension staff from the Ministries of Health, Agriculture, Education, Women's Affairs and Department of Community Development, depending on the country. The TIPs field work consisted of four home visits: during the first visit the family food security (FS) situation, feeding behaviours and dietary intake were evaluated. Subsequent home visits assessed families' ability to engage in selected improved feeding and hygiene practices, such as preparing thicker complementary foods, and/or increasing the quantity and diversity of food, increasing feeding frequency, practicing active feeding and hand washing. Recipe testing was carried out at community level, during participatory group cooking demon-

strations. General lessons and experiences will be drawn from the implementation of TIPs in diverse countries. Recent research findings from TIPs in Malawi (2011/2012) will be presented in detail and implications reviewed for the design and scaling up of recommendations.

Key words: Infant and young child feeding, complementary feeding, trials of improved practices (TIPs), developing countries.

SCALING UP FOOD SECURITY AND NUTRITION EDUCATION: OPPORTUNITIES AND CONSTRAINTS

G. Kennedy

Food and Agriculture Organization of the United Nations

There is a global call for scaling-up integrated, community-based nutrition programmes that link agriculture, health, water and sanitation, social protection and other sectors in order to secure lasting nutritional improvements. Many current initiatives such as Scaling up Nutrition (SUN), REACH (Renewed Effort Against Child Hunger and Undernutrition) and the Zero Hunger Challenge are advocating an intensified and wide-spread effort to eliminate child hunger and undernutrition. Similarly there is an increasing dialogue taking place on how to make agriculture and food systems more nutrition sensitive. This presentation will describe FAO projects in Malawi and Cambodia which combine food security activities oriented toward increasing the production and availability of nutrient dense foods with nutrition education and behavior change interventions to improve complementary feeding practices. The projects use a community based approach aimed at improving the local production of nutrient dense crops such as small animal source foods, dark green leafy vegetables, nuts and beans and fruit. These food security interventions are combined with community-based nutrition education, provided by community nutrition facilitators who are supported by agriculture, health and women's affairs extension services. Despite the increase in advocacy and attention to the importance of nutrition, efforts to scale-up activities are often challenging. The presentation will highlight the challenges and opportunities for scaling up this type of program.

Key words: Complementary feeding, food security, Cambodia, Malawi.

CHALLENGES IN APPLIED NUTRITION RESEARCH

M. Krawinkel, I. Jordan

Institute of Nutritional Sciences, Justus Liebig University Giessen, Giessen, Germany

According to Rossi and Whyte, important differences between basic and applied research are the research's motivation, the methods, financial sources, and the research arena. While basic research addresses questions focussed on details of processes and products, applied nutrition research orientates itself towards questions of immediate practical relevance for solving problems outside the laboratory. In the latter quantitative methods of epidemiology as well as qualitative methods (e.g. focus group discussions, mappings a.o.) are used. In the 1980's, Brownlee pointed out that - if applied research is to serve as a tool for solving delivery problems in developing countries - researchers and managers must work more closely together. A challenge might occur that primarily research is directed towards issues and problems of marginal interest to programme managers and the prime interests of the project managers do not coincide with the research questions. Still, applied research, its questions and methods are to be negotiated between researchers and implementers throughout the project. The risk of interfering with the project implementation through research on this process will be discussed. Today, systematic reviews and meta-analysis are considered as most promising in identifying the best problem solution for development. However, in a systematic review Masset and colleagues concluded after looking at the effectiveness of agricultural interventions aiming on improvements of the nutritional status of children in developing countries that most studies are statistically under powered to demonstrate any effects. The complexity of the pathway to a good nutritional status is long. Many causal and underlying factors impact on the outcome. A research approach acknowledging the disparity of humans and their livelihoods results in bigger sample sizes. Thus, applied research is often very costly and time consuming. Programmers and policy makers need to take this into account when asking for evidence.

Key words: Communication, nutrition research, impact assessment.

PS2-23A China's nutrition transition: Implications of rapid social and economic change for non-communicable disease risk

CHINA IN THE 1950-1982 PERIOD: A PERIOD OF SCARCITY, A VERY TRADITIONAL LIFESTYLE, AND EXTENSIVE UNDERNUTRITION

S. Du¹, F. Zhai², B. Zhang², H. Wang², B. Popkin¹

¹Nutrition Department, University of North Carolina, Chapel Hill, USA

²Institute of Nutrition and Food Safety, Chinese Center for Disease Control and Prevention, Beijing, China

Historically many have spoken of the Chinese diet as one of the great healthy diets of the world. However, little is understood about the actual diet Chinese consumed prior to the 1980's and the rapid transformation of its economy. After 110 years of poverty, civil wars, and the battle against the Japanese invasion, China in 1949 was like a wasteland: famine was common in many regions, mortality was high and life expectancy was low. The 1950-82 period represented a complex set of changes which ultimately created the basis for a revolution in food production. Initially food production and food supplies were inadequate and food rationing was utilized. Initial high levels of cereal consumption increased from 542 grams/day (80% coarse grains) in 1952 to 618 grams/day (predominantly refined rice and wheat) in 1982. Animal source food consumption was very low and slightly increased from 30 to 56 grams/day. Energy from fat increased slightly from 11% to 14% of energy over this 30-year period. Away from home eating was rare. Sugar-sweetened beverages were introduced by Coca-Cola importation in 1979. On the other hand, over 80% of the Chinese population had heavy work-related physical activities. Transportation shifted slowly from walking toward biking with limited public transportation. Few private cars and minimal television existed during this period. Consequently, malnutrition was prevalent, while overweight and obesity was rare. Till 1982, 17% of preschoolers, 20% of children and teens, and 13% of adults were underweight. Minimal overweight and obesity existed with the very highest estimates being a total of 6% of adults having BMI ≥ 25 kg/m². Large cultural, economic and communication differences existed between urban areas and rural areas. Overall, the stage of famine was replaced by one of receding famine during this period.

Key words: Malnutrition, food insecurity, overweight, poverty, physical activity, China.

THE EVOLUTION OF THE CHINESE DIET: 1991-2011

F. Zhai¹, S. D², Z. Wang³, J. Zhang³, W. Du³, B. Popkin²

¹Chinese Nutrition Society, Beijing, China

²Department of Nutrition, University of North Carolina, Chapel Hill, USA

³Chinese Center for Disease Control and Prevention, Institute of Nutrition and Food Safety, Beijing, China

China has undergone in the past two decades a major transition not only in the types of foods consumed but in basic cooking and eating behaviors. The classic high complex carbohydrate and vegetable diet with minimal animal source food and fats is gone and is increasingly being replaced by an unhealthy western type of diet but using traditional recipes. On the one hand, the basic transition has entailed a shift away from rice, wheat and coarse cereal toward more fats and proteins. This has included large increases in vegetable oil intake and animal source foods. The major animal source foods have shifted from pork to include poultry, and egg products. On the other hand cooking and eating styles have changed remarkably. The proportion of calories that come from deep fried foods has increased markedly to the point where the majority of Chinese consume over 30% of their calories from deep fried foods, and more than 60% of Chinese population consumes a diet with over 30% of energy from fat. At the same time away-from-home eating has increased greatly as has snacking. Prior to the last decade essentially there was no snacking in China except for consumption of hot water or green tea. This has shifted and continues to represent a major growth factor. The proportion of calories and fat consumed away from home also has markedly increased. The latest trend is a rapid increase in sales of sugary beverages of all sorts. The younger cohort of Chinese, those who have grown up during this economic boom period, have shifted more markedly toward eating western foods as well as their traditional cuisine. Overall vegetable intake is down considerably and most dimensions of dietary change are moving far outside the classical diet and Chinese dietary guidelines.

THE PHYSICAL ACTIVITY TRANSITION IN CHINA: 1991-2011

H. Wang¹, S W. Ng², A G. Green³, S. Chang¹, B. Zhang¹

¹Institute of Nutrition and Food Safety, Chinese Center for Disease Control and Prevention, Beijing, China

²Department of Nutrition, University of North Carolina, Chapel Hill, NC, USA
²Department of Biostatistics, University of North Carolina, Chapel Hill, USA

Econometric and epidemiological analyses have linked each dimension of activity at work, home production, transportation and inactivity with weight change. We estimate the Metabolic Equivalent of Task (MET) hours expended per week for each individual in the domains of work, home production, travel/transit and active leisure, as well as sedentary leisure hours per week. We present the observed measures among adult (19-65y) men and women, and adolescent boys and girls (12-18y) and children (6-11y) and explore the determinants of these trends.

Major shifts have occurred among adults while children have remained relatively inactive the entire period. The greatest PA declines for both adult men and women have been at work, where the majority of physical activity is reported for most individuals. Women have also reduced their home production activities (cooking, laundry, cleaning, childcare) significantly. Urbanization, shifts from agriculture-based work to manufacturing and the service sector, and improved access to energy-saving technologies at work and at home help explain these trends. In addition, we found that in the early 1990s, adult Chinese women had higher energy expenditure at work compared to men due to greater involvement by men in businesses and factory-work, while women were more involved in farming until around 2000. We also see a large gender difference in home production time and METS. Adult, travel PA has also fallen with increase vehicle ownership and improved transportation infrastructures. Active leisure PA has started to rise gradually in the last decade but remains low. Meanwhile, sedentary leisure time rose significantly from an average of 15hrs/week to 22hrs/wk between 1991 and 2011. Similar analyses on children and adolescents will be presented; however, the PA variations are small due to minimal home production, extensive studying, television and sedentary time).

Key words: Physical Activity, movement, adults, children, China.

OBESITY DYNAMICS IN CHINESE CHILDREN AND ADULTS

P. Gordon-Larsen¹, H. Wang², B. Popkin¹

¹Nutrition Department, University of North Carolina, Chapel Hill, USA

²Institute of Nutrition and Food Safety, Chinese Center for Disease Control and Prevention, Beijing, China

China presents a unique model for weight change as the country has experienced transition from a history of under-nutrition followed by the most rapid worldwide increase in obesity. The China Health and Nutrition Survey (CHNS) longitudinally documents these changes using measured height and weight across 53,298 observations from 18,059 participants collected over a 19-year period from 1991 to 2009. The prevalence of overweight (BMI \geq 25 kg/m²) in CHNS adults nearly tripled from 1991 (11.7%) to 2009 (29.2%), with age-related increases in BMI, a secular trend towards increasing BMI (stronger in males), and cohort effects underlying these dynamics. In youth during this same period, quantile regression reveals changes across the entire BMI distribution. The increase in the population-specific mean BMI was biggest between 1991 and 2000 and between 2006 and 2009 and was comparatively larger in 10 year olds than 13 year olds. By 2009, approximately 12% of children and adolescents were overweight, with 3% of 7-11 year olds and 1% of 12-17 year olds were obese (IOTF BMI 25 & 30 kg/m² equivalents). Using latent class trajectory modeling, we see substantial variation in patterns of weight gain that are masked in homogeneous classifications, with age and baseline BMI predicting patterns of weight gain. Although urbanization and income in rural and urban areas is highly predictive of increasing BMI in early years of the CHNS, in the last decade trends are more similar across all urbanicity and income levels. Yet among women in later years of CHNS, the greatest burden of overweight is in the lower educated women (the reverse is true for males – overweight was higher in higher educated men). Our findings highlight the importance of preventive measures early in the lifecycle to reduce weight gain.

Key words: Overweight, cohort effects, urbanization, China, weight trajectories.

THE EMERGENCE OF CARDIOMETABOLIC DISEASE RISK IN CHINESE CHILDREN AND ADULTS: CONSEQUENCES OF CHANGING PATTERNS OF DIET, PHYSICAL ACTIVITY, AND OBESITY

L. Adair¹, P. Gordon-Larsen¹, C. Batis¹, S. Du¹, B. Zhang², B. Popkin¹

¹Nutrition Department, University of North Carolina, Chapel Hill, USA

²Institute of Nutrition and Food Safety, Chinese Center for Disease Control and Prevention, Beijing, China

Concomitant with rapid social and economic changes, much of China's population has experienced major dietary changes and reductions in occupational physical activity, leading to an increased prevalence of obesity across all age groups. The China Health and Nutrition Survey (CHNS), an ongoing longitudinal, household-based survey of urban and rural residents of 9 provinces documents these changes, and measures the emergence of cardiometabolic (CM) disease risk. The 2009 survey measured blood pressure and collected fasting blood on >9000 individuals, ages 7-98 years and analyzed glucose; HbA1c; triglycerides (TG); total, HDL and LDL cholesterol; and CRP. We estimated prevalence of prediabetes/diabetes, dyslipidemia, inflammation, and hypertension using standard international definitions. The prevalence of CM risk factors increased with age and degree of urbanicity of residence. In 7-17 year old youth, 42% had at least one of these CM risk factors: nearly 10% had elevated TG and 9.4% had low HDL. In young adults (18-40 years), 70% of men and 60% of women had at least one risk factor, with 25% having high TG or low HDL. In young adults, for whom prevention is particularly important, abdominal obesity (waist circumference >90 cm in males, >80 cm in females) was already highly prevalent and strongly associated with all CM risk factors [e.g., odds ratios ranging from 1.5 (1.3-2.8) for high LDL to 3.2 (2.5-4.1) for hypertension]. Impaired HbA1c or diabetes (HbA1c > 5.7%) occurred in nearly 9.5% of youth and 13.7% of young adults. Using reduced rank regression, a dietary pattern characterized by higher intake of wheat products and lower intake of legumes, poultry, eggs and fish was associated with HbA1c. The high levels of CM risk in youth and young adults foreshadow high morbidity and mortality from CVD unless major efforts are made to reduce obesity.

Key words: Diabetes, cardiometabolic risk, China, adolescents, adults.

SYNTHESIS AND IMPLICATIONS: CHINA'S NUTRITION TRANSITION IN CONTEXT OF THE CHANGES ACROSS ASIA, AFRICA, LATIN AMERICA, AND THE MIDDLE EAST

B. Popkin

Nutrition Department, University of North Carolina, Chapel Hill, USA

The China Health and Nutrition Survey (CHNS) is important not only for its insights into current and future shifts in China but also for understanding underlying processes common across all Low and Middle Income Countries (LMIC) China has seen is a most rapid shift in urbanization of both urban and rural areas, major shifts in technology affecting all activity, vast shifts in dietary and activity patterns with resultant shifts first in obesity among adults and now the entire population. The resultant cardiometabolic burden is seen across the entire lifecycle, beginning in school age children. Current rapid shifts in the food system in China foretell even more rapid increases in cardiometabolic problems related to annual doubling of food sales from convenience stores and supermarkets, and large shifts in away-from-home eating with no increases in activity. Mass marketing, snacking and increased sugary beverage and processed foods will lead to new dynamics. Concurrently, the CHNS is unique as the only major longitudinal study of changes over the past two decades across LMIC in diet, activity, body composition, and cardiometabolic change in all household members across a wide geographic area in the low and middle income countries. The CHNS allowed us to study shifts in urbanization, global changes, economic and social changes in a manner not allowed in other countries. But then using cruder data we found comparable global shifts and have been able to utilize the CHNS to uncover many critical dynamics of food systems, urbanization, and technology of work, home production, movement and leisure that are affecting the LMIC in general. While it would be ideal to have similar nutrition-related and underlying socioeconomic and contextual data from across the globe, the CHNS has allowed many hypotheses to be generated and tested globally.

Key words: Nutrition transition, overweight, diet, activity, globalization, urbanization.

Many countries in transition are experiencing the “double burden” of nutritional disease. While significant advances continue to be made in medicine, 30 to 50% of hospitalized patients remain at increased nutrition risk worldwide, which impact inpatients morbidity and mortality.

Community-based nutrition programs have primarily been the focus of public health and development projects in Vietnam but increasing attention is given to hospital-based nutrition. This novel project stems from a collaboration between academia, government, and foundation. This project uses a three-pronged approach based on a partnership of US academia with the Vietnamese government, hospitals, and academia. Vietnamese and US partners have expertise in global health, hospital nutrition, education, and research. The ultimate goal of the project is to improve nutrition care, and thus patients’ nutritional status and hospital outcomes, by addressing policies, training and education, as well as research using a multi-disciplinary and integrative approach.

Educational Aims: -Describe nutrition health characteristics in the hospital settings of Vietnam -Identify steps required to form a partnership between academia, government and foundation to address nutrition medicine in a country in transition -Identify interventions that may improve process and thus inpatients nutrition status and thus morbidity/mortality in the Vietnamese hospital setting -Compare and contrast models of education in nutrition medicine

Key words: Education, malnutrition, research, training, Vietnam.

HYPOVITAMINOSIS D AND MILD HYPOCALCAEMIA ARE HIGHLY PREVALENT AMONG YOUNG VIETNAMESE CHILDREN AND WOMEN AND RELATED TO LOW DIETARY INTAKE

H. Le¹, F. Wieringa², N. Tran², M. Le¹, S. Fortin³, A. Lailou³, R. Moench-Pfanner³, J. Berger²

¹National Institute of Nutrition, Hanoi, Vietnam

²Institut de Recherche Pour Le Développement (IRD), Montpellier, France

³Global Alliance for Improved Nutrition

Background and objectives: In many developing countries including Vietnam, data are lacking on vitamin D and calcium deficiencies whereas those deficiencies can play an important role in the development of bone health and possibly non-communicable diseases.

Methods: A cross-sectional study conducted among 595 women of reproductive age and 532 children <5 years from 19 provinces of Vietnam to determine the overall prevalence of vitamin D and calcium deficiencies in women and young children. For each individual, data concerning daily diet, socioeconomic group, anthropometric status were obtained, and plasma concentrations of calcium and vitamin D were measured.

Results: The prevalence of hypovitaminosis D status was very high, with the prevalence of vitamin D deficiency (25(OH)D < 30 nmol/L) and insufficiency (25(OH)D between 30–49.9 nmol/L) being 17% and 40% in women and 21% and 37% in children, respectively. Using more liberal cut-off of 75 nmol/L, approximately 90% of the women and children were classified as having hypovitaminosis D. Overweight/obese women had a 2 times lower risk (OR=0.46, [0.24-0.90]) for vitamin D deficiency than non-overweight and non-obese women. No participant had severe calcium deficiency but moderate and mild hypocalcaemia (plasma calcium concentrations between 1.15-0.9 mmol/L for mild deficiency and between 0.9-0.8 mmol/L for moderate deficiency) affected respectively 14% and 83% of the women with 97% of the children having mild hypocalcaemia. Women and children consumed about 1% of the Institute of Medicine (IOM) recommended nutrient intake (RNI) for vitamin D and less than 43% of the RNI for calcium.

Conclusion: Our study suggests that calcium and vitamin D deficiencies represent a major public health concern in Vietnam. Thus, actions to improve the vitamin D and calcium status of the Vietnamese population should be considered.

Key words: Calcium, Vitamin D, daily intake, fortification, Vietnam.

PS3-31A Building research capacity in Latin America to address NCDs and obesity

THE CHALLENGE OF BUILDING NUTRITION RESEARCH CAPACITY IN IBERO-AMERICA: THE FINUT EXPERIENCE

A. Gil

Department of Biochemistry and Molecular Biology II, Institute of Nutrition and Food Technology, Centre of Biomedical Research, University of Granada, Spain

The Iberoamerican Nutrition Foundation (FINUT) is a non-profit organisation created in 2011 aiming to promote knowledge, research, development and innovation in the area of Nutrition and Food through international cooperation in the setting of Iberoamerica. The Board of Trustees is comprised by one IUNS, one SLAN and two SEN representatives led by a President. The FINUT is undertaking the following activities: a) Providing technical advice for and contributing to the implementation of comprehensive nutrition and food strategies at national or regional level in Iberoamerican countries. b) Providing incentives for communication and collaboration among Iberoamerican scientists in the fields of Nutrition, Food and other similar areas, in both the public and private sectors, and disseminating related information. c) Providing education and training to young Iberoamerican scientists in Nutrition

and Food. d) Developing leadership programmes in Nutrition and Food for young scientists in Iberoamerica. e) Organising conferences, symposia, workshops and expert groups, as well as promoting as many publications as are deemed of interest in the area of Nutrition and Food. f) Cooperating with public and private entities in carrying out activities and in disseminating knowledge. During the last two years the FINUT has developed a formation program for young scientists based on high quality workshops on food and nutrition hot topics. Two of them have been published as BJN supplements in 2012 and 21013- In addition, he has signed an agreement with the FAO to translate into Spanish and disseminate FAO/WHO Food and Nutrition reports. Moreover, the FINUT has organized a big exhibition on Healthy Food, Nutrition and Lifestyles in a Sustainable Environment that will last one year in Spain and later for the next four years in four cities of Latin America.

BUILDING RESEARCH CAPACITY IN NUTRITION IN THE MIDDLE EAST AND NORTH AFRICA: THE CHALLENGE FOR MENANA

S. Washi¹, I. Khateb²

¹United Arab Emirates University, United Arab Emirates

²Jordan University of Science & Technology, Siria

The Middle East and North Africa Nutrition Association (MENANA) is established as a regional association of professional nutrition societies in countries of the Middle East and North Africa. The Association enjoys affiliation status with the International Union of Nutritional Sciences (IUNS). The overall objective of the Association is to promote the advancement of nutrition sciences and the interest of professional nutritionists in the Middle East and North Africa. Specific objectives of the Association are to encourage and promote closer contact and interaction between nutritional societies and nutritional centers within the region; support holding of conferences and workshops that will allow nutritionists to exchange experiences among peers and with professionals from other continents; encourage and support training programs and educational courses that will build the capacity and improve the quality of nutritional research, teaching and service delivery, in the Middle East and North Africa; encourage communication and collaboration among nutrition scientists in the region, and promote dissemination of information in nutritional sciences through modern information and communication technology (ICT). Other activities are commensurate with promoting nutrition among scientists in the Middle East and North Africa and explaining the role of nutritionists to society in general.

The major goal of this session is to have an opportunity to enlighten international professionals about MENANA and create platform for joined research with similar associations to build the research capacity in nutrition in the Middle East and North Africa.

Key words: MENANA, research capacity, nutrition, Middle East, North Africa.

PS3-31B Traditional, Indigenous and cultural food and nutrition

TRADITIONAL MEDITERRANEAN DIET WITH NORTH AFRICAN PERSPECTIVE

R. Belahsen

Training and Research Unit on Nutrition and Food Sciences, Chouaib Doukkali University, Rabat, Morocco

Mediterranean Diet (MD) is a dietary pattern of people living in the countries bordering the Mediterranean Sea. The traditional MD is characterized by abundant consumption of fruits, vegetables, and high vegetable fat content and olive oil. Because MD is rich in biodiversity and nutritionally healthy it is reported to protect against cardiovascular risk factors. However, the demographic, nutritional and epidemiological transition that accompanies development and urbanization have also increased the prevalence of overweight and obesity in low and medium income countries including North African population in the Mediterranean basin. Obesity and overweight have been associated to many diet-related chronic diseases (diabetes, CVD, hypertension, stroke, cancer). In these countries diet is based on a large consumption of cereals (mainly wheat that is replacing traditional grains), fruit and vegetables. The consumption of animal products including fish remains very limited. Also, ready to eat food and restaurants are in continuous development leading to consumption of foods rich in sugar and fat and, to a shift from MD to westernized diet. This nutritional situation raises the problem of the sustainability of MD. On the other hand, and despite the efforts undertaken in these countries, there is a growing extension of chronic diseases (obesity, diabetes, hypertension, and metabolic syndrome) while undernourishment is still prevalent (6.8% in Morocco, 5.6% in Algeria and 1% in Tunisia). Among the causes involved are globalization, industrial agriculture and urbanization that have changed food production and consumption. There is a need to promote and protect MD as it has a beneficial role in the development of sustainable agriculture. It could be an approach to redress malnutrition in the Mediterranean region in general and in North Africa in particular.

Key words: Mediterranean diet, nutrition transition, North Africa.

RESILIENCE TO THE COMPOUNDING EFFECTS OF CLIMATE CHANGE ON THE NUTRITION TRANSITIONS EXPERIENCE BY MEMBERS OF YELLOWKNIVES DENE FIRST NATION

N. Duran¹, B. Erasmus², G. Harrison¹

¹Department of Community Health Sciences, UCLA Fielding School of Public Health, Los Angeles, USA

²Assembly of First Nations and Dene Nation, Yellowknife, Canada

Climate change has been disturbing the traditional food systems of Canada's Arctic Indigenous Peoples. Climate change, coupled with the influence of globalization, has been contributing to the nutrition transitions experienced by Indigenous Peoples.

The purpose of this study was to develop an understanding of how the members of Yellowknives Dene First Nation (YKDFN) who harvest and use Traditional Foods (TF) manage their nutrition and health in a changing climate and global environment. An ethnographic constructivist grounded theory method was used to systematically obtain and analyze data. In-depth interviews with thirteen members of YKDFN who harvest and use TF in the Northwest Territories of Canada were conducted in 2010 and 2011.

Analytic codes and categories were constructed from the data and a constant comparative method was used for analysis.

A comparative look at the resilience among members of YKDFN for whom harvesting and using TF is 'who they are' and 'how they were raised' and among those for whom it is a 'chosen lifestyle' and 'conscious effort to learn' reveals the complementary value each member contributes to securing their ancestral legacy of harvesting for future generations. Experienced hunters are sharing their knowledge and transferring their skills to novice hunters and youth interested in harvesting and using TF.

Hunters are committed to funding and supporting programs that introduce Dene youth to harvesting and using TF through formal education and community based programs. Women and young girls are also encouraged and taught how to harvest, a trend that empowers women in a rapidly changing social and cultural environment. The activities and commitment of YKDFN are positioning youth and women to utilize and become stewards of their lands and waters and serve as proactive efforts in disease prevention, health promotion and adaptation to climate change.

Key words: Climate change, Arctic Indigenous Peoples, resilience.

FROM MICRO TO MACRO POLICIES: WHY MICRO-LEVEL DIFFERENCES MATTER IN THE FIGHT TO PRESERVE ACCESS TO TRADITIONAL, INDIGENOUS FOODS

G. Pelto¹, P. Crane²

¹Division of Nutritional Sciences, Savage Hall, Cornell University, Ithaca, USA

²Conservation Genetics Laboratory, US Fish and Wildlife Service, Anchorage, USA

Protecting indigenous peoples' food security in a globalized world presents many challenges and has been the subject of research attention from the perspectives of multiple disciplines for a number of decades. Each discipline brings its own perspectives, methods and theories to bear on the choice of research focus, the conduct of study and the conclusions that are drawn. It also has implications for recommendations that affect the design and implementation of policy. In this presentation we: (1) examine the fundamental challenge of reconciling local culture and local conditions for sustaining food security with government policy, and (2) present a case study from Alaska to illustrate a model for reconciling and adjusting policy to local needs. We draw on anthropological theory and ethnographic studies, publically available documents and key informant interviews to obtain data for deriving descriptions and analysis to structure our report. State regulatory policy regarding management of salmon populations in Alaska carries the potential to interfere with local communities' cultural-ecological adaptations to ensure their food security. However, the development and operation of the Kuskokwim River Management Working Group is an example of a model to address this issue. It "provides a forum for [the various parties involved] to come together and discuss issues relevant to management." Thus, it illustrates a strategy to address the need to balance macro-level policy with micro-level community, cultural conditions. The potential conflict between macro-level policies and the requirements for preserving community adaptive strategies can be mediated through organizational models that create opportunities for exchange and for modifications that help to preserve local cultural patterns directed to sustaining household food security. It is important to search for, develop, and support appropriate models for addressing this fundamental dynamic.

Key words: Food security, micro-ecological conditions, wildlife policy.

BIODIVERSITY, FOOD SYSTEMS AND NUTRITIONAL STATUS OF THE INDIGENOUS PEOPLE OF NORTHEAST INDIA

T.Longvah

National Institute of Nutrition, Jamai Osmania, Hyderabad, India

Northeast India is one of India's two mega biodiversity hotspots inhabited by various ethnic groups who make use of the diverse plants available within their environment as food. The paper presents the case of the indigenous tribes of Northeast India, their food systems, and nutritional well-being. Neglected and underutilized plant foods constitute the bedrock of diversity in traditional food systems in Northeast India. Despite the onslaught of modernization a large proportion of traditional food systems is still underutilized food resources, including insects, indicating the importance of biodiversity in family diets. The tribal communities' traditional knowledge in regulating sustainable agriculture, natural resources management and biodiversity conservation are based on rich indigenous ecological knowledge gained over generations.

The diversity of diet in Northeast India is reflected in the better nutritional status of the population in general, lower rate of stunting, wasting and underweight among children as compared to the rest of India. The prevalence of mortality rates from cardiovascular diseases is also strikingly lower here. The indigenous populations in Northeast India are still holding on to their traditional culture and lifestyle but there is a gradual shift from dietary diversity to the adoption of simplified diets indirectly resulting in the loss of food biodiversity. Key government policies such as the Public Distribution System and the Green Revolution Technologies have contributed to the changes in the food systems. Hybrid rice is slowly replacing traditional land races and micronutrient rich staples such as millets. The consequence of the changing food systems in Northeast India can pose serious public health challenges. Therefore efforts should be made to capitalize the positive effects of traditional food systems and integrate them into contemporary food systems to be able to fully support the health and nutrition of the population.

Key words: Biodiversity, India, Indigenous Peoples, nutritional status.

TRADITIONAL CULTIVATION AND USE OF Maguey AND CACTUS PEAR IN THE UPPER MEZQUITAL VALLEY: RELEVANCE FOR SUSTAINABLE LIVELIHOODS

M D. Núñez Burbano De Lara¹, A C. Bellows¹, J A. Reyes Agüero²

¹Department of Gender and Nutrition, Institute for Social Sciences in Agriculture, University of Hohenheim, Schloss, Stuttgart, Germany

²Institute for Research in Desertic Areas, Autonomous University of San Luis Potosi, Venustiano Carranza, San Luis Potosi, Mexico

Livelihood strategies in the Upper Mezquital Valley (Mexico) have for centuries been closely intertwined with the cultivation and integral use of maguey (*Agave* spp.) and cactus pear (*Opuntia* spp.) – natural resources that not only constitute an essential component of traditional diets but are also intrinsic aspects of the cultural identity of the Nāhñú indigenous population inhabiting the region. By applying the sustainable livelihoods approach, this study explores changes in traditional maguey and cactus pear use patterns in the Nāhñú community of San Andrés and community members' perceptions about these changes.

The gradual displacement of locally manufactured items by industrial products at the beginning of the 20th century set in motion a treadmill of disturbed patterns of traditional resource use, a rapidly deteriorating natural resource base, and mass migration across the northern Mexican border. Paradoxically, this development has recently been brought to an abrupt halt through the global financial crisis that has strongly limited employment opportunities in the United States. Seemingly obsolete and therefore neglected traditional practices have served as safety nets for large numbers of migrants enabling their return to their home land. At the same time, the reduced flow of remittances has impelled the search for possibilities of adding value to the only raw materials available in the region. These trends bear both opportunities and risks; overexploitation of maguey represents a major concern among the latter. The importance of preserving traditional practices (ranging from traditional concepts of welfare, traditional diets, traditional resource use knowledge and skills, to language transmission) is discussed, as is the promotion of agro-ecological practices as management strategy for a sustainable use of maguey and cactus pear as means of securing local livelihoods. (Acknowledgment: This work was financially supported by the Foundation fiat panis.)

Key words: *Agave* spp, *Opuntia* spp, indigenous, Mexico, sustainable livelihoods.

PS3-39AENLP -Nutrition during times of economic crisis, let's cook something up!

NUTRITION DURING TIMES OF ECONOMIC CRISIS, LET'S COOK SOMETHING UP!

R. Verstraeten¹, C. Matthys²

¹Department of Food Safety and Food Quality; Ghent University, Ghent, Belgium

²Clinical and Experimental Endocrinology; KU Leuven/UZ Leuven, Leuven, Belgium

The economic crisis has hit all of us, in both developing and developed countries, while we are constantly confronted with both ends of the spectrum of malnutrition which is reflected in an increasing demand on availability of nutritious foods along with the growing world population. Urbanisation in developing regions (every day 20.000 people move from the countryside to the city) drives a demand for foods as people have less access to their own resources, while the economic crisis in the Western Countries brings people back to the kitchen and home cooking is a new trend. All these facts combined with the scarce financial resources, makes us realise that we have more challenges than ever in our daily life and work (in research, in education and in development and implementation of public health policy). So the main question is: What could be our role as nutritionists to ensure nutritious foods? Leadership, working in multi-disciplinary teams and – above all creativity are more than ever required in addressing the problems that we are confronted with. The participants will contribute to this session/workshop and harvest the best ideas to make a difference with the ultimate goal that our children have still a nutritious future in 2050.

This session is a combination of an ex cathedra lecture and workshop. A devoted keynote speaker will give examples of best practices on how to handle new challenges. In the workshop the creative thinking concept will be handled. The session will mix up juniors and seniors, which is a great opportunity for growth and networking. Creativity may be directed not only to find the best solution to the problem but also to see the emerging opportunities and thus give another dimension to our current approach.

Key words: Leadership, health, food, economics

A CHALLENGE FOR PUBLIC HEALTH NUTRITION IN A TIME OF AUSTERITY

M. Caraher

Centre For Food Policy, Department of Sociology, School of Arts and Social Sciences, City University London, UK

In a time of global financial austerity where the poor are more likely to go to be hungry what can public health nutrition do? Over one billion people will go to bed hungry tonight in both North and South. In America 60 million people, mainly women, will go without a meal today, in the EU this is 44 million with a further 80 million at severe risk. As food, fuel and housing costs rise, incomes remain stagnant thus placing great pressure on households to economise and food is one way that this can be done.

In the emerging and developing economies, individuals who go hungry and are overweight are the same groups. The new outward or visible demonstration of food poverty/insecurity is likely to be overweight or obese bodies. The fact of living in poverty introduces constraints on peoples' choices. When you are worried about hunger you may chose food which is energy dense, this represents better value per calories than fruit and vegetables.

Globally there are two strange things happening, and these are presented as tensions as opposed to being opposites. In some economies poverty is increasing but inequality is decreasing -good for health. In other economies, UK, US and Australia, poverty is increasing and inequality is also increasing -bad for health. So what are the implications for nutrition of these moves and what can we do?

The following options will be explored in the session and the workshop: - Business as usual -stick to health eating messages and not get involved in these wider debates! - Ameliorate existing conditions by giving people knowledge and skills? But not change much about their social and economic circumstances? - Focus on preventing future problems and become more concerned with social determinants that influence healthy eating?

Key words: Public health nutrition, economic crisis, poverty, inequality.

NUTRITION (HOW DO WE ENSURE NUTRITIOUS FOODS?) DURING THE ECONOMIC CRISIS

K. Raats

Karl Raats Creative Thinking Consultancy, Katowice, Poland

Challenges created by our current way of thinking, require our current way of thinking to be challenged. If we are to connect the dots, we need to first understand that everyone's knowledge, insights and experiences ARE the dots. This session aims to connect our unique, yet isolated ways of thinking, in order to create the critical mass in thinking power needed to confront and solve 21st century problems. What's the recipe? Based on the challenge at hand, participants will experience a new and far more productive way to formulate, share and enrich ideas into collectively supported solutions. In three steps participants will:

- learn how to reframe the challenge in order to reframe their thinking about it;
- be able to give constructive feedback on ideas, regardless of their basic opinion about its quality or perceived validity;
- be challenged to voluntarily support and commit to their peer's ideas. Each of these steps are made possible by means of precise, tangible and reproducible instructions and/or tools.

Key words: Creative thinking, economic crisis, solutions, food.

PS3-39B Capacity development in innovative techniques in food and nutrition research

DIET QUALITY, DETERMINANTS AND METHODS OF ASSESSMENT

I. Elmadfa^{1,2}, A. Meyer¹

¹University of Vienna, Institute of Nutritional Sciences, Vienna, Austria

²IUNS President

A high quality diet is the best source of adequate nutrient supply contributing to health and wellbeing. In turn, the current abundance of highly processed energy-dense but low-nutrient foods promotes obesity and nutrition-related diseases. Food pattern and hence, diet quality is influenced by many factors such as age, gender and cultural background. Low socio-economic status and educational level are strong predictors of less healthy eating patterns. Health effects of human diets arise from a wide variety of components and cannot be attributed to a single nutrient or food. Assessment of overall diet quality presents a better tool that, in accordance with dietary recommendations, can be based on nutrients or food components or a combination of both. Among food groups, vegetable and fruit

consumption has been used as a central marker, but other components such as fatty acid pattern, intake of wholegrain, milk products and fish are also important. Food-based approaches may be easier to apply as they do not require knowledge about food composition. In turn, nutrient-based indices require the availability of adequate food composition databases and programs for calculation of the dietary intake. The classical way focusses on adequacy scores of essential micronutrients like iron, calcium and some vitamins. Other ratings are based on special health effects of food components with unfavorable components like sugars, salt, or saturated fatty acids serving as negative indicators. Regrouping several components – food groups, nutrients as well as other aspects (e.g. quantity/portion size, processing, diversity) – in indices or scores allows a more in-depth evaluation of diet quality. Comparison with biomarkers showed the validity of some of these food quality indices. Evaluation of diet quality provides the knowledge required for effective strategies for addressing nutrition problems of the general population and specific risk groups.

Key words: Diet quality, food groups, assessment, index

GUT MICROBIOTA, TOOLS FOR ANALYZING IMMUNE FUNCTIONS

A. Gil

Department of Biochemistry and Molecular Biology II, Institute of Nutrition and Food Technology, Centre of Biomedical Research, University of Granada, Spain

Intestinal bacteria promote the early development of the host immune system. Over the course of evolution, lactobacilli, other lactic acid bacteria and bifidobacteria have been abundant colonisers of the human small intestinal mucosa and coexist in mutualistic relationships with the host. Some members of these groups exert additional probiotic properties that provide health benefits to the host via the regulation of immune system functions. These interactions primarily involve gut-associated dendritic cells (DCs), which have the capability to respond to microbial signals through toll-like receptors (TLR) signalling. Here we review the current experimental tools that can be used to ascertain the mechanism through which intestinal microorganisms exert an action on the immune functions. Although human clinical trials are the definitive tool for establishing microorganisms functionality, the use of in vitro models is necessary to select the most promising strains for these trials. Ideally, cell models should resemble the in vivo conditions; however, in most in vitro experimental models, epithelial and DC cells are cultivated as monolayers in which the establishment of functional epithelial features is not achieved. To overcome this problem, co-culture experiments with bacteria,

DCs and intestinal epithelial cells and 3D models attempt to reconcile the complex and dynamic interactions that exist in vivo between the intestinal epithelium and bacteria. Additional models include tissue explants, bioreactors and organoids. Accumulating evidence demonstrates that commensal bacteria and probiotics communicate with the host by pattern recognition receptors, such as TLR and NOD-like receptors, which modulate key signalling pathways, such as NF- κ B and MAPK, to enhance or suppress activation and influence downstream pathways. Gaining insight into the mechanisms of intestinal microorganisms action may contribute to foster the development of novel strategies for the treatment or prevention of gastrointestinal and autoimmune diseases.

Key words: Intestinal immunity, microbiota, probiotics, dendritic cells.

METROLOGY BASED MEASUREMENTS IN FOOD AND NUTRITION SCIENCES

V. Iyengar^{1,2}

¹Biomining Sciences, Rockville, USA

²FSNSP, Tufts University, Boston, USA

Metrology deals with the science of measurements and their applications. In its pivotal role, metrology provides a framework that is designed to generate the highest level of quality in a measurement outcome irrespective of the field of application. This is established by adopting metrological criteria such as metrological traceability (tracking established pathways to credibility), measurement uncertainty (credibility level) and metrological equivalence (metrological compatibility of data obtained by different analytical methods). Traceability facilitates a robust measurement system; uncertainty demonstrates method capability, and equivalence strengthens shared responsibility in collaborative measurements. When metrological criteria are met, the data quality level reaches near absolute accuracy for physical measurements (e.g. time), exceptional accuracy for certain chemical measurements (e.g. isotopic composition), and best attainable accuracy (practical and reliable) for biological measurements (e.g. body composition). Application of metrological concepts for assessment of food, dietary and related metabolic measurements is still in its infancy. Two reasons account for the lack of progress: (i) the concept of accuracy and precision is not fully understood by the food and nutrition (F&N) investigators (often, precision is over emphasized thus ignoring accuracy), (ii) excessive reliance on the experimental data generated for F&N investigations using a single analytical method (lacking method validation). Imparting metrological basis to the measurement process by analyzing natural matrix certified reference material is a vital requirement for establishing traceability. As a whole, F&N and related metabolic assays represent 3 categories of measurements, namely physical (e.g.

quantity, density and size), chemical (composition and speciation) and biological (e.g. caloric energy metabolism, bioavailability and bone density). In conclusion, F&N related measurements, although biological in nature, share some similarities with physical and chemical measurements, and therefore, can benefit from following the metrological practices prevalent in physics and chemistry areas. Several examples will be presented.

Key words: Metrology, biological metrology, traceability, uncertainty.

ISOTOPE TECHNIQUE TOOLS FOR BETTER ACCURACY OF ANALYTICAL PROCEDURES

A. Kurpad

St John's Medical College, Bangalore, India

Physiological outcomes in research investigations are often very variable. Metrology is the science of accurate measurements, and its application to the measurement of outcomes in nutritional intervention research in humans is of importance. Stable isotopes of elements are safe, typically already present in the environment. Advances in isotopic methods have made the measurement of stable isotopic dilutions in human experiments easier. This, along with the traceability of standards that allows for multiple study comparisons, has meant that these methods offer the ability to evaluate the variability of outcomes with interventions, while working in resource poor settings. These methods allow for the establishment of a quality control system that includes the use of traceable standards and the estimation of errors with multiple measurements. Examples relate to the measurement of body composition rather than body weight at different ages, the measurement of energy expenditure, lactation, amino acid fluxes and oxidation, and the bioavailability of nutrients, particularly iron.

Key words: Stable isotopes, metrology

PS4-47 Mediterranean diet and disease

MEDITERRANEAN DIET AND METABOLIC SYNDROME; AN UPDATED SYSTEMATIC REVIEW

D. Panagiotakos

Department of Nutrition and Dietetics, Harokopio University, Athens, Greece

This is an updated systematic review of epidemiological, observational studies and clinical trials on the relationship between adherence to the Mediterranean diet and prevalence of

the metabolic syndrome. English language publications in the available databases PubMed, Embase, Scopus, until May 31, 2013, were included in this review. New evidence from prospective cohort studies, cross-sectional studies and clinical trials supports the beneficial role of adherence to the Mediterranean dietary pattern regarding metabolic syndrome presence and progression. Moreover, adherence to the Mediterranean diet seems to confer further protection to all individual components of the syndrome. In conclusion, efforts should be made in order to encourage adoption of this pattern, especially in the Mediterranean countries.

Key words: Mediterranean diet, metabolic syndrome, systematic review.

MEDITERRANEAN DIET, HEALTH BENEFITS AND THE ROLE OF TRADITIONAL FOODS

A. Trichopoulou^{1,2}, E. Vasilopoulou², D. Vardis¹

¹Hellenic Health Foundation, Athens, Greece

²WHO Collaborating Center for Food and Nutrition Policies, Athens, Greece, Department of Hygiene, Epidemiology and Medical Statistics, Medical School of Athens, Greece

Background and objectives: European Commission (EC) Regulation 1924/2006 provides the legal framework for the use of nutrition and health claims on foods in the European market, on the basis of scientific evidence. Although the Mediterranean diet has long been recognized for its nutritional quality and adequacy, individual Mediterranean traditional foods are commercially under-represented. Regulation 1924/2006 could endorse nutritionally rich foods, such as Mediterranean traditional foods and, thus, increase their availability in the European households.

Methods: One hundred and ninety four Greek traditional foods were selected from the Greek food composition tables, and their nutritional composition was evaluated on the basis of the thresholds for nutrition claims set by the EC. The following nutritional values, high or low as desired, were taken into account: energy, protein, total fat and fatty acids, sugars (mono + disaccharides), salt (sodium), dietary fibre, vitamins (B6, C, A, E, riboflavin, thiamin and α -carotene) and minerals (P, Mg, Fe, Zn, Ca, Cu and K).

Results: On the basis of the compositional data used, 1024 nutrition claims could apply to the 194 foods studied, with an average of about 5 nutrition claims per food. Of those nutrition claims, 529 were related to vitamins and minerals.

Conclusions: The European regulation on nutrition claims on foods could highlight basic characteristics of the Greek traditional Mediterranean diet i.e. the ample use of olive oil and nutrient dense plant foods such as vegetables. The application of this legislation may benefit small business operators involved

in the production or promotion of traditional foods. It could also promote the health of European citizens by underlining the nutritional quality of these traditional foods and eventually increase their share in the common market.

Key words: Traditional foods, nutrition claims, Mediterranean Diet.

PS4-55 PREDIMED study

THE PREDIMED STUDY: RATIONALE, DESIGN, METHODS AND INTERVENTIONS

E. Ros^{1,2}

¹Lipid Clinic, Endocrinology & Nutrition Service, Hospital Clínic, Barcelona, Spain

²CIBERobn, Instituto de Salud Carlos III, Madrid, Spain

A recent meta-analysis of prospective studies showed that adherence to the Mediterranean diet (MeDiet) was associated with reductions in total mortality and coronary cardiovascular disease (CVD) mortality, as well as cancer mortality and incidence of neurodegenerative diseases. However, randomized clinical trials of the MeDiet with hard endpoints were lacking. We hypothesized that two traditional MeDiets, one enriched with extra-virgin olive oil (EVOO) and another enriched with nuts, both high in total fat and unsaturated fat, would be superior to the usually recommended low-fat diet for the primary prevention of CVD in a high-risk population. To test this hypothesis we designed the PREDIMED study as the first randomized trial assessing the efficacy of the MeDiet on the primary prevention of CVD. The primary aim of the trial was to assess the effects of the two MeDiets on a composite endpoint of cardiovascular death, myocardial infarction and stroke (primary endpoint) in comparison with a low-fat, control diet. Secondary endpoints are death of any cause and incidence of major chronic diseases. The study subjects are nearly 7500 individuals at high risk but free of CVD at enrolment. Participants were randomized to 3 dietary interventions: advice on MeDiet plus free provision of 1 L/week of EVOO; advice on the MeDiet plus free provision of mixed nuts (30 g/day); and advice to reduce all kinds of dietary fat (control diet). Throughout the duration of the study (mean 5 years), participants attended quarterly individual and group sessions run by dietitians, where they received written dietary instructions, seasonal shopping lists, menus and recipes adapted to group assignment. A 14-item screener was instrumental to assess MeDiet adherence and upgrade it at each visit in the MeDiet groups. All events were registered and definite ascertainment was done by the Clinical Events Committee whose members were blinded to the intervention.

Key words: Nutrition, mediterranean diet, cardiovascular disease, clinical trial, PREDIMED study.

INTERACTIONS BETWEEN MEDITERRANEAN DIET AND GENETIC VARIANTS, AND RISK OF DISEASE IN THE PREDIMED STUDY

D. Corella

Department of Preventive Medicine and Public Health, School of Medicine, University of Valencia and CIBER Fisiopatología de la Obesidad y Nutrición, Valencia, Spain

Despite the growing evidence supporting the protective role of the Mediterranean diet (MedDiet) in reducing cardiovascular diseases, diabetes or obesity, there is a lack of studies analyzing the genetic influence modulating the effects of the MedDiet in these diseases. Added to this is the fact that the majority of the studies undertaken to examine gene-diet interactions cardiovascular phenotypes such as dyslipemia, hypertension, type 2 diabetes, etc, have focused on the macronutrients of the diet, mainly on the intake of different types of fatty acids, and have not considered the overall pattern of the MedDiet. To investigate the relationship between genetics and the Mediterranean diet, both as a whole and analyzing the specific relationships of the main components in determining intermediate and final phenotypes (stroke, myocardial infarction, etc) of the most prevalent diseases. Therefore, the PREDIMED study offers an excellent opportunity to examine the interaction between the MedDiet and genetic variants in determining intermediate and disease phenotypes. We have undertaken several nutrigenetic analyses in the PREDIMED study and have analyzed the different types of interactions (biological and statistical) between the MedDiet (both at baseline and after dietary intervention) and its components and variations in key genes in lipid metabolism, inflammation, obesity, type 2 diabetes, and cardiovascular diseases (TCF7L2, MLXIPL, CETP, APOE, etc.). We have detected interesting gene-diet interactions in which a greater adherence to the MedDiet, or to some of its typical foods, is able to reverse the adverse effects that have the risk alleles in these genes on their specific phenotypes.

Key words: Mediterranean, genetics, gene-diet interactions, cardiovascular.

THE PREDIMED-PLUS TRIAL: OBJECTIVES AND IMPLEMENTATION

M A. Martinez-Gonzalez^{1,2}

¹Department of Preventive Medicine and Public Health, University of Navarra, Pamplona, Navarra, Spain

²CIBEROBN

The worldwide epidemic of obesity is alarmingly growing. The long-term consequences of this epidemic on vascular

risk and other causes of disease and death represent a global crisis and a failure of public health.

Most observational studies have consistently shown that all-cause mortality progressively grows with increased adiposity. This higher risk is specially increased for cardiovascular mortality. However, a recent (and controversial) meta-analysis challenged this assertion (Flegal, et al. JAMA 2013). In addition, the only available long-term trial conducted among type-2 diabetics (Look AHEAD, N Engl J Med 2013) did not demonstrate that an intentional weight loss may produce a reduction in cardiovascular clinical events.

The PREDIMED-1 trial showed that a Mediterranean diet (without any caloric restriction) did reduce cardiovascular clinical events (Estruch et al, N Engl J Med 2013). The aim of our new trial (PREDIMED-PLUS) is to assess whether a calorie-restricted Mediterranean diet together with specific goals for weight loss and physical activity is able to reduce the risk of cardiovascular events beyond the results obtained in PREDIMED-1. Our hypothesis is that an intensive intervention on diet and lifestyle aimed to weight loss and based in the traditional Mediterranean dietary pattern is an effective and sustainable approach for weight loss in adults with overweight/obesity and this intervention will exert a beneficial effect on cardiovascular events.

The research plan is to recruit 6,000 men (55-75 years) and women (60-75 years) with a body mass index between 27 and 40 kg/m² and at least three criteria of the metabolic syndrome. The recruitment will take place during 2013-2015. The follow-up will average 6 years. We will randomise them in 1:1 ratio to two interventions: a) control: a Mediterranean diet without any caloric restriction or special program to foster physical activity (as we did in the PREDIMED-1 trial); b) intensive intervention: a Mediterranean diet with goals for weight loss (at least 8% of initial weight), caloric restriction (30%), physical activity (walking 45 min/d or equivalent), and behavioural therapy. For the intensive intervention group, 3 contacts/month will be scheduled during the first year and 2 contacts/month during the rest of follow-up. The primary end-point will be a composite of myocardial infarction stroke or cardiovascular death.

PS5-63A Regulation Versus Innovation (IUFOST) REGULATION AND INNOVATION IN FUNCTIONAL FOODS

D. Rodriguez-Amaya

University of Campinas, Sao Paulo, Brazil

As consumers around the world are getting more informed and interested in promoting their own health and well-being, the functional food market continues to grow. Food companies are constantly searching for innovations in order to keep their niches in this dynamic, demanding and highly competitive

market. Developed countries are offering an array of bioactive ingredients (e.g., fiber, omega-3 fatty acids, isolated soy and milk proteins, probiotic, tomato concentrate, tea extracts, fruit extracts), bioactive-enriched foods (e.g., fiber enriched foods, dairy products with probiotic), as well as naturally functional foods (e.g. flax, nuts, cranberry, whole grains). Innovation, development and marketing of functional products in developing countries are limited by the prohibitive cost and needed resources for clinical trials to establish safety and substantiate health claims. Developing countries are focusing more on optimization of naturally functional traditional foods (e.g., quinoa, amaranth seeds, yerba mate) and processing native, often unexploited, plant species with high levels of bioactive components (e.g., tropical fruits). Regulating functional foods is a complicated issue as it goes beyond assuring safety; demonstration of efficacy in terms of the claimed health benefits is as critical. While it is undoubtedly important to guarantee that functional foods and beverages are safe and health claims are evidence-based, there is call for caution that regulation should not be unnecessarily restrictive so as to prevent sound innovations from getting into the market. The need for international standards and regulations is recognized, but global harmonization efforts have been beset with many complicating factors and have not been successful, although some regional harmonization has been achieved.

Key words: Functional foods, bioactive ingredients, safety, health claims, regulation.

FOOD REGULATION AND PROCESSING INNOVATION IN VIETNAM

D. Luu, T.D. Phan

Sagon Technology University, Sagon, Vietnam

As the proverb say, Vietnam is a tropical country with three magic elements for the success: Heavenly opportunities, Favorable land, and Human consensus. These conditions lead to an abundant and diversified agriculture production. Many products of VietNam have been appreciated around the world such as rice, tea, coffee, cashew nut, exotic fruits, and aquatic products... On the other hand, recent advances in food sciences and technology allow food industry to diversify their products and to toward their production to a high value products. The appearance of many new Vietnamese food products in the market showed that there is an innovation in food production. Beside that, the consumers are increasingly interested in the health benefits of foods and have begun to look the potential disease prevention and health enhancing of foods. Regulating the industry is important to maintain the high standard of food safety and quality that the consumers expect, while allowing the industry to innovate and market new products, especially in the context of integration with ASEAN and EU markets.

Today, the foodstuff quality and safety must be ensured along the supply chain “from farm to fork”. Thereby, the regulations must keep pace with the advances in technology and control the innovation in food processing to ensure the relationship between quality of foodstuffs and concerned claims. Generally, the quality and health benefits of foodstuffs are often communicated to consumers through the product packaging, websites or advertising. Such quality and health-related statements or claims are made according to the applicable regulations and guidelines. In many cases, incorrect claims related to quality and health benefits are published by industry to promote their products. Therefore, the regulations need to clarify the quality criteria and functional component in foods and control the exaggerated health claims made by manufacturers.

Key words: Food products, food regulation, processing innovation.

ADVANCING NOVEL PRESERVATION TECHNOLOGIES DEMANDS HARMONIZING INTERNATIONAL FOOD SAFETY LEGISLATION AND REGULATIONS

L. Keener

International Product Safety Consultants, Seattle, USA

Primary among the roles and responsibilities of most national governments are the protection and preservation of its citizen's health and the promotion of trade and commerce. Legislation, regulations and standards are frequently promulgated with that aim to both safeguard public health and advance economic growth. Food laws and regulations framed with a pretext of food safety are important for both, preserving public health and commerce. Owing to the great global disparity in food safety laws and regulations, however, often neither of these national priorities is achieved. The advancement and adoption, by government and industry, of novel preservation and processing technologies such as: High Pressure; Power Ultrasound; Atmospheric Cold Plasmas; and Pressure Assisted Thermal Sterilization are highly dependent on achieving consensus and harmonization on the scientific methods and the regulatory constructs used for validating novel food preservation techniques. Eliminating regulatory ambiguity in the approvals and validation processes will also stimulate innovation. Successfully resolving the incongruent regulatory issues, globally, will likewise assist in achieving public health and trade objectives. This presentation will provide an assessment of regulatory activities, globally, relating to the approval and uptake of novel and nonthermal preservation technologies.

Key words: Safety, regulations, technology, innovation, food.

HOW TO WORK WITH THE FOOD INDUSTRY TO IMPROVE THE NUTRITIONAL PROFILES OF PROCESSED FOODS

N. Sunley

Sunley Consulting, Johannesburg, South Africa

At virtually every gathering of nutrition professionals, there is strong criticism of the food industry as one of the main contributors to obesity and other public health concerns. While aggressive marketing of foods with poor nutritional composition can certainly be criticised, insufficient cognizance is taken of the very real challenges faced by food companies in improving the nutritional characteristics of their products and practical factors such as technical feasibility, cost and palatability are often insufficiently understood by the nutrition profession. In particular a confrontational approach incorporating simplistic and impractical regulatory based solutions is unlikely to achieve their desired effect due largely to the behavior related nature of many of the causes of obesity. There are a number of ways in which nutritionists and dieticians can interact in a much more constructive manner with the food industry and these will be discussed. From a technical perspective, they include working with marketing and technical personnel to understand the practical constraints that exist in changing the nutritional characteristics of particular products and constructively challenging these. A further option is using nutrient profiling as a means of assessing the effect of potential compositional changes. From a commercial perspective, it is possible to incentivise companies to improve the nutritional quality of their products by linking staff remuneration and in particular performance bonus payments to the achievement of specific average compositional criteria for their product ranges. A suggested model for this process will be proposed which includes not only product composition but also the volumes of different products sold by the companies.

Key words: Food industry, nutritional profiles, processed foods.

PS5-63B Food systems for nutrition and health: Growing, shopping, cooking and eating SUSTAINABLE AND AFFORDABLE HORTICULTURE FOR HEALTHY COMMUNITIES: AFRICAN AND ASIAN EXPERIENCES

R Y. Yang, P. Hanson, J d'A. Hughes, J D H. Keatinge

AVRDC-The World Vegetable Center, Tainan, Taiwan

Healthy diets include diverse foods from the key food groups (starchy staples, legumes and nuts, animal products, fruit and vegetables) that are enjoyable to eat, fulfill daily nu-

trient requirements, and contain health-promoting substances such as fiber and antioxidants. Vegetables are highly diverse in terms of species and varieties as well as essential and bioactive phytonutrients. Many people consume monotonous, insufficiently nutritious diets because they lack access to or cannot afford a broader range of nutritious foods with limited awareness of healthy diet importance. AVRDC – The World Vegetable Center addresses constraints along the vegetable value chain through four research and development themes—Germplasm, Breeding, Production and Consumption—to contribute to enhanced productivity, profitability, availability of vegetables and the nutritional status of consumers in developing countries, particularly in Africa and Asia. The Center develops improved tropically-adapted vegetable cultivars with emphasis on high yield, heat tolerance, multiple disease resistance, and high quality and high nutrient content. Strong collaboration with the private seed sector ensures that AVRDC's improved breeding lines reach farmers throughout the tropics. The Center designs improved horticultural practices that conserve water and soil nutrients to improve vegetable crop production in suboptimal environmental conditions and integrated pest management practices to reduce farmer reliance on pesticides. Home garden designs promoted through partners enable rural households to access vegetables throughout the year. Postharvest research offers practical solutions to reduce losses and maintain produce quality as it passes along the supply chain. The Center is engaged in nutritional and functional analyses of vegetable crops, food method improvement, and dietary strategies to enhance local appeal and nutrient bioavailability of vegetables. Jointly with colleagues and partners in agricultural, social and health sectors, the Center develops nutrition-sensitive, community-based agricultural interventions and promotion strategies to enhance access to nutritious food and promote healthy diets.

Key words: Vegetables, diversity, nutrition-sensitive, malnutrition.

INTRODUCTION TO FOODSCAPE STUDIES – WHAT THEY CAN DO FOR PUBLIC HEALTH NUTRITION

B E. Mikkelsen

Aalborg University/AAU-MENU, Aalborg, Denmark

Since the settings approach was introduced by WHO nearly 3 decades ago much intervention research has been taken as a point of departure for the everyday life arenas where health is created and lived such as the kindergarten, school, institutions and workplaces. Since these places in many cases have also a responsibility to provide food, there is a considerable interest in understanding how such arenas most effectively can work to provide healthy nutrition- for instance, by promoting healthier eating and physical activity. A new type of study – the broad ca-

tegrity of FoodScape Studies (FSS) can offer new opportunities for a deeper understanding of the socio-physical space in such arenas. The aim of this paper is to give a brief account of the origin of this new type of study and to look at some important implications for the public health nutrition agenda. The paper looks in particular at applications in public food environments – so called captive foodscapes. It introduces a typology of physical, social, mental, discursive and learning foodscapes. It concludes that the idea of foodscapes offers a suitable conceptual framework for the food, the different types of people and intermediaries and the space. Some of the important features of the notion of foodscapes are that it is able to capture the importance of place and time, contextual factors, meaning and the everyday life perspective of eating. The idea of foodscapes has important qualities to offer in terms of being able to understand the complex interactions taking place in spaces where public foods are offered. Such a typology can act as a guideline for the planning, development and the analysis of interventions in public settings where health is increasingly put on the agenda.

Key words: Foodscape, public health nutrition

COULD THE GREEK HOME GARDEN EXPLAIN THE REDUCED CARDIOVASCULAR MORTALITY IN ELDERLY GREEK MIGRANTS TO AUSTRALIA?

C. Itsiopoulos, A. Kouris-Blazos, T. Darnos-Thodis, S. Tsindos, E. Kaias

Department of Dietetics and Human Nutrition, La Trobe University, Melbourne, Australia

The well-known cardioprotective benefits of the traditional Greek Mediterranean diet were first described in the Seven Countries Study in the 1960s (Keys et al, 1986) and then by de Lorgeril et. al. (1999) in France. Elderly Greek migrants to Australia consistently show lower rates of all-cause and CHD mortality compared with Australian-born people. Paradoxically, however, this is in spite of a higher prevalence of CHD risk factors (ABS, 2008). Greek migrants to Australia have resisted dietary acculturation and retained healthy aspects of their traditional diets which may partly explain their lower mortality rates (Itsiopoulos and Brazionis, 2011; Itsiopoulos, 2007; Kouris-Blazos, 2002). Compared with Australian-born people, Greek migrants were found to have higher plasma levels of carotenoids (lycopene, lutein/zeaxanthin), biomarkers for fruit and vegetable intake (Itsiopoulos, 2007). Kouris-Blazos (1994) compared elderly Greek migrants aged > 70 years in Melbourne (n=189) to elderly Greeks living in a semi-rural area near Athens (Spata) (n=104). Over 70% of the Greek migrants reported growing a variety of vegetables in home gardens such as tomatoes, leafy green vegetables, fresh herbs, legumes, and olives. Almost 40% of the Greek migrants compared with 4% of

the Greeks in Spata reported relying solely on their home gardens for most of their vegetable intake. Consequently, Greek migrants reported higher vegetable intakes (1040g vs compared to 870g, data for men) as well as greater overall adherence to the traditional Mediterranean diet which correlated with significantly fewer deaths in a 5 year mortality follow up study (Wahlqvist et al., 2005).

Preliminary data from the Australian Mediterranean Islands Study show that Greek Islander migrants that grow tomatoes, onions and leafy greens in their gardens have a lower diastolic blood pressure (-30mmHg; P=0.049) and a trend towards lower BMI.

Key words: Traditional diets, home gardens, culinary herbs, olives, diabetes.

THE ROLE OF SHOPPING AND COOKING IN THE FOOD AND HEALTH SYSTEMS OF ELDERS

M.S. Lee¹, M.L. Wahlqvist², Y.H.Chang², R.C.Y. Chen²

¹School of Public Health, National Defense Medical Center, Taiwan, ROC

²National Health Research Institutes, Taiwan, ROC

Active ageing is a key to healthy ageing. Both shopping and cooking behaviors are important part of social life and economically relevant activities for the elderly. Considering the food and health systems together, we have investigated whether these two activities can contribute to survivorship in the elders independent of physical and cognitive function. We have linked data for some 1800 people aged 65 or over in a nationally representative free-living Taiwanese elderly cohort (NAHSIT, 1999-V2000) to the National Death Registry for decedents' time of death. During the 10-year follow-up (1999-2008), 695 participants died. Highly frequent shopping compared to never or rarely predicted survival (hazard ratio (HR)=0.54; 95% confidence interval (CI), 0.43-0.67)) with adjustment covariates HR (95%CI) was 0.73 (0.56-0.93). Elderly who shopped every day have 27% less risk of death than the least frequent shoppers. Men benefited more from everyday shopping than women with decreased HR 28% versus 23% compared to the least. Those who cooked most frequently were younger, women, unmarried, less educated, non-drinkers of alcohol, non-smokers, without chewing difficulty, had spouse as dinner companion, normal cognition, who walked or shopped more than twice weekly, who ate less meat and more vegetables. Highly frequent cooking (>5 times/week, compared with never) predicted survival (HR=0.47; 95 %CI, 0.36-0.61); with adjustment for physical function, cognitive function, nutrition knowledge awareness and other covariates, HR (95%CI) was 0.59 (0.41-0.86). Women benefited more from cooking than did men, with decreased HR, 51% vs. 24%, when most was

compared with least. Both shopping and cooking behaviors favorably predict survival. Highly frequent shopping favors men, however, highly frequent cooking favors women. Shopping and cooking capture several dimensions of personal well-being, health and security as well as contributing to the community's cohesiveness and economy and may represent or actually confer increased longevity.

Key words: Healthy ageing, longevity, function

INTEGRATING FOOD AND HEALTH WITH ECOSYSTEMS FOR HUMAN DEVELOPMENT

M.L. Wahlqvist

Monash University, Melbourne, Australia: NHRI,
Taiwan: Zhejiang University, China

The most vulnerable are those who are disconnected from their culturally and biologically relevant ecosystem unless they or their ancestors have developed some form of resilience. If we are to make significant progress with sustainable human development, we need households and communities to have food and health security and for their inhabitants to have livelihoods. Although there may be short-to-medium term benefits for well-being, physical and mental function, for health and even mortality, these are relatively few compared with the PARs (population attributable risks) and benefits which may accrue through ecological approaches. These approaches embrace intergenerational, spiritual, sociocultural, biomedical, personal behavioural (especially throughout the food system, with regular physical activity, avoidance of substance abuse with tobacco and alcohol) and livelihood dimensions. They favour affordable solutions to lifes' necessities of shelter, clothing, food, education and health. Nutritionally-related health disorders and diseases (NRHD) may reflect a spectrum of deficiencies, excesses and their combinations which manifest against a range of environmental and societal backgrounds. Their effective prevention and management requires strategies at the household and community level with foods whose progress through the system from production to consumption is known and understood. Such strategies are more implementable if people and systems involved and affected are digitally-connected. Well-rehearsed ecosystem measurement and monitoring tools are now available through the UN (<http://www.un.org/apps/news/story.asp?NewsID=39344>). When combined with national health system information about localities, they provide ways in which health, sustainability and economic problems can be defined, goals established and solutions found (<http://www.wri.org/project/mainstreaming-ecosystem-services/about>). PS5-71A The value of nutrition labelling: Has nutrition labelling reduced any chronic diseases? (IUFFoST)

NUTRITION LABELLING IN EUROPE: EFFECTIVE GUIDANCE TOWARDS MORE HEALTHFUL FOOD CHOICES?

S. Hieke, S. Storcksdieck, L. Fernández, J.M. Wills

European Food Information Council (EUFIC), Brussels, Belgium

Background and objectives: Providing nutrition information on foods and menus is considered a relevant means to guide consumers towards more healthful food choices. Assessments of the actual effectiveness among consumers of the different systems devised vary in scope, methodology and outcome. A review of the current literature appears timely, hoping to provide the informational base for actions to be taken on a public health and policy level.

Methods: We searched the following databases: CAB Abstracts, CAB Heritage, Agricola, Medline, PubMed, EBSCO Business Source Elite, and EBSCO Business Source Premier (search terms: nutrition, nutrition label, food label, labelling, food choice, consumer understanding) and included all studies published after 2000 which measured behavioural effects. A special focus was put on nutrition labelling in obesity prevention, for which we considered literature referenced in PubMed and Social Science Research Network (SSRN) from 2007 onwards (search terms: nutrition labelling, obesity), when the last major review on the subject had been published.

Results: Currently, various formats of back-of-pack and front-of-pack nutrition labelling can be found across the EU, with varying levels of penetration and directiveness. Experimental studies show that consumers are reasonably able to understand and use the different systems to identify more healthful food products from given choice sets. However, they seem to be lacking the motivation to actually seek out nutrition labelling information when shopping for food. European studies assessing the impact of nutrition labelling on actual dietary intake are scarce, and no real-life evidence exists linking nutrition label use with measured changes in body weight.

Conclusions: Looking at the question of whether nutrition labelling so far has been effective in encouraging healthy eating, results of this review may be seen as a base for evaluating future achievements of the new EU regulation which makes nutrition labelling mandatory.

Key words: Nutrition labelling, Obesity prevention, Consumer behaviour, Public policy, Information provision.

PS5-71B Urbanization and Food Security

ECOSYSTEM APPROACHES TO NUTRITION AND HEALTH SECURITY: URBANISED COMMUNITIES

M.L. Wahlqvist

Monash University, Melbourne, Australia & National Health Research Institutes, Taiwan

Localities, whatever their whereabouts, may or may not support nutritionally secure communities. It is rare for their food supply to be self-sufficient, although local food production was the hall-mark of human settlement. Arable, especially horticultural land and its water supply, has given way to residential and commercial development. This is part of a wider ecosystem loss. In a facile way, we regard this as acceptable and even sustainable because of our ability to trade, although that has considerable infrastructural dependency. Ecosystems are vital for the integrity of food systems as a whole in serving sustainable food diversity, even if that means trade between ecosystem-competent communities. Wahlqvist has made a case for communities to be connected, especially digitally, to enable food-based strategies to serve health needs (1). We know that food diversity is a valuable indicator of household food security and food variety (FV) a predictor of more favourable health outcomes. Regrettably, but not inevitably, the costs of the fruit and vegetable contributors to FV often make it less affordable. It is now also clear that the notion of *Homo sapiens* as a species discrete from its ecosystems is flawed and that, at some point, ecosystem collapse will include the decline of *Homo sapiens* (2). Measuring and monitoring the ecosystem resource and food diversity are two important methodologies for nutritional security programs. They could facilitate the development of more sustainable and affordable food systems which would also provide livelihoods and erode the unemployment mentality.

INFLUENCE OF URBANIZATION ON CLIMATE CHANGE AND NUTRITION INSECURITY

T. Atinmo

Department Of Human Nutrition, College of Medicine, University of Ibadan, Nigeria

Urbanization brings along with it infrastructural changes, technological advancement, population upsurge from migration and improved standards of living. Expectedly, climatic changes go along with all these transformations. However, usually the processes of urbanization move at geometrical rate while considerations for the effects on climatic changes and nutrition security move in arithmetic order. Many nations witnessing rapid urbanization do fail to plan for the consequences of expansion on climatic changes and the attendant nutrition insecurity. Influx of high-tech machineries, automobiles, industrial chemicals/gases and human resources etc. has great impact on climatic changes, especially as these affect global warming and ozone layer depletion. All these impacted on food production, environmental hygiene/pollution, health-care services, which are all strong variables that constitute nutrition security. Many developed worlds are highly urbanized but capable of maintaining safer climatic conditions and at the same time reduce the problem of food insecurity. It is therefore suggested that as many developing countries aspire to witness urbanization that is necessary for development, strong policy should be instituted to ensure that imported machineries and others are monitored and certified safe before they are shipped into the countries. Rural areas should be opened up for development to reduce concentration of people into the cities. Nutrition advocacy that will foster enabling environment for nutrition education should be promoted to create awareness on healthy eating, which is usually a neglected area in the process of urbanization. Urban agriculture should be supported as part of urbanization processes and a link should be created whereby some industrial wastes can be converted to organic manure to boost food production. Standard meteorological service should be instituted to serve as monitor of the environment and provide information on notable changes. Urbanization is needed for development but the effects on human survival should be of great priority to all stakeholders.

Key words: Urbanization, Climatic changes, Nutrition insecurity and National development.

CLIMATE CHANGE, URBANIZATION AND FOOD SECURITY: LINKING PRODUCTION AND CONSUMPTION

C. Tacoli

International Institute for Environment and Development, London, UK

Increasing food production is the main policy prescription to address food security. This neglects the crucial importance of access and affordability for low-income urban residents. With more than half the world's population living in urban centres, urban food insecurity is an emerging challenge that is exacerbated by climate change. While low and irregular incomes are its root cause, environmental hazards and inadequate housing and infrastructure contribute to higher levels of malnutrition in low-income settlements than in rural areas. Addressing urban food security requires attention to incomes, living conditions, access to formal and informal markets and the interconnections between rural and urban food security.

Key words: Climate change, food security, malnutrition, urbanization.

NUTRITION AND FOOD SECURITY: A CLIMATOLOGICAL PERSPECTIVE

T. Beer

Centre for Australian Weather and Climate Research, Australia

To climatologists nutritional security is dominated by the impacts of weather and climate on food systems. With growing urbanization, extreme weather events such as tropical cyclones impact directly on agriculture, but also on the logistical distribution of food. Drought affects human life and health as well as impacting dramatically on the sustainable development of society. It represents a pending danger for vulnerable agricultural systems that depend on the rainfall, water supply and reservoirs. Developed countries are affected, but the impact is disproportionate within the developing world. Drought, especially when it results in famine, can change the life and economic development of developing nations and stifle their development for decades. A holistic approach is required to understand the phenomena, to forecast catastrophic events and to predict their societal consequences.

The International Union of Geodesy and Geophysics (IUGG) is leading the WeatCliFS consortium of international scientific unions (including IUNS and IUFOST) to examine weather, climate and food security as well as to look at the interaction of food security and geophysical phenomena. The following fundamental question underpins WeatCliFS: What technologies and methodologies are required to assess the

vulnerability of people and places to hazards [such as famine] – and how might these be used at a variety of spatial and temporal scales?

This talk will review the historical link between weather, climate, drought and food supplies; examine the Australian and international situation; summarise the response of the scientific community and point out the direction for future research.

Key words: Agriculture, climate, food security, urbanization.

USING SOUTH AFRICAN FOOD COMPANIES' NUTRITION STRATEGIES AND CONSUMER KNOWLEDGE, ATTITUDES AND PRACTICES PERTAINING TO NUTRITION INFORMATION TO DEVELOP GUIDELINES FOR THE PROMOTION OF THE PREVENTION OF CHRONIC DISEASES OF LIFESTYLE

J. Badham¹, L. Kriek²

¹M.Sc Nutrition, JB Consultancy, Johannesburg, South Africa

²Consumer Science (Ed) M Nutrition, Consulting Solutions, Cape Town, South Africa

Background and objectives: The main objective of the study was to investigate the nutrition strategies that food companies in South Africa use to communicate with the consumers and to compare it with the knowledge, attitudes and practices of the consumers towards the nutrition information that they receive.

Methods: The study population consisted of a sample of 7 food companies operating in South Africa and a sample of 230 South African consumers. Data were collected through questionnaires aimed at each specific study population. The data were analysed statistically for each study population and the data between the two study populations were compared.

Results: Seventy-one percent of the food companies indicated that they address chronic diseases of lifestyle in their nutrition strategies. The medium most frequently used by food companies for consumer nutrition education, is the food label and this together with television is the preferred medium for the consumers. Both the majority of food companies and consumers agree that the food companies have a responsibility towards the nutritional education of the consumer.

Conclusions: Food companies should be actively involved with consumer education pertaining to healthy eating and healthy lifestyle habits as it is expected by the consumer. Communication with regard to evidence-based nutrition education is critical but should be consistent with an integrated approach involving all the role players including the food industry, Department of Health and Department of Education.

Key words: Food industry, healthy eating, healthy lifestyles, nutrition education.

EFFECTS OF CLIMATE CHANGE ON THE FOOD SUPPLY CHAIN AND THEIR IMPACT ON URBAN NUTRITION SECURITY

E.J. McGill

International Union of Food Science and Technology (IUFoST), Victoria, AUSTRALIA

In the FAO definition of Food Security (FAO, 1996) there is the requirement that all people at all times should have access to an adequate food supply of their preference, to maintain health, growth and continuing development (the italics are mine). However undeveloped a country may be, food supply chains exist and provide the means for the availability of enough safe food of the required quality for their population, under ideal conditions. With the rapid increase in the rate of urbanization (now > 50% of the world's population live in cities) the supply chain links within urban areas are becoming critical, if a balanced diet is to be available. Poorer communities within cities have increasing difficulty in accessing a diverse fresh food supply and hence an adequate diet. In contrast, their access to fast food outlets is very much better (London Food Programme, 2006). Developments in urban agriculture may alleviate these trends to some extent but face their own technical and supply chain difficulties.

Climate changes will impact on every stage and aspect of the food supply chain from primary production to final consumption. Loss or interruption of power supplies will reduce food safety (loss of temperature controls), transport failures will cause disruption to the 'just-in-time' retail sector and many urban citizens will be unable to travel to even local food outlets. Nutrition will suffer and starvation will become a real possibility.

To maintain and improve urban citizens' access to a sound, nutritional diet, an understanding of their food supply chain and its underpinning science and technology is required. The development of strategies to improve the adequacy, sufficiency and security of this supply chain, in the face of the potential disruptions resulting from climate change, is our ongoing challenge.

T8 AGRICULTURE, FOOD SCIENCE AND SAFETY

NPS1-8 IMAPP (Intake, Monitoring and Program Planning): Software nutrient intake data

INTAKE, MONITORING AND PLANNING PROGRAM (IMAPP) – WHAT ARE ITS CAPABILITIES?

A. Carriquiry¹, S. Murphy², L. Allen³, B. de Benoist⁴

¹Department of Statistics, Iowa State University, USA

²Cancer Research Center, University of Hawaii, USA

³USDA-ARS Western Human Nutrition Research Center, USA

⁴WHO, Switzerland

IMAPP was developed at Iowa State University in collaboration with University of Hawaii and USDA-ARS Western Human Nutrition Research Center with funding from WHO. IMAPP is freely available from <http://www.side.stat.iastate.edu/>. IMAPP can be used to assess and to plan nutrient intakes. For assessment, IMAPP implements the ISU Method (Nusser et al., 1996) to estimate usual nutrient intake distributions and the IOM recommendations (DRIs: Applications in Dietary Assessment) to compute prevalence of inadequate or of excessive intakes. For planning, IMAPP implements the recommendations by WHO/FAO in Guidelines for Food Fortification with Micronutrients (WHO 2006). IMAPP estimates usual intake distributions of nutrients for groups defined by age, gender and pregnancy/lactation using daily intake information. Ideally, two or more observations are available at least for a sub-sample of individuals. However, IMAPP permits adjustment of datasets with no replicates by using external intra-person variances supplied by the user or by IMAPP. The EARs and ULs of a long list of nutrients are built into IMAPP and the program “understands” which form of the nutrient (e.g., retinol or vitamin A) should be used to estimate inadequacy or excess. IMAPP also allows for different bioavailability of iron and zinc. Given a target prevalence of inadequacy of a nutrient in a population group and daily intake of potential vehicles, IMAPP will compute the amount of the nutrient to be added to each vehicle to meet the target prevalence in the group. It will also estimate the resulting prevalence of inadequacy and of excess in all other population sub-groups. Because of its many built-in functions, IMAPP can be used by practitioners with little statistical or computational background.

Key words: Usual intake, assessment, fortification, inadequacy, DRI.

USING THE IMAPP SOFTWARE; INFORMATION REQUIRED FOR OPTIMAL APPLICATION

S. Murphy

University of Hawaii, USA

The intake monitoring, assessment, and planning program (IMAPP) provides software to analyze nutrient inadequacies and potential excessive intakes within a population group. However, the power of the software can only be realized if accurate information is provided by the user. Before using IMAPP, it is necessary to collect daily dietary intake data (e.g., from 24 hour recalls or records) for each individual in a sample of the population. Intakes of the nutrients of interest must be provided for each person.

Thus, the user must have access to food composition data that can correctly convert food intakes into nutrient intakes.

To apply the appropriate nutrient standards, age, gender, and reproductive status should be indicated for each person. The nutrient standards that are used for the calculations are the average nutrient requirements and the safe upper levels of intake. These standards may be specified by the user or the default “harmonized” values in the program may be used. To adjust for day-to-day variation in intakes, multiple days of dietary data for at least a representative subsample of the population should be provided, although it is also possible to use default values from other populations for these variance estimates. Bioavailability factors may be specified for iron and zinc, or may be based on dietary patterns.

If IMAPP is being used to design fortification programs, daily intakes of potential food vehicles for fortification must also be provided. Intake for each vehicle should be calculated after disaggregating mixed dishes into their ingredients. IMAPP will then calculate new prevalences of nutrient inadequacies assuming specific levels of fortification of one or more food vehicles. Thus, IMAPP is an important tool for assessing intakes as well as planning intakes, but optimal application depends on high quality intake data provided by the user.

Key words: Intake assessment, intake planning, fortification.

HARMONIZING MICRONUTRIENT RECOMMENDATIONS WORLD-WIDE

L H. Allen¹, S P. Murphy²

¹USDA, ARS Western Human Nutrition Research Center, USA

²University of Hawaii Cancer Research Center, Hawaii, USA

Background and Objectives: Harmonization of nutrient intake recommendations is important because advice concerning nutrient intakes, formulation of complementary foods, levels for fortification and labeling is usually provided at the global or regional level. Actual requirements vary little across the world yet the process for creating and revising recommendations is costly and time-consuming especially for low income countries, and already includes some uncertainty. Current terms for recommended levels are inconsistent and WHO/FAO has no Estimated Average Requirements or Upper Levels. Our objective was to use a systematic approach to develop global recommendations.

Methods: Values were compared from the Institute of Medicine (IOM, US/Canada), WHO/FAO and the UK primarily. IOM was used if values differed <10%, otherwise scientific criteria were applied to choose best estimates.

Conclusion: New harmonized values were derived for use in IMAPP and elsewhere. A process for review and revision is needed.

Key words: Recommended nutrient intakes.

APPLICATION OF THE IMAPP FOR PLANNING, MONITORING AND EVALUATION OF FLOUR FORTIFICATION PROGRAMS

H. Pachon

Flour Fortification Initiative, Atlanta, USA

Background and objectives: The planning, monitoring and evaluating of cereal-grain fortification programs require dietary intake data (or proxies thereof). These data are needed to determine which food vehicle(s) to fortify and in what amounts (planning); if a change in dietary patterns warrants a change in food vehicles or fortification levels (monitoring); and whether intended beneficiaries are consuming fortified foods in sufficient quantities and frequency to expect health improvements (evaluation). The objective of this analysis is to explore the use of Intake, Monitoring and Program Planning (IMAPP) software with dietary intake data for countries that are in the planning, monitoring or evaluation stages.

Methods: Dietary data from countries (e.g. Mongolia in the planning stage, South Africa in the monitoring stage, and In-

donesia in the evaluation stage) will be analyzed using IMAPP. Results and conclusions: Recommendations for countries in the planning, monitoring and evaluation stage will be generated using IMAPP results. The pros and cons of IMAPP for such exercises in the context of fortification will be discussed.

Key words: Fortification, planning, monitoring, evaluation, IMAPP.

ESTABLISHING DESIRABLE FORTIFICANT LEVELS FOR MICRONUTRIENTS IN FOODS FOR INFANT AND YOUNG CHILD FEEDING: EXAMPLES FROM THREE ASIAN COUNTRIES

M M. Gibbs¹, A. Carriquiry², M V. Capanza³, R. Gibson¹

¹Department Human Nutrition, University of Otago, Dunedin, New Zealand

²Department Statistics, Iowa State University, Ames, Iowa, USA

³Food & Nutrition Research Institute, Bicutan, Manila, Philippines

Background and objectives: Concern has been raised whether micronutrient levels in manufactured cereal-based fortified foods for infant and young child feeding available in low income countries meet their high micronutrient needs. We used WHO recommended procedures to establish desirable fortificant levels for three problem micronutrients in Asian children's diets.

Methods: Dietary data collected earlier from Filipino (n=1374; 6-36 months), Mongolian (n=179; 12-36 months), and Cambodian (n=177; 12-36 months) children were used to assess prevalence of inadequate and excessive intakes of calcium and zinc (cut-point method) and iron (full probability approach) after adjusting usual intake distributions with PC-SIDE using internal or external within-person variances. Fortificant levels were determined by repositioning usual intake distributions so 2.5th percentile for each distribution and target population equalled the EAR (calcium, zinc) or so that full-probability prevalence of inadequate intakes of iron was no larger than 2.5%.

Results: Prevalence of inadequate intakes was 70% for calcium and iron, except Filipino infants (30% for calcium) and Cambodian toddlers (41% for iron); but <1% for zinc for toddlers in Mongolia and 20% in Cambodia. Prevalence of excessive intakes was <1% for zinc, calcium, and iron, except for Mongolian toddlers (11% for zinc). Desirable fortificant levels, although apparently negligible for zinc, were 530 to 783 mg for calcium, and 10.8 to 22.8 mg for iron (per 100 gram). Fortificant levels can be estimated from 24-hr recalls, preferably by applying internal within-person variances.

Conclusions: Fortification with calcium and iron was necessary, but seemingly not for zinc, despite a high prevalence of low serum zinc concentrations, suggesting the need for better defined cut-offs for risk of zinc deficiency in young children based on the prevalence of inadequate intakes of dietary zinc and/or serum zinc.

Acknowledgement: Supported by Univ. Otago Research Committee.

Key words: Micronutrient fortificants; PC-SIDE; within-person variation; Estimated Average Requirements.

PS1-8 Food-based approaches to improve multiple micro-nutrient deficiencies and protein quality

DIETARY APPROACHES TO DIET QUALITY IMPROVEMENT

S. Murphy

University of Hawaii, USA

Although dietary supplements and fortified foods can contribute to meeting nutrient intake standards, they do not appear to have many of the health benefits of food sources of nutrients, especially in the prevention of chronic diseases. Furthermore, they are not typically as sustainable as foods that are available locally. In the Child Nutrition Project (CNP) in rural Kenya, school-based snacks were developed to supply six micro-nutrients of concern: iron, zinc, vitamin B12, vitamin A, calcium, and riboflavin. Two snacks incorporated animal-source foods to provide several of these nutrients: the milk snack supplied calcium, vitamin B12, and riboflavin while the meat snack supplied vitamin B12 and bioavailable iron and zinc. The milk snack provided an average of 48% of the recommendations for these six nutrients, and the meat snack provided 44%. By comparison, an equi-caloric vegetarian snack provided only 17.5%. Although it was not tested, a snack that provided both milk and meat would be likely to improve dietary quality even further. Studies like CNP contribute to the design of food guides which provide practical advice on how to choose a nutritionally adequate diet using foods that are readily available to a population. Food guides that have been derived to ensure nutrient adequacy virtually always include meat and dairy groups, as well as fruits, vegetables, and starchy staples. In the United States, MyPlate presents a simple graphic showing the proportions of a plate that should be filled with foods from each food group (see www.choosemyplate.gov). Adapting such food guides to local preferences and food availability may be an important step in improving dietary quality. For countries at any level of development, these guides can then serve as the basis for educational programs as well as the foundation of national nutrition policies that promote nutritionally adequate diets.

Key words: Diet quality, food guides, micronutrients.

COMPLEMENTARY FEEDING RECOMMENDATIONS FROM LOCALLY AVAILABLE FOODS

U. Fahmida

SEAMEO-RECFON, Regional Center For Food and Nutrition, University of Indonesia, Jakarta, Indonesia

Background and objectives: Adequate nutrition during the first 2y of life is essential to ensure optimal health, growth, and development. In their Global Strategy for Infant and Young Child Feeding, WHO and UNICEF have provided guidance on appropriate complementary feeding, with emphasis on use of suitable locally available foods. Affordable, locally contextual complementary feeding recommendations (CFR) are more likely to result in long-term improvements in complementary feeding practices than general recommendations as it takes into account cultural diversity and differences in food availability. This presentation aims to describe development of CFR using linear/goal programming (LP) approach.

Methods: Four modules in LP were used (1) to formulate optimal CFR given local food availability, food pattern, and food affordability; (2) to evaluate nutrient adequacy and identify absolute or partial problem nutrients, (3) to identify locally available nutrient-dense foods to fill the nutrient gap, and (4) to choose from amongst alternatives of CFRs based on the comparative cost and nutritional benefits. Data for the analysis was from the National Basic Health Survey (Riskesdas, 2010) and several studies conducted in rural, peri-urban, and urban area of Indonesia.

Results: The developed CFRs for different age groups revealed similarities and differences in the problem nutrients across age groups. Comparing results from several studies in Indonesia, while calcium, iron, and zinc were the typical problem nutrients, the extent of deficiency and the potential nutrient-dense foods vary across age groups, area (rural, peri-urban, urban) and socioeconomic level. Animal source foods and fortified foods were identified as nutrient-dense foods which can improve micronutrient adequacy from the complementary foods.

Conclusion: CFR from locally available foods can be optimized by including available nutrient-dense foods. Achievement of nutrient adequacy from the CFR varies by age groups, area and socio-economic condition.

Key words: Complementary feeding recommendation, linear/goal programming, local foods, problem nutrient.

USE OF OMENA FISH IN KENYA

C. Gewa¹, C. Frankenfeld²

¹Department of Nutrition and Food Studies, George Mason University, USA

²Department of Global and Community Health, George Mason University, USA

High levels of infections with increased pregnancy-related nutrient demands and inadequate food supplies can place some pregnant women in resource-scarce settings in a vulnerable health status, often associated with inadequate weight gain, low-birth weight, prematurity, fetal deaths and maternal and child mortality. Animal-source foods provide a rich source of high quality protein and variety of micronutrients required for adequate growth. However, a majority of these foods are not accessible to a large proportion of populations in poor countries. Locally available small fish like Omena (*Rastrinobola argentea*) offers a likely source of nutrient-rich and affordable food among communities in Kenya. However, its potential to improve nutritional status among pregnant women is still unknown. We utilized a cross-sectional study design to assess the acceptability of fish-enhanced supplemental snacks among a sample of pregnant women in rural Kenya. Isocaloric fish-enhanced, soy-enhanced and wheat snacks were compared on taste, odor, texture and color. Wheat snacks were most preferred with more than 95% of mothers indicating that they liked its taste, odor, texture and color. Over 85% of mothers indicated that they liked the taste, odor, texture and color of the fish-enhanced snack and over 81% of mothers indicated that they liked the taste, odor, texture and color of the soy-enhanced snack. No significant differences were noted across mother's HIV status. Focus group discussions with the mothers further revealed that the fish-enhanced snack was well-liked for its crunch, taste, dark-brown color and spice. Our analysis demonstrates the potential use of locally available and affordable small animal food sources to improve nutritional status of vulnerable population groups in low-income nations.

Key words: Small fish, fish-enhanced snacks, pregnant women, Kenya.

MEATS AS COMPLEMENTARY FOOD FOR OLDER INFANTS

N. Krebs, M. Hambidge

School of Medicine, University of Colorado, Denver, USA

The relatively high iron and zinc requirements of breastfed infants older than about 6 mo of age, and the physiologic composition of human milk dictate that they must consume either

cellular animal protein foods (meats or organ tissue), or rely on fortified foods or supplements. Common infant feeding practice, however, is to introduce meats only as one of the last foods for older infants. The reasons for this include expense of meats; assumption that infants can't or won't eat meats; perception that meats are too difficult to digest until later. Data obtained by a feeding survey from infants in 4 diverse settings indicated that meats were fed to > 60% of toddlers, but to < 25% of infants, suggesting that availability and affordability were not the limiting factors within households. Prior to the Agricultural Revolution, mothers most likely pre-masticated meats to enable the infants to eat them. We have undertaken several studies to examine the potential impact of consuming meats vs cereals (fortified and unfortified) by older infants. The forms of meat used for older infants and toddlers included commercially available pureed meats; freeze dried meat cubes, which could be eaten either dry or in soups and porridges, and either as a powder or finger foods; cooked and shredded meats; and crumbled and/or mashed liver. Infants' acceptance of the meats was excellent in all studies, although cultural norms favored cereals over meats as an appropriate infant food. Animal source proteins contribute micronutrients that are critical to older infants and toddlers, and availability of meats may actually be greater than fortified products in resource poor settings. Education efforts are warranted to encourage the use of meats as complementary foods for older infants.

Key words: Infants, meat, toddlers, complementary foods, micronutrients.

CONSUMPTION OF ANIMAL SOURCE FOODS AND COGNITIVE PERFORMANCE OF PRIMARY SCHOOL CHILDREN IN HAWASSA TOWN, SOUTHERN ETHIOPIA

M. Girma¹, E. Loha³, A. Bogale^{1,2}, Y. Abebe¹, M. Hambidge⁴, B. Stoecker¹

¹School of Nutrition, Food Science & Technology, Hawassa University, Hawassa, Ethiopia

²Department of Nutritional Sciences, Oklahoma State University, Stillwater, Oklahoma, USA

³School of Public & Environmental Health, Hawassa University, Hawassa, Ethiopia

⁴School of Medicine - Pediatrics, University of Colorado, Denver, Colorado, USA

Cognitive development of children is influenced by nutritional, socioeconomic and environmental factors. This cross-sectional survey of primary school children (n=116) examined associations among anthropometrics, animal source food (ASF) consumption and cognitive performance. Five schools were randomly selected from fifty-one in Hawassa Town using

probability proportional to size sampling. Twenty-five students were randomly selected from the seven to nine year old children in these schools. Family socio-economic characteristics and child diets were collected from primary caregivers using individually-administered questionnaires. Dietary diversity was assessed using the eight indicator food groups identified by the Food and Nutrition Technical Assistance Project. Anthropometric measurements were transformed to Z-scores using WHO AnthroPlus Software. Cognitive testing utilized Raven's Colored Progressive Matrices (CPM, board version) and selected tests from the Kaufman Assessment Battery for Children (KABC-II). Data were analyzed using SPSS v.19. Median child age was eight and most had some preschool education. Thirty-six percent of mothers had no formal education while 35% had completed primary education. Thirteen percent of children were stunted and 13% were underweight. Only 3.4% of children consumed eggs in the 24 hours preceding the dietary survey and only 13.8% consumed meat, poultry or fish. Stunted (height-for-age Z [HAZ] <-2) children had significantly lower scores on the Raven's CPM, on pattern reasoning and on tests of short-term memory. Children not consuming flesh foods or eggs had lower scores for short-term memory and visual processing. Multiple regression models including HAZ, ASF, preschool attendance and maternal education predicted 18 to 26% of variability in cognitive scores. These results add to the body of data supporting importance of nutritional status for cognitive function.

Key words: Animal foods, children, cognitive performance.

MICROCREDIT WITH ENTREPRENEURIAL AND NUTRITION EDUCATION INTERVENTION IMPROVED WOMEN'S INCOMES AND CHILDREN'S ANIMAL SOURCE FOOD INTAKE AND NUTRITION IN GHANA

G. Marquis¹, E. Colecraft²

¹McGill University, Montréal, Québec, Canada

²University of Ghana, Accra, Republic of Ghana

The Enhancing Child Nutrition through Animal Source Management (ENAM) project (2004-2009) emanated from participatory formative research that identified six principal constraints to the inclusion of animal source foods (ASF) in Ghanaian children's diets: low caregiver income, poor producer-consumer linkages, inadequate nutrition knowledge and skills of extension staff and caregivers, cultural beliefs, and inequitable household food distribution. To address these constraints, the ENAM project implemented an integrated micro-

credit, entrepreneurship and nutrition education initiative with 181 caregivers of 2- to 5-y-old children in six rural communities across three agro-ecological zones of Ghana. Six matched communities from the same zones served as comparison sites. Methods included surveys, anthropometry, and dietary assessment to assess the intervention effect on children's dietary intakes and growth and 12 qualitative case studies to examine household and caregiver outcomes of interest. Women reported that the ENAM experience opened opportunities for obtaining microcredit for the first time, which helped increase their business success. Significantly more participant caregivers expanded and diversified their small businesses ($p < 0.01$), tended to have higher profits ($p < 0.01$), and had significantly higher savings ($p < 0.05$) than non-participant caregivers. Participant households tended to spend more money ($p < 0.10$) and consumed significantly more amounts (in monetary value) of ASF ($p < 0.01$) than non-participant households. About one-third of the caregivers were engaged in an ASF-related business, such as selling smoked fish or eggs, or selling cooked food that contained ASF. After accounting for locale, being involved in an ASF-related business positively predicted children's ASF diversity ($p < 0.001$). The intervention had a positive effect on children's nutritional status ($p < 0.05$). Evidence suggests that the microcredit-education link benefited women's lives with respect to their small businesses and their personal development as well as the diet and health of their young children.

Acknowledgement: Supported by GL-CRSP/USAID Grant No. PCE-G-00-98-00036-0.

Key words: Child nutrition, animal source foods.

FOOD-BASED APPROACHES TO IMPROVE MULTIPLE MICRO-NUTRIENT DEFICIENCIES AND PROTEIN QUALITY

A. Neumann

University of California, Davis, USA

Recently completed and ongoing research studies using animal source foods to improve a range of nutritional problems will be presented. Researchers from Asia, Africa, and elsewhere will make presentations during this symposium. This is a very important topic now that we have evidence-based research to support the use of food-based approaches to combat multiple micronutrient deficiencies and improve protein quality and nutrition status and function in resource-poor countries. This important approach holds promise in terms of sustainability and reaching hard to reach rural populations comprised mainly of subsistence farmers. Although short term nutrient supplements are necessary in cases of severe deficiency, we wish to share research outcomes related to the use of food-based approaches by households and communities to combat multiple micronutrient deficiencies and improve function. The

planned presentations include: Introduction and overview of global micro-nutrient Deficiency and Protein Quality, Dietary Approaches to Diet Quality Improvement Using Locally Available Foods, Ongoing Intervention Study among Pregnant Woman in Vietnam, Meat Intervention in Chinese Infants, Food-Based Approaches in Ethiopia, Use of Omena Fish in Kenya, Community Interventions for Dietary Improvements in Ghana, and Meat vs. Soy Biscuit Intervention Trial in HIV Drug Naïve Kenyan Women and Children to Protect Nutrition Status and Prevent Progression of HIV to AIDS.

Key words: Animal source foods, diet quality, micronutrients.

HIGH NUTRITION BISCUITS AS A SUPPLEMENT TO INCREASE ANIMAL PROTEIN IN DIETS OF HIV-INFECTED KENYAN WOMEN AND THEIR CHILDREN

J. Ernst¹, G. Ettyang², C. Neumann³

¹Nutrition & Dietetics, Indiana University School of Health & Rehabilitation Sciences, Indianapolis, IN, USA

²Department of Epidemiology & Nutrition, School of Public Health, Moi University, Eldoret, Kenya

³Department of Pediatrics, School of Public Health University of California, Los Angeles, USA

This project is evaluating effects of protein quality and micronutrients found in meat on the health and nutritional well-being of women living with HIV in rural Kenya and the health and development of their children. Women receive their medical care within the USAID supported Academic Model Providing Access to Healthcare (AMPATH) partnership in Western Kenya. By means of a randomized nutrition feeding intervention we are determining if meat in the diets of HIV-infected women and their children (1) protects the immune system and prevents severe infection, (2) prevents the loss of lean body mass, enhancing the quality of life among these drug naïve women and enabling women to carry out activities of daily living, and (3) supports the growth and development of their vulnerable children when compared to those given supplements with the same amount of energy, but with either soy or wheat protein. Through continuous collaboration, the research team developed the intervention foods to be basic biscuits made with wheat flour; dried beef or soy flour is added to the recipe. Boiled water is added for porridge consistency for young children and those with difficulty chewing. The beef biscuits provide women and children with significantly greater amounts of lysine, vitamin B12, bio-available zinc and iron than those in the soy or wheat groups. Data analysis is ongoing and study outcomes will soon be disseminated. The “biscuit model” is useful for nutrition supplementation studies because

it can be safely provided in a blinded and randomized fashion to a highly stigmatized population, it is well received by adults and children, it is produced with available and affordable technology and can accommodate the comparison of different sources and amounts of protein.

Acknowledgement: Research is supported by USAID Grant No. PCE-G-00-98-00036-00, 1R01HD57646-01A1 (CFDA #93.865) and Heifer Project International.

Key words: Food supplement, protein, vitamin B12.

PS2-16 Food composition (FAO)

IMPACT OF FOOD COMPOSITION DATA ON NUTRIENT INTAKES, REQUIREMENTS, PROGRAMMES AND POLICIES

S. Murphy

University of Hawaii, Hawaii, USA

Accurate food composition data are essential both for assessing nutrient intakes and for planning nutritious diets. Too often, the role of food composition tables (FCTs) is not recognized when evaluating intakes, setting requirements, and designing appropriate national and regional programmes and policies. This should be an iterative process with the first step the collection of food intake data for a population group. To determine if dietary nutrient inadequacies exist within the group, the food intake data must first be converted to nutrient intake data using a FCT that contains the foods consumed by the population of interest. Then the intakes may be compared to nutrient standards using analytic techniques that consider variation in both intakes and requirements. Sometimes nutrient standards are not available and must be imputed; intakes of these nutrients are sometimes used to decide if the standards from other countries or regions are appropriate. Standards for potentially excessive intakes are also needed to decide if intakes of some nutrients need to be reduced (e.g., calories, saturated fat, sodium, sugars). To achieve a comprehensive evaluation, FCTs need to include a wide array of food components with potential effects on health outcomes. Once the prevalences of inadequacies and potential excesses have been determined, food sources of nutrients of concern can be identified and incorporated into educational programs or dietary interventions for the population. The development of standards for the school meals program in the United States illustrates how FCTs play a key role in this process. Ultimately, an important goal of these activities is to develop dietary guidance that will (1) achieve nutrient adequacy and avoid excess; (2) maintain healthy body weights; and (3) reduce risk of chronic diseases.

Key words: Food composition, intake assessment, nutrition policy.

THE ROLE OF FOOD COMPOSITION DATA FOR NUTRITION LABELING

J. Albert

Food and Agriculture Organization of the United Nations, Rome Italy

Changing dietary patterns, expanding food trade and growing rates of obesity and diet-related non-communicable diseases have stimulated interest in the provision of nutrition information to consumers to enable them to choose foods that are appropriate for their health needs. Nutrition labeling on food products and in food outlets is becoming a common type of nutrition information that can be relevant to improving nutritional status worldwide. A variety of nutrition labels are found in markets around the world and the preponderance of labels will continue to grow.

Whether a nutrition label system is mandatory or voluntary, including a Back of Pack panel or a Front of Pack symbol, reliable and accurate food composition data are essential to ensure the credibility of the label. Yet small and medium size food enterprises, especially in developing countries, may be challenged to obtain the food composition information that is required to be compliant with labeling requirements in local or foreign markets.

Food composition data specialists play an important role in the implementation of food labeling policies. What is the public health rationale for nutrition labels, including evidence that consumers use and understand labels? What is the latest information from the Codex Alimentarius Commission related to nutrition labels? What do regional agreements and national legislative bodies require in terms of food composition information for food labeling? The challenges to expand food composition information will be discussed and options to improve the availability of food composition data will be proposed.

Key words: Food standards and legislation, consumer information.

THE CORRECT USE OF FOOD COMPOSITION DATA

D H. Markowicz Bastos, R M. Fisberg, D M L. Marchioni

Nutrition Department, School of Public Health, São Paulo University, São Paulo, Brazil

Reliable food composition data must be available for several purposes such as epidemiological studies, food labeling, planning of institutional meals, plant and animal breeding programmes, among others and, therefore, government from different countries have been investing in gathering food composition data in databases which are made available in different formats and medias. The final users of these data, usually, are not aware of the complexity behind the development of a

food composition database and the methodology by which data are gathered and this may lead to misuses of data with serious implications for nutrition, health and agriculture related programmes and policies. The correct use of food composition data must consider several aspects which are related to (i) the food item (or food group), such as identifying the correct name of the food items, to (ii) the nutrients, due, for example, to differences in definition and the analytical methodology, and to (iii) procedures for estimating nutrient values for foods, households recipes, cooking method or commercial products, or (iv) food matching. Other current and relevant aspect is the identification, in the food composition database, of the food item until the cultivar/variety/breed level, which is essential for evaluating the impact of food biodiversity on nutrition. We intend to discuss these issues and, by doing so, contribute to a better use of food composition data.

Key words: Food composition data, misuses, nutrient evaluation.

THE NEED OF NEW HIGH-QUALITY ANALYTICAL DATA FOR FOOD COMPOSITION TABLES AND FOR BIODIVERSITY AS WELL AS WILD AND UNDERUTILIZED FOODS

T. Longvah

National Institute of Nutrition, Hyderabad, India

Traditionally Food Composition tables (FCT) have been used world-wide for national nutrition monitoring and research into association between diet and disease. Many FCT contain nutrient data based on old methodology leading to serious errors while interpreting nutritional or epidemiological data threatening higher costs and inefficient use of resources. Updates in the FCT due to improved analytical techniques have shown changes in nutrient intakes as well as in the proportion of population with inadequate intakes. On the other hand studies have revealed that estimates of mineral intake from FCT versus analyzed values are not in agreement due to compromised mineral data in the FCT. Such studies illustrate the necessity for new high quality nutrient database. Reliable food composition data are essential for the provision of dietary guidelines as well as identification of sources of these nutrients. Significantly large nutrient variation exists within food cultivars that can be used to nutritional advantage. Glycemic index (GI) of foods is currently of interest to study the associations of diet and chronic disease. Rice has GI values ranging from 52 to 86 indicating the nutrient biodiversity within rice varieties and the importance of quoting appropriate GI in the FCT. Agrobiodiversity is essential for sustainable food and nutrient security, yet the nutrient composition of wild and underutilized plant foods remains neglected in most FCT severely compromising nutritional studies of indigenous populations. The

diversity of wild and underutilized foods offers vast scope for economic and nutritional benefits. In the absence of accurate food composition database as well as data on wild and underutilized foods evaluation of diets for nutritional adequacy and epidemiological research will be weak and less significant. The need to obtain high quality analytical nutrient data for foods using appropriate quality control and sampling procedures is discussed in detail.

Key words: Agobiodiversity, food composition databases, biodiversity.

LINK BETWEEN FOOD COMPOSITION, NUTRITION, AGRICULTURE AND BETTER FOOD SUPPLY TO COMBAT MALNUTRITION THROUGH FOOD-BASED APPROACHES

U.R. Charrondiere

Nutrition division, FAO, Rome, Italy

Background and objectives: Global agricultural production is theoretically sufficient to feed the world's population, yet one billion people are hungry and two billion suffer from micronutrient deficiencies. Many countries and agencies attempt to combat malnutrition with short-term health and nutrition interventions such as supplementation, fortification and sporadic health and nutrition policies and programmes. Since 2004, several international bodies have recognized the important linkage between food composition, biodiversity, nutrition and agriculture. It has been scientifically proven that compositional differences at intra-species level are statistically significant, and more importantly, nutritionally significant, with up to 1,000-fold differences documented. Therefore, the consumption of one variety or breed rather than another could represent the difference between nutrient deficiency and adequacy.

Methods: FAO and INFOODS have generated, compiled and disseminated compositional data of biodiverse foods and have included biodiversity in guidelines, tools and material for capacity development to be used in food composition, nutrition and agriculture.

Results: Databases with genetic and agricultural features are intending to link to the FAO/INFOODS Food Composition Database for Biodiversity. Member States of the Commission on Genetic Resources for Food and Agriculture recently endorsed the linkage between nutrition, biodiversity and agriculture and requested FAO and partners to continue updating the FAO/INFOODS database and to develop guidelines on integrating biodiversity into food consumption surveys. Increasingly, food composition compilers and agricultural research institutes are collaborating to explore the composition of foods before selecting those for breeding.

Conclusions: This positive trend will hopefully continue

and will lead to a large-scale agricultural production taking into account biodiversity and environmental-friendly factors, and thus resulting in sustainable food and agricultural systems. Food-based approaches based on food biodiversity can significantly contribute combating all forms of malnutrition in a sustainable manner.

Key words: FAO, INFOODS, food composition, agriculture, sustainable diets.

PS2-24 Sugars and health: The controversies continue

SWEETNESS, HEDONIC IMPACT AND FOOD INTAKE

G. Finlayson

Institute of Psychological Sciences, University of Leeds, UK

Sweetness is a potent psychobiological phenomenon. The importance comes about because the sweet taste, in nature, is normally associated with the presence of energy and therefore humans (and other animals) are likely to be strongly attracted to sweetness in foods and drinks. The sweet taste is also associated with a potent pleasure sensation. Sweetness can make foods palatable that otherwise would not be pleasant to eat; it can also raise the palatability of foods that are already pleasant. In this way sweetness offers an important strategy to increase the attractiveness of foods and to encourage consumption. The hedonic properties of sweetness means that it embodies strong reward potential with the capacity to reinforce its own consumption and behaviour associated with consumption. For this reason it can be expected that sweetness will exert positive and distinctive effects on eating behaviour, food selection and other aspects of appetite control. This talk will review some of the current thinking on the psychobiology of sweetness and taste in relation to appetite: For example, the role of sweetness in the control of food intake (satiating and satiety) and food reward (liking and wanting); interactions between sweet taste and individuals at risk of overeating; habitual high sugar consumers (sweet preferring phenotypes); and experimental approaches to examine the effects of sugar/sweet on hedonic impact and food intake. It is arguable that sweetness may have qualitatively distinct attributes of pleasure – because of the unique role of sweetness in nature. Sweetness is likely to have a 'facilitative' or 'permissive' effect on eating behaviour; however sweetness can be conferred through different types of molecules which may have distinguishable properties.

Key words: Sweetness, liking/wanting, appetite, sugar, health.

EFFECTS OF SUGARS ON METABOLIC HEALTH

L. Tappy

University of Lausanne, Lausanne, Switzerland

The prevalence of obesity and diabetes has increased in the last century. In the search for potential reasons, the hypothesis has been advanced that sugars, or more specifically its fructose component, may play a role in the development of metabolic diseases. Some specific features of fructose metabolism may potentially account for adverse metabolic effects. Unlike glucose, fructose is extensively metabolized by the gut and the liver, where it is converted into glucose, glycogen, and lactate. It can also be converted into fatty acids, although this is a minor pathway, which are then either stored as intrahepatic fat or released as VLDL-triglycerides. This may secondarily favour ectopic lipid deposition in skeletal muscle and cause insulin resistance through "lipotoxic" mechanisms. Ingestion of large amount of fructose also increases the uric acid production, which could increase the risk of gout, and also contribute to metabolic dysregulation. In animals, adding fructose, either as sucrose or as pure fructose, to rat's diet makes them become obese and diabetic, and increases their liver and muscle fat content. Similar observations are made when rats are fed a high-fat diet, however, the relative role of fructose vs excess energy intake is still debated. In humans, fructose increases plasma triglyceride concentrations and impairs hepatic insulin sensitivity, but these effects are observed with large daily fructose intake, exceeding that of the average population. Hypercaloric fructose intake also increases plasma uric acid concentrations and intrahepatic fat content, and there is concern that it may lead to the development of muscle insulin resistance and diabetes in the long term. The effects of isocaloric fructose intake on these parameters remains to be assessed. Another concern is that fructose may favour the development of obesity by increasing food intake. The physiological mechanisms relating fructose intake to inadequate satiety responses are still controversial and further studies are required to assess whether fructose specifically impairs food intake control, or is just consumed in excess as a constituent of energy-dense palatable foods.

Key words: Energy-dense palatable foods, food intake, fructose, lipotoxicity, metabolic disease, satiety.

SUGARS TO DEAL WITH FATIGUE DURING EXHAUSTING ENDURANCE PERFORMANCE

F. Brouns

Maastricht University, Maastricht, The Netherlands

Carbohydrate (CHO) is the most important energy source for high intensity endurance performance during which high oxidative energy production rates are determinants of perfor-

mance capacity. Energy release from glucose is has been shown to be 3 times as fast as from fatty acids. Glucose, stored as muscle glycogen, may, depending on exercise intensity, be depleted within 45-60 min. after which impaired glucose availability will reduce muscle power generation capacity and induce protein catabolism. CHO ingestion during exercise allows sparing of glycogen stores, reduces protein utilization and delays fatigue. Appropriate CHO ingestion during intense endurance performance and between 2 training sessions/day is important to avoid progressive fatigue development and recover well. CHO sources to be used during high intensity exercise should preferentially be rapid digestible and absorbable and should be combined with sufficient fluid intake. Glucose supplying CHO sources such as starch, hydrolyzed starches/maltodextrins/glucose polymers, glucose as simple sugar and also sucrose, are absorbed rapidly and transported to muscle for a subsequently uptake and rapid oxidation. Fructose as simple sugar is absorbed relatively slowly, converted partially to lactate and is preferentially taken up by liver leaving only in minor amounts to reach the blood. The subsequent oxidation rate is accordingly low. Supply of CHO's that are an efficient fuel for muscle, to optimize performance, is not only recommended for long distance runners and cyclists but has also been shown to improve performance in down hill skiing, ice hockey, tennis, football and other repeated sprint like sports. The use of energy drinks by children participating in leisure sports activities is not required for supporting performance and may contribute to unfavourably inducing a positive energy balance.

Key words: Glucose, fructose, sucrose, starch, sports performance, fatigue.

PS3-32 Low-calorie sweeteners: Are they safe and can they help with weight management?

DIETARY HABITS AND USE OF LOW-CALORIE SWEETENERS: AN EFFECTIVE TOOL IN THE PREVENTION OF OBESITY AND DIABETES

A. Drewnowski^{1,2}

¹Center for Public Health Nutrition, University of Washington, Seattle, USA

²Université Pierre et Marie Curie Paris VI, Paris, France

Providing sweetness without the calories, low-calorie sweeteners (LCS) help to reduce dietary energy density while maintaining diet palatability. Recent analyses based on 5 cycles of the National Health and Nutrition Examination Survey (NHANES 1999-2008) explored both demographic and time trends in LCS consumption in the US. These data were for a nationally representative survey sample of 22,231 non-pregnant adults who completed a 24-hour dietary recall. Additional analyses

focused on health behaviors of LCS users, with an emphasis on smoking, alcohol use, physical activity and weight management. Further analyses examined the cross-sectional association between LCS consumption and body mass index category, diabetes and systemic inflammations. On any given day, 30% of Americans consumed LCS contained in beverages, foods and tabletop sweeteners. Among those consumers, about 50% consumed LCS beverages, 30% consumed LCS foods, and 20% consumed tabletop LCS. The temporal increase in LCS consumption from 1999 to 2008 paralleled a drop in the consumption of added sugars in the US, both in beverages and in solid foods. LCS consumers were older, better educated and had higher incomes than did consumers of sugar sweetened beverages (SSB). Although LCS use was associated with higher obesity rates in the cross sectional NHANES database, most LCS users indicated that they were trying to actively manage body weight. This is important evidence for reverse causality, that countering suggestions that it was LCS use that led to overweight. In general, LCS users had better health behaviors, smoked less and exercise more and had better quality diets than did SSB consumers. It would appear that LCS use may be an index of positive health behaviors that are associated with the prevention of obesity and diabetes.

Key words: Energy density, diet palatability, low-calorie sweeteners, physical activity, weight management.

LOW-CALORIE SWEETENERS: SHOULD THE PUBLIC BE CONCERNED?

A. Renwick

University of Southampton, Southampton, UK

All low-calorie sweeteners are subject to comprehensive safety evaluation by regulatory authorities, prior to approval. Definitive independent information on the safety of sweeteners is freely available on the websites of regulatory authorities 1, 2, 3.

The safety testing of food additives requires studies in animals to determine what effects the compound is capable of producing when administered at high daily doses, or high dietary concentrations (hazard identification). The studies cover all life phases, including in utero and lactation. Very high dose levels are used to increase the ability of the study to detect any possible adverse effects. The highest level of intake that does not produce any adverse effect, the no-observed adverse effect level (NOAEL), is used to establish a human intake with negligible risk, which is called the acceptable daily intake (ADI). The ADI is usually calculated as the NOAEL (in mg/kg body weight per day) divided by a 100-fold safety/uncertainty factor, which is to allow for possible species differences and human variability. Metabolism data are usually available from studies in humans to support extrapolation of toxicity data from the test species to humans.

The concentrations of each sweetener that are permitted in different foods and beverages are established by regulators so that even high intakes from all sources do not exceed the corresponding ADI value. Extensive intake surveys show that actual intakes are well below the ADI values.

Although low-calorie sweeteners are often used as blends, interactions would not occur because the only shared biological property is their activity at the sweet-taste receptor.

Low-calorie sweeteners are among the most extensively studied of all food additives. Media stories about “health concerns” usually focus on a single recent observation and ignore the totality of the database available.

PS3-40 FESNAD forum

NUTRITION AND HEALTH CLAIMS: DIFFERENT ASPECTS

R. Farré Rovira

Sociedad Española de Nutrición, Spain

Different aspects related to nutritional and health claims on foods taking into account the point of view of scientists, manufacturers and consumers are discussed.

In the case of scientist one of the most challenging tasks is the substantiation of health claims, due to the difficulty in detecting physiological benefits in healthy individuals. The need of new health markers stands out. Another point to taken into account is the frontier between functional foods and drugs.

On the other hand manufacturers interested in developing functional foods are frustrated by the difficulties encountered to have the health claims approved by EFSA. The efforts made in research do not always find recognition and approval, fact that can lead to a slowing down in research and innovation. What happens in the consumer area? Are claims understood by the consumers? What would the wording be in order to obtain clear and understandable health claims? Finally, the role that nutritional and health claims can play on the diet of populations needs to be evaluated by public health experts.

Key words: Food, nutrition, health claims.

HOW IMPORTANT ARE HEALTH CLAIMS IN INFANT NUTRITION?

J.M. Moreno Villares

Hospital Universitario 12 de Octubre, Madrid, Spain

In order to get a health claim on a food EFSA has required evidence that a particular ingredient has a particular benefit for a particular population. The vast majority of claims for lipids, prebiotics, probiotics and nucleotides claiming to provide some advantages on infant's or mother's health have been rejected on the basis of very few –if any– high quality clinical studies. Some other components have received approval: addition of DHA and arachidonic acid on infant formula helps visual acuity, as the first in the row. Some people consider that health claims in infant feeding undermines confidence in breastfeeding quality and should not be allowed.

Very few others health claims have been approved: thiamine (B1) and normal neurological development and function in infants and children up to three years of age. North American FDA pointed in 2010 that for healthy infants who are not exclusively breastfed and who have a family history of allergy, feeding a 100% whey protein partially hydrolyzed infant formula from birth up to 4 months of age instead of a formula containing intact cow's milk proteins may reduce the risk of developing atopic dermatitis throughout the first year of life.

There are no data on how much of this information is known by parents and how it influences which kind of infant formula they choose, as publicity for general population on infant formula is not allowed. Professionals received this information from companies. There is a clear interest in knowing how food labels play a role in getting information both for consumers and professionals. Some European projects are dealing to study this relationship and to provide guidelines on how food labels should be. CLYMBOL ('Role of health-related claims and symbols in consumer behaviour') project is investigating consumer understanding and behaviour with respect to health information.

Key words: Children, paediatrics, health claims

CLAIMS RELATED TO FUNCTIONAL FOODS IN THE CARDIOVASCULAR AREA

J. Salas Salvadó

Human Nutrition Unit, Department of Biochemistry & Biotechnology, Faculty of Medicine and Health Sciences, Universitat Rovira I Virgili, Reus, Spain

In developed countries cardiovascular disease is the leading cause of death. In recent years a high number of studies have been done to evaluate the importance of dietary pattern, certain foods and specific nutrients provided by different foods on cardiovascular risk factors. Considering that the new Euro-

pean legislation regulates the possibility of nutritional claims in foods, the food industry has seen in functional foods for cardiovascular disease a business opportunity. During the last years a number of dossiers have been submitted by industry to the European Food Safety Agency for evaluation and a large proportion of them have been rejected for different reasons among which are: the lack of characterization of the food, the lack in the appropriate definition of the claim argument, and the lack of data demonstrating a cause-effect relationship between the consumption of a food or a constituent and the claimed effect. The guidelines published by the EFSA Scientific Committee on the requirements or effects to substantiate have approximate the positions between industry and EFSA. Most functional foods designed to control cardiovascular risk have focused on the improvement of the plasma lipid profile, oxidative stress or endothelial function, as well as decrease satiety, postprandial blood glucose levels or body weight. As improvement on classical or emerging factors of cardiovascular risk is not always associated with a reduction of cardiovascular events or mortality from these causes, it is expected that in a more or less near future requirements on functional foods increased. It is also expected that in the future personalized nutrition limits the marketing of functional foods. Studies in different populations and settings suggest that consumers need more information on the use, benefit and risk of use of functional foods.

Key words: Cardiovascular disease, functional foods, health claims.

COMMUNICATION ON FOOD AND NUTRITION IN HOSPITAL

O. Ruiz Guerrero

Hospital Virgen de La Victoria, Servicio Andaluz de Salud, Malaga, Spain

Corporate social responsibility of the hospital in relation to training and information to patients on nutritional habits makes up an increasingly important role within the public health institution. The commitment of health professionals on this area should be organized as an integrated task specialized in healthcare ensuring further continuity within primary health care. The management of knowledge concerning healthy eating and nutrition habits and their transmission to the patient-user, and their families, should be taken as a new responsibility of health centers, which car intervention should not be limited to the patient's admission period, but should continue through dissemination activities and information to the patient, once recovered from the health crisis. In addition, hospitals must become true and valued authoritative sources of nutrition information in relation to the media, in order to transmit the messages on food and nutrition to as many citizens as possible.

Key words: Nutrition, food communication ,healthy habits, hospital.

HEALTH CLAIMS. MORE SEVERE THAN THE EUROPEAN FOOD SAFETY AUTHORITY (EFSA): TO BE OR NOT TO BE?

E. Baladia, J. Basulto, M. Manera

Spanish Foundation of Dietitians & Nutritionists,
Spain

Food advertising has a great ability to influence the behavior of the population. Promises made through advertising should be consistent with reality. Tangible fraud can be easily recognized. However, non-tangible fraud (such as nutrition and health claims) is difficult to be detected by the “reasonably well-informed, and reasonably observant and circumspect consumer”. Regulation 1924/2006 (1) establishes the legal framework for such statements. While nutritional claims are well established in the regulation annex, health claims need to be specifically evaluated by an EFSA scientific panel before they can be used. Can Regulation 1924/2006 and EFSA assessments prevent all nutritional and health claim frauds? Are there loopholes that could potentially allow misleading claims? Can EFSA deny a health claim that may be scientifically well founded? Can a denied health claim be accepted in the future? Can EFSA panels have conflicts of interest? (2) The study of Regulation 353/2008 (3), the EFSA scientific opinions issued up to date, and the evidence-based medicine (4) are the key points to answer these questions. Healthcare professionals should ensure that the information delivered to consumers, whether legal or not, is scientifically proven and promotes public health. References: 1. Regulation 1924/2006 (CE) of the European Parliament and of the Council of 20 December 2006 on nutrition and health claims made on foods. OJEU; L404:9-25. 2. European Court of Auditors. Management of conflict of interest in selected EU Agencies. Report nº15. ECA; 2012 3. Key words: Legislation, nutritional claims, health claims, evidence-based medicine, fraud.

HEALTH CLAIMS IN MEAT BASED FUNCTIONAL FOODS

F. Jimenez Colmenero

Institute of Food Science, Technology and Nutrition (ICTAN), Spanish National Research Council (CSIC), Madrid, Spain

In recent years, there has been a considerable accumulation of studies concerning strategies to optimize the presence of specific components (exogenous and endogenous) with health implications for designing of potential meat-based functional foods. Because of the amount and frequency of consumption, contribution to dietary intakes of different nutrients, diversity of presentations, possibility of modifying their composition using non-meat ingredients, high consumer acceptability, etc., meat and meat products are excellent foods for delivering bioactive compounds without changing dietary habits. However despite the numerous efforts carried out to improve their composition (using strategies basically concerning with animal production practices, meat processing and storage, distribution and consumption conditions), there are very few studies involving these foods to verify whether those modifications are of relevance to human health. The objectives of this paper are to analyze the possibility to application of health claims based on generally accepted scientific proof to meat and meat products designed as functional foods, as well as to present an overview of the human intervention studies to check the functional capacity of meat-based potentially functional foods.

Key words: Health claims, meat based product.

FUNCTIONAL FOODS IN SCHOOL FEEDING PROGRAMMES

M. Espinosa

Centro de Nutrición Molecular y Enfermedades Crónicas, Santiago de Chile, Chile

School Feeding Programs (SFP) reach about 90,000,000 children in Latin America and the Caribbean. In principle established with the purpose to contribute to learning, better performance and adherence to school to prevent dropout, and targeted to most vulnerable children populations. One additional goal is to improve health, facing problems of malnutrition and its consequences in the generation of learning disabilities, cognitive ability damage, stunted growth and overall development capacity decrease. SFPs are a factor of risk protection and prevention in relation to: limitation of learning and school performance: school dropout; decrease of family budget; food and nutritional insecurity due to financial, political and environmental instability; nutritional deficiencies and chronic non-communicable diseases The state investment in PAE is impor-

tant, but distributed as an average in the region of 0.4\$ /child/day, resulting in most countries in school breakfast or snack based milk/ milk drink and bread/ cookie, which begin to be fortified mainly in iron and the presence of locally produced cereals. One aspect that SFPs have been facing is malnutrition that characterizes the population in the region and particularly children. The existence of malnutrition in several countries, the coexistence of malnutrition and obesity, in others, and in some, overweight and obesity as a fundamental characteristic makes SFPs include in their programs a view of nutrients in deficit or excess in delivered food. In this context, even modest SFP, in which locally produced food associated with culture and eating habits emerges as healthy food source, the room for functional foods is still very minor, despite their potential importance to face malnutrition. There are some recent assessments in Chile to change the nutritional structure of SFP, to confront the great problem of overweight and obesity among others by increasing the presence of antioxidants and fiber. Some results in this area are discussed.

Key words: Health, Latin America, malnutrition, school feeding programs.

PS4-48 Bellagio report on healthy agriculture, healthy nutrition, healthy people

BELLAGIO REPORT ON HEALTHY AGRICULTURE, HEALTHY NUTRITION, HEALTHY PEOPLE

A. Marcos¹ on behalf of A. P. Simopoulos², P. G. Bourne³
O. Faergeman⁴

¹ICTAN-CSIC. Spain

²The Center for Genetics, Nutrition and Health, Washington, USA

³Green Templeton College, University of Oxford, Oxford, UK

⁴Department of Internal Medicine and Cardiology, Aarhus Sygehus University Hospital, Aarhus, Denmark

The Bellagio Report on Healthy Agriculture, Healthy Nutrition, Healthy People is the result of the meeting held at the Rockefeller Foundation Bellagio Center in Lake Como, Italy, 29 October–2 November 2012. The meeting was science-based but policy-oriented. The role and amount of healthy and unhealthy fats, with attention to the relative content of omega-3 and omega-6 fatty acids, sugar, and particularly fructose in foods that may underlie the epidemics of non-communicable diseases (NCD's) worldwide were extensively discussed. The report concludes that sugar consumption, especially in the form of high energy fructose in soft drinks, poses a major and insidious health threat, especially in children, and most diets, although with regional differences, are deficient in omega-3 fatty acids and too high in omega-6 fatty acids. Gene-nutrient

interactions in growth and development and in disease prevention are fundamental to health, therefore regional Centers on Genetics, Nutrition and Fitness for Health should be established worldwide. Heads of state and government must elevate, as a matter of urgency, Nutrition as a national priority, that access to a healthy diet should be considered a human right and that the lead responsibility for Nutrition should be placed in Ministries of Health rather than agriculture so that the health requirements drive agricultural priorities, not vice versa. Nutritional security should be given the same priority as food security.

Key words: Agriculture, fats, foods, fructose, nutrition, omega-3 fatty acids, omega-6 fatty acids, sugars.

MARINE N-3 PUFA INTAKE AND RISK OF BREAST CANCER

J.S. Zheng, D. Li

Department of Food Science & Nutrition, Zhejiang University, China

The aim of the systematic review was to investigate the association between intake of fish and n-3 polyunsaturated fatty acids (n-3 PUFA) and the risk of breast cancer and to evaluate the potential dose-response relation. Twenty six publications, including 20 905 cases of breast cancer and 883 585 participants from 21 independent prospective cohort studies were eligible. Eleven articles (13 323 breast cancer events and 687 770 participants) investigated fish intake, 17 articles investigated marine n-3 PUFA (16 178 breast cancer events and 527 392 participants), and 12 articles investigated alpha linolenic acid (14 284 breast cancer events and 405 592 participants). Marine n-3 PUFA was associated with 14% reduction of risk of breast cancer (relative risk for highest v lowest category 0.86 (95% confidence interval 0.78 to 0.94), I²=54), and the relative risk remained similar whether marine n-3 PUFA was measured as dietary intake (0.85, 0.76 to 0.96, I²=67%) or as tissue biomarkers (0.86, 0.71 to 1.03, I²=8%). Subgroup analyses also indicated that the inverse association between marine n-3 PUFA and risk was more evident in studies that did not adjust for body mass index (BMI) (0.74, 0.64 to 0.86, I²=0) than in studies that did adjust for BMI (0.90, 0.80 to 1.01, I²=63.2%). Dose-response analysis indicated that risk of breast cancer was reduced by 5% per 0.1g/day (0.95, 0.90 to 1.00, I²=52%) or 0.1% energy/day (0.95, 0.90 to 1.00, I²=79%) increment of dietary marine n-3 PUFA intake. No significant association was observed for fish intake or exposure to alpha linolenic acid. We concluded that Higher consumption of dietary marine n-3 PUFA is associated with a lower risk of breast cancer. These findings could have public health implications with regard to prevention of breast cancer through dietary and lifestyle interventions.

Key words: Breast cancer, marine n-3 polyunsaturated fatty acid, fish, cohort study.

CONSUMPTION PATTERNS AND TRENDS FOR SUGAR-ADDED BEVERAGES IN MALAYSIA: IMPLICATIONS FOR HUMAN HEALTH

L.Huat Foo

Programme of Nutrition, School of Health Sciences, Universiti Sains Malaysia, Health Campus Kelantan, Malaysia

The prevalence of obesity has increased dramatically over the past three decades in different population groups in Malaysia. Obesity is now regarded as a major public health challenge because of its significant adverse association with development of several non-communicable diseases (NCDs). It is widely accepted that the escalating prevalence of obesity and NCDs are linked either to excessive food energy intake from unhealthy dietary practices or to low energy expenditure because of inactive lifestyles or to a combination of both of these factors. Hence, healthy and balanced dietary and active lifestyle practices are important strategies to diminish the risk of excessive weight gain with subsequent lower risk of acquiring NCDs throughout life. One unhealthy dietary practice is the consumption of sugar-added beverages (SSB), which has been associated with a higher risk of obesity and NCDs such as type-II diabetes, cardiovascular and other metabolic disorders. The aim of this presentation is to examine the patterns and trends of SSB consumption status in adolescent and adult populations in Malaysia and to identify any association with NCD risk factors. The trends of SSB consumption have increased considerably in people of all ages in Malaysia. Based on the recent National Health and Morbidity Survey 2011 data, three common SSB consumption practices were identified among populations in Malaysia namely the consumption of i) beverages with added sugar, ii) beverages with sweetened condensed milk or creamer and iii) carbonated soda drinks. Beverages with added sugar are reported as the most common sources of SSB, with about half of adolescents (13-18y) and adults ($\geq 18y$) reported to consume such beverages every day. Beverages with sweetened condensed milk or creamer (20-27%) were the next most commonly consumed and the least was the consumption of carbonated soda drinks at $<5\%$ daily. Not much difference was found between consumption of these SSBs between sexes, or between urban and rural geographical regions. Adults had significantly higher consumption of beverages with added sugar by at least 3 cups per day compared to adolescents (18.9% vs. 6.7%). In contrast, adolescents had almost two times greater intakes of carbonated soda drinks of 2 cups or more in a day than adults (7.0% vs. 4.3%). An almost similar pattern was found between adolescents and adults in the consumption of beverages with sweetened condensed milk or creamer for 2 cups or more a day (23.5% vs. 29.1%). In general, SSB consumption is very common in Malaysian populations, particularly among adults. In addition, multivariate regression analysis to examine the relationship between consumption of beverages with added sugar

of at least 3 cup per day and the NCD risk factors in adults, in which every state of Malaysia was used as a unit of analyses, showed that consumption of 3 cups per day or more of beverages with added sugar was significantly associated with a higher risk of becoming overweight ($p=0.008$), or developing diabetes ($p=0.044$) or hypercholesterolemia ($p=0.011$), after adjustment for fruits and vegetables intake and physical activity. This finding suggests that high daily consumption of SSBs exerts adverse health effects in adults. Several initiatives have been formulated by the Malaysia National Strategic Plan for NCD (NSP-NCD) in various settings such as community, workplaces, and schools to prevent unhealthy dietary and lifestyle practices; including the reduction of the high consumption of sugary foods and beverages among different populations in Malaysia.

Key words: Sugar-added beverages, obesity, non-communicable diseases, adolescents, adults.

SUGAR-SWEETENED BEVERAGES CONSUMPTION AND OBESITY

X.W. Shang¹, J. Ma², G.F. Xu³, Y. Li⁴, H.W. Guo⁵, L. Du⁶, T.Y. Li⁷, G.S. Ma¹

³Shandong University, Jinan, Shandong, China

⁴Public Health College, Harbin Medical University, Harbin, Heilongjiang, China

⁵Fudan University, Shanghai, China

⁶Guangzhou Center for Diseases Prevention and Control, Guangzhou, Guangdong, China

⁷Chongqing Children's Hospital, Chongqing, China

To explore the associations between sugar-sweetened beverage (SSB) consumption and obesity as well as obesity-related cardiometabolic disorders among children in China. A total of 6974 (boys 3558, girls 3412) children aged 6-13 years participated in the study. Each participant's height, weight, waist circumference, fasting glucose, triglycerides, total cholesterol, high-density lipoprotein cholesterol, and low-density lipoprotein cholesterol were measured. The type of beverage consumption was determined using a self-administered questionnaire. SSBs were consumed regularly by 46.1% of the children. The prevalence [adjusted odds ratio (95% confidence interval (CI))] of obesity was 7.6% [as the reference group (ref.)], 10.1% [1.36(1.07, 1.74)], and 11.6% [1.46(1.21, 1.75)], among children who regularly drank milk, other beverages and SSBs, respectively. Regularly drinking SSBs elevated the likelihood

of abdominal obesity [adjusted odds ratio (95% CI): 1.36(1.17, 1.59)]. The prevalence [adjusted odds ratio (95% CI)] of obesity among children who regularly drank sports/caloric beverages, carbonated beverages, sweet tea, and plant protein beverages was 16.8% [2.00(1.31, 3.07)], 12.7% [1.52(1.23, 1.88)], 11.5% [1.52(1.18, 1.95)], and 10.4% [1.41(1.03, 1.94)], respectively, which was higher than that of regular milk drinkers [7.6% (ref.)]. The prevalence [adjusted odds ratio (95% CI)] of abdominal obesity among children who regularly drank sweet tea, fruit/vegetable juices, and carbonated beverages was 17.7% [1.55(1.26, 1.90)], 16.2% [1.36(1.09, 1.70)], and 15.3% [1.24(1.03, 1.50)], respectively, which was much higher than that of regular milk drinkers [12.8% (ref.)]. Regular SSB consumption was positively related to obesity and abdominal obesity. This relationship should be investigated further using a longitudinal study design.

Key words: Sugar-sweetened Beverages, Obesity, Children.

PS4-56 Food and nutrition reporting in the media

DO MEDIA HEADLINES EQUAL CREDIBILITY AND TRUST? A LOOK AT US CONSUMER INSIGHTS ON TRUSTED SOURCES FOR FOOD & HEALTH INFORMATION

M. Smith Edge

Nutrition & Food Safety, International Food Information Council, Washington DC, USA

Research studies focusing on food, health, and nutrition often result in wide-spread media coverage. Alarming headlines span across traditional and social media platforms. This often generates global attention, but do consumers find the sources for this information credible? Do consumers view media as a trusted source for information? International Food Information Council Foundation (Foundation) research published in the peer-reviewed journal *Nutrition Today* found, “media outlets are the primary sources of consumer information on nutrition, food safety, and health; accuracy and helpfulness may be lacking because of consistent lack of context in news coverage.” When the Foundation asked consumers what impact a variety of factors would have on their willingness to believe new information about food and health, Americans indicate doing their own research would have a major impact (59%), as well as hearing the same information from many different sources (41%) and hearing the information from someone who has an advanced degree in health or nutrition (40%). Moreover, in the area of food safety, the Survey results show consumers trust primary care physicians and other health professionals to deliver accurate information (89%)—while media sources such as television news stories not so much—only 66%. These insights come from the Foundation’s 2012 and 2013 Food & Health

Survey, a US-based survey that has captured consumer attitudes toward food safety, nutrition & health since 2006. Most recently the Journal of American Academy of Nutrition and Dietetics published a 5-year retrospective of the Foundation’s Food & Health Survey titled, *Is it Time to Rethink Nutrition Communications?* In short, the answer is yes. IFIC Foundation research reveals that frequency of available information does not equate to the same level of credibility and trust for the consumer—demanding a new way to think about nutrition communications. Health professionals and scientists will need to embrace new communications concepts to promote consumer understanding, belief and ultimately behavior change. Their extended use of new communications concepts will help facilitate better communication of scientific context, information and ultimately credibility that may enable consumers to make better well-informed decisions about their diet and health.

Key words: Behaviour, consumers, nutrition communication.

COMPARISON OF REPORTING OF FOOD BENEFITS AND RISKS IN EUROPEAN NEWSPAPERS

M. Friel

European Food Information Council (EUFIC), Brussels, Belgium

The media is an important source of information for the public. It can interpret messages in certain ways and can be selective regarding the information it transmits to its audience. Therefore, as the main information disseminator in our society, the media can act as an agenda builder and can shape or change public’s perceptions, attitudes, beliefs, and behaviour. Food plays a central role in all our lives and is therefore commonly reported in newspapers and other communication channels. However, research published in 2011 on health claims reported in UK national newspapers, found that misreporting is widespread (Cooper et al., 2011). This may contribute to public misconceptions about food and health.

The objective of this research was to investigate reporting about the positive benefits and negative risks associated with food in national newspapers from eight European countries. Newspapers were selected based on circulation and readership figures (gender and socio-economic class) and were sampled over a four week period, i.e. 2 weeks in September 2011 and 2 weeks in March 2012. This research looked at i) the balance of reporting on positive benefits (e.g. nutrition claim) versus negative risks (e.g. risk/safety statement), ii) the content of the statements/claims (e.g. food type, health issue), iii) the source of the information (e.g. scientist, health authority) and iv) the accuracy of the reporting.

Key words: Consumer information, health claims, media, newspapers, nutrition.

THE CHALLENGES OF REPORTING ABOUT NUTRITION; A JOURNALIST'S PERSPECTIVE

E. de Benito Cañizares

El País, Spain

Communication on nutrition has some aspects that are specific. First of all, nutrition is a topic well known by everyone (or that's what they think): everyone eats every day, hopefully several times a day. It means that, like in football, everyone has his or her own opinions. and exposure to nutrition topics in the media can influence their opinions. In Spain we had, years ago, a very strong campaign to promote seed oils instead of olive oil, for instance, or about the risks of eating fish contaminated with heavy metals. Olive oil and fish are two core elements of the Mediterranean diet, so conflicting or alternative messages about these foods, can create confusion in some consumers. The second issue is that information on the health benefits of foods or specific ingredients, in the form of health claims on food products and adverts, is mostly provided by food companies. Some of the studies used to support those claims are naturally sponsored by industry, as the submission of scientific dossiers is needed for EFSA to evaluate the science basis for the claims. Regardless of the scientific validity of those studies, the journalists perception would be of suspicion and funding bias. The third one is that the major newspapers are not very interested in topics about positive nutrition benefits. It is not news. The fourth is not specific to nutrition: there is a problem of communication (and trust) between scientists and journalists. Sometimes they speak, literally, a different language.

Key words: Nutrition communication, mediterranean diet.

PS5-64 Feeding workers

NUTRITION AT WORK: THE INTERNATIONAL LABOUR ORGANIZATION'S APPROACH.

C. Bueno

International Labour Organization, Geneva, Switzerland

Good nutrition constitutes a basic human right and, nevertheless, it has often been ignored in the context of labour rights. The ILO has showed a concern on this matter from its foundation. The ILO Recommendation No. 102 (1956) on social services for workers recognizes the importance of nutrition in the workplace and recommends the provision of facilities such as canteens, cafes, The Recommendation No. 102 (1956) on social services for workers: recognizes the importance of nutrition in the workplace and recommends the provision of facilities such as kitchens, canteens, cafes, kitchens or kitchenettes. The ILO publication "Food at Work. Workplace solutions for malnutri-

tion, obesity and chronic diseases" was conceived in 2005 as a response to the lack of attention given to food at work. The study concluded that an inadequate nourishment of workers can cause losses of up to 20% in productivity, as well as the connection between the lack of a good nutrition and the onset of fatigue and sleepiness, with consequent implications in occupational safety and health. In line with this concern, the ILO's educational programme SOLVE, in an effort to integrate the promotion of health in the policies of safety and health at the workplace, as well as in the actions at company level, includes contents for the promotion of healthy eating habits in the workplace. Using the analytical framework established by "Food at Work" and the obvious need to deepen in the relationship between nutrition and the world of work in Chile, promoted by Sodexo and Edenred, the ILO conceived the project "A comprehensive approach to improving nutrition at the workplace: A survey of Chilean companies and tailored recommendations", turning Chile into the pilot country for this type of research at worldwide level.

Key words: Chronic diseases, labour, malnutrition, obesity.

A COMPREHENSIVE APPROACH TO IMPROVING NUTRITION AT WORKPLACE IN CHILE

E. Atalah

Faculty of Medicine, University of Chile, Santiago, Chile

Background and objectives: An important factor in the health of workers is food and eating healthy at work helps prevent chronic diseases linked to diet. To analyze labor feeding practices in Chile, knowledge, attitude and behavior of workers and employers in this regard.

Methods: Literature review, structured surveys in 995 workers from different regions of the country, interviews and focus groups with representatives from government, employers, workers and academics.

Results: The legislative framework refers only to the hygienic conditions and the time allotted for lunch. There are major shortcomings in the supply system Chilean in the feeding system of Chilean workers: 39% did not receive any benefit, 22% do not have a place to eat, improper cleaning, insufficient time, inadequate food quality. The lack of lunch generates physical and psychological discomfort that affects productivity. There is a significant prevalence of diet-related diseases, which increase with age. Most workers want a healthy diet during the workday

Conclusions: It is a priority to implement a variety of measures to improve workers' access to food, which are cost-effective and improve job satisfaction. These programs should be part of the labor policies be sustained over time and evaluated in its implementation and results. Investments in power companies recover reducing sick days, fewer accidents and increased pro-

ductivity, which determines to be cost-effective. It is necessary to establish tripartite tables that include the State, workers and employers, to strengthen social dialogue in relation to labor, employment and food security.

Key words: Feeding practices, workers, work place, Chile.

'PROGRESS AND CHALLENGES OF THE NUTRITIONAL SITUATION IN PREGNANCY IN URUGUAY: DEVELOPING AN EASY SURVEILLANCE TOOL'

C. Severi¹, X. Moratorio², G. Berruti²

¹Facultad de Medicina, Universidad de la República, Montevideo, Uruguay

²Ministerio de Salud Pública, Montevideo, Uruguay

Background and objectives: Existing data emphasizes the importance of having nutritional information systems. The objective was to develop a nutritional surveillance module based on the Perinatal Informatics Information data (SIP from CLAP/OPS/OMS).

Methods: all available Anthropometric References in pregnancy were reviewed and applied to 2010 SIP data base. That from the Ministry of Health from Chile was selected. Indicators were built: anthropometrics, weight increase and perinatal outcomes. A computer system was develop which interact with the SIP.

Results: An informatics module was developed and actually giving anthropometric information. An interface between data SIP and ANTHRO (World Health Organization) was made. This interface allowed to evaluate women from de database and showed data in friendly tables and charts that can show nutritional situation, by age, by subsector, by region, or national. Also this module can associate anthropometric women status with maternal and perinatal results. This Program showed that 14.3% (CI: 13.6-14.9) of women present low weight at beginning, 24.1% (IC:23.3-24.9) overweight and 10.0% (IC:9.4-10.6) obesity. At the end of pregnancy, 13.7% (IC:13.0-14,3) of women were with low weight, 28,8% (IC:27,9-29,7) with overweight and 17,3% (IC:16,6-18.0) with obesity. The average weight gain for women is within the recommended range among women which began normal was 13 kg (IC:13.005-13.260), with no statistically difference with those which began with low weight: 12.930 kg (CI:12.,693-13.166) (p=NS), but showed difference with those overweighed and obese 12.318 kg (IC:12.097-12.539) (p<0,05) y 9.1022 kg (IC:8.700-9.504) (p<0.05). Overweight and obesity, as well as excess weight gain is associated to birth weight > 4000g, Caesarean section, assisted delivery and pregnancy pathologies: hypertension, diabetes, and pre-eclampsia.

Conclusions: The informatics module allowed to do nutritional surveillance in an easy way. Malnutrition is a problem

in pregnancy associated with worse maternal and perinatal results.

Key words: SIP, surveillance, malnutrition

PS5-72 The shift toward a modern industrialized food system, potential implications for nutrition-related chronic diseases and for public policies EVOLUTION FROM TRADITIONAL FOOD SYSTEMS TO THE GLOBALIZING FOOD SYSTEM: A POSSIBLE MISMATCH BETWEEN HUMAN DIET AND HEALTH?

J.C. Moubarac

Center for epidemiological studies in health and nutrition, University of São Paulo, São Paulo, Brazil

The relationship between foods, dietary patterns and health is very complex and requires an interdisciplinary and comprehensive analysis of food systems. Food systems have changed from the Palaeolithic era to the current globalizing world. Building on an evolutionary perspective, we compare features of traditional food systems to the globalizing food system, and discuss the implications for human health. Traditional food systems are the products of an adaptation process between culture and nature. They share basic features including the reliance on a diverse range of local resources, the use of minimal food processing, modes of food learning based on family and peers, the importance of food symbolism and conviviality. The globalizing food system is a new and fast-changing model built on economic and political ideologies of the 20th century. Its features include the production and distribution of foods at the global scale, the reliance on a few crops, the ultra-processing of foods, trends from family and public modes of food learning to industry and private ones, and the focus on individualism. Building on an evolutionary perspective and the mismatch theory, our hypothesis is that several features of the globalizing food system have transformed traditional food systems in ways that are beyond the human capacity to adapt to food. Humans are capable to adapt to a wide variety of food and diets. However, most if not all ultra-processed products have an intrinsic unbalanced nutritional composition and share characteristics that interfere negatively with the mechanisms that regulate appetite. Food learning channels, food symbolism, modes of eating and food production have also changed in ways that undermine the selection mechanisms that operate in the development of healthy diets. If the mismatch hypothesis is confirmed, then healthy diets need to be based on a model which takes into account several features of traditional food systems.

Key Words: food system, ultra-processed products, traditional food systems, mismatch theory, evolution

THE NEW ROLE OF INDUSTRIAL FOOD PROCESSING IN FOOD SYSTEMS: IMPACT ON NUTRITION AND HEALTH – A PERSPECTIVE FROM THE SOUTH

C. Monteiro

University of São Paulo, São Paulo, Brazil

Across several low- and middle-income countries (LMIC), traditional food systems are being challenged by the globalizing food market. Our hypothesis is that industrial food processing is now the main shaping force of the global food system, and the main determinant of changes in diets and related states of health and well-being in LMIC. To investigate this hypothesis, we have developed a new classification of foodstuffs based on the extent and purpose of food processing. Every item in the diet is classified into unprocessed or minimally processed foods, processed culinary ingredients and processed or ultra-processed ready-to-consume food and drink products. Our studies in several countries show that ready-to-consume products taken together are more energy-dense, have more free sugars, sodium, and saturated or trans fats, and have less fiber, iron, zinc, potassium, and vitamin C than foods made into dishes and meals with culinary ingredients (such as oils, flours, sugar and salt). As expected, the dietary share of ready-to-consume products is strongly and inversely related with the quality of overall diet. Furthermore, because these products are often sold in large portion sizes, are manufactured to be hyperpalatable, when not habit-forming or even addictive, and are extensively and aggressively advertised, they increase the risk of passive energy over-consumption. Our studies also indicate that, today, the most significant dietary change in LMIC is the replacement of freshly prepared meals based on foods and culinary ingredients by ready-to-consume ultra-processed products. To address the epidemic of obesity and related chronic diseases in LMIC, public policies need to offer incentives to, protect and promote long-established, traditional food systems and dietary patterns based on freshly prepared dishes and meals. Reformulation of ultra-processed products may provide some advantages as a harm reduction strategy, but it isn't an option for broader public policies.

Key words: Food systems, food processing, obesity, LMI.

THE MODERN GLOBAL FOOD SYSTEM- ITS EVOLUTION AND CURRENT STATUS AND HOW IT IS RELATED TO HEALTH

B. Popkin

University of North Carolina, Chapel Hill, USA

Our modern food supply represents a major shift in eating, drinking, location of eating, and shifts in our entire eating pattern. Before WWII food purchased and consumed corresponded to minimally processed foods and processed culinary ingredients with a small proportion of processed and ultra-processed ready-to-consume food and drink products. The first grocery chains in the West emerged before WWII with minimally processed items developed over the late 19th and early 20th century [from freshly puffed whole grain cereals to peanut butter to carbonated beverages). In the US the only chain prior to WWII was the Great Atlantic and Pacific (A & P). In contrast today, we present the depth and breadth of foods and beverages available. Annually well over 1 million unique bar coded consumer packaged foods and beverages are sold globally. In the US we have documented 600,000 with about 200,000 having unique ingredients. The nature of these foods and beverages and the vast usage of added caloric sweeteners in them are used to highlight the type of shifts we are seeing globally as are related new eating behaviors (snacking). Finally levels of penetration of these modern convenience stores and supermarkets and growth of consumer packaged foods and beverages across the LMIC are presented. For instance, China, India and Vietnam are seeing annual compound growth in sales from these retailers of 28-50% each year of this new millennium. This has led to a shift from farmers selling through a complex chain to farmers selling directly to processors and supermarkets. It has also led to an explosion in access to ultra-processed foods and beverages. We then present new data from China, Mexico and Russia on the proportion of total kcal intake from packaged foods and beverages and how this differs from other foods.

Key words: Food system, sweeteners, snacking, supermarkets.

TUMOR SUPPRESSOR GLYCINE-N METHYLTRANSFERASE REGULATES ONE CARBON TRANSMETHYLATION KINETICS

Y.C. Wang¹, W.L. Lin¹, Y.J. Lin¹, F.Y. Tang², Y.M. Chen³, E.P. Chiang¹

¹National Chung Hsing University, Taiwan, China

²China Medical University, Taiwan, China

³National Yang Ming University, Taiwan, China

Background and objectives: Glycine-N methyltransferase (GNMT) is a potential tumor suppressor that is commonly inactivated in human hepatoma. However, the regulation of GNMT in 1-Carbon transmethylation kinetics remains to be established. The objective of the present study was to systematically investigate how GNMT expression affects folate status, antifolate cytotoxicity and methyl group kinetics in vitro and in vivo.

Methods: GNMT was over-expressed in GNMT-null cell-lines. Cell-lines with and without GNMT expression were cultured under different folate and methyl supplies. Folate dependent pathways and methyl group status were investigated in wildtype, GNMT transgenic (GNMT-tg) and GNMT knockout (GNMT-ko) mice. The 1-carbon flow in homocysteine transsulfuration and remethylation, and folate dependent de novo nucleotide biosynthesis were investigated using stable isotopic tracers and GC/MS.

Results: GNMT expression increased methionine clearance by inducing homocysteine transsulfuration and remethylation metabolic fluxes in high or adequate methionine. On the other hand, restoring GNMT in GNMT-null cells did not lead to sarcosine synthesis in low methionine, indicating that normal GNMT function helped conserve methyl groups because sarcosine synthesis under such condition would waste methyl groups. GNMT expression also significantly improved folate status, induced methylfolate-dependent homocysteine remethylation flux, and reduced antifolate methotrexate cytotoxicity. In addition, GNMT helped enhance de novo nucleotide biosynthesis in folate depletion that can protect cells from DNA damage both in vitro and in vivo. These data indicated that other folate cofactor dependent reactions were also enhanced by GNMT.

Conclusion: We demonstrated that GNMT affects transmethylation kinetics, facilitates the conservation of methyl groups by limiting homocysteine remethylation fluxes. Restoring GNMT assists methylfolate-dependent reactions and ameliorates the consequences of folate depletion. GNMT expression in vivo improves folate retention and bioavailability in the liver and helps reduce DNA damage both in vitro and in vivo. The present study demonstrated additional mechanisms by which GNMT can participate in tumorprevention/suppression in humans.

Key words: DNA damage, Glycine-N methyltransferase, tumour suppressor, folate status

RELATIONSHIP BETWEEN VITAMIN A STATUS OF LACTATING SENEGALESE WOMEN AND THEIR 6 MONTHS OLD INFANTS

S. Wade¹, A. Agne-Djigo¹, N. Idohou-Dossou¹, K.M. Kwadjodé¹, S.A. Tanumihardjo²

¹Université Cheikh Anta Diop De Dakar, Senegal

²University of Wisconsin Madison, Department of Nutritional Sciences, Madison, USA

Background and objectives: Breast milk is the main source of vitamin A (VA) to meet the infants' needs and build liver stores. Because of the lack of conclusive evidence of VA deficiency (VAD) among lactating Senegalese women and their 6 months old infants, we undertook this study to assess the VA status of mother-infant pairs, VA intake from human milk, and the infant's VA liver stores.

Methods: A comprehensive study was undertaken in 34 nonpregnant lactating women and their infants. None of the infants had received a VA supplement. Mothers were grouped as supplemented with 2 doses of 200,000 IU (60,000 µg; 210 µmol) retinol as retinyl palmitate (n = 13) or nonsupplemented (n = 19) after delivery. Breast milk intake was measured by the deuterium dilution technique. Plasma and breast milk retinol concentrations were measured by HPLC. Infants' VA liver stores were assessed by the modified relative dose-response (MRDR) test.

Results: Plasma retinol detected 15% VAD among infants and the MRDR test (α=0.06) indicated 73.5% with low VA liver stores. Infants' milk VA intakes were close to estimated

requirements (375 µg/d). No correlation was found between infants' plasma retinol and MRDR value. Infants' MRDR value was lower in the group from supplemented mothers (0.055 ± 0.017 vs. 0.073 ± 0.017; P = 0.009), but no difference was observed between plasma retinol concentrations of both groups of mothers; 8.8% of mothers were VA deficient based on plasma retinol <0.7 µmol/L).

Conclusion: High prevalence of vitamin A deficiency was detected by the MRDR test in 6 months old Senegalese infants, and postpartum VA supplemented mothers significantly enhanced their infants' VA liver stores.

Key words: Milk retinol, plasma retinol, MRDR test, breast milk intake, Senegal.

²Jean Mayer USDA Human Nutrition Research Center on Aging at Tufts University, Boston, USA

³Department of Epidemiology, University of Alabama at Birmingham, Birmingham, USA

⁴Department of Genetics, Washington University School of Medicine, St. Louis, USA

Background and objectives: Little is known about the interplay between individual omega-3 fatty acid and genetic variants for type 2 diabetes (T2D) traits at the genome-wide level. The present study aimed to examine the variance contribution of genotype by environment (GxE) interaction between different types of erythrocyte membrane omega-3 fatty acids and genetic variants for T2D-related traits at the genome-wide level in a white population living in the U.S.A (n = 820).

Methods: A tool for Genome-wide Complex Trait Analysis (GCTA) was used to estimate the variance contribution of GxE interaction for T2D-related traits: homeostasis model assessment of insulin resistance (HOMA-IR), fasting insulin, fasting glucose, and adiponectin. GxE genome-wide association study (GWAS) was conducted to illustrate the results of GCTA, and for each E factor, which showed significant GxE variance contribution, another non-significant E factor was served as a control.

Results: C22:5n-3 contributed a most significant GxE variance to the total phenotypic variance of both HOMA-

IR (26.5%, P=0.034) and fasting insulin (24.3%, P=0.042). C20:4n-6/(C20:5n3+C22:6n-3) ratio contributed a most significant GxE variance to the total variance of fasting glucose (27.0%, P=0.023). GxE variance of C20:4n-6/C20:5n3 ratio showed a marginally significant contribution to the adiponectin variance (16.0%, P=0.058). For each trait, GxE GWAS identified a larger number of single-nucleotide polymorphisms (SNP) (P-interaction<10E-5) for the E factor contributed a significant GxE variance than the control E factor: 9 vs. 3 SNPs for HOMA-IR, 21 vs. 6 SNPs for fasting insulin, 36 vs. 1 SNPs for fasting glucose, and 13 vs. 7 SNPs for adiponectin.

Conclusion: Erythrocyte omega-3 fatty acids contributed a significant GxE variance to T2D-related traits at the genome-wide level. Different types of omega-3 fatty acids showed different GxE patterns.

Key words: variance contribution, GCTA, GxE interaction, type 2 diabetes, omega-3 fatty acid

²National Center of Biomedical Analysis, Beijing, China

³The 1st August Children's Hospital, Beijing Military Defense Area, Beijing, China

Background and objectives: Neonatal respiratory distress syndrome (NRDS) still has a higher mortality and morbidity among premature infants. There are many complex factors contribute the NRDS. Meanwhile, the nutritional therapy of NRDS in clinical is complicated and full of argues. The metabolites which reflect the physiologic or pathologic status can be used in the diagnosis and prognosis and can indicate the organ homeostatic condition by metabonomics. The objective was to detect the different metabolites in preterm infants with or without NRDS and to find the biomarkers of NRDS in pretermatures.

Methods: All the 40 preterm infants divided into 2 groups(NRDS and control) with no differences in the gestational age and birth weight. All the blood was collected within 2 hours after birth. Two methods were used: 1. Based on 1H-NMR metabonomics with PCA and PLS-DA. 2.GC-MS. The metabolites were identified from the total ions chromatogram within the NIST02 library and processed by software named MarkerLynx, then analyzed multivariate statistically by SIMCA-P10.0 software package.

Results: 1.H-NMR:There were much higher concentration of lactate, some lipid and alcohol and lower concentration of glucose, creatine, glutamine,OAc,NAC, alanine, valine,isoleucine and isobutyric acid in group NRDS. There were much lower concentration of HC=CH lipid,NAC, Ptd-Cho ,LDL and VLDL in group NRDS by LED method. 2. GC-MS:The concentration of lactate, uric acid and creatinine were much higher while glucose, fructose, aspartic acid, palmitic acid and stearic acid were much lower in group NRDS.

Conclusions: 1.NRDS have lactate accumulation which can lead the anaerobic threshold shift left. 2. NRDS lack the main energy substances like glucose and important amino acids . 3. There exist metabolic disturbance of macro- nutrients such glucose, amino acids and lipid in preterm infants with NRDS.

Key words: Neonatal respiratory distress syndrome, metabonomics, NMR, GC-MS

²Faculty of Human Life and Environmental Science, Showa Women's University, Tokyo, Japan

³Medical school, Kochi University, Kochi, Japan

⁴Okayama Central Hospital, Okayama, Japan

⁵Watanabe Clinic, Tokyo, Japan

⁶Medical School, Nippon University, Tokyo, Japan

Background and objectives: Diabetes becomes so prevalent in the world that UN made a political declaration of warning. Taste is important for joy of life and used to be useful tools to judge foods maybe to manage nutrition intake. Diabetes may change taste as known. We studied to make clear the expression of taste receptor hTAS2Rs of diabetics.

Methods: The diabetics without appeal of taste disorders (DM, n=31) and healthy control (HC, n=92) were tested. Sample tissues were scraped from their foliate papilla and the expression characteristics of hTAS2R isoforms (1, 3, 4, 5, 7, 8, 9, 10, 13, 14, 16, 38, 39, 40, 42, 43, 44, 45, 47, 48, 49) were defined by the RT-PCR method. Food frequency questionnaire (FFQW65) was studied as a food and nutrients intake.

Results:The average age of DM were 63.9+/-15.4 yrs. and HC were 44.6+/-20.7 yrs. The average energy intake of DM were 1972+/-263 kcal/day, average energy adequacy were 110.5+/-15.9%. The average number of hTAS2R isoforms ex-

pressed in the DM subjects was 1.5+/-1.5, those in the HC were 10.4+/-5.2. hTAS2R8 was expressed in more than 90% of the HC in 40-79 yrs., but that was expressed less than 33% of DM. hTAS2R3, 10, 16 were expressed in more than 75% of the HC in 40-79 years old, but they were expressed less than 20% of DM. The expression of hTAS2R1, 13, 47, 48 were not shown in DM, in contrast they were expressed more than 50% of HC.

Conclusions:The expression of taste receptor hTAS2Rs of DM was significantly suppressed than that of HC. This result suggested that diabetics have the poor taste and low satisfaction of eating, that may make their QOL lower than healthy people. There are misgivings for diabetics about eating behaviour and nutrient intake.

Key words:taste receptor, hTAS2Rs, diabetes.

LEPTIN RECEPTOR GENETIC VARIANTS ARE SEX-SPECIFIC ASSOCIATED WITH BMI IN OBESE CHILDREN

J. Olza¹, M. Gil-Campos², R. Leis³, R. Tojo³, R. Cañete², A.Gil¹, C.M. Aguilera¹

¹Department of Biochemistry and Molecular Biology II, University of Granada, Granada, Spain

²Paediatric Research and Metabolism Unit, Reina Sofía University Hospital, Córdoba, Spain

³Paediatric Department, Clinic University Hospital of Santiago de Compostela, Santiago de Compostela, Spain

Background and objectives: Leptin (LEP) is a hormone secreted mainly from adipose tissue that plays a role on food intake and energy expenditure by activating the leptin receptor (LEPR). LEP also regulates glucose homeostasis and lipid metabolism independently of its central weight regulatory function, partly via direct action on pancreatic β -cells and hepatocytes. Genetic variation in LEP and LEPR genes modulate the LEP activity resulting in changes on body weight. We assessed the association of 28 LEPR polymorphisms with BMI and estimated the relationship of these polymorphisms with obesity-related phenotypes, inflammation and CVD risk biomarkers in Spanish children.

Methods: 532 children (292 obese and 240 with normal-BMI) were genotyped. Anthropometric data were measured and clinical, metabolic, inflammation and CVD biomarkers were analysed.

Results: All anthropometric, clinical and metabolic factors as well as inflammatory and CVD risk biomarkers were higher in the obese than in the normal-BMI group, except glucose, LDL-c and matrix metalloproteinase-9. We found five intro-

nic polymorphisms (rs11208659, rs11804091, rs10157275, rs9436303 and rs1627238) associated with BMI in the whole population. When we performed the analysis separated by sex, we observed that rs11804091 and rs10157275, and additional rs1327118, located in the promoter region, were associated with BMI only in the female group. Interestingly, the carriers of the rs11804091 risk allele have higher leptin, height, waist circumference, systolic blood pressure, insulin, HOMA-IR and TNF- α , and lower adiponectin and apolipoprotein A. No association of these polymorphisms were observed in males.

Conclusions: Our results suggest a sex-specific influence of the significant polymorphism on the early onset of obesity, and additionally, the rs11804091 on LEP and metabolic syndrome features. The obesity association of the SNPs reported here must currently be viewed as preliminary results, which require further validation in independent samples of bigger size.

Key words: Leptin, leptin receptor, childhood obesity.

THE MTHFR 677TT GENOTYPE AND ITS INTERACTION WITH RELATED B-VITAMINS IN HYPERTENSION

R. Reilly¹, H. McNulty¹, G. Horigan¹, J.J. Strain¹, M. Ward¹

¹Northern Ireland Centre for Food and Health (NICHE), University of Ulster, Coleraine, Co. Derry, Northern Ireland, UK

Background and objectives: Individuals who are homozygous for the 677C>T polymorphism (TT genotype) in the gene encoding methylenetetrahydrofolate reductase (MTHFR) are reported to have elevated blood pressure (BP). Furthermore we showed that BP can be significantly decreased in this genetically at-risk group by intervention with riboflavin; a cofactor for MTHFR [1,2]. The aim of this investigation was to examine the role of this polymorphism relative to other determinants of hypertension in a cohort of premature CVD patients and controls.

Methods: Baseline data collected from GENOVIT, a study to examine the association between genetic factors and B-vitamins in cardiovascular disease, were analysed. From a larger initial sample pre-screened for the MTHFR genotype, a total of 325 participants (TT n 70 and matched individuals with CC n 123 or CT n 132 genotypes) were available for this investigation.

Results: Of the factors analysed, the following were found to be significant determinants of hypertension; age (p 0.05), BMI (p 0.01), anti-hypertensive medication use (p < 0.001) and the TT genotype (p 0.010). After adjusting for these factors, low compared to high riboflavin status (as determined by the biomarker erythrocyte glutathione reductase activation co-

efficient; EGRac) significantly increased the risk of hypertension (OR 1.82; 95% CI 1.13-2.94; p 0.014). Red cell folate (RCF) was not found to be a risk factor for hypertension; however the combination of the TT genotype and low RCF significantly increased the risk of hypertension (OR 3.71; 95% CI 1.38-9.95; p 0.009).

Conclusion: The MTHFR 677TT genotype is a significant predictor of hypertension; an effect that is significantly modulated by B-vitamin status in this population.

Key words: Hypertension, MTHFR, B-vitamins

PRECLINICAL EVALUATION OF THE INFLUENCE OF FEEDING WITH SLOW DIGESTING CARBOHYDRATES DURING PREGNANCY ON PROGRAMMING OFFSPRING METABOLIC HEALTH (NIGOHEALTH STUDY)

R. Rueda¹, M. Manzano¹, J.M. López-Pedrosa¹

¹Discovery R&D, Abbott Nutrition, Granada, Spain

Background and objectives: Maternal obesity and obesogenic dietary intake prior to and through pregnancy program offspring to a broad spectrum of metabolic and physiological alterations later in life such as adiposity, obesity, diabetes, changes on skeletal muscle and bone development and on cognitive performance. This work summarizes preclinical results obtained up to date on NIGOHealth (Nutrition Intervention during Gestation and Offspring Health) study. The main goal for this study is to evaluate the effects of feeding with slow digesting carbohydrates (SDC) during pregnancy on programming health and prevention of disease in the offspring from obese mothers during infancy and later in life.

Methods: Rats were assigned to one of three experimental groups: Control dams fed a standard rodent diet before mating and throughout pregnancy; dams fed a high fat (HF) diet for 6 weeks before mating and then fed a HF diet containing either SDC or high digesting carbohydrates (HSD) throughout pregnancy. Offspring's body composition was analyzed by using Magnetic Resonance Imaging technology. Plasma biochemical analysis was performed by using an autoanalyzer. Western blot was used to analyze signalling pathways. Muscle transcriptome was analyzed using the Agilent whole rat genome microarray and Ingenuity software was used for biofunction pathway analysis. Morris water maze and novel object recognition were performed to test learning and memory. Bones were analyzed by Micro-CT technology.

Results: Reduction on adiposity was associated to reduce levels of plasma glucose, triacylglycerides and cholesterol.

Offspring from pregnant rats fed with SDC also showed changes on adipose tissue glucose transporters and insulin signaling, that were consistent with reduced adiposity, at weaning and adolescence. Feeding with SDC during pregnancy also enhanced skeletal muscle development in the offspring. On the other hand offspring from mother fed with SDC had improved bone architecture and bone strength at adolescence and also showed improving learning and memory.

Conclusions: Results from this study point out the importance of nutrition during critical periods of development and show the role of carbohydrate profile on maternal diet influencing metabolism and several biochemical and physiological outcomes in the offspring. This influence may translate into prevention of metabolic diseases and other alterations later in life.

Key words: Early programming, dietary carbohydrate

⁵Department of Physiotherapy and Nursing, Universidad de Zaragoza, Zaragoza, Spain

⁶Department of Pediatrics, Medical University of Vienna, Vienna, Austria

⁷Department of Nutrition, University Lille Nord de France, Lille, France

Background and objectives: Low birth weight has shown to have a programming effect on abdominal adiposity later in life, while breastfeeding in infancy has been suggested as a protective nutritional factor on the long term risk of obesity. The aim of this study was to examine whether breastfeeding may reduce the programming effect of birth weight on abdominal adiposity. Subjects and

Methods: Abdominal (in three regions: R1, R2, and R3) and truncal adiposity were measured by dual-energy X-ray absorptiometry in a total of 314 adolescents. Breastfeeding duration,

birth weight, duration of gestation and maternal educational level were obtained from questionnaire. Physical activity was objectively measured by accelerometry.

Results: We detected significant interaction effects between breastfeeding and birth weight on truncal and abdominal adiposity in the three regions ($P_s = 0.02$ to 0.07). Stratified analyses by breastfeeding categories (never vs. > 3 months of breastfeeding) showed significant associations of birth weight with truncal and abdominal adiposity in the 3 regions in the group who had never been breastfed ($\beta = -0.19$ to -0.23 ; $P_s < 0.05$), while no evidence of association was found in adolescents who had breastfeeding for >3 months ($\beta = -0.03$ to -0.07).

Conclusion: Breastfeeding may reduce the adverse influence conferred by low birth weight on abdominal adiposity in adolescents. Our findings suggest that breastfeeding may be used as a primary prevention nutritional factor of abdominal adiposity in individuals at increased risk due to fetal programming.

Key words: Abdominal adiposity, adolescents, breastfeeding, fetal programming.

NUTRITION EFFECT OF YYB INTERVENTION ON 6-24 MONTHS INFANTS IN WENCHUAN EARTH QUACK REGION IN CHINA

J.S. Huo¹, J. Sun¹, J. Huang¹, L.Y. Zhao¹, P. Fu¹, J. Wang¹, L. He¹, S.Y. Chang¹, G.S. Ma¹

¹Institute of Nutrition and Food Safety, China CDC

Background and objectives: Previous survey had showed the 2008 Wenchuan earth quack brought a serious nutrition problem of infants in the affected regions. MOH, supported by UNICEF, organized 1.5 years intervention project by freely supply YingYang Bao (YYB), a soy bean powder based complementary food supplement and infant feeding manual to the 6-23 month infant families.

Methods: YYB was distributed to 27,872 infants in 8 earth quack counties in Sichuan, Shaanxi, and Gansu Provinces through the public health system. A baseline survey was done just before beginning the distribution of YYB and follow-up surveys were done 6 months, 12 months, and 18 months thereafter. Weight, height and Hb were measured and angular stomatitis, glossitis, and rickets were determined by physical examination. Questionnaires were designed to survey family condition and daily feedings. Averagely 1129 infants were PPS sampled for each survey in 4 selected counties.

Results: Program compliances were 91.9%, 87.4% and 84.1% in 6, 12 and 18 month surveys respectively. Anemia rates decreased from 49.5 % to 24.2 %, 24 %, 22.9% in 6, 12 and 18 months survey. Stunting rate significantly decreased and

wasting rate remained unchanged as it was already very low in the baseline survey. The prevalence of angular stomatitis, glossitis and rickets were declined. A large proportion of mothers improved their knowledge of infant feeding and aware of the benefits of YYB.

Conclusion: The observation showed that YYB was benefit to at risk 6-23 month infants and it may consider feasible for public nutrition intervention on infants.

Key words: nutrition intervention, infant, ying yangbao, anemia, stunting

INFANT MACRONUTRIENT INTAKE AND CARDIOVASCULAR STRUCTURES AND FUNCTION IN CHILDHOOD: THE GENERATION R STUDY

E H. van den Hooven¹, L L. de Jonge^{1,2,3}, J C. Kiefte-de Jong¹, A. Hofman¹, V W V. Jaddoe^{1,2,3}, H A. de Mol³, O H. Franco¹

¹Department of Epidemiology, Erasmus MC, University Medical Center, Rotterdam, The Netherlands

²The Generation R Study Group, Erasmus MC, University Medical Center, Rotterdam, The Netherlands

³Department of Paediatrics, Erasmus MC, University Medical Center, Rotterdam, The Netherlands

Background and objectives: Early nutrition may influence cardiovascular development. Not much is known about the associations between dietary composition and cardiovascular risk factors in childhood. We investigated the associations between infant macronutrient intake and cardiovascular structures and function in 2882 children participating in a population-based cohort study.

Methods: Information on macronutrient intake at the age of 1 year was obtained from food frequency questionnaires filled in by the parent. Systolic and diastolic blood pressure, carotid-femoral pulse wave velocity, left cardiac structures (left atrial diameter, aortic root diameter, and left ventricular mass), and fractional shortening were measured at the age of 6 years. Linear regression analyses were performed using residual-adjusted macronutrient intakes, adjusted for maternal, child, and dietary factors.

Results: Higher total fat intake was associated with higher carotid-femoral pulse wave velocity (difference 0.11m/s, 95% confidence interval (CI) 0.02 to 0.20 for the third tertile, as compared to the first tertile), whereas higher intakes of total carbohydrate and mono- and disaccharides were associated with lower carotid-femoral pulse wave velocity. No consistent associations were observed for macronutrient intake with systolic blood pressure, diastolic blood pressure, aortic root diameter, and fractional shortening. Higher total fat, saturated fat, and monounsaturated fat intake were associated with lower

left atrial diameter (P values for trend <0.01, 0.02, and <0.01, respectively). Furthermore, the third tertile of mono- and disaccharides intake was associated with a higher left ventricular mass (difference 1.02g, 95% CI 0.18 to 1.85). There was no sufficient evidence for interaction by child's sex, BMI, or ethnicity in the associations between macronutrient intake and cardiovascular outcomes.

Conclusions: Dietary macronutrient composition may lead to cardiovascular developmental adaptations in childhood. Further studies are needed to investigate whether these adaptations have consequences for the risk of future cardiovascular disease.

Key words: cardiac development, cardiovascular function, macronutrient intake, children

MICRONUTRIENT DEFICIENCIES OF ADOLESCENT GIRLS IN CENTRAL MOZAMBIQUE – ZANE-STUDY

R. Freese¹, L. Korkalo¹, G. Alfthan², M. Mutanen¹

¹Division of Nutrition, University of Helsinki, Helsinki, Finland

²Disease Risk Unit, National Institute for Health and Welfare, Helsinki, Finland

Background and objectives: Micronutrient deficiencies are a global nutritional problem. Especially vulnerable may be adolescent girls in low-income countries who are still growing but likely to become pregnant. Here we report the prevalence of low serum concentrations of zinc, ferritin (iron), retinol and folate of girls living in different environments in central Mozambique.

Methods: A cross-sectional study was carried out among girls aged 14 to 19 years in January-February and May-June 2010. The study areas were Quelimane city (urban area), as well as the centres and rural villages of a coastal and an inland district. Non-fasting serum samples were analysed in Finland. Multiple micronutrient deficiency (MMD) was indicated if three or four out of the four micronutrient concentrations were below the relevant cut-off values.

Results: Data on micronutrient status are available from 510 girls. In the different areas, 2 to 16% of the girls were pregnant. The BMI-for-age was mostly normal but overweight existed in Quelimane (13% of non-pregnant girls) and district centres (2 and 6%). Proportions of girls with low serum concentrations ranged from 25 to 52% for zinc, 11 to 57% for ferritin, 11 to 30% for retinol and 0 to 20% for folate. MMD was most prevalent in Quelimane (17%) while it was 7% in the district centres, and 1 and 3% in the rural areas. The proportions of girls with no deficiencies were 15% in Quelimane, 30 and 39% in the coastal and inland centres, and 44 and 53% in the coastal and inland villages, respectively.

Conclusions: Micronutrient deficiencies are common among adolescent Zambian girls. MMD is most prevalent in the city where also overweight is most common. This may indicate adverse effects of nutrition transition.

Key words: micronutrient deficiency, adolescent girl, Africa

IS THE CURRENT STATUS CONTRIBUTING TO REDUCE THE EXCLUSIVE BREASTFEEDING LENGTH?

A E. M. Rinaldi¹, V. Mafre², W L. Conde²

¹Graduation Program of Nutrition In Public Health – School of Public Health – University of Sao Paulo (USP)/ School of Medicine - Federal University of Uberlandia, Uberlandia, Minas Gerais, Brazil

²Department of Nutrition/School of Public Health – University of Sao Paulo (USP), Sao Paulo, Brazil

Background and objectives: Breast milk is the best food for infant and must be offered for infant under six months in an exclusive way. The “current status” method is recommended to estimate exclusive breastfeeding length (EBL). To compare EBL for under six months infants by actual and retrospective data using different methods.

Methods: Data came from 4 pooled Demographic Health Survey (DHS) - Bolivia, Brazil, Colombia and India – carried out from 1992 to 2010, available in Measure DHS website. A total of 9522 infants under six months, alive and living with their families was included in the analysis. EBL was calculated using two different methods: M1 from mother’s declared information about the age of the first time that a varied of foods and liquids introduced – retrospective data (survival time) and M2 from mother’s declared information about foods offer in last day – actual data (current status). At the first way, for infants never breastfed time of EBL was considered ‘zero’, for infants no longer in lactation was used information recalled by mother, and for infants in exclusive breastfeeding it was used current age. In the second way, median was calculated by the current status, according to the World Health Organization (WHO) and Macro International.

Results: A total of 110 mothers (1.1%) declared that never breastfed her infants. According M1 and M2, 3934 (41.3%) and 4053 (42.5%) were in exclusive breastfeeding at the time of interview and 5589 (58.0%) and 5470 (57.4%) were no longer in exclusive breastfeeding, respectively. The EBL in M1 was 3.7 months and in M2 was 2.3 months, a 1.4 months difference.

Conclusions: Current status gives estimates lower than mother’s information. In some countries differences are minimal. The basics and causes of differences will be explored in further work.

Key words: exclusive breastfeeding, current status,.

⁴St. John’s Research Institute, Bangalore, India

⁵Department of Nutrition, London School of Hygiene and Tropical Medicine, London, UK

⁶Institut de Recherche pour le Développement (IRD), Montpellier, France

⁷Childhood Nutrition Research Centre, UCL Institute of Child Health, London, UK

Background and objectives: The nutritional quality of CF in developing countries is often insufficient to sustain optimal growth. The Winfood project evaluated the efficacy of two new, processed rice-based CF with local ASF in Cambodia: non-fortified ‘WinFood’ (WF) with 14% by dry-weight ASF from small-sized fish (*Esomus longimanus* and *Paralauca typus*) and edible spiders (*Haplopelma* sp.); an adjusted ‘lite’ WinFood (WF-L) with 10% by dry-weight ASF from small-sized fish of mixed species, and fortified with mineral/vitamins. The products were precooked by extrusion. The WF-products were compared with two standard products from World Food Programme: Corn-Soy-Blend (CSB+) and CSB++ (8% by dry-weight skimmed-milk powder), in a single-blinded randomized trial.

Methods: 419 Cambodian infants at age 6 months were randomized to daily rations of one of the four products for nine months. BC (deuterium dilution) and iron status (serum ferritin and hemoglobin) were measured before and after intervention and anthropometry (knee-heel-length, length, weight, MUAC, head circumference and skinfolds) monthly. Data were analyzed by intention-to-treat.

Results: Among 358 children completing the study, no significant difference in BC between the groups where found, but knee-heel length increments differed (P=0.046: WF-L: 3.6 cm, CSB++: 3.6 cm, WF: 3.5 cm, CSB+: 3.4 cm), suggesting that micronutrient-fortified products with 8-10% ASF (CSB++ and WF-L) promoted better linear growth than products without fortification or ASF. Knee-heel and total length increment was

significantly higher in the highest food compliance quartile compared to the lowest, across foodgroups. There were no differences in ferritin and hemoglobin concentration. There was higher prevalence of anemic children in the WF group.

Conclusion: Products with ASF (milk or small fish) and micronutrient premix resulted in slightly better linear growth. Small fish is a cheap ASF with high potential to improve locally produced industrially processed CF.

Key words: Complementary foods (CF); Body composition (BC); Animal-source foods (ASF)

MATERNAL LCPUFA STATUS DURING PREGNANCY AND CHILD INTERNALISING AND EXTERNALISING PROBLEMS. THE GENERATION R STUDY

J. Steenweg-de Graaff^{1,2}, H. Tiemeier^{2,3,4}, F C. Verhulst², S J. Roza^{2,4}

¹The Generation R Study Group, Erasmus Medical Centre, Rotterdam, The Netherlands

²Department of Child and Adolescent Psychiatry/Psychology, Erasmus Medical Centre, Rotterdam, The Netherlands

³Department of Epidemiology, Erasmus Medical Centre, Rotterdam, The Netherlands

⁴Department of Psychiatry, Erasmus Medical Centre, Rotterdam, The Netherlands

Background and objectives: Maternal prenatal omega 3 (n3) and 6 (n6) long-chain polyunsaturated fatty acids (LCPUFAs) as well as the n3:n6-ratio are important for foetal brain development and have been linked to cognitive development. Their association with offspring behaviour is less consistent. The present study aimed to assess the associations between maternal prenatal LCPUFA status and child problem behaviour.

Methods: Within a population-based cohort, we measured maternal plasma LCPUFA concentrations in second trimester of pregnancy. Child internalising and externalising problems were assessed with the Child Behaviour Checklist (CBCL) at 6 years in 5,307 children. We assessed the associations of maternal docosaheanoic acid (DHA), eicosapentaenoic acid (EPA), arachidonic acid (AA) concentrations and n3:n6-ratio with child internalising and externalising problems using logistic regression analysis. For consistency, analyses were repeated for teacher reported problem behaviour at 6 years (Teacher Report Form).

Results: After confounder adjustment, maternal DHA and n3:n6-ratio were negatively associated with child internalising problems (ORDHA = 0.90, 95% CI: 0.83-0.99; ORn3:n6 = 0.92, 95% CI: 0.84-1.00), which was also observed in both the clinical

range as well as teacher report of internalising problems. A similar association was found for maternal report of externalising problems, but this finding was not observed in the teacher report or at the clinical level.

Conclusions: Higher maternal DHA concentration and n3:n6-ratio are negatively associated with increased risk of child internalising problems. Further research into optimal prenatal intakes of LCPUFAs is needed.

Key words: Prenatal; LCPUFA; internalising problems; externalising problems; child

O016

VITAMIN B12 SUPPLEMENTATION OF BANGLADESHI WOMEN DURING PREGNANCY AND LACTATION INCREASES VITAMIN B12 IN BREAST MILK AND IMPROVES INFANT STATUS

T. Siddiqua^{1,2,3}, K. Ahsan³, M. Rashid³, S. Shahab-Ferdows², D. Hampel², T. Ahmed³, S. Ahmed³, R. Raqib³, L H. Allen^{1,2}

¹Program in International and Community Nutrition, University of California, Davis, USA

²USDA, ARS, Western Human Nutrition Research, Davis, USA

³International Centre for Diarrhoeal Disease Research, Dhaka, Bangladesh

Background and objectives: Vitamin B12 deficiency is associated with adverse outcomes in pregnancy and infancy, and results in low milk B12, increasing risk of neurological and developmental disorders in exclusively breastfed infant. It is of critical importance to know whether combined effective intervention during pregnancy and lactation can improve breast milk and infant status in populations with low animal source food intake. The objective was to evaluate effect of vitamin B12 supplementation during pregnancy and lactation on breast milk and infant B12 status.

Methods: Bangladeshi women (n=69, 18-35 y, Hb<115 g/L, 11-14 wk pregnant) were randomized to receive 250 µg/d B12 or placebo through 4 month postpartum. Both supplements contained 400 µg folic acid + 60 mg Fe. Data collected on mothers and infants included anthropometry, plasma and milk B-12 and dietary diversity.

Results: Demographic, dietary diversity and biochemical variables did not differ between groups at baseline, when 26% women were B12 deficient (<150 pmol/L), and 39% had marginal status (150-220 pmol/L). Supplementation significantly increased median plasma B12 in mothers (416 vs. 242 pmol/L) and infants (328 vs. 200 pmol/L) at 4 month (all P<0.001). B12 concentrations indicated deficiency in 29% and marginal status in 35% of infants of placebo compared to 9% deficient and

9% marginal deficiency in supplemented group. Median B12 in colostrum of supplemented group increased to 778 vs. 320 pmol/L in placebo ($P<0.001$), and 235 vs. 170 pmol/L ($P<0.05$) at 4 month in milk. Maternal B12 at baseline remained correlated ($r=0.40$, $P<0.01$) with milk concentrations at 4 month; colostrum ($r=0.28$, $P<0.05$) and milk B12 ($r=0.51$, $P<0.001$) were correlated with infant B12 at 4 month among all participants.

Conclusions: 250 µg/d B12 supplements during pregnancy and lactation are transferred to breast milk and consequently to infant, resulting in normal infant B12 status.

Key words: Vitamin B12, Pregnancy, Lactation

DIGESTIVE HEALTH AND BOWEL FUNCTION DURING THE MENSTRUAL CYCLE: THE EFFECT OF DIET AND HORMONAL CONTRACEPTIVE USE.

L. Dye¹, C. Lawton¹, R. Schnell²

¹University of Leeds, UK

²Universität Duisburg-Essen, Germany

Background and objectives: Previous research suggests that women experience variations in digestive discomfort and bowel function during the menstrual cycle. Harder stools are more likely during the luteal (premenstrual) phase with looser, more frequent stools during menstruation. This study examines the link between the menstrual cycle, stool type and frequency, digestive discomfort and wellbeing.

Methods: The study was an online UK survey of 1012 premenopausal women aged 18-48 years, representative of the female population for age and socio-economic status. The survey required women to rate their bowel movements before, during and after menstruation using the pictorial Bristol Stool Form Scale. Information on other symptoms of digestive function, psychological state and wellbeing during these phases of the menstrual cycle were also reported on 5 point Likert scales. Respondents provided demographic and other health data including use of hormonal contraception. They also indicated how comfortable they felt and with whom they would discuss menstruation and bowel function.

Results: Over 164 different patterns of stool form across the cycle were identified. Only one third of women showed the previously accepted typical pattern of bowel function. Use of hormonal contraceptive methods was associated with more stable stool form suggesting that female hormonal fluctuations do affect bowel function. Strategies to manage bowel function included medication and diet. Women were often embarrassed and reluctant to discuss their digestive health even with health professionals.

Conclusions: Bowel function is an important indicator of health and can be altered by diet as well as hormonal milieu as shown in this representative survey. Given the wide range of experiences of stool form and different patterns during the cycle, it is important that reliable sources of advice and information for women in relation to this sensitive and personal experience are available.

Key words: bowel function, digestive health, wellbeing, menstrual cycle

EVIDENCE ABOUT SUGAR-SWEETENED BEVERAGES AND WEIGHT GAIN: IS THE POTENTIAL FINANCIAL CONFLICTS OF INTEREST BIASING THE CONCLUSIONS?: A SYSTEMATIC REVIEW

M. Bes-Rastrollo¹, M B. Schulze², M. Ruiz-Canela¹, M A. Martinez-Gonzalez^{1,3}

¹Dept. of Preventive Medicine and Public Health, University of Navarra, Spain

²Dept. of Molecular Epidemiology, German Institute of Human Nutrition, Germany

³CIBERobn, Instituto de Salud Carlos III, Spain

Background and objectives: Industry sponsorship of biomedical research might bias scientific conclusions. However, available research has focused on pharmaceutical studies and little is known about the potential role of industry sponsorship in the area of nutrition. Our objective was to review if the reported financial conflicts of interest are related to the main conclusions of the systematic reviews conducted in the field of sugar sweetened beverages (SSB) and weight gain or obesity.

Methods: We conducted a search of PubMed and Cochrane databases and a hand search of reference lists to identified published systematic reviews or meta-analyses (SR/M) up to January 2013 on the association between SSB consumption and weight gain or obesity. SR/Ms were independently classified by two blinded researchers according to their conclusions into two groups: positive and non-positive association. Information about the financial conflicts of interest reported by the authors in the manuscript was also abstracted.

Results: We identified 15 systematic reviews. In 6 of them a financial conflict of interest with some food industry was disclosed. Among those reviews without any reported conflict of interest 80% stated that SSB consumption could be a potential risk factor for weight gain. By contrast, 83.3% of those disclosing some financial conflict of interest with the food industry concluded that the scientific evidence was insufficient so far to support a positive association. Those reviews with conflicts of interest were almost 5 times more likely to present a non-posi-

tive conclusion than those without them (relative risk adjusted for year of publication: 4.8, 95% CI: 1.1-20.2).

Conclusion: Financial conflicts of interest may bias conclusions regarding the association between SSB consumption and weight gain or obesity, with potentially adverse consequences for knowledge and public health.

IRON FORTIFICATION INTERVENTIONS: SYNTHESIS OF RESULTS FROM THREE RANDOMIZED TRIALS IN ASIA

J.L. Finkelstein¹, S. Mehta¹, J.D. Haas¹

¹Division of Nutritional Sciences, Cornell University, USA

Background and objectives: This study was conducted to examine the collective results of iron fortification interventions on iron status, from three randomized trials in Asia.

Methods: Three randomized controlled trials of iron biofortification interventions were included in this analysis (iron-iodine fortified salt, iron biofortified pearl millet, and rice). A total of 686 participants, were enrolled in these trials in India and the Philippines. Iron status (hemoglobin, ferritin, sTfR, body iron), inflammation (CRP, AGP), and anthropometric indices were measured at enrollment, midline, and endline in each trial. The primary outcomes evaluated included 1) hemoglobin and serum ferritin concentrations, 2) incidence of anemia (Hb<12.0 g/dL) and iron deficiency (ferritin<15.0 µg/L), 3) resolution of these outcomes, 4) sTfR, and 5) body iron. Mixed models were used to examine the effects of interventions on hematological outcomes. A meta-analysis using random effects models was conducted with the DerSimonian and Laird method.

Results: At baseline 32% of participants were anemic and 25% were iron deficient in the overall sample. In meta-analyses of data from the three trials, iron interventions significantly increased serum ferritin concentrations, but only among individuals who were iron deficient at baseline (p<0.05). Iron interventions did not significantly reduce the incidence of poor hematological outcomes over follow-up. However, iron interventions significantly increased the likelihood of resolution of iron deficiency by more than 50% (p<0.01).

Conclusions: Iron fortification interventions resolved iron deficiency during follow-up, and increased ferritin concentrations among individuals who were iron deficient at baseline. Findings provide support for iron-fortified interventions, with increased potential to benefit among iron deficient individuals.

A comprehensive approach to prevent anemia and iron deficiency, including larger samples, appropriate dosing, and targeted preventive interventions need to be examined to reduce the burden of iron deficiency in resource-limited settings.

Key words: Iron deficiency, anemia, fortification, intervention, Asia

PARENTAL SPORTS AND TV TIME AS MEDIATORS OF PARENTAL EDUCATION DIFFERENCES IN CHILDREN'S SPORTS AND TV TIME: THE ENERGY-PROJECT

J.M. Fernández Alvira^{1,2}, S.te Velde², A. Singh³, D. Jiménez Pavón¹, I. De Bourdeaudhuij⁴, E. Bere⁵, Y. Manios⁶, N. Jan⁷, E. Kovacs⁸, L. Moreno¹, J. Brug²

⁶Department of Nutrition and Dietetics, Harokopio University, Athens, Greece

⁷Slovenian Heart Foundation, Ljubljana, Slovenia

⁸Department of Paediatrics, Pecs University, Pecs, Hungary

Background and objectives: Lower socioeconomic status is associated with less favourable physical activity and sedentary behaviours in children. These patterns may be caused by parental modelling. The study aims were to explore whether differences in children's sports participation and TV time according to parental education were mediated by parental sports participation and TV time, and to explore the differences between parental and child reports as potential mediators.

Methods: 5729 children and 5183 parents participating in the ENERGY-project were included. Sports participation and TV time were assessed by child- and parent-reports. Children also reported on parental sports and TV time. Country-spe-

cific multilevel mediation analysis (product-of-coefficients test by MacKinnon) was applied to test the potential mediation effect of parental sports and TV time in the association between parental education and children's sports and TV time. All models were adjusted for children and parental age, gender and parental education.

Results: In the countries where parental education differences in children's TV time were observed (Greece, Hungary, the Netherlands and Slovenia), parent-reported parental TV time significantly mediated the associations. Evidence for mediation by child-reported parental TV time was found in Greece only. For children's sports participation, significant differences according to parental education were also observed in four countries (Greece, Hungary, Norway, Spain) and were mediated by parental self-reported sports in Greece and by child-reported parental sports in Greece and Norway.

Conclusions: Parental behaviours appear to be important in explaining parental educational differences in children's sports participation and TV time. However, Child reports of parental sports and TV time appear to be more relevant than parents' self-report as correlates of children's own sports and TV time, but parental self-reported behaviour appears to be more relevant for explaining parental educational differences in children's TV time and sports participation.

Key words: TV time, sports, parental modelling, mediation analysis

RISK FACTORS FOR PRELACTEAL FEEDINGS IN SEVEN LATIN AMERICA AND CARIBBEAN COUNTRIES.

C. Boccolini¹, R. Pérez-Escamilla²

¹Department of Social Nutrition, Rio de Janeiro State University, Brasil

²Department of Chronic Disease Epidemiology, Yale University, USA

Background and objectives: WHO recommends exclusive breastfeeding for six months of life. Pre-lacteal feeding (i.e., offering liquids before milk begins to flow) has been identified as a risk factor for shorter breastfeeding duration. We aim to identify risk factors for pre-lacteal feeding in the first three days of life in Latin America and the Caribbean.

Methods: The present study used secondary data from Demographic and Health Surveys conducted in seven countries (Colombia/2010, Bolivia/2008, Guiana/2009, Haiti/2005, Honduras/2005, Peru/2007 and Dominican Republic/2007). Binomial multivariate regression tested the influence of the following covariates on the likelihood of pre-lacteal feeding: country of residence, wealth index, place of residence (urban/

rural), maternal education level, birth weight, type of delivery (vaginal/cesarean), place of delivery (home/hospital), and sex of child.

Results: The final pooled sample (N=58,056 children) had the following characteristics: 51.3% were male; 51.6% were living in urban areas; in the first three days of life, 67.0% of the mothers gave no pre-lacteal feedings to their baby, 17.9% gave infant formula, 6.4% gave tea or infusions, 5.0% gave milk (other than breast milk), 2.0% gave plain water, and 4.5% gave other liquids before breast milk began to flow. The binomial model adjusted Odds Ratios (OR) for pre-lacteal feeding that were statistically significant ($p < 0.001$) were higher in Haiti (OR=6.65), Dominican Republic (OR=3.57), Guiana (OR=2.76), Peru (OR=2.39), Bolivia (OR=2.35) and Honduras (OR=2.21), when compared against Colombia. The OR were also significantly higher for the wealthiest mothers (OR=1.46), those with higher educational level (OR=1.33), cesarean delivery (OR=2.51), and delivery at home (OR=1.29).

Conclusion: The high prevalence of pre-lacteal feeding supports the investment in policies targeting the most vulnerable countries and individuals at risk of practicing this undesired behavior, in order to promote, support and protect breastfeeding.

Key words: breastfeeding, pre-lacteal feeding, child health, nutrition, epidemiology.

CALORIES AND ENERGY BALANCE: THE IMPORTANCE OF SMALL STEPS TO TRIGGER BIG CHANGE TOWARDS REVERSING OBESITY

L. Gable¹, L. Sutherland²

¹Healthy Weight Commitment Foundation, Washington DC, USA

²Dartmouth College, Hanover, USA

Background and objectives: Sixteen of the largest food and beverage manufacturers in the United States came together to form the Healthy Weight Commitment Foundation (HWCF). Comprising the largest industry initiative in any nation, these companies collectively pledged to reduce calories by 1 trillion by 2012 and 1.5 trillion by 2015, towards the nation's goal of reversing childhood obesity. This study compares the total number of calories HWCF companies sold in 2012 with the total number of calories HWCF companies sold at baseline (2007) to determine whether the HWCF reached its 1 trillion calorie pledge.

Methods: For the 16 participating HWCF companies data was obtained from multiple sources, including Nielsen ScanTrack, for all point of sale units sold and associated nutrition data. This created a comprehensive food and beverage product

database for analysis. The HWCF product database includes all food and beverages sold, by Uniform Product Codes, and the associated calories per serving for each product recorded during the study periods of interest. We examined the difference between calories at baseline and 2012 employing descriptive statistics. Qualitative analyses were conducted to describe differences in calories between the two study periods of interest.

Results: Between 2007 and 2012 we documented a significant decrease in total calories available in the marketplace. Qualitative results demonstrate that calorie reductions are attributed largely to an increase in lower- and no calorie choices, more calorie and portion controlled food and beverages, and consumers shifting their purchase habits towards lower calorie food and beverages.

Conclusions: Despite an increase in total US retail grocery sales over time, we documented decreases in total calories sold by the 16 HWCF companies. The HWCF initiative offer great potential for incentivizing further industry change and will point the way to future actions needed to prevent childhood obesity.

Key words: Calories, energy balance, obesity.

¹⁰Inserm, Centre for research in Epidemiology and Population Health (CESP), U1018, Nutrition, Hormones and Women's Health team, Villejuif, France

Background and objectives: Iron has been suggested to play a role in carcinogenesis. Hereditary hemochromatosis (HH) is a strong risk factor of hepatocellular cancer, and mutations in the HFE gene associated with HH and iron overload may be related to other tumors sites, but no studies have been reported for gastric cancer (GC).

Methods: A nested case-control study was conducted within the European Prospective Investigation into Cancer and Nutrition (EPIC) including 365 incident gastric adenocarcinoma and 1284 matched controls. Genotype analysis was carried out for two known functional polymorphisms of HFE (C282Y and H63D) and seven tagSNPs of the HFE genomic region. Association with all gastric adenocarcinoma, and according to anatomical localization and histological sub-type, was assessed by means of the odds ratio (OR) and 95% confidence interval (CI) estimated by unconditional logistic regression adjusted for the matching variables.

Results: We observed a significant association for H63D, with OR=1.32 (CI 1.03-1.69). In sub-group analyses, the association was stronger for noncardia anatomical sub-site (OR=1.60, CI 1.16-2.21) and intestinal histological sub-type (OR=1.82, CI 1.27-2.62). Among intestinal cases two tagSNPs (rs1572982, rs6918586) also showed a significant association that disappeared after adjustment for H63D. No association with tumors located in the cardia or of diffuse sub-type was found for any of the nine SNPs analyzed.

Conclusions: H63D mutation in HFE gene seems to be associated with GC risk of the noncardia region and intestinal type, possibly due to its association with iron overload, although a role for other mechanism cannot be entirely discounted.

Key words: gastric cancer, hemochromatosis, HFE gene

THE SPANISH OBSERVATORY OF NUTRITION AND STUDY OF OBESITY: A NECESSARY ACTION

T. Robledo de Dios¹, M A. Dal Re-Saavedra¹, N. Perez-Farinos¹, C. Villar-Villalba¹, E. Bel-Urgel¹, E. Labrado-Mendo¹, C. Biansan¹

¹Spanish Agency for Food Safety and Nutrition, Ministry of Health and Equality, Spain

Background and objectives: Information systems are essential in the study of obesity. As a great diversity of data sources exist coordination systems are needed in order to obtain suitable and quality information, and to monitor and assess politics and interventions. The aim of this action was to launch an Observatory of Nutrition and Study of Obesity in Spain, within the NAOS Strategy, the comprehensive strategy of the Spanish Ministry of Health for the promotion of healthy food habits, physical activity and obesity prevention.

Methods: An order to create the Observatory was included in the Spanish Law 7/2011 of Food Safety and Nutrition with the main goal of promoting politics and interventions based in scientific evidence. Subsequently a search of information and background concerning working and design of other observatories in Spain and abroad was performed. Features of the observatory as a complete information system were settled: data sources, studies, research projects, campaigns, programs, action plans, bibliography. In addition, a suitable framework and a working system were designed to ensure the achievement of the objectives. A website was designed as the host of information and as a permanent join with users.

Results: Afterwards all those works were performed within the working team of the NAOS Strategy in the Spanish Agency of Food Safety and Nutrition, the Observatory was officially created by the Spanish Council of Ministers in January the 3rd 2013.

Conclusions: The Observatory of Nutrition and Study of Obesity will be an essential tool in planning, monitoring and assessment of politics of obesity prevention and promotion of healthy habits in nutrition and physical activity.

Key words: observatory, obesity, nutrition; information, evaluation

EFFECTS OF DIETARY SUPPLEMENTATION WITH EICOSAPENTAENOIC ACID AND LIPOIC ACID IN HEALTHY OVERWEIGHT/OBESE WOMEN FOLLOWING AN ENERGY RESTRICTED DIET.

A. Huerta¹, S. Navas², J. Martinez², P. Prieto-Hontoria², M. Moreno²

¹Department of Food Science and Physiology, University of Navarra, Pamplona, Navarra, Spain

²CIBER Fisiopatología de la Obesidad y Nutrición (CIBEROBn), Instituto de Salud Carlos III, Spain

Background and objectives: Recent studies have shown that dietary supplementation with antioxidants such as lipoic acid and with anti-inflammatory food components such as omega-3 polyunsaturated fatty acids could help to improve obesity treatment and/or alleviate the co-morbidities related with an excessive fat storage. In the present study, the main goal was to investigate the effects of a regular administration of lipoic acid (LA) and eicosapentaenoic acid (EPA) supplements combined with a moderate calorie restriction on weight loss and body composition as well as on glucose and lipid profile in healthy overweight/obese women.

Methods: In this double-blind placebo-control trial, 99 women aged 20-50 years, with a BMI between 27.5 and 40 Kg/m² were randomly assigned to one of the four experimental groups (Control (placebo), eicosapentaenoic acid (EPA 1.3 g/d), lipoic acid (LA 0.3 g/d) and eicosapentaenoic acid plus lipoic acid (EPA 1.3 g/d + LA 0.3 g/d), all within an energy-restricted diet. Anthropometry's, body composition, blood pressure, energy expenditure, glucose and lipid profile as well as leptin and ghrelin were assessed.

Results: All groups exhibited a significant reduction ($p < 0.05$) in body weight, anthropometric measurements and fat mass, that were accompanied by decreases in total and LDL-cholesterol levels and triglycerides as well as on insulin levels and the HOMA index. The weight loss and fat mass reductions were significantly higher ($p < 0.01$) when participants were supplemented with lipoic acid. The EPA group had the higher reduction in waist to hip ratio ($p < 0.05$). At endpoint of the study was observed a significant ($p < 0.05$) reduction of leptin levels in all groups without differences respected to control.

Conclusion: The LA supplementation in conjunction with an energy-restricted diet may be useful to increase the magnitude of body weight and fat mass reduction in healthy overweight/obese women.

Key words: energy-restricted diet, lipoic acid, eicosapentaenoic acid, weight loss.

O026

IMPACT OF VITAMIN A AND ZINC ON DIARRHEAL E. COLI INFECTIONS AND ASSOCIATED DIARRHEAL EPISODES AMONG CHILDREN IN MEXICO CITY, MEXICO

K. Long¹, N. Moran², J. Santos³, J. Rosado⁴, T. Estrada-Garcia²

¹School of Population Health, University of Queensland, Australia

²CINVESTAV, Politechnical Institute of Mexico, Mexico

³School of Medicine, National Autonomous University of Mexico, Mexico

⁴School of Natural Sciences, Autonomous University of Querétaro, Mexico

⁵CINVESTAV, Politechnical Institute of Mexico, Mexico

Background and objectives: Heterogeneity in vitamin A and zinc supplementation efficacy on diarrheal disease may result from their effect on specific diarrheal pathogens. We evaluated vitamin A and zinc supplementation efficacy on diarrheal E. coli pathotype (DEP) infections among Mexican children.

Methods: A randomized, double-blind, placebo-controlled trial was conducted among 707 children, 6 to 15 months of age from periurban areas of Mexico City. Children were assigned to receive either vitamin A every 2 months, a daily zinc supplement, a combined vitamin A and zinc supplement or a placebo for 1 year. The primary end points for this analysis were infection rates and associated diarrhea for diffuse-adhering E. coli (DAEC), enteroaggregative E. coli (EAEC), enterotoxigenic E. coli (ETEC) and enteropathogenic E. coli (EPEC) among a subsample of 326 children followed from May to September 2001.

Results: DAEC and EAEC were the most frequently isolated pathogens followed by ETEC and EPEC. Vitamin A and zinc supplementation had no effect on overall pathogen outcomes. Zinc supplementation was associated with reduced DAEC infections among boys but not girls. In contrast, zinc supplementation was associated with reduced DAEC associated diarrhea among girls. EAEC infections were significantly reduced among 12-18 month old vitamin A and zinc supplemented children.

Conclusions: Vitamin A and zinc supplementation was associated with distinct DEP-specific health outcomes. These findings confirm that heterogeneity in pathogen supplementation efficacy may contribute to overall heterogeneity in supplementation efficacy.

Key words: vitamin A, zinc, diarrhea, pathogenic E. coli

O027

INPATIENT MANAGEMENT OF INFANTS SUFFERING FROM ACUTE MALNUTRITION AND THEIR OUTCOME DEPENDING OF THEIR CHARACTERISTICS

E. Chounfack¹, R. Ejoh¹, C. Mbofung¹

¹University of Ngaoundere, Cameroon

Background and objectives: Acute malnutrition remains a public health problem in developing countries including Cameroon. It increases the mortality rate by 50 %. In the North region of Cameroon, its prevalence (10.2 %) exceeds the 10 % limit of acceptability recommended by WHO. Amongst these children, 3.4 % suffer from severe acute malnutrition. Within the context of our work, our objective was to evaluate the effect of acute malnourished children's characteristic on their management's issues.

Methods: To attain its, we have did a cohort study of children aged 6 to 59 months and suffering from acute malnutrition with medical complication managed at in-patient therapeutic feeding center (ITFC) of regional hospital of Garoua from April to August 2012. Anthropometric parameters were measured and noted on a card. Information on dietary practices (mainly breastfeeding practices) and vaccination status of the child was gotten from the caretaker. HIV status was determined on admission.

Results: This study revealed that most of the children suffered from severe acute malnutrition (n = 101; 82 %). In addition to be affected by acute malnutrition, 62 % of the children were suffering from chronic malnutrition. There was a significant relation between weight variation during hospitalization and infant's issue, those who lose weight having the higher mortality rate (m= 17.8 ; p = 0.01). The mortality rate of hospitalized children suffering from severe acute malnutrition rise to 13 %, the recovery rate was 7 %, the transfer rate was 60 % and the default rate was 20%. Mean upper arm circumference lower than 115 mm is the anthropometric factor that increased significantly the mortality rate of children suffering from severe acute malnutrition (m= 6.7 ; p = 0.04). Children aged 6 to 24 months and breastfed during hospitalization had lower mortality risk.

Key words: severe acute malnutrition, child, management, mortality, ITFC

EFFECTS OF L-CARNITINE SUPPLEMENT ON PLASMA COAGULATION AND ANTICOAGULATION FACTORS IN HEMODIALYSIS PATIENTS

F. Hakeshzadeh¹, H. Tabibi¹, M. Ahmadinejad², T. Malakoutian³, M. Hedayati⁴

¹Faculty of Nutrition Sciences and Food Technology, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran

²Iranian Blood Transfusion Organization, Tehran, Islamic Republic of Iran

³Department of Nephrology, Hashemi Nejad Hospital, Iran University of Medical Sciences, Tehran, Islamic Republic of Iran

⁴Prevention & Treatment of Obesity Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran

Background and objectives: Hypercoagulability is an important risk factor for thrombosis and its complications in hemodialysis patients. This study was designed to investigate the effects of L-carnitine supplement on plasma coagulation and anticoagulation factors in hemodialysis patients.

Methods: Thirty-six hemodialysis patients were randomly assigned to either a carnitine or a placebo group. Patients in the carnitine group received 1000 mg/day oral L-carnitine for 12 weeks, whereas patients in the placebo group received a corresponding placebo. At baseline and the end of week 12, 5 mL blood was collected after a 12- to 14-hour fast and plasma fibrinogen concentration, activity of plasma protein C, coagulation factors V, VII, IX, and serum concentrations of tissue plasminogen activator (tPA), plasminogen activator inhibitor type-1 (PAI-1), free carnitine, and C-reactive protein (CRP) were measured.

Results: In the carnitine group, mean serum free carnitine concentration increased significantly to 150% of baseline ($p < 0.001$), whereas plasma fibrinogen and serum CRP had 98 mg/dL ($p < 0.01$) and 41% ($p < 0.01$) significant decreases, respectively, at the end of week 12 compared with baseline. The reductions were significant compared with the placebo group ($p < 0.05$). No significant differences were observed between the two groups with regard to mean changes of the activity of plasma protein C, coagulation factors V, VII, IX, and serum PAI-1 to tPA ratio.

Conclusion: L-Carnitine supplement reduces serum CRP, a marker of systemic inflammation, and plasma fibrinogen, an inflammation-related coagulation factor, in hemodialysis patients. Therefore, L-carnitine may play an effective role in preventing cardiovascular diseases in these patients.

Key words: anticoagulation factors, coagulation factors, hemodialysis, inflammation, L-carnitine.

THE BENEFICIAL EFFECTS OF THE RESMENA DIETARY PATTERN ON OXLDL IN PATIENTS WITH METABOLIC SYNDROME

R. De La Iglesia¹, P. Lopez-Legarrea¹, I. Abete², S. Navas-Carretero^{1,3}, J.A. Martinez^{1,3}, M.A. Zulet^{1,3}

¹Department of Nutrition, Food Science and Physiology, University of Navarra, Spain

²BioDonostia Health Research Institute, Spain

³CIBER Fisiopatología Obesidad y Nutrición (CIBEROBN) Instituto de Salud Carlos III. Spain

Background and objectives: The prevalence of metabolic syndrome (MetS) is increasing worldwide. Insulin resistance, hyperglycemia and type 2 diabetes have been considered major traits of the MetS. Moreover, oxidative stress is considered an important contributor to these pathophysiological complications. Therefore, the aim of the present study was to evaluate the interactions and effectiveness of a weight loss dietary pattern on improving the oxidative stress status on patients suffering MetS with hyperglycemia.

Methods: Seventy-nine volunteers recruited according to specific inclusion criteria were randomly assigned to two low-calorie dietary treatments (-30% Energy): the Control diet based on the American Heart Association criteria and the RESMENA diet based on a different macronutrient distribution (30% proteins, 30% lipids, 40% carbohydrates), which was characterized by a high adherence to the Mediterranean diet, increased meal frequency (7 times/day), low glycemic load (mainly in the afternoon and at night) as well as high total antioxidant capacity and omega-3 fatty acids content. Anthropometrical measurements and biochemical analyses were performed before and after 6-months of intervention. Plasma ox-LDL were measured using a capture ELISA assay kit.

Results: Both dietary groups significantly decreased body weight, BMI, waist circumference and total fat ($p < 0.001$ both groups) as well as plasma TG ($p < 0.05$ Control, $p < 0.005$ RESMENA), insulin ($p < 0.001$ both groups) and HOMA-IR ($p < 0.005$ Control, $p < 0.001$ RESMENA) levels, associated to the energy restriction. Interestingly, after the intervention, only subjects of the RESMENA group significantly reduced plasma oxLDL, the main variable of the study, resulting in significant differences between groups ($p < 0.025$).

Conclusions: the RESMENA dietary pattern might be a good option for patients specifically suffering MetS and hyperglycemia not only due to the beneficial effects of weight loss, but also on oxidative stress status.

Key words: metabolic syndrome, hyperglycemia, oxidative stress, oxLDL.

O030**EFFECT OF PHYSICAL ACTIVITY OR NUTRITION EDUCATION ON ANTHROPOMETRY AND BLOOD PRESSURE OF OVERWEIGHT OR OBESE ADOLESCENTS**

R. Valdes-Ramos¹, R M. Velasco-Martínez², P. Tlatempa-Sotelo¹, A. Domínguez-López¹, M C. Guzmán-Márquez¹, B E. Martínez-Carrillo¹, A L. Guadarrama-López¹

¹Center For Research and Graduate Studies In Health Sciences, Faculty of Medicine, UAEM

²Facultad de Medicina Humana, UNACH, México

Background and objectives: Overweight and obesity are increasing worldwide, intervention programs have given limited results. The objective of the study was to observe changes in body mass index (BMI), adiposity and blood pressure in 12 to 14 year old overweight or obese adolescents, with nutrition education (NE), physical activity (PA) or combined programs.

Methods: Adolescents from public schools in Tuxtla Gutierrez (TG) and Toluca (TO) in Mexico, participated during 26 weeks as follows: 1) NE-TG, 2) NE-TO, 3) PA-TG, 4) PA-TO, 5) NE+PA-TG, 6) NE+PA-TO. Weight and stature for BMI, waist circumference (WC), body fat (BF), and systolic (SBP) and diastolic (DBP) blood pressure were measured at baseline and weeks 14 and 26. Multivariate analysis was done in SPSS.

Results: Statistically significant effects of time by intervention group ($p < 0.05$) and time by study site and gender ($p < 0.05$) were found in BMI. WC was significantly affected by time ($p < 0.001$); time and study site ($p < 0.01$); and time by intervention group ($p < 0.05$). Body fat was significantly affected by time ($p < 0.001$), time by study site ($p < 0.05$), time by gender and time by intervention group and gender. Systolic blood pressure decreased in time with all three interventions with significant effects by time ($p < 0.001$), time and study site ($p < 0.05$); time and intervention group ($p < 0.05$), and time by study site, intervention group and gender ($p < 0.05$). Diastolic blood pressure decreased in all cases except in the females from the NE-TG group. Effects were significant for time ($p < 0.001$); time by study site ($p < 0.05$); time by intervention and gender ($p < 0.05$); time by study site, intervention and gender ($p < 0.05$).

Conclusions: Physical activity, nutritional education and their combination helped improve anthropometry and blood pressure in overweight and obese adolescents during the first 14 weeks of intervention.

Acknowledgements: This project was financed by UAEM.

Key words: Overweight, obesity, adolescents, physical activity, nutrition education

O031**NUTRITIONAL AND GENETIC DETERMINANTS OF CAROTID ATHEROSCLEROSIS, INFLAMMATORY CYTOKINES AND BONE MASS IN CHINESE ADULTS: A 3-YEAR PROSPECTIVE STUDY**

Y. Chen¹, W. Ling², L. He¹, F. Zeng¹, Y. Liu¹, Z. Zhang², J. Dun¹, Z. Chen¹, Q. Liu¹, Y. Su²

¹Department of Medical Statistics & Epidemiology, Sun Yat-Sen University, Guangzhou, China

²Department of Nutrition, Sun Yat-Sen University, Guangzhou, China

Background and objectives: Nutritional and genetic determinants of atherosclerosis and bone health remain uncertain. We examined various foods, nutrients, phytochemicals and candidate gene polymorphisms on carotid atherosclerosis, inflammatory cytokines, and bone mass in a community-based prospective study.

Methods: 3,169 (932 men) Guangzhou residents (45-75y) completed baseline survey during 2008.7-2010.6. 2524 of them was followed up during 2011.5-2012.12. At the baseline and follow-up, face-to-face interviews were conducted to assess dietary intake (by a 79-item FFQ) and general information. We determined anthropometric indices, carotid intima-media thicknesses (IMTs) via ultrasound, body fat and bone density (BMD) by DXA. Fasting blood was collected to test RBC fatty acids, serum phytochemicals (isoflavones, carotenoids, flavanones), lipids, cytokines (IL-6, IL-1B, TNF- α , MCP- α , CRP, SVCAM-1), and gene polymorphisms related to lipids, bone metabolism or antioxidation (CYP19A1, CYP2R1, SOST, SOD, DHCR7, VDR, ESR1, MTHFR, OPG, DBP, GPR177, RANK, LRP5, APOE, Wnt16). Independent effects and interactions of the various environmental and genetic factors on IMTs, BMD and cytokines and their changes were analyzed using multivariate models.

Results: After adjustment for potential covariates, we found: (i) greater intake of fruit and vegetables, higher scores of "healthy dietary pattern", higher dietary quality scores, higher blood carotenoids, flavanones, n-3 fatty acids were associated with lower IMTs and their increase rates, and with some cytokines; (ii) greater fruit and vegetables, seafoods, lean meat, tea drinking, and higher dietary quality scores, higher blood isoflavones and carotenoids were correlated to better bone density; (iii) significant associations of many gene polymorphisms with IMTs, bone mass and some cytokines; and interactions between many nutritional factors and some gene polymorphisms were observed.

Conclusions: We found many useful independent nutritional and genetic determinants, and their interactions related to carotid atherosclerosis, inflammatory cytokines and bone health in Chinese.

Key words: nutrition, gene polymorphisms, atherosclerosis, inflammatory cytokines, bone density.

EFFECTS OF ZINC SUPPLEMENTATION ON SERUM LEPTIN LEVEL AND INSULIN SENSITIVITY IN OBESE PEOPLE

L. Payahoo¹, A. Ostadrahimi¹, M. Mobasseri², Y.R. Khajebishak¹, M. Asghari jafarabadi³

¹Nutrition Research Center, Department of Nutrition, Faculty of Health and Nutrition, Tabriz University of Medical Science, Iran

²Associated professor of Endocrinology, Department of Internal Medicine, Tabriz University of Medical Science, Iran

³Assistant professor, Department of Epidemiology, Faculty of Health and Nutrition, Tabriz University of Medical Science

Background and objectives: Obesity is a crucial risk factor for many disorders. Level of minerals such as zinc is low in serum, plasma or erythrocytes of obese patients. Zinc plays a role in fat metabolism, appetite control, insulin resistance, and obesity. On the other hand, hormones such as leptin have key role in regulation of energy balance. The aim of this study was to assay effects of zinc supplementation on leptin level and insulin sensitivity in obese people.

Methods: This study was conducted on 60 eligible obese people (BMI >30 kg/m²) that were randomly divided into intervention and control groups. Intervention group received a 30mg/d zinc pill and placebo group received 30mg/d isomaltose pill for a period of 4 weeks. Serum leptin and zinc level were measured by enzyme-linked immunosorbent assay and atomic absorption spectrophotometer, respectively. In addition, Insulin level and Insulin resistance (IR) were determined by immunoenzymometric assay and (HOMA-IR) model.

Results: A significant increase in serum leptin level observed in zinc group ($p < 0.05$). There was no significant differences in post intervention serum leptin level between the two groups ($p > 0.05$). Serum zinc concentration increased in both groups, but it was significant only in intervention group. Serum insulin level and HOMA-IR index decreased in both groups after 4 weeks. These reduction were significant in zinc group compared to initial level ($p < 0.05$).

Conclusions: Zinc supplementation in obese people may be an effective approach in reduces insulin resistance complications and improving zinc deficiency. The future studies are recommended to assay other inflammatory biomarkers and with longer duration in obese population.

Key words: obesity, leptin, zinc, insulin sensitivity.

ASSOCIATION BETWEEN THE IMPROVEMENT IN ANXIETY SYMPTOMS WITH WEIGHT LOSS IN SUBJECTS WITH METABOLIC SYNDROME

A. Perez-Cornago¹, R. de la Iglesia¹, P. Lopez-Legarrea¹, I. Abete^{1,3}, S. Navas-Carretero^{1,3}, C.I. Lacunza², F. Lahortiga², J.A. Martinez^{1,3}, M.A. Zulet^{1,3},

¹Department of Nutrition, Food Science and Physiology, University of Navarra, Spain

²Department of Psychiatry and Clinical Psychology, University Clinic of Navarra, Spain

³CIBER Fisiopatología Obesidad y Nutrición (CIBEROBn), Instituto de Salud Carlos III, Spain

Background and objectives: Metabolic syndrome is a combination of medical disorders whose prevalence is increasing worldwide, leading to an increased incidence of CVD. An association between anxiety disorder and metabolic syndrome has recently been reported, however, the precise interactive pathways between these diseases still remains unclear. This study examined the effects of a hypocaloric treatment to reduce metabolic syndrome features on anxiety status.

Methods: A total of sixty-two non-demented males ($n=39$) and females ($n=23$) subjects (Age: 50 ± 10 y; BMI: 36.1 ± 4.3 kg/m²) with metabolic syndrome according to IDF criteria were enrolled in a randomized controlled clinical trial. Subjects followed two hypocaloric diets (control diet and RESMENA diet) with the same energy restriction (-30% TCV) for six months. The 20-items State-Trait Anxiety Inventory (STAI) was used to measure anxiety symptoms. STAI questionnaire as well as anthropometric and biochemical variables were analysed at the beginning and at the end of the intervention.

Results: The subjects mean weight loss was 8.5 ± 5.0 kg. Anxiety symptoms decreased during the weight loss intervention (Δ STAI: -14.7 ± 27.0) with no differences between dietary groups ($p > 0.10$). Moreover, it was found that those subjects losing more weight during the dietary intervention showed a greater decline in anxiety symptoms (Δ STAI: -22.6 ± 24.8) than those who lost less weight (Δ STAI: -7.5 ± 27.2) ($p = 0.024$).

Conclusions: This study demonstrated that an effective hypocaloric diet designed to reduce metabolic syndrome features, also improved anxiety symptoms, being this improvement higher in those subjects losing more weight during the weight loss intervention.

Key words: anxiety symptoms, metabolic syndrome, weight loss

O034

VALIDATION OF THE INTERACTIVE TWENTY-FOUR HOUR RECALL METHOD AMONG GHANAIAN CHILDREN

D. Nketiah¹, A. Lartey¹, S. Adu-Afarwuah¹, M. Steiner-Asiedu¹

¹Department of Nutrition and Food Science, University of Ghana, Legon, Ghana

Background and objectives: The 24-hour recall is a popular method for collecting dietary intake data but it has poor precision in assessing intakes. An improvement over the 24-hour recall is the interactive 24-hour recall which uses pictures of food items, food models and actual foods to assist with recall. We validated the interactive 24-hour recall method against the weighed food record in a semi-urban community in Ghana.

Methods: Dietary intake data for 51 children (8-18 months) were collected using the weighed food record on day 1 and the interactive 24-hour recall the next day. Intakes from the weighed food record and the interactive 24-hour recall were compared using paired t-test and Pearson correlation.

Results: Estimated mean \pm SD energy intake was significantly ($p = 0.04$) lower for the weighed food record (356.9 ± 303.5 kcal) than the interactive 24-hour recall (410.8 ± 229.6 kcal) but estimates of the other nutrients did not differ between the two methods. Pearson correlation coefficients of the energy and nutrient intakes from the weighed food and the interactive recall method ranged between 0.4 and 0.8.

Conclusion: The interactive 24-hour recall may overestimate energy intake, but it is nearly as good as weighed food records in estimating nutrient intakes among Ghanaian infants.

Key words: 24-hour recall, interactive 24-hour recall, weighed food record, energy intake

BODY COMPOSITION OF KUWAITI CHILDREN; ESTABLISHMENT OF A STABLE ISOTOPE FACILITY FOR ASSESSMENT OF TOTAL BODY WATER IN KUWAIT

T Al-Ati¹, T Preston², S Al-Hooti¹, N Al-Hamad³, J Al-Ghanim¹, F AlKhulifi¹, B Al-Lahou¹, A Al-Othman¹, L Davidsson¹

1Kuwait Institute For Scientific Research, Kuwait

2University of Glasgow, Scottish Universities Environmental Research Center, Scotland, UK

3Food and Nutrition Administration, Ministry of Health, Kuwait

Background and objectives: Assessment of body composition provides a much needed tool to monitor and evaluate interventions to combat obesity, in particular during childhood. Stable isotope technique to estimate total body water (TBW) is the golden standard technique for body composition. The aims of this study were to install the technique for TBW and assess body composition of Kuwaiti children.

Methods: The Isotope Ratio Mass Spectrometer (IRMS) was calibrated with defined international reference water standards. 75 boys and 83 girls (7-9 years) participated in the study. A dose of deuterium oxide (1-3 g) was consumed after an overnight fast and deuterium enrichment in baseline and post dose urine samples was measured. TBW was calculated and used to estimate fat free mass (FFM). Fat mass (FM) was estimated by difference (body weight minus FFM).

Results: IRMS measurements were confirmed to be accurate and precise. Children were classified as normal weight, overweight or obese according to the World Health Organization (WHO) based on BMI-for-age z-scores. Statistically significant differences in body composition were observed between normal weight boys and girls while only minor differences were found in overweight and obese children. Of particular interest is the finding that both boys and girls children classified as normal weight or overweight had high % body fat, over 35% and 40 % respectively.

Conclusion: The introduction of state-of-the-art technology for assessment of body composition provides an opportunity to explore a wide range of applications, within Kuwait as well as in the Gulf region.

Key words: Body composition, stable isotopes, childhood obesity, IRMS, deuterium dilution, Kuwait

O036

PERCENTILE DISTRIBUTION OF ANTHROPOMETRIC VARIABLES OF BODY COMPOSITION IN PREGNANT WOMEN

I. Rached-Sosa¹, G. Henríquez-Pérez¹

¹Centro De Atención Nutricional Infantil Antímamo CANIA, Caracas, Distrito Federal, Venezuela

Background and objectives: The anthropometric indicators of body composition which reflect the lean and fat body compartments of a pregnant woman are modified along gestation, due to which the use of percentile distribution values for each gestational age is necessary. The purpose of the study was to determine the percentile distribution of skinfolds (biceps, triceps, subscapular, thigh) and fat and muscle areas.

Methods: This cross-sectional study included 4,550 measurements of anthropometric variables in pregnant women between ages 19 and 39 years, who were well-nourished, healthy, without edema, with single pregnancy, and a validated gestational age of ≤ 13 weeks at admission, evaluated at Centro de Atención Nutricional Infantil Antímamo – CANIA from October 1998 to July 2012. The anthropometric measurements were made by standardized anthropometrists. Descriptive statistics and percentiles 3, 10, 25, 50, 75, 90 y 97 were calculated for each gestational age between the 8th and 37th weeks of gestation.

Results: The number of measurements made for each studied variable ranged between a minimum of 102 and a maximum of 244 per gestational age. The behavior of the studied variables reflecting the fat component showed increases as the gestational age advanced, whereas the muscle area showed decreases. The most noticeable variations were observed in subscapular and thigh skinfolds, as well as in the fat area. Changes in the variables referred to in the 50th percentile were: skinfolds (mm): biceps 1.3, triceps 1.4, subscapular 2.8, and thigh 5.0; and areas (cm²): fat 2.18 and muscle -0.16.

Conclusions: The percentile distribution of anthropometric variables of body composition for each gestational age is a necessary tool in the anthropometric evaluation of a pregnant woman as it allows for an adequate interpretation of the values of variables to correctly classify her nutritional status.

Key words: Percentiles distribution, pregnancy, anthropometry, body composition, nutritional assessment.

GROUNDWATER IRON IN BANGLADESH: DOES IT CONTRIBUTE TO POPULATION IRON NUTRITION?

S. Rahman¹, T. Ahmed¹, A S. Rahman¹, N. Alam²

¹Centre for Nutrition and Food Security, icddr,b, Dhaka, Bangladesh

²Centre for Population Urbanization and Climate Change, icddr,b, Dhaka, Bangladesh

Background and objectives: Bangladesh is a country with high prevalence of anemia, and iron deficiency is believed to be high. The present data on iron status of the population was collected as part of the first ever national survey on micronutrients in 2011-2012 in Bangladesh.

Methods: 150 clusters - 50 each from rural, urban, and urban slum strata, were systematically selected from the Multiple Indicator Cluster Sampling (MICS) of 2009. Prevalence of iron deficiency was assessed in preschool age children (6-59 months, Pre SAC), school age children (6-14 years, SAC) and non-pregnant, non-lactating women (NPNLW, 15-49 years). Serum ferritin was assessed by ELISA. CRP and AGP were measured and ferritin was adjusted for infection. Iron deficiency was defined as serum ferritin < 12 ng/ml in the Pre SAC and < 15 ng/ml in the SAC and NPNLW. The British Geological Survey report of 2001 was used as reference for groundwater iron status of Bangladesh.

Results: Prevalence of iron deficiency was 10.7% and 7.1% in the Pre SAC and NPNLW, respectively and 3.9% and 9.5% in the SAC aged 6-11 years and 12-14 years, respectively. Mean ferritin was higher in the areas with “high” groundwater iron than in the areas with “low” iron in the groundwater ($p < 0.001$ in all the population groups). Multiple regression analysis confirmed “high” groundwater iron as an independent predictor of serum ferritin in all groups (NPNLW: $t = 4.33$, $p < 0.001$; SAC: $t = 2.64$, $p = 0.009$; Pre SAC: $t = 3.35$, $p = 0.001$). A contemporary study in Bangladesh also found very low prevalence of iron deficiency in Bangladesh women, and attributed it to high groundwater iron consumed through drinking water.

Conclusion: Prevalence of iron deficiency was found to be lesser than the widely held assumption. High level iron from drinking groundwater might be associated with lower prevalence of iron deficiency in Bangladesh.

IDENTIFYING KEY FOOD SOURCES OF VITAMIN A, IRON AND ZINC AND POTENTIAL FOOD FORTIFICATION VEHICLES IN BANGLADESH

O. Bermudez¹, J. Fiedler², K. Lividini²

¹Tufts University School of Medicine, Boston, USA

²HarvestPlus, International Food Policy Research Institute (IFPRI), USA

Background and objectives: Bangladesh (BD) has made remarkable progress in improving health of its people over the past three decades. Progress in nutrition has been much slower. We aimed at a national evaluation in BD assessing apparent food consumption patterns and intakes of energy (E) and the micronutrients (MN): vitamin A (VitA), iron (Fe) and zinc (Zn) with the goal of identifying food vehicles for fortification.

Methods: We used the BD 2010 national household consumption and expenditure survey (HCES), with 12,240 households (hhold) and 55,580 individuals. With socio-demographic and food acquisition data from 14 days plus a nutrient database for BD, we calculated hhold distributions of food and nutrient intakes with adult consumption equivalents. Comparing the usual intakes to age/sex-specific estimated average requirements, we estimated prevalences of inadequate intakes using the cut-point (VitA and Zn) and the probability (Fe) methods. Results were stratified by region, urban/rural and poverty groups.

Results: Rice (68%) was the main source of E, followed by oils and fats (9%) and wheat flour (6%). For vitA, main sources were vegetables (66%) and milk and dairy (10%). Main contributors for Fe were vegetables, rice and wheat flour while sources of Zn were rice, vegetables and meats. Inadequate intakes of micronutrients were detected in 67%, 36% and 42% of the population for VitA, Fe and Zn, respectively. The most affected population was the hard-core poor, with inadequate intakes observed among 87% (VitA), 61% (Fe) and 77% (Zn) of them.

Conclusions: This paper contributes to laying a foundation for better understanding nutrition status in Bangladesh. Taking into account the industrial structure of candidate food vehicles, and focusing only on food purchase we identified potential fortification vehicles and estimate the coverage and quantity of the potential vehicles consumed.

Key words: Bangladesh, food consumption, micronutrient fortification

ADOLESCENT GIRLS IN INDONESIA ARE AT RISK OF INADEQUATE MICRONUTRIENT INTAKES

R. Indriasari¹, S K. Hamid¹

¹Nutrition Department, Faculty of Public Health, Hasanuddin University-Indonesia

Background and objectives: Due to their specific eating habits and lifestyles, adolescents were commonly at risk for low micronutrient intakes that may result in greater risk of micronutrient deficiencies. Adolescent girls have to consume adequate nutrition to support their rapid growth and development as well as to ensure good pre-conception nutritional status. Previous research on adolescent girls in many countries has shown that this group always did not meet the recommended values for some important micronutrients. Data on micronutrient intakes among Indonesian adolescent girls is limited, particularly those derived from large scale studies.

Methods: Analyses were undertaken on consumption data of 20030 adolescent girls derived from the national survey, RISKESDAS (Basic Health Research) 2010. Micronutrient intakes were calculated based on Indonesian food composition data using NUTRISOFT program. Micronutrient adequacies were determined according to the Indonesian recommended daily allowance 2004 and WHO references 2004. ANOVA test was performed to determine differences in average micronutrient intakes and Chi-Square test was performed to determine differences in risk of micronutrient inadequacy according to age groups, residential location, pregnancy, and menstruation status.

Results: The girls' daily micronutrient intakes (vitamin A, vitamin C, Folic Acid, Iron, Zinc, and Calcium) were low and differences were observed by age, residential location, pregnancy status, and menstruation status ($p < 0.05$, ANOVA). The prevalence of inadequate micronutrient intakes were high (above 90%) and differences were observed by age, residential location, pregnancy status, and menstruation status ($p < 0.05$, Chi-Square).

Conclusions: Indonesian adolescent girls were at risk of low micronutrient intakes that may contribute to greater risk of micronutrient deficiencies. Age, residential location, pregnancy, and menstruation, could contribute to the low intakes.

Key words: micronutrient, adolescent girls, Indonesia

THE MAIN GROWTH PARAMETERS OF 7 AND 8 YEAR-OLD LITHUANIAN CHILDREN IN HISTORICAL PERSPECTIVE

A. Petrauskien¹, E. Albavi¹, V. Žaltausk¹

¹Institute of Health Research, Academy of Medicine, Lithuanian University of Health Sciences, Kaunas, Lithuania

Background and objectives: The monitoring of a growing child is important for diagnosis of overweight and obesity. The objective of this research was to evaluate the growth and nutritional status of 7-8 year old children and compare the results with previous surveys conducted in Lithuania.

Methods: Study was performed participating in the WHO Childhood Obesity Surveillance Initiative. A cross-sectional anthropometrical study of a national representative sample of first-formers was performed in ten districts of Lithuania. In 2008 4939 and in 2010 4986 first-formers were anthropometrically measured (response rate 85.2% and 83.1% respectively). As there were no significant differences among the data on nutritional status of first-formers in 2008 and 2010 year, the final sample of 9790 7-8 year old children was used for the analyses. Nutritional status was evaluated by BMI using the growth reference recommended by the International Obesity Task Force (IOTF).

Results: The estimated mean values of body mass index (BMI) of surveyed 7 and 8 year old boys were higher than the values of girls. In 2008-2010 the prevalence of overweight and obesity among 7 and 8 year old children was 11.5%/11.7% and 5.9%/4.7% respectively. Analyzing by gender no differences were found in nutritional status of seven and eight year old boys. But the percentage of obese girls in the age group of seven was 1.4 times more if compared with the age group of eight ($p=0.01$).

Conclusion: The mean values of height, weight and BMI of 7 and 8 year old children were higher in comparison with previous studies conducted in 1985 and 2000.

Key words: Obesity, children, nutritional status

CROSS-SECTIONAL ADIPOSITY AND LEAN MASS OF SIX MONTH OLD INFANTS DETERMINED BY DEUTERIUM OXIDE DOSE-TO-INFANT IN RURAL KENYA

S. Onyango-Omollo¹, S. Konyole¹, J. Kinyuru², B. Owuor³, N. Roos⁴, H. Friis⁴, B. Estambale¹, V. Owino¹

¹Institute of Tropical and Infectious Diseases, University of Nairobi, Kenya

²Jomo Kenyatta University of Agriculture and Technology, Kenya

³Catholic University of Eastern Africa, Kenya

⁴University of Copenhagen, Denmark

Background and objectives: Adiposity and lean mass in infancy can determine health status later in life. There is inadequate data on body composition in early infancy in resource poor settings. The aim of this study was to determine body composition of six month old infants in Mumias, Kenya.

Methods: A cross-sectional study of six month old infants $n=445$ sampled from three health centers in Mumias district in Kenya. Participants were dosed with 3g deuterium oxide (0.5g/Kg body weight). Saliva was collected from each infant before the oral administration of the dose (baseline sample) and then at 1-hour and 3-hours after administration. Deuterium enrichment in saliva was determined by Fourier Transformed Infrared Spectrophotometry.

Results: Mean weight was 7.5 Kg (95% CI: 7.4; 7.6). Mean Fat Free Mass (FFM) was 6.4 Kg (95% CI: 6.3; 6.5). Mean Fat Mass (FM) was 1Kg (95% CI: 1.0; 1.1). In secondary analysis, male infants had significantly greater FFM [6.6 ± 1.0 kg vs 6.2 ± 1.1 kg ($p<0.01$)] and weight [7.7 ± 1.1 kg vs 7.3 ± 1.0 kg ($p<0.01$)] compared to female infants.

Conclusions: Males have greater lean mass than girls as early as infancy. This study has contributed valuable information on adiposity and lean mass in early infancy in resource poor settings.

Key words: adiposity, lean mass accrual, deuterium dose-to-infant technique, Kenya

O042

DADIZEIN SOY ISOFLAVONE AND ITS GUT METABOLITE, EQUOL: A REVIEW OF ANIMAL AND HUMAN STUDIES.

S Edalati¹, F Bagherzadeh¹

¹Students' Research Committee, Faculty of Health & Nutrition, Tabriz University of Medical Sciences, Tabriz, Iran

Background and objectives: Several studies have shown that the hypolipidemic, antioxidant and bone maintenance properties of soy products are primarily due to the isoflavones component. Recent studies demonstrate that equol, a metabolite of the Isoflavone daidzein that is produced by the intestinal flora, may have therapeutic benefits. Not all humans can produce significant amounts of equol. Equol and its health benefits have been widely studied. This review article summarizes the analysis of articles on: 1) the identification of intestinal strains of bacteria capable of equol production *in vitro*; 2) modification of gut microflora in non equol-producers via probiotic or prebiotic administration; and 3) clinical trials examining natural S-equol supplements.

Methods: Articles including *in vitro* or animal studies as well as clinical trials published between 2000 and 2012 in the PubMed data base on these three topics were reviewed

Results: Various bacterial strains such as those from the bifidobacterium or lactobacillus families have been isolated from the feces of different animals and humans and are able to convert daidzein to equol *in vitro*. Most studies observed the ability of some strains of bacteria to shift a human from being a non-equol producer to the equol-producer phenotype; however, the results of human interventional studies on the effect of probiotics on equol production are inconsistent, likely due to differences in the dose or kind of probiotic strain used. Few clinical trials examine the S-enantiomer of equol from natural supplements and its protective action in metabolic syndromes or alleviating hot flashes in postmenopausal women.

Conclusions: Further studies are needed to evaluate if the equol producer phenotype is a fixed characteristic of an individual or if it may be subject to probiotic, prebiotic or synbiotic manipulation.

EFFECT OF FRUCTOOLIGOSACCHARIDES AND GALACTOOLIGOSACCHARIDES IN GERM FREE MICE

M. Ortega González¹, C J. Aranda¹, A. Zarzuelo², M D. Suárez³, F. Sánchez de Medina², O. Martínez-Augustín³

¹Department of Biochemistry and Molecular Biology II, School of Pharmacy, University of Granada, Granada, Spain

²Department of Pharmacology. School of Pharmacy, University of Granada and CIBERehd Granada, Spain

³Department of Biochemistry and Molecular Biology II, School of Pharmacy, University of Granada and CIBERehd, Granada, Spain

Background and objectives: Fructooligosaccharides (FOS) and galactooligosaccharides (GOS) are widely known prebiotics products, i.e. they favor the selective growth of host friendly bacteria *in vivo*. However, they can also exert direct effects on the intestinal mucosa. Here we test the effect of FOS and GOS enriched diets on germ free mice.

Methods: NMRI mice were fed with a 5% supplemented diet with either FOS or GOS (5%) for 4 weeks immediately after weaning. Some animals also received a sterile bacterial homogenate (SBH). Small bowel and colonic tissue were processed for the determination of enzymatic activities and hematoxylin-eosin staining. Immunoglobulins were measured in plasma with a multiplex kit. Colonic RNA was isolated and analysed by using an Illumina mouse WG-6 v2.0 array platform.

Results: GOS and FOS supplementation resulted in significant changes in disaccharidase activity in the intestine. An increase in microvilli length in small bowel and a decrease in liver weight was also observed. FOS significantly reduced IgG in plasma. At the genomic level GOS and FOS induced the differential expression of 254 and 306 sequences, respectively. SBH was added to some animals to reproduce the luminal presence of bacterial antigens, resulting in changes in the expression of 408 sequences. PRRX1 was upregulated by all treatments, while 9 genes were repressed in common, including endothelin 1 and the β/δ subunits of the epithelial sodium channel (EnaC). These are expressed at low levels in normal mice.

Conclusions: FOS and GOS have significant effects on the intestine of germ free mice and may help to reestablish normal water homeostasis in these animals.

Key words: genomics, prebiotic, germ-free mice

DEVELOPMENT OF MULTIFUNCTIONAL BAKERY BIO-INGREDIENTS CONTAINING TWO IMPORTANT VITAMINS, FOLATE AND B12

J. Sych¹, S. Miescher Schwenninger¹, F. Grattepanche², M. Kinner¹, M. Kleinert¹, C. Lacroix²

¹Institute of Food and Beverage Innovation, Zurich University of Applied Sciences, Switzerland

²Institute for Food, Nutrition and Health, ETH-Zurich, Switzerland

Background and objectives: Microorganisms and their metabolites produced by biofermentations offer interesting benefits for food applications, e.g. production of specific vitamins; biopreservation and reduction of E-numbers, and improved texture of foods. Two problematic vitamins in nutrition are folate and B12, especially among women of child-bearing age, the aging population and strict vegetarians. This study aimed to develop new, natural sources of these important vitamins as well as other functional substances for adding value to bakery products.

Methods: A co-culture technology (a) using strains of *Lactobacillus plantarum* and *Propionibacterium freudenreichii* selected for complementary carbon metabolism and high production of folate and Vitamin B12, respectively, was used to produce these vitamins along with anti-microbial compounds, mainly organic acids (propionic, acetic acids and others). The resulting mixture of multifunctional (MF) bio-ingredients was tested in Semmeli breads to assess stability and effects on product quality. Dough, partly- and fully-baked Semmeli were enriched with MF bio-ingredient at 0.1% or 0.2% equivalent propionate, levels shown to exert strong anti-microbial activity in previous work.

Results: The MF bio-ingredient contained vitamin 5-formyltetrahydrofolate, known to be metabolically active and shown in baking tests to have higher stability (ca 60% recovery) than endogenous folate (35% recovery) derived from flour. Production of liquid MF ingredient in cereal-based medium using optimal conditions led to levels of folate and B12 as high as ca 6000 ng/ml, and 1000 ng/ml, respectively. Most bread-making and final quality determinations were acceptable for industry applications, as shown by physico-chemical, texture and sensory analyses.

Conclusions: This co-culture technology and MF bio-ingredients have good potential for natural food fortification, allowing to reach or exceed vitamin levels required for EU authorized health claims. In addition to bringing innovation to the baking sector, it represents a new source for developing natural food supplements.

Key words: Functional ingredients, vitamin fortification, folate, vitamin B12 (a)2010 Hugenschmidt et al. Patent WO2010078670-A2 202010078670-A3

ANTI-INFLAMMATORY EFFECTS OF HYDROALCOHOLIC EXTRACT FROM EUTERPE OLERACEA MART. (AÇAÍ)

J. Daleprane¹, C. Costa², A. Rocha², A. Resende², R. Moura²

¹Department of Basic and Experimental Nutrition, Institute of Nutrition, State University of Rio de Janeiro, Brazil

²Department of Pharmacology and Psychobiology, State University of Rio de Janeiro, Brazil

Background and objectives: The consumption of polyphenol-rich foods is associated with a decreased risk of mortality from cardiovascular diseases. We have demonstrated that the stone of *Euterpe oleracea* Mart. (açai) from the Amazon region exerts vasodilator and antioxidant actions. The aim of this study was to evaluate its anti-inflammatory effects in an in vivo model of renovascular hypertension (RH) and in endothelial cells (ECs).

Methods: Rats were treated with ASE 200 mg.kg⁻¹.day (or vehicle) for 40 days. Oxidative damage, antioxidant activity and the expression of endothelial nitric oxide synthase (eNOS), superoxide dismutase 1 and 2 (SOD 1 and 2), metalloproteinase (MMP-2) and tissue inhibitor of metalloproteinases (TIMP)-1 were determined. Structural changes in the aortic and mesenteric MMP-2 levels were evaluated. In in vitro experiments, ECs were treated with 100 µg/mL of ASE and the expressions of inflammatory markers were evaluated.

Results: ASE reduced the increased mesenteric levels of malondialdehyde and carbonyl protein in hypertensive rats. SOD, catalase and glutathione peroxidase activities and SOD1 and 2, eNOS and TIMP-1 expressions were reduced. ASE prevented the vascular remodeling, as well as, the increased MMP-2 expression and levels found in hypertensive rats. In ECs ASE was able to decrease TNF α , eNOS and IL-8 mRNA expression.

Conclusions: These results suggest that ASE prevents the endothelial dysfunction and vascular structural changes associated with hypertension. Financial Support: FAPERJ.

COMPARING THE EFFECT OF PROBIOTIC AND CONVENTIONAL YOGHURT CONSUMPTION ON LIPID PROFILE IN PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE (NAFLD)

S. Nabavi¹, M. Rafrat², F. Bagherzadeh¹

¹Students' Research Committee, Faculty of Nutrition, Tabriz University of Medical Sciences, Tabriz, Iran

²Nutritional Research Center, Tabriz University of Medical Sciences, Tabriz, Iran

Background and objectives: Non-alcoholic fatty liver disease is frequently associated with obesity. The purpose of this study was to investigate the effects of probiotic and conventional yogurt on the lipid profile in non-alcoholic fatty liver disease people.

Methods: In a randomized double-blind controlled trial, 72 people (33 males and 39 females) with non-alcoholic fatty liver disease were assigned to 2 groups. Participants consumed daily 300 g of probiotic yogurt containing *Lactobacillus acidophilus* La5 and *Bifidobacterium lactis* Bb12 or 300 g of conventional yogurt for 8 wk. Fasting blood samples, anthropometric measurements and 3-d, 24-h dietary recalls were collected at the baseline and at the end of the trial.

Results: Probiotic yogurt consumption caused a 8.4% decrease in total cholesterol and a 7.45% decrease in LDL-C compared with the control group. No significant changes from baseline were shown in triglyceride and high-density lipoprotein cholesterol (HDL-C) in the probiotic group. Probiotic yogurt improved total cholesterol and LDL-C concentrations in non-alcoholic fatty liver disease people.

Conclusion: The consumption of fermented milks with specific probiotics may contribute to the improvement of cardiovascular disease risk factors in non-alcoholic fatty liver disease.

Key words: probiotic yogurt, lipid profile, non-alcoholic fatty liver disease

O047

ROLE OF POLYPHENOL JUICE DRINKS IN THE PREVENTION OF POSTPRANDIAL INFLAMMATORY STRESS IN HUMANS

M. Serafini¹, F. Ioannone¹, A. Raguzzini¹, G. Catasta¹, E. Toti¹

¹CRA-Ex-INRAN, Rome, Italy

Background and objectives: In western societies where most of the day is spent in the postprandial state, the existence of higher oxidative and inflammatory stress, as a result of sustained dietary hyper-lipidemia and glycemia, make postprandial stress a factor involved in the development of cardiovascular risk. The response to a High Fat Meal (HFM) is mediated by pro-inflammatory cytokines, glycemia/insulin and oxidized lipids. We investigated the effect of a dietary stressor (HFM) with and without Polyphenol-Containing Juice Drinks (PJD) composed by multiple fruit juice and extracts, on markers of lipid metabolism, redox and inflammatory status in healthy overweight volunteers.

Methods: HFM was 1344 kcal meal delivering 55% energy as fat, 30% as carbohydrates and 15% as protein. In a double-blind, crossover design (10-day washout) 14 overweight volunteers were randomly assigned to HFM+500 ml placebo-beverage free from fruit juice or extracts or HFM+500 ml PJD.

Results: The ingestion of a HFM induced a clear increase in inflammatory cytokines [IL-6 ($p < 0.001$); TNF- α ($p < 0.001$)], cholesterol ($p < 0.01$), triglycerides ($p < 0.001$), glucose ($p < 0.001$) and insulin ($p < 0.001$) plasma levels. The ingestion of a HFM in conjunction with PJD strongly reduced the production of inflammatory cytokines TNF- α and IL-6 with a concomitant reduction of the metabolic redox response to inflammation and with a decline in the absorption of cholesterol and triglycerides, the efficiency of which was related to antioxidant and polyphenol composition.

Conclusions: The ingestion of PJD provided the body with an exogenous and ready to use source of redox ingredients that helped the body better cope and neutralize metabolic pathways leading to inflammatory stress as a consequence of the HFM. The results of the study and a review of the available evidence on the effect of plant foods on postprandial stress, will be presented and critically discussed.

Key words: fruit-juice drink, triglycerides, inflammation, human, postprandial stress.

O048**THE EFFECT OF DAILY ORANGE JUICE CONSUMPTION ON BLOOD LIPIDS, IN OVERWEIGHT MEN***E. Simpson¹, I. Bennett¹, I. Macdonald¹*¹School of Biomedical Sciences, University of Nottingham, Nottingham, UK

Background and objectives: There is concern in the media regarding citrus consumption and possible adverse effects of fructose on blood lipid profile. Short-term high fructose feeding studies have induced increases in triacylglycerol concentration. However, high dose citrus supplementation has been shown to decrease LDL in hypercholesterolemic patients. The objective was to investigate the effect of daily orange juice consumption on blood lipids, in overweight men, using a randomised, single-blinded, parallel group design.

Methods: Thirty-six overweight, but otherwise healthy men (40-60yrs; 27-35kg/m²), with elevated fasting serum cholesterol (5-7mmol/l), were recruited from the general population. None were taking lipid-lowering medication, using nutritional strategies to lower cholesterol, or regular consumers of citrus products. Assessment of fasting total cholesterol, LDL, HDL, non-esterified fatty acids, triacylglycerol, APO-A1 and APO-B concentrations, was made before (V1) and after (V2) participants consumed 250ml/day of orange juice (OJ), or an orange flavoured drink (CON) for 12wks. Drinks were matched for energy and sugars composition. Normally distributed data are presented as the mean (\pm SD).

Results: The two groups were matched at V1 with respect to all parameters ($P>0.05$). No variables changed significantly between visits within groups, and no differences were observed between groups, at V2. However, a numerical increase in triacylglycerol concentration at V2 (compared to V1) in CON (+0.22(0.17) mmol/l), and a corresponding numerical decrease in OJ (-0.24(0.13) mmol/l), resulted in a significant intervention effect for this variable ($P<0.05$). Moreover, in OJ, those with the highest initial triacylglycerol concentration, showed the greatest reduction after 12 wks supplementation ($r^2=0.476$; $P<0.01$), whereas there was no correlation in these variables in CON ($r^2=0.121$; $P=0.157$).

Conclusions: Three months' daily consumption of a drink containing 22 g of sugars (including 12g of fructose), did not adversely affect fasting blood lipids. Daily consumption of 250 ml of orange juice may help reduce elevated triacylglycerol concentration.

Key words: orange juice, fructose, blood lipids

O049**A FRAXINUS EXCELSIOR L. SEED EXTRACT, FRAXIPURE® HAS FAVORABLE EFFECTS ON GLUCOSE HOMEOSTASIS IN ELDERLY OVERWEIGHT SUBJECTS***J. Flanagan¹, M.A. Zulet², S. Navas-Carretero², D. Lara Y. Sánchez², I. Abete², M. Roller¹, N. Issaly³, J.A. Martínez¹*¹Naturex S.A, Avignon, France²Dpt of Nutrition, Food Science and Physiology, University of Navarra Pamplona, Spain³Naturex Spain S.L. Valencia, Spain

Background and objectives: Botanical extracts with biologically active compounds may have positive effects on body homeostasis and have been reported to treat different metabolic impairments. In this context, an extract obtained from seeds of the European ash tree (*Fraxinus excelsior* L; Oleaceae) was investigated in order to determine the potential benefits on insulin sensitivity in overweight/obese subjects.

Methods: The intervention study was carried out in 22 participants (50-80 years-old) with an initial BMI <40.0 kg/m² (mean value at baseline 31.0 kg/m²), who followed a balanced covert energyrestricted diet (-15% Energy) for 7 weeks. The design was a longitudinal, randomized, crossover, and double-blinded nutritional intervention, with a one week wash-out period between the 2 intervention periods of 3 weeks. Experimental groups were administered 1 g daily of either placebo capsules (control) or capsules containing an extract from *Fraxinus excelsior* L. seeds (FraxipureR). Anthropometrical and biochemical measurements were performed at the beginning and at the end of the interventions for both cross-over periods.

Results: Statistical analysis revealed that administration of 1 g of FraxiPureR for 3 weeks resulted in significantly lower glucose AUC values ($p<0.005$) while no significant change was observed in the placebo group (-13.9% vs. -3.9%). Interestingly, fructosamine levels were significantly reduced by the ash tree seed extract (-4.13 fÉmol/L vs. 7.51 fÉmol/L ; $p<0.004$) as compared to placebo. The experimental product administration produced no relevant changes on body weight and lean mass as compared to the control, but the fat content was significantly reduced (-1.26% vs. -0.19 %; $p=0.042$) by the botanical extract compared to placebo.

Conclusions: The administration of an extract from *Fraxinus excelsior* L. seeds in combination with a hypocaloric diet induced favorable effects in glucose homeostasis in overweight/obese subjects.

Key words: FraxiPureR, Glucose homeostasis, Fructosamine, Elderly This study was financed by Naturex and the Spanish Centre for the Development of Industrial Technology (CDTI) as part of the SENIFOOD project, which belongs to the CENIT subvention program.

RELAPSES FROM ACUTE MALNUTRITION IN A COMMUNITY-BASED MANAGEMENT PROGRAM IN BURKINA-FASO

Y E. Somasse¹, M. Dramaix¹, P. Bahwere¹, P. Donnen¹

¹Ecole de Santé Publique, Université Libre De Bruxelles, Brussels, Belgium

Background and objectives: Community-based Management of Acute Malnutrition (CMAM) is an effective strategy for treating Severe Acute Malnutrition (SAM) (WHZ<-3) or Moderate Acute Malnutrition (MAM) (WHZ<-2). However, post-discharge follow-up often lacks. We aimed to assess the relapse rate and the related factors in a CMAM program in Burkina-Faso in which children without medical complications and who have good appetite are treated in their village by community volunteers with a Ready-To-Use-Therapeutic food (for SAM) or Corn Soya Flour (for MAM).

Methods: In one-stage cluster design, the retrospective cohort data for recovered children (WHZ>-2) who were discharged from the program between January 2010 and July 2011 were collected in 45 villages of 210 in January 2012. Children were asked after discharge to return to the community center for follow-up every three months. A questionnaire including sociodemographic and economic variables and information on household food availability (for Household Food Insecurity Access Scale) and the child's food consumption in the last 24 hours (qualitative recall for dietary diversity score) was administered. A multivariate Cox model regression was used to identify the relapse predictors.

Results: Of the 509 children, 14 have died and 123 were lost to follow-up. Children admitted with SAM were more likely to die after discharge. The relapse rate was 14.2 per 100 children-years and the predictors were no oil/fat consumption in the last 24 hours, a mid-upper arm circumference (MUAC) <125mm at discharge, incomplete vaccination and illiteracy of mothers.

Conclusions: The CMAM program should avoid premature discharge (before a MUAC of at least 125 mm) to limit relapses. Nutrition education for mothers should focus on the role of nutrients especially fat as important energy component of diet for children. Promoting good immunization and fighting against illiteracy are essential to promote child growth.

Key words: acute malnutrition, community-based management, relapse, related factors.

O051

NATIONAL DIETARY SURVEY (NDS): FAMILIAL AGGREGATION OF DIETARY PATTERNS IN BRAZIL

F. Albernaz¹, E. Yokoo¹, D. Cunha², A P. Muraro², B. Souza², R. Sichieri²

¹Institute of Community Health of Fluminense Federal University, Niterói, Rio de Janeiro, Brazil

²Institute of Social Medicine, Rio de Janeiro State University, Rio de Janeiro, Brazil

Background and objectives: Over the time, new dietary patterns have been established and associated with aspects involved in the increase of chronic non-communicable diseases, such as environmental, cultural and behavioral factors, and not only the genetic component. The identification of the familial aggregation of dietary patterns is important for clarifying this situation yet poorly understood. The objective of this study was to identify dietary patterns consumed in Brazil and their possible correlation among members of the same family (father, mother and children).

Methods: It was used the database of the NDS, a nationwide survey conducted in 2008/2009, with individuals of both sexes and more than 10 years old of age. Dietary intakes were estimated based on two food records and the total 1,120 foods cited was classified into 27 groups, according to similarity in content and frequency of consumption. Dietary patterns were identified by using factorial analysis and the familial aggregation by their correlations. Both procedures were executed considering the complexity of the sample survey and the expansion of the data, using the software SAS 9.3.

Results: Three major dietary patterns were identified: Traditional coffee break (1): coffee, breads, cheeses and oils and fats; Traditional main meal (2): rice, beans and other legumes and meats; Fast food type meals (3): sandwiches, processed meats, soft drinks, snacks and pizzas. Highest correlations occurred in Pattern 2 for all family pairs investigated. In Pattern 3 were found inverse correlations with: mother/daughter and mother/son.

Conclusion: It was found familial correlation in Pattern 1, showing the importance of family influence on traditional food. However, children have an inverse relationship with mothers considering the Pattern 3, which suggests greater adhesion of the new generation to contemporary habits, therefore food consumption modification in Brazil.

Key words: dietary pattern, familial aggregation, national survey

O052

THE MEDITERRANEAN DIET IMPROVES THE LOW-DENSITY LIPOPROTEIN PARTICLE SIZE PHENOTYPE IN MEN WITH METABOLIC SYNDROME

C. Richard¹, P. Couture¹, S. Desroches¹, B. Lamarche¹

¹Institute of Nutrition and Functional Foods, Laval University, Quebec, Quebec, Canada

Background and objectives: Studies have indicated that individuals with small, dense low density lipoprotein (LDL) particles are at increased risk of cardiovascular disease. The impact of the Mediterranean diet (MedDiet) on various electrophoretic characteristics of LDL particles has not been extensively studied to date. The objective of the study was to investigate the effect of the MedDiet without weight loss (-WL) and with weight loss (+WL) on various features of the LDL particle size phenotype in men with metabolic syndrome (MetS).

Methods: The diet of 19 men with MetS (NCEP-ATP III, age 24-62 years) was first standardized to a typical North American control diet that they consumed for 5 weeks under isoenergetic feeding conditions (all foods and beverages provided). Subjects were then fed a MedDiet for 5 weeks also under isoenergetic conditions (MedDiet-WL), after which they underwent a 20-week weight loss period in free-living conditions (average weight loss $-10.2 \pm 2.9\%$ body weight, $P < 0.01$). This was followed by consumption of the MedDiet (5 weeks) under isoenergetic conditions (MedDiet+WL). Features of the LDL size phenotype were determined at the end of each isoenergetic feeding period by polyacrylamide gradient gel electrophoresis.

Results: MedDiet-WL led to a significant increase in LDL-peak particle diameter (LDL-PPD, +0.7%) and in the proportion of medium size LDL (LDL₂₅₅₋₂₆₀ Å, +11.1%) and reduced the proportion of small dense LDL (LDL_{<255} Å, -11.7%) vs. the control diet (all $P < 0.05$). MedDiet+WL was associated with a further increase in LDL-PPD (0.2%, $P < 0.05$) but had no further impact on the proportion of small dense LDL compared with MedDiet-WL.

Conclusions: Data from this controlled feeding study suggest that consumption of MedDiet, even in the absence of weight loss, beneficially alters the atherogenic properties of LDL particles in high risk men with MetS.

Key words: Mediterranean diet, metabolic syndrome, weight loss, LDL particle size.

O053

IMPACT OF FORTIFIED FOODS DURING LAST DECADE IN THE NETHERLANDS

C. Van Rossum, J. Verkaik-Kloosterma, M. Beukers, S. Westenbrink

National Institute For Public Health and The Environment (RIVM), Bilthoven, The Netherlands

Background and objectives: Since 2006 the addition of vitamins and minerals is regulated in the European Union. This regulation may affect the composition of foods and intake of micronutrients.

Objective: To get insight in the impact of the addition of micronutrients in foods on intake in the Netherlands during the last decade.

Methods: Consumption data and nutrient data from the Dutch National food consumption surveys among young adults aged 19-30 years (2003, n=750) and the general population aged 7-69 years (2007-2010; n =3819) was used. The consumption of fortified foods, the contribution of fortified foods to the intake of micronutrients before and after the implementation of the regulation was estimated.

Results: Among young adults the consumption of fortified foods increased from 2003 to 2007-2010; the number of fortified foods has increased and these products were consumed more often. Also, the contribution of fortified foods to micronutrient intake of young adults and the absolute micronutrient intake amount from fortified foods increased during the last decade. The most recent data from the general population shows that children were more often consumers of fortified products compared to adults. The main food groups enriched with micronutrients are spreads, dairy products and non-alcoholic beverages. In addition, it showed that these fortified foods contributed most to the intake of vitamins and less to the intake of minerals. For vitamin D more than 35% of the intake was derived from fortified foods. For retinol, vitamin E, Vitamin B6, this was about 20-25%.

Conclusion: Since the EU-regulation on addition of vitamins and minerals, the consumption of fortified foods is increased in The Netherlands. These products contributed most to the intake of vitamins. The main food groups enriched with vitamins and minerals are spreads, dairy products and non-alcoholic beverages.

Key words: fortified foods, trends, vitamins, minerals, food consumption survey

FOOD SECURITY AND NUTRITIONAL STATUS OF FISHING COMMUNITIES IN THE BOLIVIAN AMAZON BASIN

S. Baker French¹, J. McLean¹, T. Perez², T. Green¹, J. Carolsfeld³

¹Faculty of Land and Food Systems, University of British Columbia, Vancouver, Canada

²Faunagua Association, Cochabamba, Bolivia

³World Fisheries Trust, Victoria, Canada

Background and objectives: The Bolivian Amazon, among the poorest regions in Latin America, is undergoing a 'nutrition transition,' facing both under and over nutrition. Fishing communities are thought to be at particularly high risk of malnutrition, despite the availability of high quality protein. However, household food security and nutrition status of households in these communities is unknown. Our objectives were to measure household food security as well as maternal and child height and weight among urban and rural fisher communities along the Bolivian Amazon Basin.

Methods: A cross-sectional survey was conducted among 410 urban and 401 rural households in the low-water season (October-November). A subset of seasonally sensitive questions was repeated among 186 urban and 297 rural households in the high-water season (February-March). Interviewers collected information on demographics, dietary intake and food security status. Height and weight were determined for mothers and their youngest child under five.

Results: Food insecurity, as measured by the Household Food Insecurity Access Scale, was reported by 55% of the urban households in the low-water and 38% in the high-water seasons, ($p=0.001$). Rural households reported similar food insecurity in both seasons (66.7% and 60.9% respectively, $p=0.12$). Similarly, urban household dietary diversity averaged 9.2 and 8.7 on a 12 point scale in the low-water and high-water season ($p=0.001$), respectively. In the rural population dietary diversity was 7.3 in the low-water and 7.1 in the high-water seasons, ($p=0.13$). Less than 10% of children and 4% of women were wasted or underweight. However, among urban and rural populations 30% and 44% of children were stunted and 56% and 45% of women were overweight or obese, respectively.

Conclusions: High levels of food insecurity, childhood stunting and maternal overweight are present in urban and rural fishing communities of the Amazon Basin.

Key words: Food insecurity, childhood malnutrition, dietary diversity.

O055

WEIGHT OF MODERNITY PART II: THE NUTRITION AND HEALTH IMPLICATIONS OF THE DISAPPEARING AUSTRALIAN DESSERT

C. Banwell¹, J. Dixon¹, A. Davies¹, D. Broom¹

¹National Centre For Epidemiology and Population Health, Australian National University, Canberra, Australia

Background and objectives: A simple, home-made sweet dessert, following the savoury main course, was a traditional part of the Australian family meal until the last few decades. We examine the social, economic and technological changes that have contributed to disappearance of dessert from the family menu.

Methods: This study is based upon a unique set of more than 111 qualitative, in-depth interviews conducted face to face with three generations of Australians whose lives span most of the 20th century and into the 21st century.

Results: Increasingly, middle-aged and younger Australians eat commercially produced sweet and savoury food products at home and in the form of takeaway, and at restaurants and cafés. Older Australians are more likely to retain their traditional food habits. While the dessert is now rarely part of the family meal, sweets, cakes and confectionary are likely to be eaten at any time and in any place. Some participants thought the disappearance of desserts was healthy while others were not so sure. Meanwhile, Australian domestic sugar consumption has declined somewhat.

Conclusions: The disappearance of dessert illustrates the complexity of untangling shifting socio-cultural food practices in the context of broad social change. We discuss what the disappearing dessert means for Australians' health in light of the rising prevalence of obesity.

Key words: Obesity, Australian family meal, sugar.

O056

DIETS OF MALIAN AND MOROCCAN PEOPLE LIVING IN THEIR HOME COUNTRIES AND IN FRANCE AND ITS ASSOCIATION WITH ECONOMIC STATUS

S. Fortin¹, E. Landais¹, N. Hibbi², M. Lebrun³, N. Calandre⁴, A. Derouiche², N. Bricas³, B. Maire¹

¹UMR 204 Nutripass, IRD-UM2-UM1 - Institut De Recherche Pour Le Développement (IRD), Montpellier, F-34 394, France.

²Laboratoire de Recherche sur les Lipoprotéines, Faculté des Sciences Ben Msik, Casablanca, Maroc

³UMR Moisa, CIRAD, Montpellier, France

⁴UMR 8177, EHESS-CNRS, Centre Edgar Morin, Paris, France

Background and objectives: Little is known about changes due to migration both within a country (from rural to urban) and outside a country (from home country to host country). The present study focussed on dietary diversity of Malian and Moroccan people living in their home countries and in France and its association with economic status.

Methods: Cross-sectional surveys were conducted in 2010 among Malian and Moroccan households living in urban Ile-de-France (IdF) and in rural and urban areas of Mali (the area of Kayes and Bamako respectively) and Morocco (the Souss and Casablanca respectively). In each area, 300 households were surveyed. Diet was assessed using an Individual Dietary Diversity Score (IDDS) based on 12 food groups consumed/24h. Economic characteristics were collected to classify households into 5 ordered groups.

Results: The mean IDDS was 7.2 for Malians and 7.7 for Moroccans. Compared to urban areas, the IDDS was better in both rural Mali (7.7 vs. 6.4, $p < 0.01$) and Morocco (7.8 vs. 7.3, $p < 0.01$). In IdF, the mean IDDS was 7.5 for Malians and 8.2 for Moroccans. Compared to rural Moroccans, Moroccans in IdF had greater IDDS ($p < 0.01$). IDDS increased with economic status in rural and urban Mali (6.8 to 9.1, $p < 0.01$ and 6.0 to 7.1, $p < 0.01$, respectively) and in rural and urban Morocco (6.5 to 9.0, $p < 0.01$ and 6.5 to 8.3, $p < 0.01$, respectively) but decreased for Malian people living in IdF (8.0 to 7.1, $p = 0.04$).

Conclusions: In home countries, IDDS was better in rural compared to urban areas. Whilst it increased with economic status in Mali and Morocco, it decreased for Malian people living in IdF. Dietary diversity and its association with economic status depend on living areas and might depend on the stage of the nutrition transition as well.

Key words: Dietary diversity, economic status, home and host countries.

O057

UPGRADE ON THE NUTRITIONAL TRANSITION IN BOLIVIA

F J A. Perez-Cueto¹

¹Aalborg University, Meal Science and Public Health Nutrition Research Unit (MENU), A.C.Meyers Vænge, Copenhagen, Denmark

Background and objectives: Latin America is a region that experienced the paradox of economic growth together with social instability in the past decade. This has contributed to rising levels of overweight and the abandonment of traditional diets. The objective of this study is to upgrade the evidence regarding the trends in overweight and obesity in women of childbearing age, and to describe ecologically disparities in food availability within the country.

Methods: Secondary analysis of nationally representative Bolivian Demographic and Health Surveys (DHS) 1994, 1998, 2003 and 2008 to upgrade overweight and obesity trends in women of childbearing age. Datasets have been made available by Measure DHS. Previous estimations of household food availability have been updated with data from the nationally representative Household Surveys of 2005, 2008 and 2009, available publicly through the Bolivian National Statistic Institute.

Results: DHS survey data revealed a steady raising trend in levels of overweight and obesity among women in childbearing age (20–45 years), reaching 50% if both combined by 2008 and revealing disparities. The increment in overweight levels was more pronounced if women were poor, uneducated or dwellers of rural areas. Underweight remained below 2%, although it is concentrated in women between 15–30y. Household Survey data highlighted the “within-country” disparities in food availability that could be ecologically associated to the observed nutritional status. Rural households systematically recorded lower amounts of food available. Households in lower income quintiles recorded higher availability for potatoes and cereals.

Conclusion: This overview highlights that Bolivia is further into the nutrition transition, with half of the women being overweight. Further, underscores the importance of including prevention of weight gain in future Bolivian public health nutrition policies, together with the promotion of traditional diets, mostly based on foods of plant origin.

Key words: Bolivia, Nutrition Transition, Women, Demographic and Health Surveys.

INFLUENCE OF PROXIMATE VALUES ON VITAMIN A STABILITY OF NIGERIAN WHEAT FLOUR AND BREAD

F. Uchendu¹, D. Oyewole², T. Atinmo²

¹National Open University of Nigeria, Lagos

²University of Ibadan, Ibadan, Nigeria

Background and objectives: Nigeria embarked on a mandatory vitamin A fortification of wheat flour (30 IU/g or 9.0µgRAE/g) to eradicate vitamin A deficiency (VAD). Study aimed at determining influence of proximate values on vitamin A stability in wheat flour and bread.

Methods: Retinyl palmitate content of sixteen and fourteen samples of commercial wheat flour and bread respectively were randomly selected from bakeries in four Local Government Areas in Lagos Metropolis. Samples were analyzed at 0, 5 days (bread) and 0, 30 days (wheat flour) respectively at room temperature using High Performance Liquid Chromatography. Proximate analysis was done using AOAC, (2005). Results were analyzed using SPSS 17.0.

Results: Vitamin A stability was 0-83% (wheat flour) and 0-68% (bread). Mean proximate values for wheat flour were 0.88±0.18; 0.77±0.09 (ash contents) and 12.51±0.16; 13.10±0.55 (moisture contents) at zero and 30 days storage respectively. Mean proximate values for bread were 1.78±0.25; 1.68±0.24 (ash) and 24.74±2.6; 31.30±2.24 (moisture) at zero and 5 days storage respectively. There was an inverse relationship between vitamin A content of wheat flour samples and proximate values which was not statistically significant ($F = 0.857$; $P = 0.447$). However, there was a statistically significant difference between the ash content of flour at zero and 30 days storage ($P < 0.05$). Statistical significant relationship also existed between vitamin A, ash and moisture contents of bread at 0 and 5 days ($p < 0.05$).

Conclusion: Proximate values influenced vitamin A content and stability in flour and bread. For adequate vitamin A stability in wheat flour, extraction rate and ash content must be lower than standard for normal flour. Copper content should be zero. Adequate total quality control must be insured.

Key words: Vitamin A, retinol, wheat flour, bread.

O059

THE DISTRIBUTION AND CONTENT OF FOUR PURINES IN 600 COMMON FOOD

Y. Yang¹, H. Pan^{1,2}

¹Institute of Nutrition and Food Safety, Chinese CDC

²Department of 2 Hygiene Inspection, School of Public Health, Harbin Medical University, Heilongjiang, China

Background and objectives: Eating habits and gout incidence in large number of men it was found to be due to eating food rich in purines. The aim of study was to determine the four purines content in a variety of food items in China.

Methods: Near 600 food samples including animal and plant food selected from the supermarket China. The HPLC test method were optimized and used to determine the content of purines include adenine, guanine, hypoxanthine, and xanthine in common foods and cooking food.

Results: The content of purine varied significantly among different kinds of food. Totally shrimps is the highest food containing purines; the purine content in visceral organs was 2.5 times higher than in meats, liver: 2752 mg/kg; duck liver: 4150 mg/kg, similar with Mussel meat. The main component are guanine and adenine in livers, hypoxanthine is higher in meats. The content of purine in dried fungi and dried legumes and legumes products were higher than other plant foods, The content of purine in vegetables and vegetables products and fruit and fruit products was low.

Conclusions: As a whole, the content of purines was in the shrimps > livers > meats > dried fungi and algae > dried legumes and legumes products > nuts and seeds > fresh fungi and algae > cereals and cereals products > vegetables and vegetables products > fruit and fruit products > tubers, starches and products.

Key words: Purine content and components; animal and plant foods; HPLC.

NUTRITIONAL AND TOXICOLOGICAL ANALYSES OF LEAVES AND FRUITS OF SOLANUM MACROCARPON LINN (SOLANACEAE) IN COTONOU (BENIN)

V. Dougnon^{1,2}, H. Bankolé², J. Dougnon², J. Klotoé², P. Edorh¹, F. Loko², M. Boko¹

¹Polytechnic School of Abomey-Calavi, Research Laboratory in Applied Biology, University of Abomey-Calavi, Cotonou, Benin

²Interfaculty Center of Formation and Research in Environment for the Sustainable Development, Laboratory of Toxicology and Environmental Health, University of Abomey-Calavi (UAC), Cotonou, Benin

Background and objectives: Vegetables are very important sources of protein and minerals. Despite the large number of studies carried out on various vegetables and vegetable crops, very few have scientifically explored the usefulness of *S. macrocarpon*. This study identified the main groups of chemicals and mineral elements. It has also identified some toxic elements contained in this vegetable.

Methods: Cytotoxicity shrimp larvae test has been done on *S. macrocarpon*. Phytochemical screening was carried out on the leaves. Some mineral elements were determined by Atomic Absorption Spectrophotometry (sodium, potassium, calcium, magnesium) while protein, phosphorous, iron, copper, zinc and toxic metals (lead, cadmium) were determined by Molecular Absorption Spectrophotometry. Fat, ash, moisture and vitamins were sought. After hatching shrimp larvae for 48 hours, they were brought into contact with aqueous dilutions of the leaves as well as fruit. The variation in larval mortality as a function of concentration has been translated by a curve and semi-lethal concentrations were determined.

Results: The study showed that the leaves of *S. macrocarpon* were very nutritious. The high protein content of the leaves suggests an interesting nutritive property. The presence of chemical groups and toxic elements (lead, cadmium) in *S. macrocarpon* require that the consumption of vegetables should be as varied as possible. Vitamins C, A and K1 were found in this vegetable very rich in water while vitamin E has not been detected. *S. macrocarpon* also contains lipids at various levels. In addition, the values of the half-lethal concentration were all greater than the upper limit of toxicity.

Conclusions: This vegetable can therefore be used both in traditional medicine and nutrition without immediate or medium-term major risks.

Key words: Cytotoxicity, vegetables, nutrients.

O061

AN EVALUATION OF THE HEALTH AND ECONOMIC IMPACT OF THE CURRENT NATIONAL POLICY TO ELIMINATE TRANS FAT ACIDS (TFA) IN ARGENTINA

A. Rubinstein¹, N. Elorriaga¹, U. Garay¹, R. Poggio¹, J. Caporale¹, D. Mozaffarian², A. Pichon Riviere¹

¹CESCAS, Institute For Clinical Effectiveness and Health Policy, Boston, USA

²Department of Nutrition, Harvard School of Public Health, Boston, USA

Background and objectives: On per-calorie basis, TFA increase risk of coronary heart disease (CHD) more than any other macronutrient. Argentina has initiated a national policy to reduce TFA through voluntary agreements with industry (2001), mandatory labeling (2006) and elimination of industrialized TFA by 2014. We aimed to evaluate the impact of this policy on the reduction of CHD events, DALYs and costs.

Methods: A review of dietary trials/local studies, and consultations with experts/ industry were performed to estimate baseline consumption in 2000 (2%E) and replacements used from 2001-2012, where TFA were substituted mainly by high-oleic sunflower oil and beef tallow. We built an epidemiological simulation model calculating two scenarios: 1) estimating the effects of isocaloric replacement of TFA on the change of total and HDL cholesterol ratio Δ TC/HDL by using alternatives to partially hydrogenated oils; 2) accounting for pleiotrophic effects of TFA reported in prospective studies. We used Framingham risk equations to generate the expected pattern of first CHD events according to person's age-sex-risk factors distributions (including Δ TC/HDL) on an Argentine population-based sample. We estimated CHD risk before (2000) and after full policy implementation (2015), weighting by age-sex-CHD risk factor prevalence, and calibrated our I; of CHD risk to the risk reported by national statistics.

Results: From 2001-2015, based on changes in TC/HDL, 2,802 deaths and 24,708 non-fatal CHD events, and 145,715 DALYs will have been averted, and USD 106,762,155 saved. If we include the effects reported in prospective studies, almost 10% of CHD events would have been averted. Thus, given the approximated 200,000 annual CHD events in Argentina, near-elimination of industrial TFA might avoid between 2% to 10% of CHD events each year.

Conclusions: These results will help inform evidence-based policies in Argentina and other developing countries on the huge impact of nutritional interventions.

Key words: TFA, CHD, health-policy.

LEAF PROTEIN CONCENTRATES FROM INDIGENOUS PLANTS FOR IMPROVING NUTRITIONAL QUALITY OF LOCAL FOODS IN THE GARHWAL HIMALAYAS, INDIA

A. Dutta¹, C. Dev¹, B. Khanduri¹, S. Sachan¹

¹G.B.Pant University of Agriculture & Technology ,
Teheri Garhwal, India

Background and objectives: Many of nutritious plants in the Garhwal Himalayas, India are destroyed by farmers to keep their land free from unwanted foliage. These may be used to develop protein and mineral concentrates for nutritional improvement of the local population. The objectives were: 1. identify indigenous plants for protein extraction. 2. Standardize protein extraction techniques. 3. Develop fortified foods from protein concentrates

Methods: Selection of Study Area was done through purposive sampling technique. Data was collected using standardized survey schedule. Nutritional analysis was done through Proximate analysis and assessment of toxicants was also done. Protein extraction was done by the method given by A.E. Ghaly et al. in American Journal of Applied Sciences 7 (3): 331-342, 2010. Value added products using traditional recipes were developed. Sensory evaluation of developed products was done to ascertain the feasibility of protein extracts for food fortification.

Results: 152 families in 22 villages were studied to identify indigenous wild plants known for their nutritional properties. 6 most popular used plants *Rumex dentatus*, *Murraya koenigii*, *Bahunia variegata*, *Chenopodium*, *Urtica dioica*, and *Amaranthus caudatus* were shortlisted for analysis. Nutritional estimation of plants revealed that *Chenopodium* had the highest protein content (19.215%). *Rumex dentatus* had oxalic acid content of 0.2025 as well as a 50% increased protein concentration in the extracted protein concentrate. Different ratios of protein concentrates of *Rumex dentatus* and *Urtica dioica* were incorporated as an ingredient in a popular local snack called "mathri". Sensory evaluation of the snack revealed that "mathri" with 10% *Urtica dioica* protein concentrate had higher acceptability than "mathri" with 20% content. The response was similar for *Rumex dentatus*. Between the 2 protein sources the former had a better acceptance.

Conclusions: Based on the protein content it may be concluded that *Chenopodium* leaf protein concentrate has better potential for utilization as an enriching component of the local diet in the Himalayas.

Key words: Protein Concentrates, Indigenous plants, Himalayas, *Chenopodium*

EVALUATION OF MACRO AND MICRO NUTRIENT COMPOSITION ON SOME PROCESSED LESSER KNOWN GREEN LEAFY VEGETABLES IN SOUTH EAST NIGERIA

O. Grace Taiwo Olawale¹, O. Olawale², N. Joy Ugo¹, U. Rose kelechi¹

¹University of Nigeria Nsukka, Nigeria

²Department of Biochemistry, Federal University Wukari, Taraba State, Nigeria

Background and objectives: Lesser known vegetables (LKVS) that have high nutritional and medicinal values are in most cases reported not to be in regular utilization and consumption because they are going extinct. Our objective is to evaluate macro and micro nutrient composition of some processed LKVS (*Vitex doniana*, *Pterocarpus santalinoides*, *Myranthus arboreus*, *Ficus capensis*, *Ficus thonningli* and *Mucuna pruriens*).

Methods: The sampled leaves were separated into three equal parts; one part was shade dried and milled, second part was cooked for five minutes and the third was blended raw. The macro and micro nutrient composition were analysed chemically in triplicates by standard methods of AOAC. The data collected were subjected to statistical analysis and means were compared using the analysis of variance (ANOVA) and FLSD at 0.05% level of probability.

Results: The results macro and micro nutrient content showed that *M. pruriens* had (17.42%) protein and crude fibre (10.82%); *P. santalinoides* (15.09%) protein and crude fibre (14.73%); *V. doniana* had (13.85%) protein and crude fibre (7.67%). Vitamin C, A, and calcium content of *F. capensis* were (6.25 mg, 42.92 mg and 158.58 mg/100 g) respectively while *F. thonningli* had highest vitamin C (59.69 mg/100 g). Generally, shade drying increased significantly ($P < 0.05$) some of the macro and micro nutrient such as protein, crude fibre, ash, iron and calcium.

Conclusion: We recommend the consumption of these vegetables because of their high nutrient composition

Key words: Macro and micro nutrient evaluation, processing, green leafy vegetables

THE HIGHER THE INTAKE OF PROCESSED AND ULTRA-PROCESSED FOOD PRODUCTS, THE LOWER THE AMOUNT OF FRUITS IN THE BRAZILIAN DIET

A P. Martins¹, D. Canella¹, M L. Louzada¹, L. Baraldi¹, R. Levy^{1,2}, R. Claro^{1,3}, J C. Moubarac¹, G. Cannon¹, C A. Monteiro¹

¹Núcleo De Pesquisas Epidemiológicas Em Nutrição E Saúde - NUPENS/USP, Brazil

²Departamento de Medicina Preventiva da Faculdade de Medicina da Universidade de São Paulo

³Departamento de Nutrição da Escola de Enfermagem da Universidade Federal de Minas Gerais

Background and objectives: Processed food products are manufactured by adding substances such as salt, sugar, or oil to whole foods. Ultra-processed products are formulated mostly or entirely from industrial ingredients, and typically contain little or no whole foods. These products are unhealthy. They have an unbalanced nutrient profile, they are liable to be over-consumed, and they tend to displace fresh and minimally processed foods. The objective of this study was to evaluate the association between consumption of processed and ultra-processed products and the consumption of fruits, in Brazil.

Methods: Data analyzed were from a national representative sample of 34,003 Brazilians aged >10 studied in 2008-2009. Dietary data were obtained through two 24-hour food records. For this study, foodstuffs were classified into three groups: processed or ultra-processed products; fresh fruits; and all other food items. We estimated the amount (in grams) and the dietary share (% of total calories) of fruits according to quintiles of the dietary share of processed and ultra-processed products. The association between consumption of processed or ultra-processed products and consumption of fruits was tested by linear regression, controlling for income.

Results: The dietary energy share of processed and ultra-processed products averaged 30.5%. This ranged from 5.4% of total dietary energy in the lowest quintile, to 60.1% in the highest quintile. The share of fruits averaged 3.0%. This decreased across the quintiles of the share of processed and ultra-processed products, from 3.4% to 2.7%. This inverse association increased after control for income. Income-adjusted intake of fruits among people in the lowest quintile of processed and ultra-processed products consumption was 14 g higher than the intake in the highest quintile ($p < 0.05$).

Conclusions: The higher the intake of processed and ultra-processed food and drink products, the lower the amount of fruits in the Brazilian diet.

Key words: food processing, fruits, Brazil

STUNTING AMONG CHILDREN UNDER TWO IN RURAL NEPAL: THE ROLE OF WOMEN'S EMPOWERMENT IN AGRICULTURE

Kenda Cunningham¹, Elaine Ferguson¹, Ricardo Uauy^{1,2}, Purnima Menon³, George Ploubidis¹, Suneetha Kadiyala³, Marie Ruel³, Bhavani Shankar⁴

¹Department of Population Health, London School of Hygiene and Tropical Medicine, London, UK

²Institute of Food Nutrition and Food Technology (INTA), Santiago, Chile

³Poverty Health and Nutrition Division, International Food Policy Research Institute, Delhi, India

⁴Center for Development, Environment, and Poverty, School of Oriental and African Studies, London, UK

Background and objective: Undernutrition among Nepali children (<5y) is high; 41% stunted, 29% underweight, and 11% wasted. Women's disempowerment is hypothesized to contribute to persistent child malnutrition in South Asia, since women are primary caregivers. This study investigates the contribution of women's empowerment in agriculture to undernutrition among children (<2y) in rural Nepal.

Methods: We conducted a cross-sectional survey of 1,787 rural households with children (<2y) in 16 districts of Nepal. Multivariate regression analyses were used to test associations of child (<2y) undernutrition and women's empowerment in agriculture including decision-making regarding household food production, access to resources, control of income, community leadership, and time devoted to work and leisure activities. Regression models were used to adjust for district-level clustering and control for child, maternal, and household characteristics.

Results: Women's empowerment in agriculture is positively associated with HAZ ($\beta = 0.41$, $P = 0.001$, $R^2 = 0.33$) and WAZ ($\beta = 0.32$, $P = 0.040$, $R^2 = 0.20$), but not WHZ, even after controlling for child age and sex; maternal age, height, and education; and household socio-economic status and total number of children under five. Four domains of women's empowerment in agriculture explain most of the statistically significant association with HAZ: access to and decision-making on credit ($\beta = 0.26$, $P = 0.003$), control of income ($\beta = 0.24$, $P = 0.001$), confidence speaking in public ($\beta = 0.30$, $P = 0.002$), and time for leisure activities ($\beta = 0.36$, $P = 0.001$). For WAZ, access to and decision-making on credit ($\beta = 0.21$, $P = 0.028$), control of income ($\beta = 0.18$, $P = 0.024$) and autonomy in production decisions ($\beta = 0.20$, $P = 0.045$) are statistically significant, whereas time for leisure activities is only marginally significant ($\beta = 0.26$, $P = 0.077$).

Conclusion: Women's lack of empowerment contributes to low child HAZ and WAZ in rural Nepal. Programs and policies

prioritizing women's empowerment within agricultural households are required to address undernutrition, particularly during the most vulnerable period of the first two years of life.

Key words: Under-nutrition, South Asia, women's empowerment.

⁴Division of Statistical Genomics in the Center for Genome Sciences, Washington University School of Medicine, Saint Louis, USA

⁵Department of Cardiovascular Epidemiology and Population Genetics, Centro Nacional de Investigaciones Cardiovasculares (CNIC), Madrid, Spain

Background and objectives: Combining multiple genetic variants related to obesity into a global genetic risk score (GRS) might improve identification of individuals at risk of developing obesity. Moreover, characterizing gene-diet interactions is a research challenge aimed at investigating dietary recommendations for individuals with higher predisposition to obesity. The aim was to analyze the association between obesity GRS and BMI in a US population, with focus on gene-diet interactions with total and saturated fat intake.

Methods: A cross-sectional study including 783 participants from the Genetics of Lipid lowering Drugs and Diet Network study. A weighted GRS was calculated based on 11 obesity-associated variants. Biochemical measurements were made by using standard procedures. Dietary intakes were estimated with a validated questionnaire.

Results: Interactions were observed between total energy and fat intake and the obesity GRS for BMI (P for interaction=0.021 and 0.004, respectively for continuously evaluated dietary and GRS variables). We also identified an interaction between saturated fat intake and GRS evaluated continuously

for BMI (P for interaction=0.004). Finally, we obtained similar results when the GRS was evaluated dichotomously according to low and high values (P for interaction=0.034 for categorical GRS). In subjects with high GRS, saturated fat intake was associated with greater BMI ($\beta=0.0861$ kg/m²; 95% CI: 0.0109 to 0.1612; P=0.025) but in those with low GRS, saturated fat intake was not associated with BMI ($\beta=0.0130$ kg/m²; 95% CI: -0.0463 to 0.0723; P=0.668).

Conclusion: Total energy and saturated fat intake interact with an obesity GRS in determining BMI in a US population.

Key words: BMI, genetic risk score, saturated fat

O067

OBESITY IN ADOLESCENTS FROM SOUTH OF EUROPE VERSUS CENTER-NORTH OF EUROPE: ROLE OF PHYSICAL ACTIVITY, DIET AND GENETICS

F.B. Ortega¹

¹University of Granada, Granada, Spain

Background and objectives: Coordinated European projects using standardized methodology can identify health inequalities across Europe. The HELENA study, involving adolescents from 10 European cities provides a unique opportunity to address this issue. We aimed to: 1) compare overweight/obesity prevalence and adiposity levels in adolescents from South versus Center-North of Europe; 2) explore whether physical activity (PA), diet or selected genetic factors explained these differences.

Methods: The HELENA study comprised 3528 adolescents from South (4-cities) and Center-North (6-cities) of Europe. Fitness (strength, speed-agility and cardiorespiratory fitness), total and central fatness (anthropometry and bioelectrical impedance analysis (BIA)) and cardiometabolic risk (z-scores including fitness, fatness, lipids, insulin resistance and blood pressure markers) were assessed. The analyses were adjusted for socioeconomic factors, objectively measured PA (accelerometry), total energy intake and diet quality, and genetic variants of the FTO rs9939609 polymorphism.

Results: The prevalence of overweight/obesity was higher in adolescents from South compared to Center-North of Europe, i.e. 31% versus 21%, Odds Ratio=1.7, 95% Confidence Interval=1.42-2.05. Likewise, adolescents from South of Europe had higher levels of total and central fatness, as indicated by body mass index, fat mass and waist circumference, compared to adolescents from Center-North of Europe, all P<0.001. Differences in total and central fatness were not explained by PA, nor energy intake, diet quality or FTO rs9939609 polymorphism.

Conclusions: Adolescents from South of Europe are fatter than those from Center-North of Europe, yet the causes for

these geographical differences remain. The inclusion of different markers of total and central fatness measured by different methods, the objective assessment of PA, the inclusion of dietary and genetics variables, and the thorough standardization of the measurements and timeframe for data collection, make of this study one of the most comprehensive examinations about health inequalities in adolescence across Europe.

Key words: fatness, obesity, body fat distribution, adolescence

RIBOFLAVIN LOWERS BLOOD-PRESSURE IN HYPERTENSIVE'S WITH THE MTHFR 677TT GENOTYPE

M. Ward¹, C. Wilson¹, J. Strain¹, J. Scott², T. Trouton³, B. Hoefl⁴, P. Weber⁴, L. McAnena¹, G. Horigan¹, H. McNulty¹

¹Northern Ireland Centre for Food and Health, University of Ulster, Coleraine, Northern Ireland, UK

²School of Biochemistry and Immunology, Trinity College Dublin, Dublin, Ireland

³Cardiac Unit, Antrim Area Hospital, Antrim, Northern Ireland, UK

⁴DSM Nutritional Products Ltd., Kaiseraugst, Switzerland

Background and objectives: Intervention with riboflavin has been shown to produce a genotype-specific lowering of blood pressure (BP) in premature cardiovascular disease (CVD) patients homozygous for the 677C>T polymorphism (TT genotype) in the gene encoding the enzyme methylenetetrahydrofolate reductase (MTHFR)1. Whether this effect is confined to high risk CVD patients is unknown. The aim of this randomized trial, therefore, was to investigate the responsiveness of BP to riboflavin in hypertensive individuals with the TT genotype but without overt CVD.

Methods: From an available sample of 1427 hypertensive patients, 157 with the MTHFR 677TT genotype were identified, 91 of whom agreed to participate in the trial. Participants were stratified by systolic BP and randomized to receive placebo or riboflavin (1.6mg/d) for 16 weeks.

Results: A significant improvement in the biomarker status of riboflavin was observed in response to intervention. Correspondingly, despite being prescribed multiple classes of antihypertensive drugs, a significant decrease from 141.8 mmHg \pm 19.4 mmHg to 137.1 mmHg \pm 19.8mmHg in systolic BP was achieved (P=0.031), with no significant change in diastolic BP.

Conclusion: In conclusion, these results show that riboflavin supplementation targeted at hypertensive individuals with the MTHFR 677TT genotype can significantly lower BP

compared to treatment with antihypertensive drugs alone, and indicate the potential for a personalized approach to the management of hypertension in this genetically at-risk group. 1. Horigan G, McNulty H, Ward M et al. (2010) J Hypertens 28, 478-486.

O069

CHRONO-NUTRITION: MOLECULAR MECHANISM OF DISRUPTION OF LIVER CLOCK BY IRREGULAR FEEDING

I. Oda, Y. Kataoka, S. Kobayashi, D. Yamajuku

Laboratory of Nutritional Biochemistry, Nagoya University, Japan

Background and objectives: Circadian rhythms in peripheral tissues are controlled strongly by feeding, including the liver. We have demonstrated that suppression of feeding timing (irregular feeding) shows hypercholesterolemia in rats even if rats eat the same amount of same diet (1). In addition, the feeding has been revealed to synchronize the liver clock via insulin (2). In the present study, in order to examine how suppression of feeding timing act on core clock genes in the liver, we measured clock gene expression at mRNA level and at transcription level.

Methods: Male Wistar rats were challenged by an irregular feeding regimen. Results and discussion: Serum cholesterol level was increased in the irregular feeding group, and the peak of CYP7A1 gene expression advanced. The peak of DBP gene expression also advanced. However, apparent advance of DBP transcription was not observed, although it was advanced. Therefore, phase advance of DBP mRNA level was mainly due to the stability of the mRNA by irregular feeding. On the other hand, Dec1 became bimodal and Dec2 rhythm was lost at mRNA and transcription levels. Amplitude of Clock, Per1,2 and Cry1 rhythms was smaller at mRNA and transcription levels. There was no effect on Rev-erba, β , ROR α and Bmal1.

Conclusions: From the above results, the irregular feeding disrupt Dec1,2 rhythm and reduced the amplitude of the core clock gene loop, then leading to phase advance of DBP and CYP7A1. Irregular feeding broke hepatic circadian rhythm of clock genes at a transcription level, causing abnormalities of lipid metabolism. 1) Yamajuku, D. et al., Circulation Res. 105, 545-548 (2009) 2) Yamajuku, D. et al., Scientific Rep. 2, 439; DOI:10.1038/srep00439 (2012)

O070**DIETARY LOW PROTEIN COMBINED WITH HIGH FAT INDUCES ABDOMINAL FAT ACCUMULATION IN RATS**

L. Otani¹, T. Mori¹, A. Koyama¹, K. Saito¹, S-I. Takahashi², H. Kato¹

¹Food for Life, Organization for Interdisciplinary Research Projects, The University of Tokyo, Japan

²Animal Sciences, Graduate School of Agricultural and Life Sciences, The University of Tokyo, Japan

Background and objectives: Although dietary protein restriction is well known to have a strong impact on body composition and energy balance, the mechanism underlying the alteration of glucose and lipid metabolism by protein nutrition remains to be elucidated. It was reported that dietary supplementation with arginine also affects lipid metabolism. Here we examined in mature rats the effects of protein restriction combined with high fat and arginine supplementation on body fat deposition. Then the hepatic gene expression profiles were compared focusing mainly on the regulation of glucose and lipid metabolism.

Methods: Male Wistar rats were divided into 5 groups, normal protein group (15P: 15% protein, 12.5% kcal fat), normal protein-high fat group (15P-HF: 35% kcal fat), low protein group (5P: 5% protein, 12.5% kcal fat), low protein-high fat diet group (5P-HF), and low protein-high fat with 2% arginine diet group (5P-HFA). Total RNA was extracted from the liver and subjected to DNA microarray analysis. 5P-HF group showed increased abdominal fat weight and increased ectopic lipid content (liver and muscle) as compared with rats of 15P or 5P group. These effects were alleviated by arginine supplementation (5P-HFA). No difference was observed in abdominal fat weight and ectopic lipid content between 15P-HF and 15P group. Hierarchical clustering analysis of DNA microarray data demonstrated clear separation of low protein diet groups (5P, 5P-HF, 5P-HFA) and normal protein diet groups (15P, 15P-HF). In addition, low protein-high fat diet groups showed higher expression of genes related to glycolysis and fatty acid synthesis, which remain unchanged or even decreased in 15P-HF.

Conclusions: Feeding low protein diets may accelerate de novo synthesis of fatty acid through up-regulation of related genes, leading to accumulation of visceral and ectopic fat.

Acknowledgements: This work was supported by the Program for Promotion of Basic and Applied Researches for Innovations in Bio-oriented Industry.

O071**THE ANTI-PROLIFERATIVE EFFECT OF BOWMAN-BIRK INHIBITORS ON HT29 COLON CANCER CELLS IS ASSOCIATED WITH THE INHIBITION OF SERINE PROTEASES**

A. Clemente¹, M Carmen. Marin-Manzano¹, M Carmen. Arques¹, C. Domoney²

¹Department of Physiology and Biochemistry of Animal Nutrition, Estacion Experimental Del Zaidin (CSIC), Granada, Spain

²Department of Metabolic Biology, John Innes Centre, Norwich, UK

Background and objectives: Bowman-Birk inhibitors (BBI) from legumes are naturally-occurring plant protease inhibitors which inhibit specifically serine (predominantly trypsin- and chymotrypsin-like) proteases. BBI can survive both acidic conditions and the action of proteolytic enzymes within the stomach and small intestine, permitting physiologically relevant amounts to reach the large intestine where they may exert anti-carcinogenic and anti-inflammatory properties. Recent studies have demonstrated a significant concentration- and time-dependent decrease in the growth of HT29 human colon adenocarcinoma cells in vitro, following treatment with BBI from several legume sources, including soybean, pea and lentil. In this study, we have investigated the relationship between the anti-proliferative properties of TII1, a major iso-inhibitor from pea seeds, on colon cancer cells and the inhibition of serine proteases.

Methods: Using HT29 colon cancer cells, we have compared the effect on cell growth of variant TII1 proteins, heterologously expressed in *Pichia pastoris*. The study included a mutant protein, engineered to have an amino acid substitution at the P1 position of each inhibitory domain.

Results: The active TII1 protein inhibited both trypsin and chymotrypsin, with K_i values at nanomolar concentrations, whereas the mutant protein was inactive against both serine proteases. The proliferation of HT29 colon cancer cells was significantly affected by active TII1 in a dose-dependent manner ($IC_{50} = 31 \pm 7 \mu M$); in contrast, the mutant protein did not show any significant suppressive effect on cell growth. Neither protein affected the growth of control non-malignant colonic fibroblastic CCD-18Co cells.

Conclusions: Cellular serine proteases should be considered as BBI targets in further investigations of their chemopreventive properties during early stage colorectal carcinogenesis.

Key words: Bowman-Birk inhibitors, cell proliferation, colorectal cancer cells, protease inhibition, serine proteases

⁷Department of Pathology, SCR Main Hospital, Hyderabad, Andhra Pradesh, India

⁸Pathology Department, Asian Institute of Gastroenterology, Hyderabad, Andhra Pradesh, India

Background and objectives: Cancer is one of the leading causes of human morbidity and mortality around the world. The Aldo-keto-reductase (AKR) family has 140 proteins including Aldose reductase (AR or AKR1B1) and AR like proteins (AKR1B10). AR is the rate-limiting polyol pathway enzyme that converts glucose into sorbitol and involved in secondary complications of diabetes. It is also upregulated in many cancer cells and is thought to be involved in resistance to chemotherapeutic drugs. To study A) Specific activity of AR in RBCs. (B) Specific activity and expression of AR and AKR1B10 in tumor and non-tumor areas.

Methods: Whole blood samples were collected from 127 cancer patients and 60 Controls. Fresh post-surgical tumor tissues (127) were from stomach (28), colon (21), rectum (14), ovary (18), cervix (11), oral (19) and thyroid (16). AR and AKR1B10 were studied by immunoblotting [for expression] and enzyme activity studies. Histopathology evaluation for typing and grading of tumors was done. Statistical analysis was done using Mann-Whitney U- test.

Results: Specific activity of AR in RBCs of patients was significantly increased compared to Controls and in all three grades of tumors. Specific activity and expression of AR and AKR1B10 levels were increased in tumors compared to non-tumor samples of stomach, cervix, ovary, oral and thyroid samples.

Conclusions: Our study indicates for the first time, presumably, that increased AR activity levels in RBCs correlated with increased levels in tumors and may be useful as an indicator to denote a malignant process underway (stomach, cervix, ovary, oral and thyroid), which could alert the individual to seek medical opinion and extensive screening for detecting possible malignancy at an early stage and improve quality of life in such subjects. Also, AR is not increased in all tumors.

Key words: Aldosereductase, activity, expression, RBC, tumor.

O073

INFLUENCE OF DIET ON COLONIC FERMENTATION AND ENDOGENOUS FORMATION OF N-NITROSO COMPOUNDS

S W. Gratz¹, A J. Richardson², C. Fyfe², A M. Johnstone², G. Holtrop²

¹Biomathematics and Statistics Scotland, Aberdeen, UK

²Rowett Institute of Nutrition and Health, University of Aberdeen, UK

Background and objectives: High-protein, low carbohydrate diets are popular weight loss regimes. Nonetheless, negative effects on gut health might be expected if less carbohydrate and more protein reach the large intestine, due to shifts in short chain fatty acid (SCFA) patterns and the formation of protein degradation products, including potentially carcinogenic N-nitroso compounds (NOC). Diet is the main driver for endogenous N-nitrosation with red meat being the most important factor, while nitrate and vitamin C also contribute. Previous studies have focused on single dietary components, but to date no study has investigated the combined effect of various dietary components. The aim of the current study was to assess the impact of various dietary components on endogenous formation of NOC and faecal SCFA.

Methods: We conducted three studies in obese men comparing body weight maintenance diets and different high protein weight loss diets. Dietary intakes were estimated from food diaries and correlated with faecal fermentation products and NOC. We studied the effect of protein components (total protein, total meat, red and white meat), carbohydrate components (total carbohydrates, digestible and non-digestible carbohydrates), and vitamin C and nitrate on NOC.

Results: We observed that shifts in the dietary carbohydrate/protein ratio resulted in alterations in faecal SCFA patterns. Furthermore, using random effects multiple linear regression, we confirmed red meat as the strongest contributor to endogenous NOC formation, but nitrate, vitamin C, non-starch polysaccharides and total energy also played a significant role.

Conclusions: We have identified the contributions of various dietary components to endogenous NOC formation and formulated a prediction model for NOC formation in obese men, based on their dietary intakes. This model could improve the estimation of endogenous NOC formation in epidemiological studies into diet and cancer, which is currently based on red meat intake only.

Key words: N-nitroso compounds, diet, faeces, fermentation

MATERNAL OBESITY, PRE-PREGNANCY AND GESTATIONAL DIABETES AND IMPACT ON BIRTH SIZE OF OFFSPRING, AUSTRALIA

P H. Lahmann¹, K. Gibbons², A P. Hills², S. Street², H D. McIntyre³

¹School of Population Health, University of Queensland, Herston Road, Herston, Australia

²Mater Medical Research Institute, Brisbane, Australia

³Mater Clinical School, Brisbane, Australia

Background and objectives: Maternal obesity and diabetes (DM) are established risk factors for fetal overgrowth. Less is known about the extent birthweight (BW) and other indicators are affected by different grades of maternal obesity. We examined the maternal obesity-birth size association according to obesity levels, and investigated whether BMI modified the pre-pregnancy DM-birth size relationship.

Methods: Retrospective cohort study of 71,510 women with singleton pregnancies, available pre-pregnancy BMI(kg/m²) and offspring BW(g), who gave birth in a tertiary referral maternity hospital, Brisbane (01/1998-12/2009). Anthropometric birth measures included BW, birth length (cm), and ponderal index (PI, g/cm³), small (<10th centile) and large (>90th centile) for gestational age (SGA, LGA), and macrosomia (BW≥4000g). We used multivariate logistic regression models to derive odds ratios (ORs) for the association of maternal BMI with birth size, based on five BMI categories (18.5-25, reference; 25-30; 30-35; 35-40; ≥40), and for BMI≥40 vs. BMI 30-40, adjusted for selected perinatal/maternal factors.

Results: Of all mothers (mean age 30.5y), 22% were overweight (BMI 25-30), 13% obese (BMI>30). Mean BW, PI, and %LGA and macrosomic newborns, increased significantly across maternal overweight/obese categories, compared to mothers with normal weight. Among obese mothers the risk of a macrosomic birth or high PI (>90th centile) at birth was approximately 2.5-fold or 1.5-fold higher, respectively, than in reference mothers. The likelihood of high BW offspring was not significantly greater among mothers with BMI>40 com-

pared to those with reference BMI 30-40 (adj. OR=1.14, 95%CI 0.96-1.35), neither was the risk of high PI, or LGA. After adjustment for BMI, pre-pregnancy DM, remained a significant risk factor for macrosomia, high PI and LGA; gestational DM was a risk for LGA only.

Conclusions: Higher maternal BMI is strongly related to fetal size while risk differences between morbidly obese and obese women remain small.

Key words: maternal BMI, birthweight, macrosomia

O075

LOW OMEGA-3 INDEX IN PREGNANCY IS A POSSIBLE BIOLOGICAL RISK FACTOR FOR POSTPARTUM DEPRESSION

M W. Markhus¹, I E. Graff¹, S. Skotheim², H C. Braarud², K M. Stormark², L. Frøyland¹, M K. Malde¹

¹National Institute of Nutrition and Seafood Research (NIFES), Bergen, Norway

²Regional Centre for Child and Youth Mental Health and Child Welfare/Uni Health/Uni Research, Bergen, Norway

Background and objectives: Postpartum depression (PPD) is a common disorder affecting 10-15% women in the postpartum period. PPD can disrupt early mother-infant interaction, and thus constitutes a risk factor for child development. Recently, attention has been drawn to the hypothesis that a low intake of marine omega-3 fatty acids in pregnancy can be a risk factor for PPD. The hypothesis tested in this study was that a low marine omega-3 fatty acid status in pregnancy might be a risk factor for PPD.

Methods: In a community based prospective cohort in a municipality in Western Norway, we investigated both nutritional and psychological risk factors for postpartum depression. The source population was all women who were pregnant within the period November 2009 - June 2011. The fatty acid status (relative and absolute amount) in red blood cells was assessed in the 28th gestation week and participants were screened for postpartum depression using the Edinburgh Postpartum Depression Scale (EPDS) 3 months after giving birth.

Results: In a simple regression model, the omega-3 index was associated with the EPDS score in a nonlinear inverse fashion with an adjusted R square of 17. The omega-3 index explained 16% of the variation in the depression score. The DHA content, omega-3 index, omega-3/omega-6 ratio, and the omega-3 HUFA score were all inversely correlated with the depression score. Depression scores of participants in the lowest omega-3 index quartile were significantly lower than the three other omega-3 index quartiles.

Conclusions: In this study population, low omega-3 index in late pregnancy was associated with higher depression score three months postpartum in an inverse non-linear fashion.

Key words: Marine omega-3 fatty acids, pregnancy, maternal omega-3 index, postpartum depression

O076

EFFICACY OF DRIED AMARANTH LEAVES (*Amaranthus cruentus*) CONSUMPTION ON VITAMIN A, IRON AND ZINC OF CHILDREN IN KAJIADO COUNTY, KENYA

P. Chege¹, E. Kuria¹, J. Kimiywe¹, H. Nyambaka²

¹Department of Food, Nutrition and Dietetics, Kenyatta University, Kenya

²Department of Chemistry, Kenyatta University, Kenya

Background and objectives: Children under five years are more vulnerable to deficiencies of vitamin A, iron and zinc with a prevalence of 84%, 74% and 50%, respectively in Kenya. Minimal information exists on how intake of dried vegetables incorporated into cereal flours would translate to micronutrient status. The study aimed to assess the efficacy of dried amaranth leaves (DAL) on the status of vitamin A, iron and zinc among children under fives in Kajiado, Kenya.

Methods: A pre-test–post-test control group design was adopted. A comprehensive sample of 42 children aged 24 - 48 months for experimental group and 46 for control group was used. A maize-amaranth blend porridge (85:15%) which provided at least 100% of the RDAs for vitamin A was used among the experimental group while pure fermented maize flour was used among the control group for six months. Serum levels for β -carotene, retinol, ferritin and zinc were done at baseline and after six months. Serum level analysis was done by use of AAS (MINI VIDAS) for ferritin and Shimadzu AA-680 for zinc levels. HPLC was used to for serum β - carotene and retinol. Data were analyzed using SPSS computer software.

Results: Majority of the children from both groups had low mean serum levels for retinol, β - carotene, ferritin and zinc at baseline showing deficiency. This significantly increased ($p < 0.05$) by 25.6%, 232.7%, 28.0% and 28.9% for serum retinol, β - carotene, ferritin and zinc, respectively among the experimental group by the sixth month. The change among the control group was not significant ($p > 0.05$).

Conclusions: Results suggest the role of DAL in improving micronutrients. Use of DAL incorporated into cereals can significantly increase micronutrients intake. This study recommends the use of DAL as part of diet for children.

Key words: Dried amaranth leaves, retinol, β -carotene, ferritin, zinc

⁵Financial Support: Comisión Interministerial de Ciencia y Tecnología, Spain (SAF2005/05096); The Spanish Ministry of Health (Instituto de Salud Carlos III, Fondo de Investigaciones Sanitarias), project PI:10/00335; Institut d'Investigació Sanitària Pere Virgili

Background and objectives: We investigated whether high first trimester plasma folate (PF) status modulates the effect of the MTHFR 677C>T polymorphism on red cell folate (RCF) during pregnancy.

Methods: 443 women from the Reus-Tarragona Birth Cohort (NUTCIR phase; University hospitals Sant Joan, Reus, Joan XXIII, Tarragona) were prescribed a first trimester daily supplement containing 400 μ g of folic acid and 2 μ g of cyanocobalamin. The MTHFR 677C>T polymorphism was determined and also PF and RCF at <12, 15, 24-27 and 34 gestational weeks (GW), and labor (PF). PF tertiles were used as an indicator of folic acid supplement use. We investigated how they affected the association between the MTHFR 677C>T polymorphism and RCF.

Results: 47.9% of the participants adhered strictly to, 16.5% sporadically to and 31.2% exceeded the recommended supplement regime. We excluded non-users (4.5%). Between 15 and 24-27GW, PF was reduced between 35%-46% in all supplement groups, and then no further. At labor, it was highest (15 [12.6-17.8] nmol/L) in the "excess" group ($p < 0.001$). No differences in RCF were observed between MTHFR 677C>T homozygotes (18.3%) and wild types (34.5%) at any time of pregnancy in participants that had high tertile >32.5 nmol/L) first trimester PF. However, RCF (nmol/L) [mean (95%CI), * $p < 0.05$] was lower in homozygotes compared to wild types with low tertile PF <19.9 nmol/L) at 15GW: 721 (603,864) versus 968

(818,1146)*, low (<8.6 nmol/L) or mid (>8.6-<16.2 nmol/L) tertiles at 24-27 GW: 646 (540-774) vs 830 (750,919)* and 959 (844,1090) versus 1118 (1035,1207)* respectively; low (<6.9 nmol/L) or mid (>6.9-<13.2 nmol/L) tertiles at 34GW: 521 (454,597) versus 634 (575,699)* and 697 (550,882) versus 850 (765,944), (p=0.066).

Conclusions: High first trimester folate status is associated with higher RCF and no effect of the MTHFR 677C>T polymorphism on RCF, for the duration of pregnancy.

Key words: folic acid, pregnancy, MTHFR 677C>T, supplementation

O078

THE DIETARY PATTERNS OF MOTHERS DURING PREGNANCY, THEIR CHILD AT AGE FIVE YEARS AND CHILD WEIGHT STATUS.

C. Murrin, A. Shrivastava, C. Kelleher

School of Public Health, Physiotherapy, and Population Science, University College Dublin, Dublin, Ireland

Background and Objectives: Children's diet patterns are likely to be influenced by their mothers' diet pattern. The aim of this study was to examine whether diet patterns of mothers during pregnancy and diet patterns of their children can predict child obesity.

Methods: Food frequency methods were used to assess the food intake of children and mothers in the Lifeways Cross-Generation cohort study. Dietary patterns for each group were identified by principal components analysis.

Results: The child's diet pattern at age five was significantly associated with some of the maternal patterns during pregnancy (n=437). The mother's 'health conscious' pattern was correlated with the child's 'healthy' pattern (r=0.195, P<0.001) and 'pasta and vegetable' pattern (r=0.181, P<0.001). The strongest relationship was found between the mother's 'processed' pattern and the child's 'junk' pattern (r=0.246, P<0.001). Furthermore the maternal 'processed' pattern was significantly negatively correlated with the 'pasta and veg' pattern. In multivariate logistic regression analysis the upper tertile of child 'cereal and juice' (OR 0.44, 95%CI 0.21-0.91) and the middle tertile of the 'pasta and veg' patterns (0.37, 95%CI 0.18-0.75) were negatively associated with overweight and obesity. Maternal processed pattern during pregnancy was positively associated with offspring overweight and obesity. These diet pattern associations remained significantly associated in the model when adjusted for other known risk factors including birthweight, maternal prepregnancy BMI, smoking, education and parity.

Conclusion: Analysis of dietary food patterns amongst families may help to develop dietary interventions that may be more effective at different stages during the Lifecourse.

Key words: dietary patterns mothers children obesity

⁵Division of Neonatology, Cincinnati Children's Hospital, Cincinnati, USA

⁶World Vision International, Washington DC, USA

⁷Departments of Anthropology, Nutritional Sciences and Dalla Lana School of Public Health, University of Toronto, Canada

Background and objectives: In Kenya cell phone use is high and presents opportunities to support breastfeeding with lower cost and wider reach as an mHealth innovation. Data from a randomized intervention trial showing cell phone based support (CPS) increases the prevalence of exclusive breastfeeding (EBF) were used to investigate pathways through which such support may strengthen maternal efforts to meet breastfeeding national recommendations.

Methods: Trained peer leaders (TPL=12) completed national training to support EBF and supported both pregnant and post-partum women randomized to CPS and monthly peer support group (PSG) from late pregnancy (32-26 weeks) to 3 months postpartum. We analyzed maternal reports on breastfeeding support and problems at home visits conducted at 3 months postpartum with women who had been randomly allocated to CPS (153), PSG (173) or existing facility-based standard of care (SOC=control; 179).

Results: Mothers allocated to CPS were more likely to report receiving postpartum help with breastfeeding (88.8% vs 62.4% and 41.4% for PSG, SOC; p<0.0001) but not infant feeding advice from health care workers or others. Fewer reported any breast pain (2.6% vs 8.7% and 8.4% for PSG, SOC; p=0.0513). Other indicators did not differ significantly, e.g. engorgement (9.8% vs 12.1% and 14.5% for PSG, SOC; p=0.425).

Conclusions: Cell phone based peer support is associated with maternal reports of more frequent help with breastfeeding between 1 week and 3 months postpartum. More frequent help may mediate a relationship between cell phone based support and increased EBF.

Key words: Exclusive breastfeeding, peer support, Health

EFFECT OF BREASTFEEDING PATTERN ON GROWTH AND MOTOR MILESTONE DEVELOPMENT OF INFANTS ATTENDING BABY CLINIC IN A NIGERIAN TEACHING HOSPITAL

H. Ene-Obong¹, D. Ihekuna²

¹Department of Biochemistry (Nutrition Unit), University of Calabar, Calabar, Cross River State, Nigeria

²Institute of Child health, University of Nigeria Teaching Hospital, Ituku-Ozalla, Enugu, Enugu State, Nigeria

Background and objectives: The first two years of life is a “critical window” for the promotion of optimal growth and development. This study examined the effect of breastfeeding pattern on the growth and motor milestone development of infants.

Methods: A longitudinal survey involving 130 mother-infant pairs randomly selected during clinic days was conducted. Mothers’ background data and infant feeding practices were collected using validated, pre-tested questionnaires. Duplicate measurements of infants’ weights and heights were taken for 12 months using standard procedures. Information on gross motor milestones development were obtained from mothers and confirmed using standard testing procedures. Data obtained were analyzed using descriptive statistics and analysis of variance.

Results: Majority (75%) of mothers initiated breastfeeding within 24 hours. On enrollment, 60.8% practiced exclusive breastfeeding (EBF), 23.8% predominant breastfeeding, and 15.6% partial breastfeeding. Only 30% of the population practiced EBF up to 6 months; 86.2% were still breastfeeding at one year. Exclusively breastfed infants had higher ($p < 0.05$) weight velocity in the first three months; that of partially breastfed infants was higher from the 6th to the 10th month. Weight velocity

of predominantly breastfed infants was lower ($p < 0.05$) than that of the exclusively and partially breastfed infants especially from the 7th month. All nutritional indices were lower for predominantly breastfed infants. Possible risk of obesity was higher among exclusively and partially breastfed infants. The mean ages for development of all the milestones were lower than the mean ages recommended by the World Health Organization, except for standing with assistance (8.18 months), which was still within the range of values recommended. Exclusively breastfed infants walked with assistance and walked alone earlier than predominantly breastfed infants

Conclusion: Concerted and deliberate efforts must be continued in order to improve and promote appropriate infant feeding practices in baby clinics

Key words: Breastfeeding pattern, growth, motor milestone development

THE DIETARY EFFECT OF SERVING SCHOOL MEALS BASED ON THE NEW NORDIC DIET – A RANDOMISED CONTROLLED TRIAL IN DANISH CHILDREN

R. Andersen¹, A. Biloft-Jensen¹, T. Christensen¹, E. W. Andersen², M. Ege¹, A. V. Thorsen¹, V. K. Knudsen¹, S-M. Dalskov³, C. Damsgaard³, A. Astrup³, K. F. Michaelsen³, I. Tetens¹

¹Division of Nutrition, National Food Institute, Technical University of Denmark, Denmark

²Department of Applied Mathematics and Computer Science, Technical University of Denmark, Denmark

³Department of Nutrition, Exercise and Sports, Faculty of Science, University of Copenhagen, Denmark

Background and objectives: The OPUS study is a school-based intervention study testing selected health effects of New Nordic Diet (NND). Children are served lunch and snacks based on NND. The hypothesis is that Danish school children eat a healthier diet when receiving NND school meals as compared with packed lunch brought from home. To investigate the effects on intake of selected macronutrients in Danish school children when served school meals based on NND compared with packed lunch.

Methods: In a cluster-randomized controlled unblinded cross-over study children received school meals based on NND for 3 months and their usual packed lunch for 3 months. The daily intake of food and beverages was recorded 3 times during 7 consecutive days using a validated self-administered web-

based dietary assessment software tool for children. Statistical analysis was performed by hierarchical mixed models.

Results: 834 children from 9 schools were included and 96%, 89% and 80% filled out the first, second and third dietary assessment sufficiently (4-7 days), respectively. The preliminary results showed that the effect of serving NND resulted in a reduction in fat E% ($P<0.0001$), total fat ($P=0.0007$) and saturated fat ($P<0.0001$) intake for the NND compared to packed lunch; and an increase in protein E% ($P<0.0001$), and a borderline significant increase in dietary fiber intake ($P=0.0471$). There was no effect for energy intake, carbohydrate E% and added sugar E% ($P>0.05$). Effects are adjusted for BMI, season and household education.

Conclusions: Danish school children's dietary intake of total and saturated fat decreased, fat E% decreased and protein E% increased when eating NND lunch and snacks compared to packed lunch brought from home. The OPUS project (Optimal well-being, development and health for Danish children through a healthy New Nordic Diet) is supported by the Norddea Foundation.

PRESCHOOL FOOD AND DRINK PROVISION AND CONSUMPTION IN EARLY YEARS EDUCATION AND CARE SETTINGS IN ENGLAND

J. Nicholas¹, L. Stevens¹, L. Briggs¹, L. Woods¹, M. Nelson¹

¹Children's Food Trust, Sheffield, UK

Background and objectives: New voluntary guidelines for healthy food and drink provision for early years settings in England were published by the Children's Food Trust in collaboration with national early years providers. Because the guidelines were due for implementation in September 2012, the survey, conducted between April and July 2012, provided baseline information on food and drink provision in early years settings in England in order to subsequently evaluate the guidelines' impact; to assess the extent to which current provision met the guidelines; and to determine factors associated with healthier provision and consumption.

Methods: 67 settings (childminders, Children's Centres, sessional and full day care providers, nursery classes in primary schools) were recruited in three local authorities in England. 57 returned usable data. Over five days in each setting, trained observers measured food and drink provision, consumption, and wastage; provision by parents/carers; and setting characteristics.

Results: Data were collected in 794 sessions from 1312 children eating food provided by settings and 132 by parents.

The food provided reflected societal norms for specific meals (e.g. breakfast cereal and milk at breakfast; main dishes plus vegetables, salad, fruit and dessert at lunch). Food provided by settings at lunch was typically healthier than parent-provided: more protein, fibre, vitamin A and folate, less sodium (279mg and 431mg, respectively) and less sugar (10% and 15% of total energy, respectively). Mean fruit and vegetable consumption was 1.2 portions per session). Compared with the guidelines, lunch provided less energy, carbohydrate, iron and zinc than recommended, enough protein, vitamin A, vitamin C and calcium, and too much salt. Provision at teatime met most of the standards apart from iron, zinc, and sodium.

Conclusions: The guidelines provide a useful framework for improving food and drink provision in early years education and care settings.

Key words: preschool, food, drink, England

INTAKE OF WHOLE GRAINS AND INCIDENCE OF GASTRIC AND OESOPHAGEAL CANCER IN THE HELGA COHORT

G. Skeie¹, T. Braaten¹, A. Olsen², L M. Nilsson³, R. Landberg⁴, L A. Åsli¹, T. Bakken¹, E. Lund¹

¹Department of Community Medicine, University of Tromsø, Tromsø, Norway

²Danish Cancer Society Research Center, Copenhagen, Denmark

³Department of Public Health and Clinical Medicine, Nutritional Research, Umeå University, Umeå, Sweden

⁴Department of Food Science, BioCenter, Swedish University of Agricultural Sciences, Uppsala, Sweden

Background and objectives: Whole grains are a good source of dietary fibre, but beneficial effects might also stem from other components of the grain. Very few studies exist on intake of whole grains and incidence of stomach and oesophageal cancer, but studies on dietary fibre and these cancers suggest a protective effect. The objective of this work was to study the association between intake of whole grains and incidence of oesophageal and gastric cancer.

Methods: The Helga cohort has 120 000 participants from the Norwegian Women and Cancer study, The Northern Sweden Health and Disease study and the Danish Diet, Cancer and Health study, recruited in 1992-1999. After exclusions, 112 cases of oesophageal cancer, 185 cases of gastric cancer and 113 700 other cohort members were included in the analyses. They provided dietary information in semi-quantitative FFQs at baseline, and also information about other risk factors. Cancer

information was obtained by linkage to the respective cancer registries. The association between whole grain intake and cancer was analysed with Cox proportional hazards models.

Results: The median whole-grain intake was 47.4 g/day (5th-95th percentile: 13.3-101.1) in the non-cases, 37.5 g/day (10.8-87.2) in oesophageal cancer cases, and 45.1 g/day (8.1-99.1) in gastric cancer cases. A decreased risk of oesophageal cancer was observed, HR=0.83 (CI 0.69-0.99) $p=0.04$ per 20 g of whole grains. The HR for highest compared with lowest tertile of intake was 0.56 (0.32-0.97) $p=0.03$. The analyses were adjusted for country, smoking status, age at baseline, sex, processed meat, alcohol and vitamin C. No association was found for whole grains and gastric cancer.

Conclusion: In this study, higher intake of whole grains was associated with lower risk of oesophageal cancer.

Acknowledgements: This work was supported by Nor-
dForsk – Centre of excellence programme HELGA (070015).

Key words: Whole grains, gastric cancer, oesophageal cancer, cohort, epidemiology

PHYSICAL ACTIVITY LEVELS AMONG COLOMBIAN ADULTS: INEQUALITIES BY SEX AND SOCIOECONOMIC STATUS

S. González¹, O. Sarmiento¹, A. Ramírez¹, C. Grijalba¹, O. Lozano²

¹Department of Public Health, School of Medicine, Universidad de los Andes, Bogotá, Colombia

²Administrative Department of sport, recreation and the use of leisure time, Coldeportes, Bogotá, Colombia

Background and objectives: Worldwide studies show inequalities in physical activity (PA) levels related to socio-demographic characteristics. In Colombia, the most unequal country in Latin America, assessing PA inequalities is imperative. The objective was to evaluate sex and socioeconomic status (SES) inequalities on meeting PA recommendations among Colombian adults.

Methods: A secondary analysis of data from 2010 National Surveys was conducted. The sample included 14465 adults (18-64 years). The International Physical Activity Questionnaire was used to measure leisure time and transport domains. SES was measured by Sisben level (life standard measure in Colombia). Data analysis was performed using a Poisson regression.

Results: Overall, prevalence of meeting PA recommendations was 53.5%. Compared to men, women were less likely to meet PA recommendations (leisure time, women 13.8% vs. men 28.2%, $p<0.0001$, walking for transport 31.2% vs. 37.4%, $p<0.0001$ and biking for transport 1.6% vs. 11.0%,

$p<0.0001$). Compared to adults from high SES households, low SES had lower prevalence of meeting PA recommendations during leisure time (22.5% vs. 16.1%, $p<0.0001$). In contrast, biking for transport was lower in high SES, compared to low SES (4.5% vs. 7.4%, $p<0.0001$). Meeting PA recommendations associated factors differed by sex and PA domain. Among women, leisure time PA was positively associated with high SES, higher education and study as occupation, while age < 49 years and underweight were negatively associated. In transport domain, age < 29 years or being head of household were positively associated, while middle SES, retirement and household chores were negatively associated. Among men, leisure time PA was positively associated with age < 29 years, higher education and retirement. Transport domain PA was negatively associated with age < 29 years, higher education, higher SES, retirement and overweight.

Conclusions: Future interventions to increase PA levels in Colombia must consider inequalities by sex and SES. Of special concern are the low prevalences of meeting PA recommendations during leisure time among women and low SES population.

Key words: Inequality, physical activity, socioeconomic factors

O085

CONSUMPTION OF ULTRA-PROCESSED PRODUCTS IS ASSOCIATED WITH OBESITY IN ADOLESCENTS AND ADULTS IN BRAZIL

M L C. Louzada¹, A P B. Martins¹, D S. Canella¹, L G. Baraldi¹, R B. Levy², R M. Claro^{1,3}, J C. Moubarac¹, G. Cannon¹, CA. Monteiro¹

¹School of Public Health/University of Sao Paulo, Brazil

²Faculty of Medicine/University of Sao Paulo, Brazil

³School of Nursing, Department of Nutrition/Federal University of Minas Gerais, Brazil

Background and objectives: Although it is generally considered that increased consumption of industrially processed foods is an important cause of the current pandemic of obesity, the evidence linking their intake to obesity is restricted to a few items such as soft drinks. A reason for this is that the role of processing as such is largely overlooked. The objective of this study was to assess the association between the consumption of ultra-processed food products and the occurrence of obesity in Brazil in 2008-2009.

Methods: Data analyzed refer to a national representative sample of 34,003 Brazilians aged 10 and older studied in 2008-2009. Dietary data were obtained through two 24-hour food records. Body mass index (BMI) was calculated from directly

measured weight and height. Obesity was defined as BMI-for-age z-score >2 for adolescents (based on WHO standards) and BMI >30 kg/m² for adults. Foodstuffs were classified based on the nature, extent and purpose of food processing. Ultra-processed products were defined as formulations made mainly from substances extracted from foods (such as oils and fats, starches, and sugars) and containing little or no whole foods. Logistic regression was used to assess the independent association between quintiles of consumption of ultra-processed products and obesity. Confounders included income and other socio-demographic variables and also calories other than from ultra-processed products.

Results: The more that people consumed ultra-processed products, the more likely it was that they would be obese. There was a direct, dose-responsive, independent relationship between dietary energy intake from ultra-processed products and rates of obesity ($P < 0.01$ for linear trend). The odds of being obese in the upper quintile of the energy intake from ultra-processed products, compared with the lower quintile, was 1.23 (95% CI 1.04-1.44).

Conclusions: The greater the consumption of ultra-processed products, the more likely it is that consumers will be obese.

Key words: Industrialized foods; food processing; obesity

O086

COMPARISON OF MUAC AND PERCENT WEIGHT GAIN AS DISCHARGE CRITERION IN A LARGE TFP PROGRAM IN BURKINA FASO - 2007-2011

S. Cohuet¹, S. Goossens², S. Shepherd², M. Shaefer², A. Munger²

¹Epicentre Medecins Sans Frontieres, France

²Medecins Sans Frontieres, France

Background and objectives: The World Health Organization [WHO] has endorsed mid-upper arm circumference [MUAC] as an independent admission criterion to therapeutic feeding programs [TFP] for children 6-59 months old with severe acute malnutrition. However, WHO still recommends weight gain to assess nutritional recovery due to lack of evidence. Here we report on nutritional recovery as assessed by weight gain and MUAC for a large TFP using MUAC < 120 mm as the admission criterion and compare program outcomes for both discharge criteria.

Methods: We analyzed data of patients admitted in a TFP in Burkina Faso between 2007 and 2011. From September 2007 "C March 2009 [Period A] recovery was defined by 15% weight gain based on admission weight. From April 2009 "C December 2011 [Period B] recovery was achieved at MUAC > 124 mm, with a 4 week minimum stay.

Results: 50,841 children were admitted with MUAC < 120 mm. Median age was 13 months. Ninety percent of all admissions recovered: 22,094 (89.1%) during period A and 23,865 (91.6%) during period B. Average length of stay [ALS] for children recovered during period A was 53.9 days compared to 37.0 for those recovered over period B. During period A, ALS was paradoxically shorter for the most malnourished. During period B, ALS was inversely related to MUAC at admission and anthropometry upon discharge was similar across all MUAC admission categories for both MUAC and weight-for-height Z score.

Conclusion: MUAC > 124 mm is a superior criterion to assess nutritional recovery in this cohort. Its use allocates program resources more efficiently.

Key words: severe acute malnutrition, mid-upper arm circumference, therapeutic feeding programme

O087

DAILY SODIUM CONSUMPTION AND CARDIOVASCULAR MORTALITY IN GENERAL POPULATION. SYSTEMATIC REVIEW AND META-ANALYSIS OF PROSPECTIVE STUDIES

R. Poggio¹, L. Gutierrez¹, N. Elorriaga¹, V. Irazola¹, A. Rubinstein¹

¹Institute For Clinical Effectiveness and Health Policy (IECS), Buenos Aires, Argentina

Background and objectives: Sodium intake and blood pressure levels have a well-established causal relationship but the evidence regarding sodium intake and cardiovascular (CV) mortality is still controversial. The important heterogeneity between studies and target populations makes difficult to combine data for evidence synthesis. Therefore, we aimed to determine whether elevated dietary salt intake is associated with CV mortality in a general population with no previous cardiovascular events.

Methods: Systematic review and meta-analysis of prospective studies representing general population without previous cardiovascular events assessing the relationship between daily salt intake and CV mortality.

Results: 13 studies met the criteria to be included in the analysis. The final population was 259,213 participants with a mean follow-up period of 13.2 years (range 5-20), contributing to 10,967 cardiovascular deaths. Higher sodium intake was significantly associated with higher cardiovascular mortality (RR= 1.12 - CI 95% 1.07-1.17). However, we also found a significant heterogeneity among the studies included ($\chi^2=39.34$ [d.f.=17] $p = 0.002$ and $I^2=56.8\%$). The most relevant source of heterogeneity was related to the sodium intake assessment. Only when sodium was assessed by urinary sodium excretion

the association was not significant (RR= 1.05-CI 95% 0.95-1.16). Variance-weighted least-squares regression showed that for every 50 mmol/day increase in sodium intake, the rate of CV mortality would increase 4.3 %; however, that trend was not significant.

Conclusions: Higher sodium intake would be associated with higher cardiovascular mortality in general population although this should be taken with caution due to the observation of a significant heterogeneity among studies. Some harmonization efforts to assess sodium intake should be implemented in future observational studies in order to reduce the sources of heterogeneity and make data more comparable for evidence synthesis.

Key words: cardiovascular mortality; meta-analysis; sodium intake

O088

DIETARY PROTEIN INTAKE AND THE INCIDENCE OF TYPE 2 DIABETES IN EUROPE: THE EPIC-INTERACT CASE-COHORT STUDY

M. van Nielen¹, E. Feskens¹, M. Mensink¹, N. Forouhi², N. Wareham² On behalf of the InterAct Consortium

¹Division of Human Nutrition, Wageningen University, Wageningen, The Netherlands

²MRC Epidemiology Unit, Cambridge, UK

Background and objectives: Short-term studies have shown beneficial effects of dietary protein on weight loss, satiety and glycaemic control. However, the long-term association between dietary protein and type 2 diabetes incidence is uncertain. The objective of this present study was to investigate the association between total, animal and plant protein intake and the incidence of type 2 diabetes in the EPIC-InterAct Case-Cohort Study, a prospective study in 8 countries from the European Investigation into Cancer and Nutrition (EPIC).

Methods: Among 340,234 participants contributing 3.99 million person-years of follow-up 12,403 incident cases of type 2 diabetes were identified and a stratified subcohort of 16,835 participants was selected. Type 2 diabetes was based on multiple sources, where self-report was verified against medical information. Habitual protein intake was assessed using validated dietary questionnaires. Prentice-weighted Cox regression analyses were used to estimate HR and 95% CI for type 2 diabetes incidence according to protein intake.

Results: After adjustment for major diabetes risk factors and dietary factors the incidence of type 2 diabetes was higher in those with high intake of total protein (per 10g: HR 1.06; 95% CI 1.02-1.09, P-trend <0.0001) and animal protein (HR 1.05; 95% CI 1.02-1.08, P-trend 0.001). Effect modification by sex (p<0.001) and BMI among women (p<0.001) was observed.

Compared to the overall analyses, associations were stronger in women, more specifically obese women with a BMI>30 kg/m² (HR 1.19; 95% CI 1.09-1.32 for animal protein), and non-significant in men. Plant protein intake was not associated with type 2 diabetes (HR 1.04; 95% CI 0.93-1.16, P-trend 0.098).

Conclusions: High total and animal protein intake was associated with a modest elevated risk of type 2 diabetes in a large cohort of European adults.

Key words: Dietary protein, type 2 diabetes, nutritional epidemiology, case-cohort, prospective study.

LOW DIETARY DIVERSITY IS ASSOCIATED WITH CHILD STUNTING IN RURAL ETHIOPIA

E. Custodio¹, J. Pérez-Formigó², E. Gadisa³, L. Sordo⁴, I. Cruz⁵, C. Cañavate⁵, J. Nieto⁵, C. Chicharro⁵, A. Aseffa³, J. Moreno⁵

¹Centro Nacional de Medicina Tropical, Instituto de Salud Carlos III, Madrid, Spain

²Escuela Nacional de Sanidad, Instituto de Salud Carlos III, Madrid, Spain

³Armauer Hansen Research Institute, Addis Abeba, Ethiopia

⁴Centro Nacional de Epidemiología, Instituto de Salud Carlos III, Madrid, Spain

⁵Servicio de Parasitología, Centro Nacional de Microbiología, Instituto de Salud Carlos III, Madrid, Spain

Background and objectives: Diet diversity is related to overall quality and nutrient adequacy of the diet in low-income countries. The aim of this study was to determine the level of dietary diversity in school-aged children of a rural area in Ethiopia, and assess its association with their nutritional status.

Methods: We conducted a cross-sectional study, using multistaged cluster survey methodology, in rural villages of Libo Kemkem and Fogera districts in Amhara Regional State, Ethiopia. Food intake was assessed by a 24 hour recall. A Diet Diversity Score (DDS) was created by summing the number of unique food groups consumed during last 24 hours. The Minimum Dietary Diversity Intake (MDDI) was defined as DDS > 4. Stunting and wasting were defined as Height-for-Age and Body-Mass Index-for-Age Z scores < -2 standard deviations in relation to WHO 2007 Reference. Descriptive and univariate analyses were carried out.

Results: A total of 711 children were surveyed; 43% were stunted and 22% were wasted. Overall, 83.6% of the children did not reach a MDDI and this proportion was higher among stunted children (86.4%) than among non-stunted (81.5%), p=0.05. Also, a lower proportion of stunted children reported

consuming food products from the meat/poultry/fish group compared to the non-stunted (8.3% and 13.3% respectively, $p=0.023$) and from the Vitamin A-rich-fruits-and-vegetables group (1.7% among non-stunted versus 4.7% among stunted, $p=0.021$). On the other hand, stunted children reported an increased consumption of legumes (92.7%) compared to non-stunted children (88.7%), $p=0.045$. No association was found between DDS or food groups and wasting.

Conclusions: Child stunting and reduced dietary diversity intake are highly prevalent in this area, and seem to be related. The inclusion of a variety of vitamin A rich foods and animal-source-food products may be essential for improving child growth and nutritional status.

Key words: diet diversity, Ethiopia, malnutrition

DNA DAMAGE AND CHROMOSOMAL STABILITY IN HEALTHY AND DIABETIC INDIVIDUALS AND THE IMPACT OF VEGETABLES AND WALNUT OIL

E. Müllner¹, M. Wallner¹, H. Brath², K.H. Wagner¹

¹Department of Nutritional Sciences, University of Vienna, Austria

²Diabetes Outpatient Clinic, Health Centre South, Vienna, Austria

Background and objectives: Diabetes mellitus is a metabolic disorder characterized by high blood glucose levels which are a consequence of impaired insulin secretion and insulin function. Recent studies suggest that people with type 2 diabetes are more likely to die from cancer than people without diabetes. Reasons for the increased cancer risk involve obesity, hyperglycaemia and hyperinsulinaemia. The objective was to investigate the amount of DNA and chromosomal damage in T2DM subjects and the impact of a dietary intervention rich in vegetables and polyunsaturated fatty acids on biomarkers for oxidative DNA damage and cancer risk.

Methods: An intervention study with 76 diabetic and 21 non-diabetic subjects was performed. Subjects were randomly assigned to the information or intervention group. All subjects received information about the beneficial effects of a healthy diet and subjects randomised to the intervention group additionally received 300 g of vegetables and 25 ml of walnut oil rich daily for 8 weeks. DNA damage was measured with Comet Assay, levels of chromosomal damage were evaluated with Micronucleus Assay.

Results: The intervention led to a significant reduction in DNA damage in diabetic subjects after 4 and 8 weeks of intervention. Levels of DNA damage did not change in non-diabetic subjects of the intervention group and in subjects of the information group. Biomarkers for cancer risk evaluated by Micro-

nucleus Assay remained constant during the intervention with vegetables and oil, however associations with glucose metabolism were observed.

Conclusions: The results of our study suggest that a healthy diet can reduce levels of oxidative DNA damage in diabetic individuals. Levels of chromosomal damage were not changed; however, results suggest a strong relation to glycemic control.

Key words: Diabetes mellitus, cancer risk, DNA damage

O091

IMPACT OF RELATIVE PROTEIN INTAKE DURING SEVERE ENERGY RESTRICTION ON BODY COMPOSITION AND RESTING ENERGY EXPENDITURE IN OBESE ADULTS

N. Byrne¹, A. Hills²

¹School of Exercise and Nutrition Sciences & Institute of Health and Biomedical Innovation, Queensland University of Technology, Brisbane, Queensland, Australia

²Mater Mothers Hospital, Mater Medical Research Institute and Centre for Musculoskeletal Research, Griffith Health, Griffith University, Australia

Background and objectives: When body weight is lost rapidly, there is some concern that a greater proportion of the tissue lost is fat-free mass (FFM) and that this can adversely impact on resting energy expenditure (REE). Both exercise training and higher relative protein intakes are reported to be effective in preserving FFM during weight loss. Therefore we examined: [1] the extent of FFM loss when a very low energy diet (VLED) was used in combination with exercise training; and [2] the association between relative protein intake and changes in FFM and REE.

Methods: Sixteen sedentary obese but otherwise healthy men and women (40.5 ± 9.0 y; 39.3 ± 6.3 kg/m²) were measured in energy balance before and after a 12-week VLED plus exercise training intervention. Exercise training involved 4 aerobic and 2 resistance sessions/wk. The relative energy deficit was severe (from 75-89%). Body composition was measured by DXA and REE by indirect calorimetry.

Results: Change in weight (-18.6 ± 5.0 kg), FM (-15.5 ± 4.3 kg), and FFM (-3.1 ± 1.9 kg) did not differ between genders. FFM represented $16\pm 8\%$ (range:4-29%) of the weight loss. The ratio of FM:FFM loss was not related to the weight loss, nor to baseline body composition. Protein intake (g/kg/d) was negatively correlated with FFM loss expressed in absolute (kg; $R=0.55$, $P<0.01$) and relative (%; $R=0.44$, $P<0.05$) terms. Further, protein intake was negatively correlated with the reduction in REE ($R=0.46$, $P<0.05$).

Conclusions: Loss of FFM was modest, suggesting that exercise training may have an important effect on body composition during severe energy restriction. However, lower relative protein intake was associated with greater FFM loss, and greater reductions in REE. Higher protein intakes combined with the anabolic stimulus of exercise training may be warranted during severe energy restriction to limit negative effects on body composition and metabolism.

Key words: Weight loss, protein intake, exercise, obesity, body composition

NUTRITIONAL STUDY WITH FUNCTIONAL OMEGA-3 ENRICHED MILK IN CELIAC DISEASE PATIENTS. THE CIBOM STUDY.

J. Fonollá², A. Rodríguez-Montealegre¹, J. Valle³, D. Pineda³, MP. Díaz-Ropero², E. Corral⁴, S. Bastida¹, M. Seranillos³, F.J. Sánchez-Muniz¹

¹Departamento de Nutrición, Facultad de Farmacia, Universidad Complutense de Madrid, Spain

²Biosearch S.A., Granada, Spain

³Hospital Virgen de la Salud, Toledo, Spain

⁴Lactalis Puleva S.L., Granada, Spain

Background and objectives: Celiac disease is caused by an abnormal sensitivity to cereal gluten and courses with increased pro-inflammatory to anti-inflammatory interleukins ratio and elevated antibodies levels to gliadin. Scientific evidence is available on the role of omega-3 fatty acids as anti-inflammatory agents. The Celiac, Inflammatory Biomarkers Omega Milk study (CIBOM study) was designed with the aim to test the possible protective effects of omega-3 fatty acids enriched-milk in celiac patients.

Methods: The design consisted in a double-blind, randomized, in parallel, controlled study of 6 months duration. Omega-3 enriched milk (500 mg/LEPA+DHA) was tested vs a control semi-skimmed milk. Informed consent was obtained from participants. Patients were instructed to drink 500ml/day of milk in 2 doses and to maintain a mixed diet (with avoidance of food containing real or potential gluten). Blood samples were taken at 0, 1 and 6 months. Serum fatty acid profile, lipids, lipoproteins, interleukins and other markers were analyzed. A triple 72h food register questionnaire and FFQ were performed.

Results: Celiac disease diagnosis was performed by intestinal biopsies. Fifty-five volunteers were enrolled in the study. Thirty eight completed the 6 month treatment. Information on factors at gestation, food introduction calendar and diet is available and being to study. In general terms volunteers have appreciated or considered adequate both assayed milks. Fatty acid profile would permit to assure omega-3 consumption, as high bioavailability has been already found in other studies.

Conclusion: Results from this on-going pilot study would permit to evaluate the potential benefits of omega-3 enriched milk in celiac patients and to perform a high-scale project in those patients.

Key words: Celiac disease, omega-3, milk, inflammation, markers

EFFECTS OF TWO ENERGY-RESTRICTED DIETS DIFFERING ON PROTEIN CONTENT ON THE INFLAMMATION STATE OF OBESE SUBJECTS WITH METABOLIC SYNDROME FEATURES

P. Lopez-Legarrea¹, R. de la Iglesia¹, A. Perez-Cornago¹, I. Abete², S. Navas-Carretero^{1,3}, M.A. Zulet^{1,3}, J. A. Martinez^{1,3}

¹Department of Nutrition, Food Science and Physiology, University of Navarra, Spain

²BioDonostia Health Research Institute, Spain

³CIBER Fisiopatología Obesidad y Nutrición (CIBEROBn) Instituto de Salud Carlos III, Spain

Background and objectives: Metabolic syndrome (MetS) traits encompass the main cardiovascular risk factors. Inflammation has been proposed as a potential link between obesity and related vascular comorbidities. Therefore, adequate dietary strategies to fight against MetS must target on the improvement on the inflammatory status, in addition to weight/fat loss. Some beneficial effects of increasing protein of the diet on weight loss/maintenance have been reported but the role on inflammation still being controversial. This study aimed at comparing the effect of two energy-restricted diets with different protein content on the inflammation state of obese subjects presenting MetS features.

Methods: Ninety-six obese (BMI= 35.85±4.67 kg/m²) participants with MetS symptoms completed an 8-week randomized intervention trial to compare the RESMENA diet (-30% Energy, 30% protein, 40% carbohydrates, 30% lipids) with a Control diet based on the American Heart Association guidelines (-30% Energy, 15% protein, 55% carbohydrates, 30% lipids). Four inflammation markers (hsCRP, TNFα, IL-6, PAI-I) were measured at baseline and at the end of the intervention and considered as a score in order to assess the inflammation condition.

Results: Control and RESMENA groups significantly reduced body weight (6.73±0.71 kg vs. 7.09±0.82 kg) without differences between groups. The inflammation score was significantly lower (p=0.012) in the low-protein group (6.81±2.32 vs. 7.94±1.94) at the end of the intervention. Total protein intake was positively associated with inflammation (p=0.007), as well as animal protein (p=0.025) and meat derived protein

($p=0.015$). Nonetheless, neither vegetal origin protein nor fish derived one were found to influence the inflammation state.

Conclusion: The type of protein more than the total amount consumed within an energy-restricted diet influence the inflammation status associated to obesity-related vascular damage. www.clinicaltrials.gov; NCT01087086/March 2010

Key words: inflammation markers, weight loss, macronutrient distribution, type of protein.

INCREASING ENERGY AND ZINC INTAKES TO LEVEL RECOMMENDED BY WHO IMPROVE FAT-FREE MASS BUT NOT ZINC STATUS IN HIV/AIDS PEOPLE

A. Badiane¹, A. Diouf¹, N M. Manga², P S. Sow², N. Idohou-Dossou¹, S. Wade¹

¹Laboratoire De Nutrition, Département De Biologie Animale, Faculté des Sciences et Techniques, Université Cheikh Anta Diop De Dakar, Senegal

²Services des Maladies infectieuses, Centre Hospitalier Universitaire de Fann, Dakar, Senegal

Background and objectives: Malnutrition is common complications of HIV. The aim of this study was to assess individual dietary intakes and the impact of high energy fortified food (HEFF) on body composition and zinc status of hospitalized people living with HIV (PLWH) in Senegal.

Methods: A clinical trial was conducted in 65 PLWH randomly allocated to receive during 3 months the standard hospital diet alone (Control group; $n=33$), or the diet with 100 g/day of HEFF mixed with rice porridge (HEFF group; $n=32$). Individual dietary intakes were measured during hospitalization and compared to the Recommended Dietary Allowances (RDA) for PLWH. Body composition was determined by BIA. Plasma zinc concentration was assessed by atomic absorption and adjusted to inflammation/infection (CRP and $\alpha 1$ -AGP). All measures were conducted on admission, discharge and after 9 weeks follow up at home.

Results: In both groups, 30% were severely malnourished ($BMI < 16 \text{ kg/m}^2$) and 50% were zinc deficient. Compared to RDA, energy and zinc intakes from the standard diet alone were low in the Control group ($1178 \pm 708 \text{ Kcal}$, $3.3 \pm 0.9 \text{ mg}$), and in the HEFF group ($1558 \pm 692 \text{ Kcal}$, $3.4 \pm 0.7 \text{ mg}$). Zinc and energy requirements of the PLWH (as recommended by WHO) were covered when 100 g HEFF (543 kcal, 7 mg zinc) is added to the standard diet. After 3 months of supplementation, weight (+11%) and fat-free mass (+11.8%) significantly increased ($P=0.033$), while body fat percentage decreased (-0.3%; $P=0.018$) in the HEFF group compared to the Control group. However, the zinc status of the patients remained unchanged.

Conclusion: The standard hospital diet did not provided adequate amount of energy and zinc for PLWH. When the diet

was improved with HEFF, intakes reached the RDA and the body composition of the patients improved after 3 months but not their zinc status.

Key words: food supplementation, PLWH, BIA, Senegal

LIFESTYLE RECOMMENDATIONS FOR CANCER PREVENTION AND SURVIVAL AFTER DIAGNOSIS OF COLORECTAL CANCER: RESULTS FROM THE EPIC STUDY

D. Romaguera^{1,2,3}, H. Ward³, P A. Wark³, A C. Vergnaud³, P H. Peeters³, C H. van Gils⁴, V. Fedirko⁵, M. Jenab⁵, E. Riboli³, T. Norat³

¹Research Unit, University Hospital Son Espases, Spain

²CIBER Obesidad y Nutrición, Spain

³Department of Epidemiology and Biostatistics, School of Public Health, Imperial College London, UK

⁴University Medical Centre Utrecht, The Netherlands

⁵International Agency for Research on Cancer (IARC), France

Background and objectives: A score reflecting lifestyle recommendations on diet, nutrition, physical activity and weight management for cancer prevention proposed by the World Cancer Research Fund/American Institute of Cancer Research (WCRF/AICR score) has been associated with a lower incidence of colorectal cancer (CRC) in participants of the European Prospective Investigation into Cancer and Nutrition (EPIC) cohort, but the influence of this score on mortality after CRC diagnosis is unknown.

Methods: The association between the WCRF/AICR score (including the recommendations on weight management, physical activity, foods and drinks that promote weight gain, plant foods, animal foods, alcoholic drinks, and breastfeeding for women; score range was 0–6 in men and 0–7 in women) and CRC-specific ($n=929$) and overall mortality ($n=1,113$) was prospectively examined among 3,292 participants diagnosed with CRC between 1992–1999 in the EPIC cohort (mean follow-up time 4.2 years). Multivariable Cox proportional hazard models were used to calculate hazard ratios (HRs) and 95% confidence intervals (CIs) according to four pre-determined categories of the score.

Results: The HRs (95% CIs) for CRC-specific mortality among participants in the 2nd (score range in men/women: $>2-<3/>3-<4$), 3rd ($3-<4/4-<5$) and 4th ($4-6/5-7$) category of the score were 0.91 (0.75–1.09), 0.76 (0.63–0.93) and 0.74 (0.58–0.95) respectively (p for trend 0.003), compared to participants with the lowest adherence to the recommendations (category

1 of the score: 0-2/0-3). Similar HRs for overall mortality were observed (p for trend 0.006).

Conclusions: Higher pre-diagnostic adherence to the WCRF/AICR recommendations on diet, nutrition, physical activity and weight management are associated with improved survival among patients with CRC.

Key words: healthy lifestyle, diet, physical activity, weight, colorectal cancer, survival.

O096

DID THE CYCLONE "SENDONG" IN PHILIPPINES AFFECT MALNUTRITION LEVELS OF CHILDREN IN THE PHILIPPINES?

E. Rivero¹

¹Acción Contra El Hambre, Madrid, Spain

Background and objectives: Few controlled and geographically restricted epidemiological studies are available on the nutritional impact of floods on children. The hypothesis that households affected by the cyclone Sendong are at higher risk of having children undernourished was tested to improve the understanding of the relationship between exposure to floods and malnutrition in Philippines.

Methods: Datasets from two cross sectional studies done by ACF in the affected area after the floods were merged and analysed after attributing specific weightings to each of the surveys. ENA software was used to generate anthropometric scores and STATA was used to analyse the information. The association between malnutrition indicators (wasting, stunting and underweight) and the level of exposure that households had to floods was assessed by using univariate and multivariate logistic regression. Adjustment for confounding was carried out using a forward fitting approach model.

Results: The overall prevalence of wasting, stunting and underweight in children aged 6-59 months was 4.6%, 42.8% and 24.7%. Adjusted analysis for potential confounders revealed that within four months of the cyclone, wasting and stunting did not differ among children living in totally affected houses and those living in partially and non-affected houses. However, the risk of being underweight was lower in those children living in the most heavily affected houses (crude OR: 0.40, 95%:0.19-0.83).

Conclusions: Prevalence of malnutrition did not raise emergency thresholds. Household which were highly affected tended to have less children suffering from being underweight, as opposed those living in partially and non-affected households, likely because the majority of those more heavily affected were moved to evacuation centres where humanitarian aid was more efficiently distributed. A better understanding of the mechanisms and impact that natural disasters have on the nu-

tritional status of children is required to devise more effective interventions to reduce malnutrition.

Key words: floods, malnutrition, children

O097

DIETARY CAROTENOIDS AND BREAST CANCER RISK AMONG CHINESE WOMEN

C. Zhang¹, L. Wang¹, F. Lin², Y. Chen¹

¹Department of Medical Statistics and Epidemiology, Sun Yat-Sen University, Guangzhou, People's Republic of China

²Nursing Department, the First Affiliated Hospital of Sun Yat-sen University, Guangzhou, People's Republic of China

Background and objectives: Although vegetables and fruits have been implicated in the etiology of breast cancer, the role of carotenoids in these food groups has received little attention in Chinese populations. And the protective effect of carotenoids on breast cancer has been inconclusive. The present study aimed to assess the association of dietary carotenoids with breast cancer risk among Chinese women.

Methods: A case-control study was conducted between September 2011 and December 2012 in Guangzhou, China. Five hundred and twenty-three breast cancer cases were matched in frequency to 523 controls by age (5-year interval) and residence (urban/rural). Dietary intake was assessed by face-to-face interviews using a validated food frequency questionnaire. The US Department of Agriculture-Nutrition Coordinating Center Carotenoid Database was used to calculate the specific carotenoids intake. The logistic regression models were used to estimate multivariate-adjusted odds ratios (ORs) and 95% confidence intervals (CIs).

Results: A significant inverse association was found between specific carotenoids intakes and breast cancer risk. The adjusted ORs for the highest quartile versus the lowest quartile were 0.33 (95% CI: 0.21-0.51, trend test P<0.01) for α -carotene, 0.29 (95% CI: 0.18-0.44, trend test P<0.01) for β -carotene, 0.44 (95%CI 0.28-0.68, trend test P<0.01) for β -cryptoxanthin, and 0.38 (95% CI: 0.25-0.58, trend test P<0.01) for lutein+zeaxanthin, respectively. Lycopene intake was not found to be associated with breast cancer risk. The protective effect of the specific carotenoids on breast cancer risk was more evident among premenopausal women but not among postmenopausal women.

Conclusions: This study indicated that higher intakes of specific carotenoids were associated with a lower risk of breast cancer among Chinese women.

Key words: carotenoids, breast cancer, Chinese women

ZINC ABSORPTION FROM RICE IS SIMILAR WHEN ZINC IS INTRINSICALLY INCREASED THROUGH BIOFORTIFICATION OR EXTRINSICALLY ADDED AS ZNSO4

M. Brnic¹, R. Wegmüller¹, A. Melse-Boonstra², C. Zeder¹, F M. Tay³, R F. Hurrell¹

¹Laboratory of Human Nutrition, Institute of Food, Nutrition and Health, ETH Zurich, Switzerland

²Division of Human Nutrition, Wageningen University, The Netherlands

³Clinical Trials Center, University Hospital Zurich, Switzerland

Background and objectives: Increasing zinc content of a staple food crop through biofortification is a promising strategy to prevent and reduce zinc deficiency and is particularly interesting for rice and crops that are not consumed as flours and are thus not a good vehicle for post-harvest fortification. The efficacy of biofortification depends on the bioavailability of zinc from the improved crop, as the native phytic acid content and the interaction of the native zinc with the grain matrix may strongly influence zinc absorption. The aim of this study was to evaluate zinc absorption from a biofortified rice and to compare it to a rice fortified with ZnSO₄ before consumption to the same total zinc content (1.12 mg/meal).

Methods: Fractional absorption of zinc (FAZ) was measured using the double isotopic tracer ratio method. ⁷⁰Zn label was present intrinsically in the biofortified rice, and it was added before consumption to the extrinsically fortified rice. Sixteen young healthy adults consumed the two single meals in a crossover design.

Results: The geometric mean FAZ (-SD; +SD) from the biofortified rice was 23.7 % (16.4; 34.2), similar to the 19.5 % FAZ (13.4; 28.5) measured in the extrinsically fortified rice (*p* = 0.06).

Conclusions: The results suggest that the zinc intrinsically present in the biofortified rice is released from the rice matrix in the gastrointestinal tract and its absorption is influenced by phytic acid and other food components similarly to that of the extrinsically added zinc.

Key words: zinc absorption, biofortification, rice Funding: The INSTAPA project receives funding from the European Union's Seventh Framework Programme [FP7/2007-2013] under grant agreement no 211484.

O099

SEX DIFFERENCES OF VITAMIN E METABOLISM IN RATS

A. Takenaka¹, N. Fujita¹

¹Department of Agricultural Biochemistry, School of Agriculture, Meiji University, Kawasaki, Kanagawa, Japan

Background and objectives: Alpha-tocopherol, a form of vitamin E, is preferentially accumulated in human and rodents by means of alpha-tocopherol transfer protein. It has been reported that plasma and tissue concentrations of alpha-tocopherol are higher in females than in males that may be related to the sex difference of antioxidative activity. In order to clarify the mechanism of this difference, we investigated the sex differences of alpha-tocopherol metabolism in rats.

Methods: Urinary excretion of alpha-carboxyethyl-hydroxychromans (CEHC), a major alpha-tocopherol metabolite, was measured and compared between 1) male and female rats of 9 weeks old, 2) male and female rats of 3 weeks old, 3) ovariectomized and sham-operated female rats, 4) castrated and sham-operated male rats, 5) castrated male rats with or without testosterone propionate injection (8 mg / kg body weight). Plasma and liver alpha-tocopherol concentrations and lipid concentrations were also measured.

Results: Urinary alpha-CEHC excretion was significantly higher in female than male rats of 9 weeks old, but the difference was not observed in rats of 3 weeks old. Castration increased urinary CEHC concentration while ovariectomy did not have any effect. Testosterone injection to castrated rats reduced urinary CEHC excretion. Testosterone decreased plasma and liver alpha-tocopherol concentrations and liver triglyceride concentrations.

Conclusions: Urinary excretion of alpha-tocopherol metabolite was higher in female rats than in males, and this difference was caused by the effect of testosterone. The results that testosterone decreased both alpha-tocopherol metabolism and accumulation in body indicated that testosterone reduced lipid and tocopherol accumulation that cause the reduced tocopherol metabolism in male rats. To clarify the mechanism of low tocopherol accumulation in male rats needs further investigation.

Key words: alpha-carboxyethyl-hydroxychroman, alpha-tocopherol, ovariectomy, vitamin E

O100**IODINE EXCRETION HAS DECREASED IN DENMARK DURING THE LAST 5-6 YEARS**

L. B. Rasmussen¹, L. Bjergved², A. Krejbjerg³, T. Jørgensen², P. Laurberg³, H. Perrild⁴, L. Ovesen⁵,

¹Division of Nutrition, National Food Institute, Technical University of Denmark

²Research Centre for Prevention and Health, The Capital Region of Denmark, Glostrup, Denmark

³Department of Endocrinology and Medicine, Aalborg Hospital, Aalborg, Denmark

⁴Department of Endocrinology and Gastroenterology, Bispebjerg University Hospital, Copenhagen, Denmark

⁵Department of Gastroenterology, Slagelse Hospital, Slagelse, Denmark

Background and objectives: Before 1998 mild to moderate iodine deficiency existed in Denmark. A voluntary iodine fortification program was introduced in Denmark in 1998, and changed to a mandatory fortification of household salt and bread salt in 2000. The objective of this study was to compare iodine excretion and iodine intake in 2004-2005 and 2008-2010.

Methods: Two population based studies were carried out after fortification in 2004-2005 and in 2008-2010 in two cities in Denmark. The first study included 3579 randomly recruited adult participants (participation rate 46.6 %). The second study included 2465 adult participants (59.1 %), recruited among participants in a cross-sectional study carried out in 1997-1998. Iodine in casual urine samples was measured by the Ce-As method. Creatinine was measured on a Vitros 250 chemistry system. Intake of iodine rich food was assessed by food frequency questionnaire. To calculate estimated 24-h iodine excretion the iodine/creatinine ratio was multiplied by expected daily creatinine excretion for the given individual.

Results: Median (25-75 percentiles) iodine excretion was 101 (57-151) µg/l in 2004-2005 and 83 (47-133) µg/l in 2008-2010, $P < 0.001$. A higher estimated fluid intake (½ glass) in 2008-2010 compared with 2004-2005 might partly explain this decrease. However, median estimated 24 h iodine excretion decreased from 150 (101-235) µg/day to 134 (93-206) µg/day, respectively ($P < 0.001$). This measure takes the dilution of the urine into account. Dietary intake of iodine rich food did not change significantly but percent who used dietary supplements with iodine increased from 30 % and 36 % ($P < 0.01$).

Conclusion: Iodine excretion in Denmark has decreased significantly between 2004-2005 and 2008-2010 to a level indicating mild iodine deficiency in the population, despite an unchanged fortification program. These results suggest that the iodine content in food, e.g. milk, may have changed.

Key words: iodine fortification, iodine intake, Denmark

O101**EVALUATION OF ZINC STATUS AND COMMUNITY PERCEPTIONS IN PAKISTAN: THE NATIONAL NUTRITION SURVEY 2011**

S. Soofi¹, A. Habib¹, Z. Bhutta¹, I. Hussain¹, D. Alam¹

¹Department of Paediatrics & Child Health, Aga Khan University, Pakistan

Background and objectives: Over a third of the global population is at risk of zinc deficiency. Zinc deficiency is the fifth leading risk factor for childhood illnesses in the developing world. Several systematic reviews of preventive and therapeutic strategies have highlighted potential benefits of zinc. Pakistan is recognized as a country with a significant proportion of its population at risk of zinc deficiency. Previous National Nutrition Survey in 2001 identified over a third of the women and children as zinc deficient on the basis of plasma zinc estimation. In the last decade, other than the introduction of zinc for the management of diarrhea, no large scale preventive interventions have been evaluated. In order to understand the population prevalence of zinc, we evaluated the zinc status as part of the recently concluded National Nutrition Survey 2011.

Methods: The survey was conducted on a national and provincial sampling frame weighted for urban and rural populations and targeted women of reproductive age (WRA) 15-49 years and children under 5 (U5C) 0-59 months. All seven provinces of the country were included and in a two stage stratified survey. Altogether 30,000 households were surveyed and 12,000 blood specimens each from WRA and U5C analysed for a range of micronutrients using standard procedures in a CDC certified central micronutrient laboratory.

Results: Preliminary findings from the survey indicate that overall nutritional status of children in Pakistan have not improved since 2001. Stunting rates range from 37-54% and between 5-9% of children severely wasted. Among WRA 5-18% BMI < 18.5. Preliminary findings of the overall prevalence of zinc deficiency suggest that 38% of U5C and 48% of WRA have serum zinc concentrations < 60 µg/dL).

Conclusion: To reduce the burden of zinc deficiency in low resource countries, fortification of food may be the only solution at a population level.

Key words: Zn deficiency, urban, rural, Pakistan

O102**DEFINING OBESITY USING BIOLOGICAL END POINT IN CHILDREN**

V.P. Wickramasinghe¹, C. Arambepola², P. Bandara¹, M. Abeyssekera¹, S. Kuruppu¹, P. Dilshan¹, B.S. Dissanayake¹

¹Department of Paediatrics, University of Colombo, Sri Lanka

²Department of Community Medicine, University of Colombo, Sri Lanka

Background and objective: Obesity is defined as presence of excessive body fat mass (FM) associated with morbidity. FM associated with morbidity in children is debatable and only few studies have tried to identify the critical FM which varies between 20%-25 % in boys and 25%-32% in girls. This study attempts to identify the %FM that would define obesity among Sri Lankan children.

Methods: A cross sectional descriptive study conducted among 5-15 year old children in Colombo district. FM was assessed using InBody-230 BIA machine (Boispace Co Ltd, South Korea) and validated against Sri Lanka body composition equations. Waist circumference (WC) was measured. After a 12 hour fast, blood was drawn for fasting blood glucose (FBS) and lipid profile. OGTT was done with anhydrous glucose 1.75 g/kg body weight and random blood sugar (RBS) done 2 hours later. Metabolic derangements were defined as: WC for age >90th centile (UK standards); FBS >100 mg/dl or RBS >140 mg/dl; HDL-C <40 mg/dl; triglyceride >150 mg/dl; and SBP/DBP >+2SD for age (UK standards). Metabolic syndrome (MetS) was diagnosed by a high WC with ≥2 metabolic derangements. ROC were drawn to determine best %FM that predicts MetS as well as ≥2 metabolic derangements.

Results: 920 children were studied (boys 547). 15 (1.6%) had MetS. 95 (10.3%) had two and 16 (1.7%) had ≥3 metabolic derangements. MetS in boys was associated with a %FM of 28.6 (sensitivity 0.857; specificity 0.870) and in girls 32.6 (sensitivity 0.833; specificity 0.789). ≥2 metabolic abnormalities were associated with a %FM of 17.1 in boys and 25.7 in girls.

Conclusion: FM associated with adverse health outcomes in this population is comparable to other available data. A %FM 28% for boys and 32% for girls would be an acceptable cutoff limit.

Acknowledgements: Study carried out through an educational grant from Anchor institute, to University of Colombo.

Key words: Fat mass, Obesity, metabolic derangement, Sri Lankan children

O103**RIBOFLAVIN STATUS IS INVERSELY ASSOCIATED WITH HOMOCYSTEINE AND DETERMINES THE EFFECT OF THE MTHFR 677C>T POLYMORPHISM ON HOMOCYSTEINE DURING PREGNANCY**

⁵Financial Support: Comisión Interministerial de Ciencia y Tecnología, Spain (SAF2005/05096); The Spanish Ministry of Health (Instituto de Salud Carlos III, Fondo de Investigaciones Sanitarias), project PI:10/00335; Institut d'Investigació Sanitària Pere Virgili

Background and objectives: The function of FAD-dependent methylenetetrahydrofolate reductase (MTHFR) may be affected by riboflavin status. We investigated the effect of riboflavin status during pregnancy on homocysteine (tHcy) and on the relationship between the MTHFR 677C>T polymorphism and tHcy.

Methods: 400 women from the Reus-Tarragona Birth Cohort (NUTCIR phase; University hospitals Sant Joan, Reus and Joan XXIII, Tarragona) were studied. Erythrocyte glutathione reductase activation coefficient (EGRAC, functional riboflavin status indicator), red cell folate (RCF), plasma cobalamin and tHcy at <12, 24-27 and 34 gestational weeks (GW), and the MTHFR 677C>T polymorphism were determined. The association between EGRAC and tHcy and how EGRAC status affected the association between the polymorphism and tHcy were investigated using multiple linear regression analysis (MLRA) at each of the studied time points. The models were adjusted for RCF, cobalamin, creatinine, smoking, caffeine, study centre, maternal age and GW at the moment of the extraction.

Results: EGRAC increased as pregnancy progressed indicating worsening status (12GW vs 34GW, mean[SD]) (1.15[0.17] vs 1.19[0.18] p<0.05). tHcy [μ mol/L, geometric mean(SD)] was higher at 24-27GW in participants with riboflavin deficiency (EGRAC >1.4) (5.13[1.07]) compared to those with optimal riboflavin status (EGRAC < 1.2) (4.51[1.02], p<0.05) and at 34GW in those with deficient (6.21[1.07] vs 5.00[1.02],

p<0.001) or borderline (EGRAC >1.2-<1.4) riboflavin status (5.73[1.02], p<0.01). MLRA showed that tHcy was 18% higher in MTHFR 677C>T homozygotes in the highest EGRAC tertile >1.17) at <12GW compared to the reference group (heterozygotes and wild types combined) and 18.8% higher at 34GW (high EGRAC tertile: > 1.22). The respective interaction terms (EGRAC * MTHFR 677C>T genotype) were significant: p=0.002 and p<0.001.

Conclusion: Riboflavin status worsened as pregnancy progressed, was inversely associated with tHcy in mid-late pregnancy and determined the effect of the MTHFR 677C>T polymorphism on tHcy.

Key words: Riboflavin, homocysteine, MTHFR 677C>T, pregnancy.

¹⁰GENUD: "Growth, Exercise, Nutrition and Development" Research Group, University of Zaragoza, Zaragoza, Spain

Background and objectives: Fruit and vegetables intake is recommended as high intakes are associated with a reduced outcome of chronic disease and positive health status. Especially adolescents often have an inadequate intake of fruit and vegetables, and this could be linked to an undersupply of nutrients, and specifically, vitamins. The association between fruit and vegetable consumption (FVC) and vitamin status in European adolescents participating in the HELENA (Healthy Lifestyle in Europe by Nutrition in Adolescence) cross-sectional study is examined.

Methods: In 1089 adolescents (580 females), FVC were assessed by means of a validated questionnaire and blood vitamin concentrations [plasma folate (PF), red blood cell folate (RBC folate), whole blood folate (WBF), cobalamin, holotranscobalamin, total-homocystein, vitamin B6, vitamin C, β -carotene, α -tocopherol, retinol, and 25-OH-vitamin D]. The fruit and vegetable intake was classified into 3 groups: A: intake less or equal to once a week; B: 2-6 times per week, C: at least once per day. Vitamin status was assessed by chromatography (RP-HPLC) or immunoassays. Statistical differences were assessed by ANOVA analysis (p<0.05, SPSS).

Results: Group C with regular fruit and vegetable consumption included the lowest percentage of adolescents (for fruits: boys = 14.6%, girls 21.4%, for vegetables: boys =10.3%, girls = 16.5%). In both gender, significantly higher PF levels were observed with higher FVC. In boys, FVC was positively correlated to WPF and RBC-folate (p<0.05). Only in girls, a higher vegetable intake was also associated with significantly higher cobalamin, vitamin C and β -carotene levels. Fruit intake in boys was inversely associated with α -tocopherol concentrations (p<0.05).

Conclusions: Less than 20% of adolescents consumed fruit and vegetables at least once per day. Only folate was positively influenced by FVC and in addition in girls, cobalamin, vitamin C, and β -carotene concentrations were related to vegetable intake.

Key words: vitamin status, fruit and vegetable intake, adolescents

O105

CLASSIFICATION OF BODY MASS INDEX OF RURAL AND PERI-URBAN SCHOOL CHILDREN AND ADOLESCENTS IN NIGERIA USING TWO INTERNATIONAL STANDARDS

H. Ene-Obong,¹ E. Ekweagwu,² E. Agabi.¹

¹Department of Biochemistry (Nutrition Unit), University of Calabar, Calabar, Cross River State, Nigeria

²Department of Home Science, Nutrition and Dietetic, University of Nigeria, Nsukka, Enugu State, Nigeria

Background and objectives: Body mass index (BMI) has been identified as a useful tool for defining overweight/obesity in children and adolescents. Age- and sex- specific cut-off points have been developed by the International Obesity Task Force (IOTF) and World Health Organization (WHO) and recommended for international comparison of the prevalence. The aim of this paper is to compare the sensitivity of two international standards in defining body mass index (BMI) status of rural and peri-urban populations of school children and adolescents.

Methods: Cross-sectional studies were conducted involving 360 and 410 randomly selected school children and adolescents in Ebonyi State (rural communities) and Cross River State (peri-urban communities). Weights and heights of the subjects were measured using standard procedures. Age was obtained from school records/birth certificates. BMI was calculated using the formula: Weight (kg)/Height (m²). Overweight, obesity, thinness/underweight were defined using the IOTF cut-off points for children 2-18 years and the WHO BMI-for-age Z-scores for 2-5 year and 5-19 year olds. Descriptive statistics was used to analyze data.

Results: Using the WHO classification, the prevalence of underweight/thinness, overweight and obesity in the rural area were 30%, 4.7% and 0%, while the IOTF classified them as: thinness grade I (68%), grade II (15%) and grade III (11.7%). For the peri-urban population, using the WHO reference standard, the prevalence of underweight, overweight, and obesity were 7.9%, 7.1%, and 0.2%, while the IOTF cut-off classified the same population as: underweight, 21.9%; overweight, 4.4%; obesity, 0.2%.

Conclusions: There are considerable differences using these standards; while the WHO standard magnifies the prevalence of overweight, the IOTF cut-offs appears to exaggerate the prevalence of underweight/thinness. This calls for caution in the interpretation of results obtained using these standards and the need for national/regional standards.

Key words: Body mass index, sensitivity, international standards, children, adolescents

O106

FRUIT MACROANTIOXIDANTS, A NEW TYPE OF MAJOR PLANT FOOD CONSTITUENTS, SIGNIFICANTLY CONTRIBUTE TO THE INTAKE OF ANTIOXIDANTS IN THE DIET

J. Pérez-Jiménez¹, M.E. Díaz-Rubio¹, F. Saura-Calixto¹

¹Department Metabolism and Nutrition, Institute of Food Science, Technology and Nutrition (ICTAN-CSIC), Madrid, Spain

Background and objectives: The association between antioxidants intake and a decrease in the risk to develop certain chronic diseases is commonly attributed to low molecular weight antioxidants (vitamin C, vitamin E, carotenoids, certain polyphenols, etc.). These compounds provide a daily antioxidant intake of 3,300 antioxidant units (umol Trolox equivalents) in the Spanish diet. However, recent works have reported the existence of macroantioxidants, high-molecular weight antioxidants that reach nearly intact the colon and that may have specific health-related properties (Arranz et al., *Molec. Nutr. Food Res.*, 54, 2010, 1646-58; Hamauzu et al. *Plant Foods Human Nutr.*, 66, 2011, 70-77). In this work, macroantioxidants and associated antioxidant capacity in the most consumed fruits in Europe were evaluated, aiming to elucidate the contribution that they may have to total antioxidant intake.

Methods: Eight fruits were selected, corresponding to the 75-80% of the consumption in Spain, Holland, France and Germany. Macroantioxidants and low molecular weight antioxidants were evaluated by different methodologies, including HPLC-MS analysis. Associated antioxidant capacity was evaluated by three complementary methods.

Results: Macroantioxidants content in fruits commonly consumed in Europe ranges from 212 to 3560 mg/100 g dry matter in melon and in banana, respectively. In the Spanish diet, macroantioxidants from fruits provide a daily intake of 458 antioxidant units (umol Trolox equivalents determined by ABTS, 2,2α-Azino-bis-3-ethylbenzothiazoline-6-sulfonic acid assay). Some individual macroantioxidants were identified, such as quercetin or vanillic acid.

Conclusions: Macroantioxidants, usually ignored, provide similar antioxidant units intake than low molecular weight antioxidants in fruits (458 vs 430). Further research is needed, including all plant foods, to elucidate the contribution of macroantioxidants to the reported health-effects of diets rich in antioxidants.

Key words: macroantioxidants, dietary antioxidants, fruits

O107

EFFECT OF A DIETARY SUPPLEMENT IN BODY COMPOSITION IN PERIMENOPAUSAL WOMEN

V. Calabria Torres¹, C. Prado Marínez¹, M D. Marrodán Serrano², M. Carmenate Moreno¹, A. del Valle Ramírez¹, A H.Nielsen Anderson¹

¹Universidad Autónoma de Madrid, Madrid, Spain

²Universidad Complutense de Madrid, Madrid, Spain

Background and objectives: Recent studies have highlighted the effectiveness of the drugs combination with a modification of lifestyle therefore relates to the reduction of body weight. In this paper we analyze the effect of a dietary supplement, not yet available in the European market, on body composition, lipid profile and blood count.

Methods: The used sample was 92 perimenopausal women with a mean age of 48.1 ± 7.4 years. A randomized double-blind protocol to compare the group A (product) and the group B (placebo) was designed. For inclusion in the study women should submit a BMI within categories of overweight or obesity grade I, not have hepatic or renal disease, not have gastric reduction surgery, no pregnant or following any diet at the moment of the study. The treatment period was two months with somatic, physiological and hematic controls, at the beginning, at the end of the treatment product/placebo and 2,5 months following the finish. The women were informed and advised on lifestyle and nutrition but not imposed any diet or exercise during the months of study.

Results: The most relevant results found indicate that while weight loss has been discreet in women who have taken the food supplement, however, have experienced a significant increase in muscle mass ($p < 0.03$) and tissue hydration ($p < 0.01$), not altering bone mass values. In both groups there has been a significant reduction of about 1% in the fat component. Finally, in postmenopausal women showed a decrease in the percentage of total fat only in those who consumed the food supplement and not the placebo group.

Conclusion: The administration of a supplement to perimenopausal women can lead to specific changes in body composition.

Key words: body composition, climacteric women, food supplement, antioxidant.

²Departamento de Medicina y Cirugía Animal. Facultad de Veterinaria. Universidad Complutense de Madrid, Madrid, Spain

³Departamento de Farmacología; Facultad de Farmacia, Universidad Complutense de Madrid, Madrid, Spain

⁴Departamento de Nutrición, Bromatología y Toxicología, Facultad de Farmacia, Universidad de Alcalá, Madrid, Spain

Background and objectives: Seaweeds, being prolific sources of bioactive components have gained interest in recent years. Diets prepared from seaweeds can be given as supplements. The aim of this investigation was to identify whether the liver damage markers of normal or hypercholesterolaemic rats was affected by dietary supplementing diets with restructured meat (RM) containing Wakame (W), Nori (N) and Sea Spaghetti (S).

Methods: Eight rat groups were fed a mix of 85% AIN-93M rodent-diet plus 15% freeze-dried RM for 35 days. The control group (C) consumed control RM, the algae groups, RM with 5% Wakame, 5% Sea spaghetti and 5% Nori, respectively. Animals on added cholesterol diets (CC, CW, and CN) consumed their corresponding basal diets added with cholesterol (2%) and cholic acid (0.4%). The histology technique was used to evaluate liver injuries.

Results: CN and CS diet induced significantly lower plasma cholesterol levels ($P < 0.001$) than the CW diet. Only partial injury could be observed by histology in the liver of rats receiving CC as compared with the C group. Histological analyses did not demonstrate any remarkable changes in the liver with respect to CC groups. However, the incidence of non-dense glycogen-like vacuole presence observed in livers of the Nori rats was significantly higher ($P < 0.05$) than in Wakame and control rat livers.

Conclusions: N and S blocked the hypercholesterolaemic effects of the dietary cholesterol but were unable to reduce the incidence of several liver alterations. Effects of some seaweed seem to be a two-edged sword as they increased liver damage or plays a role in detoxification. More studies are needed to ascertain the utility of consuming algae as part of very cholesterol-rich diets.

Acknowledgments: Granted by AGL-2011-29644-C02-02, Consolider-Ingenio 2010 # CSD2007-00016 and predoctoral fellowship to Adriana Schultz-Moreira by Universidad Complutense, Madrid, Spain.

Key words: Liver, histology, restructured-meat, seaweeds, cholesterol

²Tumor Inmunología y Señalización Celular. Hospital La Paz Health Research Institute, Madrid, Spain

³Investigación en Nutrición y Alimentos Funcionales (NUTRINVEST). Hospital La Paz Health Research Institute, Madrid, Spain

Background and objectives: Among physiological changes associated to obesity it has been reported alterations in the intestinal microbiota which may contribute to a systemic proinflammatory status. It was aimed to evaluate the interaction of *Lactobacillus plantarum* 3547 (Lp3547) with innate immune system and its ability to counteract inflammation by diet induced obesity in animal model.

Methods: Human monocytes isolated from healthy volunteers were used to obtain macrophages (MØ) which were pre-treated with Lp3547 for 6 hours. After washed MØ were kept in medium for 1, 2, 4, 7 and 10 prior to a second stimulation with *Escherichia coli*, *Staphylococcus aureus* or LPS. Levels of cytokines were analyzed by CBA and membrane proteins by Western blot. In addition, male Wistar rats were supplemented with control (n=16) or hipercaloric diet (n=16) for 22 weeks followed by 2 weeks of Lp3547 supplementation (2x10⁹ cfu/kg). Cytokine profile was quantified in plasma, intestine, liver and adipose tissue.

Results: MØ improved its reprogramming ability in response to pathogen bacteria when were exposed to Lp3547. Moreover, the elevated expression of CD64, HLA-DR and TREM1 suggested a high phagocytic ability. Plasma and ileal IL10 concentrations were higher in obese and control animals when supplemented with Lp3547. Also, probiotic treated obese animals showed lower TNF α ; concentrations in plasma and adipose tissue than obese control, presenting values similar to the observed in control lean animals.

Conclusions: Lp3547 seems to have an immunomodulatory effect in MØ and it points a putative protective role in the inflammatory process associated to obesity.

Acknowledgements: This work was supported by Carinsa group thought the project HUENUFOOD (CEN- 20101016) inside the CENIT program from the Spanish Ministry of Economy and Competitiveness

Key words: *Lactobacillus plantarum*, immunomodulation, obesity

⁸FrieslandCampina, Amersfoort, The Netherlands

Background and objectives: Probiotics and milk calcium may increase resistance to intestinal infection, but their effect on growth, iron and zinc status of Indonesian children is uncertain. We investigated the hypotheses that cow's milk added with probiotics would improve growth, and iron and zinc status of Indonesian children, whereas milk calcium alone would improve growth, but reduce iron and zinc status.

Methods: A six-month randomized trial was conducted in low-socioeconomic urban communities of Jakarta. Healthy children (n=494) were randomly assigned to receive low-lactose milk: with low-calcium content ~50 mg/d (LC; n=124), regular-calcium content ~440 mg/d (RC; n=126), RC with

5x10⁸ colony-forming unit/d Lactobacillus casei CRL 431 (casei; n=120); or RC with 5x10⁸ colony-forming unit/d Lactobacillus reuteri DSM 17938 (reuteri; n=124). Growth, anemia, iron and zinc status were assessed before and after the intervention.

Results: Compared to RC, the reuteri group had significantly greater weight gain [0.22 (95% CI: 0.02, 0.42) kg], weight-for-age Z-score (WAZ) changes [0.09 (95% CI: 0.01, 0.17)], and monthly weight [0.03 (95% CI: 0.002, 0.05) kg/mo] and height [0.03 (95% CI: 0.01, 0.05) cm/mo] velocities. Casei significantly increased monthly weight velocity [0.03 (95% CI: 0.001, 0.05) kg], but not height. However, the changes in underweight, stunting and anemia prevalence, and iron and zinc status were similar between groups.

Conclusions: L. reuteri DSM 17938 modestly improved growth, by increasing weight gain, WAZ changes, and weight and height velocity, while L. casei CRL 431 modestly improved weight velocity. Independent from probiotics supplementation, regular milk calcium neither affected growth, nor iron and zinc status.

Key words: probiotics, calcium, growth, iron and zinc status, Indonesian children

⁴Nutrition Unit, Hospital Virgen de las Nieves, Servicio Andaluz de Salud, Junta de Andalucía, Granada, Spain

Background and objectives: Several studies in animals and humans have demonstrated that citrus flavanones as hesperidin and naringin have a cardiovascular protector effect. The aim of the study was to evaluate the influence of a dietary intervention including a polyphenol-rich orange juice (OJ) on endothelial function markers in overweight and obese adults.

Methods: 151 volunteers (18-65y) included in a randomized, placebo-controlled, double-blind, crossover trial. 45 were overweight (25-30kg/m²) and 106 obese (30-40kg/m²) and were randomly assigned into two groups. One group consumed two daily doses (250ml each) of a polyphenol-rich OJ (582.5mg of hesperidin, 125mg of narirutin and 34mg of didymin, daily) during 12 weeks, and after a 4-8 week wash-out period, they consumed an OJ with lower levels of polyphenol (237mg of hesperidin, 45mg of narirutin and 17mg of didymin, daily) during 12 weeks. The second group followed up the order conversely. Resistin and soluble forms of intercellular adhesion molecule (sICAM-1) and vascular cell adhesion molecule (sVCAM) were analysed using xMap technology. Flavanones excretion in urine was measured using UPLC-MS/MS. A linear mixed model was used to evaluate differences between groups. Correlations between parameters were estimated by computing Pearson's correlation coefficient. All statistical analyses were performed with the SPSS 20.

Results: Hesperidin and naringin excretion increased significantly in both groups after 12-wk consumption, but being considerably higher in the polyphenol-rich OJ group (p<0.001). Moreover, plasma concentration of resistin and sICAM-1 significantly decreased after polyphenol-rich OJ consumption (p-values<0.001). However, no changes were observed in sVCAM concentration. Nevertheless, sICAM decreases were negatively correlated with hesperidin in urine (p-value<0.05).

Conclusions: Consumption of a polyphenol-rich OJ for 12 weeks improves condition of cardiovascular risk biomarkers as resistin and sICAM-1 in overweight and obese adults.

Key words: Polyphenols, orange juice, obesity, cardiovascular disease biomarkers.

O112

TEMPE AND TOFU FLOUR MAY HAVE POSITIVE EFFECT ON COGNITIVE FUNCTION

A. Kridawati¹, A. Kridawati², Hardinsyah², A. Sulaelman², R. Damanik², A. Winarto³, T B W. Rahardjo⁴, E. Hogervorst⁵

¹Faculty of Health Sciences, University of Respati Indonesia, Indonesia

²Department of Community Nutrition, Faculty of Human Ecology, IPB, Indonesia

³Faculty of Veterinary Medicine, IPB, Indonesia

⁴Center of Aging Studies, Universitas Indonesia

⁵Department of Human Sciences, Loughborough University, UK

Background and objectives: Previous observational work in humans suggested that phytoestrogens may have a time li-

mitted, dose dependent, and age dependent effects on cognition in postmenopausal women. Indonesia is a country where people commonly consume large amounts of tempe and tofu – soy products rich in phytoestrogens. Where tofu had positive associations with memory in middle-aged women, negative associations were found in older women. The objective of this study was to assess effects of tempe and tofu on memory in elderly female rates.

Methods: Ninety white female Sprague Dawley strain rats aged 12 months were randomly assigned to three intervention groups (tempe, tofu, and estradiol) after ovariectomy and two control groups (casein ovariectomy and casein-non ovariectomy). Memory was assessed by a modified T maze test before and after ovariectomy and after 2, 5 and 8 weeks of treatment. Isoflavone content of tofu and tempe was assessed using HPLC assays.

Results: The content of isoflavones in tempe flour was twice that of tofu flour. The group of rats fed with tempe showed better cognitive function (faster times to maze completion and longer distance covered within the first five minutes) than tofu, estradiol and casein non ovariectomy, but then a reversal was seen at 8 weeks, similar with tofu, estradiol, and casein non ovariectomy. The casein group showed no change in learning time, although distance covered was seen to drop after week 2. For both products tempe and tofu efficacy increased with consumption over time and after 8 weeks a reversal of effects was seen.

Conclusion: Regular high intake of phytoestrogens derived from tempe may have short term positive effects on memory in older female subjects. Future studies should include older and young rats to identify mechanisms and be followed by a clinical trial.

Key words: tempe flour, tofu flour, cognitive, elderly female rats.

O113

EFFECT OF ADMINISTRATION OF CARNITINE ON THE CARDIAC AND ERYTHROPOIETIC FUNCTION OF CARNITINE DEFICIENT PATIENTS

Y. Aoki^{1,2}, T. Yamamoto¹, Y. Ishimori², Y. Okubo²

¹Institute of Medullasin, Florida, USA

²Fureai Clicic Izumi, Japan

Background and objectives: Various amounts of carnitine were administered to hemodialytic patients to evaluate changes of both cardiac and erythropietic function in them.

Methods: Patients receiving hemodialytic therapy (26 patients) were employed in the study. Every patient receiving hemodialysis showed extremely low carnitine concentration in plasma, because carnitine is easily removed through dialysis

membrane and generation of carnitine in the kidney is extremely low in the atrophic kidney with decreased oral intake of it. Administration of carnitine (2.4g/day) to patients receiving hemodialysis increased its level in plasma above normal levels in two weeks. Plasma carnitine concentration was measured by determining the amount of CoA released from the reaction between carnitine and acetyl-CoA.

Results: Doses of erythropoietin required for maintaining hemoglobin levels in peripheral blood between 10 and 11g/dl decreased about 55% of the doses initially required. Therefore, carnitine is considered to increase erythropoiesis by the mechanism other than the increase in the oxidation of fatty acids in mitochondria. Effect of administration of carnitine on cardiac function of hemodialysis patients was also examined by measuring the ejection fraction in echo cardiography. It increased significantly ($p < 0.05$) after carnitine therapy. Both human atrial natriuretic peptides in plasma and cardiothoracic ratio decreased after carnitine therapy significantly ($p < 0.05$).

Conclusions: These results indicate that administration of carnitine to hemodialytic patients improved cardiac function, because carnitine enhanced the entry of fatty acids into mitochondrial matrix to increase their oxidation to produce ATP.

Key words: Carnitine, hemodialysis, erythropoietin, ejection fraction.

O114

SOCIAL REPRESENTATION OF OBESITY IN A RURAL COMMUNITY OF MEXICO

T. Ochoa¹

¹Health Department, Iberoamerican University, Mexico

Background and objectives: Obesity is generally conceived as a disease and therefore is undesirable for individuals. Different conceptions of the biological-medical model are present in the ideology and way of living in different cultures so it is important to recognize and understand social representations of obesity to implement rational programs in societies in nutritional transition to prevent and reduce obesity. The aim of the study was to identify the social representations of obesity in a rural community: San Jeronimo Amanalco located two hours distance from Mexico City.

Methods: The ethnographic method was used and the researcher lived for five summers in the community from 2006 to 2010. Depth interviews and informal conversations were conducted to general population of the community (about 3000 interviews in total).

Results: People of the community recognize two types of obesity: obese persons and inflated individuals. Obesity is caused by overeating. An inflated person results by consuming

large quantities of sodas, beer and junk food. From a nutritional and medical standpoint both categories fall within the overweight or obese, but for the people an inflated person is not obese. The inflated category arises in the community about 50 years ago, coinciding with the entry process industrialized food to the community. On the other hand, an obese person is considered as a sign of health and wellness and thinness is synonymous with anemic person. The ideal of the married woman's body is being obese as it is a sign that your husband is a good provider in the home.

Conclusion: In San Jerónimo Amanalco, people see obesity as normal. Understanding the social representations of obesity is an essential element for the implementation of health programs in nutrition transition societies. Unfortunately, currently used strategies in Mexico are not considering these cultural aspects about obesity.

Key words: social representation of obesity, culture, Mexico

MAJOR DIETARY PATTERNS OF IRANIAN WOMEN AND THEIR RELATION WITH ETHNICITY AND DURATION OF RESIDENCE IN THE CAPITAL CITY (TEHRAN).

A. Rezazadeh^{1,2}, N. Omidvar¹, B. Rashidkhani¹

¹Community Nutrition Department, Faculty of Nutrition and Food Technology, Shahid Beheshti University of Medical Sciences and Health Services, Tehran, Iran

²Students Research Committee, Shahid Beheshti University of Medical Sciences and Health Services, Tehran, Iran

Background and objectives: Tehran, capital of Iran, is a multi ethnic city. Various ethnic groups may follow different eating pattern. Also, living in a Metropolis may change the habits to healthier or unhealthier patterns due to acculturation. The aim of this study was to detect major dietary patterns and their relation with ethnicity and duration of residency in Tehran (DRT).

Methods: In a cross-sectional study, 460 women aged 20-50 years old living in Tehran, were selected by stratified random sampling method. Dietary information was collected by a valid and reliable semi-quantitative F.F.Q. Ethnicity and DRT was asked by interview. Belonging to an ethnicity (Fars, Turk, Northern [Tabari & Gilaki], Kurd, Lor, Balouch, Turkmen, Arab) was decided based on ethnicity of three generations behind a person and speaking language and dialect. Dietary patterns were defined by factor analysis method. To compare ethnicities and DRT, across quartiles of dietary pattern, chi-

square and ANOVA tests were used, respectively. Relationship between ethnicity, DRT and adherence to the dietary patterns was assessed by ANCOVA test (adjustment of age and socioeconomic status).

Results: Two major dietary patterns were extracted: 'Healthy' (high in vegetables, fruits, yogurt drink, low fat dairies, poultry, olive, nuts, fruit juice, potato, garlic, coffee, dried fruits, legumes) and 'Unhealthy' (high in processed meat, mayonnaise, soft drinks, sweets, refined grains, snacks, industrial juice, red meat, nuts, French fries, hydrogenated fats, egg, butter, high fat dairies, sugars and organ meats). Higher percents of Turks were at the highest and greater percent of Northern group were at the lowest quartile of 'Unhealthy' scores ($p < 0.05$). Turks in comparison with Fars (reference group) ethnicity ($B = 0.44; p < 0.01$) had positive associations with 'Unhealthy'; and, DRT had negative associations with healthy pattern ($B = 0.01; p < 0.01$). Other associations weren't significant.

Conclusions: Our findings showed being Turkish and higher DRT was associated with tendency toward an unhealthier pattern in the studied women.

Key words: Dietary patterns, ethnicity, duration of residence, women, Tehran.

O116

CONTRIBUTION OF SORGHUM TO ENERGY, IRON AND ZINC INTAKES OF MOTHERS AND PRESCHOOL CHILDREN IN RURAL BURKINA FASO

Y. Martin-Prevel¹, L. Nikiéma², M. Moursi³, I. Kossivavi-Ayassou¹, H. Lanou², P. Allemand¹, F. F. Moura³

¹Institut de Recherche Pour Le Développement (IRD) - UMR204 NutriPass IRD, UM2, UM1, France

²Institut de Recherches en Sciences de la Santé, Ouagadougou, Burkina Faso

³HarvestPlus, IFPRI/CIAT, Washington, D.C., USA

Background and objectives: People in Burkina Faso, particularly women and young children, are still suffering from under-nutrition including micronutrient deficiencies. Sorghum is their primary source of food in most rural areas. A strategy to alleviate malnutrition in such a context is to develop new varieties of sorghum that contain higher levels of micronutrients. In order to determine target levels, the present study aimed at providing information about current contribution of sorghum to energy, iron and zinc intakes of mothers and preschool children.

Methods: In 2010, a dietary survey was carried out in two rural provinces on a representative sample of 240 mothers and their 36-47 months old children in each province. The survey comprised two rounds of data collection, in the lean and post-

harvest season respectively. Women and children were administered multiple pass 24H recalls at each round. CS dietary software was used to compute daily energy, iron and zinc intakes and contribution of sorghum to these intakes was analyzed.

Results: In the lean season, mean daily intakes of sorghum were of 357 g of dry matter for mothers and 195 g for children; corresponding figures in post-harvest season were 237 and 114 g, respectively. Sorghum contributed 60.9%, 51.1% and 68.5% of mothers' energy, iron and zinc intakes, respectively, and 58.1%, 46.8% and 43.5% in those of children, in the lean season. In post-harvest season, corresponding figures were 40.7%, 26.6% and 45.2% for mothers; and 34.4%, 20.7% and 39.1% for children.

Conclusions: Sorghum was the main contributor to energy, iron and zinc intakes of both mothers and preschool children in rural Burkina Faso. Intakes were higher in the lean than in the post-harvest season. Sorghum contribution to intakes was slightly higher in mothers than in children.

Key words: Sorghum, micronutrient deficiencies, Africa

HYDRATION STATUS AND ITS RISK FACTORS AMONG INDONESIAN ADOLESCENTS AND ADULTS

H. Hardinsyah¹, G. Gustam¹, D. Briawan¹

¹Food and Nutrition Society of Indonesia; and Department of Community Nutrition, Bogor Agricultural University, Kampus IPB, Jl Raya Darmaga, Bogor, Indonesia

Background and objectives: No study had been done in Indonesia on hydration status and its risk factors. The objective of this study was to analyze dehydration problem and its risk factors among adolescents and adults in Indonesia.

Methods: This study called the THIRST (The Indonesian Regional Hydration Study) was carried out among 606 adolescent males and females aged 15-18 yrs and 594 adult males and females aged 25-55 yrs in lowland (North Jakarta, Surabaya and Makassar) and highland (West Bandung, Malang and Malino) areas of Indonesia. Urine specific gravity was used to determine hydration status; and a 6x24 hours record of food and beverage intake was used to estimate total fluid intake.

Results: The results show that the mean fluid intake subjects is 2750 ± 753 ml/d. Based on the urine specific gravity, 46.29% of the subjects categorized as dehydration. The results of logistic regression analysis showed the dehydration risk factors were ecological areas, body temperature, fluid intake, hydration knowledge, and overweight. Subjects who live in the lowlands had a risk of dehydration 2.75 times more compared

to those who live in the highlands. Subjects who had body temperature outside the normal range had a risk of dehydration 1.54 times compared to those who had a normal body temperature. Subjects that consumed less fluid had a risk of dehydration 1.30 times more compared to those who consumed adequate fluid. Subjects with less hydration knowledge had a risk of dehydration 1.33 times more compared to subjects with better hydration knowledge. Overweight subjects had a risk of dehydration 1.35 times more compared to those who had a normal or underweight body mass index.

Conclusions: This study reveals almost half of Indonesian adolescent and adults suffering from dehydration; and the main risk factors are ecology, body temperature and fluid intake

Key words: dehydration, risk factors, ecology

O118

SODIUM AND NUTRIENT DENSITY OF SOME TRADITIONAL DISHES AS CONSUMED IN NIGERIAN URBAN POPULATION IN RELATION TO CARDIOVASCULAR DISEASE (CVD)

E.A. Udentia¹, R.A. Adewunmi¹

¹University of Nigeria, Nsukka, Nigeria

Background and objectives: In the 2011 and 2012 international African nutrition conferences, high sodium intake and the risk of developing CVD was one of the topical issues linked with nutrition transition. Any impact-oriented action should be evidence-based in order to key into strategies to scale-up nutrition. Sodium and nutrient density of some traditional dishes as consumed in Nigerian urban population in relation to cardiovascular disease (CVD) was evaluated. Specific objectives were to collate recipes of dishes documented from a previously conducted household survey, determine their proximate composition and some CVD-related nutrient content (sodium, calcium, potassium, magnesium, folate, selenium and anti-oxidant vitamins (A, E, C) and elucidate their nutrient density relative to FAO/WHO/UNU standard values.

Methods: Recipes of various traditional dishes consumed by 300 households were recorded. A 3-day nutrient intake study was conducted on 10% of the population. Frequency distribution was used to identify the most widely consumed dishes. Twenty-six dishes, which were used by 30-80% of the study population, were selected, prepared and analyzed chemically, using standard methods. Nutrient density of the dishes was determined using FAO/WHO/UNU food-based dietary guidelines.

Results: Only 20% of the dishes had moderate protein density (54.43 and 57.76%); 10% had high fat density (84.45% versus 10.04-31.43% for other dishes); 60% had moderate to high vitamin A density (60-345%). Only 20% were sodium dense

(73.93 and 85.23% versus 20.37- 48.57% for others). All the analyzed dishes were carbohydrate, vitamin E, folate and selenium dense ($\geq 70\%$) but had low calcium density ($\leq 29.95\%$).

Conclusion: The traditional diets have potential for control and prevention of CVD if traditional dietary habits are maintained, with improvement in protein, calcium, vitamin C and Mg content of diets as consumed to alleviate these nutrient deficiencies.

Key words: Traditional diets, nutrient density, CVD.

O119

IDENTIFICATION OF TRADITIONAL FOOD RESOURCES AND THEIR IMPORTANCE IN A RURAL FARMING COMMUNITY IN SOUTHWESTERN NIGERIA

S. I. Ejoh¹, I. O. Akinyele¹

¹Department of Human Nutrition, Faculty of Public Health, College of Medicine, University of Ibadan

Background and objectives: In recent times, the use of traditional foods is decreasing and they have been labeled poverty foods. However, these food resources are still important for the subsistence of many rural and indigenous communities around the world. The aim of this study was to identify available traditional foods, their current level of consumption, and their importance to a rural farming community in Southwest Nigeria.

Methods: Data was collected using three focus group discussions (FGDs) by gender groups. Discussions included: foods available in the community – traditional and introduced; those commonly consumed and not commonly consumed; changes in their level of consumption; their preferred choice between traditional and introduced foods; reasons for these preferences; benefits of their traditional foods. Thematic analysis was used to analyse the FGDs.

Results: The following themes were identified: 1) list of foods; 21 staples, 28 soups (mostly vegetables) and 13 fruits; 2) preference between traditional versus foreign foods- majority of focus group participants showed more preference for traditional foods because of their importance to their livelihoods, nutrition and health; 3) cultivated foods versus wild foods; 4) benefits of traditional foods; 5) changes in consumption pattern of traditional foods – identified decline more among the youths, and was mostly attributed to modernization and migration from the rural areas; suggested solutions- make traditional diets more attractive, government's intervention especially to plight of rural farmers; 6) the seasonality of the foods especially vegetables.

Conclusions: The study showed that although there was a reduction in consumption of traditional foods, there was still preference for their consumption because of their importance in the subsistence, livelihood, nutrition and health of this rural

community. There is need for researchers and government to pay attention to the traditional food resources of indigenous peoples through research and policy.

Key words: Traditional foods, rural communities, importance.

O120

ECONOMIC INEQUALITY AND OBESITY: MULTILEVEL ANALYSIS OF INDONESIAN COMMUNITIES

K. Sari¹, N. Amaliah¹, N. Utami¹

¹The Center for Public Health Intervention Technology, The National Institute of Health Research and Development, Indonesian Ministry of Health, Central Jakarta, Indonesia

Background and objectives: Obesity rate has increased and been considered as a threat and a challenge for the public health sector for develop as well as developing countries. On the other hand inequality has risen in line with economic growth. Inequality was proven in studies in the western countries. The purpose of this study was to examine the association of economic inequality and obesity in Indonesia that is still rarely studied in Asia (Southeast Asia) in particular.

Methods: The data were obtained from a cross-sectional Indonesian Basic Health Research (Riskesdas) year 2010. The subjects consisted of 125563 respondents ages 19-55 years old that derived from 251388 household members nested within 69300 households nested within 2798 communities nested within 33 regions. Obese was categorized as body mass index more than 25. Community level exposures included economic inequality that based on Gini coefficient. The data were analyzed with multilevel logistic regression.

Results: The prevalence of obesity in Indonesia was 22.96%. The obesity prevalence of the 20% poorest and 20% richest were 14.4% and 32.2%, respectively. The economic inequality was ranged from 0.18-0.69 across 33 provinces in Indonesia. Controlling for individual factors, a significant gradient was observed between income and obesity, with very high income most likely to be obese (OR=2.03) followed by high (OR=1.68), middle (OR=1.41), low (OR=1.22), and very low as reference. Controlling for community effects of income, the results indicated that economic inequality has significant positive effect on obesity (OR=1.33).

Conclusions: The findings of this study show another new evidence for the effects of economic inequality on obesity. More unequal communities associated with greater probability of obesity.

Key words: economic inequality, inequality, obesity.

O121

INADEQUATE ENERGY AND PROTEIN INTAKES HAVE CONTRIBUTED TO THE HIGH PREVALENCE OF STUNTING IN INDONESIAN YOUNG CHILDREN

H. Hadi¹, T. Arjuna², G. Baldi³, E. Martini³

¹Department of Public Health, Faculty of Medicine, University of Gadjah Mada, Jl. Farmako, Sekip Utara, Yogyakarta, Indonesia

²Nutrition Alma Ata Center for Healthy Life and Food (ACHEAF), Yogyakarta, Indonesia

³Indonesia Country Office of World Food Programme, Jakarta, Indonesia

Background and objectives: About 58% of preschool children in East Nusa Tenggara, Indonesia are stunted. This study was conducted to assess whether inadequate food and nutrient intakes are associated with an increased risk of being stunted among Indonesian young children.

Methods: A cross-sectional study was conducted in Timor Tengah Selatan District. The study subjects were 408 children aged 6-24 months and their mothers. Energy and protein intakes were collected using a 24-hour recall questionnaires, weight of the children was measured using a calibrated digital weighing scale (SECA) with precision of 0.1 kg, while recumbent length was measured using a portable recumbent length board with precision of 0,1 cm by trained nutritionists. Data on breastfeeding history, demographic and socio-economic factors were collected using structured questionnaires. Height for Age and Weight for Height Z-Scores were computed using WHO Anthro2005 software.

Results: Energy and protein intakes in children aged 6-24 mo, on average, were 641 kcal/ day and 16.5 gram/ day respectively. These intakes represented to 76% and 77.4% of Indonesian Nutrient Requirements. The deficit of energy intake was 11.8% higher in males than in females and 20.7% higher in older (13-24 mo) than in younger (6-12 mo) children. Likewise, the deficit of protein intake was 22.4% higher in males than in females and 11.4% higher in older than in younger children. The odds of being stunted were 1.4 times (OR=1.45: 95% CI=0.97 – 2.27) higher in males than in females, and 4.6 times (OR=4.6: 95% CI=2.94 – 7.34) higher in older than in younger children adjusting for breastfeeding history and the remaining demographic and socio-economic factors.

Conclusions: Inadequate energy and protein intakes might have contributed to the high prevalence of stunting in young children of East Nusa Tenggara, Indonesia.

Key words: energy intake, stunting, children, Indonesia.

O122

CONFLICTING INDICATORS OF FOOD INSECURITY FROM A PILOT STUDY OF WATER, SANITATION, HYGIENE AND NUTRITION INTERVENTIONS IN RURAL WESTERN KENYA

A. Williams¹, V. Owino², S. Oiy³, A. Pickering⁴, H. Dentz^{3,5}, C. Null⁵, C. Stewart¹

¹Program in International and Community Nutrition, University of California, Davis, CA, USA

²Winfoods Project Kenya, University of Nairobi Institute for Tropical & Infectious Diseases

³Innovations for Poverty Action, Busia, Kenya

⁴Woods Institute for the Environment, Stanford University, CA, USA

⁵Hubert Department of Global Health, Emory Rollins School of Public Health, Atlanta, GA, USA

Background and objectives: Standard measures of food security are under scrutiny for cross-cultural competence and validity.

Methods: During a pilot RCT of water, sanitation, hygiene, and nutrition interventions for households with children <2 years old in rural Western Kenya (n=156), cross-sectional data were collected on food security using the household food insecurity access scale (HFIAS) and household hunger score (HHS); food intake using 24-hour and 7-day food frequency questionnaire (FFQ); and anthropometric data, in July 2012. Diet diversity (DD) was calculated based on WHO infant young child feeding (IYCF) food group categories, and 7 day FFQ was summarized to represent single days' worth of intake.

Results: Severe food insecurity prevalence was 64.7% by HFIAS and moderate hunger was 36.5% by HHS. Mean(SD) child age was 16.2(3.9)mo; z-score weight-for-length (WLZ) was 0.3(1.1); length-for-age (LAZ) was -1.2(1.3); weight-for-age (WAZ) was -0.4(1.1); maternal BMI was 21.6(3.1) kg/m². Prevalence of wasting (WLZ < -2SD), stunting (LAZ < -2SD) and underweight (WAZ < -2SD) were 2.2%, 30.9% and 9.4%, respectively. There were no significant differences in child anthropometrics by HFIAS/HHS (p>0.1). Mean maternal BMI did not differ by HFIAS (p=0.82), but did by HHS (p=0.04): 22.0(3.3) for little/no hunger and 20.9(2.5) for moderate hunger. There were no significant associations between maternal DD, measured by 7 day FFQ, and HHS (p=0.11) or HFIAS (p=0.84). Similarly, child DD was not associated with HFIAS or HHS. The proportion of children receiving >4 food groups/day was 85%.

Conclusions: Despite high self-reported prevalence of food insecurity, there appeared to be good evidence of DD and no significant association between food insecurity and child WLZ, WAZ, and LAZ. The HHS indicator may be more sensitive to detecting under-nutrition among women.

Acknowledgements: Funded by a grant to UC Berkeley from the Bill & Melinda Gates Foundation.

Key words: Food security, dietary diversity, Kenya.

O123

AVAILABILITY OF NUTRITION SERVICES IN MATERNAL, NEONATAL AND CHILD HEALTH (MNCH) FACILITIES IN BANGLADESH

M. Mridha¹, B. Sarker¹, J. Ferdous¹, L. Reichenbach¹

¹International Center For Diarrheal Disease Research, Bangladesh

Background and objectives: In 2011, the Government of Bangladesh started to mainstream nutrition services through its health system. This study was aimed at reporting the availability of nutrition services in maternal, neonatal and child health facilities in public, not-for-profit (NGO) and for-profit private (Private) sectors before the commencement of the mainstreaming nutrition initiative.

Methods: The study was part of a national health facility assessment (HFA) in Bangladesh. The HFA covered almost all public and private facilities (n=7680) that provide any MNCH care. During the HFA, the data collection team used a checklist to collect data on location, human resources, service provisions, equipment and drugs, and performance and cost of key services from the MNCH facilities. Availability of 12 (7 maternal, 3 neonatal and 2 child) nutrition services is reported in this paper.

Results: Routine iron and folic acid supplementation during pregnancy was available in 73.7% public, 88.6% NGO and 69.0% private facilities. Routine calcium supplementation during pregnancy was available in 47.9% public, 63.4% NGO and 60.0% private facilities. Fifty four percent public (53.6%), 70.3% NGO and 66.9% private facilities provide vitamin A supplementation to postpartum women. Fifty two percent (51.7%) public, 29.8% NGO and 90.8% private facilities provide advice for initiation of breastfeeding within 1 hour of childbirth. Fifty six (56.0%) public, 46.4% NGO and 87.8% private facilities provide routine health education on exclusive breastfeeding. Use of Zinc for treating diarrhea was available in 67.9% public, 56.5% NGO and 58.5% private facilities.

Conclusions: Key maternal, neonatal and child nutrition services are not available in all public, NGO and private facilities in Bangladesh. The government of Bangladesh should emphasize scaling up key maternal, neonatal and child nutrition services in all health facilities for further improving the mainstreaming nutrition initiative.

Acknowledgements: The study was funded and supported by UKAID and USAID.

Key words: Breast feeding, child nutrition, health

O124

COMBATING VITAMIN A DEFICIENCY DISEASES: BUILDING THE EVIDENCE BASE AND PARTNERSHIPS FOR FOOD BASED APPROACHES

J. Low¹, M. McEwan¹

¹Regional Office for Sub-Saharan Africa, International Potato Center, Nairobi, Kenya

Background and objectives: It is often stated that there is a lack of convincing evidence to show that food based approaches to address micro-nutrient deficiencies are successful. The objectives of the paper are firstly to trace how the evidence base was built for a specific food-based approach; and secondly, the implications for policy and intervention strategies.

Methods: Through a review of key research projects the paper assesses how the evidence base for the efficacy and effectiveness of using pro-vitamin A rich orange-fleshed sweetpotato (OFSP) for combatting Vitamin A Deficiency Diseases (VADD) was built over 17 years, and the most effective ways to integrate nutritional concerns into agricultural and health projects using OFSP as a key entry point.

Results: The results show how several questions which are relevant not only for the example of OFSP were addressed: 1) Will the OFSP varieties be competitive with existing local varieties? 2) Are producers and consumers willing to accept a sweetpotato variety with a distinct color difference? 3) How can we ensure that OFSP will be consumed by those target groups most at risk of VAD, and 4) Will donors and governments support OFSP-based interventions? The results show how different types of partnerships arrangements have been used to deliver OFSP interventions including delivery systems based on agricultural, market, health and educational entry points.

Conclusions: Efforts to support behaviour change towards the consumption of novel crops and new foods need to be based on an understanding of current dietary patterns and practices, local food and agricultural systems, and the policy context. Approaches need to balance local specificity, flexibility, with the pressures to rapidly expand geographical and population coverage. Thus food-based approaches need to be framed as complementary and contributory to sustainable development goals and rights based approaches for nutrition.

Key words: Vitamin A, food-based approaches.

O125

DELIVERY OF MICRONUTRIENT POWDER SACHETS THROUGH SALES BY FRONTLINE HEALTH WORKERS ENABLES HIGH REACH, BUT HOUSEHOLD POVERTY CONSTRAINS UPTAKE

R. Rawat¹, K. Saha², A. Kennedy¹, M. Ruel¹, P. Menon³

¹International Food Policy Research Institute (IFPRI), Washington, DC, USA

²IFPRI, Dhaka, Bangladesh

³IFPRI, New Delhi, India

Background and objectives: Micronutrient powders (MNP) are effective at reducing infant anemia, but little is known about how different delivery platforms can be used to effectively reach at-risk populations. One innovative delivery platform in Bangladesh utilizes a market-based approach, wherein MNPs are sold by BRAC frontline health workers (FHW), at home visits. We conducted a program-theory driven process evaluation, within the context of a cluster-randomized impact evaluation, examining the determinants of MNP awareness and purchase, and adherence to recommended dosage.

Methods: Mid-term surveys were conducted in 10 of 20 evaluation sub-districts. Two samples of households with at least one child aged 6-23 months were drawn: 1) a random sample (n=462), and 2) a purposive sample of MNP-purchaser households (n=338).

Results: At this 18-month assessment, reach of the FHW network was high (73%), but awareness of MNPs was low in the random sample (38%). FHWs were the primary source of information for 75% of households. Awareness of MNPs in the random sample was greater among households with greater socio-economic status (SES) (p=0.104), any reported exposure to FHWs (p=0.036), and greater total exposure to FHWs (p<0.001). MNP purchase in the random sample was low (17%), but with greater likelihood of MNP purchase among households with any exposure to FHW (p<0.001), and with greater total exposure to FHWs (p=0.006). There was no association between household SES and ever purchasing MNPs, but the total number of sachet purchases was higher in the highest, compared to lowest SES households in both the random (p=0.037) and MNP-purchaser households (p=0.006).

Conclusions: Although overall MNP purchase was low, these results highlight the potential for this delivery model to succeed, given the reach of FHWs and their influence on MNP awareness. However, different distribution channels might be more effective for lower SES households.

Key words: Micronutrient powders, Bangladesh, delivery platforms.

O126

UPDATED NUTRIENT DATA ON DANISH BEEF AND VEAL

U. Kehlet¹, MT. Darr¹, K. Jensen¹, NT. Madsen¹, L. Kristensen¹

¹Danish Meat Research Institute, roskilde, Denmark

Background and objectives: The forthcoming EU nutrition labelling rules valid from 2014/2016 require a mandatory declaration of energy, fat, saturated fat, carbohydrates, sugars, protein and salt on packed food. In the Danish Food Composition database, nutrient data on fat and saturated fat for beef and veal are based on 30-40 years old data sources and are therefore outdated regarding modern production, commercial cuts and more extensive trimming. The objective of this study was to document up-to-date nutrient data on total and saturated fat as well as protein and salt content in Danish veal and beef cuts.

Methods: Based on Danish slaughter statistics, representative and average veal (n=8) and beef (n=8) carcasses were selected to generate a complete set of commercial cuts. Mean values of total fat, saturated fat, protein and sodium were determined by accredited analyses.

Results: A clear linear relationship between total and saturated fat was established on subsamples of veal and beef cuts as well as ground beef. Based on this relationship, the saturated fat content in veal and beef products can be easily calculated from the equation: 0.42 x total fat (g per 100 g) - 0.19. For total fat, the levels differed between veal and beef as veal has a lower fat content, nevertheless, the majority of Danish red meat cuts contained less than 10 g fat per 100 g. The updated nutrient data can be used as documentation for nutrition labelling at cut level.

Conclusions: Updated nutrient data on Danish veal and beef offer numerous products with ≤10 g fat per 100 g. The low levels of fat reflect the changes in animal production and product trimming that have occurred during the last 20-30 years. These updated data will benefit consumers, health professionals and scientists to make appropriate dietary decisions.

Key words: Beef, labelling, nutrient composition

O127

CHARACTERIZATION OF OATS SAFETY IN CELIAC DISEASE IN RELATION TO THE CULTIVAR

M. Silano¹, F. Uberti², O. Vincentini¹, C. Felli¹, A. Budelli³, E. Penas², P. Restani²

¹Unit of Human Nutrition and Health, Istituto Superiore Di Sanità, Rome, Italy

²Department of Pharmacological Sciences, Università degli Studi di Milano, Milan, Italy

³Global Infant & Nutrition, Heinz Italia S.p.A., Milan, Italy

Background and objectives: Celiac disease (CD) is a permanent autoimmune enteropathy, triggered in genetically predisposed individuals, by dietary gluten. The only therapy is a strict gluten-free diet (GFD). The inclusion of oats in GFD could be of great value for its nutritional and health benefits. The safety of oats in CD is still matter of debate. However, most studies performed to evaluate the suitability in CD have not considered the oats variety. Our aims were to study the toxicity of different oats cultivars in some in vitro and ex vivo models of celiac epithelial activation and to correlate the ability in activating this pathway with oats protein profile.

Methods: The electrophoretic pattern of oats peptic-tryptic (PT) digests and the corresponding reactivity versus anti-gliadin antibodies was evaluated. Oats PT digests were evaluated in some in vitro models of celiac inflammation: K562(S) cells, human intestinal epithelial cells and celiac bowel mucosa.

Results: Our results showed that the Nave cultivar and its digests agglutinated the K562(S) cells, affected the transepithelial electrical resistance (TEER) of T84 cell monolayers, significantly increased the Tumor Necrosis Factor (TNF) - alpha concentration in T84 cell culture and increased the levels of transglutaminase 2 and p-tyrosine 42-44 in a similar way to wheat. However, Irina and Potenza varieties did not exert any effect on these in vitro models. Moreover, a straight correlation of the toxicity of oats cultivar with the electrophoretic pattern and the reactivity to anti-gliadin antibodies was found.

Conclusions: There is a significant difference among oats cultivars in eliciting the very precocious events occurring at the cell surface that are responsible for the mucosa inflammation in CD. The inclusion of oats in GFD might be valuable, but a suitable evaluation on their safety by means of biochemical/biological models of CD is recommended.

Key words: Oats, gluten-free, celiac disease.

O128

HOUSEHOLD WATER ACCESS AND SANITATION AS INDICATORS OF VITAMIN A AND ZINC EFFICACY ON GUT PARASITE RESOLUTION

K. Long¹, P. Vasan², H. Raga³, J. Santos⁴, J. Rosado⁵, A. Mamun⁶

¹School of Population Health, University of Queensland, Australia

²Government Primary Health Center, Madurai, India

³UN World Food Programme, West Timor, Indonesia

⁴School of Medicine, National Autonomous University of Mexico, Mexico

⁵School of Natural Sciences, Universidad Autónoma de Querétaro, Querétaro, Mexico

⁶School of Population Health, University of Queensland, Australia

Background and objectives: Vitamin A and zinc supplementation can reduce childhood intestinal parasite burden but household characteristics involved in parasite transmission may modify efficacy. We evaluated supplementation efficacy on *Ascaris lumbricoides*, *Entamoeba histolytica* and *Giardia lamblia* infection resolution among children from households differing in water access, sanitation and hygiene.

Methods: A randomized, double-blind, placebo-controlled trial carried out in Mexico City assigned children 6-15 mo of age to receive vitamin A every 2 months, a daily zinc supplement, a combined vitamin A - zinc supplement or a placebo and followed them for 1 year. Parasite infection durations among children in the different treatment arms determined in monthly collected stools were compared using hazard analyses stratified by personal and household factors.

Results: Vitamin A + zinc supplemented children from households with no piped water had reduced *G. lamblia* infection resolution compared to children from households with piped water. Children in all three treatment arms from households with dirt floors had reduced *A. lumbricoides* resolution compared to children from households with concrete floors (P for interaction=0.06, 0.01 and 0.07, respectively). Increased *E. histolytica* infection resolution was found among vitamin A supplemented children from households with dirt floors and no indoor bathrooms.

Conclusions: The contrasting outcomes of supplementation found in the stratified analyses suggest that children enrolled in mass chemoprophylaxis programs may be targeted for specific supplementation regimens using household characteristics as indicators.

Key words: Vitamin A, zinc, gastro-intestinal parasites, children

²Wallon Center of Industrial Biology (CWBI), Gembloux Agro Bio -Tech , University of Liège

Background and objectives: Deglet – Nour is a variety of dates largely consumed in Algeria and the most requested in the world. The objective of this study was to determine in this variety of dates the total phenolics using Folin –Ciocalteu reagent and the anthocyanins by the pH differential method. The oxygen radical absorbance capacity (ORAC- FL) was used to determine the antioxidant activity of the sample. The results obtained were expressed as means \pm standard deviation ($n = 3$) on a fresh weight basis.

Results: In this work, total polyphenolics values were about $240,854 \pm 7,31$ and $245,32 \pm 13,12$ mg/ 100 g gallic acid equivalent (GAE). Anthocyanins determination have shown a good results $0,853 \pm 0,040$ and $0,916 \pm 0,045$ mg of cyanidin 3-glucoside equivalent/100 g of sample in comparison to those reported by AL-Farsi et al (2005). Deglet-Nour was found as a good source of antioxidants ($4352, 333 \pm 19,56$ and $4817, 666 \pm 32,14$ micromoles of Trolox equivalent/ 100 g) of sample.

Conclusion: Dates fruit presents a good antioxidant property despite its low phenolics content level, as it was reported in literature for other dates varieties, this may be due to a combined activity of different compounds such as free phenolics, peptides and organic acids.

Key words: Dates, Deglet–Noor, phenolics,anthocyanins, ORAC-FL.

O130

LONG-TERM HEALTH CONSEQUENCES OF EARLY-LIFE STARVATION: EVIDENCE FROM FAMINE-BORN COHORTS IN UKRAINE

A. Vaiserman¹, M. Khalangot²

¹Laboratory of Epigenetics, Institute of Gerontology, Kiev, Ukraine

²Laboratory of Epidemiology of Diabetes Mellitus, Institute of Endocrinology and Metabolism, Kiev, Ukraine

Background and objectives: There is increasing evidence that malnutrition in early life affects long-term health outcomes including metabolic and cardiovascular disorders. To examine whether a link exists between exposure to starvation in early life and health status in adulthood, we determine the risk of developing type 2 diabetes (T2D) in cohorts born before, during, and after the Ukraine famine of 1933.

Methods: The sample studied consisted of 28,358 T2D patients born in the period of 1930-1938 and living in four Ukraine regions that suffered significant demographic losses due to famine: Chernihiv, Vinnitsa, Kharkiv and Kherson. Reference populations were based on the Ukraine census 2001 (total $n = 2,153,335$).

Results: It was approximate 1.5-fold increase in the risk of developing T2D during adulthood in both men and women who were born in the first half of the 1934 year as compared to the individuals who were born in the pre-famine and post-famine cohorts. These differences are highly significant compared to the appropriate reference cohorts born in 1938 [odds ratios are 1,48 (95%CI: 1,29-1,69) and 1,52 (95%CI: 1,40-1,66) for men and women, respectively]. For the second half year-born individuals in all cohorts studied, no significant difference was found compared to the corresponding reference cohorts. Remarkably, those individuals who were born in the first half of the 1934 and who have higher risk of developing T2D were exposed to the famine periconceptionally suggesting an epigenetic basis for risk and resilience across the lifespan.

Conclusions: These results support the view that periconceptual exposure to starvation may lead to persistent epigenetic changes that have adaptive significance during early postnatal development but predispose to metabolic disorders in adult life.

Key words: malnutrition in early life, Ukraine famine of 1933, persistent epigenetic changes, type 2 diabetes.

CHANGES IN IRON METABOLISM, HAEMATOLOGICAL AND INFLAMMATORY PARAMETERS OF DIABETIC RATS TREATED WITH VANADIUM AS AN ANTIDIABETIC AGENT

C. Sanchez-Gonzalez¹, C. Lopez-Chaves¹, C E. Trenzado², P. Aranda¹, M. Montes-Bayon³, A. Sanz-Medel³, J. Llopis¹

¹Department of Physiology, University of Granada, Granada, Spain

²Department of Animal Biology, University of Granada, Granada, Spain

³Department of Analytical Chemistry, University of Oviedo, Oviedo, Spain

Background and objectives: The increasing use of nutritional supplements of vanadium as an anabolic agent by the healthy population jointly with the increasing study of V as an hypoglycaemic agent in diabetes, justify the investigation of the interactions of V with the metabolism of other metals in the vanadium exposed organisms. Several studies reveal that the metabolism and distribution of V and Fe are related. The objective was to analyze the changes in the metabolism of iron and in the inflammatory status of diabetic streptozotocin rats following treatment with vanadium as an antidiabetic agent.

Methods: Four study groups were examined: Control; Diabetic; Diabetic treated with 1mgV/day (DMV); and Diabetic treated with 3mgV/day (DMVH). The V was supplied in drinking water as bis(maltolato) oxovanadium (IV)(BMOV). The experiment had a duration of five weeks. Iron was measured in food, faeces, urine, serum, muscle, kidney, liver, spleen and femur. Transferrin, ferritin, C-reactive protein (CRP), number of red (RBC) and white (WBC) blood cells and haemoglobin (Hb) were determined in samples of serum or whole blood.

Results: In the diabetic animals, we recorded higher levels of Fe absorbed, Fe content in kidney, muscle and femur. In DMVH, there was a significant decrease in fasting glycaemia, transferrin, Hb and increased serum CRP, Fe content in the liver, spleen and heart, in comparison with the diabetic rats.

Conclusion: BMOV is a dose-dependent hypoglycaemic agent. Treatment with 3 mgV/day provokes an inflammatory syndrome that produces an anaemic state together with increased iron deposits in the tissues.

Key words: Pathology, metabolism, inflammation, vanadium

O133

PUFA AND OXIDATIVE STRESS. FROM CYTOTOXIC EFFECT TOWARD ANTIOXIDANT DEFENCES

M. Di Nunzio¹, V. Valli², A. Bordoni²

¹Interdepartmental Centre for Industrial Agri-Food Research, University of Bologna, Cesena, Italy

²Department of Agri-Food Science and Technology, University of Bologna, Cesena, Italy

Background and objectives: Despite their important role in the nutritional prevention of many diseases, polyunsaturated fatty acids (PUFA) might be dangerous since they are particularly susceptible to free radical attack by reactive oxygen species, and might undergo oxidation in the body. On the other side diets enriched with n-3 PUFA have been shown to up-regulate antioxidant systems [1] and it has been speculated that this could be related to a sub-toxic stress imposed by PUFA peroxidation [2]. PUFA oxidation byproducts may activate nuclear factors such as erythroid 2-related factor 2 (Nrf2), which is associated to transcriptional activation of antioxidant response defences. In the current investigation we addressed the question of whether n-6 and n-3 PUFA protect or sensitize liver cells from oxidative damage.

Methods: HepG2 cells were supplemented with different PUFA at physiological concentration, and then exposed to an oxidative stress (0.2mM H₂O₂).

Results: All PUFA but docosahexaenoic acid enhanced cell susceptibility to H₂O₂-induced cytotoxicity and lipid oxidation. Furthermore, cell antioxidant defenses were differently modulated by the individual PUFA.

Conclusions: Our results highlight deep differences in the cell response to the individual fatty acids, stressing that PUFA cannot be considered as a unique category. Dietary recommendation on PUFA should not be generalized but must address the specific fatty acid. This work was partially supported by a grant of Italian MIUR (RFO A.B.) and of Italian Ministry of Economic Development (Industria 2015 – MIAOVER50 project). [1] Wang H et al. *Cardiovasc Res.* 2004;61:169-76. [2] Uchida K. *Prog Lipid Res.* 2003;42:318-43.

DIETARY COFFEE POLYPHENOLS DON'T ATTENUATE FEATURES OF THE METABOLIC SYNDROME AND ENDOTHELIAL DYSFUNCTION IN MICE FED A HIGH-FAT DIET

N. Ward¹, J. Li Kwok Cheong¹, P. Henry¹, J. Hodgson¹, K. Croft¹

¹School of Medicine & Pharmacology, University of Western Australia, Perth, Australia

Background and objectives: Coffee is a popular beverage in western society. There is a growing interest in the potential health benefits of dietary polyphenols as recent epidemiological studies have demonstrated associations with reduced risk of type 2 diabetes. Endothelial dysfunction, obesity, type 2 diabetes and the metabolic syndrome are all major risk factors associated with CVD, and are thought to involve oxidative stress. The aim of this study was to investigate the effects of chlorogenic acid (CGA), a major coffee polyphenol on obesity, glucose and insulin resistance, oxidative stress and endothelial function in a mouse model of the metabolic syndrome.

Methods: Thirty 6-8 weeks old male C57BL6 mice were randomly divided into one of three groups (i) normal diet, (ii) high fat diet (HFD), and (iii) HFD supplemented with 0.5% w/w CGA isolated from green coffee beans.

Results: Following 12 weeks of feeding, both the HFD and HFD + CGA fed mice demonstrated features of the metabolic syndrome, including; increased weight gain, increased oxidative stress (F2-isoprostanes), impaired glucose tolerance and insulin resistance. There was no indication of endothelial dysfunction in isolated aortic rings of any of the mice. CGA also failed to protect aorta which were subject to oxidative stress-induced endothelial dysfunction by external application of hypochlorous acid.

Conclusions: This study suggests that CGA, a major coffee polyphenolic does not protect against features of the metabolic syndrome.

Key words: chlorogenic acid, metabolic syndrome, endothelial function.

O135

THE INFLUENCE OF BLOOD SELENIUM STATUS AND SELENOPROTEIN GENE VARIATION ON COLORECTAL CANCER RISK

D. Hughes¹, V. Fedirko², C. Méplan³, J. Hesketh³, L. Schomburg⁴, H. Bas. B. de-Mesquita⁵, E. Riboli⁶, M. Jenab (on behalf of EPIC group)⁷

¹Department of Physiology & Medical Physics & Centre for Systems Medicine, Royal College of Surgeons in Ireland, Dublin, Ireland

⁵Department of Gastroenterology and Hepatology, University Medical Center, Utrecht, The Netherlands

⁶School of Public Health, Imperial College London, UK

⁷Section of Nutrition and Metabolism, International Agency for Research on Cancer, Lyon, France

Background and objectives: Suboptimal intakes of the essential micronutrient selenium (Se), as in many parts of Europe, may contribute to colorectal cancer (CRC). Se exerts its biological roles through 25 selenoproteins involved in cell protection from oxidative stress, redox control and inflammatory response. Variants in several selenoprotein genes have been reported to affect CRC risk. We are currently using the European Prospective Investigation into Cancer and Nutrition (EPIC) cohort to assess both the association of selenoprotein genotype and Se status with CRC risk, and their interaction in disease risk modification.

Methods: We are using a case-control study of 1500 CRCs and 1500 matched healthy controls nested within the EPIC cohort. Se concentration was measured by Total Reflection X-ray Fluorescence in serum available from 1000 of these cases and 1000 controls. Multivariable conditional logistic regression was used to assess the influence of Se levels on CRC risk. Selenoprotein genotypes are currently being assayed by Illumina GoldenGate.

Results: Analyses conditioned on the matching factors show a borderline non-significant 9% decrease per 25 ug/ L increase in Se concentration (HR = 0.91; 95% CI = 0.82-1.02). However, for females only a significant 18% decreased CRC risk was observed per 25 µg/ L Se increase (HR = 0.82; 95% CI = 0.70-0.95) and a 39% significant decrease when comparing the lowest to the highest quartile of Se concentration (HR = 0.61; 95% CI = 0.41-0.91; P trend =0.030).

Conclusions: This study should contribute to our understanding of the role that Se status and selenoprotein gene variation play in CRC development. The serum Se results indicate a suboptimal Se status in many Europeans and suggest that European women with suboptimal Se status may especially benefit from an increased dietary Se intake for CRC prevention.

Key words: Selenium status, selenoprotein gene variation, colorectal cancer risk, EPIC

O136

RELATIONSHIP BETWEEN METHIONINE METABOLISM PATHWAY GENES WITH PLASMA HOMOCYSTEINE AND RISK OF TYPE 2 DIABETES IN CHINESE

T. Huang¹, D. Xu², J. Sun², D. Li¹

¹Zhejiang University, China

²Fudan University, China

Background and Objectives: There is no data on the associations of genetic variants of homocysteine (Hcy) metabolic genes with type 2 diabetes (T2DM) in Chinese. The objective of the present study was to investigate the relationship between the gene mutations in Hcy metabolism related enzymes and plasma Hcy levels and T2DM susceptibility in Chinese.

Methods: Seven hundred and seventy-four T2DM patients and 500 healthy subjects were recruited from 30 Hospitals of 20 provinces in China. The plasma Hcy concentration was determined, 13 polymorphisms of 6 genes involved in homocysteine/folate pathway were genotyped. Genetic and haplotype analysis and the associations with plasma Hcy and T2DM were also evaluated.

Results: The prevalence of Hyperhomocysteinemia (HHcy) in T2DM was significantly lower (20.35%) than in healthy subjects (26.97%) ($p=0.023$). MTHFR (rs1801131, rs1801133), MTR (rs1805087, rs16834521), MAT1A (rs3851059, rs4933327), PEMT (rs4646406) was significantly associated with plasma Hcy in T2DM. MTHFR (rs1801133), MTRR (rs162036, rs1532268), MTR (rs16834521), MAT1A (rs3851059, rs4933327) was significantly associated with plasma Hcy in healthy subjects. MTHFR (rs1801131) showed a significant association with increased risk of T2DM (OR=1.93 for CC vs AA, $P=0.041$; OR=3.13 for CC vs AA+AC, $P=0.017$, respectively). The variant MTHFD (rs2236225) also showed significant association with decreased risk of T2DM (OR=0.36, for AA vs GG, $P=0.027$; OR=0.36 for AA vs GG+GA, $P=0.017$, respectively). In addition, PEMT (rs4646356) variants displayed a significant association with increased risk of T2DM (OR=1.52 for CT+TT vs CC, $P=0.042$). However, PEMT (rs4646406) variants was significantly associated with decreased risk of T2DM (OR=0.48 for TT vs AA, $P=0.048$).

Conclusions: MTHFR, MTR, MAT1A, PEMT, and MTRR variants are associated with alterations in plasma Hcy. MTHFR, MTHFD, and PEMT genetic variants associate with the susceptibility to T2DM in Chinese.

Key words: homocysteine, type 2 diabetes mellitus, genetic variants, methionine metabolism: Chinese

Background and objectives: Blood-cell transcripts have shown to be good biomarkers of metabolic alterations and their use in early detection and prevention of future disorders is promising. The beneficial effect of breast-feeding in protecting against later obesity and its metabolic-associated problems is well-established. The aim of this study was to examine whether there is a relationship between the protective effects of breast-feeding on later metabolic alterations and blood-cell expression levels of selected genes (CPT1A, SLC27A2, INSR, FASN, UCP2, LEPR and PPAR α), previously proposed as biomarkers of metabolic status, in a subset of children from the baseline survey of the IDEFICS project.

Methods: 237 children aged 2-9 years from 8 different European countries were included in the study. Blood-cell transcript levels of selected genes, characteristics of subjects and the type of infant feeding were considered.

Results: breast-fed children showed higher expression levels of SLC27A2, FASN, PPAR α and INSR, and lower risk of being overweight and of having high plasma triglyceride levels compared with formula-fed children. Besides, overweight formula-fed children presented higher HOMA-index than overweight breast-fed children, however this negative effect was absent in formula-fed children with high transcript levels of SLC27A2. Moreover, subjects with low expression levels of SLC27A2, FASN, PPAR α or INSR showed high levels of triglycerides but, among these, being breast-fed resulted in lower levels of triglycerides, similar to children with high expression levels of these genes.

Conclusions: The protective effects of breast-feeding on later metabolic alterations is reflected in higher expression levels of the above blood-cell transcript-based biomarkers, which may also serve to discriminate the formula-fed children that are at higher risk of later metabolic alterations.

Key words: Formula-feeding, gene expression, IDEFICS project, lactation, metabolic programming

ANTENATAL MULTIPLE MICRONUTRIENTS COMPARED TO IRON-FOLIC ACID LENGTHENS GESTATION, INCREASES BIRTH SIZE AND REDUCES RISK OF LBW IN RURAL BANGLADESH

A. A. Shamim¹, P. Christian², A. B. Labrique², H. Ali¹, S. Shaikh¹, S. Mehra², K. J. Schulze², R. D. W. Klemm², L. Wu², R. D. Merrill², K. P. West Jr²

¹Jivita Project, Gaibandha, Bangladesh

²Center for Human Nutrition, Johns Hopkins University, Baltimore, USA

Background and objectives: Micronutrient deficiencies during pregnancy may adversely affect fetal growth but the extent and mechanisms of this effect remain poorly understood.

Methods: A cluster-randomized, double-masked trial in rural Bangladesh evaluated in 44,567 pregnant women the efficacy of a daily multiple micronutrient (MM, with 15 vitamins and minerals) vs iron folic acid (IFA) in improving gestational health and fetal growth. Mothers were supplemented from the 1st trimester to 12 wk postpartum. Sample size (N_{MM}=22,162, N_{IFA}=22,405), SES and maternal diet, morbidity and gestational (GA) age at enrollment, and intake of intended supplements [median: 94 (IQR: 84-100) %] were similar across groups.

Results: There were 28,516 live born infants, equally divided by allocation. Compared to IFA supplementation, MM supplementation increased the length of gestation by mean of 0.3 weeks ($p < 0.0001$), leading to an increase in mean birth weight, length, and arm, chest and head circumference of 55 g, 0.21 cm, 0.11 cm, 0.25 cm and 0.21 cm, respectively (all $p < 0.001$), a 13% lower risk in preterm birth (relative risk (RR); 95% CI: 0.87; 0.82-0.92) and 12% decreased risk of low birth weight (0.88; 0.85-0.91). Effects were comparable by sex. There was no detectable difference in size for GA.

Conclusion: Daily antenatal MM supplementation lengthened gestation, thereby increasing birth size and reducing risks of preterm birth and low birth weight in rural Bangladesh.

Key words: preterm, low birth weight, micronutrient, iron, Bangladesh Supported by The Bill and Melinda Gates Foundation (Grant GH614).

O139

GLOBAL PROGRESS ON REDUCING ANEMIA IN PREGNANT WOMEN AND YOUNG CHILDREN

R. Galloway¹, J. Kavle¹, K. Krasovec²

¹Maternal and Child Health Integrated Program (MCHIP)/Program For Appropriate Technology In Health (PATH), Wahington, USA

²Better Health Systems Project, University Research Corporation (URC), Phnom Penh, Cambodia

Background and objectives: Anemia is a prevalent public health problem (PHP) globally. Demographic and Health Surveys (DHS), which provide information on anemia prevalence (AP) and programs, were examined to determine progress in reducing anemia.

Methods: Ninety DHS reports were reviewed for anemia information in pregnant women (PW) and children 6-59 months, including AP, reduction, and control program coverage.

Results: Twenty-two countries had two anemia surveys for PW; 24 countries for children (14 for PW and 16 for children in Africa and for both: 2 in the Middle East; 1 in Europe; 3 in Asia; 2 in Latin America/ Caribbean). AP was <40% in 10/22 and 3/24 countries for PW and children, respectively. Three African countries had relatively low AP in PW--Ethiopia (31%), Lesotho (25%), and Rwanda (29%), but AP in children was 1.5-2.0-fold higher than in PW. While 14/22 and 16/24 countries showed decreasing AP in PW and children, respectively, the decline was >20% in only in 7 and 4 countries for PW and children, respectively. Severe anemia continues to be a PHP ($\geq 2\%$) in 11/22 and 12/24 countries for PW and children, respectively. Increased coverage for bed nets may be why AP has decreased in some African countries. Few countries showed significant increases in coverage for iron-folic acid (IFA) supplements in PW and deworming in PW and children. Malaria in pregnancy coverage is limited and there is no information on or poor coverage of IFA for children. Consumption of iron-rich foods continues to be poor except possibly in Ethiopia, Lesotho, and Rwanda where PW but not children may consume more iron-rich foods but this requires further investigation.

Conclusions: While anemia has decreased in some countries, progress remains slow and coverage of an integrated package to control anemia remains low.

Key words: Anemia, malaria, deworming

O140

INCREASED N-3 PUFA STATUS IS ASSOCIATED WITH IMPROVED MATH AND READING PERFORMANCE IN THE OPUS SCHOOL MEAL STUDY

L. B. Soerensen¹, L. Lauritzen¹, N. Egelund², C. B. Dyssegaard², S. Dalskov¹, R. A. Petersen¹, R. P. Laursen¹, K. D. Stark³, A. Astrup¹, C. T. Damsgaard¹, K. F. Michaelsen¹

¹Department of Nutrition, Exercise and Sports, University of Copenhagen, Copenhagen, Denmark

²Centre for Strategic Research in Education and Competence, Aarhus University, Copenhagen, Denmark

³Department of Kinesiology, University of Waterloo, Waterloo, Ontario, Canada

Background and objectives: n-3 polyunsaturated fatty acids (PUFA) have been hypothesised to influence cognitive function, but few studies have focused on their effect in school aged children. This study investigates if school meals with fish twice a week increased n-3 PUFA-status and if this increase correlated with an improved cognitive performance in 3rd and 4th grade children. The OPUS project 'Optimal well-being, development and health for Danish children through a healthy New Nordic Diet' was supported by a grant from the Nordea Foundation.

Methods: OPUS School Meal Study was a cluster-randomized, cross-over intervention comparing packed lunch with school meals based on the New Nordic Diet (NND) for 3 months each. n-3 PUFA-status was determined as percentage of total fatty acids in whole-blood (w%). The statistical analyses using linear mixed models included 713 children.

Results: Baseline total n-3 PUFA-status was 5.09 ± 1.07 (mean \pm SD) w%; 2.96 ± 0.74 for docosahexaenoic acid (DHA) and $0.56 [0.42;0.73]$ (median[IQR]) for eicosapentaenoic acid (EPA). NND increased total n-3 PUFA-status 0.33 w% in 4th grade ($p < 0.001$) and 0.12 w% in 3rd grade ($p = 0.024$). With regards to DHA-status, NND increased DHA 0.22 w% in 4th grade ($p < 0.001$) and 0.07 w% in 3rd grade ($p = 0.027$). However, EPA-status increased equally in both grades (0.05 w%, $p < 0.001$). A 1-w% increase in total n-3 PUFA and DHA was associated with increased number of correct answers in math test, but only in 4th grade (0.8 , $p = 0.011$ and 1.2 , $p = 0.008$, respectively). A 1-w% increase in EPA was associated with improved reading performance (3.6 more correct sentences, $p = 0.004$). There were no associations between markers of n-3 PUFA-status and concentration performance.

Conclusions: School meals based on NND increased markers of n-3 PUFA-status in Danish school-children. Results indicate that math and reading skills are positively associated with levels of n-3 PUFA.

Key words: Child, school, omega-3 fatty acids, cognition

O141

MOTHER'S POSITIVE ATTITUDE AND FAMILIARITY TOWARDS FORMULA MILK MAY CONTRIBUTE TO LOW DIETARY DIVERSITY AMONGST INDONESIAN URBAN YOUNG CHILDREN

A. Roshita¹, A. Page³, L. Schubert², M. Whittaker²

¹SEAMEO RECFON University of Indonesia, Indonesia

²School of Population Health, University of Queensland, Australia

³School of Science and Health, University of Western Sydney, Australia

Background and Objectives: Indonesia is one of the countries facing nutrition transition with an increased proportion of the middle-class population. Few studies explored young child feeding practice amongst middle class families in developing countries. This study aims to assess child feeding practices and their associations with child nutritional status in urban area of Indonesia.

Methods: The study was designed as a mixed-method study in an urban middle-class community, comprising of a qualitative study amongst 26 families of young children and a case-control study involving 288 (109 cases and 179 controls) children aged 12-36 months. Cases were mild to moderately underweight children, while controls were normal weight children. The data collection methods consisted of in-depth interview for the qualitative phase and anthropometry measurements, structured interviews pertaining to child feeding practices and 24-hours recall for the quantitative phase.

Results: The qualitative study suggested that mothers appeared to have positive attitude and were familiar with many brands of toddler formula milk. Mothers reported challenges in encouraging their children to eat and relied on formula milk to increase child's food intake. The results of the case-control study showed that only 10.4% children received six-month exclusive breastfeeding and there was a significantly higher proportion of control than case children who were offered formula milk within their first month of life. Almost all children (91.7%, CI = 87.7 – 94.5) had low dietary diversity (consumed 1-3 food groups) in the last 24 hours. Formula milk was the largest contributor to child's energy intake amongst the control children.

Conclusions: The low dietary diversity warn potential problems for the health of Indonesian children. A large government strategy on complementary feeding practices including controlling the marketing activities of formula milk need to be enhanced.

Key words: Child feeding practices, child nutritional status, Indonesia.

O142

LONG-CHAIN POLYUNSATURATED FATTY ACIDS IN THE DIET AND MILK OF CROATIAN MOTHERS AT THREE MONTHS POSTPARTUM

G. Kresic¹, M. Dujmovic¹, M. Mandic², I. Delas³, N. Mrduljas¹

¹Department of Food and Nutrition; Faculty of Tourism and Hospitality Management, University of Rijeka, Opatija, Croatia

²Department of Food and Nutrition Research, Faculty of Food Technology, University of Osijek, Osijek, Croatia

³Department of Chemistry and Biochemistry, School of Medicine, University of Zagreb, Zagreb, Croatia

Background and objectives: Long-chain polyunsaturated fatty acids (LCPUFA), especially docosahexaenoic (DHA, C22:6n-3) and arachidonic (AA, C20:4n-6) are essential for prenatal and postnatal neural development. In breast milk they originate from a maternal diet and their supply to breast-feeding infants is an important issue. Since no data have been reported in Croatia or neighbouring countries, this research aimed to determine the fatty acid composition, including LCPUFA, of Croatian women's breast milk and correlate these data with their fatty acids intake.

Methods: The study enrolled 83 women (average age of 31.8 years), lactating for 3 months. Dietary evaluation involved two consecutive 24-hour dietary recalls. Fatty acid composition of milk was determined by gas chromatography.

Results: Dietary evaluation has shown that in total fat intake, which makes on average 35.10% of daily energy intake, the share of saturated, monounsaturated and polyunsaturated fatty acid was 13.88%, 14.46% and 6.76%, respectively. The total dietary n-6:n-3 fatty acids ratio was 14.57. The average daily intake of DHA and AA was 110 and 54 mg, respectively. Milk samples contained 32.63% of saturated, 43.42% of monounsaturated and 18.87% of polyunsaturated fatty acids. The content of DHA and AA were 0.21% and 0.39%, respectively. The significant influence of mothers' DHA intake on its content in milk was confirmed ($r=0.477$; $P<0.001$). Significant correlation was also confirmed between concentrations of DHA and AA in milk fat.

Conclusion: Since dietary intake of LCPUFA is sub-optimal, of concern is its low level in breast milk, especially that of DHA. Infants being breastfed were receiving only half of the recommended amounts of DHA. Croatian breastfeeding women should be educated about the importance of LCPUFA for infants' development and about food sources which could ensure their adequate supply.

Key words: arachidonic acid, breast milk, docosahexaenoic acid, dietary intake, long-chain polyunsaturated fatty acids.

O143

ASSOCIATION BETWEEN DIETARY CALCIUM INTAKE AND BLOOD PRESSURE AMONG PORTUGUESE CHILDREN

S. Abreu¹, P. Moreira^{1,2}, J. Mota¹, R. Santos^{1,3}, C. Moreira¹, P.C. Santos^{1,3}, L. Soares-Miranda¹, S. Vale¹

¹Research Centre in Physical Activity, Health and Leisure, Faculty of Sport, University of Porto, Porto, Portugal

²Faculty of Nutrition and Food Science, University of Porto, Porto, Portugal

³ISMAI Institute of Higher Education, Maia, Portugal

⁴Department of Physiotherapy, School of Health Technology of Porto, Polytechnic Institute of Porto, Porto, Portugal

Background and objectives: Higher blood pressure (BP) in childhood is associated with cardiovascular risk. It has been described that dietary calcium intake may affect BP regulation. The objective of this study was to analyze the association between dietary calcium intake and BP in children.

Methods: A cross-sectional study was conducted with 128 Portuguese children (47.7% of boys) aged 6-8. Anthropometric measurements were recorded (weight, height, biceps, triceps, subscapular and suprailiac skinfolds) and physical activity was assessed during 7 consecutive days by accelerometry. Dietary intake was assessed using a 3-day food record completed by parents. Dietary calcium intake was expressed as the calcium-to-protein ratio. BP was measured using an electronic sphygmomanometer (COLIN DP 8800). Two measurements were taken and the mean of these was considered. Data was analyzed separately for girls and boys, and linear regression analysis was used to estimate the association between calcium intake and systolic and diastolic BP (SBP and DBP, respectively) adjusting for age, height, sum of skinfolds, physical activity, energy intake, magnesium, potassium and sodium intake.

Results: For girls and boys, respectively, SBP mean was 95.4±7.6 and 97.5±6.5mmHg (P=0.101), DBP mean was 56.3±6.5 and 57.6±5.9mmHg (P=0.220). No significant difference was seen in the calcium intake and calcium-to-protein ratio of girls compared to boys (P>0.05, for all). After adjusting for confounders, calcium-to-protein ratio was significantly inversely associated with SBP in girls (girls: $r = -0.685$, $P = 0.034$ and boys: $r = -0.010$, $P = 0.979$). No association was found with DBP in both genders.

Conclusions: In our sample, calcium intake seems to be inversely related to SBP in girls. Further studies are needed to test the effects of dietary calcium intake on BP in children.

Acknowledgments: This study was supported by PEst-OE/SAU/UI0617/2011, SFRH/BPD/81566/2011 and PTDC/DES/116586/2010.

FREQUENCY AND DETERMINANTS OF DHA SUPPLEMENT USAGE IN PREGNANCY AND LACTATION IN GERMANY

L. Libuda, M. Stimming, C. Mesch, M. Kersting

Research Institute of Child Nutrition Dortmund, University of Bonn, Germany

Background and objectives: Docosahexaenoic acid (DHA) supply in pregnancy via placenta and in infancy via breast milk depends on mother's food intake. Beside fish as a natural source, DHA supplements might be an alternative approach to ensure an adequate supply. Major aim was to describe frequencies and determinants of DHA supplementation in pregnancy (DHA-P) and during lactation (DHA-L) in a nationwide survey of mothers in Germany.

Methods: The survey was nested in the randomized controlled trial PINGU on fatty acid status optimization in infancy. From an existing panel for consumer surveys (Kantar Health GmbH) mothers with children up to 36 months of age were selected for an online interview on mother's and children's intake of polyunsaturated fatty acid-rich foods (field period: December 2010). Data of 985 mothers were weighted to ensure representativeness for mothers in Germany.

Results: 27.8% of mothers in Germany used DHA supplements during pregnancy, 16.8% during lactation. DHA-P and DHA-L was higher in mothers with first children compared with later children (DHA-P: 31.5% vs. 24.6%, $p = 0.015$; DHA-L: 19.2% vs. 14.7%, $p = 0.06$) and in high compared with low social classes (DHA-P: 35.8% vs. 23.6%, $p = 0.001$; DHA-L: 24.4% vs. 14.4%, $p = 0.0001$), but did not differ between younger and older mothers. The proportion of mothers eating fish at least one time per week was higher among supplement users compared with non-users (pregnancy: 53.8% vs. 36.3, $p = 0.0001$; lactation: 62.9% vs. 36.8%, $p = 0.0001$).

Conclusion: DHA supplementation is common in German mothers especially in pregnancy, but also during lactation. However, the benefit of supplementation was questionable in the majority of supplementing mothers since fish was already part of the usual diet. DHA supplements might be promoted especially in lower social classes, if fish is disliked.

Key words: DHA, supplements, pregnancy, lactation. Funded by the German Federal Ministry of Education and Research

O145**MOST EFFECTIVE PERIOD TO CONTROL ANAEMIA IN PREGNANCY: ADOLESCENCE OR PRE-PREGNANCY?**

⁶Ministry of Health, Colombo, Sri Lanka

Background and objectives: In 2002 the prevalence of anaemia among school going adolescents' aged 10-15 years were assessed as a baseline and it was 11.1%. Highest prevalence was recorded among grade 7 children and the prevalence was varied from 11% to 30% within districts. As a result, it was decided to address anaemia in school adolescents aged 10-15 years by giving a high priority through schools. In 2002–2003, a study was carried out in 5 districts to assess the impact of anaemia in schoolchildren with weekly iron supplementation for a period of 6 months. It revealed when the supplementation coverage is more than 30%, the reduction of anaemia was 50%. As a result weekly iron supplementation was initiated in all schools in the country annually for a period of 6 months among adolescents aged 11-15 years of age since 2004. This study was conducted to assess the impact of iron supplementation programme after 5 years.

Methods: A household survey was carried out using a multistage cluster sampling method to draw nationally representative sample. Haemoglobin was assessed using haemocue among non-pregnant and non-lactating women aged 15-20 years to represent the previously iron supplemented adolescents.

Results: The prevalence of anaemia was 13.3%, 26.7% and 23.5% among pregnant, lactating and non pregnant and non lactating women in the study population.

Conclusion: Iron supplementation during the early adolescent period was not sufficient to maintain iron levels for a long period of time as a strategy to control anaemia in pre pregnant women. It is recommended to initiate a sustainable cost effective solution to control anaemia in adolescents and pre pregnant women such as fortification.

Key words: Anaemia, adolescents, prepregnancy

O146**DIETARY PATTERNS ASSOCIATED WITH METABOLIC SYNDROME: THE KHORRAMABAD STUDY**

E. Falahi¹, K H. Anbari², F. Ebrahimzadeh³, A. Esmailzadeh⁴

⁴Department of Community Nutrition, School of Nutrition and Food Sciences, Isfahan University of Medical Sciences, Isfahan, Iran

Background and objectives: Metabolic syndrome (MetS) is a complex disorder with high socioeconomic cost that is considered a worldwide epidemic. The aim of this study was characterize the dietary patterns of Iranian adults and to examine association with metabolic syndrome.

Methods: In this descriptive, cross-sectional, correlation design 1980 persons aged ≥ 18 y were selected by using multistage cluster, random sampling method in Khorramabad city, located in west of Iran. Dietary intake was assessed with the use of a validated, 168 food- item, self-administrated, semi-quantitative food-frequency questionnaire. Factor analysis, linear regressions and ANCOVA were used to data analysis.

Results: Three major dietary patterns were identified: the western dietary pattern (WDP), the healthy dietary pattern (HDP), and the traditional dietary pattern (TDP). Subjects in the highest quintile of the HDP had lower odds of the metabolic syndrome (OR: 0.45; 95% CI: 0.27-0.77) than did those in the lowest quintile, whereas those in the highest quintile of the WDP score had greater odds of the MetS (OR: 3.44; 95% CI: 2.08-5.70) than did those in the lowest quintile. Multi linear regression showed that the WDP score was associated negatively with serum HDL cholesterol and positively with other components of MetS.

Conclusions: In conclusion, a dietary pattern characterized by high consumption of poultry, dairy products, vegetables, fruits, legumes, whole grains, fish, and olives are associated with reduced risk of the metabolic syndrome in both male and female. In contrast, a dietary pattern with high amounts of red meats, organs meat, processed meats, soft drinks, snacks, sweet and deserts, condiments, margarine, and coffee is associated with a greater risk of the metabolic syndrome.

²Department of Physiology, Faculty of Medicine, University of Colombo, Sri Lanka

³Department of Public Health, Faculty of Medicine, University of Kelaniya, Ragama, Sri Lanka

⁴Endocrine Unit, National Hospital of Colombo, Sri Lanka

Background and objectives: In the context of rising prevalence of non communicable diseases in Asia, assessing healthy lifestyle practices and their influence on biochemical and anthropometric parameters is of importance. However, evidence for links between food habits, physical activity and cardiometabolic risk markers are limited. Our objective was to assess the relationship between lifestyle practices related to diet and cardiometabolic risk parameters among urban Sri Lankan women.

Methods: 2800 urban women (30 - 45 years) were selected by random cluster sampling and screened for dysglycaemia for a final sample of 272 newly diagnosed, drug naive dysglycaemic and 345 normoglycaemic women. Glycaemic status was confirmed by HbA1c. An interviewer administered questionnaire was used to obtain data on lifestyle practices. Anthropometry and blood pressure were recorded using standard protocols. FBS, HbA1c, serum insulin, serum cholesterol and serum triglycerides were measured. % fat mass was determined by bioelectrical impedance analysis. Chi square test was used to assess statistical significance.

Results: 95.6% of newly diagnosed dysglycaemic women did not engage in at least 30 minutes of exercise. A higher proportion of newly diagnosed dysglycaemics demonstrated undesirable food habits ($p < 0.001$) compared to normoglycaemic women [inability to resist fatty food; dysglycaemics (65 %), normoglycaemics (18 %), inability to resist sugary food; dysglycaemics (61.4 %), normoglycaemics (14.5 %), snacking while watching TV; dysglycaemics (66.2 %), normoglycaemics (25.8 %)] Waist circumference, % Fat Mass, Body Mass Index, HbA1c, serum insulin, serum cholesterol and serum triglycerides were significantly higher among those who had poor practices, and did not achieve recommended levels of exercise.

Conclusions: Our study demonstrates a link between negative eating behaviors and cardiometabolic risk with implications for intervention strategies relevant to women in similar urban environments in South Asia. (Funding IAEA-15920)

O148

THE ECONOMIC IMPACT OF ANAEMIA IN PERU

I. Lasa Hernandez¹, L. Alcazar²

¹Country Director, Action Against Hunger Spain, Lima, Peru

²Director, GRADE, Lima, Peru

Background and objectives: Anaemia in Peru is a severe public health problem that affects more than 50% of preschool children and more than 20% of women of reproductive age. It affects society socially and economically, as well as the lives of those who suffer from it. This study aims to estimate the economic costs for the Peruvian economy caused by the prevalence of iron-deficiency anaemia, and to show the importance and implications of the problem and the possible savings of a stronger, more systematic and effective policy for fighting anaemia.

Methods: The methodology, mainly based on Ross & Horton (1998) as part of the Micronutrient Initiative, estimates the economic impact of iron-deficiency anaemia based on: loss of future work productivity of children who currently suffer from anaemia, loss of work productivity of adults who currently suffer from anaemia and cost associated with caring for women who gave birth prematurely due to anaemia. The methodology also considers costs the state would incur to prevent anaemia among children and pregnant women.

Results: The study finds that anaemia costs Peru S./ 2.777 billion, or 0.62% of GDP. The most important element that associated with the effects in adulthood of the cognitive impairment generated by anaemia in childhood, at approximately S/. 1.285 billion. The costs faced by the state stand at S/. 623 million and the cost incurred for treating anaemia is S/. 22 million. In contrast, the cost of prevention would be S/. 18 million.

Conclusions: Anaemia represents a major burden for the Peruvian economy, a total cost equivalent to almost 38% of the national health budget for a year. The cost of preventing anaemia represents just 2.8% of the total cost that anaemia generates for the state, indicating that an anaemia prevention programme would be highly cost effective.

Key words: anaemia, Peru, cost effectiveness

MICRONUTRIENT DEFICIENCY: A PUBLIC HEALTH PROBLEM IN HO CHI MINH CITY, VIETNAM

T.T. Minh Hanh¹, P. Nguyen. T. Binh¹, D. Ngoc Diep¹

¹Nutrition Center of Ho Chi Minh City, Vietnam

Background and objectives: Children and women are vulnerable to micronutrient deficiency. This research determines

the magnitude of this public health problem in relation to vitamin A deficiency, and iron deficiency anemia among children and women in HCMC, and iodine deficiency among women.

Methods:Data were collected from epidemiological cross-sectional surveys of 644 children under 5 years, 776 pregnant women, and 718 breast-feeding women in 2007-2008 in HCMC. Serum retinol concentration <0.7 mol/L and breast-milk retinol concentration <1.05 mol/L were classified as sub-clinical vitamin A deficiency (VAD) in children under 5 years and breastfeeding women, respectively. Hemoglobin <11 g/dl (for children under 5 years) and Hb <10 g/dl (for women) were classified as anemic. Iodine deficiency (ID) was determined by spot urinary iodine as <10 g/dl.

Results:The prevalence of VAD of children under 5 was 4.2% and is highest in children under 6 months of age (21.7%). Multivariate analysis shows that not taking vitamin A supplement 6 months before the survey (OR=3.99, 95% CI 1.79 - 8.92, $p<0.005$) was associated with VAD. The prevalence of VAD in breastfeeding women was 28.0%. The prevalence of anemia in pregnant women and children under 5 was 17.5% and 14.0%, respectively. Based on a single 24h recall women in their last two trimesters were only consuming 40% of the RDA for iron. The prevalence of ID in pregnant women was 72.8%, of which, 27.3% moderately deficient, and 11.9% severe. The prevalence of pregnant women using iodized salt was 56.8% and its use decreased risk of ID by 45.0%.

Conclusions:Despite recent economic gains in Viet Nam, micronutrient deficiencies continue to be a significant public health problem in HCMC. In particular, according to WHO, iodine deficiency in pregnant women and vitamin A deficiency in breastfeeding women can be considered severe. There is a need for continued focus to improve the micronutrient status of these groups.

Key words: micronutrient deficiency, HCMC.

male obesity and over 40% of the female obesity across Europe, could be attributable to social inequalities. The prevalence of FI is growing faster over the world, including Portugal, as a result of the economic crisis, which had led to the increasing of health inequalities, namely by an unequal distribution of obesity and other diet-related chronic diseases through the most vulnerable groups. We aim to analyze the coexistence of FI and overweight/obesity in a sample of Portuguese households.

Methods: Cross-sectional study, conducted in 1187 Portuguese households. Data were collected by face-to-face interviews and FI was evaluated using a psychometric scale adapted from the Brazilian Food Insecurity Scale. Logistic regression models adjusted for socioeconomic variables, were used to identify the association between FI and body mass index (BMI) in Portuguese adults.

Results: We found a higher prevalence of FI (for all FI levels – low, moderate, severe) in overweight (OR=1.635; CI95% 1.202-2.224) and obesity individuals (OR=1.657; CI95% 1.140-2.409). When we analysed just the moderate and severe levels of FI, underweight individuals were at higher risk for FI (OR=6.591; CI95% 1.956-22.214) than the overweight, obese and normal subjects.

Conclusions: A significant association between the BMI and FI was found. FI was more prevalent among overweight/obese Portuguese adults' families. When FI was analyzed by levels, we observed that low and moderate FI was associated with higher risk of obesity and severe FI was associated with a higher risk of underweight. These findings could be helpful for health authorities in planning strategies to prevent obesity and other chronic diseases, addressing FI as an influencing factor.

⁹Mälardalens University, Västerås, Sweden

¹⁰University of Crete, Heraklion, Greece

Background and objectives: Dietary pattern (DP) analysis has emerged as an alternative and complementary approach to addressing diet-diseases associations. The aim of the present study is to examine DP in European adolescents and their relationship with the time that adolescents spent studying.

Methods: A multinational cross-sectional study was carried out in 2,202 adolescents (45.4% boys) aged 12.5 to 17.5 years. A self-reported questionnaire with information on sedentary behaviours, separately for weekdays and weekend days, and two non-consecutive 24 hour-recalls were used. Principal component analysis (PCA) was used to obtain DP, and linear regression examined the association between DP scores and sedentary behaviour indicators.

Results: Four DPs for boys (“plant based”, “snacking”, “breakfast” and “health conscious”) and five DPs for girls (“confectionary and snacking”, “plant based”, “breakfast”, “animal protein” and “health conscious”) were obtained. Boys who study between 2 to 4 hours and more than 4 hours during weekdays had higher adherence to the “breakfast” DP ($\beta=0.11$, CI: 0.01, 0.20) and $\beta=0.19$, CI: 0.08, 0.29), respectively). In girls, studying between 2-4 hours during weekend days were associated with lower adherence to the “snacking” DP $\beta=0.06$, CI: 0.01, 0.12) and with higher adherence to the “plant based” $\beta=-0.06$, CI: -0.11, -0.01) and “breakfast” DP $\beta=0.07$, CI: 0.01, 0.13).

Conclusions: Study time is related positively with healthy DP and negatively with unhealthy DP. Such findings may help

to generate interventions focusing on increasing the time that adolescents spent studying.

Key words: Dietary patterns, study time, adolescents

Background and objectives: The metabolic syndrome (MetS) is a cluster of metabolic disorders most likely to be recognized in midlife and includes high fasting blood glucose levels, hypertension, dyslipidemia, and abdominal obesity. In this study the relationship of dietary pattern analysis with among non- menopausal women was studied.

Methods: A Nested case- control was conducted on 920 non- menopausal women 18-50 yrs old. MetS was defined according to IDF guideline. Dietary intakes were assessed via 168 item semi- quantitative FFQ, in 26 food groups. Using factor analysis, the predominant food patterns were drawn. 135 subjects with MetS were matched to 137 controls for age, and odds ratio of MetS and its components in dietary pattern scores, was assessed using logistic regression, adjusting confounding variables.

Results: Two dietary patterns were identified based on desirable food pattern was characterized by the consumption of raw vegetables, fruits, starchy vegetables, olive, oiled vegetables, low fat dairy, legumes, nuts, egg, oil, whole grains, fish, high fat dairy and chicken, and undesirable food by cola and commercial fruit juice, cookies and sugar, ready foods, mayonnaise, snacks (chips and puffed corn), fat, pickle, organ meats, refined grains, meat and salt. Adjusting for various confounding variables, the desirable food pattern was inversely associa-

ted with MetS (OR: 0.87, 95% CI: 0.16-0.73, P-value < 0.001), and hyperglycemia (OR: 0.34, 95% CI: 0.13-0.87, P-value < 0.05). No associations were observed between MetS and undesirable food pattern, and among components of MetS, only triglycerides were associated with this food pattern (OR: 2.17, 95% CI: 1.09-4.32, P-value < 0.001).

Conclusion: Desirable food pattern was significantly associated with reduced MetS, whereas undesirable food pattern has no association.

Background and objectives: The Healthy Diet Indicator (HDI) measures adherence to the WHO guidelines for preventing diet related chronic diseases, and can be applied to assess associations of diet with health across populations. We examined the association between the HDI and all-cause mortality in European and American elderly people aged 60 years and above.

Methods: We analysed data on 395,863 men and women from 11 prospective cohort studies from the Consortium on Health and Ageing: Network of Cohorts In Europe And The United States (CHANCES). Across cohorts, the follow-up periods ranged from 10 to 20 yrs. Diet was assessed through validated methods. For the translation of foods to nutrients, country specific food composition tables were used. The continuously scored HDI (range mean and SD HDI score 45±9 to 54±7 across cohorts) was based on intakes of saturated and polyunsaturated fatty acids, mono- and disaccharides, protein, cholesterol, dietary fibre and fruits and vegetables. The association between the HDI and all-cause mortality was evaluated in each cohort separately, by multiple Cox proportional hazards regression. A pooled hazard ratio (HR) was subsequently estimated using a random-effects model.

Results: Across all cohorts, 84,863 people died during 4,492,298 person-years of follow-up. Adjusted HR of death, for a 10 point increment in HDI score, ranged between 0.81 (95% CI 0.77-0.86) in Denmark and 0.99 (95% CI, 0.84-1.16) in Poland. The pooled adjusted HR estimate showed a significant inverse association of 0.90 (95% CI 0.87-0.93) but there was a significant heterogeneity between studies (p=0.001, I²=66%).

Conclusion: Our results show that higher dietary quality is inversely associated with all- cause mortality but the heterogeneity between studies warrants further research.

CHARACTERIZATION OF BIOLOGICAL BARRIERS THAT IMPACT NUTRITIONAL STATUS AMONG HIV-POSTIVE AND HIV-NEGATIVE WOMEN AND THEIR INFANTS IN SEMI-RURAL TANZANIA

A.L. Wilkinson¹, S.H. Pedersen¹, M. Urassa², D.M. Mkwashi², A. Andreasen³, S. Kinung'hi², J. Todd³, J. Changalucha², J.M. McDermid¹

¹Cornell University, Ithaca, New York, USA

²National Institute for Medical Research, Mwanza, Tanzania

³London School of Hygiene and Tropical Medicine, London, United Kingdom

Background and objectives: HIV-infected women are at increased risk for malnutrition; however, the relative contributions of food insecurity in resource-constrained regions that have high generalized infectious disease burdens versus HIV infection-induced changes in appetite regulation, metabolism and body composition are unknown. The objective of this study was to characterize maternal cachectic cytokine and appetite-regulation hormone profiles during pregnancy and relate these to maternal HIV-status and therapy, nutritional status, self-reported appetite and birth outcomes.

Methods: Forty-three HIV-infected and 70 HIV-uninfected pregnant women attending a semi-rural health facility in north-west Tanzania were recruited at their first antenatal visit. Maternal nutritional status was assessed twice during pregnancy, and birth outcome data was obtained at delivery. Baseline plasma cytokines and leptin concentrations were multiplexed. This study was powered to detect significant differences in tumor necrosis factor (TNF)- α concentration.

Results: TNF- α , a pro-inflammatory cytokine implicated in cachexia-related appetite suppression, showed an inverse dose-response relationship with ART (antiretroviral therapy) ($p=0.001$) (baseline TNF- α concentrations: ART-naïve 88.8; ART <4 weeks 79.3; ART >4 weeks 56.6; HIV-negative 63.2 pg/mL). Similar patterns were observed for interleukin (IL)-10, an indicator of immune activation, and the pro-inflammatory hormone and appetite-suppressant leptin, however, group numbers were small and differences not significant. There was a non-significant dose-response relationship with ART corresponding to maternal gestational weight gain (median: ART-naïve 1.4; ART <4 weeks 1.5, ART >4 weeks 3.2; HIV-negative 2.7 kg/month). All HIV-exposed infants had reduced birth weight (2.9 vs. 3.2 kg; $p=0.006$) and length (45.3 vs. 47.0 cm; $p<0.001$) compared to all HIV-unexposed infants.

Conclusions: Findings suggest that appetite-regulating factors are different based on HIV status in pregnant women, and among HIV-positive women according to ART duration. Biological barriers may contribute to a reduced ability to respond to nutritional interventions that alleviate maternal malnutri-

tion, with further consequences for the health of HIV-exposed infants.

Key words: HIV, inflammation, pregnancy, malnutrition, antiretroviral

O155

MALNUTRITION AMONG EGYPTIAN CHILDREN

S. El-Masry¹

¹Biological Anthropology Dept., National Research Centre, Cairo, Egypt

Background and objectives: Malnutrition constitutes varying proportions in developing countries, and anthropometry is a simple tool to assess its magnitude in children. The objective is to identify the prevalence of malnutrition (under and over) among Egyptian children and to test various anthropometric indicators for classification of malnutrition.

Methods: The study included 1365 children, their age ranged from 6 -11 years (1 year \pm 6 months). They were collected from two public schools in Giza governorate. Height, weight and mid upper-arm circumference were recorded and children were classified by WHO criterion (Z-score) using different nutritional indices i.e. weight for age, height for age, weight for height, and mid upper-arm circumference for age, and percentiles of BMI for the reference population. Egyptian growth curves (2008) data were used as reference population.

Results: The prevalence of stunting (Z-scores for height-for-age [HAZ] <-2), wasting (Z-scores for weight-for-height [WHZ] <-2) and being underweight (Z-scores for weight-for-age [WAZ] <-2) was 3.7%, 0.7% and 0.0%, while that of at risk of stunting, wasting and underweight (Z-score <-1 SD) was 18.2%, 13.4% and 8.1% respectively. On the other hand, the prevalence of overweight identified by WHZ (>1 SD) was 10.8% and obesity (>2 SD) was 5.3%, while that by BMI (< 85th and 95th percentiles) were 10.9% and 5.6% respectively. Mid-upper arm circumference (MUAC), needed to be used with caution since they are not sensitive enough to detect all cases of overweight. However, BMI had more specificity and less sensitivity than the MUAC in identification of underweight, but its specificity and sensitivity were nearly similar to that of WAZ.

Conclusions: MUAC for identification of overweight in this age is impractical. Further investigations are needed for the use of BMI with different cutoff points in identification of underweight children.

Key words: Under nutrition, overweight, obesity, children

PROCOLLAGEN III N-TERMINAL PROPEPTIDE BEYOND A FIBROSIS BIOMARKER IN NON-ALCOHOLIC FATTY LIVER DISEASE ASSOCIATED WITH OBESITY IN CHILDREN

O. Rangel¹, I. Aguiar-Santana², C. Mata³, M. Gil-Campos³, R. Cañete¹, A. Gil¹, C. Aguilera¹

¹Department of Biochemistry and Molecular Biology II, Institute of Nutrition and Food Technology, Biomedical Research Centre, University of Granada, Granada, Spain

²Gastroenterology Unit, Hepatology and Pediatric Nutrition. University Hospital Insular Materno-Infantil de Las Palmas, Spain

³Unit of Pediatric Endocrinology, Reina Sofia University Hospital, Córdoba, Spain

Background and objectives: Procollagen III N-Terminal Propeptide (PIIINP) is a product of the proteolytic cleavage during collagen synthesis in connective tissue. It has been proposed as a biomarker of fibrosis in nonalcoholic fatty liver disease (NAFLD) discriminating between simple steatosis and steatohepatitis or advanced fibrosis. The objective of this study was to determine serum PIIINP concentration in obese children with and without NAFLD and its relationship with obesity.

Methods: 158 Caucasian children aged 5-16 years were recruited, including 52 with normal weight without NAFLD (determined by abdominal ultrasonography), 55 obese without NAFLD and 47 obese with NAFLD. Anthropometric, clinical and metabolic markers as well as adipokines, inflammatory biomarkers as C reactive protein, Interleukin 1 (IL1), IL-6, IL-8 and tumour necrosis factor- α and cardiovascular disease risk biomarkers as monocyte chemoattractant protein 1 and plasminogen activator inhibitor 1 (tPAI1) were analyzed. PIIINP was determined using a commercial ELISA kit. One-way ANOVA test were used to compare means among groups. A posterior Bonferroni tests were performed to evaluate specific differences between groups. A backward-step multiple linear regression analysis to evaluate the independent risk factors for PIIINP (SPSS 20 software).

Results: Mean serum levels of PIIINP were different between normal weight children (53 ± 8 ng/ml) versus obese without NAFLD (150 ± 10) and with NAFLD (160 ± 11) ($p < 0.001$), but none differences were observed between the two obese groups. Correlation analysis revealed that weight, BMI, BMI zscore, waist circumference, body fat percentage, insulin, HOMA, uric acid, leptin, tPAI1 and resistin were significantly associated with serum levels of PIIINP ($r > 0.4$, $P < 10^{-9}$). BMI zscore ($\beta = 0.307$ $p < 0.002$), tPAI1 ($\beta = 0.247$ $p < 0.016$), and resistin ($\beta = 0.207$ $p < 0.029$) were independent predictors of serum PIIINP. Conclusions Serum PIIINP did not discriminate NA-

FLD presence in obese children, but it is an early biomarker of metabolic derangement and CVD risk in childhood obesity.

Key words: Procollagen III, obesity, cardiovascular, children.

O157

POST-PRANDIAL APPETITIVE AND GLYCEMIA-REGULATING EFFECTS OF ALMONDS CONSUMED WITH MEALS OR AS SNACKS

S Y. Tan¹, R. Mattes¹

¹Department of Nutrition Science, Purdue University, West Lafayette, Indiana, USA

Background and objectives: Snacking is prevalent and contributes to daily consumption of essential nutrients, but may also increase the risk for weight gain. Almonds, which are commonly consumed as a meal accompaniment or snack, have been previously shown to modulate postprandial glycemia and appetite. These effects were examined when almonds were consumed only with meals or alone as snacks.

Methods: Acute appetitive and glycemic responses were measured over a four-week randomized, controlled trial. Participants were randomized into the Control (CL), Meal groups receiving almonds (43g) with breakfast (BF) or lunch (LN), or Snack groups receiving almonds as morning (MS) or afternoon (AS) snacks during a 490-minute clinical session. Breakfast (0 min) and lunch (240 min) were provided to participants under all conditions. Post-prandial serum glucose and appetite (hunger, fullness, desire-to-eat) were measured at fixed intervals and compared between study arms and between the combined Meal and Snack groups.

Results: The post-prandial glucose response was significantly reduced by almond consumption in the BF, LN, MS, and AS groups compared to the CL group (interaction effects, $p < 0.001$). When combined into Meal or Snack groups, the effects just failed to reach statistical significance ($p = 0.078$) ($S < M$). All appetite ratings also showed significant interaction effects between all groups, but only hunger ratings remained statistically significant when compared across Control, Meal, and Snack groups ($p = 0.022$). When calculated as the area-under-the-curve (AUC), post-prandial hunger and desire-to-eat AUC followed the order Snack $<$ Meal $<$ Control ($p = 0.026$ & $p = 0.023$ respectively). Glucose and fullness AUCs were not significantly different between Control, Meal, or Snack groups.

Conclusions: The inclusion of almonds modulated post-prandial glycemia regardless of timing of consumption, but suppressed hunger and desire-to-eat more when consumed as snacks.

Key words: almonds, appetite, glycemia

O158

CARDIOVASCULAR PREVENTIVE EFFECT OF FRUITS AND VEGETABLES: IS IT MODIFIED BY OLIVE OIL CONSUMPTION?

J M. Nunez-Cordoba¹, M. Bes-Rastrollo¹, E. Toledo¹, A. Gea¹, M. Ruiz-Canela¹, M A. Martinez-Gonzalez¹

¹Department of Preventive Medicine and Public Health, Medical School - Clinica, Universidad De Navarra

²CIBER Fisiopatología de la Obesidad y Nutrición (CIBERObn), Instituto de Salud Carlos III, Spain

Background and objectives: In the context of the Mediterranean diet, a selective beneficial effect of fruits and vegetables (F&V) on prevalent and incident hypertension only among participants with lower olive oil (OO) consumption has been reported. As hypertension is one of the most important risk factors for CVD, our objective was to prospectively evaluate the association between F&V intake and incident CVD, and the potential effect modification by OO consumption.

Methods: We followed-up 16,042 participants (60.3 percent women, mean age: 37.7 years) initially free of CVD during a median of 8.1 years. Participants were part of a prospective cohort study of university graduates from all regions of Spain (The SUN Project). Baseline diet was assessed using a validated 136-item food-frequency questionnaire. A CVD event was defined as the combined outcome measure of incident acute coronary syndromes (myocardial infarction), revascularization procedures or stroke.

Results: We observed 126 incident cases of CVD (82 acute coronary syndromes or revascularization procedures and 44 non-fatal strokes). Multivariate Cox regression analyses showed a significant inverse association between F&V consumption and the risk of CVD only among participants with low OO consumption (<15.5 grams/day); hazard ratios and 95% confidence intervals [HR (95%CI)] for 3 to 4 servings/day and for 5 or more were 0.45 (0.23-0.86) and 0.64 (95%CI: 0.35-1.17), respectively, compared with those who consumed <3 servings/day. Among those with high OO consumption (15.5 or more grams/day), HR (95%CI) for 3 to 4 servings/day and for 5 or more were 0.64 (0.24-1.72) and 1.11 (0.45-2.75), respectively, compared with the reference category. The interaction between OO and F&V was not statistically significant (P=0.262).

Conclusions: The preventive effect of F&V intake on the risk of CVD appears to be restricted to participants with lower OO consumption, although the effect modification was not statistically significant.

Key words: Fruit, vegetable, olive oil, cardiovascular.

O159

THE ROLE OF NUT CONSUMPTION IN MAINTAINING CARDIOVASCULAR HEALTH AND COGNITIVE FUNCTION

J. Barbour¹, P. Howe¹, J. Buckley¹, J. Bryan², A. Coates¹

¹Nutritional Physiology Research Centre, University of South Australia, Adelaide, South Australia, Australia

²Social Work and Social Policy, University of South Australia, Adelaide, South Australia, Australia

Background and objectives: The purpose of this review was to examine the association between nut consumption, cardiovascular health and cognitive function. Nuts contain many bioactive ingredients including polyphenols, amino acids and fatty acids that have the potential to deliver benefits for both vascular and cognitive health. Increased cerebrovascular perfusion has been hypothesised to underpin improvements in cognitive function.

Methods: A systematic search of epidemiological and intervention studies examining the effect of nut consumption on blood pressure, endothelial vasodilator function, arterial compliance, inflammation and cognitive performance was performed in November 2012. A wide variety of intakes, length of supplementation and comparator foods made data difficult to interpret. Hence where data were available, weighted mean effects and 95% CI were calculated for changes in blood pressure, inflammatory markers and endothelial function.

Results: Of the 61 articles included, data were available to calculate weighted mean changes for 36 of 49 intervention studies. Nut consumption was associated with reductions in systolic and diastolic blood pressure of 1.3% (95% CI -2.3 to -0.3) and 0.7% (95% CI -1.4 to 0.04) respectively and reductions in ICAM-1, VCAM -1 and CRP of 8.6% (95% CI -23.6 to 3.3), 5.8% (95% CI -14.1 to 2.5) and 12% (95% CI -23.6 to -0.3) respectively, whilst endothelial function improved by 19.7% (95% CI 4.3 to 35.0). Individual studies suggest nut consumption may also have potential to improve cognitive performance but data were limited.

Conclusions: Current evidence indicates that nut consumption can significantly reduce some components of inflammation and blood pressure and improve endothelial function which may be a mechanism for improving cognitive performance.

Key words: Nuts, cardiovascular, endothelium, inflammation, cognitive function

O160**EFFECTS OF PARENTERAL NUTRITION FORMULAS ON PLASMA LIPID PROFILE IN CHILDREN WITH BONE MARROW TRANSPLANTATION**

M. Gil-Campos¹, M A. Baena-Gomez¹, M D. Mesa², F J. Llorente-Cantarero¹, J L. Perez-Navero¹, M J. De La Torre Aguilar³

¹Reina Sofia University Hospital, Córdoba, Spain

²University of Granada, Granada, Spain

³Instituto Maimonides de Investigación Biomedica de Cordoba (IMIBIC), Córdoba, Spain

Background and objectives: In children undergoing bone marrow transplantation (BMT) it is often required parenteral nutrition (PN). This study compares plasma lipid and fatty acids profiles after a fish oil or soybean PN in BMT children.

Methods: 14 children with BMT and requiring PN for at least 10 days were selected. They were randomized to use a lipid emulsion with fish oil, or soybean oil. Blood samples before starting and at the end of the PN were taken to analyze lipids.

Results: Similar changes in plasma levels of cHDL, cLDL, triglycerides (TG) and apolipoprotein A were detected with both formulas. TG levels increased more after the administration of the emulsion of fish oil although levels of cHDL, and apo A decreased more after administration of soybean oil. There were no differences by groups in plasma linolenic acid levels although in both formulas, levels increased after 10 days of PN. Eicosapentaenoic acid increased in fish oil formula group respect to soybean fed; their levels were higher at the end of the supplementation compared with the basal levels. Linoleic acid did not differ between the two groups. Also, arachidonic acid levels in fish oil formula were reduced at 10 days respect to baseline and when PN last 21 days, this acid decreased in patients with both formulas.

Conclusions: PN for 10 days are effective and safe in children. There are initial changes in plasma lipid profile more dependent on the duration of PN, than the type of lipid formula itself. However, plasma fatty acid profile changes are related with the omega fatty acid composition of the formulas. Other paediatric studies are necessary in order to establish the importance of the duration of interventions and the use of non-traditional lipid composition of PN formulas.

Key words: bone marrow transplant, parenteral nutrition, fatty acids.

O161**ABUNDANCE AND DIVERSITY OF MICROBIOTA IN METABOLIC SYNDROME**

M. Remely¹, S. Dworzak¹, B. Hippe¹, H. Brath², A. Haslberger¹

¹Department of Nutritional Sciences, University Vienna, Vienna, Austria

²Gebietskrankenkasse, Vienna, Austria

Background and objectives: Inflammatory reactions leading to the progression of metabolic syndrome contribute to changes in composition of the GIT microbiota. The objective of this study was to investigate differences of gut microbiota in obese and type 2 diabetics, and the response to intervention for estimating its potential role in controlling metabolic syndrome.

Methods: We analyzed fecal microbiota at three time points in fourteen obese participants, nineteen lean controls and twenty-four type 2 diabetes patients. Obese and type 2 diabetics received an intervention of nutritional counseling, type 2 diabetics an additional therapy with Victoza®. The microbiota composition was analyzed for abundance and diversity by quantitative real-time polymerase chain reaction, denaturing gradient gel electrophoresis and high throughput sequencing.

Results: In type 2 diabetics an increase of diversity was observed with intervention whereas the values of lean controls remained unaffected. In the lean and obesity groups, a lower Firmicutes: Bacteroidetes ratio correlated with lower BMI. In type 2 diabetics the ratio of Firmicutes to Bacteroidetes increased throughout the intervention period. Type 2 diabetics showed a significantly enhanced proportion of lactic acid bacteria before and after intervention, also Akkermansia and Enterobacteria showed a higher abundance in type 2 diabetics, increasing throughout the study period. Archaea were significantly more frequent in type 2 diabetics. Whether differences seen in abundance of certain groups and diversity of microbiota reflect different underlying inflammatory mechanisms of type 2 diabetes and obesity or rather the progression of the metabolic disease remains unclear and needs long-term investigation.

Key words: metabolic syndrome, ratio Firmicutes: Bacteroidetes, lactic acid bacteria, Akkermansia.

O162

INTELLIGENCE AND ITS ASSOCIATION WITH NUTRITIONAL STATUS IN PRIMARY SCHOOL PUPILS IN LAFIA, NIGERIA.

S. Okolo¹, H. Abdu¹, R. Adah¹, N. Okolo²

¹Department of Paediatrics, Jos University Teaching Hospital, Jos, Nigeria

²Department of Biochemistry, University of Jos, Nigeria

Background and objectives: Acute effects of malnutrition underlie 50% of the causes of mortality in developing countries. Long term effects have resulted in altering brain growth and development. However, there has been inadequate research into the relationship between nutritional status and intelligence performance among children in these regions. This study assessed the nutritional status and intelligence among primary school pupils using Non-verbal intelligence tools.

Methods: A cross-sectional study among school pupils in Nasarawa state, Nigeria was done. Information on socio-demographic characteristics was obtained. Intelligence assessed with group administration of Raven Standard Progressive matrices (RSPM) consisting of 60 questions and Draw –a-Person test (DAP). Nutritional status Z scores were determined for height, weight, and BMI using WHO Antroplus.

Results: The mean age of 342 pupils was 9 ±1.9 years with more females (54.1%) and M:F ratio 1:1.1. Mean weight, height and BMI were 27.45± 7.1 kg, 132.4± 10.8 cm and 15± 2.4kg/m² respectively. More wasted (p=0.016) and stunted (p=.00) children seen in public schools. Performance of the pupils using RSPM showed that 2%, 4.1%, 31.9%, 37.1%, and 24.9% were intellectually superior, above average, average, dull, and deficit respectively; while using DAP, 0.2% were intellectually superior, 3.8% above average, 40.9% average, 33.3% dull and 21.5% intellectually deficit. Both tests strongly correlated (r=4.9, p=.00). HAZ and WAZ ≤2SD were significantly associated with poor performances on RSPM ((p=.03 and p=.05 respectively). Similar findings were seen with the DAP[HAZ (P=.00) and WAZ (p=.048)]

Conclusion: Poor nutritional indices with its attendant effect on intelligence is a major problem of childhood in developing countries.

Key words: intelligence, nutritional status, children

O163

INCREASED RESTING ENERGY EXPENDITURE IN YOUNG ADULTS WITH HIGH TRIGLICERYDES

M A. Anaya-Loyola¹, R. Reyes Márquez¹, L N. Chávez¹, M. Camacho Barrón¹, T. García-Gasca¹,

¹Maestría en Nutrición Humana. Facultad de de Ciencias Naturales-Campus Juriquilla, Universidad Autónoma de Querétaro, México

Background and objectives: At present there is an increased percentage of young people that have been affected by diseases that normally were appearing in old adults, such as cardiovascular diseases, diabetes and obesity. For this reason the aim of this study was to evaluate the effect of metabolic alterations related to glucose and lipid profile on resting energy expenditure (REE) of young adults from Queretaro (central Mexico).

Methods: A total of 225 Mexicans, aged 20-45 y, were recruited in this study. After signed informed consent, the participants were cited in fasting conditions for anthropometric evaluation. Besides, a blood draw was collected for the analysis of glucose (Glc), triglycerides (TG), total cholesterol (T-Chol), LDL and HDL. Body composition was assessed by bioimpedance and RER was measured by mean of a CO₂/O₂-calorimeter.

Results: Overweigh and obesity (OW/OB) were presented in 29.1% of the participants. Abnormal glucose was absent; however, 6.4% presented elevated T-Chol, 36.0 % low HDL, 5.1% high LDL and 10.4% elevated TG. Body fat was elevated in 22.2%, being women the most affected. RER was greater in men than women. A higher RER was observed in participants with elevated TG compared to those with normal TG when controlling by lean body mass (1693.8±387.4 vs. 1521.6±212.9 kcal/d; P=0.0055), and remain significant when adjusting by body mass index, thus RER was significantly higher in normal weighed participants with elevated TG (1332.0±152.7 vs. 1480.4±198.4 Kcal/d P=0.01523) and either in OW/OB participants with elevated TG (1814.3±368.3 vs. 1650.5±211.1 Kcal/d, P=0.01049).

Conclusions: RER measurement can be used along or together with anthropometric evaluation as a better indicator that can be used for the diagnosis of metabolic alterations since young age and to prevent the onset of metabolic disease in old age.

Key words: Resting energy expenditure, triglycerides, metabolic alterations, young adults

SERUM RETINOL AND ANTHROPOMETRIC STATUS OF 2-5-YEAR-OLD SOUTH AFRICAN CHILDREN AND THEIR CAREGIVERS WITH DIVERSE DIETARY PATTERNS

M. Faber¹, M. Van Stuijvenberg¹, P. Van Jaarsveld¹, E. Kunneke², S. Kruger³, S. Schoeman¹

¹Nutritional Intervention Research Unit, Medical Research Council, South Africa

²Division Dietetics University of the Western Cape, South Africa

³Centre of Excellence for Nutrition, North-West University, Potchefstroom, South Africa

Background and objectives: According to a 2005 national survey, 63.6% of 1-9-year-old South African children and 27.2% of women were vitamin A deficient (serum retinol <20 µg/dL). South Africa's cultural, geographical and socio-economic diversity is reflected in the eating habits of its population. This study determined anthropometric status, dietary intake and vitamin A status of 2-5-year-old children and their caregivers in four diverse resource-poor geographical sites.

Methods: Children-caregiver pairs were randomly selected in two rural (n=140 and 206, respectively) and two urban sites (n=194 and 207, respectively). Height and weight measurements were used to calculate z-scores for children using WHO 2006/2007 growth standards, and BMI for caregivers. The caregivers' 24-hr dietary recall data was used to construct a dietary diversity score (range: 0-9). Blood samples were analysed for serum retinol; CRP and AGP were measured as indicators of infection. Socio-demographic information was collected through an interviewer-administered questionnaire.

Results: For caregivers, the prevalence of overweight/obesity in the four study sites ranged from 50.2% to 83.8%; underweight was more prevalent in the urban sites (12.2% and 15.8%). Stunting in children ranged from 13.9% to 40.9%; and overweight from 1.2% to 15.1%. Less than 1% of children were wasted. The prevalence of low dietary diversity (<4) ranged from 26.0% to 57.8%. Less than 15% children and 2% caregivers across the four study sites had serum retinol concentrations <20 µg/dL, which is significantly lower than the national levels reported previously; compulsory fortification of bread flour and maize meal since 2003 could have contributed towards these findings.

Conclusions: A low prevalence of vitamin A deficiency was observed. The large variation in anthropometric status of children and caregivers across the study sites highlights the importance of targeting nutrition interventions across geographical sites within a country.

Key words: vitamin A, overweight, stunting.

O165

DESIGN, ASSESSMENT OF REPRODUCIBILITY AND VALIDITY OF A FOOD FREQUENCY QUESTIONNAIRE IN A SAMPLE OF ADULTS LIVING IN QUITO-ECUADOR(QFA-QUITO)

M. Silva¹, M. Neutzling², M. Drehmer²

¹Department of Public Health Nutrition, Ministry of Health, Quito, Ecuador

²Epidemiology Department, Federal University of Rio Grande do Sul, Porto Alegre, Brasil

Background and objectives: The food frequency questionnaire (FFQ) is one of the most used tools in epidemiologic studies to assess long-term nutritional exposure. The purpose of this study was to assess the reliability and validity of a FFQ design to evaluate usual intake of adults in Quito-Ecuador over the past year.

Methods: This study included two phases: (1) the development of a quantitative FFQ and (2) the reliability and validity of the FFQ. Dietary data using 24h recalls were used to design the list of usually consumed foods. Relative validity of a 111-item FFQ was evaluated by comparing nutrient intakes against three non-consecutive 24h recalls. The comparisons between the FFQ and the R24h were assessed by the Pearson correlation coefficient. Nutrients were categorized into quartiles and assessed using weighted kappa statistics. The level of agreement between methods was evaluated by Bland & Altman analysis. Reliability was assessed using two FFQs and assessed by the Intraclass correlation coefficient.

Results: The FFQ produced higher energy and nutrient intakes. Reproducibility correlation coefficient after adjusting for energy, ranged from 0.62 (protein) to 0.88 (calcium). For the validity study, energy-adjusted and deattenuated correlation coefficients between the questionnaire and the recalls ranged from 0.21 (fat) to 0.65 (calcium). Only 4% of the subjects were grossly misclassified and 46% had weighted Kappa higher than 0.42. Bland & Altman plot showed that differences tended to increase between methods from energy intake equal or greater than 2.500 kcal.

Conclusions: The FFQ showed reasonably good relative validity and reliable measurements, and can be used to assess nutrient intake in this population.

Key words: Validity studies, reliability, food frequency questionnaires, dietary intakes

RELATIONSHIP BETWEEN MAGNESIUM INTAKE, C- REACTIVE PROTEIN LEVELS AND THE METABOLIC SYNDROME COMPONENTS IN A HEALTHY ADULT POPULATION FROM MADRID

TK. Villalobos¹, M. Mascaraque¹, P. Andrés², A M. López-Sobaler¹

¹Department of Nutrition, Faculty of Pharmacy Universidad Complutense de Madrid, Madrid, Madrid, Spain

²Departmental Section of Analytical Chemistry, Faculty of Pharmacy, Universidad Complutense de Madrid, Madrid, Madrid, Spain

Background and objectives: Evidence suggests that low magnesium intake is related with some metabolic abnormalities involved in Metabolic Syndrome (MS); some of these abnormalities are also associated with increased levels of C-reactive protein (CRP). The aim of this study was to investigate the relationship between magnesium intake, plasma CRP concentrations and the prevalence of MS components in a healthy adult population.

Methods: Anthropometric, dietary (3 day food record) and biochemical data were obtained from 129 subjects aged 18-50 years (62 men and 67 women) from Madrid. Energy adjusted magnesium intakes were calculated and divided in tertiles. A BMI and age-adjusted model was developed to understand the relationship of magnesium and CRP. MS was defined using ATP-III criterion. The statistical analysis was performed using SPSS v.20.0, dietary data was calculated using Dial software (Alce Ingeniería 2010).

Results: The prevalence of MS in the studied population was 4% and 29% of the subjects had at least one MS component. 81.2% covered their recommended Intake of magnesium. Mean magnesium intakes for ascending tertiles were 247.5±21.7, 252.5±18.9, 396.8±55.8 mg/day which corresponded to 81.1±13.2, 104.0±15.1 and 132.4±25.7% of the Estimated Average Requirement of magnesium, respectively. Magnesium intake was inversely associated with plasma CRP levels ($r=-0.483$ $p<0.001$); the mean CRP levels for ascending tertiles of magnesium were 1.8, 1.4, .87 mg/l, respectively (P trend 0.001). Comparing with first tertile, subjects in the highest tertile of magnesium intake were more likely to have CPR values <3 mg/l (OR= 10.25 [95% CI 1.21–86.2 $p<0.001$]). As number of MS components increased, higher CPR levels and lower magnesium intakes are observed.

Conclusions: In this healthy population those with higher magnesium intake had lower inflammation risk and lower number of MS components.

Key words: Magnesium, C-reactive protein, metabolic syndrome

DETERMINANTS OF VITAMIN D STATUS IN PATIENTS WITH STABLE ANGINA

J. Dierkes¹, E. Degerud¹, O. Nygard¹, O. Midttun², P M Ueland²

¹University of Bergen, Dept. of Clinical Medicine, Norway

²Bevital AS, Bergen, Norway

Background and objectives: Scandinavia is situated far north of the equator, but the vitamin D status is better than in many countries further south. Many Norwegians consume cod liver oil, which is a dietary supplement rich in vitamin D. We assessed whether cod liver oil and other relevant factors associated with vitamin D status in patients with stable angina.

Methods: We measured serum 25-hydroxyvitamin D (25OHD) by LC-MS/MS in 3273 participants with stable angina pectoris from the Western Norway Coronary Angiography Cohort (WECAC, 2000–2004). We modelled 25OHD as a continuous variable using multivariate linear regression.

Results: A daily intake of cod liver oil was associated with a 9.9 nmol/L increase in 25OHD levels compared to those with no intake (p for trend <0.001). Any intake of cod liver oil improved 25OHD levels (p for trend <0.001) compared to no intake. Having blood drawn between April and October was associated with a 9.9 nmol/L increase in 25OHD levels ($p<0.001$) compared to blood draw between November and March. Obesity (BMI 30-40) was associated ($p<0.001$) with a 6.2 nmol/L decrease in 25OHD levels compared to normal weight (BMI 17.5-25) individuals. Increased glomerular filtration rate was associated with reduced 25OHD levels ($p<0.001$). C-reactive protein (3-10 mg/L) was associated with a decrease in 25OHD of 2.0 nmol/L compared to those with CRP below 1 mg/L.

Conclusion: Any intake of cod liver oil is associated with a higher vitamin D status. Obesity and low grade inflammation were associated with lower vitamin D status. These findings reflect that other factors than vitamin D intake influence the vitamin D status and should be taken into account.

Key words: Vitamin D, 25OHD, determinants, cod liver oil.

O168

RISK FACTORS OF IRON DEFICIENCY AMONG CHILDREN 6-59 MONTHS IN THE NORTHERN REGION OF GHANA.

B. Abu¹, V. Louw², A. Dannhauser¹, J. Raubenheimer³, L. Van den Berg¹

¹Department of Nutrition and Dietetics, University of the Free State, Bloemfontein, Free State, South Africa

²Division of Clinical Haematology, Department of Internal Medicine, University of the Free State, Bloemfontein, Free State, South Africa

³Department of Biostatistics, University of the Free State, Bloemfontein, Free State, South Africa

Background and objectives: Most anemia worldwide is due to iron deficiency (ID). This study assessed risk factors for ID among children 6-59 months in the Northern Region of Ghana where the prevalence of anemia is 81% among this group.

Methods: Structured interviews were administered to 161 mothers in two selected districts regarding the diets of all their children 6-59 months (N=175; 54.5% female), using a food frequency questionnaire, 3x24-hour recalls, and questionnaires on socio-demography and iron bioavailability. WHO Anthro Plus[®] software and Food Processor Plus[®] (Version 6.02) software were used for data analysis. Adequacy of iron intake at 5% and 10% bioavailability was assessed with the probability method.

Results: Most children (90.9%) were born at home (birth-weights unknown). A third (30.4%) was moderately stunted and 16.7% severely stunted. Most children (58.9%) were still breastfeeding; 73.7% ate maize porridge (“koko”) daily; and 54.7% drank tea in the 24 hours before survey. The probability of inadequate iron intake was 31.2% at 5% bioavailability and 14.8% at 10% bioavailability. Mean fiber intake was 13.3g/day. Although 49.7% of households reported running out of food/money for food in the previous 12 months, only 3.1% indicated that children had gone to bed hungry. Of the children 31.6% did not sleep in treated mosquito nets, with the mothers’ reasons listed as not possessing a net, the net being torn, weather being hot, or that there were no mosquitoes. In the 3 months before the study 36.6% of the children had malaria, for which 5% were treated with herbal remedies and 21% with over-the-counter drugs.

Conclusion: Dietary practices and inadequate care practices in this population may negatively affect the iron status of children. Educating mothers regarding these factors may to an extent reduce ID among children in Northern Ghana.

Key words: Iron deficiency, risk factors, children, Northern Ghana

TOWARDS A COMPREHENSIVE WEB-BASED DIETARY RESEARCH INFRASTRUCTURE TO SUPPORT INTERNATIONAL MONITORING AND EPIDEMIOLOGICAL NUTRITIONAL STUDIES

N. Slimani¹, C. Casagrande¹, G. Nicolas¹, G. Le Moine¹, I. Huybrechts¹, H. Freisling¹, S. Crispim¹

¹International Agency For Research On Cancer, Dietary Exposure Assessment Group, Lyon, France

Background and objectives: The double nutritional disease burden observed worldwide requires standardized methodologies to measure/follow-up dietary exposures and to evaluate diet-disease associations to support public health actions across countries. Through different EU-funded projects, a standardized computerized 24-hour dietary recall program (EPIC-Soft[®]) has been successfully developed, validated and used in international epidemiological studies and monitoring surveys. However, beside this standardized methodology for collecting dietary information across countries, it is equally important to provide a comprehensive framework and technical and managerial infrastructures to support international studies.

Methods: To respond to these needs, a centralised web-based platform, the dietary e-Standardised Methodologies Platform (e-SMP), is under development at IARC. It comprises 4 main modules: 1) maintenance of the EPIC-Soft[®] databases, 2) interview collection using EPIC-Soft[®], 3) management of collected interview data, and 4) administration. The step-wise approach used to develop and evaluate the platform includes 4 successive phases, 1) conceptual design; 2) evaluation by internal and external end-users; 3) development of the applications and the web-platform; 4) evaluation of the applications and web-platform internally, by end-users and in real study conditions.

Results: Although the development of e-SMP is still ongoing, the overall general and detailed concepts have been developed. A first release focusing particularly on the “Interview Management Application” and other facilities to support international studies, in terms of implementation, data collection and management was launched. The first evaluation of this release is currently in process and results are expected by the end of April. Communication and data synchronisation/exchange will also be facilitated and e-training facilities will be provided to the platform users.

Conclusions: This e-SMP platform should facilitate the standardization of dietary methodologies between countries/projects. The concepts, development and evaluation of this web-based platform will be presented.

Key words: research infrastructure, standardisation, dietary assessment

COLD PRESSED OILS AS A SOURCE OF BIOACTIVE COMPOUNDS

A. Obiedzinska^{1,2}, B. Waszkiewicz-Robak²

¹Institute of Agricultural and Food Economics - National Research Institute, Warsaw, Poland

²Department of Functional Food and Commodities, Faculty of Human Nutrition and Consumer Sciences, Warsaw University of Life Sciences (SGGW), Warsaw, Poland

Background and objectives: Consumers awareness regarding health and diseases prevention, functionality of food products, create demand for minimal processed food as a rich source of bioactive compounds. The beneficial influence on human health of the cold pressed oils is coming from the presence of the major and minor constituents such as fatty acids, sterols, tocopherols or phenolic compounds. The objective of the study was to determine bioactive compounds in selected cold pressed oils.

Methods: As a study material were used cold pressed oils obtained from Flax (Linseed), Camelina, Pumpkin, Borage and Evening primrose seeds. Oils were characterized by gas chromatography coupled with mass spectrometry (GC/MS) in respect of profiles of fatty acids, sterols and squalene and liquid chromatography (HPLC) in profiles of tocopherols.

Results: Oils showed a wide variation in the content of individual fatty acids and the sum of the groups of fatty acids: saturated, monounsaturated and polyunsaturated (PUFA). Oils were characterized by a high content of unsaturated fatty acids and borage oil had the highest content of PUFAs (86.9 g/100g of oil). Flax and camelina oils seeds were the only representatives of the major content of α -linolenic acid. Borage and evening primrose oils were characterized by high content of γ -linolenic acid. Comparing content of sterols in studied oils, evening primrose seed oil had the highest content (997.63 mg/100 g of sterols oil) and this value was much higher than in other oils. Borage oil had the highest content of tocopherols (258.3 mg/100g). Presence of squalene has been shown only in pumpkin oil (353.5 mg/100 g).

Conclusions: As a result of unique composition of fatty acids and minor constituents cold pressed oils can have significant influence on lowering risk of chronic diseases, especially coronary artery disease.

Key words: cold pressed oils, fatty acids, sterols, tocopherols, squalene

INHIBITORY EFFECTS OF LYCOPENE ON THE PROLIFERATION AND PROGRESSION OF HUMAN COLON CANCER CELLS IN BOTH IN VITRO AND IN VIVO MODELS

F. Tang¹, M. Pai², X. Wang³, E. Chiang⁴

¹Department of Nutrition, China Medical University, China

²Department of Anatomy, Taipei Medical University, China

³Gerald J. and Dorothy R. Friedman School of Nutrition Science and Policy, Tufts University, Boston, USA

⁴Department of Food Science and Biotechnology, National Chung Hsing University, Taiwan, China

Background and objectives: Colorectal cancer (CRC) is one of the leading causes of cancer death in many countries. Epidemiologic studies reported statistically significant inverse association between tomato consumption and colon cancer risk for humans. The anticancer effects of lycopene on the growth and progression of human colon cancer cells have not been well demonstrated yet. To achieve our specific aims, we investigated the inhibitory effects of lycopene on the proliferation and progression of human colon cancer cells in both in vitro and in vivo studies.

Methods: This study was examined by using MTT assay, western blotting assay, bioluminescence imaging, histopathological, immunofluorescence (IFC), immunohistochemical (IHC) staining, ELISA, zymogram assay and Real Time-PCR analysis.

Results: The current study demonstrated that lycopene significantly inhibited the proliferation of human colon cancer cells in vitro. Moreover, consumption of lycopene prevented the growth and progression of colorectal tumor in a mouse xenograft model. Bioluminescence imaging, histopathological, immunofluorescence (IFC), and immunohistochemical (IHC) staining results indicated that lycopene effectively suppressed the growth and progression of colon cancer. The results demonstrated that lycopene significantly suppressed the nuclear expression of PCNA and β -catenin proteins. Consumption of lycopene augmented the E-cadherin adherent molecule and nuclear levels of cell cycle inhibitor p21CIP1/WAF1 protein. The chemopreventive effects of lycopene were associated with suppression of COX-2, PGE2, and phosphorylated ERK1/2 proteins. Furthermore, the inhibitory effects of lycopene were inversely correlated with the plasma levels of matrix metalloproteinase 9 (MMP-9) in tumor-bearing mice.

Conclusions: These results suggested that lycopene could act as a chemopreventive agent against the growth and progression of colorectal cancer in a mouse xenograft model.

Key words: Lycopene; Akt; β -catenin; matrix metalloproteinase; colorectal cancer

O172

ANTI-INFLAMMATORY AND ANTIOXIDANT PROPERTIES OF FLAVONOID-RICH EXTRACTS FROM HELICHRYSUM AND GRAPEFRUIT IN INSULIN RESISTANT RATS

A L. De La Garza¹, U. Etxeberria¹, F. Milagro^{1,2}, M. Olivas³, O. Bañuelos³, J. A. Martinez^{1,2}

¹Department of Nutrition, Food Science and Physiology, University of Navarra, Spain

²CIBER Fisiopatología Obesidad y Nutrición (CIBEROBn), Instituto de Salud Carlos III, Spain

³Discovery Laboratory, Health and Nutrition Department, Biosearch S.A. 18004, Spain

Background and objectives: Obesity is a multifactorial disease associated with insulin resistance, resulting in an increased risk of developing type 2 diabetes mellitus. Likewise, oxidative stress is a process implicated in these pathological conditions which contributes to generate a chronic low-grade inflammatory condition. Several flavonoids have been demonstrated to exert antioxidant and anti-inflammatory properties. Thus, the aim of this study was to determine the effects of dietary supplementation with flavonoid-rich extracts isolated from helichrysum and grapefruit, on inflammation and oxidative stress-related states in rats fed high-fat sucrose (HFS) diet-induced insulin resistance.

Methods: Thirty eight male Wistar rats were randomly assigned into two groups: Control group (n=8) and HFS group (n=30). After 22 days of ad libitum water and food access, the rats fed HFS diet were divided into three groups: Non-supplemented group (n=10), helichrysum group (2g/kg bw) (n=10) and grapefruit group (1g/kg bw) (n=10). After 35 days of supplementation, rats were sacrificed and tissue samples and serum were obtained. Thiobarbituric acid reactive substrates (TBARS) were analyzed in liver and serum, while cytokines in serum. The expression of different cytokines was analyzed in epididymal adipose tissue and intestinal mucosa.

Results: Rats supplemented with both extracts gained less body weight, which was accompanied by lower visceral fat in the grapefruit group. Both supplemented groups displayed lower liver TBARS levels than the non-supplemented group. Serum adiponectin levels were significantly higher in the grapefruit group, whereas TNF α levels were decreased in the helichrysum group. Helichrysum and grapefruit extracts reduced the expression of several proinflammatory cytokines in visceral adipose tissue.

Conclusions: These results demonstrate that helichrysum and grapefruit extracts rich in flavonoids regulate the expression associated of several proinflammatory cytokines and improved their circulating levels in insulin-resistant rats, decreasing also the HFS diet-induced oxidative stress in liver.

Key words: flavonoids, inflammation, insulin resistance, oxidative stress

O173

ORAL INTAKE OF A SPECIFIC OREGANO EXTRACT BY HEALTHY HUMANS INCREASES CALMNESS, VIGILANCE AND MENTAL PROCESSING SPEED

M H. Mohajeri¹, R R. Goralczyk¹, A. Wyss¹, J. Wittwer¹, K. Prudence¹

¹DSM Nutritional Products, Human Nutrition, Basel, Switzerland

Background and objectives: We have recently reported the identification of a specific oregano extract (OE) with the ability to inhibit the reuptake of the monoamine neurotransmitters, serotonin, noradrenalin and dopamine, in a dose-dependent manner (triple reuptake inhibitory effect). In vivo microdialysis experiments in rats revealed a significant elevation of serotonin levels in the brain. Moreover, mice treated with OE performed better in animal models broadly accepted to test the effectiveness of antidepressant and anxiolytic compounds (Mechan et al, 2011).

Methods: We assessed the biological effects of OE on brain functions by analyzing the local field potentials in freely moving rats and in healthy humans after acute oral supplementation.

Results: Acute oral intake of OE produced fast and robust dose and time dependent EEG alterations consisting of significant changes of spectral power in comparison to controls. Strongest effects were seen in alpha1, alpha2 and beta1 waves representing an activation of serotonergic, dopaminergic and glutamatergic neurotransmission, respectively (Mohajeri et al., 2012). In agreement to rodent data, we observed an increase in absolute energy of alpha-1 and beta-1 frequency bands in resting condition in adult young healthy males (n=20). Moreover, Evoked-Related Potentials (ERPs) measurements revealed a significant increase in P300 amplitude.

Conclusions: These results indicate that a single dose of OE induced a state of wakeful relaxation, enhanced vigilance and improved concentration in addition to increased mental capacity and a possible increase in processing speed. In summary, the presented data support using of OE as a dietary supplement to promote mood, motivation and mental wellbeing.

Key words: EEG, neurotransmission, diet, serotonin, reuptake inhibition

O174

IMPROVEMENT EFFECTS OF CHLOROGENIC ACID ON LATE DIABETES THROUGH ADIPONECTIN RECEPTOR SIGNALING PATHWAYS IN DB/DB MICE

C. Chang¹, S. Jin¹, L. Zhang¹, Y. Liu¹, X. Huang¹, Z. Chen¹

¹3rd Hospital of Peking University, Peking, China

Background and objectives: Chlorogenic acid (CGA) is a kind of phenolic acid condensed by caffeic acid and quinic acid, widely available in plants foods such as seeds, fruit, vegetables and coffee drinks. CGA is known to be likely beneficial for preventing diabetes, but the researches on mechanism are limited. In this study, we examined the effects of CGA on glucose and lipid metabolism of late diabetes as well as on adiponectin receptors and their signaling molecules.

Methods: 16 female db/db mice aged 5-6 weeks were randomly divided into db/db-CGA and db/db-CON group equally, respectively. db/m mice as control mice. The mice in CGA-groups were administered 80mg /kg/d CGA by lavage for 12 weeks. At the end of intervention, we detected the parameters of glucose and lipid metabolism in plasma, aldose reductase (AR) and transformation growth factor-1(TGFβ-1) in kidney, measured adiponectin receptors and their signaling molecules proteins expression in liver and muscle tissues respectively.

Results: Compared with db/db-CON group, FPG and HbA1c in db/db-CGA group significantly decreased by 28.8% and 22.9% respectively, TGFβ-1 protein expression and AR activity of kidney decreased by 33.3% and 29.5% respectively, adiponectin level of visceral adipose increased by 50.2%. ADPNR-2 of liver and ADPNR-1 of muscle protein expression, AMPK protein phosphorylation level in liver and muscle, PPAR-α mRNA and protein expression in liver, GLUT4 protein expression in muscle were all significantly higher in db/db-CGA group than in db/db-CON group, but glucose-6-phosphatase activity in liver was lower significantly in db/db-CGA. In db/m mice, CGA decreased HbA1c by 45.2% , increased plasma insulin level and adiponectin of visceral adipose, compared to db/m-CON.

Conclusion: CGA could low FPG and HbA1c of late diabetes, and improve kidney fibrosis in some extent by adiponectin receptor signaling pathways in db/db mice.

Key words: chlorogenic acid; adiponectin receptors; pAMPK

YOUNG ZEA MAYS POWDER IMPROVES SOME NUTRIENT COMPOSITION AND REDUCES GLYCEMIC INDEX OF BUTTER BISCUIT

W R.W i¹, C.Anis Jauharah¹, C M.Zain¹, RS Daniel¹, E. A N¹

¹University Sains Malaysia, Malaysia

Background and objectives: Zea mays was previously studied to be rich in dietary fibre, antioxidants, vitamins and minerals which could benefit human health. The aim of the present study was to assess the effects of young corn powder (YCP) on glycemic index (GI) and physicochemical properties of biscuit.

Methods: Dried young corn was used to partially substitute wheat flour in biscuit formulations at different levels (0%, 10%, 20% and 30%). The effects of YCP incorporation on proximate compositions and physical characteristics (hardness and fracturability) and sensorial attributes (colour, aroma, appearance, crispiness, flavor and overall acceptance) were explored. Based on sensory evaluation using 7-point hedonic scale by 60 volunteers, the most acceptable formulation was continued with GI investigation. Eleven healthy subjects were fed with 25 g available carbohydrate portions of glucose (reference food) and test foods (biscuits) on 5 separate sessions after an overnight fast. Capillary blood samples were collected at 0, 15, 30, 45, 60, 90, and 120 minutes after consuming the biscuits.

Results: The incremental area under the blood glucose curve values for the 2 different types of biscuits were significantly low compared with reference food glucose (p<0.001). The GI value of the biscuits with 0% YCP and 10% YCP was 61±11 and 46±13, respectively. It was noted that the biscuit added with 10% of YCP had significantly increased protein (p=0.023) and total dietary fibre (p<0.001) when compared with biscuit without YCP. There was no significant difference in hardness (p=0.583) and fracturability (p=0.935) attributes between 0% and 10% level of YCP addition. Biscuit containing 10% YCP received better overall acceptance score (5.27±1.02) than control (4.97±1.30).

Conclusion: The results of this study showed that biscuit added with 10% YCP has a low GI with acceptable physicochemical properties.

Key words: Young Zea mays, nutrient composition, glycemic index

O176

GLYCEMIC AND INSULINEMIC RESPONSES DIFFER DEPENDING ON THE CONTENT OF SLOWLY DIGESTIBLE STARCH IN CEREAL PRODUCTS INCLUDED IN BREAKFAST

A. Meynier¹, F. Atkinson², J. Brand-Miller², S. Vinoy¹

¹Mondelez International R&D, Nutrition Department, Saclay, France

²Human Nutrition Unit, School of Molecular Bioscience G08, Sydney University, Sydney, Australia

Background and objectives: Low glycemic index (GI) diets have shown beneficial effects on the prevention of metabolic diseases. For cereal products, several studies have linked glycemic response with digestibility rate of starch. The aim was to study the postprandial effect of two cereal products differing by their Slowly Digestible Starch (SDS) content on glycemic and insulinemic responses when consumed within a breakfast.

Methods: Twelve healthy volunteers consumed in a randomised crossover study two breakfasts containing a cereal product (biscuit or bread-substitute with High SDS=18g/100g and Low SDS=1g/100g, respectively) with milk and a non-caloric hot beverage. Breakfasts were matched for their calorie and carbohydrate contents. Glycaemia and insulinaemia were measured at regular intervals during the postprandial period (270 min). In addition, GI and insulinemic index (II) of cereal products were measured separately.

Results: GI of biscuit was lower compared to GI of bread-substitute (43 ± 3 and 67 ± 7 , respectively). II of both cereal products were consistent with their GI values (56 ± 6 and 75 ± 7 , respectively). Glycemic response was significantly higher with low SDS (LSDS) breakfast compared to high SDS (HSDS) breakfast over 120 min. After 75 min, the curves inversed such that the HSDS breakfast induced higher glycemia compared to LSDS breakfast on the second part of the morning between 120 – 270 min. Similar results were observed on insulinaemic responses with lower responses during the first part of the morning with HSDS breakfast compared to LSDS breakfast. The inversion of the insulinaemic responses is still present but not significant between 120-270 min. Conclusion. This study confirmed that, whatever the cereal food category tested, a high SDS product induced lower glycemic and insulinemic responses compared to a low SDS product, due to a slower release of carbohydrates into the blood.

Key words: Slowly digestible starch, glycemia, insulinemia.

COMPARISON OF THE EFFECT OF DARK AND WHITE CHOCOLATE ON APO B, APOA-1, LIPID PROFILE, HS-CRP, GLYCAEMIC CONTROL AND BLOOD PRESSURE IN HYPERTENSIVE TYPE 2 DIABETICS

S. Eghtesadi¹, A. Rostami¹, I. Heidari², F. Shidfar¹, F. Hosseini³

¹Department of Nutrition and Biochemistry, Tehran University of Medical Sciences, Tehran, Iran

²Institute of Endocrinology and Metabolism, Tehran University of Medical Sciences, Tehran, Iran

³Department of Biostatistics, School of Health Management and Bioinformatics, Tehran University of Medical Sciences, Tehran, Iran

Background and objectives: Given the inverse correlation between the dietary intake of flavanols and the mortality of cardiovascular disease, the aim of this study was to examine the effects of high flavanol chocolate on lipid profile, weight, blood pressure, glycaemic control and inflammation in individuals with Type 2 diabetes and hypertension.

Methods: Sixty nine individuals with Type 2 diabetes on stable medication were enrolled in a randomized, placebo-controlled double-blind study, receiving either 25 g dark chocolate (DCG) or white chocolate (WCG) for 8 weeks. Changes in weight, blood pressure, glycaemic control, lipid profile and high sensitivity C-reactive protein (hsCRP) were measured at the beginning and at the end of intervention.

Results: Energy intake, macronutrient and micronutrient composition of the diet were not different between groups at baseline and did not change in the DCG or WCG during the intervention period. Fasting blood glucose (FBG), blood pressure, HbA1c, triglyceride levels, Apo-lipoprotein A-1 and Apo-lipoprotein B and hsCRP levels in the DCG was significantly changed after the intervention compared with baseline ($p < 0.05$); however no such effects were observed in the WCG. Systolic and diastolic blood pressure decreased significantly ($P = 0.002$ and $P = 0.001$ respectively) and TG levels were also reduced meaningfully in DCG compared with WCG ($P = 0.007$). There were not any significant changes in Body weight and BMI in both groups at the end of the study.

Conclusions: High polyphenol chocolate is effective in improving TG levels and decreasing blood pressure in hypertensive diabetic patients.

Key words: chocolate, Polyphenols, type 2 diabetes *This study was funded by a grant (No989) awarded by Tehran University of Medical Sciences.

O178

ADOLESCENT DIETARY PATTERNS: TRADITION OR CONVENIENCE

M. De Lanerolle-Dias¹, A. de Silva², P. Lanerolle¹, S. Atukorala¹

¹Department of Biochemistry and Molecular Biology, Faculty of Medicine, University of Colombo, Colombo 8, Sri Lanka

²Department of Physiology, Faculty of Medicine, University of Colombo, Colombo 8, Sri Lanka

Background and objectives: Dietary habits and practices instilled during adolescence influences future health. The aim of this study was to identify major dietary patterns of female Sri Lankan adolescent school dropouts and lifestyle factors that influence dietary patterns.

Methods: BMI was calculated in n = 600 adolescent school dropouts (15-19 years). Percentage body-fat was calculated using a population specific skin-fold thickness equation. The sum of hours / week spent on walking, exercising and carrying out strenuous activities was used for calculation of physical activity. Focus group discussions (FGD) were held following standard protocol. Dietary patterns were identified based on information obtained from a pretested food frequency questionnaire. Principal component analysis was used for the extraction of factors.

Results: Two dietary patterns were identified; Pattern-1 (Urban) with higher factor loadings for starchy foods other than rice, animal food, dairy products, fruits, sweetened food and fried food, Pattern-2 (traditional) with higher factor loadings for rice, tubers and potatoes, vegetables and dark green leafy vegetables. Scores for pattern-1 were significantly ($p < 0.005$) higher for girls with central obesity (Waist circumference > 80cm), overweight and low physical activity. When controlled for both BMI and physical activity, a girl residing in the urban area had a 70% greater likelihood of consuming pattern-1 than a girl in the rural area. When controlled for physical activity, a girl consuming pattern-1 has a 64% chance of being centrally obese and a 40% chance of not being overweight. FGD results indicate that urban girls preferred purchase of food from vendors and rural girl preferred and consumed home-cooked meals.

Conclusion: Girls consuming an urban dietary pattern (pattern-1) with lower physical activity were associated with un-healthy body composition indices. Urbanization was linked with convenience foods.

Key words: Dietary pattern, adolescent girls, urban, rural

O179

IMPROVING WOMEN AND CHILDREN NUTRITION THROUGH TARGETED CAPACITY BUILDING INTERVENTIONS: EXPERIENCE FROM ETHIOPIA

M. Medhin¹, A. Jirga¹, A. Guyon¹

¹John Snow Inc.(JSI), Ethiopia

Background and objectives: Children and women are vulnerable to malnutrition because of low dietary intakes, infectious diseases, limited access to health care, and lack of appropriate care. In Ethiopia, progress have been made as the Ethiopian Demographic Health Surveys show 14 percent point reduction in stunting (2000-2011) and 10 percent point reduction of anemia in women and in children under-five (2005-2011). Since 2003, USAID funded projects have assisted the government of Ethiopia. The Integrated Family Health Program (IFHP) focus on implementing at scale (292 woredas with 33.4 people) reproductive health, new born & child health, Nutrition, HIV /AIDS and Malaria

Methods: The program integrates and harmonizes all its plans with the ministry of health. The activities included: building the capacity of health workers, health extension workers, post training follow up visits and logistic support . The government recognized Essential Nutrition Actions (ENA) framework training s materials as well as “family Health Card” were used to implement of high impact nutrition interventions through counseling, communication skills and management of severe acute malnutrition.

Results: Achievements were assessed by comparing representative household surveys in 2008 and 2012. Significant improvements were documented, 50% of pregnant women received iron/folic acid during the last pregnancy compared to 18%, 76% of newborns started breastfeeding within the first hour compared to 62% and introduction at 6 months of solid and semisolid complementary food increased from 54% to 63%; Vitamin A supplementation to children 6-23 months also increased from 66% to 87%.

Conclusion: Using multiple existing contacts and platforms of the implementation of the ENA framework, high impact nutrition interventions were effectively delivered to contribute to the improvement women and children nutrition.

Key words: Children, counseling, vitamin A, nutrition

O180

CONDITIONS OF NUTRITION OF CHILDREN FROM 7 TO 10 YEARS IN PUBLIC SCHOOLS AT REGION MARUÍPE, VITORIA/ES - BRAZIL

L. Salaroli¹, M. Molina¹, R. Silva¹

¹Department of Education Integrated Health; Federal University of Espírito Santo, Brazil

Background and objectives: The implementation of nutritional programs in schools and, consequently, the creation of a healthy environment, which implicates promotion of healthier alimentation and lifestyle, is a strategy to solve nutritional problems and avoid them in the future. Therefore it is needed to study the factors that may be associated to the low quality of alimentation among children.

Methods: A research was developed at 6 different public schools in Vitoria/ES (Brazil) with children between 7 and 10 old. Anthropometrics, health, socioeconomic and life style data were collected, and then associated with the quality of alimentation, measured by the "Índice de Alimentação Escolar" (ALES) that classified into: low, medium and good quality. Subsequently were collected data about pedagogical policies related to nutrition at schools, cafeterias and adjacent markets to identify food items sold at these places and classify them by its nutritional aspects (advisable or of moderate consumption).

Results: 204 students have participated in the study, of whom 121 (59,3%) are female. 31,3% of the students presented an excess of weight and 65,7% had a normal weight. The alimentation quality of 41,5% of the children was categorized as low, whereas 37,1% presented good alimentation. Among these, 46,3% watch TV for less than 4 hours a day ($p=0,03$) and 51,7% practice sports. There was not found any relation between the nutritional state and alimentation quality. The ALES indices showed that the nutritive quality was medium, what contradicts the positive results of institution's participation promoting healthy meals, showing that the nutritional education is not only being made by trained staff. The statistical analysis was made by frequencies test and qui-square, with significance of $p<0,05$.

Conclusions: The practice of a healthy alimentation is associated with other healthy lifestyles and can be influenced by adequate nutritional education in childhood.

Key words: Diet quality, Alimentation at school, nutritional education.

O181

TRENDS IN FOOD CONSUMPTION OVER 25 YEARS IN A DUTCH ADULT POPULATION.

M. Geurts¹, S. Westenbrink¹, J. Verkaik-Kloosterman¹, C. T. van Rossum¹

¹Centre for Nutrition, Prevention and Health services, National Institute of Public Health and the Environment, The Netherlands

Background and objectives: Food consumption might change over time, influenced by an increasing variety and availability of foods, food campaigns and other societal challenges. Identifying time trends provides valuable information to support policy regarding health and safe foods. The aim of this study was to identify trends over a 25-year time period in a Dutch adult population.

Methods: Dietary data of participants aged 19-69 years included in the Dutch food consumption surveys of 1987-1988 ($n=3975$) and 2007-2010 ($n=2106$) were used for this study. Data was collected with a two-day food record in 1987-1988 and two non-consecutive 24-hour dietary recalls in 2007-2010. To account for methodological differences between studies, only data from the first collecting day was used. Consumption of food groups in 2007-2010 were compared with that from 25 years ago. Food groups were categorized using the classification from the Dutch food Composition Database.

Results: The absolute intake of non-alcoholic beverages (like water, syrups, fruit-, soft- and isodrinks) and fortified foods increased between 1987 and 2010. Vegetable and fruit consumption decreased, however the variety of fruits increased. For milk, a shift from full fat to skimmed milk and to other dairy products was seen. Also, the consumption of diet-margarine instead of margarines increased. The type of meat that was consumed changed to relatively more poultry and processed meat.

Conclusions: Over the past 25 years beneficial changes in food consumption were observed, for example from full fat to skimmed milk. The identified changes for fruit and vegetable consumption were less favorable. It is important for food and nutrition policies to connect with present food habits of a population. Therefore continuously monitoring of the food assortment and food consumption remains to be important.

Key words: Time trends, food consumption, foods

O182

SOCIO-DEMOGRAPHIC PATTERNS OF HYPERTENSION, KNOWLEDGE, BEHAVIOURS AND PRACTICES OF ADULT TRIBAL (ADIVASIS) POPULATION IN INDIA: A FIRST NATIONAL MONITORING SURVEY

A. Laxmaiah¹, N. Arlappa¹, I.I. Meshram², N. Balakrishna¹, K. Mallikharjuna Rao¹, C. Galreddy¹, S. Kumar¹, M. Ravindranath¹

¹Division of Community Studies, National Institute of Nutrition, Hyderabad, India

²Division of Biostatistics, NIN, Hyderabad, India

Background and objectives: The prevalence of hypertension has been increasing in epidemic proportions among adults even in developing countries like India. In the age olden days, the prevalence was significantly higher among urban population compared to others. Currently, the differences were not observed. The objective of the study was to assess the prevalence of hypertension, their knowledge, practices and risk behaviours.

Methods: It was a community based study and adopted multi-stage random sampling. The study was carried out by National Nutrition Monitoring Bureau (NNMB) in 9 major states in India, as a part of National Monitoring Programme.

Results: A total of 47,401 adult subjects (>20y) were participated in the study. In general, the prevalence of hypertension among tribals was 24%, while it was not significantly different across the different socio-economic groups (24-30%). Only 8% of were aware of their hypertension and of them, about three quarters (74.1%) were on treatment. However, the risk of hypertension was higher among subjects, whose BMI ≥ 25 (1.47; CI =1.23-1.77) and WHR ≥ 0.95 (1.59 (CI=1.45-1.74) and among women the risk was still higher (1.79; CI=1.52-2.11 and 1.20; CI 1.11-1.30 respectively). Abdominal obesity showed 2 times higher risk (OR: 1.86; CI=1.49-2.33). Tobacco (CI: 1.64) and alcohol (CI: 1.37) consumption was significantly ($p < 0.01$) associated with hypertension. Tobacco, alcohol consumption and obesity were observed to be significantly associated with the hypertension. Awareness, knowledge, practice of anti-hypertension medication and health seeking behavior of tribals was very poor.

Conclusion: The prevalence of hypertension is a major public health problem even among tribal population, which could be due to decline of physical activity and nutrition transition. Timely and an appropriate strategies are needed for its prevention and control.

Key words: Hypertension, tribal adults, overweight, India, NNMB

O183

THE EFFECT OF AFRICAN LEAFY VEGETABLES ON THE MICRONUTRIENT STATUS OF SCHOOL CHILDREN IN SOUTH AFRICA: A RANDOMIZED CONTROLLED TRIAL

M. Van Der Hoeven^{1,2}, J. Osei¹, A. Kruger², M. Faber³, C. M. Smuts¹

¹Centre of Excellence For Nutrition (CEN), North-West University, South Africa

²Africa Unit For Transdisciplinary Health Research (AUTHeR), North-West University, South Africa

³Nutritional Intervention Research Unit, Medical Research Council, South Africa

Background and objectives: Food and nutrition insecurity severely compromises the quality of life in rural farm communities in South Africa. To achieve optimal dietary requirements to combat malnutrition a possible more sustainable approach is the use of indigenous and traditional foods. The aim was to investigate the effect of micronutrient-rich African Leafy Vegetables (ALVs) on children's iron, zinc and vitamin A status.

Methods: Children of two rural farm schools in the North West Province were randomly allocated per grade to receive either 300 gram cooked ALVs and school meal starch (N=86) or the normal school meal (N=81) as daily meal (5/weeks) for 3 months. The vegetables in the intervention meal consisted for 80% out of *Amaranthus cruentus* and for 20% out of either *Cleome gynandra*, *Cucurbita maxima*, or *Vigna unguiculata*. Iron, zinc and vitamin A contributions of ALVs were 3.9-4.2 mg, 1.15-1.37 mg and 373-439 μg RAE per meal, respectively. Potential intervention effects were analysed by using ANCOVA on the endpoint measurement adjusting for respective baseline values, gender, age, school and compliance.

Results: Zinc deficiency (serum zinc $< 65 \mu\text{g}/\text{dl}$) was the most prevalent (76%) micronutrient deficiency. Deficiency prevalence in iron (serum ferritin $< 15 \mu\text{g}/\text{l}$) and vitamin A (serum retinol $< 20 \mu\text{g}/\text{dl}$) were 17.6% and 4.9%, respectively, while 12.8% of the children were anaemic (haemoglobin $< 11.5\text{g}/\text{dl}$). No intervention effects were found on blood haemoglobin, serum ferritin, serum transferrin receptor, zinc protoporphyrin, serum zinc and serum retinol.

Conclusions: Consumption of ALVs did not improve or deteriorate the micronutrient status of the children during the intervention. Hence, including micronutrient rich dark leafy vegetables in children's diet might not be enough to alleviate mild micronutrient deficiencies. However, these indigenous vegetables can play an important role in the diversification of diets in a low-cost and sustainable way.

Key words: African Leafy Vegetables, micronutrients

DEVELOPING HEALTHY INDIGENOUS MENUS THROUGH WOMEN'S GROUP PARTICIPATION

S. Poosawang¹, N. Sikhiram¹

¹Faculty of Humanities, Chiang Mai University, Chiang Mai, Thailand

Background and objectives: Northern Thailand rural communities have created homestay tourism services as supplementary occupation for the villagers. Food preparation for tourists is the responsibility of women groups. Thailand's Health Ministry is supporting homestay communities to focus on health tourism. One area of health tourism is healthy food that is prepared with indigenous ingredients. The researchers conducted a participatory study with women's group in two homestay communities in Chiang Mai and Lampang in order to improve healthy indigenous menus for tourists.

Methods: The Participatory Action Research focused on basic and applied nutrition knowledge incorporating indigenous ingredients. The researchers' conducted SWOT analysis with women's group in developing healthy indigenous menu and food management.

Results: Women's group had a limited knowledge of creating healthy items for menu. Indigenous menus improvement was focused only in lowering of salt, fat and sugar and high in fiber. Some of the original indigenous diets were high in sodium, cholesterol and calories in set menu items. Women's group could manage healthy diets by lowering sodium, fat and cholesterol with reducing/replacing some ingredients, by adding good source of fiber, preparing the correct serving size, and by setting menu items based on nutritional value hence the ability to develop healthy menus. SWOT analysis showed the key statements which support setting up a master model of food items and nutritional value for a healthy food menu which is proper for health tourism community and easily prepared by women's groups.

Conclusions: Women groups are able to offer healthy indigenous menus (at least 4 set menus) for serving tourists in two homestay tourism communities.

Key words: Indigenous menus, women's group, health tourism, homestay community.

PURCHASES OF ULTRA-PROCESSED PRODUCTS BY COLOMBIAN HOUSEHOLDS AND THEIR ASSOCIATION WITH DIETARY QUALITY

C. Arango¹, C. Mejia¹, J.C. Moubarac², C. Monteiro²

¹National School of Public Health, University of Antioquia, Medellín, Antioquia, Colombia

²Núcleo de Pesquisas Epidemiológicas em Nutrição e Saúde, Universidade de São Paulo, São Paulo, Brasil

Background and objectives: The production and consumption of readily available "fast" or "convenience" ready-to-eat or ready-to-heat processed food is growing throughout the world. In Colombia, consumption of ultra-processed products is unknown. The objective was to analyze purchases of ultra-processed products by Colombian households and to assess their association with dietary quality.

Methods: Design: Application of a classification of foodstuffs based on the nature, extent and purpose of food processing to data from the most recent national household food budget survey conducted in Colombia by the Departamento Nacional de Estadística (DANE) of Colombia throughout 2006. Foods are classified as unprocessed/minimally processed foods (Group 1), processed culinary ingredients (Group 2) or ultra-processed products (Group 3). Setting: 25 departments of Colombia, 2006. Subjects: Households (n 30 644).

Results: All food purchases made by Colombian households for home consumption in 2006 added up to a mean per capita energy availability of 1344 kcal/d (SD=311). Over 49,9% of all energy purchased was from unprocessed or minimally processed foods (Group 1); 32% was from processed culinary ingredients (Group 2); and a total of 18,1% was from ultra-processed products (Group 3). The overall diet exceeded WHO upper limits for fat, saturated fat, free sugars and sodium density, with less fibre than recommended. Group 3 products taken together are more fatty, carbohydrates, and energy dense than a combination of Group 1 and Group 2 items. Significant differences were observed with group 2 and 3 over the total energy availability according with the household socio economic situation

Conclusions: As reported by those findings, Colombian diet on 2006 was dominated by unprocessed/minimally processed foods, with lower consumption of ultra-processed products. Food policies should promote healthy diets including control, marketing and consumption of processed culinary ingredients by ultra-processed food products.

Key words: Processed food, nutrition, diet, food classification.

O186

THE INFORMAS FRAMEWORK FOR MONITORING AND BENCHMARKING DIET QUALITY GLOBALLY: A STEP-BASED APPROACH

S. Vandevijvere¹, T. Lobstein², A. Lee³, J. Albert⁴, S. Krebs-Smith⁵, B. Swinburn¹, C. Monteiro⁶,

¹School of Population Health, Department of Epidemiology and Biostatistics, University of Auckland, New Zealand

²International Association for the Study of Obesity, UK

³School of Public Health and Social Work, Queensland University of Technology, Australia

⁴Food and Agricultural Organisation, Italy

⁵National Cancer Institute, USA

⁶School of Public Health, Department of Nutrition, University of Sao Paulo, Brazil

Background and objectives: Complementary to WHO monitoring efforts, the International Network for Food and Obesity/NCD Research, Monitoring and Action Support (INFORMAS) is setting benchmarks for creating healthy food environments and reducing obesity and NCDs. This paper describes the INFORMAS framework for monitoring and benchmarking population diet quality. To assess the impact of changes in food environments on national diet quality, national food consumption data are needed on a regular basis, comparable over time and if possible across countries.

Methods: An overview of existing sources of dietary data and their strengths and limitations for monitoring dietary quality was prepared and a review of pre-existing indicators of dietary quality was performed. A step-based framework was developed for INFORMAS to monitor and benchmark population dietary quality globally, both between countries and within countries over time.

Results: Food Balance Sheets (FBS) can be used in the 'minimal approach' to explore national trends of availability of several food groups and energy from fats, sugar and proteins. Household Budget Surveys (HBS) are the most suitable source of dietary data for INFORMAS, as they are available for many countries and provide more details than FBS. In the 'expanded approach', the share of ultra-processed products in the diet will be measured as a predictive indicator of energy-dense, nutrient-poor diets using either HBS or food intake surveys. The 'optimal approach' will include pre-defined and validated indices of overall dietary quality using data from national dietary surveys.

Conclusions: FBS, HBS and food intake surveys can all be used to assess quality of population diets at different levels. Dietary quality can be expressed through the share of ultra-processed products in the diet and dietary quality indices.

More work is needed in future to improve both data collection methods and diet quality indicators.

Key words: Food environments, benchmarking, diet quality, ultra-processed foods.

MONITORING THE NUTRITIONAL COMPOSITION OF FOODS TO IMPROVE THE GLOBAL FOOD SUPPLY

E. Dunford¹, J. Webster¹, A. Blanco-Metzler², B. Legetic³, N. Campbell⁴, B. Neal¹

¹The George Institute For Global Health, Sydney, Australia

²INCIENSA, Tres Rios, Costa Rica

³Pan-American Health Organization, Washington DC, USA

⁴University of Calgary, Alberta, Canada

Background and objectives: Non-communicable diseases account for more than 60% of total deaths globally. Growing rates of overweight and obesity, along with a rise in nutrition-related diseases, mean that the food industry has an increasingly important role to play in public health. The United Nations (UN) and regional governments are calling for concerted and strategic population-wide preventive measures based upon an improved food supply.

Methods: The Food Monitoring Group was established in 2010 to create a global branded food database to allow direct comparisons of nutritional composition between countries and over time.

Results: There are 29 countries involved globally, with high level input from the Food and Agriculture Organisation of the United Nations, World Health Organisation and Pan-American Health Organisation. Training seminars have been held in several countries to increase capacity to undertake data collection in low and middle income countries in the Asia-Pacific and Latin America, advanced technologies to improve data collection have been developed and distributed to eight countries, pilot data have been collected in Argentina, Australia, Brazil, Canada, Costa Rica, Fiji, Mongolia, New Zealand and the UK with data collection in six additional countries planned for 2013. Pilot data have already shown the often wide variation in nutrient levels in foods (e.g. sodium), lack of consistency with how nutrients are displayed on nutrition labels both nationally and globally, and variations in locally made versus imported products in lower and middle income countries as opposed to developed countries.

Conclusions: This project will identify where food reformulation activities will have the greatest impact, will lead to improvements in the healthiness of the global food supply and

contribute significantly to tracking progress of the food industry and governments towards commitments made at the recent UN high level meeting on chronic disease.

Key words: food composition, public health nutrition, food industry

O188

HIGH BIOAVAILABILITY IRON MAIZE (*Zea mays* L.) DEVELOPED THROUGH MOLECULAR BREEDING PROVIDES MORE ABSORBABLE IRON IN-VITRO (CACO-2) AND IN-VIVO (*Gallus gallus*)

E. Tako¹, O.A. Hoekenga¹, L.V. Kochian¹, R.P. Glahn¹

¹USDA-ARS, Robert Holley Center For Agriculture and Health, Cornell University, New York, USA

Background and objectives: Iron (Fe) deficiency is the most common micronutrient deficiency worldwide. Iron biofortification is a preventative strategy that alleviates Fe deficiency by improving the amount of absorbable Fe in crops. Here we used an in vitro digestion/Caco-2 cell culture model as the guiding tool for breeding and development of two maize lines with contrasting Fe bioavailability (Low and High). Our objective was to confirm and validate the in-vitro results and approach. Also, to compare the capacities of our two maize hybrid varieties to deliver Fe for hemoglobin (Hb) synthesis and to improve the Fe status of Fe deficient broiler-chickens.

Methods: We compared the Fe-bioavailability between these two maize varieties with the presence or absence of added Fe in the maize based-diets. Diets were made with 75% (w/w) maize of either low or high Fe-bioavailability maize +/- Fe (ferric-citrate). Chicks were fed the diets for 6wks. Hb, liver ferritin and Fe related transporter/enzyme gene-expression were measured. Hemoglobin maintenance efficiency (HME) and total body Hb-Fe values were used to estimate Fe bioavailability from the diets.

Results: DMT-1, DcytB and ferroportin expressions were higher ($P<0.05$) in the 'Low-Fe' group than in the 'High-Fe' group (no added Fe), indicating lower Fe status and adaptation to less Fe-bioavailability. At-times, Hb concentrations, HME, Hb-Fe and liver ferritin were higher in the 'High Fe' than in the 'Low Fe' groups ($P<0.05$), indicating greater Fe absorption from the diet and improved Fe-status.

Conclusions: We conclude that the High Fe-bioavailability maize contains more bioavailable Fe than the Low Fe-bioavailability maize, presumably due to a more favorable matrix for absorption. Maize shows promise for Fe biofortification; therefore, human trials should be conducted to determine the efficacy of consuming the high bioavailable Fe maize to reduce Fe deficiency.

Key words: Maize, biofortification, iron bioavailability, in vitro digestion/Caco-2 cell model, broiler-chicken.

O189

ASSOCIATION BETWEEN DIETARY INTAKES OF POLYCHLORINATED BIPHENYLS (PCBS) AND RISK OF OBESITY

C. Donat-Vargas¹, A. Gea¹, C. Sayon-Orea¹, J.M. Nuñez-Cordoba¹, E. Toledo¹, M.A. Martinez-Gonzalez¹, M. Bes-Rastrollo¹

¹A.Dept. of Preventive Medicine and Public Health, University of Navarra, Pamplona, Spain; CIBER Fisiopatología de la Obesidad y Nutrición (CIBERObn), Instituto De Salud Carlos III, Spain

Background and objectives: Polychlorinated biphenyls (PCBs) are persistent organic pollutants (POPs) that we consume because of their bioaccumulation through the food chain. Recent studies have highlighted the implication of POPs in the development of metabolic diseases like type 2 diabetes and obesity. However, this relationship is not entirely consistent and has not been investigated in longitudinal studies. We aimed to prospectively examine the association between dietary intakes of PCBs and the incidence of obesity in the SUN Project.

Methods: Prospective study of 11,701 participants without obesity at baseline followed-up for a median of 8.15 years. Daily dietary intakes of PCBs, expressed as World Health Organization toxic equivalents, were assessed at baseline with a validated 136-item semi-quantitative food-frequency questionnaire and the published concentration levels of PCBs measured in samples of foodstuffs consumed in Spain. Cox regression models were fitted through successive quintiles of PCBs intake, to estimate multivariable-adjusted hazard ratios (HR) and 95% confidence interval for incident obesity.

Results: During follow-up, we observed 436 incident cases of obesity. Participants in the fifth quintile of PCBs intake were at higher risk of becoming obese [adjusted HR: 1.66; (95% CI: 1.21 to 2.27)] compared with those in the first quintile. Moreover dose-response was evaluated, and the p for linear trend was statistically significant ($p=0.001$). After additional analyses of energy-adjusted PCBs intake through the residual method, results did not substantially change.

Conclusions: Increasing concentrations of PCBs were positively associated with the incidence of obesity. More longitudinal studies are needed to confirm our results. Funding: The SUN Study has received funding from the Spanish Government (Grants PI01/0619, PI030678, PI040233, PI042241, PI050976, PI070240, PI070312, PI081943, PI080819, PI1002658, PI1002293, RD06/0045, G03/140 and 87/2010), and the Navarra Regional Government (36/2001, 43/2002, 41/2005, 36/2008, 45/2011).

Key words: Obesity, Polychlorinated biphenyls (PCBs), Cohort study, BMI, Prospective study

COMPARISON OF EFFECT OF CASH TRANSFER WITH OR WITHOUT SPECIAL NUTRITIOUS FOOD ON PREVENTING CHILDHOOD ACUTE MALNUTRITION IN NIGER

C. Langendorf¹, T. Roederer¹, S. de Pee², D. Brown³, S. Doyon⁴, A. Mamaty⁵, L W M.Toure⁵, M L. Manzo⁶, R F. Grais¹

¹Epicentre, Paris, France

²Policy and Strategy Division, World Food Programme, Rome, Italy

³World Food Programme, Niamey, Niger

⁴Médecins Sans Frontières, Paris, France

⁵Epicentre, Niamey, Niger

⁶Regional Department of the Ministry of Public Health, Maradi, Niger

Background and objectives: Finding the most appropriate strategy for the prevention of childhood acute malnutrition is essential in countries like Niger with annual hunger gaps. Although ready-to-use supplementary foods (RUSF) are effective options for large-scale preventive distributions, the role of cash transfers, as household support or nutritional interventions, requires further investigation. Here, we compare different preventive strategies on the incidence of acute malnutrition and mortality among children 6-23 months.

Methods: Exhaustive open observational cohorts including all children 60cm to 80cm, resident in 29 villages of Madarounfa, Niger. Three different strategies of monthly distributions were assessed: 1) and 2) RUSF 500kcal/d or RUSF 250kcal/d for 15 months along with cash transfer (38€/month) for the first 5 months; 3) cash transfers only (43€/month) for the first 5 months. Anthropometric and clinical data were collected monthly. All children had access to the same primary health care package. Endpoints included wasting (WLZ<-2) and mortality.

Results: A total of 1,741 children were included in August 2011. At 5-months of follow-up, both strategies involving RUSF with cash transfer showed reduced incidence of wasting compared to cash transfers alone (cash vs. RUSF 500kcal/d(ref) HR=1.93, 95%CI:1.52-2.44; cash vs. RUSF 250kcal/d(ref) HR=2.19, 95%CI:1.76-2.74). Over 15 months, incidence of wasting was similar between the RUSF 500kcal/d and the RUSF 250kcal/d groups (HR=0.96, 95%CI:0.98-1.22). Mortality in the RUSF 500kcal/d group (0.72 death/10,000 child-days) and the RUSF 250kcal/d group (0.46 death/10,000 child-days) were not different (HR=0.80, 95%CI:0.40-1.57).

Conclusions: A 15-month supplementation with RUSF 500kcal/d or RUSF 250kcal/d had a similar effect on wasting and mortality in a region with high acute malnutrition. During the hunger gap, strategies where a cash transfer to support households was combined with supplementary foods were more

effective for preventing acute malnutrition compared to cash transfer alone.

Key words: Acute malnutrition, prevention, ready-to-use-supplementary food, cash transfer, Niger

O191

POTENTIAL OF WILD EDIBLE PLANTS TO COMBAT NUTRITIONAL AND FOOD INSECURITY: A CASE FROM INDIAN HIMALAYAN REGION

I. Bhatt¹, R. Rawal¹, A. Jugran¹

¹G.B. Pant Institute of Himalayan Environment and Development, India

Background and objectives: The traditional system of food has strong bondage to combine cultures and play an important role in biodiversity conservation. This relationship between food, biodiversity and cultural diversity significantly contributes in ensuring sustainable human development. However, over the time the rapidly changing socio-economic and environmental scenario has greatly affected the traditional systems of food, leading to disruption of these linkages and existing knowledge systems. This has consequently narrowed the food base. Implication of this deterioration in food base is wide ranging and needs revival. In this context, wild edibles, which have historically remained a part of dietary system in traditional societies in the mountains region deserve attention.

Methods: In this study, we have analyzed nutritional and antioxidant properties of selected wild edibles growing in Himalayan region through standard methods.

Results: Analysis of the nutritional and antioxidant properties of the selected wild edibles proved that they are potential source of nutritional and antioxidant activities. For instance, fruits of Berberis species contained high content of fiber (4.4-8.1%), protein (4.7-8.5%), fat (2.6-5.3%). Similarly, total phenolics (0.92-76.67 mg/g GAE) and flavonoids (4.77-6.8567 mg/g GAE) in Terminalia chebula, anthocyanins (upto 24.59 mg/g) in Berberis asiatica, ascorbic acid (34.15 mg/g) in Embelica officinale, was considerably high. The phenolics compound namely, gallic acid, catechin, chlorogenic acid, caffeic acid and β -coumaric acid analyzed through high performance liquid chromatography (HPLC method) showed significantly (<0.01) higher values in Terminalia chebula. Antioxidant activity was evaluated by 3 in vitro assays showed a positive relationship with total phenolics (ABTS - r = 0.894; DPPH-r=0.877; FRAP-r= 0.994).

Conclusion: This study attempts to establish that the wild edibles are rich source of nutritional and antioxidants and can be utilized as complementary food resource to fulfill nutritional as well as health requirement of local inhabitant.

Key words: Antioxidants, Himalaya, nutrients, wild edibles

O192

EFFECTIVE COMMUNICATION CHANNELS FOR COMMUNITY MOBILIZATION DURING VITAMIN A SUPPLEMENTATION CAMPAIGNS IN 3 STATES OF NIGERIA

I. Chima¹, B. Adebisi¹, A. Okpara¹, P. Mukoro¹

¹Helen Keller International, Abuja, Nigeria

Background and objectives: Vitamin A supplementation (VAS) is an important child survival intervention known to reduce all-cause mortality in children under-five by 24%-30%. In Nigeria, VAS is delivered through biannual Maternal Newborn and Child Health Weeks (MNCHW), an integrated package of preventive interventions to pregnant & lactating women and children under-5. Many VAS programs struggle to meet target population coverage levels due to poor community mobilisation. Formative research can help improve effectiveness of communication messages.

Methods: Exit interviews were conducted for 676 caregivers in Benue, Federal Capital Territory (FCT) and Adamawa states attending MNCHW at health facilities in May and November 2012. Respondents were asked the source of information through which they heard about the week.

Results: In May, Benue caregivers heard about MNCHW mainly through worship centres (WC) and word-of-mouth (WoM) (33.85% each) but none radio. In November, main sources were WC (78.1%), TAs (34.3%) radio (27.6%) and WoM (19.1%). In May, Adamawa caregivers heard through radio (44%), TAs (42%) and WC (32%); in November main sources included radio (40%), TAs (33%), WC or WoM (31% each). In May, FCT caregivers heard mainly through health workers (53.9%), WoM (38.5%) and WC (25.6%); in November main sources were radio (28.8%), WoM (55.6%) and WC or TAs (38.9% each). Comparing May and November 2012 rounds, Vitamin A coverage improved from 78% to 97% in Benue and from 61% to 79.4% in FCT, while it dropped from 80% to 75.6% in Adamawa.

Conclusions: Radio, places of worship, town announcers, WoM and health workers were main sources of information about MNCHW and may be effective tools for community mobilisation to improve coverage of VAS. While factors contributing to improved Vitamin A coverage are multifactorial, introduction of radio jingles corresponded with concurrent improvement in coverage in Benue and FCT.

Key words: VAS, community mobilisation

O193

PHYTOCHEMICAL COMPOSITION OF PROCESSED AND RAW SAMPLES OF SOME LESSER KNOWN VEGETABLES FROM EASTERN ZONE NIGERIA

O. Olawale¹, O. G Taiwo Olawale², N. Joy Ugo², O. Evangeline Chiyere²

¹Federal University Wukari, Nigeria

²University of Nigeria, Nsukka, Enugu state, Nigeria

Background and objectives: Phytochemicals are non-nutrient bio-active compounds found in vegetables and fruits. Increased awareness of their health protecting properties found has attracted immense attention to green leafy vegetables as vital component of daily diets. Our objective is to determine qualitative and quantitative phytochemicals on processed Agbara (*Mucuna pruriens*), Akokoro (*Ficus capensis*), Uturukpa (*Pterocarpus santalinoides*), Ogbu (*Ficus thonningli*), Uchakiri (*Vitex doniana*) and Ujuju (*Myranthus arboreus*).

Methods: The leaves (700 g) each were separated into three equal parts; shade dried, cooked for five minutes and the third sample was blended raw. Qualitative and quantitative phytochemical compositions were analysed chemically in triplicates by standard method of AOAC. The data collected were subjected to statistical analysis.

Results: The phytochemicals evaluated were alkaloid, anthocyanin, carotenoid, flavonoid, glycoside, oxalate, saponin and tannin. The result showed that phytochemical content of the vegetables varied significantly. Shade drying increased significantly ($p < 0.05$) the phytochemicals content of the vegetables while cooking reduced it. Quantitatively, *Ficus capensis* and *Ficus thonningli* had the highest Alkaloids 3.47 g/100 g and 2.29 g/100 g and the least was found in *Mucuna pruriens* (0.10 g/100 g). But the shade dried *F. capensis* and *F. thonningli* Alkaloids were 4.94 g/100 g and 3.21 g/100 g while the cooked samples had 1.20 g/100 g and 0.87 g/100 g alkaloids. *M. pruriens* with shade drying had higher flavonoid, saponin and tannin (4.69 g, 6.44 g and 4.24 g/100 g) respectively.

Conclusion: Therefore the evaluated green leafy vegetables offer cheap but rich sources of a number of phytochemicals having health protective properties.

Key words: Lesser known vegetables (LKVS), phytochemical composition, Health protecting properties, processing.

O194

TOWARDS NUTRITION GUIDELINES FOR MATERNAL AND INFANT NUTRITION TO INFLUENCE LONG-TERM HEALTH OF THE OFFSPRING: THE PAST AND FUTURE OF ILSI EUROPE WORK ON METABOLIC IMPRINTING

*R Rueda*¹

¹Department of Research and Development, Abbott Nutrition, Granada, Spain, ,

Background and objectives: Increasing evidence suggests that maternal and infant nutrition influence long-term health of the offspring. The ILSI Europe Task Force on Metabolic Imprinting aims to provide insight into the effects of the diet in various phases of early life on both disease and health endpoints.

Methods: Since its inception in 2006, the Metabolic Imprinting Task Force has brought together leading global experts to address specific questions including: research priorities and future opportunities in imprinting, programming and epigenetics; the effects of pre- and postnatal nutrition of infants with overweight and obese mothers; implications of obesity in pregnancy; and harmonization of mother-child cohort studies to improve available data. These efforts have resulted in publications widely disseminated and leading to the current project evaluating the impact of growth velocity on later health, which will be also covered.

Results: The Expert Groups established under Task Force have collected disparate and multi-disciplinary evidence in the field to highlight the knowledge gaps for future research. Thus far, the deliverables address factors contributing to offspring obesity, how to improve mother-child study designs and make optimal use of existing data. Given that growth velocity was noted to be a key risk factor, an Expert Group is now undertaking a review of current knowledge on the relationships between early growth (velocity) and later health. Data from this exercise initiated in 2013 will be presented.

Conclusions: The body of research in the field of metabolic imprinting as related to offspring health is rapidly expanding. The ILSI Europe Task Force on Metabolic Imprinting has organized small Expert Groups to collate and evaluate this wealth of data and contribute to understanding the totality of information to identify research needs.

Key words: Metabolic imprinting, programming, maternal weight, offspring.

TOTAL BODY IRON OF WOMEN RESIDING IN THE PEARL MILLET PRODUCING BELTS OF RURAL BANASKANTHA, GUJARAT, INDIA

V S. Nambiar¹, R. Desai¹, A. Baptist¹, H. Matela¹, H. Shah¹, T. Shahu¹, J.J. Dhaduk², E. Boy³

¹Principal Investigator, Pearl Millet Project-Gujarat, Department of Foods and Nutrition, The M S University of Baroda, Vadodara, Gujarat, India

²Contributing Collaborator, PMP Gujarat, SDAU, SK Nagar, Banaskantha, Gujarat, India

³Nutrition Coordinator, Harvest Plus, IFPRI, Washington, USA

Background and objectives: Low dietary intake of iron rich foods and faulty feeding practices has led to detrimental increase in iron deficiency anemia across the world. Populations residing on Pearl millet with iron 8mg/100g FW and anti nutritional factors such as phytates and phenols, which may decrease bioavailability of iron, may be anemic with low iron stores. The present study aimed to assess the relationship between dietary iron intake from pearl millet and total body iron of women of child bearing age from the pearl millet producing district of Banaskantha, Gujarat, Western India.

Methods: A cross-sectional, 30-cluster sampling design covering 1075 women from 30 villages of 3 districts of Banaskantha. Dietary data (24DRM) was elicited and assessed using the CS dietary software developed by Harvest Plus, USA. Iron status indicators, Hb, (Serum ferritin (SF) and transferrin receptors (TfR) were assessed from a subsample of 360 women (non-pregnant, age 18-35 y) and were used to calculate the total body iron (mg/kg).

Results: Average Pearl millet consumption in the form of Rotla, Khichadi, Ghes, kuler or matar ranged from 250-350 g/day contributing to an iron intake of 23.13mg/d. Overall in 358 women the total body iron was found to be 4.04 mg/kg. Among these, 78.77% women had a positive body iron store of 6.19 mg/kg.

Conclusions: Adequate meal combinations with enhancers along with pearl millet may improve the iron status of the mi-

llet based population which suffered from mild to moderate anemia and improve the total body iron stores.

Key words: pearl millet, anemia, dietary profile, total body iron.

PO002

EXCHANGEABLE ZN POOL SIZE AND ZN ABSORPTION FROM SPRINKLES AND TRADITIONAL FOODS IN PAKISTANI INFANTS/TODDLERS

S S. Ariff¹, S S B. Soofi¹, N N. Krebs², J J. Westcott², Z Z. Bhatti¹, Z Z A. Bhutta¹,

¹Department of Pediatrics & Child Health, The Aga Khan University, Karachi, Pakistan

²Nutrition Division, University of Colorado School of Medicine, USA

Background and objective: Zinc supplementation is being promoted on wide scale, but the biological implications of long term, routine supplementation at population level have not yet been fully evaluated. Our objective was to determine absorption of zinc (AZ) from a test meal consisting of local complimentary food (kitchri) with multiple-micronutrient powder MNP added to it and to compare the size of (EZP).

Methods: This was a community based nested study within a large prospective cluster randomized trial. Subjects were randomized to receive MNP alone or MNP+Zinc mixed with local complimentary diet (Kitchri) in a cohort of children 6-18 months age. Stable isotope methodology was applied to repeated measures of zinc absorption from test meals (kitchri) containing (MMP) vs. (MMP+Zinc) at 6-9 months and at 6 months follow up. Urine samples were collected for measurement of isotope ratios and determination of fractional absorption of zinc (FAZ) by dual isotope tracer ratio (DITR).

Results: Mean EZP declined in both groups at 6 months follow up (5.8mg/kg \pm 0.91 vs. 4.5mg/kg \pm 1.03 $p < 0.001$). FAZ was higher in the MMP group: 0.30 \pm 0.11 vs. 0.16 \pm 0.08 at baseline and 0.33 \pm 0.11 vs. 0.13 \pm 0.09, at follow up ($p < 0.001$). AZ was significantly higher in the zinc group both at baseline and at follow up: ($p < 0.001$).

Conclusions: Declining EZP over a period of 6 months may reflect decline in compliance, technical difficulties or growth rates. The amount of test meal kitchri consumed varied signifi-

cantly and also the absorbed Zinc, despite that, the two groups differ in their absorbed zinc AZ. This confirms that the Zn from the sprinkles in kitchri was absorbed. Based on our absorption of Zn and FAZ data, we hypothesize that addition of MMP can be a method of food fortification in low resource settings.

Key words: EZP exchangeable Zinc pools, Multiple micro-nutrient powder, Dual isotope Tracer ratio DITR

PO003

EFFECT OF DATE PLANTING AND CUTTING ON YIELD AND YIELD COMPONENTS OF BARLEY IN DIFFERENT NITROGEN FERTILIZATION

F. Bazrafshan¹, O. Dehghani¹

¹Azad University, Firoozabad, Shiraz, Iran

Background and objectives: To survey and determine the best planting time of dual purpose barley under various levels of nitrogen.

Methods: A research in the field of Islamic Azad University of Ahvaz in 1389 was conducted. This experiment was carried out in split plot factorial in randomized complete block design with four replications. The planting times in this experiment are 01/08/89, 21/08/89 and 11/09/89 and application of different amounts of nitrogen fertilizer is 90 kg and 120 kg N ha, in the main and factorial plots. Moreover, cutting treatment consists of without cutting (control) and one time cutting take out on the subplots.

Results: Based on the results of this experiment, planting time treatment showed significant difference on harvesting index, seed weight, ($p < 0.05$). So that the delay in planting increased harvest index and reduced seed weight. Meanwhile, nitrogen fertilizer increased the biological yield and harvest index. On the other hand, among traits which were affected by cutting treatment, only harvest index increased grain yield, biological yield, and reduced grain weight. In addition, interaction effect of factors on traits was significant. So that, the interaction effect of planting time and nitrogen fertilizer on biological yield showed ($p < 0.05$). Interaction effects of cutting and planting time on green fodder yield, showed significant difference ($p < 0.001$). Meanwhile, interaction effects of nitrogen fertilizer and cutting had significant effect on grain yield, harvest index and number of spikes per unit area ($p < 0.05$).

Conclusions: There is a significant correlation between planting time and other harvest variables.

Key words: barley, nitrogen fertilizer, planting time, cutting

PO004

STUDY OF ALLERGENIC PROPERTIES OF A PROTEIN HYDROLYZATE OF RICE ON THE INTESTINAL MUCOSA OF BALB/C MICE IMMUNIZED WITH THE (β -LG)

S. Addou¹, H. Bessayih¹, A. Merzouk¹, A. Brahim Chérifa¹, O. Khéroua¹, D. Saidi¹

¹Département de Biologie, faculté des sciences, University of Oran, Algiers

Background and objectives: The allergy in proteins of cow's milk represents a real public health problem, the processing of this affection requires a real coverage, and several hydrolysate was marketed and recommended to the affected infants. Among these preparations our interest concerned an infantile formula with protein of rice which could be a possible alternative in the processing of this pathology.

Methods: The purpose of our work is to study the allergenic properties of a milky formula with hydrolysed proteins of rice (Modilac Expert rice) on the structure of the intestinal mucous membrane. The technique consists in immunizing mice Balb / c with β -Lg, and then to feed them with some hydrolysed rice milk.

Results: The obtained results show that: The mice of the experimental group immunized with β -Lg and fed with the rice milk present a height villositaire comparable to that obtained to the negative control group as well as a number reduces of DREGS with regard to the positive control group of mouse. The mouse of the positive control group presents an atrophy villositaire pronounced with an important infiltration of lymphocytes compared with the experimental group and with the two control groups.

Conclusions: This type of milk is an interesting perspective as substitution for the children with allergy to cow's milk.

Key words: Proteins of cow's milk, hydrolysed rice milk, allergy to cow's milk proteins in children

PO005**THE EFFECT OF DIFFERENT NO₃- / NH₄⁺ RATIO ON QUALITATIVE AND QUANTITATIVE CHARACTERISTICS OF APPLE FRUIT CULTIVARS GALA AND GOLAB**

S. Mohammad Sokri¹, M. Babalar¹, H. Lesani¹, M. Asgari¹

¹Horticulture Department, Faculty of Agriculture, University of Tehran, Karaj, Iran

Background and objectives: In this research the effect of different nitrate to ammonium ratio on quality and quantity characteristics of apple fruit was studied.

Methods: The nitrate to ammonium ratios were (2.5 : 0.1, 6 : 0.3, 6 : 0.5, 6 : 0.7, 6 : 1 meq/l). nutrient solution pH on the 6.5 ± 0.1 was adjusted. The experimental design was randomized complete block and was performed in three replicate. Qualitative and quantitative evaluation of fruit characteristics including fruit length, fruit diameter, fruit length to diameter ratio (L / D), fruit weight, hardness, pH, soluble solids and acidity (TA).

Results: Results of statistical analysis showed that with increasing Ammonium concentration increased acidity, firmness, fruit weight and diameter and with decreasing concentration of ammonium characteristics such as soluble solids, pH, length and fruit length to diameter ratio (L / D) increased. The highest percentage of soluble solids, length and L / D ratio in terms of quality and quantity of fruit very impressive in 4 and 5 solution, respectively, that ammonium concentrations were low, was observed.

Conclusions: Nitrate to ammonium ratio has a definite effect on apple fruit.

Key words: Nutrient solution, Cultivar, nitrate to ammonium ratio, quality and quantity characteristics.

PO006**ADVANCE ON THE POLYPHENOL-PROTEINS INTERACTION IN FOOD**

J. Xiao¹, L. Chen¹, S. Xu¹, Y. Lv¹

¹Research Center of Engineering Technology for Extraction of Bioactive Compounds, Anhui Institute of Applied Technology, Suixi Road, Hefei, Anhui, PR China

Dietary flavonoids and stilbenes are important polyphenols in foods, such as, e.g., fruits, vegetables, nuts, and tea. A variety of chemical structures are possible within this group of polyphenols. Recently, the polyphenol-protein interaction (PPI) has obtained wide attentions. The effect of food proteins on the antioxidant activity of dietary polyphenols has been the subject of much controversy. For example, the dual effects of milk

proteins on the antioxidant capacity of tea polyphenols were reported. The structural characterization of the interaction between food proteins and dietary polyphenols is a major step to illustrate the induced effects on food protein structure and on the antioxidant activity of polyphenols. This review will focus on the advance on the interaction of dietary polyphenols and food proteins on following aspects: Influence of food proteins on bioactivities of dietary polyphenols. Effects of polyphenol-protein interaction on the quality of foods. Polyphenol-protein complex as functional food. Influence of dietary polyphenols on the structure of food proteins. Proteins of plant origin and polyphenols in the wine/milk/beer system. Structure-affinity relationship of polyphenol-food proteins interaction. Application of polyphenol-protein interaction in food. Advanced methods used to study the polyphenol-protein interaction.

PO007**FRUIT QUALITY AND QUANTITY AND N, K, CA CONCENTRATION OF 'GALA' AND 'GOLAB' APPLE (MALUS DOMESTICA B.) TREES AS INFLUENCED BY DIFFERENT NO₃-/NH₄⁺ RATIO.**

S. Mohammad Sokri¹, M. Babalar¹, H. Lesani¹, M. Asgari¹

¹Horticulture Department, Faculty of Agriculture, University of Tehran, Karaj, Iran

Background and objectives: We aimed to assess the influence of nitrate to ammonium ratio on apple maturation.

Methods: Responses of pot-grown apple trees (*Malus domestica* B.) with five nitrate to ammonium ratio of fruit quality and quantity characteristics and N, K, Ca concentration in two cultivars including gala and golab (Iranian cultivar) on Malling 9 (M.9) was studied. The nitrate to ammonium ratios solution of 1 to a solution of 5 were (2.5 : 0.1, 6 : 1, 6 : 0.7, 6 : 0.5, 6 : 0.3 meq/l) respectively. Nutrient solution pH on the 6.5 ± 0.1 was adjusted. Substrate consisting of soil and perlite with a volume ratio of 1/3 and 2/3 respectively. The experimental design was randomized complete block and was performed in three replicate. Qualitative and quantitative characteristics evaluation of fruit including fruit length, fruit diameter, length/ diameter (L / D), fruit weight, firmness, Juice pH, total soluble solids (TSS), titrable acidity (TA), TSS/TA, humidity and dry matter(DM) percentage. And mineral nutrient measured were N, K, Ca.

Results: Results of statistical analysis showed that TSS/TA, TA, firmness characteristics and N, K and Ca concentration show the significant influence of ammonium and higher calcium and potassium concentration, firmness, TSS/TA obtained in ratio of (2.5:0.1) which had the lowest concentration of ammonium, among other solutions and increasing concentrations of ammonium Stimulate increased nitrogen concentrations

but fruit weight, fruit length, fruit diameter, length/ diameter (L/D), juice pH, dry matter and humidity percentage showed no significant effect with increase ammonium.

Conclusions: There is a significant influence of nitrate to ammonium ratio on apple maturation.

Key words: *Malus domestica*, Pot culture, quality and quantity characteristics

PO008

FONIO (DIGITARIA EXILIS) AS A STAPLE FOOD IN MALI: AN APPROACH TO UPGRADE NUTRITIONAL VALUE

*N. Fanou-Fogny*¹

¹Department Nutrition and Food Sciences, Faculty of Agronomic Sciences, University of Abomey Calavi, Abomey Calavi, Republic of Benin

Background and objectives: Fonio (*Digitaria exilis*) is the most ancient West African cereal representing a key crop in food supply during crop shortfall periods. Less is known about the potential of fonio to contribute to nutrition and health in West Africa. We explored a set of strategies as possible solutions to existing nutritional problems among West African women, using fonio as product.

Methods: Randomly selected samples of women of reproductive age in two West African countries (Mali and Benin). Dietary assessment; food ethnography focused on fonio; and iron absorption study using stable isotopes.

Results: Average daily frequency consumption (68% consuming 1 to 3 times/month) and daily portion size of fonio (152 g) was relatively low as compared to other staples. Fonio consumption was strongly predicted by intention to consume ($r = 0.78$, $P < 0.001$), which was influenced by positive beliefs and attributes ($b = 0.32$, $P < 0.05$). Subjective norms (opinion of the husband, the family and the neighborhood) motivated intention to consume fonio ($r = 0.26$, $P < 0.001$). Time-consuming processing and lack of skills in cooking fonio had a significant interaction between intention to consume and fonio consumption ($b = -0.72$, $P < 0.05$). Dephytinisation with intrinsic wheat phytase reduced phytate-to-iron molar ratio from 23.7:1 to 2.7:1 and iron fortification decreased the molar ratio to 0.3:1. Dephytinisation with wheat phytase and fortification significantly increased iron absorption from 2.6% to 8.2% in fonio porridges.

Conclusions: Dephytinisation with native wheat phytase and iron fortification appeared relevant for adding nutritional value to fonio. Enhancing fonio consumption should emphasize positive attitudes and opinions of men, family and neighbors, while strengthening skills of women in cooking good quality fonio meals.

Key words: Fonio (*Digitaria exilis*); dietary intake and nutritional status of women in Mali; the value chain approach for nutritional goals

PO009

IMPROVMENT OF YIELD, PROTEIN, ASH AND IRON CONCENTRATION OF FORAGE MAIZE 704 BY USING POTTASIAM , MICRONUTRIENTS AND DROGHT STRESS

*A. Gholynejad*¹, *A. Majlesy*²

¹Assistant Professor, Department of Agronomy, Payame Noor University, Urmia, Iran

²Teacher , Department of Agronomy, Payame Noor University, Urmia, Iran

Background and objectives: To study the effect of drought stress, potassium and, soil and foliar application of micronutrient on yield and yield components of hybrid grain-maize K.S.C.704.

Methods: This study was conducted in split-split-plot experiment based on RCBD with three replications in Urmia. The factors were: drought stress as a main factor with two levels(normal irrigation and drought stress), potassium as a sub-plot factor with two levels(non-application and 200kg/ha application) and micronutrients as sub-sub-plot factor with three levels(non-application, soil application for Fe, Mn and Zn at the rate of 100, 100 and 60 kg/ha and foliar application at the rate of 5kg/ha). The studied factors were:, biomass,concentration of Fe, percentage of protein and ash in grain, leaf and stalk.

Results: Our results show that intraction of droght stress and foliar application of micronutrients significantly increased concentration of leaf iron, stalk proteine and leaf ash. With drought stress and pottasium using; foliar application of micronutrients increased biomass, Iron concentration of grain and stalk and grain ash significantly, but soil application of micronutrients increased prolin, stalk ash and grain protein significantly, and non application of micronutrienuts under this situation significantly increased grain protein.

Conclusions: It can be concluded that in drought stress, using potassium with micronutrients leads to improvement of growth index, therefore under this conditions using these nutrients is recommended in Urmia.

Key words: drought stress, forage maize, micronutrients, potassium

PO010**CONSUMPTION AND CONTRIBUTION OF BISCUIT TO VITAMIN A DIETARY INTAKE OF PRESCHOOLERS IN POOR-URBAN METROPOLITAN LAGOS***F. Uchendu¹, T. Atinmo²*

¹Department of Health Sciences, School of Science and Technology, National Open University of Nigeria, Nigeria

²Department of Human Nutrition, Department of Human Nutrition, University of Ibadan, Ibadan, Nigeria

Background and objectives: Nigerian biscuit is baked with vitamin A fortified wheat flour. Aim of study is to determine consumption pattern and contribution to preschooler's vitamin A dietary intake.

Methods: A cross-sectional and experimental study was carried out in four poor-urban Local Government areas (LGAs) in Lagos Metropolis, Nigeria. Pretested food frequency questionnaire was administered to randomly selected mothers of 1280 preschoolers (24-59 months). Retinyl Palmitate content of seven biscuit samples was analyzed at 0 and 30 days at room temperature using High Performance Liquid Chromatography. Data was analyzed at $p < .05$.

Results: Biscuit was consumed 4-7 times/week by 71.3% preschoolers. Mean total intake of vitamin A was 278.6 ± 298.82 IU ($83.58 \mu\text{g RAE}$). Biscuit contributed 3.0-72.4% of preschoolers RDA ($1333 \text{ i.u./} 400 \mu\text{g RAE}$). Mean contribution to vitamin A intake was 21%. Linear by linear association existed between total vitamin A intake and % RDA ($p < .01$).

Conclusions: Biscuit make an important contribution towards vitamin A intake in poor-urban Lagosian preschoolers.

Key words: biscuit, preschoolers, Lagos, RDA, vitamin A dietary intake

PO011**MONITORING IMMUNE MODULATION BY NUTRITION IN THE GENERAL POPULATION: IDENTIFYING AND SUBSTANTIATING EFFECTS ON HUMAN HEALTH***R. Albers¹, R. Bourdet-Sicard², P C. Calder⁴, U. Herz⁵, C. Lambert⁶, I. Lenoir-Winkoop⁷, A. Meheust⁸, A. Ouwehand⁹, P. Phothirath¹⁰, T. Sako¹¹, S. Salimen¹², A. Siemensma¹³, H. van Loveren¹⁴, U. Sack¹⁵, D. Braun³*

¹⁰Department of Obstetrics and Gynecology, Faculty of Medicine, University of Zaragoza, Lozano Blesa University Hospital, Spain

Background and objectives: There is a need for guidance on the assessment and interpretation of immune modulation by nutrition as optimal immune function is essential for health and wellbeing in the general population.

Methods: ILSI Europe commissioned an Expert Group (EG) comprising experts from academia, government and the food industry to prepare a guidance document. An early draft was discussed at a workshop involving additional experts to refine the recommendations.

Results: The EG first agreed upon scaled criteria to evaluate usefulness of immune markers in a structured manner. Over 75 markers were scored within the context of three distinct functions of the immune system: A) defence against pathogens, B) prevention of allergy and C) control of low-grade inflammation. The most useful markers were classified depending on whether by themselves they signify clinical relevance AND/OR involvement of immune function. In addition, five theoretical scenarios were drafted describing potential changes in marker values compared to a relevant reference, including (significant) modulation within the reference range; modulation from outside the range back into the range; modulation from within the range out of the range; prevention of modulation induced by other factors; and modulation from a less favourable range to the reference range of a comparator group with a more desired immune function (e.g. from bottle-fed to breast-fed infants). Finally, all elements were combined providing a framework to aid the design and interpretation of studies assessing effects of nutrition on immune function.

Conclusions: The step-wise approach offers a rationale for selecting markers for future trials and helps to provide a framework for the interpretation of outcomes. In fact, a similar step-wise approach may also be useful to rationalize the selection and interpretation of markers for other physiological processes critical to the maintenance of health and wellbeing.

Key words: biomarkers, immune function, validation, guidance, criteria

⁵Sina Trauma & Surgery Research Center, Tehran Medical University, Tehran, I. R. Iran

⁶Advanced Diagnostic and interventional Radiology Research Center, Tehran Medical University, Tehran, I. R. Iran

Background and objectives: This study was conducted to identify and assess the trend of nutrition research English publications in Iranian and international English journals, 2000-2010.

Methods: A descriptive study was done in two phases. First, all English Iranian journals were identified through the databases named Iran Medex, SID and Magiran and all nutrition related articles were determined. Second, all English nutrition articles published by Iranian authors and their population studies were Iranian searched and determined by using CABI keywords in Scopus, pubmed and ISI:WOS databases. Type, design and subject headings of the articles were assessed.

Results: All the English articles were 1426. More than 60% of English papers by Iranian researchers published in international English journals. English original articles were 93.6%. Clinical nutrition with 44% was in the first place. Then nutrition and health (15%), nutritional biochemistry and physiology (13%), foods (23%) and finally techniques (5%) were respectively. Descriptive articles were 45.1% regarding the design. Interventional and In vitro articles were 19.8% and 19.6% were respectively. Cohort studies with the lowest 2% showed the least. Among the interventional articles, clinical trials and community trials were 67% and 33% respectively. Statistical comparison regarding type, design and subject of papers in two five year periods did not show any significant changes in the trend of publication type and subjects except in foods which its P value was in the borderline of significance ($p=0.057$). Also, there were significant differences in descriptive ($p=0.025$) and interventional ($p=0.023$) article trends.

Conclusions: Type, design and subject headings of papers did not follow a defined planning and policy. The present study provided essential data for planning longitudinal projects and to promote national food and nutrition research programs to planners and policy makers.

³Faculty of Nutrition & Food Technology, Int. Branch of Shahid Beheshti Medical University, Tehran, I. R. Iran

⁴Department of Community Nutrition, National Nutrition & Food Technology Research Institute, Faculty of Nutrition & Food Technology Shahid Beheshti Medical University, Tehran, I. R. Iran

Background and objectives: Due to increasing the trend of lipid levels, performance difficulties and in compliance of diets in diabetic patients and side effects of medicines, this study

compare the effects of oat and barley bread on lipid profile and blood glucose of type 2 diabetic patients.

Methods: A double blind cross over trial was conducted on 36 patients with type 2 diabetes. Subjects were selected based on the fasting blood sugar higher than 126 mg/dl and one of the lipidemic indexes that was out of the normal limit, and then randomly assigned into 2 bread groups. Patients were then given daily 250 gr oat or barley bread for 3 weeks. 5 cc of venous blood was taken before, after 10 days and at the end of trial for respective assay. Patients were entered into a washout period in which had their usual diet, for 3 weeks. They were then moved into the opposite group and all of the previous phase was accomplished similarly. 3 day food recall questionnaire was completed at the 1st, 10th and 21st days in both phases of the trial.

Results: Findings indicated that all of the metabolic and anthropometric indicators were improved in both groups unless WHR. The mean differences of serum fasting glucose in barley group and oat bread group were -32 ± 2.7 and 6.2 ± 9.2 mg/dL and for serum HDL in barley group and oat bread group were 9.2 ± 1.8 and 1.34 ± 0.2 mg/dL, respectively, but the trend of the differences in fasting glucose and HDL were significant between two groups ($P=0.001$).

Conclusions: This study indicated that both oat and barley bread are effective on improvement of anthropometric and metabolic indicators, the beneficial effects of oat bread was higher to reduce blood glucose and HDL cholesterol.

Key words: Diabetes type 2, Oat bread, Barley bread, Dyslipidemia, Lipid profile

EVALUATIONS OF FRUIT QUALITY AND NITROGEN, POTASSIUM, AND CALCIUM CONCENTRATION OF APPLE (MALUS DOMESTICA BORKH. CVS. GALA AND GOLAB) GROWN WITH FIVE TREATMENTS OF NO₃-:NH₄⁺ RATIOS WERE MADE IN POT CULTURE.

S. Mohammad Sokri¹, M. Babalar¹, H. Lesani¹, M. Asgari¹

¹Horticulture Department, Faculty of Agriculture, University of Tehran, Karaj, Iran

Background and objectives: To assess the effect of NO₃-:NH₄⁺ ratios on apple.

Methods: Evaluations of fruit quality and nitrogen, potassium, and calcium concentration of apple (*Malus domestica* Borkh. cvs. Gala and Golab) grown with five treatments of NO₃-:NH₄⁺ ratios were made in pot culture. The concentrations of NO₃-:NH₄⁺ ratios were 2.5:0.1, 6:1, 6:0.7, 6:0.5, 6:0.3 meq L⁻¹.

Results: Fruit size, percent dry matter, total dissolved solids, total acidity, or juice pH was not affected by increased ammonium in the ratio. Firmness decreased as the proportion of NH₄⁺ increased. Gala and Golab differed in some of these parameters. Concentrations of N and K increased as NH₄⁺ increased, whereas Ca had no trend or decreased. Generally, the treatment of 2.5:0.1 produced fruits with lower N but higher K and Ca concentrations than the other treatments.

Conclusions: This research showed that some parameters such as fruit weight, length, and diameter, juice pH, and dry matter were not affected significantly by NH₄⁺ concentration whereas composition was affected.

Key words: *Malus domestica*, plant nutrition, plant composition

⁷Institute of Psychological Sciences, University of Leeds, Leeds, UK

⁸Kellogg Europe, Den Bosch, The Netherlands

⁹Department of Biomedical Sciences, University of Copenhagen, Copenhagen, Denmark

¹⁰Department of Medicine and Endocrinology MEA, Aarhus University Hospital, Aarhus, Denmark

Background and objectives: Postprandial glycaemia (PPG) (and related insulinemia and lipidemia) has been implicated in the etiology of metabolic chronic diseases. Obesity and related health complications lead to reduced quality of life, massive healthcare costs and ultimately premature death, indicating the

urgency for simple cost-effective strategies for prevention and management.

Methods: The International Life Sciences Institute, European Branch assembled an Expert Group to evaluate the data relating PPG to chronic metabolic diseases.

Results: Body weight control Studies suggest that the types of foods which elicit a lower PPG response may be useful as part of an overall strategy for combating obesity, and its associated burden of chronic disease, but the evidence for a role of PPG per se in these effects is considerably weaker. Several underlying mechanisms linking PPG to satiety have been suggested involving hormonal and metabolic changes. There currently exists little data on the chronic impact of reducing PPG on body weight. Type 2 diabetes mellitus There is mechanistic evidence from animal and human studies that elevated blood glucose and an altered pattern of PPG, together with an elevated insulin concentration, lead to transitory deleterious metabolic and hormonal state in healthy subjects. These phenomena are exacerbated in impaired glucose tolerant subjects. Thus, there exists evidence that reducing blood glucose and insulin responses is beneficial to prevent type 2 diabetes genesis. One of the principal challenges in clinical experiments is to provide effective low-glucose response diets to be able to draw a more definite conclusion on the role of PPG in diabetes prevention.

Conclusions: It is evident that more randomised controlled dietary intervention trials inducing effective low glucose response diets are necessary to be able to draw more definitive conclusions on the role of postprandial glycaemia in relation to health.

PO016

NUTRACEUTICALS IN PREVENTION AND FIRST LINE ERADICATION OF HELICOBACTER PYLORI-FROM NATURAL MEDICINE TO SCIENTIFIC EVIDENCE

D S S. Bonny¹, A. Aronis²

¹National Nutritional Program , Abidjan Cote d'Ivoire

²Institute of Biochemistry, Food Science and Nutrition, Faculty of Agriculture, Food and Environment, Hebrew University of Jerusalem, Rehovot, Israel

Background and objectives: Helicobacter pylori is a gram negative bacteria which is reported widely in humans and is known to be harmful. The emergences of antibiotics resistance makes the treatment so complicated that alternative treatments are still needed. Nutraceuticals appear to be a good approach of the treatment of H. pylori infection. The present study evalua-

tes scientific evidence for the rational use of nutraceuticals like probiotics, curcumin and cranberry juice in eradication of H. pylori and describes their mechanism of action.

Methods: To attain these goals, articles were review dating from January to February 2012. Initial stage of this research was focused on H. pylori eradication or reduction in reported symptoms of infection on patients followed in cohort study or clinical trials or any study according to the review articles. An additional aim of this review was to describe mechanisms of action of nutraceuticals.

Results: Nutraceuticals present an interesting alternative to prevent or support eradication of gastrointestinal tract infection. The use of probiotics, curcumin and cranberry juice in some clinical trials has shown their benefit by reducing H.pylori infection. The mechanisms of action have shown that probiotic increase barrier functions and antimicrobial activity by direct interaction with gastrointestinal cells while curcumin inhibits the growth of H pylori and cranberry juice exerts an anti-adhesion effect on H pylori.

Conclusions: Nutraceuticals may give a new approach to manage gastrointestinal tract infection but more clinical trials should be conducted in a larger population group in order to assess the eradication potential of nutraceuticals.

Key words: nutraceuticals, probiotics, curcumin, cranberry juice

PO017

THE ROLE OF BREAKFAST ENERGY IN TOTAL DAILY ENERGY INTAKE

M. Moabom¹

¹Tamale Polytechnic, Ghana

Background and objectives: The role of breakfast energy in total daily energy intake is a matter of debate. Acute feeding experiments demonstrated that high breakfast energy leads to greater overall intake supported by cross-sectional data of a free-living population. On the other hand, a large intra-individual analysis has indicated that a high proportion of breakfast to overall intake is associated with lower daily energy intake. To evaluate these apparently contradictory results in greater detail both ways of analysis were applied to the same data set of dietary records in Tamale central Hospital (Ghana).

Methods: On an intra-individual basis total daily energy intake was related to the absolute values of breakfast energy intake or to the ratio of breakfast to overall intake, respectively. Food intake of 280 obese and 100 normal weight subjects was analyzed who recorded over 10 (obese) or 14 (normal weight) consecutive days, respectively.

Results: Increasing breakfast energy was associated with greater overall intake in normal weight and obese subjects. The increasing ratio of breakfast to total daily energy intake was associated with a significant reduction of overall intake on days

where post-breakfast energy was significantly reduced. Correlation and multiple regression analysis support the concept that absolute breakfast calories have the strongest influence on daily energy intake.

Conclusions: Reduced breakfast energy intake is associated with lower total daily intake. The influence of the ratio of breakfast to overall energy intake largely depends on the post-breakfast rather than breakfast intake pattern. Therefore, overweight and obese subjects should consider the reduction of breakfast calories as a simple option to improve their daily energy balance.

Key words: breakfast, food intake, obesity, correlation

IMPROVEMENT OF SOME METABOLIC SYNDROME PARAMETERS ON RATS AND HUMANS BY HYPODAHNIIS ZENKERI

C. Etoundi¹, D. Kuate², J.L. Ngondi³, J. Oben³

¹Department of Biochemistry, University of Douala, Douala, Cameroon

²Department of Biochemistry, University of Dschang, Dschang, Cameroon

³Department of Biochemistry, University of Yaoundé I, Yaoundé, Cameroon

Background and objectives: Obesity is characterized by alterations in metabolism resulting in a variety of clinical complications. His management must include the improvement of some, or all parameters of metabolic syndrome. The barks of *Hypodaphnis zenkeri* (HZ) are used as spices in Cameroon. We therefore proposed to study their effect on some metabolic syndrome parameters of rats and overweight or obese subjects.

Methods: Three groups of Wistar rats were used. Groups 1 and 2 received a High fat High sucrose (HFHS) diet for 6 months; while group 3 received a standard diet. Simultaneously, group 1 received the dry powder of HZ in the diet at a proportion of 10%. At the beginning and the end of the experiment, a glucose tolerance test have been done, body weight measured each week until the end of the experiment where rats were sacrificed and plasma prepared for the evaluation of lipid parameters. Subsequently, a pilot study involving 30 overweight and obese subjects has been conducted and the two test groups received HZ at concentrations of 250 or 400mg, two times per day. Anthropometric parameters, blood lipids and blood glucose measured during the experiment.

Results: The treatment with HZ inhibited the weight gain, reduced the TG blood levels and the evolution of postprandial glycaemia on rats. In human study, we observed a significant ($P < 0, 05$) decrease of body weight, body fat, and waist circumference on the entire treated group with the elevated percentage of variation with the 250mg treated group. Triglyceri-

des, LDL and cholesterol were also reduced with the increased level of HDL.

Conclusions: We have shown that the barks of HZ can play a positive role in some complications linked to obesity and insulin resistance.

Key words: *Hypodaphnis zenkeri*, metabolic syndrome, obesity

PO019

FOOD BEHAVIOR AND EATING HABITS IN SCHOOL CHILDREN

F. Tebbani¹, H. Oulamara¹, A. Agli¹

¹Department of nutrition, Institut of Nutrition, Food and Food Technologies, Constantine, Algeria

Background and objectives: Among the features of the contemporary food appear skipping meals, high consumption of sugary drinks, consumption of products ready to use and eating meals in front of the TV. These factors may be associated with the current epidemic of obesity. We aim to estimate the prevalence of overweight and obesity in our study population and to assess the nutritional status of children by studying their food behavior and eating habits.

Methods: A study was conducted on a sample of 340 children (153 girls and 187 boys) aged 6 to 12 years old, enrolled in the commune of Constantine in 2011. Data included anthropometric measurements, dietary habits and socioeconomic status. The IOTF criteria were used to assess overweight and obesity. Statistics were performed using the software Statview™. The significance level was set at 0.05.

Results: The overall prevalence of overweight is 21.76%. That of obesity is 5%. A significant association was observed between obesity and female gender ($p = 0.007$). Overweight and obesity are more common in families of low socioeconomic level (51.35%, 52.94%) compared to the average (12.16%, 23.53%) and the high level (33.78%, 17.65%). Most obese children do not have breakfast compared to children of normal weight (23.53% vs 11.65%, $p < 0.0001$). They are more likely to take their lunch twice a day (64.70% vs 59.84%, $p < 0.05$). Dinner is consumed by 97% of children at home. A percentage of 30.52% of normal weight children, 27.03% overweight and 29.41% obese children eat their meals in front of the television. Carbonated soft drinks are taken by 15.59% of children more than five times a week.

Conclusions: Our study reveals the existence of behaviors associated with an increased risk of overweight and obesity, including unhealthy eating habits and low socioeconomic status.

Key words: children, obesity, prevalence, food behavior

PO020**THE FUTURE OF PERSONALISED NUTRITION: IS PHENOTYPIC CLUSTERING THE KEY?**

C O. Donovan¹, M. Walsh¹, M J. Gibney¹, E R. Gibney¹, L. Brennan¹

¹Institute of Food & Health, University College Dublin, Ireland

Background and objectives: Personalised nutrition can be defined as giving tailored advice based on an individual's diet, phenotype or genetic profile. As this is an area still in its infancy, it is felt that there is insufficient evidence to deliver advice at an individual level. A more conservative approach would be to give advice at a group level, often referred to as 'targeted nutrition'. The objectives of this study were: to investigate whether cluster analysis can be used to identify groups or clusters in the population and to determine if this technique could be used to find certain groups who could be given specific/tailored dietary advice.

Methods: The present work was performed on biochemical data obtained from 1,500 free living adults as part of the National Adult Nutrition Survey (NANS). K-means clustering was used to identify groups based on blood markers of metabolic health (triglycerides, total-cholesterol, direct HDL-cholesterol and glucose) (n=875). ANOVA with Bonferonni post hoc tests were performed to investigate differences between the groups, adjusting for age and gender.

Results: The three clusters identified were found to be significantly different in terms of anthropometric measures such as body weight (p=2.22e-13) and various biochemical markers including NEFA (p=4.05e-07), leptin (p=0.002) and adiponectin (p=1.27e-23). Cluster 3 had an 'at risk' metabolic profile with the highest levels in terms of BMI (29.26±4.67), insulin resistance (HOMA scores 3.71±3.99), TNF alpha (7.73±2.74) and the highest percentage of subjects with the metabolic syndrome (35.5%).

Conclusions: Phenotypic clustering can be used to identify adverse biochemical profiles in the Irish population using markers of metabolic health. This method could potentially be used in populations to identify metabolically 'at risk' groups that could be given specific dietary advice i.e. targeted nutrition.

Key words: personalised nutrition, phenotype, clustering.

PO021**RELATION BETWEEN DIETARY PATTERN AND INFERTILITY IN MEN AND WOMEN**

B. Hosseini¹, M. Ghavam sadri¹

¹Department of nutrition, Shahid Beheshti University of Medical Sciences, Tehran, Iran

Background and objectives: Infertility is said to be 12 months of unsuccessful attempts to fertilization. The most common type of infertility is ovarian infertility for women and disorder in sperm motility in men. Infertility statistics is 15 % in the world. Studies show the effects of macronutrients, micronutrients, food groups, isoflavonoids and heavy metals in the prevention or the occurrence of infertility. The present study aims to review the relationship between dietary pattern and infertility in men and women.

Methods: In order to review the studies on the relationship between nutrition and fertility the authors searched many sites such as Scencedirect.com, Pubmed and google scholar within the years 1978 to 2012 by some keywords such as food pattern, food groups, nutrient, sperm production, infertility, ovulation, nutritional epidemiology. A total of 90 articles were obtained.

Results: with the review of studies, it was found that the women who had the lowest fertility problem followed a dietary pattern with plant resources, with a low glycemic load (p = 0.01), no animal protein (p = 0.03) and Trans fats (p=0.02). They also served at least 1 unit of full-fat dairy products. (p = 0.01). Studies also show the impact of nutrients on male infertility, such as selenium (p <0.001), zinc (p <0.05), vitamin C (p <0.001), vitamin E (p <0.001) L - carnitine (p <0.001) and Coenzyme Q10 (p <0.05). A dietary pattern based on soybeans and other isoflavonoids results in sperm concentration reduction. (p=0.02). Seafood consumption is associated with blood mercury levels. Infertile men and women had higher blood mercury concentrations. (p <0.05).

Conclusions: Studies show that dietary patterns in terms of macronutrients, micro nutrients, food groups, antioxidants, flavonoids and heavy metals have direct effects on fertility in males and females.

Key words: Dietary patterns, nutrients, infertility, ovulation, sperm production

PO022**NUTRITIONAL QUALITY AND SAFETY OF POTENTIAL COMPLEMENTARY FOOD BLENDS PRODUCED AT SMALL SCALE INDUSTRIES IN TANZANIA***E. Towo¹, C. Mgoba¹, A. Kamala¹, W. Mehji¹*¹Tanzania Food and Nutrition Centre, Tanzania

Background and objectives: Various complementary foods based on cereal/legume flour mixtures have been increasing in the markets, stalls and retail shops in urban areas. These products are processed by small scale food processors in their backyards as part of income generating activities. The availability of the products could be an opportunity but the challenge is that quality and safety of these products is not ascertained. A study was conducted to evaluate the nutritional quality and safety of cereal/legume flour blends used as complementary foods.

Methods: Proximate analysis was used to establish nutritional composition and spread plate technique for microbiological analysis. Aflatoxin was determined qualitatively using Minicolumn method and rancidity by Kreis Test.

Results: A total of 21 different complementary brands were documented. The nutrition quality and safety analysis showed that moisture content and ash were within levels as per Tanzania Bureau of Standards (TBS) recommendations i.e. 5.3 to 10.3% moisture and 0.4 to 2.6% ash. Protein content ranged between 6.4 to 27.3% with a median value of 8.5% (mean 9.7%) which is below recommended levels by TBS that is 15%. Almost half of the samples had gone rancid and aflatoxins were detected in four samples. Microbiologically, only three samples were within the acceptable range of coliform bacteria content i.e. not more than 10 colon forming units per gram sample.

Conclusions: Whereas these foods may be convenient for users as an opportunity, the way and conditions under which they are produced may be hazardous to consumers. We recommend that, the producers be sensitized and educated on basic principles of hazard analysis critical control points and good manufacturing practices to ensure acceptable quality and safe products for their customers. Standards and guidelines for the preparation of complementary foods should also be in place.

Key words: Complementary, quality, safety

PO023**GENOME HEALTH EFFECT OF ZINC SUPPLEMENT IN ELDERLY AUSTRALIAN POPULATION WITH LOW ZIN STATUS***R. Sharif¹, P. Thomas², P. Zalewski³, M. Fenech²*¹Universiti Kebangsaan, Malaysia²CSIRO Animal, Food and Health Sciences, Adelaide, Australia³School of Medicine, University of Adelaide, Adelaide, Australia

Background and objectives: An increased intake of Zinc (Zn) may reduce the risk of degenerative diseases but may be toxic if taken in excess. This study aimed to investigate whether taking daily supplements (20mg of Zn carnosine) can improve Zn status and genome stability events in an elderly South Australian cohort with low Zn status.

Methods: 208 volunteers were screened for low plasma Zn levels ($\leq 10.5 \mu\text{M}$) and 90 were selected and randomized into two groups. A 12 week placebo-controlled intervention trial was performed with 84 volunteers completing the study, (Placebo, $n=42$) and (Zn group, $n=42$). Fasted blood was collected at baseline and at the end of the 12 week intervention.

Results: In the placebo group, plasma Zn showed a significant drop after 12 weeks from $0.907 \pm 0.099 \text{ mg/L}$ to $0.861 \pm 0.080 \text{ mg/L}$. Plasma Zn was significantly increased by 5.69% in the Zn supplemented group after 12 weeks raising plasma zinc levels from $0.926 \pm 0.096 \text{ mg/L}$ to $0.972 \pm 0.135 \text{ mg/L}$. A significant decrease in the micronucleus frequency (24.18%) was observed for the Zinc supplemented cohort relative to baseline compared to the placebo group which also recorded a small increase of the micronucleus frequency with 1.77%. Comet assay results showed a significant effect of time and treatment of Zn supplementation for both tail moment and tail intensity ($p < 0.05$). Telomere base damage was found to be significantly decreased in the Zn group ($p < 0.05$) (Baseline: 13.82 ± 18.04 , 12 weeks: 6.89 ± 15.18 [8 oxodG/kb telomere]), but no change was observed between groups.

Conclusions: Zn supplementation may prove to have a beneficial effect in an elderly population with low Zn levels by improving Zn status and lowering DNA damage events.

Key words: zinc supplement, micronuclei, tail moment and tail intensity, elderly

PO024**ZINC DEFICIENCY INCREASES TELOMERE LENGTH AND IS ASSOCIATED WITH INCREASED TELOMERE BASE DAMAGE, DNA STRAND BREAKS AND CHROMOSOMAL INSTABILITY**

R. Sharif¹, P. Thomas², P. Zalewski³, N. O'Callaghan², M. Fenech²

¹Universiti Kebangsaan Malaysia

²CSIRO Animal, Food and Health Sciences, Adelaide, Australia

³School of Medicine, University of Adelaide, Adelaide, Australia

Background and objectives: This study aimed to investigate the impact of Zinc (Zn) on telomere length and telomere base damage in two different human cells types namely the WIL2-NS lymphoblastoid cell line and the Human Oral Keratinocyte cell line (HOK).

Methods: Zn deficient medium (0 µM) was produced following Chelex treatment, and two Zn compounds, Zinc Sulphate (ZnSO₄) and Zinc Carnosine (ZnC) were tested at concentrations of 0.0, 0.4, 4.0, 16.0 and 32.0 µM.

Results: Telomere length and telomere base damage (both measured by qPCR) increased in Zn-deficient WIL2-NS and HOK cells (p<0.05). The relationship of telomere length and telomere base damage together with DNA damage biomarkers as measured by the comet and the cytokinesis block micronucleus cytome assay, were determined using correlation analysis. For WIL2-NS cells, telomere length was significantly positively correlated (p<0.05) with telomere base damage (r= 0.474), micronuclei (r= 0.380), nucleoplasmic bridges (r= 0.444) and nuclear buds (r= 0.332). Telomere base damage was significantly positively correlated with micronuclei (r=0.409), nucleoplasmic bridges (r=0.692) and nuclear buds (r=0.351). For the HOK cells, the only significant correlation (p<0.05) observed involved a positive association between telomere length and tail moment (r= 0.607), tail intensity (r= 0.425), micronuclei (r= 0.420) and nucleoplasmic bridges (r= 0.301).

Conclusions: These results suggest that Zn may play an important role in telomere length maintenance. Furthermore, these data indicate that longer telomeres induced by Zn deficiency are not indicative of improved chromosomal stability and that other parameters, such as telomere base damage, are required to obtain a more reliable assessment of telomere integrity and telomere functionality.

Key words: telomere length, telomere base damage, zinc, chromosomal instability, DNA strand breaks

PO025**ASSOCIATION OF PLACE, TIME OF MEAL AND TYPE OF MACRONUTRIENT CONSUMED WITH A SUCCESSFUL PROGRAM OF WEIGHT LOSS**

E. Morales-Falo¹, A. Esteban², P. Fardy³, J. Rice³, M. Garaulet³

¹Departamento de Química Agrícola, Universidad Autónoma de Madrid, Spain

²Centros de Nutrición Garaulet, Murcia, Spain

³Departamento de Fisiología, Universidad de Murcia, Spain

Background and objectives: Current treatment of overweight and obesity focuses on diet, physical exercise and behavior modification. The purpose of this study was to evaluate the effect of place, time and type of diet consumed at each meal in subjects participating in a weight loss program based on Mediterranean diet, physical activity, and behavior modification.

Methods: The study included three hundred ninety two patients (330 female and 62 male), mean age 38.9±11.9 and mean IMC 31.1±5.2. that were enrolled in a weight loss program. Subjects maintained a nutritional diary for seven days during the treatment. Successful weight loss (>5% of original weight) was evaluated in relation to place, time, and the type of diet consumed at breakfast, lunch, afternoon snack and dinner.

Results: Eighty four percent of those who always ate at home achieved weight loss success versus eighty two percent of those who ate outside the home. A key finding was that weight loss was associated significantly with the two last meals of the day, afternoon snack and dinner. It was also related to the macronutrient composition of the meals. Indeed, those patients who achieved their weight loss had higher protein and lower lipids at the last two meals of the day.

Conclusions: The effectiveness of the treatment is related to the place, time and composition of food of the two last meals of the day.

Key words: place, time, type of food, weight loss, obesity

PO026**TRULY NIACIN DEFICIENCY IN QUINOLINIC ACID PHOSPHORIBOSYLTRANSFERASE (QPRT) KNOCK-OUT MICE**

K. Shibata¹, M. Terakara¹, T. Fukuwatari¹, M. Sano¹, S. Fukuoka²

¹The University of Shiga Prefecture, Hikone, Japan

²Aoyama Gakuin University, Hikone, Japan

Background and objectives: Pyridine nucleotide coenzymes (PNCs) are involved in over 500 enzyme reactions. PNCs are biosynthesized from the amino acid L-tryptophan (L-Trp), as well as the vitamin niacin. Hence, “true” niacin-deficient animals cannot be “created” using nutritional techniques. We wanted to establish a truly niacin-deficient model animal using a protocol that did not involve manipulating dietary L-Trp.

Methods: We generated mice that are missing of the quinolinic acid phosphoribosyltransferase (QPRT) gene. QPRT activity was not detected in *qpert*^{-/-} mice. The *qpert*^{+/+}, *qpert*^{+/-} or *qpert*^{-/-} mice (8 weeks old) were fed a complete diet containing 30 mg nicotinic acid (NiA) and 2.3 g L-Trp/kg diet or an NiA-free diet containing 2.3 g L-Trp/kg diet for 23 d.

Results: When *qpert*^{-/-} mice were fed a complete diet, food intake and body weight gain did not differ from those of the *qpert*^{+/+} and the *qpert*^{+/-} mice. On the contrary, in the *qpert*^{-/-} mice fed the NiA-free diet, food intake and body weight were reduced to 60% ($P < 0.01$) and 70% ($P < 0.05$) of the corresponding values for the *qpert*^{-/-} mice fed the complete diet at d 23, respectively. The nutritional levels of niacin such as blood and liver NAD concentrations were also lower in the *qpert*^{-/-} mice than in the *qpert*^{+/+} and the *qpert*^{+/-} mice. Urinary excretion of quinolinic acid was greater in the *qpert*^{-/-} mice than in the *qpert*^{+/+} and the *qpert*^{+/-} mice ($P < 0.01$).

Conclusions: These data suggest that we generated truly niacin-deficient mice.

Key words: mice, niacin-deficient, pellagra, quinolinate phosphoribosyltransferase, tryptophan.

PO027**DEVELOPMENT OF VALUE ADDED “DEHRORI” A TRADITIONAL CHHATTISGARHI, (INDIAN) PRODUCT AND ITS IMPACT ON SCHOOL CHILDREN**

A. Joglekar¹, S. Verma², B. Nair³

¹Department of Nutrition, Govt. G.N.A. College, Bhatapara, Pt.R.S.University, Raipur, Chhattisgarh, India

²Department of Nutrition, Arts and Commerce Girls College, Pt.R.S.University, Raipur, Chhattisgarh, India

³Higher education, Vivekananda Vidyapeeth, Pt.R.S.University, Raipur, Chhattisgarh, India

Background and objectives: Cereals and pulses are considered as major source of energy and protein all over the world. It is a known fact that cereals are good source of energy but they contain less protein than animal protein. Dehrori is one of the popular sweet in Chhattisgarh. It is an indigenous product which is nutritionally beneficial, tasty and low cost also. The present study was undertaken to determine the physical properties and organoleptic analysis of traditional rice based product of Chhattisgarh with slight modifications. The traditional product is mainly prepared by cereal only, so the study was designed for value addition of traditional product with soybean.

Methods: The new product was prepared out of rice and soy flour. The rice flour was substituted by soy flour for the generation of a protein rice based traditional dish. All the ingredients were purchased from local market. Four types of Dehrori namely, standard Dehrori, RSP1, P2 and P3 were prepared substituting 10, 20 and 25% full soy flour to rice. All the products were analyzed for sensory, organoleptic and proximate analysis. The results were then compared with standard Dehrori.

Results: Dehrori prepared with 20-25% soy flour qualified as high protein product, approximately 19.03gm and 21.89 gm respectively, as reflected by their protein content. The overall appearance and taste of the product was not affected by the soy flour used. The acceptability and taste of the product decreased with increasing percentage of soy flour above 25% level. The team of panelist had shown high acceptability for the new developed Dehrori with 20% soy flour substituted to the basic rice flour.

Conclusions: The fortification of traditional dishes can be used as a way of improving nutritional status of vulnerable group in the society.

Key words: traditional product, soy fortification, protein rich product

PO028**NUTRITIONAL FACTS, TRACE ELEMENTS AND SENSORY ACCEPTABILITY OF BOILED INCUBATED FERTILIZED DUCK EGG (BALUT), AN INDIGENOUS FOOD IN THE PHILIPPINES**

N. Sanceda¹, H. Tsuchiya¹, T. Matsukawa², K. Yokoyama², E. Suzuki¹, K. Kubota¹, M. Kasai¹

¹Department of Nutrition and Food Science, Ochanomizu University, Tokyo, Japan

²Department of Epidemiology and Environmental Health, Juntendo University School of Medicine, Tokyo, Japan

Background and objectives: Balut is a fertilized duck egg incubated for about 18 days with a developed embryo inside that is boiled and eaten in the shell. The high protein content is known as an energizer, especially, to pregnant women in Vietnam and students in the Philippines who eat balut for energy without necessarily knowing the actual nutrition facts about this food. Objectives This study aimed to investigate trace elements, nutritional value and chemical aspects of balut, and determine the sensory acceptability of the newly developed cuisine of the egg product.

Methods: Two 'Balut' recipes were introduced. Commercial duck eggs purchased in Japan were incubated in the university laboratory at 37°C, and fresh duck eggs and balut from the Philippines were used as samples.

Results: Results of this study showed that saturated fatty acids decreased and EPA and DHA increased in balut. The total amino acid content specifically taurine significantly increased with the development of embryo during incubation. Moisture decreased and ash content conformed to the increasing values of Na, Mg, K, Ca, Fe, Zn, and P after incubation. Trace elements I, Mo, and Se were detected and these elements had been reported to be generally accepted as essential for health and wellbeing in higher animals. Other trace elements considered detrimental to health were found but concentrations were low and out of threat with large intake. Total cholesterol increased after incubation. Sensory evaluation on balut by unfamiliar panelists accepted the taste but rejected the appearance and smell. The new cuisine was accepted by almost all of the 50 untrained panelists.

Conclusions: Balut has higher nutritional value than the control. This information will bolster consumer's knowledge of the nutrition facts in balut and promote a widespread consumption with the introduction of new cuisine.

Key words: Balut, incubated duck egg, indigenous food, Philippines

PO029**STUDY ON ASSESSMENT OF FOOD SAFETY AND HYGIENE PRACTICES AMONG STREET FOOD VENDORS IN DELHI, INDIA**

C. Thakur¹

¹Public Health Foundation of India, India

Background and objectives: A study was done to assess food safety and hygiene practices among street food vendors in Delhi, India.

Methods: Practices and hygiene status of 200 street food vendors were studied by questionnaire based findings and observations of vending site. Data was entered and analyzed with the help of statistical tools.

Results: It was found that majority of the respondents (33%) were in the age group of 25+ years i.e. 25 to 34 years and 24% were illiterate. Around 36% of the vendors were permanent resident of Delhi and from rest of the respondents 55% were from Uttar Pradesh only. Ninety percent (90%) of the vendors were operating full time and 40% were earning more than Rs. 10,000 and above per month. None of the respondents were registered or licensed. Seventy percent were disposing garbage in open lid bins and 16% were throwing it on the road. With regard to personal hygiene, only 3% of the vendors were using hand gloves and from rest of the respondents only 2% were washing hands before and after handling raw or cooked food. Majority of respondents (72%) had short clean nails and few (4%) had open wounds present. While observing for the environmental conditions, presence of flies/mosquitoes was observed in 45% of the vending sites. Sixty one percent (61%) of the vendors were using DDA water for drinking and 19% were washing utensils in open only.

Conclusions: Food vended is of different flavor, cheap and tasty, which becomes popular among people easily. This study highlighted few points which need to be addressed for better hygiene status and food practices among street food vendors. There is need of generating awareness among street vendors and WHO's five keys to safety should be incorporated. Another recommendation can be to implement the policies effectively and proper interventions.

Key words: Food Safety, Food Vendors, Hygiene Practices, Nutrition, street food

PO030**PLASMA 25-HYDROXYVITAMIN D DETERMINES THE ASSOCIATION OF INSULIN RECEPTOR SUBSTRATE 1 RS2943641 WITH TYPE 2 DIABETES AND INSULIN RESISTANCE**

J.S. Zheng¹, L.D. Parnell², C.E. Smith², Y.C. Lee², Y. Ma², D. Li¹, K.L. Tucker³, J.M. Ordovás², C.Q. Lai²

¹Department of Food Science and Nutrition, Zhejiang University, Hangzhou, China

²Jean Mayer USDA Human Nutrition Research Center on Aging at Tufts University, Boston, MA, USA

³Department of Health Sciences, Northeastern University, Boston, MA, USA

Background and objectives: Associations of either insulin receptor substrate 1 (IRS1) genetic variants or circulating 25-hydroxyvitamin D (25(OH)D) with type 2 diabetes are inconsistent. Few studies have examined the interaction of IRS1 variants with circulating 25(OH)D. This study aimed to determine whether plasma 25(OH)D modulated the association of a potential functional variant at IRS1 (rs2943641) with T2D risk and insulin resistance in the Boston Puerto Rican Health Study.

Methods: Plasma 25(OH)D, fasting insulin, glucose and rs2943641 genotype were measured in 1144 Puerto Rican adults. T2D was defined as fasting glucose ≥ 7 mmol/L or taking diabetes medication. Insulin resistance was estimated with the homeostasis model assessment of insulin resistance (HOMA-IR).

Results: Higher plasma 25(OH)D was significantly associated with lower risk of T2D (P -trend=0.046), but not associated with HOMA-IR or insulin. A significant inverse association of 25(OH)D with HOMA-IR (P =0.041) and insulin (P =0.043) was observed only in rs2943641 minor allele T homozygotes, and not in C allele carriers (P -interaction=0.036 for HOMA-IR, and 0.02 for insulin). Subjects with high plasma 25(OH)D (>17 ng/mL) had a lower risk of T2D compared to subjects with low 25(OH)D ≥ 17 ng/mL only in T allele homozygotes (odds ratio = 0.16; 95%CI: 0.04, 0.65; P = 0.011), not in C allele carriers (P -interaction=0.016).

Conclusions: Higher concentrations of plasma 25(OH)D are associated with lower insulin resistance, insulin and risk of T2D only in IRS1 variant rs2943641 minor allele T homozygotes, but not in C allele carriers. Our findings warrant replication in other populations.

Key words: IRS1; genetic variant; 25-hydroxyvitamin D; type 2 diabetes; interaction

PO031**AQUEOUS GARLIC EXTRACT MITIGATE HYPERCHOLESTEROLEMIA AND HYPERGLYCEMIA; RABBIT EXPERIMENTAL MODELLING**

H A R. Suleria¹, M S. Butt², F M. Anjum², M. Arshad¹, N. Khalid³

¹Department of Food Science, Government College University Faisalabad, Pakistan

²National Institute of Food Science and Technology, University of Agriculture, Faisalabad, Pakistan

³Department of Global Agriculture, The University of Tokyo, Japan

Background and objectives: Functional foods are gaining popularity worldwide owing to the consumer's preference towards the consumption of natural product in dietary modifications. Garlic (*Allium sativum*), is one of the most essential vegetables provides health promoting perspectives due to array of bioactive ingredients. These bioactive moieties especially sulfur containing compounds are responsible for curing various lifestyle related disorders like diabetes, hyperlipidemia and cancer insurgence.

Methods: Considering the aim, garlic extraction was carried out using various solvents (aqueous ethanol, aqueous methanol and water) at different intervals (4, 5 and 6 hours) for best solvent extraction efficiency. In vitro studies were carried out to evaluate the status of antioxidant potential in these extracts. For the purpose, DPPH assay, antioxidant activity, FRAP test and glucose diffusion were examined. Efficacy study was conducted using New Zealand type Rabbits by providing best aqueous garlic extract for a period of 28 days. Accordingly, four groups were designed using different doses of extract (control, 3, 6 and 9 mL/kg b.w).

Results: Functional garlic extract containing water soluble active components resulted in significant reduction in total cholesterol and LDL level indicating their effectiveness against hypercholesterolemic perspectives. Maximum reduction in total cholesterol and LDL was 8.9% and 4.5% respectively in G2 consumed garlic extract @ 6 mL/Kg b.w. Likewise, serum glucose was also substantially reduced however, effect was more pronounced in G2 as compare to other groups. Similarly, hematological analyses were also improved by phytotherapy of functional food diets. Furthermore, serum biochemistry, protein ratios, electrolytes and non-electrolytes were within normal range revealing safety of its utilization in food products.

Conclusions: From the present investigation, it is deduced that garlic preparations like aqueous extract, garlic oil, garlic macerates are effective against hypercholesterolemia and hyperglycemia therefore, proposed to cure various life threatening disorders.

Key words: Functional food, aqueous garlic extract, hypercholesterolemia & hyperglycemia and rabbit modeling

PO032**EFFECTS OF RESVERATROL ON THE METHYLATION OF LIPOGENIC ENZYME GENES IN 3T3-L1 ADIPOCYTES**

G. Alberdi¹, L. Wakeling², A. Lasa¹, V.M. Rodríguez¹, M.T. Macarulla¹, D. Ford², M.P. Portillo¹

¹University of The Basque Country, Vitoria –Gasteiz, Spain

²Human Nutrition Research Centre, Newcastle University, Newcastle, UK

Background and objectives: Epigenetic modifications, induced partially by environmental factors, may have a role in the etiology of obesity. Methylation fluctuation of CpG-islands in the promoter-region is a mechanism known to silence/activate genes. Polyphenols show potential in addressing diseases like obesity. Resveratrol (RSV), a phytoalexin found in grapes, wine, nuts and berries, has been proposed as anti-obesity molecule. The present study aimed to assess the effect of resveratrol on the methylation of genes involved in lipogenesis and to relate these effects with its anti-obesity action.

Methods: 3T3-L1 pre-adipocytes were grown in a medium with DMEM+10% FBS. Two days after confluence, differentiation was induced (day-0). Cells were treated from day-0 either with ethanol (control) or 10 µM of RSV. Medium was changed every 2 days. On day-10, DNA was extracted and underwent bisulfite modification. Pyrosequencing was used to determine the nucleotide sequence of Acetyl-CoA-Carboxylase (ACC) and Fatty-acid-synthase (FASN). Kruskal-Wallis non-parametric test was used for statistical analysis.

Results: A significant increase in the methylation of 3 CpG-sites in the ACC promoter-region was observed in resveratrol treated cells. Likewise, there was a clear trend towards increased DNA methylation in all the CpG-sites of FASN, being statistically significant at 3 CpG-sites. The overall methylation status of ACC showed a significant increase; however for FASN, although there was a trend towards increased methylation, statistical significance was not achieved.

Conclusions: Resveratrol induces methylation of CpG dinucleotides in the promoter regions of ACC and FASN, suggesting gene silencing. Therefore, the anti-obesity effect of this polyphenol observed in vivo may be, at least in part, achieved by methylation of genes involved in lipogenesis.

Key words: Epigenetics, methylation, resveratrol, obesity, lipogenesis.

PO033**THE DIFFERENTIAL EFFECTS OF FULL-TIME AND PART-TIME WORK STATUS ON BREASTFEEDING**

D. Dewi¹

¹Lecture In University of Respati Yogyakarta, Sleman Yogyakarta, Indonesia

Background and objectives: Return to work is associated with diminished breastfeeding. Although more mothers breastfeed after returning to work compared to a decade ago, research has not documented the variations in breastfeeding initiation and duration based on full-time and part-time (less than 35 h/week) work status. In this study, we clarify these differences.

Methods: Cohort study, collected between 2010 and 2011, for over 200 mothers are used. In analyzing initiation, mother's work status was categorized by the expected number of hours she planned to work postpartum. In the duration model, work status was categorized based on the actual number of hours worked upon mother's return to employment after controlling for baby's age when she returned to work. Covariates in logistic and censored regressions included demographics, maternity leave, parity, past breastfeeding experience, hospital experience, and social support.

Results: Compared with expecting not to work, expecting to work <35 h/week was not associated with breastfeeding initiation while expecting to work full-time decreased breastfeeding initiation. Compared with breastfeeding mothers who did not work, returning to work within 12 weeks regardless of work status and returning to work after 12 weeks while working more than 34 h/week were associated with significantly shorter breastfeeding duration.

Conclusions: Part-time work and increased amount of leave taken promote breastfeeding initiation and duration.

Key words: Full time and part time breastfeeding, work status

PO034**EXPLOITING THE POTENTIAL HEALTH BENEFITS OF WATER YAM**

*F. Wireko-Manu*¹, *I. Oduro*¹, *W. Oto Ellis*¹, *R. Asiedu*², *B. Maziya-Dixon*²

¹Kwame Nkrumah University of Science and Technology (KNUST), Kumasi, Ghana

²International Institute of Tropical Agriculture (IITA), c/o LW Lambourn and Co., Carolyn House, 26 Dingwall Road, Croydon, UK

Background and objectives: Yam tubers are mainly used as food providing relatively cheaper calories to its consumers. Few yam species are grown for use as health food and for medicinal purposes. The potential exist to explore yam, especially the underutilized and less preferred ones such as *D. alata*, for health benefits. The study aimed at investigating the total dietary fibre and selected mineral composition of *D. alata* to ascertain its potential contribution to better human health.

Methods: Twenty varieties of *D. alata* and one reference variety, *D. rotundata* were used. The tubers of nine months maturity were processed into flour. Dry matter, amylose, total dietary fibre and mineral contents were determined. Statistical analysis was done with Statistical Analysis Systems (SAS) package (2003) and LSD test was used to test significant differences ($p < 0.05$) between means.

Results: Dry matter content ranged from 19.10 to 33.80% and amylose was from 27.90 to 32.30%. Total Dietary fibre (TDF) composition varied widely from 4.10 to 11.00%. In mg/kg, mineral content of the varieties were from 10.10-17.60 for Zn, 10550-20100 for K, 83-131 for Na, 260-535 for Ca, and 390-595 for Mg. The results show significant differences ($P > 0.05$) among the test varieties in all the parameters determined.

Conclusions: The test varieties had lower dry matter but higher total dietary fibre and amylose contents in comparison to the reference variety. The test varieties had appreciable amount of Zn, P, Ca and Mn; and higher total dietary fibre than what is reported for brown rice with only 2 varieties having comparable values to whole wheat flour. The results show water yam has significant amounts of dietary fibre and minerals which can be tapped by health conscious individuals and by the food industry for health benefits. .

Key words: total dietary fibre, minerals, water yam, untapped health benefits

PO035**EFFECT OF RESVERATROL METABOLITES ON ADIPOKINES EXPRESSION AND SECRETION IN 3T3-L1 MATURING ADIPOCYTES**

*A. Lasa Elgezua*², *I. Eseberri Barace*¹, *I. Txurruka Ortega*³, *J. Miranda Gomez*⁴, *M. Portillo Baquedano*⁵

¹University of Basque Country, Vitoria, Spain

Background and objectives: Resveratrol is rapidly metabolised in enterocytes and liver. Consequently, glucuronide and sulfate metabolites are produced and high concentrations of them reach plasma and tissues. Although very little data exists concerning their biological activity, they have shown to exert anticarcinogenic effects. However, little is known concerning their effect on insulin function and glucose homeostasis. The aim of the present study was to determine whether resveratrol metabolites have any effect on the expression and secretion of adipokines involved in the glycaemic control in 3T3-L1 maturing pre-adipocytes.

Methods: 3T3-L1 pre-adipocytes were cultured in DMEM+FBS media. Two days after confluence, differentiation was induced. Cells were treated on day 0, 2, 4 and 6 of differentiation with 25 μ M trans-resveratrol or its metabolites (trans-resveratrol-3-O-glucuronide, trans-resveratrol-4'-O-glucuronide and trans-resveratrol-3-O-sulfate) and on day 8, medium was removed and cells were harvested. Adipokine (leptin, adiponectin, visfatin and apelin) gene expression and secretion were analyzed by Real Time RT-PCR and ELISA respectively. The statistical study was performed by using Student's t test.

Results: Resveratrol reduced mRNA levels of leptin and increased those of adiponectin, visfatin and apelin. Trans-resveratrol-3-O-glucuronide and trans-resveratrol-4'-O-glucuronide increased adiponectin, apelin and visfatin mRNA levels and reduced leptin secretion. Trans-resveratrol-3'-O-sulfate increased adiponectin and leptin mRNA levels and reduced those of apelin.

Conclusions: The present study shows for the first time the regulatory effect of resveratrol metabolites on adipokine expression and secretion during adipocyte differentiation. Taking into account that resveratrol has demonstrated to improve insulin sensitivity, and considering that these adipokines are involved in this function, it may be proposed that resveratrol metabolites contribute to this beneficial effect of resveratrol.

Key words: 3T3-L1 preadipocytes, Adipokines, Glucuronide metabolites, Resveratrol, Sulfate metabolites

PO036**LIPID PROFILE OF RATS FED WHITE GUINEA YAM(DIOSCOREA ROTUNDATA) DIETS**

J. Lawal¹, M. Agiang¹, Y. Alozie², M. Eteng¹

¹University of Calabar, Calabar, Nigeria

²University of Uyo, Uyo, Nigeria

Background and objectives: White Guinea Yam(*Dioscorea rotundata*) locally known as 'ehuru' is commonly consumed in different diet forms in Ibarapa area of South-West Nigeria, hence it was necessary to determine their effect on lipid profile.

Methods: The yams were freshly purchased and transported to the department of Biochemistry laboratory of the University of Calabar. The diets were prepared as boiled yam (BY), pounded yam with soup and stew (PYSS), boiled yam and stew (BYS), fried yam and stew (FYS) and boiled yam with palm oil (BYPo), in cue with traditional. Normal rat chow served as the control. The soup was prepared using the tender leaves of Okro (*Abelmoschus esculentus*) known locally as 'Ilasa'. The diets were fed to the rats for a period of eleven weeks until the female rats littered to produce the first generation. The weaned rats were further placed on the same diets while the parent rats were sacrificed, blood sample obtained and used for lipid profile determination using standard methods.

Results: The triacylglyceride (TG) levels in the female rats ranged from 13.01 to 81.23mg/dl and 11.24 to 85.33mg/dl in the male rats. High density lipoprotein cholesterol (HDL-c) levels in the female rats ranged from 10.56 to 15.92mg/dl while the male rats recorded a range of 12.86 to 23.04mg/dl. Results also showed TG and HDL-c levels in PYSS were significantly higher ($P<0.05$) than in other diets and RY in both the male and female rats. LDL-c level was lowest in PYSS for female rats and FYS for male rats. The LDL-c/HDL-c ratio was lowest in the female rats. **Conclusions:** These results showed no significant risk factors in lipid profile levels in both sexes. The results also suggested that the diets may not predispose to atherogenesis.

Key words: *Dioscorea rotundata* diets, lipid profile, *Abelmoschus esculentus* and Wistar rats.

PO037**EFFECTS OF LIVE LACTOBACILLUS PARACASEI ON PLASMA LIPID CONCENTRATION IN RATS FED AN ETHANOL-CONTAINING DIET**

N. Komatsuzaki¹, S. Fujiwara¹, J. Shima²

¹Department of Human Nutrition, Seitoku University, Matsudo, Japan

²Research Division of Microbial Sciences, Kyoto University, Kyoto, Japan

Background and objectives: *Lactobacillus paracasei* NFRI 7415 isolated from a Japanese traditional fermented fish (funasushi) showed high γ -aminobutyric acid (GABA)-producing ability. Although we showed that *Lb. paracasei* NFRI 7415 was able to use the development of functional fermented food, this ability has not yet been studied in vivo for humans and animals. Alcoholic liver disease (ALD) has been increasing in Japan, as can be seen in several recent surveys. This study examined the protective effects of live *Lactobacillus paracasei* NFRI 7415 on alcoholic liver disease were investigated.

Methods: Male Fischer 344 rats were fed a control diet (CD), an ethanol diet (ED) (35.8% of total energy from ethanol), or an ethanol diet containing 20% live *Lb. paracasei* NFRI 7415 (107 cfu/g) (LD) for 10 weeks.

Results: The results indicated that the live *Lb. paracasei* NFRI 7415 reduced the total cholesterol concentration of plasma and liver in rats fed the LD. The level of docosahexaenoic acid (DHA; 22:6 n-3) in the plasma and liver of the LD group was higher than that in the ED group. The chronic alcohol consumption decreased the level of n-3 fatty acid in the plasma and liver of the ED group.

Conclusions: These results showed that the live *Lb. paracasei* NFRI 7415 can adjust the fatty acid composition of plasma and liver, and that it is possible to decrease liver damage when chronic alcohol intake.

Key words: *Lactobacillus paracasei*; Ethanol containing diet; Alcoholic liver disease; Plasma fatty acid; Liver fatty acid

PO038**EFFECTIVENESS OF HOME FORTIFICATION WITH MULTI-MICRONUTRIENT POWDERS IN BHUTANESE REFUGEE CHILDREN: A FIVE YEAR FOLLOW-UP**

O. Bilukha¹, C. Wilkinson², E. Andresen², F. Husain¹, L. Jacobson¹

¹Center for Global Health, Centers for Disease Control and Prevention, Atlanta, Georgia, USA

²United Nations High Commissioner for Refugees, Geneva, Switzerland

Background and objectives: Anemia remains a significant public health problem in refugee settings. Efficacy of micronutrient powders in reducing anemia in moderately anemic children aged 6-24 months has been demonstrated in several trials. Effectiveness of this intervention when scaled up and targeted at all children aged 6-59 months is unknown. This study was conducted to evaluate the effectiveness of a large-scale micronutrient powder distribution program in refugee children aged 6-59 months.

Methods: Six representative cross-sectional surveys were conducted during 2007-2012: 13 months before, and 7, 14, 26, 45 and 56 months after initiation of supplementation program. Data collected on children aged 6-59 months included hemoglobin concentration, anthropometric indicators, morbidity, feeding practices, and information on micronutrient distribution program.

Results: Sample sizes of the six surveys ranged from 497 to 569. The overall prevalence of anemia was 43.3% at baseline. It remained relatively stable during the first three follow-up surveys, decreased to 26.1% at 45 months, and increased to 49.9% at 56 months post-intervention. The prevalence of moderate anemia decreased from 18.9% at baseline to 7.6% at 45 months, and increased to 18.8% at 56 months. The prevalence of stunting decreased significantly from 39.2% at baseline to 19.8% at 56 months ($p < 0.0001$). Reported coverage, use and acceptance of micronutrient supplements remained consistently high throughout the study.

Conclusions: In absence of control group, changes in key outcomes should be interpreted with caution. Minor effect on hemoglobin status overall and large increase in anemia at the last follow-up are puzzling and require further investigation of underlying causes of anemia in this population. Large positive effect on linear growth may be a significant benefit of supplementation, if confirmed by future studies. Effectiveness of micronutrient powders in reducing anemia in large-scale programs targeting all children aged 6-59 months requires further investigation.

Key words: micronutrient powders, anemia, effectiveness

PO039**LIPID PROFILE AND PREVALENCE OF CARDIOVASCULAR RISK FACTORS IN A MEDITERRANEAN POPULATION OF WOMEN IN NUTRITION TRANSITION**

M. Mziwira¹, M. El ayachi², D. Lairon³, R. Belahsen⁴

¹Training and Research Unit On Nutrition & Food Sciences. Chouaib Doukkali University. School of Sciences, El Jadida, Morocco

²Training and Research Unit On Nutrition & Food Sciences. Chouaib Doukkali University. School of Sciences, El Jadida, Morocco

³INSERM, UMR476, «Nutriments Lipidiques et Prévention des Maladies Métaboliques»; INRA 1260; Univ Aix-Marseille 1 & 2, Faculté de Médecine, IPHM-IFR 125, Marseille, F-13385 France.

⁴Training and Research Unit On Nutrition & Food Sciences. Chouaib Doukkali University. School of Sciences, El Jadida, Morocco

Background and objectives: To study the lipid and apolipoprotein profile, and the adherence to Mediterranean dietary (MD) pattern in urban adult Moroccan women at procreating age, living in an agricultural Mediterranean province; El Jadida.

Methods: A random sample ($n=213$) of Moroccan women (18-55 years old) was interviewed. Plasma cholesterol (TC), triglycerides (TG), high-density lipoprotein cholesterol (HDL-C) and low-density lipoprotein cholesterol (LDL-C) concentration were determined. Plasma apolipoproteins AI, B, E, apoB48, ApoCIII and the triglyceride-rich lipoprotein (TRL-TG) fraction (VLDL and chylomicrons and their remnants) were also measured. The Metabolic Syndrome (MS) prevalence was determined by the ATP III criteria. Adherence to the Mediterranean diet (MD) was defined according to a score constructed considering the consumption of known MD components.

Results: The women studied showed elevated TC, TG and LDL-C levels among 10%, 12.7% and 19.4% respectively; low HDL-C levels in 45%. Obesity and hypertension were highly prevalent among 23.9% and 35.8% respectively. TRL-TG level higher than 0,8 mmol/l was found in 13.4%. Plasma TG concentration was closely correlated with plasma TRL-TG ($R=0.86$, $P=0.0001$), apo B ($R=0.50$, $P=0.0001$) and apo CIII ($R=0.52$, $P=0.0001$) concentration and moderately correlated with levels of HDL-C ($R=0.3$, $P=0.0001$) and BMI ($R=0.4$, $P=0.0001$). Obesity, BP, TRL-C, TRL-TG, TG, apo B, and apo CIII increased with age. The overall prevalence of MS was 20.9%. The mean adherence to MD was 62.84 %. Some components of the MD such as Cereals and mono-unsaturated to saturated fatty acids showed a protective effect on MS.

Conclusions: The results show a high prevalence of metabolic syndrome associated with altered lipid profiles in this po-

pulation. This can be explained by the nutrition transition and its influence certainly on food habits and adherence to the MD.

Key words: Lipid profile, metabolic syndrome, Mediterranean diet, cardiovascular risk, Morocco

PO040

HEAVY METAL EXPOSURE ASSESSMENT IN KOREAN ADULTS

K. Sungok¹, K. Sunghee²

¹Kyung Hee University, Seoul, Korea

²Hanyang University, Seoul, Korea

Background and objectives: Global interest in the adverse health effects of heavy metal have focused on dietary exposure as the principal source of heavy metal exposure to the general populations. Heavy metal not only the long-term, but also the short-term intake may be important, depending on the health effects considered.

Methods: We studied populations of Korean adults (n=2,101) > 19 years old who were registered for the Korean Research Project on the Integrated Exposure Assessment to Hazardous Materials for Food safety (KRIEFS), 2010-2011. The two non-consecutive 24-hour dietary recalls and Food Frequency Questionnaire (FFQ) were used to calculate dietary intakes of lead, cadmium, mercury.

Results: Lead intakes were 0.12 µ/kg b.w./day for 24 h-recall and 0.16 µ/kg b.w./day for FFQ. Cadmium intakes were 0.21 µ/kg b.w./day for 24 h-recall and 0.18 µ/kg b.w./day for FFQ. Mercury intakes were 0.07 µ/kg b.w./day for 24 h-recall and 0.10 µ/kg b.w./day for FFQ. The food groups that contributed to the major part of heavy metal exposure were vegetables (25.5%) for lead, cereals (40.1%) for cadmium, and 37.4% fishes & shellfishes for mercury. 14% of PTWI of FFQ, 24hr-recall 10% for mercury 21% for FFQ, 18% for 24 h-recall for cadmium. 4.5% for FFQ, 3.4% for 24hr-recall for lead.

Conclusions: The average lead, cadmium, and mercury dietary intakes for Korean adults are considered safe. However, the high level of dietary heavy metal intakes of adults deserves our attention. These data may be thus used to establish safety standards for fish and shellfish consumption.

Key words: heavy metals, food safety, mercury, lead, cadmium

DIOXINS AND DIOXIN-LIKE PCBs LEVELS IN FOOD AND ANIMAL FEED IN KUWAITI MARKET

B. Dashti¹, M. Wadi, A. Hussain

¹Kuwait Institute For Scientific Research, Safat, Kuwait

Background and objectives: Dioxins and dioxin-like PCBs are highly toxic environmental pollutants. They are considered as a class 1 carcinogen by the world health organization and can cause many serious health problems to human. Dioxins are produced as byproducts of burning chlorine-based chemicals with hydrocarbons in some industrial processes. Human exposure to dioxin is mainly from diet in Kuwait over 90% of the foodstuffs are being imported from different countries where control measures vary. Therefore it becomes of utmost importance to test foodstuffs that are being marketed in Kuwait for the presence of these contaminants. The objective of the study was to determine the levels of dioxins and dioxin-like PCBs in animal feed and foodstuffs that are consumed in Kuwait.

Methods: A total of 317 meat, chicken, milk, egg and animal feed samples of local and imported origin were purchased from Kuwait market. Samples were prepared and analyzed by DR CALUX bioassay (Dioxin Responsive- Chemically Activated Luciferase Expression) as well as by a high resolution gas chromatography-high resolution mass spectrometry (HRGC-HRMS) for total PCDD/PCDF/dl-PCB-TEQ (polychlorinated dibenzo-p-dioxin, polychlorinated dibenzofuran, dioxin-like polychlorinated biphenyl toxic equivalent).

Results: Results showed out of the 317 samples, 12 samples were selected for confirmation by HRGC-HRMS. Out of 12 samples analyzed by HRGC-HRMS, only two beef samples were positive.

Conclusions: This study provided the first database on dioxin and dioxin-like PCB levels in feed and foodstuffs in the State of Kuwait. Expansion on these data is essential at this stage to further conduct a total diet study for the assessment of dioxins and dioxin-like PCBs intake by the population for health risk assessment.

Key words: Dioxin, DR CALUX, Kuwait

PO042**ASSOCIATION Gln223Arg POLYMORPHISM OF GENE LEPR, LEVELS OF LEPTINA AND NOURISHING HABITS IN MEXICAN ADOLESCENTS WITH MORBID OBESITY**

C. Beltrán¹, M. López¹, M. Pita¹, M. Valderrama², M. Navarro¹

¹Behavioral Feeding and Nutrition Research Center, Universidad de Guadalajara- CUSUR, CD. Guzmán, Jalisco, México

²Departamento de Salud Publica, Universidad de Guadalajara- CUCBA, Guadalajara, Jalisco, México

Background and objectives: Mexico occupies the second world-wide place of morbid obese people (10- 12 million). Factors that predispose the development of MO are: genetic, environmental, physiological, psycho-social and behavioral (nourishing habits. Objective: Associate Gln223Arg polymorphism of gene LEPR, levels of leptina and nourishing habits with the presence of morbid obesity in adolescents of the south of Jalisco (México).

Methods: In 41 adolescents (18 normal weight and 23 morbid obesity) of 12 to 19 years of age, both sexes which were measured size and weight with tanita scale and stadimeter to determine IMC. Morbid obesity was determined by tables of the WHO and was established with a standard deviation >3. The Gln223Arg polymorphism will be identified by PCR and leptina levels by ELISA. Nourishing habits was evaluated by the questionnaire the Adolescent Food Habits Checklist. The statistical analysis was performed to compare mean scores obtained from the questionnaire when we compare morbid obesity vs normal weight adolescents with $p=0.03$ and a significance of 95%.

Results: Gene and allelic frequencies were not statistically significant when compared to normal weight adolescents with obesity morbidity with $p = 0.011$ and $p = 0.279$ respectively. Leptin levels and nourishing habits were associated with morbid obesity.

Conclusions: Dietary habits and leptin levels in adolescents are important factor that predisposes the development of obesity in adolescents. the presence of the polymorphism are not associated with morbid obesity in these subjects.

Key words: Leptin, Nourishing habits and morbid obesity.

PO043**THE IMPACT OF THE FIVE YEAR NUTRITION PROJECT IN SELENGE PROVINCE OF MONGOLIA**

B. Khurlee¹, H. Haisma¹

¹Asian Development Bank, Ulaanbaatr, Mongolia

²Rosalind Franklin Fellow, Dept of Demography, Population Research Centre, University of Groningen, The Netherland

Background and objectives: Thesis is based on the result of a study of the impact of World Vision Mongolia's five year Nutrition Project which was implemented in the poor nomadic area, Selenge province of Mongolia. The general objective of this thesis is to analyse the child nutritional status in Selenge province since the project implementation and assess whether the changes in child nutritional outcomes were associated with the nutrition project interventions.

Methods: In collaboration with Nutrition Research Centre the nutrition project assessment was done pre and post intervention design with the comparison of indicators from the baseline and the evaluation. Within the scope of this thesis all data collected during the surveys will be analysed. A literature review of studies on main interventions will be done in order to look at impacts of those interventions in developing countries.

Results: The implementation of the Nutrition Project contributed to the improvement of the child nutritional impact and nutritional status of children under five and mothers despite their poor socio-economic condition. The Nutrition Project reached its goal of elimination of severe PEM and 50% of reduction of moderate PEM among children under five. The mean prevalence of stunting decreased from 16.4% to 6.4%. Underweight and wasting declined from 5.1% to 1.8% and from 2.2% to 0.6% respectively. Project was unable to achieve its target to reduce anaemia by 30% but did achieve its target to reduce 30% of the prevalence of rickets.

Conclusions: The implementation of the WVM Nutrition project was associated with improved child macronutrient nutritional status but not with micronutrient nutritional status in the nomadic soums of Selenge province. In terms of the supplementation, the project almost achieved its target coverage 80%. Recommendation Define the project specific target group as children under two years.

Key words: Mongolia, malnutrition, maternal-child nutrition, micronutrients deficiency

PO044**EFFECT OF DIFFERENT CONCENTRATIONS OF VITAMIN A ON THE CHICK BROILER EMBRYO DEVELOPMENT**

A. Hussein¹, Z. mazaid¹

¹University of Basrah, Irak

Background and objectives: Vitamin A used in this study as the purest form of vitamin A palmtate , it solved in sterilized corn oil before incubation, Four concentrations of vitamin A were taken , one was lower than LD50 (3500 I.U) , LD50 concentration (4200 I.U), and tow higher than LD50 (6000,6800 I.U). These concentrations were injected directly before the incubation. The acute toxicity of vitamin A was carried out by injection the vitamin in the air space of fertilized eggs , the LD50 was 4200 I.U. According to this test .

Methods: Used in these study eggs of chick broiler *Gallus domesticus* ,the number of eggs is 360 , the eggs transferred to an incubator , incubated at 38C for 21 days. The morphological abnormalities were studied in different ages (3,5,7,9,11,13 and 21 days respectively). From the incubation .

Results: The concentration (3500 I.U) shows lower embryo's death (41.67%) while the highest death ratio (69.57%) was in a concentration (6800I.U), the other concentration shows different death ratio between these two ratios. The different concentration of vitamin A show clear side effects on embryos weight and length , the effect increased with the increase of concentration in all ages. The morphological examination of embryos in different ages shows many deformations in the eyes, head , brain, beak, heart , limbs, thorax and abdomen as omphalocele. They also show deformation in head and brain like Anencephaly, Exencephaly and undifferentiated brain seen in earlier stages of growth (three days of incubation) , deformation in the upper beak and eyes (Anophthalmia, Microphthalmia, different eyes size or prominent small eye and other big eye, deformation in limbs similar that in the length of front and hind limbs, crooked hind limbs with immotile embryo, crooked fingers, short tail, in addition to deformation in heart which appear short and un prominent in the early stages while in the late stage of growth, the deformation appear abnormal and outside the thorax cavity. Also, new swelling organ found in the embryo after hatch in a concentration of 6800 I.U.

Conclusions: Vitamin A has a significant impact on chick broiler embryo development.

Key words: Incubation, Abnormalities, Omphalocele, deformation

PO045**BIOCHEMICAL MARKERS AND BONE MINERAL DENSITY IN CHILDREN WITH PHENYLKETONURIA**

H. Koura¹, N. Ismail¹, S. Zaki², E. Salama¹, D. El- Lebedy³, L. Effat⁴

¹Department of pediatrics, National Research Centre, Cairo, Egypt

²Department of Anatomy, Faculty of Medicine, Cairo University, Egypt

³Department of Clinical Pathology, National Research Centre, Cairo, Egypt

⁴Department of Molecular Genetics, National Research Centre, Egypt

Background and objectives: Most Phenylketonuria (PKU) patients develop bone turnover impairment and low bone mineral density (BMD). Measurements of BMD reflect only bone mineral status but not the dynamics of bone turnover. Bone markers are noninvasive tools to assess bone formation and resorption processes. This study was to assess bone markers in PKU children in order to select a screening marker to be combined with BMD for appropriate follow up.

Methods: 33 classic PKU children were studied (mean age 8.4±4.6 yrs), and 30 age- and sex-matched children served as controls. Dual energy X-ray absorptiometry (DXA) was used to measure the Z score for total bone mineral content (TBMC), bone mineral density of femur neck (BMD-FN), and BMD of lumbar vertebrae (BMD-L). Total alkaline phosphatase (ALP), osteocalcin (OC) and Carboxy-terminal propeptide of type I collagen (CICP) as bone formation markers; osteoprotegerin (OPG) and receptor activator of nuclear factor κ ligand (RANKL) as markers of osteoclast activity; as well as Deoxyypyridinoline (DPD) as a bone collagen breakdown marker were assayed.

Results: PKU children showed significantly decreased TBMC (P=0.000), BMD-FN (P= 0.000), BMD-L (P=0.01), OC (P =0.000), ALP (P=0.005) and DPD (P= 0.000). As regards OP and CICP, no significant differences were found between PKU patients and controls. Interestingly, ALP showed a high significant negative correlation with TBMC on one hand and BMD-L on the other hand. No other significant correlations were observed.

Conclusions: ALP provides a good indicator of bone formation in PKU patients and can be used as a screening and/or follow-up marker in these patients. Detection of low ALP levels could be followed by BMD measurements and other specific markers to verify the dynamics of bone turnover. This will reduce the exposure risk hazards of DXA, and limit its use to the highly suspected cases.

Key words: Phenylketonuria, bone markers.

PO046**THE PROTECTIVE EFFECT OF SESAME OIL AGAINST NONALCOHOLIC STEATOHEPATITIS INDUCED HEPATIC FIBROSIS IN MICE***S. Chien¹, P. Chang², D. Hsu², S. Periasamy², M. Liu²*

1Department of Food and Beverage Services, Tainan University of Technology, Tainan, Taiwan

²Department of Environmental and Occupational Health, National Cheng Kung University, College of Medicine, Tainan, Taiwan

Background and objectives: Nonalcoholic steatohepatitis (NASH) is a chronic liver disease. In Western countries and Taiwan, the prevalence of NASH is 3-15%. Steatosis, oxidative stress, and inflammation are major risk factors in NASH by which may lead to fibrosis, cirrhosis, and hepatic carcinoma. Sesame oil is a potent functional food with anti-steatosis, anti-oxidation, and anti-inflammation against various diseases. The protective effect of sesame oil against NASH induced hepatic fibrosis was unclear. We examined the effect of sesame oil against NASH-induced hepatic fibrosis in mice.

Methods: Mice were fed with methionine and choline deficient (MCD) diet for 21 days to induce NASH and for 28 and 35 days to induce different grades of hepatic fibrosis. Seven doses of sesame oil (1, 2, or 4 ml/kg/day) were given orally from 22nd to 28th and 29th to 35th, respectively. Those mice were killed at 29th and 36th days and serum and tissue were collected to examine the effect of sesame oil on NASH-induced hepatic fibrosis.

Results: Sesame oil decreased malonaldehyde, tumor necrosis factor- α , leptin, transforming growth factor- β , metalloproteinase-2, metalloproteinase-9, but it increased tissue inhibitor of metalloproteinase-1 and peroxisome proliferator activated receptors- α . Sesame oil given from 22nd to 28th days prevented NASH-induced hepatic fibrosis. In addition, sesame oil given from 29th to 35th days inhibited the progression of NASH-induced hepatic fibrosis.

Conclusions: Sesame oil protected against NASH-induced hepatic fibrosis in mice.

Key words: NASH, steatosis, oxidative stress, inflammation, hepatic fibrosis

PO047**ANALYSIS OF MICRO NUTRIENT SUBSTANCE (IRON, FOLIC ACID AND ZINC) IN PREGNANT WOMEN ANEMIA IN BONTONOMPO AND SOUTH BONTONOMPO GOWA REGENCY SOUTH SULAWESI INDONESIA 2012***M. Syah¹, A. Thaha¹, C. Citrakesumasari¹, A. Otoluwa¹*

¹Departemen of Nutrition Public Health Faculty Hasanuddin University, Makassar, Indonesia

Background and objectives: Micro nutrients that may interact with the iron in hemoglobin synthesis function in pretty much the two of them are folic acid and zinc. So far it is known that iron deficiency is not the only cause of the anemia. For it is necessary a study that analyzes the status and role of substance micro nutrient especially iron, folic acid and zinc in pregnant women anemia. That objective is to determine the status of micronutrients (iron, folic acid and zinc) in maternal anemia.

Methods: This study is an observational study with cross-sectional. The sample in this research were 69 pregnant women. Carried out for 2 months, from September to October 2012. This study will analyze the status of micronutrients on the incidence of first trimester maternal anemia by using SPSS 18.0.

Results: The results obtained are characteristic of 33.3% of respondents have a lifespan of 25-30 years, 27.5% graduated levels SD / MI and SMP / MI, and 78.3% are housewives (IRT). There are 39.1% of pregnant women trimester I are anemia. The results for respondents who have low ferritin <12 mcg/ml are 100% anemia, for respondents with folic acid levels <6.7 ng / ml are 50% for respondents with anemia and zinc levels <65 mg / l are 39.1 % anemia. Ferritin levels had a significant association with the incidence of anemia with $p = 0.027$ ($p < 0.05$). As for the levels of folic acid and zinc did not have a significant association.

Conclusions: The conclusions obtained there is a significant association between levels of ferritin in this case is the iron status with hemoglobin levels (anemia) in pregnant women first trimester in Gowa regency.

Key words: Iron, Folic, Zinc, Anemia, Pregnant

PO048**UNHEALTHY DIETARY HABITS IN ADOLESCENTS MIGHT INFLUENCE THE CELLULAR METABOLISM THROUGH AN EFFECT ON MEMBRANE STRUCTURAL PROPERTIES**

F. Barceló¹, M. Aguilar-Cordero², E. Gonzalez-Jimenez², A. Sureda³, J. Perona⁴

¹Clinical and Translational Research Group, University of The Balearic Islands, Palma of Mallorca, Spain

²Departamento de Enfermería. Facultad de Ciencias de la Salud. Universidad de Granada, Granada, Spain

³Research Group on Community Nutrition and Oxidative Stress, University of the Balearic Islands, Palma of Mallorca, Spain.

⁴Instituto de la Grasa, Consejo Superior de Investigaciones Científicas (IG-CSIC), Sevilla, Spain

Background and objectives: There is an increasing trend of overweight and obese adolescents in the developed countries. Due to the importance of the problem, there has been increasing research on the relationship between adolescence lifestyle and obesity. If the diet can induce changes in the lipid profile of cell membranes [Barceló et al. Hypertension 54 (2009) 1143-1150], then dietary habits in obese adolescents can affect the structural membrane properties and may influence membrane protein functions that take part in relevant physiological activities. In this context, we set out a pilot study to compare the structural properties of erythrocyte membranes of obese and normal-weight adolescent subjects, assuming that the erythrocyte membrane lipid profile could be a dietary biomarker.

Methods: The study was conducted in a group of 12 obese and 12 normal-weight adolescent subjects. By conventional methods, we analysed the lipid profile, lipid peroxidation and acetylcholinesterase enzyme (AChE) activity. The structural properties of reconstituted erythrocyte membranes were characterized by X-ray diffraction.

Results: Comparatively, obese adolescents showed a lipid profile differentiated by a higher cholesterol/phospholipid ratio, an increase in SFA and a decrease in MUFA and n-6 PUFA fatty acids and lower AChE activity. Differences in the lipid content were associated with changes in the structural properties of reconstituted membranes and the membrane oxidative damage.

Conclusions: Our data indicate that the consequences of unhealthy dietary habits are reflected in the erythrocyte membrane properties and may influence the activity of membrane associated proteins and membrane functions. They also suggest that such interrelations may have implications in the development of diseases associated with the obesity in adolescents.

Key words: Erythrocyte membrane structure; obesity; adolescent subjects

PO049**LYCOPENE IN NATURE OR CAPSULES FOR SYSTEMIC PHOTOPROTECTION AGAINST ULTRAVIOLET B: A RANDOMIZED AND COMPARATIVE STUDY**

L. Sokoloski¹, M. Borges¹, E. Bagatin¹

¹Department of Dermatology, Federal University of Sao Paulo, Brasil

Background and objectives: carotenoids are endogenous antioxidant agents. Lycopene, the most powerful carotenoid, reduces the immediate erythema after exposure to ultraviolet B (UVB) radiation. The objective was to evaluate and compare the photoprotective effect of synthetic (capsules) or in nature (tomato paste) lycopene.

Methods: interventional, randomized, comparative 10-weeks study, including 21 subjects, divided in two groups: 11 for capsule, 10 for tomato pasta intake. Blood samples were collected for serum lycopene dosage by high performance liquid chromatography (HPLC). Colorimetry (Chromatometer CR400 Konica Minolta Sensing Inc. Japan) was used to measure minimal erythematous dose (MED) 24 hours after UVB irradiation (Ultraviolet Solar Simulator Model Solar Light Co. Inc. USA) and variation of color a (maximum erythema 24 hours after skin irradiation compared to normal skin). Evaluations were made at baseline and after 4, 8, 10 weeks. Data were analysed by ANOVA with repeated measures.

Results: three subjects dropped out after 4 weeks. Serum lycopene demonstrated great variability with no possibility of statistical analysis; for subjects taking capsules it ranged from 0.15 µmol/L to 0.55 µmol/L at baseline and, after 10 weeks, from 0.2 µmol/L to 0.73 µmol/L; for those receiving tomato pasta it ranged from 0.2 µmol/L to 0.5 µmol/L at baseline and, after 10 weeks, from 0.25 µmol/L to 0.42 µmol/L. No visual change for MED was observed in all evaluations, for both groups. Chromatometer measures showed no difference in the mean MED at baseline between groups, but variation of color a from baseline to 10 weeks was observed [marginally significant (p=0.054)]. Therefore, reduction in delta a occurred, with a tendency to be greater for capsule [marginally significant (p=0.066)].

Conclusions: Lycopene regular intake, in capsule or in nature, has demonstrated some positive effect for systemic photoprotection that indicates the advantage of promoting its regular intake.

Key words: carotenoids, lycopene, photoprotection

PO050**EFFECT OF DIETARY FORAGE SOURCE ON EGYPTIAN LACTATING BUFFALOES PERFORMANCE***M. Adel*¹¹Animal production Department, Agriculture Faculty, Cairo University, Egypt

Background and objectives: green forage represent very important part in lactating animal rations, so this study was conducted to determine the effect of dietary forage sources (berseem or/and corn silage) on digestibility, blood metabolites, milk performance of lactating buffalo.

Methods: Buffaloes (on average 580 kg LW ± 25 kg weight and 10 kg milk per d) in 3x3 Latin square design with 4 replications (n = 12) after 8 weeks of calving. Each group of buffaloes was fed one of the three diets with different source of forage: berseem as control group (B), berseem plus corn silage (BCS), or corn silage (CS). Animals were fed forage and concentrate feed mixture (CFM) in the 1:1 ratio. The experiment was conducted over three independent 30-day periods with the last 7 days used for data collection. Nutrients digestibility were determined by (AIA) technique. Blood samples were collected from all the buffaloes at the end of tested period of each ration.

Results: The lowest digestibility of DM, CP and cellulose (P<0.05) with corn silage ration compared with the other rations (66.84%, 69.49% and 62.76%, respectively for all diets). Crude fiber digestibility showed significant increase when B ration was fed (69.60%), compared to CS (67.64%) and BCS (62.00%) diets. TDN of rations were; 62.27, 63.33, 64.55 % for B, BCS and CS diets respectively with insignificant differences. Milk yield and SNF appeared insignificant effect of tested forage, however milk fat and protein content was significantly lower in CS ration, compared with the other treatments. TS of milk were lower with B and CS rations comparing to BCS ration.

Conclusions: Buffaloes receiving B or corn BCS forage diets had improved digestibility of nutrients that reflected on milk composition especially fat and protein content.

Key words: berseem, silage, buffaloes.

PO051**HAEMOGLOBIN, SERUM FERRITIN AND C - REACTIVE PROTEIN LEVELS AMONG WOMEN IN PERI-URBAN SETTLEMENTS IN GHANA***I. Agbemafle¹, M. Steiner-Asiedu¹, F Saali¹, J. Setorglo², D. Nakimbugwe³, J. Chen⁴, R. Philips⁴*¹Department of Nutrition and Food Science, University of Ghana, Legon-Ghana²Department of Medical Biochemistry, University of Cape Coast, Cape Coast³Department of Food Technology and Nutrition, University of Makerere, Uganda⁴Department of Food Science, University of Georgia, Griffin, USA

Background and objectives: Micronutrient under-nutrition of women in developing countries is a public health concern. To date only a few studies have focused on the interaction between infection and indicators of nutritional anaemia. This study assessed the prevalence of iron deficiency (ID) and iron deficiency anaemia (IDA) among women of reproductive age (WRA) in peri-urban settlements in Ghana.

Methods: We studied at baseline; inflammation, ID and IDA among 134 women enrolled in a peanut-based clinical trial. Whole blood was used to measure haemoglobin concentration using haematology automated analyzer. Serum ferritin was measured by an automated immune assay. C-reactive protein (CRP) was determined using an enhanced turbidimetric immunoassay technique. Associations with CRP were determined by stratifying ferritin and haemoglobin concentration across categories of CRP.

Results: The mean age of the women was 28.93 ± 8.24years. Mean haemoglobin and serum ferritin concentrations were 12.09 ± 1.79g/dL and 175.18 ± 66.06µg/L respectively while positive CRP values ranged from 12.0mg/L to 48.0mg/L. Mild, moderate and severe anaemia due to iron deficiency were present in 35.8%, 6.7% and 1.5%, of women respectively. Serum ferritin was within normal range for 39.8% of the women while 60.2% were at severe risk of iron overload. CRP was positive for 17.8% of the women, an indication of inflammation. CRP was poorly associated with ferritin and haemoglobin concentrations (r=0.03 and r=0.12 respectively; P>0.05)

Conclusions: Anaemia due to iron deficiency and iron overload co-exist as a public health problem among women in peri-urban settlements in Ghana. Inflammation does not appear to affect ferritin and iron deficiency anaemia.

Key words: Women, anaemia, inflammation

PO052**HIGH SENSITIVITY C-REACTIVE PROTEIN AND TOTAL ANTIOXIDANT STATUS IN PATIENTS WITH CHRONIC KIDNEY DISEASE, DIABETES AND HYPERTENSION**

H. Oboh¹, S. Idogun², A. Ukwuowo¹, J. Omole¹, E. Unigbe³

¹Department of Medical Biochemistry, University of Benin, Benin City, Edo state, Nigeria

²Department of Chemical Pathology, University of Benin, Benin City, Edo state, Nigeria

³Department of Internal Medicine, University of Benin, Benin City, Edo state, Nigeria

Background and objectives: Low grade systemic inflammation and total antioxidant status can be assessed by the levels of high sensitivity C-reactive protein (hs-CRP) and Total antioxidant capacity (TAC). The study was carried out to evaluate the levels of hs-CRP and antioxidant status in chronic kidney disease, diabetic and hypertensive subjects in the presence of traditional risk factors. The relationship between total antioxidant capacity, C-reactive protein and other risk factors like blood pressure and Anthropometric measurements were also evaluated.

Methods: A total of 180 patients (90 control, 90 test (45 males ; 45 females respectively) aged 18-76 years old, diagnosed as having chronic kidney disease, Diabetes and hypertension, but clinically stable were recruited from University of Benin Teaching Hospital. The controls were apparently healthy individuals. Anthropometric measurements were carried out (weight and height to calculate the Body mass index (BMI). Serum samples were collected for hs- CRP and TAC assays.

Results: BMI increased significantly ($P < 0.05$) in hypertensive and Diabetic patients but no change was observed in CKD. Blood pressure was increased in CKD subjects. The Diabetic subjects had normal Blood Pressure values while it was uncontrolled in the hypertensive. The results revealed that hs-CRP levels were significantly increased ($P < 0.05$) while TAC levels were decreased in all the subjects recruited for the study. The CKD subjects showed no correlation ($P > 0.05$) between CRP, BMI and TAC. However, in hypertensive and Diabetic patients, CRP and TAC correlated positively with BMI and blood pressure. TAC correlated negatively with CRP.

Conclusions: Low grade systemic inflammation as measured by hs-CRP and TAC was increased in the chronic kidney disease, diabetes and hypertension subjects. CRP correlated positively with BMI in hypertensive and diabetic patients.

Key words: High sensitivity CRP, Total antioxidant capacity, chronic kidney disease, Diabetes, hypertension

PO053**NUTRIENT COMPOSITION AND DENSITY OF FOUR COMMONLY USED LOCALLY FORMULATED COMPLEMENTARY FOODS IN AKWA IBOM STATE, NIGERIA**

O. Adepoju¹, A. Etukumoh¹

¹Department of Human Nutrition, Faculty of Public Health, College of Medicine, University of Ibadan, Ibadan, Nigeria

Background and objectives: Childhood malnutrition in form of protein-energy malnutrition and micronutrient deficiencies is still prevalent in many developing countries of the world, Nigeria inclusive. Adequate nutrition between conception and the first twenty-four months of life serve as window of opportunity for optimal growth. However, malnutrition sets in for most children from introduction to complementary foods as many of the locally formulated ones are energy dense but low in micronutrients. The study was designed to evaluate the nutrient composition and adequacy of four commonly used complementary foods in Akwa Ibom State, Nigeria.

Methods: A cross-sectional survey was conducted at two immunization centres each in two Local Government Areas (Urban and Rural) of Akwa Ibom State using 300 mothers of 6 – 24 months children attending the centres. Validated questionnaire was used to obtain information on commonly used complementary foods, and the four identified most commonly used complementary foods were standardised (unripe banana porridge with biscuit bone (BPBB), unripe banana and bonga fish (BPBF), mixed cereals (millet, guinea corn, maize) fortified with soybean, crayfish and groundnut (MCTB), mashed beans (MB)) and analysed using standard Methods of analyses of AOAC.

Results: 100g portion of the complementary foods contained 2.5 - 6.7g protein, 1.3 -7.2g lipid, 8.2-14.0g carbohydrates and 60.0-148.0Kcal of energy. Minerals ranged between 31.58 - 230.40mg potassium, 46.78-184.68mg calcium, 55.23-120.93mg phosphorus, 10.37-23.26mg iron, 7.53- 18.53mg zinc/100g portion. Their antinutrient levels were very low and cannot pose health hazards in infants. The complementary foods were nutrient dense, contained all essential nutrients in required proportions to meet nutrient needs for optimal growth of 0-24 months children.

Conclusions: Right combination of indigenous foodstuffs in complementary foods pose to be promising in reducing childhood malnutrition, and encourage dietary diversification in infant feeding.

Key words: Complementary foods, Nutrient density, Standardised diets, Micronutrients

PO054**CONCURRENT NUTRITIONAL DEFICIENCIES AND CARDIO-METABOLIC RISK FACTORS IN BURKINA FASO ADULTS: THE DOUBLE BURDEN OF MALNUTRITION***H. Delisle¹, A. Zeba^{1,2}*¹University of Montreal, Department of Nutrition, Montreal, Canada²Health Science Research Centre, Republic of Benin, West Africa

Background and objectives: The 'double burden of malnutrition' is usually fostered by a rapid nutrition transition in low and middle-income countries. It has primarily been described as concurrent undernutrition and 'overnutrition' (obesity) in the same populations or households, and not in the same individuals. The purpose of the present study was to document the double burden of nutritional deficiencies and nutrition-related cardio-metabolic risk factors (CMRF) in West-African urban adults, and to identify its correlates.

Methods: In Ouagadougou, capital city of Burkina Faso, 330 adults aged 25y-60y were randomly selected after stratification by income level. Anthropometric, socioeconomic and biochemical data were collected. Undernutrition indicators were underweight, iron depletion and vitamin A deficiency. Cardio-metabolic risk factors were those of the metabolic syndrome, plus overweight/obesity based on BMI >25.

Results: A total of 310 subjects completed the study (51.9% women). Overall, 23.6% presented with at least one nutritional deficiency combined with one CMRF. The following double burden phenotypes were identified: 1) Micronutrient deficiency + CMRF other than overweight/obesity (9%); 2) Micronutrient deficiency + obesity/overweight (7.8%); 3) Underweight + CMRF (6.8%). Women had a higher prevalence of iron depletion, vitamin A deficiency and overweight/obesity than men, explaining a significantly higher rate of double burden of malnutrition (30.4% vs 16.1%). CMRF other than overweight/obesity were as prevalent in men as in women. The occurrence of the double burden was also significantly higher among the non-educated and lower income subjects.

Conclusions: Concurrent nutritional deficiencies and nutrition-related CMRFs appear to be widespread in urban adults of low-income countries. Undernutrition and obesity is not the only double burden phenotype. This double burden of malnutrition represents a dual challenge and it is of particular concern as it affects proportionally more women and lower socioeconomic status individuals. This study was funded by CIDA.

Key words: Double burden of malnutrition; Africa

PO056**IDENTIFYING FOODS THAT CONTRIBUTES TO SOUTH AFRICANS' HIGH SALT INTAKE***E. Wentzel-Viljoen¹, R. Laubscher², K. Steyn³*¹Centre of Excellence For Nutrition, Faculty of Health Sciences, North-West Univeristy²Biostatistics Unit, SA Medical Research Council, Parow, South Africa³Chronic Disease Initiative in Africa Department of Medicine, University of Cape Town, South Africa

Background and objectives: Hypertension contributes significantly to mortality in South Africa and in 2000 accounted for 9% of all deaths in people 30 years and older. One of the most cost-effective ways to reduce blood pressure is by lowering sodium intake in a population to less than 2000mg per day. For a country to initiate a salt reducing policy it is necessary to ascertain which commonly consumed foods in the population's food pattern contribute most to their high salt intake in order to accurately define the required policy steps. This paper summarises data on sodium intake using sodium urinary excretion and dietary as well as the major food sources of sodium intake

Methods: Secondary data analyses of cross-sectional dietary studies undertaken in adult South Africans were conducted to assess the quantities and food sources of Na intake.

Results: Sodium intake based on urinary excretion ranged from 2000 to over 4000 mg/day. The sodium intake from dietary surveys ranged from 855 mg to 2733 mg per day. Discretionary salt intake ranged between 33% and 46% for different groups. Bread is the largest contributor to the salt intake in all South Africans and contributed more to the intake in the different black populations (31–52%) than in the coloured (16–31%), white (15–25%) and Indian (22%) groups. Gravy/soup powders contributed 14% and 16% (males and females) to sodium intake in a black population.

Conclusions: The level of sodium intake in South Africa is too high and contributes to high rates of hypertension. Based on these results, draft legislation has been published to reduce the salt content of processed foods, especially bread. A salt reduction strategy should also include a population based campaign to motivate the population to use less salt during food preparation, adding less salt at table and use less salty products.

Key words: Sodium, food, legislation

PO057**BIOFORTIFIED BLACK BEANS (PHASEOLUS VULGARIS L.) BASED DIET PROVIDES MORE BIOAVAILABLE IRON IN VITRO (CACO-2) AND IN VIVO (GALLUS GALLUS)**

E. Tako¹, S. Beebe², R. Glahn¹

¹USDA-ARS, Robert Holley Center For Agriculture and Health, Cornell University, NY, USA

²Centro Internacional de Agricultura Tropical (CIAT), Columbia

Background and objectives: Iron (Fe) deficiency is the most common nutrient deficiency worldwide. A major cause of Fe-deficiency is low bioavailability from plant-based diets containing mineral absorption inhibitors such as polyphenols. The common bean, provides significant quantities of protein and energy and is a source of vitamins and minerals including Fe. The common bean is an attractive candidate for Fe-biofortification because there is genetic variability of Fe concentration and therefore it is possible to breed for significant increases in Fe concentrations in beans. Also, Fe concentrations in beans are high relative to the cereals and therefore beans can deliver substantial increased amounts of Fe. Our objective was to compare the capacities of biofortified (88ig-Fe/g) and standard (59ig-Fe/g) black beans to deliver Fe for hemoglobin (Hb) synthesis.

Methods: Bean based diets (no added Fe) were formulated (dietary Fe concentrations were 39.4±0.2 and 52.9±0.9mg/kg). Chicks were fed the diets for 6wks (n=12) and Hb, feed-consumption and BW were measured.

Results: Hb-maintenance-efficiency was different between groups on wks 2-4 (P<0.05). Total body Hb-Fe contents were different between standard (23.32±0.6mg) and biofortified (25.50±0.8mg) bean groups (P<0.05). Duodenal DMT1, DcytB, and ferroportin expressions were higher and liver ferritin was lower (P>0.05) in standard vs. the biofortified groups. In-vitro analysis showed no significant differences in Fe bioavailability between diets. The in-vivo results suggested a relatively small nutritional benefit to the biofortified bean variety.

Conclusions: Evidence suggests that the nutritional benefit of the biofortified beans is reduced by the presence of polyphenols. Hence, modification of the bean seed coat polyphenols may be a means to improve bean Fe bioavailability. We conclude that biofortified beans are a promising vehicle for increasing intakes of bioavailable Fe in populations that consume these beans as a dietary staple.

Key words: Beans, biofortification, iron-bioavailability, in vitro digestion/Caco-2 cell model, broiler-chicken, intestine.

PO058**GROWTH SUPPRESSION AND NON-APOPTOTIC CELL DEATH BY PYRIDOZAL IS DEPENDENT ON P53 IN THE HUMAN BREAST CANCER CELL LINE MCF-7**

H. Kanouchi¹

¹Department of Veterinary Pathobiology, Joint Faculty of Veterinary Medicine, Kagoshima University, Japan

Background and objectives: In animal experiments, B6 compound, pyridoxine (PN), has shown anti-tumor action. In vitro experiments have also demonstrated that PN suppresses growth of the feline mammary tumor FRM cells, and human breast cancer MCF-7 cells. Additionally, B6 has been reported to suppress both proliferation-related gene expression. Our previous experiments showed that PN induces expression of insulin like growth factor binding protein-3 (IGFBP-3) to arrest proliferation and induce cell death. of note, this induction was inhibited by the p53 specific inhibitor pifithrin- α . Here, we report that another B6 compound, pyridoxal (PL), is a more potent inhibitor of MCF-7 cell growth than PN. [

Methods: cell culture, real-time PCR, immunoblot and immunocytochemistry.

Results: PL induced the G0/G1 arrest, which is an indicator of inhibition of proliferation. It appears that PL induced cell death is non-apoptotic cell death, because PL treated cells did not increase annexin V positive cells and accumulate active caspase-3 in cells. Because the protein p53 is important for cell-cycle regulation, we evaluated whether PL-induced growth inhibition were associated with p53 function using real-time PCR, immunoblot and immunocytochemistry. Although p53 mRNA was not induced, 0.5 mM PL increased the protein level and nuclear transfer of p53. Thus, we hypothesized that PL activates p53 resulting in accumulation of cells and arrest cell proliferation. Indeed, in line with a role for p53 in PL-induced inhibition of proliferation, cell growth suppression by PL did not occur when p53 expression was knocked-down using siRNA.

Conclusions: PL-induced cell growth suppression is dependent on p53 in MCF-7 breast cancer cells.

Key words: Vitamin B6, Pyridoxal, IGFBP-3, MCF-7, p53

PO059**CHANGES IN BIOCHEMICAL MARKERS OF VITAMINS AND TRACE MINERALS AFTER FORTIFIED MILK CONSUMPTION**

T. Trinidad¹, A. Mallillin¹, R. Sagum¹, M. de Leon¹, M. Borlagdan¹, A. Baquiran¹

¹Food and Nutrition Research Institute, Department of Science and Technology, Tagnig City Philippines

Background and objectives: Micronutrient fortification of commonly consumed foods remains to be practical and sustainable option to fight malnutrition. The study determined the changes in biochemical markers of vitamins and trace minerals after fortified milk consumption among 6 year-old schoolchildren.

Methods: A total of 141 school children were grouped into three: the water group; 1-glass milk group and 2-glasses milk group. Blood was collected at baseline, midline and endline to measure hemoglobin, serum ferritin, serum zinc, serum vitamins A, C, and D. Urine samples were collected at baseline, midline and endline for urinary iodine analysis.

Results: The hemoglobin concentration of study participants was considered borderline anemic (11.5-11.6 mg/dL) at baseline. At midline, the hemoglobin concentration of the 2-glasses group significantly increased. The serum ferritin of the study participants were within the normal values of <12 ug/L at baseline, midline and endline. A significant increase was observed for serum zinc in children fed with 1-glass and 2-glasses but more pronounced for 2-glasses (P<0.05). Urinary iodine for all groups was within acceptable levels at baseline, midline and endline. Similar results were observed for vitamin A. All children were vitamin C deficient at baseline (0.2-0.3 mg/dL), and attained normalcy at endline. No vitamin D deficiency was observed among study participants at baseline but a significant increase was observed at endline within acceptable levels.

Conclusions: Fortified milk supplementation among 6-year-old school children is effective for significant changes in hemoglobin and serum zinc and is more pronounced at 2-glasses/day. More studies are needed on the ratio of iron to zinc in fortifying milk to improve iron bioavailability. Drinking 2-glasses of fortified milk among 6-year old school children is recommended for proper nutrition and growth.

Key words: fortified milk, minerals, vitamins, school children

PO060**DIETARY FIBER AND MINERAL AVAILABILITY OF MILLED, BROWN AND OPTIMIZED BROWN RICE OF THE SAME VARIETY**

T. Trinidad¹, A. Mallillin¹, M. de Leon¹, J. Alcantara¹, R. Sagum¹

¹Food and Nutrition Research Institute, Department of Science and Technology, Tagnig City Philippines

Background and objectives: Brown rice has greater mineral content than that of milled rice. Its high dietary fiber and phytic acid may suppress mineral absorption.

Methods: Mineral availability, dietary fiber and its fermentability characteristics from milled, brown and optimized brown rice at 0-6 months were determined. Raw and cooked milled, brown and optimized brown rice e.g. Rc160, Rc216, PHB71 and SL8 were used in the study. Freeze-dried samples were analysed for proximate composition, dietary fiber, iron, zinc and calcium. Mineral availability and fermentability of dietary fiber were determined in vitro.

Results: Significant differences in mineral content and availability was observed from raw and cooked rice with raw>cooked (P<0.05). The mineral content and availability was not affected by time (0-6 months) except for SL8. All rice varieties have greater zinc content and availability from optimized brown rice than milled rice but not with brown rice. Similar results were obtained for iron and calcium and its availability for Rc216 and PHB71 (iron) and Rc216 (calcium). Dietary fiber and phytic acid of brown and optimized brown rice were significantly greater than that of milled rice and did not show inhibitory effect on mineral availability. The dietary fiber content of all rice samples were fermentable producing greater propionate that showed some protective effect for cholesterol synthesis.

Conclusions: Brown and optimized brown rice have significantly greater mineral content and availability than that of milled rice. All rice varieties were good sources of dietary fiber and produced short chain fatty acids after fermentation with greater propionate. Propionate may have a significant role in the prevention for risk of cardiovascular diseases. A nutrition intervention study is recommended to validate the promising health and nutritional benefits of brown rice varieties used in this study.

Key words: Dietary fiber, mineral, phytic acid

PO061**DOES CARDIOVASCULAR RISK EXISTS IN PREPUBERTAL CHILDREN WITH A HISTORY OF EXTRAUTERINE GROWTH RESTRICTION?**

M. Gil-Campos¹, M. Ortiz-Espejo¹, J. Olza², M C. Muñoz-Villanueva³, C M. Aguilera², J L. Perez-navero¹

¹Reina Sofia University Hospital, Córdoba, Spain

²University of Granada, Granada, Spain

³Maimonides Institute for Biomedical Research (IMIBIC), Córdoba, Spain

Background and objectives: Metabolic and inflammatory alterations have been reported in infants with intrauterine growth restriction. Nutritional deficit during perinatal stage may induce significant alterations in adipose tissue and increase the risk of metabolic syndrome and cardiovascular disease in children with a history of extrauterine growth restriction (EUGR). The aim of this study was to describe the nutritional status in neonatal and prepubertal with a history of EUGR, and to analyze anthropometric measurements, blood pressure (BP) and inflammation markers in prepubertal age to establish an association between EUGR and later risk conditions.

Methods: 38 prepubertal children born between 1996-2008 with a history of EUGR and a control group including 123 age- and-sex matched children were selected. Both groups were asked to answer a food frequency questionnaire and BP and anthropometric parameters were measured in both groups. Serum C-reactive protein (CRP) levels, plasma levels of hepatocyte growth factor (HGF), interleukin 6 (IL-6), interleukin 8 (IL-8), monocyte chemotactic protein type 1 (MCP1), neural growth factor (NGF), tumor necrosis factor alpha (TNF- α) and plasminogen activator inhibitor type 1 (PAI-1) were also quantified.

Results: At the prepubertal stage, daily fiber and fatty acid intake in EUGR group were below the recommended intake. This group presented shorter length and lower BMI, and higher BP values compared to controls ($P < 0,001$). Concentrations of inflammatory biomarkers CRP, HGF, IL-8, MCP1 and TNF- α ; were higher in the EUGR group as compared to control group ($P < 0,001$). After adjustment for gestational age, birth weight and length, BP and TNF α values remained higher in the EUGR children.

Conclusions: Appropriate nutrition education strategies should be developed for EUGR children to prevent later pathologies. Further investigation focused on these children is needed; this group may be in higher risk for inflammatory or cardiovascular diseases associated with this neonatal condition.

Key words: adipokines, inflammation, growth restriction

PO062**ASSOCIATIONS BETWEEN EATING MEALS, EATING MEALS WHILE WATCHING TV AND WEIGHT STATUS AMONG CHILDREN, 10-12 YEARS: THE ENERGY-CROSS SECTIONAL STUDY**

F N Vik¹, H B. Bjørnarå¹, N C. Øverby¹, N. Lien², O. Androustos³, L. Maes⁴, N. Jan⁵, E. Kovacs⁶, L A. Moreno⁷, A. Dössegger⁸, Y. Manios³, J. Brug⁹, E. Bere¹

⁹EMGO Institute for Health and Care Research and the department of Epidemiology and Biostatistics, VU University Medical Center, Amsterdam, the Netherlands

¹⁰Department of Pediatrics, University of Pécs, Hungary

Background and objectives: Recent research show that energy balance-related behaviors are relevant for obesity prevention among children. The aims of this study were to assess the association of eating meals as well as eating meals while watching TV with weight status among children, 10-12 years, across Europe.

Methods: 7915 children (mean age: 11.5 years) in 8 European countries (Belgium, Greece, Hungary, the Netherlands, Norway, Slovenia, Spain and Switzerland) completed a questionnaire at school. Data on meals eaten the day before questionnaire administration and the frequency of eating meals while watching TV were collected. Height and weight were objectively assessed. Multinomial and binary regression analyses were conducted to test associations of eating meals (adjusted for gender and ethnicity) and eating meals while watching TV (adjusted for gender, ethnicity and total TV time) with overweight/obesity, and to test for country- and socio-demographic differences.

Results: The proportions of children reporting eating breakfast, lunch and dinner were 85%, 96%, and 93% respectively, and 55%, 46% and 32% reported to never watch TV at breakfast, lunch and dinner respectively. The children who ate

breakfast (OR = 0.6 (95% CI 0.5-0.7)) and dinner (OR = 0.4 (95% CI 0.3-0.5)), had lower odds of being overweight compared to those who did not. The children who watched TV at lunch (OR = 1.3 (95% CI 1.2-1.5)) and dinner (OR = 1.3 (95% CI 1.1-1.5)) had higher odds of being overweight compared to those who did not watch TV at the respective meals.

Conclusions: The odds of being overweight was lower for children who ate breakfast and dinner compared to those who did not eat the respective meals. The odds of being overweight was higher for children who reported watching TV at lunch and dinner compared to those who did not.

Key words: children, obesity, meals, TV viewing

³Food Science and Technology Department, Universidad Autonoma de Madrid, Madrid, Spain

⁴Nutrition and Genomics Laboratory, Jean Mayer US Department of Agriculture Human Nutrition Research Center on Aging, Tufts University, Boston, MA, USA

Background and objectives: Genetic studies of population may represent a step forward in understanding the response to dairy foods, depending on genetic variations, with the aim of improving cardiovascular health. The aim of this study was to explore the role of genetic polymorphisms within lipid metabolism on change in cardiovascular risk biomarkers after consumption of skimmed or semi-skimmed milk in moderate cardiovascular risk volunteers.

Methods: This work is a part of a previous placebo-controlled and double-blind study in moderate CV risk volunteers (age range: 25-65 years). Subjects were randomly assigned into two groups: semi-skimmed milk and skimmed milk consumers as part of their usual diet. Blood samples were taken at 0 and 12 month to determine cardiovascular risk by TC/HDL and LDL/HDL ratios. Fourteen polymorphisms in nine genes related to lipid metabolism and inflammation were selected. Genomic DNA was isolated from total blood and genotyped

by Taqman OpenArray Genotyping Platform and the 7900HT Fast Real-Time PCR System. Interactions were tested with R statistical package through repeated measures analysis in dominant model.

Results: Subjects with TT variant for PPARA rs 135549 had decreased TC/HDL and LDL/HDL ratios [mean (95%CI)]: [-0.29 (-0.63 - 0.05) and -0.31 (-0.58 - -0.03)] after skimmed milk intake and increased after semi-skimmed milk intake [0.52 (0.19 - 0.86) and 0.47 (0.16 - 0.79)] (adjusted p value <0.05), whereas no differences were observed in C carriers.

Conclusions: Determining PPARA rs135549 genotype may be useful in identifying individuals who are most likely to benefit from skimmed milk consumption in the prevention of cardiovascular disease. These genotype differences might help to explain some of the discordant results in studies evaluating the effect of milk fat on cardiovascular risk.

Key words: PPARA, skimmed milk, cardiovascular risk, nutrigenetics

PO064

EFFECTS OF RESVERATROL ON OBESITY-RELATED INFLAMMATION IN ADIPOSE TISSUE OF OBESE ZUCKER RATS

S. Gomez-Zorita¹, A. Fernández-Quintela¹, E. Hijona², A. Lasa¹, L. Bujanda², M.P. Portillo¹

¹Department of Nutrition and Food Science, University of the Basque Country (UPV/EHU), Vitoria, Spain

²Department of Gastroenterology, University of the Basque Country (UPV/EHU), Biodonostia Institute, Hospital Donostia, Centro de Investigación Biomédica en Enfermedades Hepáticas (CIBERehd), San Sebastián, Spain

Background and objectives: Obesity increases the amount of pro-inflammatory cytokines produced either by adipocytes or by recruited macrophages. Consequently, obesity has been considered as a chronic low-grade inflammatory state. The aim of this study was to examine whether resveratrol could represent a promising molecule to reduce adipose tissue chronic inflammation in a model of genetic obesity.

Methods: Twenty fa/fa Zucker rats were assigned to two experimental groups and orally treated with resveratrol (15 mg/kg body weight/d) or saline (control group) for 6 weeks. Commercial kits were used for the assessment of serum cytokine concentrations and Nuclear Factor-KappaB (NF-κB) activation. Gene expressions were analyzed by RT-PCR.

Results: Resveratrol reduced internal adipose tissue weights (-15%). With the exception of interleukin 6, which remained unchanged, serum concentrations of the pro-inflammatory

markers were reduced: tumor necrosis factor α (-15%), monocyte chemoattractant protein 1 (MCP1) (-25%) and C-reactive protein (-7%). These effects were quite well mirrored by changes in adipokine gene expression in adipose tissue. This reduction in cytokine expression and production in adipose tissue might be due to a decrease in the number of macrophages, as suggested by the reduction in MCP1 expression, and to a direct effect of resveratrol on inflammatory pathways in both macrophages and adipocytes. The expressions of toll-like receptor 2 and toll-like receptor 4 were not modified, but the activity of the transcriptional factor NF- κ B was reduced ($P < 0.05$).

Conclusions: Resveratrol modulates plasma cytokine concentrations by reducing macrophage infiltration in adipose tissue and by reducing NF- κ B activity. Consequently, the use of resveratrol represents a promising new therapeutic approach to reducing the low-inflammatory state associated to obesity.

Key words: Resveratrol, adipose tissue, inflammation

PO065

GENETIC VARIANTS IN LIPID METABOLISM AND ASSOCIATION WITH CARDIOVASCULAR RISK IN THE CANTOBLANCO PLATFORM OF FOOD AND NUTRITIONAL GENOMICS (GENYAL)

U. Loria-Kohen¹, I. Espinosa-Salinas¹, S. Molina¹, J. Herranz¹, G. Reglero^{1,2}, J.M. Ordovas^{1,3}, A. Ramirez de Molina¹

¹IMDEA-Food Institute, CEI UAM+CSIC, Madrid, Spain

²Food Science and Technology Department, Universidad Autónoma de Madrid, Madrid, Spain

³Nutrition and Genomics Laboratory, Jean Mayer US Department of Agriculture Human Nutrition Research Center on Aging, Tufts University, Boston, MA, USA

Background and objectives: Cardiovascular disease is influenced by many environmental and genetic factors. The aim of this study was to determine the association between variants in candidate genes an increased cardiovascular risk (CVR) at GENYAL population.

Methods: Sixty-four polymorphisms (SNPs) in genes related to lipid metabolism, inflammation and oxidative stress were determined in 114 participants. Genomic DNA from each subject was isolated from total blood. Genetic variants were analyzed using Taqman OpenArray Genotyping Platform and the 7900HT Fast Real-Time PCR System. TC/HDL and LDL/HDL cholesterol ratios were determined as indicators of CVR. A logistic regression model was applied to estimate the OR and 95% CI, adjusted for: sex, age and waist circumference and Bonferroni was applied to correct for multiple testing.

Results: Among the GENYAL population 18.42% of the participants displayed greater CVR according to LDL/HDL ratio. 114 participants (29 men and 85 women), mean age: 37.5 ± 12.5 years and BMI: 24.22 ± 4.24 kg/m² were genotyped for lipid metabolism-related genes, finding that common homozygote variants for APOB rs10199768, rs512535, rs1367117 and rs520354 were associated with an increased OR (95%CI): 13.58 (1.57-117.61) $p = 0.020$; 30.2 (1.96-4838.85) $p = 0.020$; 53.53 (2.7-1059.89) $p = 0.013$; 8.38 (1.09-64.31) $p = 0.030$. In addition, heterozygote variant for PPAR α was associated with increased CVR OR (95%CI): 42.13 (5.09-1064.3) $p = 0.001$, association that was maintained after adjustment for multiple testing ($p = 0.019$). Thus, though ORs data shows a strong association of these polymorphisms with CVR, additional studies increasing the number of participants are still necessary for a more precise estimation.

Conclusions: Determination of genetic variants in APOB and PPARA might be useful for identifying young population with increased risk of cardiovascular disease. GENYAL Platform opened to research groups and enterprises, is a high-level tool for Nutrigenomics and Nutrigenetics studies within nutrition and health.

Key words: nutrigenetics, cardiovascular risk, lipid metabolism

PO066

APPETITE ASSESSMENT IN HEMODIALYSIS PATIENTS

G. Kiziltan¹, P. Türker¹

¹Baskent University, Health Science Faculty, Department of Nutrition and Dietetics, Ankara, Turkey

Background and objectives: Malnutrition is highly prevalent and strongly associated with higher mortality risk in the hemodialysis (HD) population. Poor appetite is an important barrier to adequate nutrition among hemodialysis patients and may be influenced by many factors. The present study aimed to assess appetite in HD patients and to define the factors associated with appetite.

Methods: The study was conducted on 102 hemodialysis patients (33 women, 69 men). Anthropometric measurements and some biochemical parameters were analyzed. Appetite was assessed by 8-item Council on Nutrition Appetite Questionnaire (CNAQ). Responses are scored by using a 5-point verbally labeled, likert-type scale. The total CNAQ score was the sum of scores on the 8 items, with lower scores indicating deterioration in appetite. Possible scores range from 8 (worst) to 40 (best). All data was evaluated by SPSS 13.0 for Windows.

Results: The mean age of the patients was 54.3 ± 15.81 years. The percentages of the patients who were underweight and

obese were 10.8% and 32.3%, respectively. The mean duration of chronic renal failure was 11.7 ± 7.53 years and the mean duration of undergoing hemodialysis was 113.2 ± 86.81 months. The mean CNAQ score was 27.4 ± 3.88 . There were no relationships between appetite and patient demographic (age, gender, education, health insurance) or medical (cause of renal failure, years on dialysis, number of co-morbid conditions, URR) characteristics. The mean appetite score was lower in patients with a BMI $< 18.5 \text{ kg/m}^2$ than the patients with a BMI between $18.5 - 24.9 \text{ kg/m}^2$ ($p < 0.05$). There were significant positive correlations between serum hemoglobin, albumin levels and appetite scores ($r = 0.220$, $p = 0.026$; $r = 0.265$, $p = 0.007$, respectively).

Conclusions: As a conclusion poor appetite is prevalent in hemodialysis patients. Many factors are related with appetite in these patients. Patients who report poor or very poor appetites should be monitored, and they should receive more comprehensive nutritional assessments.

Key words: Malnutrition, appetite, hemodialysis

CASEIN PHOSPHOPEPTIDES AND CALCIUM BIOAVAILABILITY: AN EXAMPLE OF FUNCTIONAL FOOD

S. Perego¹, E. Del Favero², P. de Luca¹, A. Fiorilli¹, L. Cantù², A. Ferraretto¹

¹Dipartimento di Scienze Biomediche per la Salute, University of Milan, Segrate, Italy

²Dipartimento di Biotecnologie Mediche e Medicina Traslationale, University of Milan, Segrate, Italy

Background and objectives: a prerequisite for a “functional food” is the retention or acquisition of a specific biological activity after the digestion process. Caseinphosphopeptides (CPPs), derived by casein proteolysis, have the ability to bind and maintain in solution calcium ions. In vitro studies using human intestinal cell models have demonstrated the involvement of CPPs in cell calcium uptake, depending on the formation of CPP-calcium aggregates and on the degree of differentiation of the intestinal cells. The present study has verified i) the persistence of the CPP-calcium aggregates ii) the maintenance of the ability by the CPP-calcium aggregates to induce intracellular calcium increase during and after the digestion process.

Methods: a calcium enriched CPP preparation of commercial origin was subjected to in vitro digestion by means of intestinal proteases and bile acids. The supramolecular structure of the CPP-calcium complexes was studied by laser-light and X-ray scattering. The bioactivity of the pre and post digested CPP-calcium complexes was analyzed monitoring the intracellular calcium increases in differentiated Caco2 cells (VideoImaging experiments using Fura-2).

Results: the supramolecular structure of the CPP-calcium aggregates is resistant to digestion, although a decrease in the size of the complexes was evidenced. The administration of the digested CPP in Caco2 cells gives rise to a higher percentage of cells that respond with an increase of intracellular calcium concentration than that due to the administration of not digested CPP ($p < 0.01$ t-student, ± 2 test). In these cells CPP interacts with TRPV6 channel, which is localized in the duodenum, where the transport of calcium is active, vitamin D-dependent and triggered by low quantities of the mineral.

Conclusions: These results show that digestion renders the CPP-calcium complexes more bioavailable for transcellular calcium absorption and claims for a recognized role of CPPs as functional foods.

Key words: caseinphosphopeptides, intestinal cells, calcium, in vitro digestion.

PO068

EXPERIMENTAL ASSESSMENT OF DIETS WITH VARIOUS LEVELS OF CALCIUM AND VITAMIN D

A. Korolev¹, E. Nikitenko¹, R. Fetisov¹, A. Istomin¹

¹Department of Human Ecology and Environmental Hygiene, I. M. Sechenov First Moscow State Medical University, Russia

Background and objectives: The solution of the alimentary calcium deficiency problem is connected with increase in bioefficiency of calcium in functional foods. This study aimed to assess and analyze the optimum level of enrichment of food calcium and vitamin D.

Methods: In work Wistar rats which were on diets with the various content of calcium and vitamin D were used: from deficiency to several physiological levels. Indicators of mineral balance were exposed to the analysis: the weight of tibiae, levels of calcium, phosphorus, zinc and alkaline phosphatase in serum of blood, calcium and zinc in urine. Safety of enrichment was estimated on dynamics malonic dialdehyde (MDA) in erythrocytes.

Results: The diets which have been at the same time enriched with calcium and vitamin D at the level of two physiological norms appeared the most optimum. The most essential increase in weight of a body, and also relative and absolute weight of tibiae, in comparison with control was thus noted. At the animals receiving diets with double norm of calcium and vitamin D it wasn't noted zinc losses with urine. At the same time the increased intake of calcium without parallel enrichment of a diet by vitamin D led to reliable increase - for 81,7% ($p < 0,05$) calcium losses with urine. At a combination of high level of vitamin D and low level of calcium in a diet were observed the increase: in activity of alkaline phosphatase on 124% ($p < 0,05$),

removal of zinc with urine on 180% ($p < 0,05$) and MDA in erythrocytes on 48% ($p < 0,05$) in comparison with control.

Conclusions: The ratio of double norm of calcium and vitamin D in a diet most effectively supports mineral balance, without leading to zinc and calcium losses with urine.

Key words: calcium, vitamin D, zinc, functional foods

PO069

THE INSULIN SENSITIVITY MARKER LEVELS IN NEONATES IS ASSOCIATED TO THEIR MOTHER'S FTO GENE POLYMORPHISMS

F. J. Sánchez-Muniz¹, E. Gesteiro², C. Ortega-Azorín³, S. Bastida¹, M. Guillen³, D. Corella³

¹Universidad Complutense de Madrid, Madrid, Spain

²Servicio de Análisis Clínicos, Hospital de Mérida, Spain

³Universidad de Valencia, Valencia, Spain

Background and objectives: Fat Mass and Obesity (FTO) gene shows very strong association with obesity and fat mass. To the best of our knowledge the influence of maternal FTO polymorphism on neonatal insulin sensitivity/resistance biomarkers has not been tested.

Methods: We analyzed the association between the common FTO rs9939609 polymorphism and neonatal anthropometrical measurements and hormone concentrations and insulin sensitivity at birth. Population. 63 at term, normal-weight Caucasian newborns from the Mérida cohort.

Results: 22 (34.9%) mothers were genotyped as TT, 32 (50.8%) as TA, and 9 (14.3%) as AA. 30% of neonates presented high insulinemia (>quartile 75 for insulinemia according to Gesteiro et al Eur J Ped 2009; 168: 281-288). Non-significant mother gene-influence was found for neonatal bodyweight, BMI or ponderal index. However, mother FTO gene polymorphisms were associated to significant differences in glucose, insulin, HOMA-IR (resistance), HOMA-IS (sensitivity) and glucose/insulin and insulin/cortisol ratio (all $p < 0.05$) at birth. Neonates whose mothers were AA carriers showed at birth lower glucose, insulin and HOMA-IR, but higher HOMA-IS than neonates whose mother were TT carriers. 90% of neonates presenting high insulinemia were delivered by mothers carrying the T allele, while only 10% in their AA mother homozygote counterparts.

Conclusions: These findings suggest that mother FTO polymorphisms affect neonatal glucose homeostasis. The lower insulin and the higher insulin sensitivity of neonates from the mother AA group, suggests that these neonates would develop obesity later in life, as it is known for small-for-gestational-age-

children, if they consume inadequate diets (e.g. rich in energy and/or SFA, non-Mediterranean profile).

Key words: FTO gene, neonates, insulin, HOMA, sensitivity/resistance markers.

⁴Departament de Bioquímica i Biotecnologia, IISPV, Universitat Rovira i Virgili, Reus, Spain

⁵Review, Study and Scientific Position Statement Group of the Spanish Association of Dietitians-Nutritionist, Barcelona, Spain

⁶Departament de Bioquímica i Biotecnologia, Hospital Universitari de Sant Joan, IISPV, Universitat Rovira i Virgili, Centro de Investigación Biomédica en Red Fisiopatología de la Obesidad y Nutrición (CIBEROBn). Instituto de Salud Carlos III, Reus, Spain

Background and objectives: Potentially, food labelling is a valuable tool to help consumers make informed decisions about their diet in order to improve health and prevent chronic diseases. Our objectives are to compare two models of front-of-pack GDAs in terms of a) consumer friendliness and acceptance, and b) the ability of the consumer to choose a diet closer to nutritional recommendations in adolescents.

Methods: A randomized crossover study was designed to compare two simplified front-of-pack GDA nutrition labels. Eighty-one healthy adolescents aged between 14 and 16 years were recruited. Participants were randomly exposed to two experimental non-real food-choice conditions using multiple traffic-light or monochrome nutritional labels. Participants had to choose options from a closed menu for five days on the basis of the experimental front-of-pack labelling. For each meal, three food options with different nutritional compositions were given to the participants. The total energy and fat, saturated fat, sugar and salt of the chosen options were calculated.

Results: There were no significant differences in baseline socio-demographic and anthropometric characteristics between individuals regardless of the experimental condition in which they started. There were no carryover effects between the experimental sequences. It was observed that when participants used the multiple traffic light system they chose significantly less total energy (-29.4 ± 50.4 kcal; $p < .001$), sugar (-4.5 ± 4.6 g; $p < .000$), fat (-2.1 ± 4.5 g; $p = .006$), saturated fat (-1.0 ± 1.9 g; $p = .002$) and salt (-0.4 ± 0.5 g; $p < .000$) than when they used the monochrome GDA system.

Conclusions: Compared to the monochrome GDA front-of-pack nutritional label, the multiple traffic-light system helped adolescents to differentiate between healthier and less healthy food, making it theoretically possible for them to choose a diet closer to dietary recommendations.

Key words: Front-of-pack food label, traffic-light, consumer preference, adolescent.

PO071

EFFECTS OF UNDERNUTRITION DURING DEVELOPMENT ON POST-DEPRIVATION FOOD INTAKE AND BODY WEIGHT ON WISTAR RATS

A. Zepeda-Salvador¹, A. López-Espinoza¹, R. Mancilla-González¹, A. Martínez¹, A. Cárdenas¹, A. Espinoza¹

¹Behavioral Feeding and Nutrition Research Center, CUSur-University of Guadalajara, México

Background and objectives: Experimental and epidemiological studies demonstrate the relationship between the organism development period and factors such as the environment, diseases, stress and maternal diet. These factors influence the intrauterine environment and have a relationship with changes on feeding behavior. Studies that examined malnutrition effect on feeding behavior and body weight reported an increase in water and food consumption per unit of body weight, retarded growth and a lower body weight even after a free access stage to food. This study determined the feed restriction effects during development on body weight and food intake of rats in a free access period following water and food deprivation.

Methods: Eighteen Wistar rats were exposed to one of three food restriction programs (50% relative to controls): pregnancy restriction, pregnancy and lactation restriction, and restriction from gestation to day 60 of age, another group was under open access to food and water condition throughout their life. On day 60 of age were deprived of food and water for 72 hours. At the end of the period of deprivation, water and food were available. Body weight and food consumption was recorded throughout the experiment.

Results: Results suggest that there aren't big post deprivation food consumptions. There was a small loss and a faster re-

covery of body weight in food-restricted groups. Furthermore, there was a greater impact of food restriction on males body weight.

Conclusions: Maternal food restriction duration is related to the loss and recovery of body weight and feed intake of pups.

Key words: Undernutrition, deprivation, food intake, body weight, rats

LOW BIRTH WEIGHT CHARACTERIZATION AND RELATED FACTORS, COLOMBIA 2004-2008

C. Roncancio Melgarejo¹, E. Quiroga Villalobos¹, E. Sischacá Ávila¹, V. Izquierdo Charry¹, F. Prieto Alvarado¹

¹Field Epidemiology Training Program Colombia

Background and objectives: Birth weight is an indicator of public health, gestational, fetal and neonatal conditions. Through vital statistics it is possible to analyze low birth weight and some related factors. The purpose was to describe the trend and association with variables of birth vital statistics and guide strategies to control.

Methods: Descriptive analytical study of births (Colombia 2004-2008). Records include birth weight defined as dependent variable. The association was studied by a multivariate binary logistic regression. Three categories of analysis were made: total, preterm and term cases. Birth weight was recategorized based on gestational age.

Results: National average of births 710,000; of those 90% born at term; 78% in urban areas. 66% were of mothers from 20 to 34 years. Between 73-81% of pregnant women attended +3 prenatal visits. Pregnancies were single (97%) and (42%) was the first child. Low birth weight increased from 7.3% to 8.8%; it was higher in premature (56%) and girls (9.6%), the 50% were in term births. Girls low birth weight could be attributed mainly whose mothers were <20 and >35 years old OR1.10 (IC1.08-1.13), who delivered by cesarean OR1.68 (IC1.64-1.61) and did not attend prenatal care OR1.32 (IC1.29-1.36). This same condition, although higher, was presented in children born at term. Women who gave birth to their first child, had greater risk. With birth weight adjusted by gestational age, the association increased in girls OR1.36 (IC1.33- 1.39).

Conclusions: Low birth weight has increased and is higher than national and international surveys. There was association with female, primiparous and attending +3 prenatal visits, being a teenage mother, living in rural area, being unmarried and having basic education level; when prematurity was controlled, sex, maternal age and education level showed better associations.

Key words: birth weight, vital statistics, live births, Colombia

PO073**ILSI PERSPECTIVE – ILSI EUROPE MARKER INITIATIVE: WHAT MAKES A MARKER A VALID MARKER?**

A. Chiodini^{1,2}, C. Matthys¹

¹University of LEUVEN, Departement of Endocrinology, Leuven, Belgium

²ILSI Europe, Brussels, Belgium

Background and objectives: Nutrition science seeks to understand how what we eat impacts our health. For various reasons, aspects of health often cannot be directly measured, therefore there is the need to seek criteria for the validation of markers, which can be anything that is measurable and 'marks' a health endpoint.

Methods: The first step of the activity was to review generic criteria markers validation. In parallel with this, experts in several health domains discussed and documented the empirical criteria used in their domain of nutrition research. Subsequently, a workshop in Lisbon in June 2012 sought to integrate these two approaches into one set of criteria by comparing the empirical reality with the current theoretical framework.

Results: The following criteria were identified during the workshop: -Analytics Method of measurement must be valid according to recognised guidelines. This may include robustness, analytical sensitivity, reproducibility, accuracy, quality assurance and standardization. -Marker must reflect a health endpoint a. There must be a statistically significant association between marker and health endpoint. This must be observed in a population representative where the marker is to be used. b. Across intervention studies on the impact on both the putative marker and the health endpoint it supposedly marks, one must see an association between the impacts on the marker and on the endpoint. The marker must change consistently with a change in the endpoint. This can be supported by observational human studies, and animal and in vitro studies. Additional mechanistic understanding of how the marker may reflect the endpoint should be also provided.

Conclusions: The next step of the activity will be to develop a system for grading and weighing the evidence for validity of markers. This system will be elaborated taking into account diverse areas in nutrition research.

Key words: Markers, criteria, nutrition, validation

PO074**CORRELATIONS BETWEEN BODY FAT AND BODY MASS INDEX IN AUSTRIAN CHILDREN**

V. Hasenegger¹, I. Elmadfa¹

¹Institute of Nutritional Sciences, University of Vienna, Vienna, Austria

Background and objectives: For the assessment of overweight and obesity in children measurement of BMI is recommended. Although there is evidence that BMI correlates with body fat, especially in childhood there are age-related variances, which are due to growth-related changes in the proportion of muscle and bone mass to fat mass. So the question arises: is the measurement of BMI alone an adequate indicator of body fat? We aimed to identify the correlation between body fat and BMI among Austrian children.

Methods: 188 girls and 198 boys aged between 7 and 14 years participated in the study. BMI was calculated from measured data of body height and body weight. Body fat (in %) was measured using bioelectrical impedance. For the definition of overweight and obesity the 90th and 97th BMI percentiles were used, for the classification of body fat standard values using the 90th percentile as a cut-off point.

Results: The prevalence of overweight and obesity calculated using BMI was 21.7% in girls and 26.1% in boys. While, 24.5% of the girls and 10.9% of the boys were found to be above the 90th percentile of body fat. Although the correlation between BMI and body fat was significant in both, girls ($\rho=0.793$; $p<0.001$) and boys ($\rho=0.682$; $p<0.001$), especially among boys there is a big discrepancy between these values.

Conclusions: The increase of BMI during adolescence in boys is mainly based on an increase in LBM whereas girls gain mainly body fat mass. In girls body fat contributes more than LBM to overweight. So it is useful to measure both, BMI and body fat, for the assessment of overweight and obesity.

Key words: body fat, bmi, children

PO075**EFFECT OF COOKING ON PHYSICAL PROPERTIES, SENSORY EVALUATION, ANTHOCYANINE, AND POLYPHENOLIC CONTENTS OF PIGMENTED RICE GRAINS**

L. Lotfy¹, G. Anis²

¹Department of Home Economics, Faculty of Specific Education, Kafrelsheikh University, 33516 Kafrelsheikh, Egypt

²Department of Plant breeding and genetics, Rice Research and Training Center (RRTC) 33717 Sakha, Kafrelsheikh, Egypt

Background and objectives: The economic value of rice depends on its cooking and processing quality. During cooking, rice was changed in physical properties and nutritional qualities. The objectives of this research were to study effects of three cooking methods on four pigmented rice grains as boiling, steaming and rice cooker.

Methods: Physical properties such as colour, amylose content, sensory attributes, total anthocyanine (TAC) and phenolic contents (TPC).

Results: Steaming cooked black rice (*Oryza sativa* L. indica) was the most darkness with L* value of 39.63, while black rice was the best lowest stickiness in all cooking methods as (5.31, 4.18 and 4.08 N) for boiling, steaming and rice cooker, respectively. Black rice (23.76%) which was classified as intermediate amylose rice (20-25%) before cooking kept intermediate after cooking by rice cooker as (21.56%). Waxy rice belonged to moist and sticky rice's after cooking as amylose content (7.24%). Steamed black rice was the most preferred appearance (8.59), black rice which cooked by rice cooker scored the highest accepted texture (8.04), while boiled black rice was the most accepted taste as (9.04). Steamed Egyptian jasmine white rice was the highest accepted aroma (8.69). Black rice contains the highest naturally occurring (TAC) as (235.68 - 290.78 mg/100 gm) after cooking. That indicated that cooking rice by steaming is the preference cooking method caused the lowest loses in (TAC). (TPC) differed significantly between the varieties. All methods of cooking rice caused a significant decrease in total polyphenols. Cooking rice by steaming also was the best way for decreasing loses of (TPC) for all rice varieties as (25.54, 47.61, 71.22 and 29.34 mg GAE/g), respectively.

Conclusions: Guides in using steaming which was found to provide the most desirable quality for rice cooking in terms of physical quality, sensory properties with enhanced antioxidants compounds.

Keywords: Pigmented-rice, cooking, amylose, anthocyanins, phenolics.

PO076**PROTEIN QUALITY OF HIBISCUS SABDARIFFA L. (ROSELLE) SEEDS CULTIVATED IN TWO AGRO ECOLOGICAL AREAS IN CAMEROON**

G. Maffo Tazoho¹, E. Agbor¹, I. Gouado²

¹Department of Biochemistry, Faculty of Science, University of Dschang, Cameroun

²Department of Biochemistry, Faculty of Science, University of Douala, Cameroon

Background and objectives: Protein malnutrition is real in most developing countries because of the low level animal protein intake. There is a need to diversify protein sources. Roselle seeds have been found to contain high protein value. This study investigated the bioavailability of three sets (raw, boiled, toasted) of Roselle proteins seeds.

Methods: Seeds were harvested in the North (area I) and West (area II) regions of Cameroon. Raw seeds were processed by sun-drying, boiled seeds were boiled for 50 min and toasted seeds were toasted for 7 min. 48 rats of 21 to 25 days were used and fed for fourteen days with 10% (w/w) protein from raw (RRSI, RRSII), boiled (BRSI, BRSII), and toasted (TRSI, TRSII) Roselle seeds of area I and II respectively where egg white was used as standard protein (S). The nitrogen balance parameters and transaminases were measured. Results were reported as mean \pm SD and statistical analysis was done using one way ANOVA and Bonferroni tests. A P value of less than .05 was considered statistically significant.

Results: Results show that crude protein content of boiled seeds was slightly high. There was significant difference ($P < 0.05$) in food intake of all groups of rats compared with S, except for BRSI and BRSII. The weight gained, protein efficiency ratio (PER), net protein ratio (NPR), growth rate (GR), efficiency of food utilization (EFU) and true digestibility (TD) of rats fed with boiled seeds diet were significantly higher ($P < 0.05$) than raw and toasted seeds diets.

Conclusions: These findings show that Roselle proteins seeds cultivated in Cameroon are bioavailable especially for boiled seeds. Proteins seeds quality is not influenced by the agroecological area. No toxic effect was observed as far as transaminases are concerned except for raw seeds which shown significant hepatotoxicity effect.

Key words: Roselle seeds, proteins, bioavailability, rats.

PO077**SAMBUCUS EBULUS FRUIT EXTRACTS REDUCE TNF α AND IL6 EXPRESSION ELEVATED IN ETHANOL-TREATED 3T3-L1 PREADIPOCYTES**

D. Ivanova¹, O. Tasinov¹, N. Nazifova¹, Y. Kiselova-Kaneva¹

¹Department of Biochemistry, Molecular Medicine and Nutrigenomics, Medical University Varna, Bulgaria

Background and objectives: It is well known that ethanol (EtOH) consumption is linked with development of many pathological conditions. Studies focused on EtOH effect find out that it can cause oxidative stress, inflammation and related diseases. *Sambucus ebulus* L. (SE, Dwarf elder) is a plant with fruits rich in polyphenol compounds including anthocyanins and phenolic acids, which explains its antioxidant and anti-inflammatory potential. In traditional medicine of the Balkans, Anatolia and Middle East it is applied for immunostimulation and treatment of inflammatory related disorders. Tumor necrosis factor alpha (TNF) and interleukin 6 (IL-6) are cytokines which elevated levels are involved in inflammation. This study aims to examine the effect of SE fruit ethyl acetate fraction (EAF) on TNF α and IL-6 gene expression in EtOH treated 3T3-L1 mouse preadipocytes.

Methods: 3T3-L1 cells were treated with SE EAF dissolved in EtOH and with EtOH as a control in different concentrations. Real Time quantitative polymerase chain reaction (RT qPCR) was performed to measure TNF α and IL-6 gene expression levels. Relative gene expression levels were calculated using 2- $\Delta\Delta$ Ct method. All measurements were performed in triplicates.

Results: EtOH treatment caused an elevation of TNF α and IL-6 gene expression in 3T3-L1 preadipocytes. In cells treated with SE EAF in EtOH, TNF α and IL-6 expression was lower. Concentration of SE EAF 0.02% w/v in the culture medium caused 64% ($p < 0.01$) lower expression of TNF α gene and concentration of SE EAF 0.01% w/v caused 71% ($p < 0.01$) lower expression of IL-6 gene, as compared to controls.

Conclusions: Results from this study testify for anti-inflammatory potential of SE fruit extract and suppose a possible therapeutic action in case of EtOH induced inflammation and related disorders.

Key words: *Sambucus ebulus*, ethanol, IL-6, TNF α , 3T3-L1

PO078**EFFECT OF HEMODIALYSIS AND PERITONEAL DIALYSIS ON MALNUTRITION, INFLAMMATION AND ATHEROSCLEROSIS (MIA) SYNDROME IN CHRONIC RENAL FAILURE PATIENTS**

H F. Tbahriti¹, D. Meknassi², Z. Chellouai³, R. Mousaoui³, A. Messaoudi³, A. Kaddous², M. Bouchenak¹, K. Mekki¹

¹Laboratoire de Nutrition Clinique Et Métabolique, Faculté Des Sciences, Université D'Oran, Algérie

²Service de Néphrologie, E.H.U d'Oran, Algérie

³Service de Biochimie, E.H.U d'Oran, Algérie

Background and objectives: Malnutrition, inflammation and atherosclerosis (MIA) syndrome are common in patients with chronic renal failure (CRF) and are associated with an increased risk of cardiovascular disease (CVD). The aim of this study was to compare MIA syndrome components in two dialysis modalities.

Methods: A cross-sectional study was carried out in 80 patients divided into 3 groups: moderate CRF ($n = 28$), hemodialysis (HD; $n = 40$) and peritoneal dialysis (PD; $n = 12$). Serum albumin was measured by standard techniques using an automatic analyzer (HumaStar 600). Pre-albumin and transferrin were measured by nephelometric immunoassay (MINI-NEPHTM human transferrin kit: ZK070.R). Tumor Necrosis Factor (TNF- α interleukin-1 β (IL-1 β interleukin-6 (IL-6) and C-reactive protein (CRP) were analyzed by assay kit (ELISA) (Cayman Chemical's ACETM EIA kit), tHcy was determined by fluorescence polarization immunoanalysis (HPLC, Perkin-Elmer 200 series).

Results: Compared to CRF and DP, we noted a significant decrease ($p < 0.001$) in serum transferrin (1.86 ± 0.39 g/l), albumin (41.40 ± 4.48 g/l) and pre-albumin (0.32 ± 0.11 g/l) concentrations in HD patients. Whereas, significant increase in TNF- α ($16, 38 \pm 5.52$ pg/ml), IL-1 β (9.63 ± 3.50 pg/ml), IL-6 (11.05 ± 3.59 pg/ml) and CRP (18.17 ± 6.38 mg/l) concentrations were noted in HD ($p < 0.001$). Similarly, a significant increase in tHcy was observed in HD and PD compared to CRF ($p < 0.001$), with mean values: (32.27 ± 12.08 μ mol/l) in HD, (28.37 ± 4.98 μ mol/l) in DP and (8.05 ± 2.43 μ mol/l) in CRF.

Conclusions: Renal replacement therapies have a strong effect on the increased concentration of homocysteine and cytokines, which leads to an increase in the spread of inflammation and risk of atherosclerosis leading to a decrease in appetite which explains malnutrition.

Key words: Pro-inflammatory cytokines, homocysteine, nutritional status, Renal replacement therapies.

PO079**COMPARISON OF COMPONENTS OF DIET OF MOTHERS WHO DELIVERED FULL-TERM BABIES, PRETERM BABIES, AND SMALL FOR GESTATIONAL AGE INFANTS**

R. Bobiński¹, M. Mikulska¹, H. Mojska², M. Simon³

¹Faculty of Health Science, University of Bielsko-Biala, Bielsko-Biala, Poland

²Chemical Safety of Food Laboratory, National Food and Nutrition Institute, Warsaw, Poland

³Department of Neonatology, Provincial Specialist Hospital, Tychy Poland

Background and objectives: Numerous studies have shown that an inadequate supply of certain dietary components in pregnant women's diets can lead to their children having health problems, both before and after birth. The aim of our study was to determine whether the dietary microelement and vitamin intake of mothers who gave birth to preterm, and full-term but small for gestational age neonates, differed from the diet of mothers whose children were born appropriate for gestational age.

Methods: The study population consisted of 103 women divided into three groups. Group A (n = 50): healthy mothers of full-term neonates. Group B (n = 30): mothers who gave birth prematurely – between 35-37 weeks. Group C (n = 23): mothers who gave birth to full-term but small for gestational age neonates. The women's eating habits and dietary composition were estimated based on the monthly dietary questionnaire designed by the National Food and Nutrition Institute in Warsaw, Poland.

Results: There were no statistical differences in levels of any of the studied vitamins between the three groups. Amongst the microelements studied, calcium was the only component which varied in level between groups. The difference in levels of calcium concerned mothers in groups A and B. The average daily calcium intake of mothers in group A was 1235 mg; 955 mg in group B, and 1022 mg in group C. The calcium intake of mothers in groups A and C represents an adequate calcium intake. The group B findings represent a lower than expected calcium intake.

Conclusions: The microelement and vitamin intake of mothers was similar across the three groups studied and were all found to be within the normal range. Calcium was the only dietary component which varied significantly in level between groups, being significantly lower in group B – mothers who gave birth prematurely.

Key words: Microelements, vitamins, pregnancy

PO080**DETERMINANTS OF SEVERE MALNUTRITION OF CHILDREN AND OBSTACLES OF ITS MANAGEMENT AT OUAGADOUGOU (BURKINA FASO)**

E W R. Compaore¹, O. Ouedraogo¹, P A. Nikiema¹, A E. Kousanta², A S. Traore¹

¹Department of Biochemistry-Microbiology, CRS-BAN, University of Ouagadougou, Ouagadougou, Burkina Faso

²Department of Biochemistry, University of Kara, Kara, Togo

Background and objectives: Children malnutrition is a public health problem in sub-Saharan Africa particularly in Burkina Faso where the mortality rate is always high compare to international recommendations. Poverty, difficulties to access health centers and ignorance are the main constraints for eradication of morbidity and mortality due to malnutrition. The general objective of this study is to describe the route followed by children during malnutrition management and know the different obstacles between admission and recovery. It help to detect probably causes of children malnutrition, types of interactions, eating behaviors and the family context associated to appearance and evolution of children illness.

Methods: A longitudinal study was carried out on 60 severely malnourished children aged 6 to 59 months admitted at nutritional and rehabilitation unit (CREN) of Centre Medical Saint Camille Ouagadougou. Weight, height/length, age and MUAC were taken for each child. A structured questions focused to socio economic, clinical, environment, health facilities and history parameters were been asked to parents or care givers.

Results: It appears that 80% of mothers did not have a job or access to a regular income. The duration of malnutrition is around 28 ± 6 days with an efficacy of 86,7%. Analysis by correlation indicated interaction between the economic situation of the family and the household food insecurity ($r = 0,257$; $p = 0,007$). There is a strong interaction between the status of the child in the siblings, maternal isolation, and the role of health facilities to the child ($r = 0,356$, $p = 0,000$).

Conclusions: These results indicated that a better knowledge of the social environment, food history, access to care and food, the purchasing power and the improvement of parents' education must be integrate into malnutrition management in order to alleviate high prevalence of malnutrition.

Key words: malnutrition, determinants, children, Burkina Faso

PO081**NOVEL STRATEGY FOR PREVENTING POSTPARTUM DEPRESSION**

Y. Dowlati^{1,2}, A. Ravindran^{1,2,3}, M. Steiner^{1,3,4}, J. Meyer^{1,2,3}

¹Institute of Medical Sciences, University of Toronto, Toronto, Ontario, Canada

²Research Imaging Centre, Centre for Addiction and Mental Health, Toronto, Ontario, Canada

³Department of Psychiatry, University of Toronto, Toronto, Ontario, Canada

⁴Department of Psychiatry and Behavioral Neurosciences, McMaster University, Hamilton, Ontario, Canada

Background and objectives: Postpartum depression (PPD) is the most common complication of childbearing with a 13% prevalence rate. Currently there are no routinely available

Methods of prevention besides antidepressant medication. Tyrosine, tryptophan and tryptophan containing proteins have potential for preventing PPD as they are precursors for the mood supporting neurochemicals serotonin, norepinephrine and dopamine. This is the first study investigating whether oral intake of tyrosine and tryptophan influences their concentrations in breast milk.

Methods: 48 healthy breastfeeding women were randomly assigned to one of 8 conditions. These were administration of single oral doses of 2, 5, and 10 grams of tyrosine, 2 and 4 grams of tryptophan, 20 and 40 grams of alpha-lactalbumin; or a control condition of no supplement. Five breast milk and 7 blood samples were obtained over the subsequent 8 hours. Free tyrosine and tryptophan was also measured in common infant formulas (12 formulas tested, n=6 samples per formula)

Results: There was no rise in total tyrosine and total tryptophan in breast milk with any dose (RM ANOVA: p=0.321, p=0.787 respectively). A significant rise in maternal plasma tyrosine and tryptophan occurred (p<0.005, p<0.005). There was a significant rise in free tyrosine and free tryptophan in breast milk in each group (p<0.005, p<0.005). Free tyrosine and tryptophan levels in breast milk were similar to the infant formulas.

Conclusions: Tyrosine, tryptophan and alpha-lactalbumin administration did not change total tyrosine and tryptophan and the free levels were within the range of what is observed in approved infant formulas. Also, free tyrosine is less than 1/200 of the total tyrosine in breast milk; and free tryptophan is less than 1/1000 of total tryptophan in breast milk. The negligible effect of these supplements upon breast milk creates further opportunity to develop this novel prevention strategy for PPD.

Key words: Postpartum Depression, Prophylaxis, Supplements

PO083**DOCOSAHEXAENOIC ACID INHIBITS TNF α -INDUCED ICAM-1 EXPRESSION VIA ATTENUATING EARLY GROWTH RESPONSE-1 EXPRESSION IN EA.HY926 CELLS**

H W. Chen¹, T W. Chia¹

¹China Medical University, China

Background and objectives: Tumor necrosis factor-alpha (TNF α), a potent inflammatory mediator, has multiple effects on the pathogenesis of atherosclerosis. Early growth response-1 (Egr-1), a zinc finger transcription factor, participates in cell growth and differentiation. Recently, Egr-1 has emerged as a key regulator in the development of atherosclerosis. Docosahexaenoic acid (DHA), an omega-3 fatty acid (n-3 FA), has potent anti-inflammatory effect. It is demonstrated that G protein-coupled receptor 120 (GPR120) functions as an n-3 FA receptor. In our previous study, we have demonstrated that DHA inhibits TNF α -induced intercellular adhesion molecule 1 (ICAM-1) expression via enhancing HO-1 expression. In this study, we try to identify the role of Egr-1 in DHA inhibition of TNF α -induced ICAM-1 expression in EA.hy926 cells.

Methods: In this study, we used EA.hy926 endothelial-like cells as cell model, and used Western blotting, real-time PCR, shRNA, and adhesion assay to explore the anti-inflammatory activity of DHA.

Results: TNF α markedly induces the phosphorylation of ERK1/2, p38 and Akt. Treatment with ERK inhibitor, PD98059, or PI3K inhibitor, LY294002, abolishes TNF α -induced Egr-1 expression; however, ICAM-1 expression is only blocked by PD98059. Transfection with shEgr-1 knocked down Egr-1 expression, and blocked TNF α -induced ICAM-1 expression. Transfection with shGPR120 knocked down GPR120 expression, and reversed the DHA-mediated inhibition of TNF α -induced ICAM-1 expression. In addition, TNF α -induced adhesion of HL-60 to EA.hy926 cells was abolished by PD98059 or SB203580.

Conclusions: Taken together, the anti-inflammatory effect of DHA is partially via GPR120, and followed by down-regulation of ERK-1/2-dependent Egr-1 and ICAM-1 expression.

Key words: DHA, Egr-1, ERK1/2, Inflammation, EA.hy926

PO085**CULTURAL INFLUENCES, VITAMIN D STATUS AND CARDIO-METABOLIC HEALTH IN EAST ASIAN ADULTS LIVING IN AUSTRALIA***S. Guo¹, R. Lucas¹*

¹National Centre For Epidemiology & Population Health, The Australian National University, Australia

Background and objectives: The East Asian population represents one of the most rapidly growing in Australia and is relatively young. Few studies have addressed the relationship between culture transition, vitamin D status and cardio-metabolic risks, despite a large influx of Asian migrants in the past decade. Objective: To investigate vitamin D status and markers of cardio-metabolic health in East Asian community-based individuals living in Canberra, Australia; and to explore the association between acculturation and cardio-metabolic risks.

Methods: The study group consisted of 100 East-Asian Australians (i.e. with a Chinese, Korean or Japanese ancestry) with age ranging from 20-80 years. Data were collected on a range of measures of sun exposure, physical activity and diet. Acculturation was measured using a short form of an acculturation rating scale for Asian migrants. Measurements of height and weight (to calculate body mass index), waist circumference and blood pressure were taken during a face-to-face interview. Serum 25-hydroxyvitamin D (25(OH)D) concentration and fasting blood glucose, lipids (triglyceride, high-density lipoprotein cholesterol, low density lipoprotein cholesterol and total cholesterol) and hsCRP were measured. Participants were categorized into three groups (Traditional, Bicultural, Acculturated) based on the acculturation score, using cluster analysis. Descriptive statistics were used to describe relevant health behaviours, serum 25(OH)D levels and concentrations of cardio-metabolic markers in each group. Ordinal logistic regression models were fitted to assess the association between acculturation level and vitamin D deficiency (<50nmol/L) using the traditional group as reference. Pearson's correlation was used to assess the correlation between Serum 25(OH)D level and each cardio-metabolic markers.

Results: Data collection for the Asian Australian Health Study is ongoing. Study results will be presented at the conference.

Conclusions: Our results will allow us to better understand the influence of culture on cardio-metabolic health in a multicultural community.

Key words: Acculturation, Vitamin D, East Asian, Cardio-metabolic health

PO086**A STUDY OF DEVELOPMENT THE SERVING SIZE OF FOOD AND NUTRIENT RICH INDEX IN TAIWAN***S.C. Hsu¹, Y.J. Chen², C.J. Huang²*

¹Department of Tourism and Hospitality Management, Kainan University, Taoyuan, Taiwan

²Department of Biochemical Science and Technology, National Taiwan University, Taipei, Taiwan

Background and objectives: According to the daily food guides, proper food intake means proper quantity and quality of food selected by energy density and nutrient density, but the standard of serving size for proper food intake is not established yet. The problem in practice is that the difference of definition and standard of serving size and nutrition facts between market commodities and the exchange list could make the consumer confused to choose proper food. Therefore, it is necessary to establish a convenient and unified standard of serving size and nutrition rich food index for the public to choose proper food and nutrients.

Methods: We used a Taiwan food nutrient database for 837 foods. The serving size was defined by the Taiwan new daily food guide, and we calculated the weight of 837 foods. The nutrient rich food 9.2 indexes (NRF9.2) was defined as the food values for 11 nutrients, based on serving size and 100 cal of food.

Results: Significant result of this study was found that the one serving size of rice and vegetables were 50 g and 100 g that defined by the food exchange list was different from the definition of the new daily food guide. The one serving size of rice and vegetables defined by the new daily food guide were 38 g and >100 g. On the other hand, we used a Taiwan food nutrient database for 837 foods, including 136 grains, 304 meats, 160 vegetables, 101 fruits, low fat dairy, and 71 fat and nuts. The NRF9.2 index defined as the serving size was different from that defined as 100 kcal.

Conclusions: The NRF9.2 index defined as the serving size could be readily expected to rank foods based on nutrient density.

Key words: diet, serving size, dietary behavior, nutrient density, nutrient profiling

PO087**ANTIOXIDANT STATUS OF ALLIUM SCHOENOPRASUM TISSUE CULTURE ORGANS**

D. Stajner¹, B. Popovic¹, A. Popovic¹, D. Calic², S. Zdravkovic-Korac²

¹Faculty of Agriculture, Novi Sad, Serbia

²Institute for Biological Research 'Siniša Stankovic', Novi Sad, Serbia

Background and objectives: This study was designed to examine *Allium schoenoprasum* tissue culture organs antioxidant and scavenging activity. Cultured plant cells synthesize, accumulate and sometimes exude many classes of metabolites. Medicinal compounds are of particular interest and much effort has been devoted to obtaining some of the most active and precious therapeutics. Numerous compounds which possess antioxidant activity have been reported from in vitro cultures.

Methods: This study reports the results on the root, stalk and leaf antioxidant enzyme activities (superoxide dismutase, catalase, guaiacol peroxidase and glutathione peroxidase), total phenol content, different radical (DPPH, NO[•], O₂^{•-} and HO[•]) scavenging capacities and also H₂O₂ scavenger capacity. In *Allium schoenoprasum* tissue culture organs the total antioxidant capacity was determined by the FRAP method.

Results: The present results indicated that the crude extract of *Allium schoenoprasum* tissue culture exhibited antioxidant and scavenging abilities in all investigated plant parts. Antioxidant enzyme activities and radical scavenging capacities (except NO[•]) showed the highest values in the roots and therefore the lowest lipid peroxidation. The highest values of NO[•] and H₂O₂ scavenging capacities were in the leaves. Therefore the leaves of *Allium schoenoprasum* tissue culture could be used as a source of natural antioxidants in the pharmaceutical, cosmetic and food industries for manufacturing un toxic products with potent medicinal and antioxidant activity.

Conclusions: Our investigation could be a starting point for further phytochemical investigations of *Allium schoenoprasum* tissue culture organs. The present results could be also beneficial for conventional herbalism and the possible future use of in vitro cultures as remedies.

Key words: antioxidant; *Allium schoenoprasum*; tissue culture; FRAP, DPPH

PO088**MATERNAL EMPLOYMENT AND NUTRITIONAL STATUS OF PRE-SCHOOL CHILDREN IN RESOURCE LIMITED SETTINGS OF OYO-STATE, NIGERIA**

A. Michael¹

¹The Federal Polytechnic, Bauchi, Nigeria

Background and objectives: Childhood nutrition is known to have a considerable impact on children's health. The objective of the present study is the relationship between maternal employment and nutritional status of pre-school children from resource limited settings in akunfo, a rural area located in iddo local government of oyo-state, Nigeria.

Methods: A total of 950 pre-school children were studied to assess anthropometric measurements of height, weight, mid-upper arm, head and chest circumferences for each pre-school child using standard procedures together with structured questionnaires which sought information on maternal daily working time, income, education and use of substitute care givers.

Results: The findings showed that maternal education and working time are the two most important intervening factors in the relationship of maternal employment to child's nutritional status in many of the variables considered. Variations in time mothers spent with their children daily were found to be significantly ($p < 0.05$) related with their occupational status. Using weight for age parameters, 27.8% had mild protein-energy malnutrition (pem), 20.1% were moderately malnourished and 12.8% were severely malnourished. The level of malnutrition was 41.2%, 24.8% and 14.8% for mild, moderate and severe respectively using height for age. However level of wasting was 28.3% for mild pem, while 16.6% and 10.6% for moderate and severe respectively.

Conclusions: Maternal education and working time are the two most important intervening factors in the relationship of maternal employment to child's nutritional status in many of the variables considered. Variations in time mothers spent with their children daily were found to be significantly ($p < 0.05$) related with their occupational status.

Key words: pem, nutritional status, maternal employment, resource limited settings, pre-school children.

PO089**ASSESSMENT OF DIETARY HABITS IN OBESE PATIENTS**

M. Domínguez-López¹, I. González-Molero¹, M. González-Marín¹, M. García¹, M.S. Ruiz de Adana¹

¹Endocrinology and Nutrition Service, Carlos Haya Hospital, Málaga, Spain

Background and objectives: A key factor in the progressive increase in the prevalence of obesity is poor dietary habits. Treatment of obesity with regular diets often fail, so knowing the specific habits of can be very useful to individualize treatment. We aimed to evaluate the dietary habits of subjects consulting for obesity.

Methods: We conducted a survey of eating habits for obese patients who consulted for this reason during previous two months.

Results: Data from 68 patients were collected. Mean age: 52.8 +/- 17.5 years, 34.4% males. 64.7% had diabetes, 50% were hypertensive and 58.8% dyslipidemic. Mean BMI at first visit was 39.77 +/- 5.45 and BMI at the time of the survey 37.62 +/- 7.24 (66.7% between 25 and 40 and 33.3% over 40). Mean weight: 112.0 +/- 24.36 kg initially vs 105.1 +/- 21.77 kg finally, with a mean follow-up of 2.5 +/- 2.1 years. 81,3% had received dietary advice by a dietitian. 28.5% of patients responded correctly to more than 75% of questions, 39,% between 50 and 75% and 32,1% responded adequately to less than 50%. Subjectively, patients thought their diet was poor, fair, good, very good and excellent in 3.6%, 53.6%, 32.1%, 10.7% and 0% respectively. There was a significant association between subjective scores and dietary questionnaire: subjects who responded appropriately to more than 75% felt their diet was poor, fair, good or very good in 0%, 25%, 50% and 25% of cases and subjects who responded correctly to less than 50% of questionnaire felt that their diet was poor in 11.1%, fair in 77.8% and good in 11,1% (p 0.007). Presence of adequate habits (over 75% correctly responses) was significantly associated with instruction by the dietitian (34.8% in instructed vs 0% in subjects not instructed, PO.047) but there was no association to any other features studied: BMI (22.2% in morbid vs 23.5% in no morbid), sex (35.3% in women vs 18.2% in men), age (31.6% in > 40 years vs 22.2% in < 40 years), diabetes (25% in diabetics vs 33.3% in non-diabetics), hypertension (35.7% vs 21.4%) or dyslipidemia (28.6% vs 28.6%).

Conclusions: Although dietary education improves eating habits of obese patients, a high percentage remain with inadequate dietetic costumes, which could be a key factor in the failure of obesity treatment.

Key words: obesity, dietary customs

PO090**ALIMENTATE SANO: AN INTERNET TOOL TO EVALUATE AND PROMOTE HEALTHY LIFESTYLES FOR PREVENTION OF CHRONIC DISEASES**

G. Echeverría¹, P. Jiménez¹, S. D'Acuntilde¹, I. Urquiaga¹, A. Rigotti¹, F. Leighton¹

¹Centro de Nutrición Molecular Y Enfermedades Crónicas, Pontificia Universidad Católica, Santiago de Chile, Chile

Background and objectives: Web-based programs offer good potential for health education. Aliméntate Sano (AS, www.alimentatesano.cl) is an internet tool developed in Spanish to promote and educate on healthy lifestyles -including Mediterranean Diet (MD)- as strategy to prevent chronic diseases in adult population (> 20 years old).

Methods: AS has two sections: 1) Education on healthy lifestyles (MD, physical activity and no-smoking) and chronic disease prevention; and 2) Fitbook: personal and private evaluation and follow-up of lifestyle and disease risk. Lifestyle was assessed through a MD Score (MDS, ranging from 0 (very-unhealthy diet) to 14 (very-healthy diet)) as well as questionnaires of physical activity (IPAQ short Spanish version), smoking, and resting and eating habits. Health condition was measured by self-reported metabolic syndrome (MS) components and body mass index (BMI). Based on evaluation, users received recommendations and periodical reminders to improve their lifestyle.

Results: After 2 years of operation, AS has over 55,000 users. Data from 30,000 Chileans who completed all their records were analyzed. 61% were women, 72% young adults (20-40 years old), and 80% had higher education. To reduce biases, lifestyle and health data were weighed by age and sex. In this sample, only 11% of Chilean adults eat healthy diet (MDS \geq 9), 46% have low physical activity and 37% smoke. With regard to health status, 65% show overweight or obesity and 25% have MS. Adults with bad lifestyle have 4-fold higher prevalence of MS than those with excellent lifestyle. Users who maintained at least one year adherence to AS, improved their diet from 6.0 to 6.9 in MDS (p value < 0.0001).

Conclusions: AS is a feasible approach for education and promotion of healthy lifestyles and it can improve dietary intake in users. Website-based strategies may have significant impact in chronic disease prevention.

Key words: Mediterranean diet, lifestyles, e-learning.

PO091**NUTRITIONAL FACTORS INFLUENCE BONE MICROARCHITECTURE DURING GROWTH. SHAHMORADI N, IULIANO-BURNS S, WANG XF, GHASEM-ZADEH A, ZEBAZE R, WANG Q AND SEEMAN E DEPTS OF ENDOCRINOLOGY AND MEDICINE**

N. Shahmoradi¹, E. seeman¹, S. Iuliano-Burns¹, X. Wang¹, A. ghasemzadeh¹, Q. wang, Z. roger¹

¹Endocrinology, Nutrition, Austin Health, University of Melbourne, Melbourne, Australia

Background and objectives: High resorptive modeling (not followed by formation at the same location) and remodeling activity excavate the medullary canal determining cortical thickness together with periosteal apposition during growth. At the ends of long bones, endochondral apposition and condensation of growth plate trabeculae form the metaphyseal cortex with varying degrees of porosity determined by the differing tempo of longitudinal and appositional growth. We hypothesized that a higher intake of calcium, vitamin D and protein during childhood are associated with attainment of a more robust appendicular skeleton; thicker and less porous cortices and a smaller medullary canal.

Methods: We measured tibial macro- and micro-architecture using high-resolution peripheral quantitative computed tomography (HR-pQCT). Dietary intakes: using 3-day weighed-food diaries.

Results: Cross-sectional study of 62 healthy boys and girls aged from 6 to 18 years (mean 11 years) of whom 53.2% were prepubertal, 27.4% peripubertal and 19.4% postpubertal. Intakes were calcium (803 mg, range 216 to 1623), vitamin D (2.89 ug, range 0.6 to 9.9) and protein (82 g, range 25.9 to 208). Results were expressed as mean, 95% confidence interval (CI). In a General Linear Model multivariate analysis, the effect size (ES) estimated from the partial beta² is greater between cortical volumetric bone mineral density (vBMD) and calcium intake (ES= 0.025%, 95% CI, -0.095 to 0.022) and vitamin D intake (ES= 0.054%, 95%CI, -18.5 to 0.72). Protein intakes explained the greatest effect size (ES= 0.054, 95 % CI, 0.107 to 3.206%) on total cross sectional area of the tibia compare to other bone macro- and microarchitecture results.

Conclusions: Two factors limit the power of this study, the small sample size and the range of nutritional intakes which may be above those defining 'insufficiency'. Within these constraints we infer that ensuring adequate protein intake may benefit the attainment of peak bone microstructure during growth.

Key words: HR-pQCT, modelling, remodelling

PO092**EVALUATION OF AVAILABLE ENERGY OF SEVERAL DIETARY FIBER MATERIALS BASED ON THE FERMENTABILITY FROM BREATH HYDROGEN EXCRETION IN HEALTHY SUBJECTS**

T. Oku¹, S. Nakamura¹

¹University of Nagasaki Siebold, Japan

Background and objectives: Dietary fiber is fermented readily or poorly by intestinal microbiota. Short-chain fatty acids, which are the product of fermentation, are utilized solely as the energy source of the host. However, the method used to evaluate the available energy (AE) of nondigestible and fermentable carbohydrates has not been established. The objective was to evaluate AE of major dietary fiber materials (DFMs) based on the fermentability from breath hydrogen excretion (BHE) in healthy subjects.

Methods: Fructooligosaccharide (FOS) which is not digested and fermented completely by intestinal microbes was a positive control. Experimental design: Within-subject, repeated measures design

Results: After DFM ingestion, end-expiratory gas (750-mL) was collected at 1-h intervals for 8 h, as well as 2-h intervals between 8 h and 14 h. After a sleeping, breath gas was collected 30 min after waking up and 24 h after DFM ingestion. Hydrogen concentration in breath gas was assessed with gas chromatograph. AE of DFMs tested was evaluated based on the area under the curve (AUC) of FOS. AE of polydextrose, partially hydrolysed guar gum, resistant maltodextrin and partially hydrolysed alginate was 1 kcal/g, and that of glucomannan, heat-moisture treatment and high amylose corn starch and cellulose was 0 kcal/g, based on the ratio of AUC for 8 h. However, AE of all tested materials was 1 kcal/g in the calculation based on AUCs for 14 h and 24 h.

Conclusions: We tried to evaluate AE of nondigestible and fermentable carbohydrates using the fermentability based on BHE for >14 h, and found that the collection period 8 h after ingestion of the test material is too short to evaluate AE. AE of tested dietary fiber materials including cellulose and glucomannan was 1 kcal/g, based on the fermentability from BHE for 14 h in healthy subjects.

Key words: fiber, expiratory gas

PO093**AN ASSESSMENT OF DIETARY FACTORS IN JAPANESE NON-ALCOHOLIC FATTY LIVER DISEASE PATIENTS AND THE RELATIONSHIP WITH BLOOD PARAMETERS**

H. Tatsumi¹, Y. Kobayashi¹, S. Wada¹, M. Kuwahata¹, Y. Sumida², Y. Kido¹

¹Graduate School of Life and Environmental Sciences, Kyoto Prefectural University, Kyoto, Japan

²Department of Molecular Gastroenterology and Hepatology, Kyoto Prefectural University of Medicine, Kyoto, Japan

Background and objectives: The number of non-alcoholic fatty liver disease (NAFLD) and steatohepatitis (NASH) patients have been increasing along with the increase in life-style related diseases throughout the world. However, little is known about the actual eating habits of NAFLD/NASH patients, especially in Japan. In this study, we assessed the dietary intake of Japanese NAFLD/NASH disease patients, and investigated the relationship between the dietary factors and blood parameters.

Methods: A cross-sectional study was conducted involving 91 Japanese NAFLD/NASH patients (42 males and 49 females, diagnosed by liver biopsy) aged 16-85 years over a 1-month period with a self-administered diet history questionnaire. Assessment of the dietary factors intake was performed using the Dietary Reference Intakes and National Nutrition Survey in Japan. The correlations between the dietary factors and the blood parameters were analyzed using a stepwise multiple regression analysis method.

Results: The results showed: (1) a high-level consumption of sugar and confectionery and a low intake of cereals and potatoes, (2) a low intake of vitamins, minerals, and dietary fiber, probably due to a low consumption of vegetables, mushrooms, and/or algae, (3) the hepatic dysfunction and dyslipidemia-related parameters showed a significant correlation with animal food intake, (4) HbA1c and the hepatic dysfunction-related parameters demonstrated a significant correlation with the intake of fat, vitamins, minerals, and dietary fiber, and (5) female subjects showed a high intake of fat as well as a significant positive correlation with HbA1c and the carbohydrate energy ratio.

Conclusions: This study showed that Japanese NAFLD/NASH patients were biased in the selection of high carbohydrate foods, with a high-level intake of fat and a low intake of vitamins, minerals, and dietary fiber. Moreover, the results suggested a relationship between the dietary factors and the development of disease in NAFLD/NASH patients.

Key words: NAFLD/NASH, Dietary reference intakes, Dietary habits, Japanese

PO094**IMMUNOCYTIC PROFILES AND RESPONSES OF HYPERURICEMIC RATS FED WITH CASEIN OR SOY PROTEIN COMBINED WITH PALM OR SAFFLOWER OIL**

H-C. Lo¹, Y. Yang²

¹Department of Nutritional Science, Fu Jen Catholic University, New Taipei City, Taiwan

²Division of Nephrology, Internal Medicine, Changhua Christian Hospital, Changhua, Taiwan

Background and objectives: Uric acid (UA) is one of the antioxidants in the plasma; however, the pro-oxidant and free radical features of UA may activate proinflammatory response. Previous study revealed that ingestion of soy protein with safflower oil may lower serum UA and ingestion of casein with safflower oil may attenuate hyperuricemia-associated renal damage. In this study we further investigated the effects of these protein and oil combinations on immunocytic profiles and responses in hyperuricemia.

Methods: Male Wistar rats administered with oxonic acid and UA to induce hyperuricemia were fed with casein or soy protein plus palm or safflower oil for 8 weeks. Normal rats fed with conventional diet composed of casein plus corn oil were included.

Results: Hyperuricemic rats had significantly decreased serum albumin and increased UA, leukocyte numbers, and spleen weights compared to normal rats (one-way ANOVA, $p < 0.05$). In hyperuricemic rats, casein was the factor to increase plasma interferon- γ , soy protein was the factor to increase B-splenocytes, palm oil was the factor to increase plasma nitrite/nitrate, and safflower oil was the factor to decrease plasma UA and to reverse changes in T-cytotoxic splenocytes and B-leukocyte (two-way ANOVA, $p < 0.05$). In peripheral blood leukocytes, spontaneous and Con A-stimulated decreases in interleukin-10 production were significantly reversed by the four different combinations and lipopolysaccharide-stimulated increases in interleukin-10 production were significantly decreased by the combination of soy protein and safflower oil in hyperuricemic rats. In splenocytes with and without Con A or lipopolysaccharide stimulations, soy protein with palm or safflower oils significantly decreased tumor necrosis factor- α and increased interleukin-10 productions in hyperuricemic rats.

Conclusions: These results suggest that ingestion of soy protein and safflower oil may alleviate hyperuricemia and splenocytic pro-inflammatory response and may elevate leukocytic and splenocytic Th2 responses in hyperuricemia.

Key words: hyperuricemia, immunocyte, cytokine, soy protein, safflower oil

PO095**CARDIOMETABOLIC RISK IN RELATION TO OBESITY GRADES AMONG EGYPTIAN SCHOOL STUDENTS**

S. El-Masry¹, N. Hassan¹, M. Abd El-moniem², M. Al-Tohamy¹

¹Biological Anthropology Dept., National Research Centre, El Cairo, Egypt

²Medical Biochemistry Departments, National Research Centre, El Cairo, Egypt

Background and objectives: Childhood obesity is a risk factor for developing cardio metabolic diseases in adulthood. Objective: Studying the association of cardio metabolic risk factors in students (7 - 16 years) with different obesity grades.

Methods: Cross-sectional study including 169 student: 72 obese [body mass index (BMI) > 95th percentile] and 97 extremely obese (BMI > 97th percentile) for age and gender based on Egyptian Growth Reference Charts. Interrelationships between risk factors prevalence: hypertension, high waist circumference (WC), impaired fasting glucose, hyperinsulinemia, insulin resistance, and dyslipidaemia (abnormal TC, LDL-C, HDL-C, and triglyceride), according to age groups and degree of obesity were assessed. A set of cardio metabolic risk factors were defined for each individual, ranging from 0 (no risk factors) to 9 (all risk factors).

Results: In younger age group (7 - 11 years), extremely obese students were proven to have higher frequencies of cardio metabolic risk factors in comparison to obese group, with highly significant differences regarding fasting glucose level and WC. Older students aged 12- 16 years recorded insignificant differences in the frequency of cardio metabolic risk factors between obese and extremely obese ones. For both age groups, elevated total and LDL-Cholesterol were significantly linked to disturbances of carbohydrate metabolism; indicated by fasting glucose level. Highly significant positive interrelationships between WC and triglycerides for children, and diastolic blood pressure for adolescents were detected. Among extremely obese students, 81% of younger and 60% of older had a cluster of at least three risk factors or more in comparison to only 56.7% and 48.7% of obese.

Conclusions: Cardio metabolic risk factors are associated with degree of obesity in young age (7-11 years), but not in those aged 12-16 years. Elevated triglycerides are the most common risk factors in both age groups.

Key words: Obesity; risk factors; children, adolescents.

PO096**ROLE OF SLOW DIGESTING CARBOHYDRATES DURING PREGNANCY FOR IMPROVING LEARNING AND MEMORY IN OFFSPRING OF OBESE RATS. (NIGOHEALTH STUDY)**

M.J. Martin¹, E. Oliveros¹, M. Manzano¹, J.M. Lopez-Pedrosa¹, R. Rueda¹

¹Discovery R&D, Abbott Nutrition, Granada, Spain

Background and objectives: Maternal obesity and accompanying obesogenic dietary intake prior to and throughout pregnancy and lactation program offspring physiological system predisposing to a high risk of developing metabolic syndrome and reduced cognitive performance later in life. We examined the effects of two mixtures of carbohydrates (CHO) consumed by pregnant rats, exposed to high fat diet, on cognitive abilities of the adult offspring.

Methods: Virgin rats were assigned to one of three experimental groups: control (C) dams fed a standard rodent diet before mating and throughout pregnancy; dams fed a high fat 6 weeks before mating and then fed a HF diet containing either CHO with high (HF/HC) or low (HF/LC) digestion rate throughout pregnancy. At delivery all the animals were fed with the standard rodent diet for the remainder of the study (13 weeks). Morris water maze and novel object recognition (NOR) were performed to test learning and memory.

Results: In both paradigms, HF/LC rats performed better than HF/HC rats and more similar to control rats. In water-maze, HF/LC rats learned quicker the location of the platform and 24h after last training trial, they were able to remember its location once removed, while HF/HC rats were not. Regarding NOR, both control and HF/LC rats differentiated between the novel and the familiar objects while HF/HC rats did not distinguish between them.

Conclusions: These data demonstrate that the selected CHO mixture is effective in improving cognitive abilities in the offspring later in life.

Key words: Early programming, adiposity, dietary carbohydrates, cognition.

PO097**ROLE OF SLOW DIGESTING CARBOHYDRATES DURING PREGNANCY FOR PREVENTING ADIPOSITY PROGRAMMING IN OFFSPRING OF OBESE RATS. (NIGOHEALTH STUDY)**

J M. Lopez-Pedrosa¹, M. Manzano¹, P. Bueno-Vargas¹, M.J. Martin¹, C. Ramirez Tortosa², R. Rueda¹

¹Discovery R&D, Abbott Nutrition, Granada, Spain

²Dpt of Pathology, Complejo Hospitalario de Jaen, Jaen, Spain

Background and objectives: Maternal obesity and accompanying obesogenic dietary intake prior to and throughout pregnancy and lactation program offspring physiological system predisposing to a high risk of developing metabolic syndrome later in life. We examined the effects of two mixtures of carbohydrates (CHO) consumed by pregnant rats, exposed to high fat diet, on body adiposity either in the pregnant mothers or in the offspring.

Methods: Virgin rats were assigned to one of three experimental groups: control (C) dams fed a standard rodent diet before mating and throughout pregnancy; dams fed a high fat 6 weeks before mating and then fed a HF diet containing either CHO with high (HF/HC) or low (HF/LC) digestion rate throughout pregnancy. At delivery all the animals were fed with the standard rodent diet for the remainder of the study (13 weeks). Body composition was analyzed longitudinally by using Magnetic Resonance Imaging technology. Plasma biochemical analysis was performed by using Pentra autoanalyzer.

Results: HF/HC dams had significant lower body weight gain compared to C and HF/LC dams. Litter size and sex ratios were not significantly different among the groups. Only HF/HC offspring had significantly higher fat mass accretion at adolescence than the C offspring group (t-test; $p < 0.05$). HF/HC offspring adiposity was paralleled to high levels of plasma glucose, leptin, triacylglycerides and cholesterol ($p < 0.05$). In contrast, HF/LC offspring exhibited similar adiposity than the C offspring group. Ingenuity pathway analysis associated obesity to HF/HC rats compared to C and HF/LC.

Conclusions: These data further reinforce the importance of maternal nutrition during this critical window of development and clearly show that altering the carbohydrate profile of maternal diet has the potential to influence metabolism in offspring preventing the susceptibility to adiposity-related complications later in life.

Key words: Early programming, adiposity, dietary carbohydrates

PO098**DEMISPAN MAY BE A BETTER INDICATOR OF NUTRITIONAL STATUS AMONG THE AGED IN THE GREATER ACCRA REGION**

R K D. Turkson¹

¹Dept. of Nutrition, National University of Lesotho, Lesotho

Background and objectives: Dietary intake and nutritional status are important determinants of health throughout the life cycle of human beings. Alterations in physiological structure and function that occur with age may be as a result of disease and disability as well as diet deficiency in nutrients intake. No study has been carried out on the nutritional status of the aged in Ghana and there was the need to fill in the knowledge gap. The objective of the study was to compare the nutritional status of the aged using demispan and body mass index and to determine the dietary patterns of the aged in the Greater Accra Region of Ghana.

Methods: A cross sectional study was carried out in 2006 using semi-structured questionnaire comprising socio-demographic characteristics, dietary patterns (food frequency questionnaire (FFQ) and 24 hour recall), and anthropometry.

Results: The analysis showed that 41% males and 59% females were deficient in energy intake while 53% of males and 57% of female respondents exceeded their requirement for protein. The FFQ and 24-hour recall showed that dietary pattern of the respondents was monotonous, mostly carbohydrate based. Nutritional status of the respondents was computed using body mass index (BMI) from height and weight and Demispan (from finger web to sternal notch). The BMI revealed that 28% males and 23% females were overweight, and 15% females were obese. The demispan also revealed that 72% males and 35% females were underweight, 6% males and 17% females were overweight and 18% females were morbidly obese. BMI and Demispan were significantly correlated ($r = 0.91$ and 0.75) for females and males respectively and majority of the respondents had negative energy balance.

Conclusions: Demispan was more effective in determining the nutritional status of the aged.

Key words: Demispan, Aged, Nutritional Status.

PO099**MEASURING FRUIT AND VEGETABLE CONSUMPTION – USE OF COMBINED OR SINGLE BIOMARKERS**

J. Woodside¹, L. Hamill¹, I. Young¹, M. McKinley¹

¹Queen's University Belfast, Northern Ireland, UK

Background and objectives: A high intake of fruits and vegetables (FV) is associated with reduced risk of chronic disease. Blood biomarkers offer an objective indicator of FV intake. A valid biomarker of overall FV intake would be able to confirm population intakes, more precisely evaluate the association between intakes and health outcomes and confirm compliance in FV interventions. Several substances have been proposed as biomarkers of FV intake: vitamin C, the carotenoids, and polyphenols. Certain biomarkers are strong predictors of single FV, however, proposed single biomarkers of FV consumption are only modestly predictive of overall FV consumption. A number of studies have suggested that summing individual urinary flavonoids correlates better with FV intake than individual flavonoid excretion. It may therefore be possible to combine potential biomarkers of FV intake and better predict intake with a combined biomarker approach rather than using single markers or a panel of single markers.

Methods: The FAVRIT study was an 8 week FV intervention study in mild hypertension. Participants were randomised to consume 1, 4 or 7 portions FV/d, and received weekly deliveries of FV. Compliance was encouraged during weekly phone calls from the research team. Participants (n=132) completed 7 day food diaries at baseline and week 8, while plasma vitamin C and serum carotenoid concentrations were assessed at the same time points.

Results: Change in vitamin C was most closely associated with change in self-reported FV intake ($r=0.29$; $p=0.006$), but when the changes in six carotenoids (lutein, zeaxanthin, β -cryptoxanthin, α -carotene, β -carotene and lycopene) were added to the model, the percentage of variation explained in self-reported FV intake increased from 8.4% to 36.6%, which represents a 4.4-fold increase.

Conclusions: Therefore this study shows that a combined biomarker approach may better predict FV consumption than single biomarkers.

Key words: fruit and vegetables; vitamin C; carotenoids; biomarkers

PO100**CONTRIBUTION OF NUCLEAR TECHNIQUES TO NUTRITION PROGRAMMES IN LATIN AMERICA**

Background and objectives: Over the past 15 years, the International Atomic Energy Agency, through its technical cooperation programme has supported 10 regional and 7 national projects in Latin America, to apply nuclear techniques in assessing aspects of the double burden of malnutrition.

Methods: Stable isotope techniques were used in eighteen countries to assess body composition, human milk intake, energy expenditure, micronutrient bioavailability and micronutrient status, *H.pylori* infection, and the health consequences of obesity. Traditional techniques such as dietary recall, anthropometry, bioelectrical impedance and anti-*H.pylori* antibodies were validated against isotopic techniques.

Results: Adequacy of intake, total energy expenditure and low levels of physical activity were identified. Energy requirements of children were measured. Prediction equations for body fat for school children and elderly, were generated and validated. Human milk intake by other Methods, appeared to be overestimated. No association between anaemia and *H.pylori* infection was identified. Body fat accretion in children was associated with parents' overweight, higher blood pressure, poor nutrition, inflammation, and glucose intolerance.

Conclusions: Stable isotope techniques have been used as reference Methods for validation of simpler methodology to be used in evaluation of nutritional interventions in Latin America.

Key words: isotopic techniques, nutrition, Latin America

PO101**POMEGRANATE EXTRACT SUPPLEMENTATION INFLUENCES BLOOD PRESSURE AND HOMA-IR IN HUMAN VOLUNTEERS: A 4-WEEK RANDOMISED, DOUBLE-BLIND, PLACEBO-CONTROLLED PILOT STUDY**

E. Al-Dujaili¹, A. Stockton¹, I. Davidson¹, S. Drummond¹

¹Dietetics, Nutrition & Biological Sciences, Queen Margaret University, Edinburgh, UK

Background and objectives: Interest in antioxidant polyphenol-rich pomegranate (*Punica granatum* L.) products has increased in recent years with growing reports of potential health benefits (Borges et al, 2010). Pomegranate polyphenols have been noted to lower systolic blood pressure (SBP) and insulin resistance in several trials involving participants who are hypertensive or normotensive volunteers (Carpenter et al, 2010; Tsang et al, 2012). The aim of this research was to investigate the effect of a new pomegranate extract (PomeGreat PurePlus) supplementation on blood pressure and insulin resistance (HOMA-IR) in human volunteers.

Methods: Ethical approval was granted by the Divisional Ethics Committee at Queen Margaret University. Volunteers (7 males and 22 females) participated in a randomised, double-blind, placebo-controlled parallel study (Mean BMI was $25.05 \pm 3.91 \text{ kg/m}^2$ ranged from 18.57 to 32.46 kg/m^2 ; Mean age was 34.5 ± 13.7 years (range 19-62). After randomization, participants consumed either one pomegranate extract or placebo capsule daily for 4 weeks. Each capsule weighed 1.2g and contained either 370mg of pomegranate extract or inert substance. Dietary history and anthropometric measures were also recorded to assess confounding factors. Fasting blood samples were obtained at baseline and after 4 weeks for glucose, insulin and insulin resistance assessment.

Results: The pomegranate extract group exhibited a significant decrease in SBP from 120.3 ± 13.3 to $115.6 \pm 13.1 \text{ mmHg}$ ($P=0.012$). Diastolic BP was slightly reduced but not significant ($p=0.192$). There was also a significant reduction in the HOMA-IR levels from 2.22 ± 2.6 to 1.61 ± 1.9 ($P=0.045$). For those receiving the placebo, no significant changes were recorded.

Conclusions: These results suggest that if pomegranate extract consumption in normotensive volunteers reduces blood pressure, it may ameliorate recognized cardiovascular risk factors in overweight and obese populations. The concurrent ability to decrease insulin resistance could be of benefit to those who suffer from type2 diabetes, metabolic syndrome or obesity.

Key words: Pomegranate; Blood pressure; Insulin resistance; Obesity; Polyphenols.

PO102**ROLE OF SLOW-DIGESTING CARBOHYDRATES DURING PREGNANCY FOR IMPROVING ADIPOSE TISSUE GLUCOSE TRANSPORT AND INSULIN SIGNALING IN OBESE RATS' OFFSPRING (NIGO-HEALTH STUDY)**

M.D. Girón², R. Salto², M. Manzano¹, J.D. Vilchez², E. Cabrera², P. Bueno¹, M.J. Martín¹, R. Rueda¹, J.M. López-Pedrosa¹

¹Discovery R&D, Abbott Nutrition, Granada, Spain

²Department of Biochemistry and Molecular Biology, School of Pharmacy, University of Granada, Spain

Background and objectives: Maternal obesity and accompanying obesogenic dietary intake prior to and throughout pregnancy and lactation program offspring physiological system predisposing to a high risk of developing metabolic syndrome later in life. We examined the effects of two mixtures of carbohydrates (CHO) consumed by pregnant rats, exposed to high fat diet, on adipose tissue glucose transporters and insulin signaling in offspring at weaning and adolescence.

Methods: Virgin rats were assigned to one of three experimental groups: control (C) dams fed a standard rodent diet before mating and throughout pregnancy; dams fed a high fat 6 weeks before mating and then fed a HF diet containing either CHO with high (HF/HC) or low (HF/LC) digestion rate throughout pregnancy. At delivery all the animals were fed with the standard rodent diet for the remainder of the study (13 weeks). Lysates from adipose tissue were used to analyze glucose transporters, insulin signaling and glycolytic and adipogenic enzymes by western blot.

Results: HF/LC offspring had significant higher GLUT4 and phosphorylated PKB/Akt than C and HF/HC groups at weaning. At adolescence, both remained higher in the HF/LC compared to HF/HC rats. Moreover, it is noticeable that HF/HC group had higher levels of adipogenic enzymes, such as pyruvate carboxylase, phosphoenolpyruvate carboxykinase and acetyl-CoA carboxylase, which is consistent with an increase in adipogenesis.

Conclusions: Data support the importance of CHO profile during pregnancy to modulate the glucose transport in the offspring. The high level of GLUT4 in slow digesting CHO rats may lead to increased sensibility to insulin. Even keeping an obesogenic diet during pregnancy, this CHO system given to the pregnant rat was able to reduce the expression of adipogenic enzymes in the adipose tissue of the offspring.

Key words: Early programming, adipose tissue, dietary carbohydrate.

PO103**BODY MASS INDEX AND ITS RELATIONSHIPS WITH VISCERAL AND SUBCUTANEOUS ADIPOSITY IN CUBAN CHILDREN AND ADOLESCENTS***M. Esquivel¹, C. González¹, M. Ruben²*

¹Department of Human Growth and Development. Julio Trigo López Medical School, Medical University of Havana, Cuba

²Center of Cybernetics Applied to Medicine, Medical University of Havana, Cuba

Background and objectives: The rising prevalence of obesity in children and adolescents is an important public health problem in both developed and developing countries; this situation has given a new urgency to understand the relations between body mass index -which is considered the most useful indicator of obesity in clinical practice - and visceral and subcutaneous adiposity, that have not been fully defined in these ages. We aimed to determine the associations of body mass index and visceral and subcutaneous adiposity indicators in this population.

Methods: Weight(W), height (H), waist circumference (WC) and triceps (TS), subscapular (SS) and suprailiac (SIS) skinfolds were measured in 4564 randomly sampled Havana children and adolescents aged 7,5 and 18,5 years. The associations between body mass index (BMI), visceral adiposity -using WC - and subcutaneous adiposity -using TS, SS, SIS and the sum of them (SUS) - were assessed through Pearson's correlation coefficients and linear regression. Receiver-operating characteristic analysis was employed to derive optimal age-adjusted sex-specific BMI thresholds for predicting high adiposity (> 90 percentil of WC and SUS).

Results: All anthropometric variables studied were positive and significantly correlated but the most striking result was the stronger association displayed of BMI with indicators of adiposity compared to the relations between WC and SUS. Age-specific cutoff BMI values in boys/girls to identify high visceral and subcutaneous adiposity were established. Mechanisms related with adipose tissue biology and fat distribution were explored.

Conclusions: Visceral fat plays a major role in the obesity assessment by BMI in this population whereas subcutaneous fat has a lesser role. Increasing understanding of the mechanisms involved in adiposity at these ages may potentially improve our ability to understand the role of excess weight and adiposity in health risks.

Key words: visceral fat, subcutaneous fat, BMI

PO104**GENETIC CHARACTERISTICS OF ANTIOXIDANT ENZYMATIC DEFENSE IN MEXICAN POPULATION WITH OVERWEIGHT AND OBESITY DEGREES I TO III***C. Hernández-Guerrero¹, A. Parra¹, N. Martínez¹, C. Trejo¹, M. Díaz¹, M. Iturbe¹*

¹Departamento de Salud, Universidad Iberoamericana Ciudad de México, México

Background and objectives: Oxidative stress is associated with obesity and their principal comorbidities. The Manganese Superóxido Dismutase (MSD) and the Glutathione Peroxidase (GPX) are important antioxidant enzymes. The gene of MSD has a single nucleotide polymorphism (SNP) at codon 16 (Ala16Val; rs4880) and the GPX has a SNP at codon 198 (Pro198Leu; rs1050450). In both cases the SNPs abrogate the activity of corresponding enzymes. The objective of the study was to evaluate the association of SOD-Ala16Val and GPX-Pro198Leu in Mexican population with normal weight, overweight and obesity.

Methods: An observational, transversal and comparative study was conducted with mestizo Mexican population at the Nutrition Clinic of the Universidad Iberoamericana Ciudad de México. The study included 50 participants with normal weight, 36 with overweight, 26 with obesity grade-I, 20 with grade-II and 23 with grade-III (OB-III). ADN was isolated from peripheral blood. The identification of SNPs was done by Polymerase Chain Reaction technique follows of Restriction Fragment Length Polymorphism technique using the Apa I enzyme to SOD-Ala16Val and Bsa WI to GPX-Pro198Leu. The results were analyzed by Xi square and a $p < 0.05$ was accepted as statistical difference.

Results: The frequencies of mutated alleles of MSD-Ala16Val and GPX-Pro198Val (homozygotes plus heterozygotes) were 0.34 and 0.48 in control (CG); 0.50 and 0.69 in overweight; 0.65 and 0.59 in obesity (OB) grades I-III groups, respectively. There were only statistical differences between CG and OB grades I-III ($\chi^2=10.1$; $p=0.001$; O/R=3.6; I.C. 95% 1.6-7.8) and between CG and OB-III ($\chi^2=6.6$; $p=0.009$; O/R=4.4; I.C. 95% 1.5-12.8) for SOD-Ala16Val.

Conclusions: Mexican people with obesity included in the study show higher frequency of SOD-Ala16Val mutated allele in comparison with persons with normal weight. People with morbid obesity (IMC>40) account the higher prevalence of before mentioned mutation between obesity group.

⁸Department of Public Health, Ghent University, Ghent, Belgium

⁹National Research Institute for Food and Nutrition, Roma, Italia

¹⁰Michigan State University, East Lansing, MI, USA

Background and objectives: The number of risk factors for insulin resistance increased in the last decade and Vitamin D emerged as pleiotropic regulator of many cells. We sought to identify the relevance of a complete set of risk factors for insulin resistance in adolescents from Europe and to consider their possible gender-specific associations.

Methods: The Healthy Lifestyle in Europe by Nutrition in Adolescence Cross-Sectional Study (HELENA-CSS) was conducted in European adolescents aged 12.5 to 17.5 years from nine countries. A total of 1053 participants with valid body mass index (BMI) homeostasis model assessment (HOMA) index data were included in the study. HOMA was used as marker of insulin resistance. Three markers of body fat were used based on anthropometric measurements. A dietary index was calculated and total energy intake estimated from questionnaire. C-reactive protein, leptin and vitamin D were assessed and physical activity, cardiorespiratory fitness and muscular stren-

gth were measured. Center, socioeconomic status, pubertal status and season were controlled.

Results: In males, leptin was the only risk factor for insulin resistance after adjusting for confounders including markers of body fat (Odds ratios; ORs from 1.49 to 1.60). In females, leptin, vitamin D, and cardiorespiratory fitness were the remaining independent risk factors for insulin resistance after adjustments (ORs 2.11, CI. 1.29 to 3.45; 0.50, CI. 0.31 to 0.80; and 0.54, CI. 0.33 to 0.87, respectively).

Conclusions: Our observations suggest a gender dimorphism in the identification of risk factors for high insulin resistance. Preventive strategies should focus, in addition to control leptin level, on improving modifiable factors such as cardiorespiratory fitness and ensuring vitamin D sufficiency. Randomized control trials are necessary to warrant their efficacy.

Key words: leptin, vitamin D, fitness, adolescence, insulin resistance.

PO106**FOCAL NUTRITION LEARNING CENTER: DOES THE USE OF LOCAL FOODS AND PRACTICES IMPACT CHILD MALNUTRITION? A CASE OF BURUNDI**

A. Madagasha¹, M. Loha², S. Sinamo Boltena², J. Mugenzi²

¹World Vision Burundi, Burundi

²World Vision International East Africa Region

Background and objectives: Chronic malnutrition is a serious public health problem in Burundi. Nationally 58% children are stunted and nearly 45% of them are anemic. To reduce the impact of malnutrition WV designed a community based nutrition program called, FARN (Foyer d'Apprentissage et de Réhabilitation Nutritionnelle - Nutrition Education and Rehabilitation Centers). The purpose of this study is to share the impact of local foods and practices to improve complementary feeding practice and child growth.

Methods: A critical nine steps were used to discovery (nutrition status, local foods, practices), mobilize the community, conduct 12 days nutrition education sessions and two weeks home follow up. Children were monitored for their growth in admission. Follow up weight was taken at 12 days and end of one month to check the graduation criteria. Background, anthropometric and attendance data were collected excel based software and analysis was conducted manually.

Results: between 2011-2012 2052 children, nearly half of them were between 6 - 23 months, participated. On 12 days 76% of children gained 200 gms and discharged from the sessions for home follow up. By the end of 30 days 78% of children had gained 400gms meeting the graduation criteria. The average weight gain of children was 373gms and 689gms on 12

and 30 days respectively. Based on the national classification of growth rate by the end of 30 days, 92.1% of children achieved accelerated growth, 6% achieved adequate growth and the rest, 1.9%, inadequate growth. Further analysis showed reduction in severe form of under nutrition by more than 50%. Care givers and parents observed change in nutrition status of the children.

Conclusions: use of appropriate nutrition promotion approach is essential for effective contribution of local foods in reducing the burden of malnutrition in resource poor settings.

Key words: weight gain, local foods and practices, FARN, graduation

PO107

PROJECT ENERGIZE: REDUCING CHILDHOOD OBESITY; TRANSLATION FROM A RANDOMISED CONTROLLED TRIAL TO AN EFFECTIVE REGIONAL HEALTH SERVICE

E. Rush¹, S. Mc Lennan²

¹Child Health Research, Auckland University of Technology, Auckland, New Zealand

²Active Living, Sport Waikato, Hamilton, New Zealand

Background and objectives: Globally, and in New Zealand, the prevalence of childhood obesity continues to rise. An urgent public health need is effective physical activity and nutrition interventions for children. In 62 control and 62 intervention primary schools a 2004-2006 randomised controlled trial (RCT) of the Energize through-school Programme demonstrated favourable changes in body size and the programme was rolled out as a health service to all 244 regional schools.

Methods: Effectiveness evaluation in 2011 included measures of height, weight, waist and run speed of 2665 7 year-old and 2589 10 year-old children (36% Māori, the indigenous people). An economic model was used to extrapolate the programme effects, initial costs, lifetime health treatment cost structures, quality-adjusted-life-years gained and increased life expectancy to the general and Māori child population of New Zealand.

Results: Adjusted for age, gender, ethnicity, socioeconomic status and school cluster effects, the 2011 children younger and older children had combined prevalence of obesity and overweight 31% and 15% lower compared with unEnergized children measured in the 2004-2006 RCT. Compared to children from another region the time to complete a 550 m run was quicker by 13.7% and 11.3% for younger and older children respectively. These effects were seen for boys and girls, both indigenous Māori and non-Māori children, and across socioeconomic status. In 2010 there were 42,067 children attending Energize schools and in the same year NZ\$1891175 was spent to deliver the programme; a cost of \$44.96/child/year.

Incremental cost/quality-adjusted-life-year gained was \$30438 for the younger and \$24690 for the older children, and lower for Māori (younger \$28241, older \$22151).

Conclusions: Project Energize may lead to a regional reduction in overweight and obesity prevalence and gains in physical fitness that may reduce the risk of obesity and Type 2 diabetes in later life.

Key words: children, obesity, prevention

PO108

THE THYROID HORMONE T3 IMPROVES ANTIOXIDANT CAPABILITY AND SURVIVAL OF HEPG2 DURING IN VITRO CULTURE

X. Tang^{1,2}, L.L. Chen^{1,2}, G.W. Le^{1,2}, Y.H. Shi^{1,2}, J. Sun^{1,2}, X.R. Chen^{1,2}

¹State Key Laboratory of Food Science and Technology, Jiangnan University, Wuxi, Jiangsu, China

²Institution of Food Nutrition and Functional Factor, School of Food Science and Technology, Jiangnan University, Wuxi, Jiangsu, China

Background and objectives: Thyroid hormone (T3) has a profound influence on normal development, differentiation and metabolism. However antioxidant properties of thyroid hormone is poorly understood. Aim of our study was to analyze whether T3 could have an antioxidant effect on cultured HepG2 cells undergoing oxidative stress

Methods: To develop a model of oxidative stress, human hepatoma HepG2 cells were incubated in serum-free DMEM with different concentrations of H₂O₂ (10 μ M, 50 μ M, 100 μ M and 200 μ M) for 4 h. Then, cellular reactive oxygen species (ROS) levels and cell proliferation were analyzed. In the antioxidant studies, cells were plated in 6- or 96-well plate, and after 24 h the thyroid hormone T3 or vehicle alone were added to culture medium; the cells were then exposed to H₂O₂ (100 μ M) for 4 h in the presence or absence of the thyroid hormone, T3 10⁻⁷M. Viable cells were harvested, and the cell proliferation, ROS level, glutathione (GSH) and glutathione disulphide (GSSG) content, malandialdehyde (MDA) level, superoxide dismutase (SOD) and catalase CAT activity were assayed with the appropriate test kits.

Results: H₂O₂ elevated the ROS production and reduced cell proliferation in a dose-dependent manner in the basal glucose condition. Preincubation with T3 (10⁻⁷M, 24 h) inhibit the 100 μ M H₂O₂-stimulated cell apoptosis. Moreover, T3 reduced the ROS and MDA generation induced by H₂O₂ via regulation of the GSH/GSSG ratio and enhancement of antioxidant enzymes SOD and CAT activity.

Conclusions: These findings indicates that T3 could be considered a antioxidant factor protecting HepG2 cells from oxidative damage. Acknowledgements: the present study was

supported by the 12th Five-Year Plan for Science and Technology Development (No. 2012BAD33B05)

Key words: thyroid hormones, T3, cell survival, antioxidant capacity, human HepG2 cell

PO109

ACCEPTABILITY AND EFFICACY OF READY-TO-USE THERAPEUTIC FOOD IN 6-24 MONTHS OLD CHILDREN WITH SEVERE ACUTE MALNUTRITION IN BANGLADESH

S. Huq¹, M.I. Hossain¹, M.M. Islam¹, T. Ahmed¹

¹Centre For Nutrition and Food Security, International Centre For Diarrhoeal Disease Research, Bangladesh (icddr,b)

Background and objectives: Severe acute malnutrition (SAM) defined as weight-for-height <-3Z-score or having bilateral-nutritional-edema is an important cause of childhood-death globally. Approximately 600,000 under-5 children in Bangladesh are suffering from SAM. Provision of energy- and nutrient-dense food is essential for successful management of SAM. Although ready-to-use-therapeutic-food (RUTF) has been found to be effective in Africa, but yet to be evaluated in South-East Asia, where the global burden of SAM is the highest. The current study was conducted to assess the comparative acceptability and efficacy of commercial RUTF (plumpy nut) and rice-lentils based traditional-diets (khichuri and halwa).

Methods: It was a randomized, unmasked, controlled clinical trial conducted during 2009-2012 in the Nutrition Rehabilitation Unit of icddr,b. 6 -24 mo old, 224 SAM children were randomly and in equal numbers were allocated to traditional diets or RUTF and managed according to the standardized protocol. Children were discharged upon achieving edema-free 15% weight gain from admission.

Results: The study children's age was 12±4.7mo, where half of them were female. Clinical and nutritional characteristics of the study participants did not differ between groups both at admission and discharge. Overall 82% children completed the treatment successfully. Median (IQR) rate of weight gain was 9.3 (7, 14) vs. 9.2 (6, 12) g/kg.bwt/d, and duration of hospital stay was 15 (11,19) vs 14 (11, 19) days, in RUTF and traditional diet groups and respectively. Water intake (527 ± 292 vs. 250 ± 87 ml/d;p<0.01) and diarrheal episodes were higher in RUTF group than traditional diets (45 (40%) vs. 21 (19%), p<0.01).

Conclusions: Traditional diets were more acceptable and efficacious as RUTF. Diarrheal episodes were more evident in RUTF group. Where cooking facilities are available rice-lentils based diets would be a better option for nutritional rehabilitation of SAM children in countries like Bangladesh.

Key words: Severe Acute Malnutrition, RUTF, khichuri, halwa.

PO110

NUTRITIONAL CONTRIBUTION OF STREET FOODS TO THE DIET OF PEOPLE IN DEVELOPING COUNTRIES

N. Steyn¹, Z. Mchiza², J. Hill², Y. Davids¹, I. Venter³, E. Hinrichsen³, M. Opperman⁴, J. Rumbelow⁵, P. Jacobs⁶

¹Population Health, Health Systems and Innovation, Human Sciences Research Council, South African

⁴Functional Foods Research Unit, Cape Peninsula University of Technology

⁵Centre for Science & Technology Innovation Indicators, Human Sciences Research Council

⁶Economic Performance and Development, Human Sciences Research Council

Background and objectives: Due to rapid urbanization in many developing countries, street foods (SFs) have become increasingly important as an income generating strategy and as a fast and economical meal option. There is however, a paucity of data on the nutritional contribution of SFs to the diet. The aim of this study was to review studies which had determined the nutritional value of street foods (SFs) and their contribution to the diet of consumers in developing countries.

Methods: The electronic databases of Pubmed/Medline, Web of Science, Proquest Health, and Science Direct were searched according to predetermined search criteria.

Results: From a total of 639 articles, 23 studies were retained since they met the inclusion criteria. In summary, daily energy intake (EI) from SFs in adults ranged from 13%EI to 50.3%EI and in children from 13%EI to 40%EI. Although the amounts differed from place to place, even at the lowest values of the percent energy range, energy contribution from SFs made a significant contribution to the diet. Furthermore, the majority of studies suggest that SFs contribute significantly to the daily intake of protein, often at 50% of the recommended dietary allowance (RDA). The data on fat and carbohydrate intakes are of some concern because of the assumed high contribution of SF to the total intake of fat, trans fats, salt and sugar in numerous studies and their possible role in the development of obesity and non-communicable diseases. Few studies have provided data on the intake of micronutrients, but these tended to be high for iron and vitamin A, but low for calcium and thiamin.

Conclusions: Street foods make a significant contribution to energy and protein intake of people in developing countries and their use should be encouraged if they are healthy traditional foods.

Key words: Street food; urbanization; dietary intake; macronutrients

PO111**INFLUENCE OF A COLD-PRESSED RAPESEED OIL ON SERUM LIPOPROTEINS IN RELATION TO 75G/A APO AI GENOTYPE- PRELIMINARY STUDY**

M. Włodarczyk¹, B. Jablonowska-Lietz¹, G. Nowicka², J. Tys³

¹Department of Nutrigenomics, National Food and Nutrition Institute, Warsaw, Poland

²Department of Pharmacogenomics, Medical University of Warsaw, Warsaw, Poland

³Department of Physical Properties of Plant Materials, Institute of Agrophysics Polish Academy of Science, Lublin, Poland

Background and objectives: Metabolic benefits of MUFA have been noticed, but relation between MUFA consumption, occurrence of specific genetic variants and serum lipoprotein levels has not been clarified. Influence of an adenine to guanine mutation in the promoter of the apolipoprotein AI gene (apoAI) on HDL levels has been reported. We investigated the effect of high-MUFA diet on lipoproteins in women with different 75G/A apoAI genotypes.

Methods: The study group consisted of 27 healthy, nonsmoking, premenopausal women aged 47±8 years, who replaced virgin oil in the diet with the cold-pressed rapeseed oil (RO) for 4 weeks (40g/day). The oil has been obtained from selected varieties and the patented technology of the production provided a maximum content of bioactive compounds (80% of oleic fatty acid; 1.2:1 n6/n3 ratio). Blood samples were collected at baseline and after 4 weeks of RO consumption. Serum lipids and apolipoproteins AI and B concentrations were analyzed and 75G/A apoAI polymorphism was performed by PCR with MspI enzyme.

Results: After 4 weeks of RO diet total cholesterol decreased by 9mg (4%) and LDL-cholesterol by 8mg (6%) in all participants. The effect of RO on HDL-cholesterol and apoAI concentration was analyzed in relation to 75G/A variants of apoAI gene. Among AA homozygotes (n=6) the strongest positive effect of MUFA diet was observed. The concentration of HDL-cholesterol increased by 5mg (9%) and apoAI by 11mg (8%) and was accompanied by a reduction in triglycerides (22mg-24%). No changes in these parameters were observed in GG homozygotes. The small number of participants may be a cause of non-significance of our results, and further study are needed to confirm our preliminary observations.

Conclusions: The present study indicates an interaction between 75G/A variants in apoAI gene and MUFA consumption and its influence on HDL-cholesterol and apoAI concentrations.

Key words: dyslipemia, cholesterol, genetics

PO112**THE EFFECT OF APPLE JUICE RICH IN CHLOROGENIC ACID ON MMP-9 SECRETION BY LPS-STIMULATED NEUTROPHILS- PRELIMINARY REPORT**

M. Włodarczyk¹, M. Czerwinska², M. Wrzosek³, M. Swieca⁴, G. Nowicka³

¹Department of Nutrigenomics, National Food and Nutrition Institute, Warsaw, Poland

²Department of Pharmacognosy and Molecular Basis of Phytotherapy, Medical University of Warsaw, Poland

³Department of Pharmacogenomics, Medical University of Warsaw, Poland

⁴Department of Biochemistry and Food Chemistry, University of Life Science, Lublin, Poland

Background and objectives: Dietary polyphenols are known to possess antioxidant and anti-inflammatory properties, and their protective effects on the cardiovascular system and cancer have been reported. Chlorogenic acid (CGA) has been found to be a main phenolic compound present in apples, coffee or pears. Matrix metalloproteinase (MMP) enzymes are released by inflammatory cells and smooth muscle cells and regulate the vascular remodeling process. MMP-9 has been shown to be involved in vascular elastin degradation, collagen remodeling, atherosclerosis plaque formation, and play an important role in pathogenesis of cardiovascular disease. The aim of the study was to evaluate the effect of lyophilized apple juice on the MMP-9 release by LPS-stimulated neutrophils in relation to chlorogenic acid as a positive control.

Methods: Neutrophils were isolated from venous blood of healthy adult volunteers by dextran sedimentation prior to hypotonic lysis of erythrocytes and to centrifugation in a Ficoll-Hypaque gradient. Cells were incubated with apple juice and CGA following the LPS-stimulation (100 ng/ml) for 24 h. The effect on MMP-9 production was measured using ELISA method.

Results: HPLC analyses of the commercially available cloudy apple juice used in this study revealed CGA as its main polyphenolic compound occurring at the concentration of 90.29 µg/ml. Pure CGA (10-100 µg/ml) was found to inhibit MMP-9 production by LPS-stimulated neutrophils dose-dependently. It inhibits the MMP-9 release by 30% at the concentration of 50 µg/ml. At the same concentration the apple juice rich in CGA inhibits MMP-9 release by 25%. However, no clear dose-dependent MMP-9 inhibition by apple juice was observed. Compared to stimulated neutrophils, in untreated cells after chlorogenic acid supplementation 50% decrease of MMP-9 production was found.

Conclusions: This study revealed that both pure CGA as well as apple juice rich in CGA inhibited MMP-9 production by neutrophils.

Key words: MMP-9, apple juice, LPS

PO113**URINARY VITAMIN C EXCRETION IN 24-HOUR URINE SAMPLE COLLECTIONS AS A COMPLIANCE BIOMARKER IN FRUIT AND VEGETABLE INTERVENTION STUDIES**

A. Mc Grath¹, L L. Hamill¹, G. Graham¹, S. Gilchrist¹, I S. Young¹, M C. McKinley¹, J V. Woodside¹

¹Centre For Public Health, Queen's University Belfast, Institute of Clinical Science B, Grosvenor Road, Belfast, Northern Ireland, UK

Background and objectives: Observational evidence consistently indicates rich fruit and vegetable (FV) diets may protect against non-communicable diseases. Progression of research on the FV-disease risk relationship is hindered by inaccuracies involved in traditional dietary intake assessment

Methods: Accurate, reliable, independent, objective nutritional biomarkers are therefore crucial to modern epidemiological research. Plasma vitamin C concentrations are widely used as indicators of fruit and vegetable (FV) intake, however little attention has focused on use of urinary vitamin C as a biomarker of FV intake. Thus, using data from a randomised FV intervention, we examined the use of 24-hour urinary vitamin C as a potential novel objective biomarker of compliance of participants in FV intervention studies. Subjects were aged 40-65 years and hypertensive (blood pressure of 140-179/90-109mmHg). Following a one portion FV/day four-week run-in-period, participants were randomised to 1,3 or 6 portions FV/day for eight-weeks. Fasting plasma and 24-hour urine samples were collected at the start and end of the intervention. Vitamin C was measured using a fluorimetric method on an automated Cobas Fara centrifugal analyser.

Results: A total of 117 subjects completed the 12-week study. Across the intervention groups plasma vitamin C increased, but plateaued between 3 and 6 portions/d, and the test for linear trend across the groups did not reach statistical significance ($p=0.06$). In contrast, urinary vitamin C concentration significantly increased with increasing FV consumption (comparison between 1, 3 and 6 portions/day groups (p -value for linear trend <0.001)).

Conclusions: Urinary vitamin C (24 h) increased linearly with increasing FV consumption, in contrast to plateauing plasma vitamin C concentration. This suggests 24-hour urinary vitamin C is a potential non-invasive biomarker of compliance in FV interventions.

Key words: Urinary vitamin C, biomarker, fruit, vegetables, novel

PO114**LEVEL OF ADHERENCE TO A MEDITERRANEAN DIET AND RELATIONSHIP WITH COGNITIVE FUNCTION IN AN AUSTRALIAN SAMPLE**

K. Murphy¹, G. Crichton¹, J. Bryan^{1,2}, J. Hodgson³

¹Nutritional Physiology Research Centre, University of South Australia, Adelaide, South Australia, Australia

²School of Psychology, Social Work and Social Policy, University of South Australia, Adelaide, South Australia, Australia

³School of Medicine and Pharmacology, Royal Perth Hospital, University of Western Australia, Perth, Western Australia, Australia

Background and objectives: A Mediterranean diet (MedDiet) is reported to reduce mortality, reduce cognitive decline and Alzheimer's disease. In a cross-sectional study with 1183 Australians, aged 40-65 years, we calculated the level of adherence to a MedDiet, determined the major foods characteristic of a MedDiet and subsequently examined relationships with MedDiet adherence and self-reported cognitive function and psychological well-being.

Methods: Mean intakes of foods typical of a MedDiet and typical of an Australian diet were calculated from a validated food frequency questionnaire. Adherence to a MedDiet was determined based on an 11-point scale, 11 being maximal adherence to a MedDiet. Measures of cognitive function and psychological well-being included self-esteem, anxiety, stress, memory functioning, cognitive failures, general health and physical function. MedDiet scores were divided into tertiles to define level of MedDiet adherence. Relationships between MedDiet adherence, intakes of food groups representative of a MedDiet and cognitive function were examined using standard linear regression controlling for confounders.

Results: 20% (8-11 points), 72% (4-7 points) and 8% (0-3 points) of the Australian sample had a high, medium and low adherence to a MedDiet, respectively. Intakes of total plant foods (fruit, vegetables, nuts, legumes), dairy products and breads/cereals was 6.3 ± 2.9 , 1.0 ± 0.9 and 5.2 ± 2.5 servings per day, respectively, while meat, fish and poultry was 0.1 ± 0.1 , 0.2 ± 0.3 and 0.1 ± 0.2 servings per day, respectively. Overall MedDiet adherence was not related to cognitive function, however intakes of plant foods was positively associated with measures of physical function ($P=0.021$) and general health ($P<0.001$), and negatively associated with depression ($P=0.012$), perceived stress ($P=0.016$) and trait anxiety ($P=0.015$).

Conclusions: A substantial proportion of the diet in this Australian sample came from foods uncharacteristic of a MedDiet resulting in medium adherence, which is a major limitation when attempting to compare adherence to a MedDiet across populations.

Key words: Mediterranean diet, adherence, cognition

PO115**THE ASSOCIATION BETWEEN SIRT1 GENE AND KOREAN CHILDREN OBESITY: SEOUL-KURO COHORT STUDY***S.L. Choi¹, S.M. Kim², M. Lee^{1,3}*

¹Department of Food and Nutrition, Sungshin Womens University, Seoul, Republic of Korea,

²Department of Family Medicine, School of Medicine, Korea University Guro Hospital, Seoul, Republic of Korea

³Research Institute of Obesity Sciences, Sungshin Womens University, Seoul, Republic of Korea

Background and objectives: Sirtuin 1 (SIRT1) is the longevity gene protected cells against oxidative and genotoxic stress. The association of SIRT1 polymorphism with Korean childhood obesity is not reported. The purposes of this study are confirming whether SIRT1(rs7895833) would be related to the children obesity and reducing the prevalence of adult obesity based on 3 years of the follow-up study.

Methods: The subjects were 3rd grade elementary school students 491 (boy: 246, girl: 245) at 2007 and we measured anthropometries, blood chemistry and dietary intakes. The 6th grade students on 2010, the obesity risk factors were re-examined. 219 (boy: 101, girl: 118) subjects were followed and the follow-up rate was 44.24%.

Results: Anthropometric parameters increased, however, biochemical and nutrient intake decreased after 3 years. Most of children, 88% of normal children and the 85% of obese children, kept their BMI for 3 years. That means it was hard to change BMI in children because of many environmental reasons. However, it was focused that 15% of normal children became obese. The relative frequencies of GG wild type, GA heterozygote and AA mutant type of SIRT1 were 57.1%, 38.8%, and 4.1%. In obese girl, the number of GA/AA variants were significantly higher than that in normal (64.0% vs 38.7%, respectively, $P < 0.05$). Although the energy and cholesterol intakes were remarkably higher in the GG type than in GA/AA types, children with GG tend to decrease BMI and WC. Moreover, the more carbohydrate intakes, the less plasma TG and HOMA-IR was shown in obese girls with GG in particular.

Conclusions: SIRT1 polymorphism was associated with obesity in Korean children. GG wild type might protect hypertriglyceridemia and insulin resistance in obese children

Key words: SIRT1, children obesity, cohort study

This study supported by Mid-career Researcher Program through NRF grant (MEST2010-0000147), Korea Food & Drug Administration in 2011(11162KFDA154, 11162KFDA162), and Korea Food Research Institute.

PO116**EVALUATION OF POLYPHENOLS AND ANTIOXIDANT ACTIVITY OF COFFEE AND COFFEE BEVERAGES***G. Kroyer¹, M. Zakaria¹*

¹Institute of Chemical Engineering, University of Technology, Vienna, Austria

Background and objectives: Coffee is one of the most popular beverages. Beside caffeine as bioactive ingredient other nutritional-physiological active compounds may contribute to the valuable properties of coffee beverages. Coffee has been identified as a rich source of polyphenols which are well-known for their antioxidant properties and health benefits. Green and roasted coffee beans from different origins (*Coffea Arabica* from Nicaragua, Brazil and Ethiopia and *Coffea Robusta* from Ecuador) as well as coffee beverages prepared by commonly used procedures as espresso and filter coffee were analyzed in regard to their content of polyphenols and their antioxidant properties.

Methods: Total polyphenols were determined using the Folin-Ciocalteu assay. Antioxidant activities were determined with the DPPH* radical scavenging method as well as with the ABTS-radical assay in terms of their Trolox Equivalent Antioxidant Capacity TEAC.

Results: In the different coffee beans and coffee beverages the content of total polyphenols was determined in the range of 39,6 to 55,8 mg/g with the highest amounts in Robusta coffee from Ecuador followed by the Arabicas in the order Ethiopia, Nicaragua and Brazil. The same trend was observed with the corresponding coffee beverages with higher amounts in espresso (32,6 - 39,7 mg/g) than in filter coffee (26,4 - 29,2 mg/g). All the coffee beans and coffee beverages possessed high antioxidant capacity in the same order and in correlation to the content of polyphenol compounds with TEAC-values of 0,15 - 0,41 mmol TE/g.

Conclusions: In conclusion the highest antioxidant activity was observed in Robusta from Ecuador, green coffee beans showed higher antioxidant activity than roasted coffee beans and espresso better radical scavenging capacity than filter coffee. The results of this study indicate that coffee beverages have high antioxidant and radical scavenging properties in correlation with the content of polyphenols and are a good source of dietary antioxidants.

Key words: coffee, polyphenols, antioxidant activity

PO117**INFLUENCE OF MATERNAL ALIMENTATION ON OUTCOME OF PREGNANCY AT CONSTANTINE (ALGERIA)**

D.J. Touati-Mecheri¹, H. Oulamara¹, S. Rebbouh¹, F. Rebbouh¹, A. Agli¹, G. Potier de Courcy²

¹Nutritional Department, INATAA, University Constantine1, Algeria

²UMR U557 Inserm/ U 1125 Inra/ Cnam/ Paris 13, France

Background and objectives: Pregnancy and its outcome events are sensitive to environmental exposure. To characterise the impact of food intakes of pregnant women in the child's weight at birth and to examine whether an association exists between the quality of these inputs and pregnancy outcome.

Methods: The epidemiological investigation and descriptive focused on the monitoring of 808 pregnant women living at Constantine, revised journals, childbirth, anthropometric data, inputs food and nutrition (estimated by the tables of FAO) have been collected. The socioeconomic status (SES) was assessed according three category such lower, medium, high. The association between variables was studied by analysis of variance.

Results: The mean age of parturients was 30.4 ± 5.6 years, Body Mass Index (BMI) before pregnancy of 24.9 ± 3.3 kg/m². The term is 39.6 ± 1.6 weeks, the birth weight of 3264 ± 494 g. The SES is low in almost one third of women. The mean energy intake (1584 ± 495 kcal), is relatively low compared with the recommendations but the balance between carbohydrates (64.9% of TEI), protein (14.8%) and lipids (20.3%) is satisfactory. The newborn's (NB) weight is positively related to maternal age ($p = 0.007$), with its initial weight ($p = 0.006$) and its protein intake ($p = 0.03$) only in those with low SES. Our study was to demonstrate that children normotrophes, in term babies of normal weight, this was correlated with the degree of SES and dietary protein intake, which, without being unbalanced or insufficient, has a slight deficit in relation to living conditions.

Conclusions: According to the literature, our analysis highlights the relationship of the child's weight at birth with age, weight and size of the mother. In group NB normotrophes, weight was correlated with the degree of SES, and dietary protein intake.

Key words: Pregnancy, nutrition, SES, birthweight, Constantine

PO118**GLOBAL ACUTE MALNUTRITION (WASTING) IN UGANDA WHAT'S WORKING; WHAT'S FAILING?**

H. Namusoke¹, J. Kamugisha¹, E. Babirekere¹, E. Kiboneka¹

¹Mwanamugimu Nutrition Unit, Mulago National Referral Hospital, Kampala, Uganda

Background and objectives: 2011 Uganda Demographic and Health Survey (UDHS) reports declining childhood malnutrition; stunting, from percentage (%) 39, 38 to 33 in 2001, 2006 and 2011 respectively. Underweight dropped from 23, 16 to 14, while wasting remains stagnant; 4, through 6 to 5. We present the magnitude of complicated wasting, sharing what is making success possible and what is failing the expertise at the national nutrition rehabilitation unit, Mwanamugimu.

Methods: In-depth analysis of reports on the number admitted and performance indicators through the years (2009 to 2012).

Results: Each year, we register higher numbers of the malnourished. Having treated a total of 5211 wasted and complicated malnourished children, annual admissions rose from 1053, 1165, 1455 to 1538 for the period 2009 to 2012 in that order. There is also an exaggerated admission between April to August; a trend that is failing treatment and rehabilitation, to an extent. In that period, there are aggravated cases of malnutrition, often resulting in more deaths than is seen in any other months; a trend that is failing the existing expertise. However on a whole, there is improved average cure rate (%) recorded annually; in that, 58.9, 59.2, 69.9 and 68.3 were cured that period. There are many efforts, not limited to the new approaches, including the integrated management of acute malnutrition (IMAM), in identifying and treating the malnourished. This could be a major reason for the rise in accessing services; in addition to improved performance.

Conclusions: UDHS reports declining malnutrition, but the unit records show otherwise, a problem most felt between April and August; and often failing expertise at the clinic. Even when IMAM may have made treatment possible, thus improving performance, there are still unacceptable levels of deaths during peak.

Key words: Wasting, Uganda

PO119**THE IMPACT OF A SORGHUM BASED COMMERCIAL PRODUCT ON NUTRITIONAL STATUS OF CHILDREN**

J. Kearney¹, W. Oldewage-Theron¹

¹Hospitality, Tourism & PR Management Department, Vaal University of Technology, Vanderbijlpark, Gauteng, South Africa

Background and objectives: The objective of this paper was to determine the cost of a commercial sorghum based product as well as the impact on the nutritional status of primary school children in an informal urban settlement in Southern Gauteng in South Africa.

Methods: The randomly selected sample consisted of 82 (commercial product) and 60 (control group) primary school children aged 6 to 13 residing in the informal settlement. The measuring instruments included a QFFQ, 24-hour dietary recall, as well as anthropometric and biochemical measurements. Statistical analyses included descriptive statistics [mean and standard deviation (SD)], and independent t-tests to determine statistical significance within and between the two groups.

Results: Pre-intervention results for nutrient intake in both groups indicated that the mean daily energy intake of all the children was below the DRIs for children between ages 7 to 10 years. The post intervention results indicated that the food consumption patterns did not change substantially during the intervention. The anthropometric results for severely underweight children decreased from 10,4% to 7,8% after intervention. The children at risk of being underweight in this group decreased significantly from 39% to 24,7%, and the normal group increased from 37,7% to 51,9%. The results for both vitamins A and E showed an increase from 594,1 µg to 630,1 µg and 5,0 mg to 5,6 mg respectively. The biochemical results indicated that normal values were present for the majority of the parameters

Conclusions: The commercial sorghum based product evaluated in this study proved to be cost effective, and had a positive effect on the nutritional status of the primary school children, thus indicating that these products can be successfully implemented in a school feeding programme for hungry children in this specific community.

Key words: nutrition, school feeding, primary school children

PO120**IMPLICATION OF SELENIUM IN THE METABOLIC SYNDROME PROGRAMMING**

R M. Rúa¹, P. Muñoz del Valle¹, M L. Ojeda¹, F. Nogales¹, M L. Murillo¹, O. Carreras¹

¹Department of Physiology, University of Seville, Spain

Background and objectives: there is evidence that the nutritional status of mother during pregnancy can impact on progeny metabolism and health. Metabolic syndrome is a new epidemic in developed countries. Selenium is an essential mineral as forms part of 25 selenoproteins with biological properties; the most known one is the antioxidant family: Glutathione Peroxidase (GPx). In this context, some authors defend that Se is increased in metabolic syndrome patients, and that it could alter insulin resistance by the action of GPx in the liver. The aim of this study is to elucidate if a diet rich in fructose provided to dams, induces metabolic syndrome in the progeny, and if these alterations are related to Se levels and GPx activity in liver.

Methods: two groups of pregnant rats were used, one with a diet rich in fructose in order to develop a metabolic syndrome model, and other with normal diet as control. Some risk factors related to metabolic syndrome were measured, such as body mass index (BMI), liver somatic index, thoracic circumference, abdominal circumference, and serum levels of triglycerides, cholesterol and glucose. Selenium in milk and in liver was measured by graphite-furnace atomic absorption spectrometry. Liver GPx activity was estimated by spectrophotometry. All the determinations were analyzed in rats of 21 days old.

Results: the induced metabolic syndrome in dams causes an increase in all the risk factors measured in offspring. Despite that Se in milk was similar in both groups; Se levels and GPx activity in liver were increased in pups from treated dams.

Conclusions: dams with metabolic syndrome make the pups suffer the same symptoms. In this context, we have proved that Se is related with this metabolic disorder, probably increasing insulin resistance via GPx activity.

Key words: selenium, progeny, diet rich in fructose, metabolic syndrome, Glutathione Peroxidase

PO121**EXCESS WEIGHT AT ANY AGE AFTER BIRTH IS ASSOCIATED WITH OBESITY IN MID-CHILDHOOD: THERE ARE NO CRITICAL PERIODS***C. Corvalán¹, J. Kain¹, M. Martínez¹*¹INTA, University of Chile, Chile

Background and objectives: In Chile, childhood obesity has tripled over the last decades; presently 23% of 6-y olds are obese. It has been suggested that there are critical periods for the acquisition of obesity. Objective: to determine in which periods between birth and 7 y, the incidence and/or prevalence of overweight is associated with general and central obesity at 7 y.

Methods: We have been following a cohort of 1100 low-income children from 0-7 y (GOCS cohort). We defined 5 periods: 0, 0-6, 6-24, 24-48, 48-72; the study sample (N=628) was restricted to children with anthropometric measurements in all periods. We calculated BMI, overweight (BMI 1-2 Z) and obesity (BMI > 2 Z) using WHO references 2006/2007. We calculated incidence and prevalence of overweight in each period by sex and determined the OR (95% CI) of general and central obesity (waist circumference > 75th percentile) at 7 y according to these proportions.

Results: At 7y, 20% of the children presented general obesity while 33% had central obesity. In both sexes, most of the incidence of excess weight concentrated before 24 months (i.e. ~20% 6-24 months vs. 8.0 % 48-72 months). In all the periods, incidence of overweight was not associated with increased risk of general or central obesity (i.e. girls overweight incidence 6-24 months OR= 0.93 (0.51-1.70 for obesity at 7y). Conversely, being overweight from as early as 6 months was associated with twice the risk of being obese at 7y (boys overweight prevalence 6-24 months OR=2.26 (1.30-3.92). For central obesity, an increased risk was only observed for the 48-72 period (boys overweight prevalence 48-72 months OR=2.57 (1.53-4.31).

Conclusions: our results do not support that there are critical periods for the development of obesity in mid-childhood; obesity prevention should start the first year of life.

Key words: children, obesity, critical periods

PO122**EFFECTS OF THE UNSAPONIABLE FRACTION OF POMACE OLIVE OIL ON THE COMPOSITION OF POSTPRANDIAL TRIACYLGLYCEROL-RICH LIPOPROTEINS***J. Sanchez Perona¹, F. Rivas García², M J. Aguilar³, J L. Prada³, A. del Arco³, V. Ruiz-Gutierrez¹*¹Instituto de la Grasa (CSIC), Sevilla, Spain²Ayuntamiento de Guadix, Granada, Spain³HHUU, Costa del Sol, Marbella, Spain,

Background and objectives: Alterations in lipid metabolism is one of the side effects of HAART. Pomace olive oil (POO) is obtained by chemical processes from the residues of the mechanical extraction of virgin olive oil. There are nutritional differences between POO and other olive oils. The objective of this study is to show how POO intake affects the postprandial concentration of triacylglycerol, cholesterol, apolipoproteins and fat soluble vitamins in the serum and triacylglycerol-rich lipoproteins (TRL) of HIV patients on HAART.

Methods: 13 HIV-infected male volunteers Costa del Sol Hospital in Marbella (Málaga), aged 40.7 ± 5.0 on HAART received two meals rich in refined olive oil (ROO) or POO. Blood was collected in fasting conditions and after the intake of the meals. TRL were isolated and triacylglycerols, cholesterol were determined using commercial kits, vitamins were analyzed by HPLC and apolipoproteins by electrophoresis.

Results: In serum, after ingestion of POO, triacylglycerol and α -tocopherol were higher in the postprandial period. Retinol concentration decreased. In TRL, POO intake caused a decrease in apo B, apo C- II and apo E compared to ROO.

Conclusions: The actions of POO show a potential beneficial effect in reducing HIV lipid disorders.

Key words: HAART; Pomace Olive Oil; Triacylglycerol-rich lipoproteins

PO123**LOW BIRTH WEIGHT RATES HIGHER AMONG BANGLADESHI NEONATES MEASURED DURING ACTIVE BIRTH SURVEILLANCE COMPARED TO NATIONAL SURVEY DATA***R. Klemm¹, R. Merrill¹, L. Wu¹, AA. Shamim², H. Ali², A. Labrique¹, P. Christian¹, K. West, Jr¹*¹Johns Hopkins University, Baltimore, USA²JiVitA Project, Gaibanda, Bangladesh

Background and objectives: Birth size is an important gauge of fetal and neonatal health. Accurate birth size measure-

ments are challenging to collect in settings such as rural Bangladesh where a majority of births occur in the home.

Methods: Birth size measurements were collected at home within 72 hours of life for a cohort of live born, singleton infants (n=16,290) who participated in maternal and newborn vitamin A trial in rural northwest Bangladesh. Gestational age was calculated based on date of initiation of the last menstrual period collected in early pregnancy. Newborns were classified as small for gestational age (SGA) based on a birth weight below the 10th percentile for gestational age, using three sets of US reference data. Birth size distributions were explored based on raw values as well as after z score standardization in reference to WHO 2006 growth standards.

Results: Mean (SD) birth weight (gm), length (cm), and head circumference (cm) measurements, completed within (median (25th, 75th percentile)) 15 (8, 23) hours of life, were 2,433 (425), 46.4 (2.4), and 32.4 (1.6), respectively. Twenty-two percent were born preterm. Over one half (55.3%) of infants were born low birth weight; 46.6%, 37.0% and 33.6% had a weight-, length- and head circumference below -2 Z-scores of the WHO growth standard at birth; and 70.9%, 72.2% and 59.8% were SGA for weight based Alexander (1996), Oken (2003) and Olsen (2010) references, respectively.

Conclusions: Infants in this typical rural Bangladesh setting were commonly born small reflecting a high burden of fetal growth restriction and preterm birth. Our findings, produced by active birth surveillance, suggest that low birth weight is far more common than suggested by cross sectional, survey estimates. Interventions which improve fetal growth during pregnancy may have the largest impact on reducing SGA rates.

Key words: low-birth-weight, small-for-gestational-age, preterm, pregnancy

PO124

SCOTTISH DIETITIANS KNOWLEDGE AND PRACTICE OF OBESITY AND WEIGHT MANAGEMENT; INFLUENCE OF CLINICAL GUIDELINES.

C. Hankey¹, J. Gries¹, M. Lean¹, W. Leslie¹

¹University of Glasgow, Glasgow, UK

Background and objectives: Dietitians, leading practitioners and educators in the management of obesity must remain abreast of developments and be aware of recommendations of national clinical guidelines. This study examined knowledge, attitudes and opinions on obesity and weight management after publication of two obesity specific guidelines.

Methods: Census of dietitians with British Dietetic Association membership resident in Scotland in 1998 and 2012. Individuals were invited to complete a questionnaire to determine knowledge and current dietetic practice in obesity and weight

management in 1998 (paper) and 2012 (on-line). Comparisons were made between surveys, and reported practice compared with guidelines.

Results: Response rate for the 2012 survey was lower than in 1998 (30% vs. 72%). A majority of dietitians showed clear understanding of links between obesity and health, though deficits in knowledge persisted. More 2012 respondents vs. 1998 thought people with diabetes should not eat fruit (10% vs. <1%), and that starchy foods were fattening (10% vs. <1%). A higher proportion of respondents (10% in 2012 vs. 2% in 1998) failed to recognise the influence of obesity on cancer risk. Twenty-six percent incorrectly reported that a daily energy intake of 3347-5020 kJ would fail to produce weight loss: 46% believed this to be possible in 1998. Reported readership of key clinical guidelines was lower in 2012 (64% vs. 96%).

Conclusions: Different response rates limit interpretation of these findings. While most dietitians have some knowledge about weight management and obesity, a greater proportion of respondents in 2012 seemed to lack knowledge regarding obesity and links between obesity and health. Knowledge deficits suggest that clinical guideline recommendations cannot be implemented by all dietitians. Training and education is essential to ensure clear and consistent advice to patients and other health professionals.

Key words: dietetic; obesity management; clinical guidelines

PO125

IS THE RISK OF POVERTY A DETERMINANT OF IMPAIRED NUTRITION IN ITALY?

M. Baldini¹, A. Bordoni¹, F. Pasqui², G. Picone¹, F. Capozzi¹

¹Department of Food Sciences and Technologies, University of Bologna, Italy

²Department of Medicine and Chirurgic, Polo Murri, Sant'Orsola, Bologna, Italy

Background and objectives: Low income people have been reported to be at high risk of developing diet-related diseases. Population at risk of poverty (ROP) consumes unbalanced diets resulting in the presence of malnutrition; furthermore, in Italy social determinants have major influence on health outcomes, and access to preventive services [1]. Data on nutrient intake in ROP groups are very fragmentary. The aim of this study, carried out within the 7FP EU Project CHANCHE, was to identify food consumption patterns and nutritional criticalities in Italian ROP women.

Methods: 300 Italian women aged 24-65y were recruited (200 ROP; 100 affluent-AFF). Anthropometric data were recorded and questionnaires on physical activity and nutritional

evaluation (FFQ, two repeated 24H-recall) were administered. Nutritional data analysis was performed using the Winfood software tool.

Results: The survey showed a lower incidence of overweight and obesity than previously reported in Italy, without any differences between ROP and AFF. No differences were detected between groups in physical activity and in the dietary pattern (from FFQ), although a lower intake of cereal products, fruit and vegetables was found in ROP. The contribution of total fats and total sugars was higher than recommended in about 60% and 30% (respectively) of participants regardless the income; fiber intake was very low in both groups. The intakes of almost all vitamins and minerals were below the AR in high percentages of ROP and AFF, and only folate and iron intakes were significantly lower in ROP than in AFF.

Conclusions: The main nutritional criticalities pointed out in Italian ROP women were the same highlighted in participants with a higher income. These criticalities will be considered as targets in new foods to be formulated within the CHANCE project.

Key words: risk of poverty – nutritional criticalities - health

FECAL CALPROTECTIN AMONG GUATEMALAN PRESCHOOL CHILDREN: ANTHROPOMETRIC AND PARASITOLOGICAL DISTRIBUTION

M E. Romero-Abal¹, M J. Soto-Méndez¹, G. Hidalgo², N W. Solomons¹, K. Schümann³, A. Gil⁴

¹Center For Studies of Sensory Impairment, Aging and Metabolism -CESSIAM-, Guatemala

²Hospital La Democracia Laboratory, Quetzaltenango, Guatemala

³Molecular Nutrition Unit, ZIEL, Research Center for Nutrition and Food Science, Technische Universität München, Germany

⁴Department of Biochemistry and Molecular Biology II, Universidad de Granada, Spain

Background and objectives: Intestinal parasites such as *Ascaris lumbricoides*, *Trichuris trichiura* and *Giardia lamblia* are reputed to accelerate intestinal transit affecting nitrogen balance through excessive stool losses, in addition to CHO intolerance and nutrient malabsorption, as well as intestinal inflammation. Fecal calprotectin is a neutrophil-derived protein detectable in stools, used as a biomarker of intestinal inflammation. We report here its distribution in a group of pre-school children and its association with parasitic infection and nutrition.

Methods: Fecal samples were obtained from 87 children living in the western highlands of Guatemala (mean age: 54.5±16.4 mo). Height and weight was measured and anthropometric indicators (WAZ, HAZ and WHZ) were calculated using the WHO norms. Calprotectin was measured using a simple enzyme-linked immunosorbent assay (CalproLab™ ELISA kit, Oslo, Norway). Non-quantitative detection of ova and protozoa was done using direct, wet-smear light-microscopy, with intensity of helminthic infection gauged by modified Kato-Katz.

Results: Overall stunting rate was 66%. 30 of 87 children (34.4%) were parasitized by one or another (or both) methods. We obtained a relatively low infection intensity in eggs/g of feces terms among 12 positive subjects. Overall median fecal calprotectin was 57.5 mg/Kg (range: 10.0 to 950.0 mg/Kg), without difference by sex, age-category, WAZ, WHZ or parasite status. In exploring interactions, the respective calprotectin medians were: 55.0 mg/Kg (normal-HAZ, non-parasitized); 62.5 mg/Kg (normal-HAZ, parasitized); 57.5 mg/Kg (abnor-HAZ, non-parasitized); and 57.5 mg/Kg (abnor-HAZ, parasitized). No significant differences were found among groups (p=0.61).

Conclusions: Median fecal calprotectin values were not different from those reported in other studies for free-living children of the same age in developed or developing countries. We find no evidence for protozoan or helminthic infections or nutritional status influencing the fecal calprotectin levels.

Key words: Calprotectin, Feces, Parasitic infection

PO127

INVESTIGATION OF THE USE OF IODIZED SALT IN BREAD PRODUCTION FOR THE PREVENTION OF IODINE DEFICIENCY IN THE RUSSIAN FEDERATION

G. Garrett¹, M. Kostyuchenko², R. Spohrer¹

¹Large-Scale Food Fortification, Global Alliance For Improved Nutrition, Geneva, Switzerland

²State Research and Development Institute of Baking Industry, Russian Academy of Agricultural Sciences (SRI GOSNIIP RAAS), Moscow, Russia

Background and objectives: Universal Salt Iodization (USI) is the most cost-effective measure to prevent and control iodine deficiency. Russia suffers from iodine deficiency, and iodized salt is consumed by less than 30% of households. Bread is estimated to account for 20% of daily salt intake. Researchers tested the effect of iodized salt on Russian bread baking technology, bread quality, growth of *Bacillus subtilis* and mold fungi, and iodine retention.

Methods: Wheat (white) and wheat-rye (black) breads were produced in the laboratory according to state standards. Tests were done in 3 replications with control samples using non-iodized salt. Rheological properties and gas production were measured using a “Chopin” alveograph and rheofermentometer. Organoleptic properties were evaluated according to state standards. Growth of potato disease-causing bacteria and mold fungi were measured in culture medium and in baked bread. Iodine retention was measured by the anodic stripping-voltammetric method using a PLC-2A anodic stripping-voltammetric analyzer.

Results: Iodized salt reduced wheat dough resilience by 9% and distensibility by 3.8%, however had no influence on gas production (rising). Organoleptic properties were identical for bread with iodized vs. non-iodized salt. Iodized salt slowed potato disease development in white bread by 2-24 hours and mold formation in black bread by 11 days. Iodine losses were 29-33% for white bread and 14-23% for black bread after baking, and 7-14% additionally for black bread after 72-hour storage.

Conclusions: Iodized salt does not significantly change bread baking technology or quality, and helps prevent development of potato disease in white bread and mold formation in black bread. Considering an average per capita consumption of bread in Russia of 200g/day, using iodized salt would provide an additional 50.4 – 68.8ug/day of iodine or 34 - 46% recommended nutrient intake for adults and 23 -31% for pregnant women.

Key words: Universal Salt Iodization, iodine deficiency, bread, Russia

of the prescribed menus in a day-care center network (Hogares Comunitarios), with feeding subsidize by the Secretariat of Beneficial Works of the First Lady of Guatemala (SOSEP).

Methods: The official rotating-menus, with a repeating 8-week cycle, were the pattern of reference. It prescribes a total of 435 items -- 317 food items and 118 beverage items – across a daily breakfast, mid-morning snack, lunch, and afternoon snack, over 40 institutional-days. We defined “non-fidelity” as any instance when the prescribed item was substituted for another (others) or omitted altogether. Daily menu adherence was recorded over 8 weeks in two semi-urban centers (C1 and C3) and one rural center (C2), with monitoring conducted July–November, 2012.

Results: Holidays or other interruptions led to 112 days of observation among a theoretical 120 attendance-days (93%) across all centers. These 112 days would have obligated serving 1217 menu-items. Items not served as planned (non-fidelity) occurred for 169 items (13.8%). Illustrative examples are frankfurter prescribed in the menu substituted with chicken, or noodles substituted for rice. By institution, non-fidelity rates were (4.1%) in C1, (18.1%) in C2 and (20.5%) in C3. Food items suffered non-fidelity 12.6% of the time, and beverages, 17.3%. Across all centers, they occurred most frequently at lunch (45.6%) followed by afternoon snack (33.1%), breakfast (14.8%) and mid-morning snack (6.5%). With respect to food-groups, the three highest percentages of non-fidelity related to sugars/fats (32%) followed by herbs/vegetables (24%) and fruits (17%).

Conclusions: Non-adherence to the SOSEP menu occurred in less than ~1/5 of instances in any center, and most often involved substitutions within the least healthful food-group.

Key words: Menus, beverages, Guatemala

PO129

HOW MUCH FOR DOING IT RIGHT?

C. Lopez-Martin¹, J. Abiles¹, F Ferrer¹, R. Romero¹, J J. Arenas¹, M E. Blanco¹, M. Garrido¹, V. Faus¹

¹Department of Pharmacy and Nutrition, AS Hospital Costa del Sol, Marbella, Málaga, Spain

Background and objectives: Parenteral nutrition (PN) is essential for many hospitalized patients; however its use is associated with complications which could be controlled with an appropriate monitoring. The aim is to show that the creation of a nutritional support team (NST) reduces PN complications and increases PN quality standards; and calculate the incremental cost associated to the NST.

Methods: Patients with PN were selected between May–June, the year before and after NST implementation. NST involved the patient nutritional evaluation, daily monitoring of vital

signs and glycemia, analytical control (weekly, at the beginning and end of PN) and management of PN complications. The incremental cost was calculated considering the nutritionist's salary, the cost of analytical control and the incremental cost associated to PN including the cost of preparation (technician): (average cost of PN before NST/patient) – (average cost of PN after NST/ patient).

Results: We obtained 24 and 38 patients before and after NST (Group 1 and 2, respectively). Quality of PN was increased (Group 1 vs 2): PN<7 days 67% vs 22%, analytical control 4% vs 79%, nutritional evaluation 0% vs 100%, daily monitoring 0% vs 100%, individualized calculation of requirements 0% vs 100% ($p<0,001$ for all). After NST, albumin and prealbumin increased in 66% and 88% of patients, respectively. No patient reached triglyceride>400mg/dl. 34% of patients showed glycemia>140mg/dl (100% were solved adding insulin to PN). 26% of patients showed hepatic dysfunction due to PN (50% were solved using Cyclic PN and Taurine). No refeeding syndrome was reported, thiamine was added in patients at risk (34%). The incremental cost estimated was 559 €/patient.

Conclusions: The implementation of NST improves the quality of PN and reduces its complications. The benefits achieved by NST are associated with an incremental cost of 559 €/patient.

Key words: complications, cost, nutritional support team, parenteral nutrition

¹Institute of Nutrition and Food Hygiene, La Habana, Cuba

²Provincial Hygiene and Epidemiology Center, La Habana, Cuba

Background and objectives: Different intervention programs were designed for anemia prevention for Cuban preschool children. The objective was to assess nutritional anemia, epidemiological factors and iron deficiency in children 6 to 59 month old.

Methods: A cross sectional study with systematic random sampling of 3527 children in 2011-2012 was completed in Eastern, Center and Western of Cuba. Anemia status was assessed by hemoglobin. Iron and vitamin C rich-food intake were evaluated by food frequency questionnaire. Epidemiological factor sex, rural/urban residence, assistance of daycare center (DCC) and previous infections (PI) were collected. In subsample of 6-23 months old additional factors exclusive breast milk, anemia during pregnancy and birth weight were into consideration, nutritional iron status was assessed by serum ferritin and CRP in subsample. Logistic Regression Analysis included residence, group of age (GA)<2SD, DCC no/yes, sex female/male; PI yes/no, and group of foods never+few/frequently intake were evaluated.

Results: The prevalence of anemia (hemoglobin < 11.0 g/dL) was 26.0% (95%CI 24.2-27.8) in Eastern, 12.0% (95%CI 10.0-14.0) in Center and 20.6% (95%CI 17.3-23.9) in Western provinces. Never+few intake eggs (OR=1.53 95%CI 1.33-1.77), vegetables (OR=1.25 95%CI 1.08-1.44), beans (OR=1.18 95%CI 1.03-1.36), and bread (OR=1.63 95%CI 1.30-2.04) were significant associated of anemia in Eastern, and never+few intake eggs (OR=1.69 95%CI 1.20-2.38) and fruits (OR=1.72 95%CI 1.19-2.49) in the Center. No statistic associations with sex, residence or breast milk intake were found. Depleted iron stocks in 54.5% children were found and 27% with adequate ferritin were anemic. Significant variables in logistic regression analysis in Eastern DCC (OR=2.59 95%CI 1.81-3.70), GA (OR=2.61 95%CI 2.11-3.23), earache (OR=1.90 95%CI 1.27-2.84), diarrhea (OR=1.78 95%CI 1.33-2.36), flu (OR=1.31 95%CI 1.03-1.66) and eggs (OR=1.25 95%CI 1.02-1.55); in Center only GA was significant (OR=4.23 95%CI 2.68-6.67).

Conclusions: Anemia is an important public health problem in preschool children in Cuba, and different factors beside food intake should also be considered.

Key words: anemia, preschool-children, food-intake, iron-deficiency

PO131

TASTE AND NUTRITION EFFECT ON THE SUGAR APPETITE OF RATS

A. Martínez¹, A. López-Espinoza¹, C. García-Flores¹, P. López-Uriarte²

¹Feeding and Nutritional Behavioral Research Center-University of Guadalajara, México

²Centro Universitario de Ciencias de la Salud- University of Guadalajara, México

Background and objectives: The appetite of sugars solutions differing in concentration is typically taken as a measure of palatability, but the differences test procedures (short or

long-term) and other variables like time of availability of solutions would be considerable. The objective was to compare the influence of the taste and the nutritional composition of solution on the short- and long-term test intake of a sugar solution.

Methods. Twenty albino rats received a sweet-nutritive solution, sweet-nonnutritive solution, or both in the short and long-term tests. Licking behavior was monitored 30 min/day access.

Results: It showed high licking behavior in sweet-nutritive solution group in comparison with sweet-nonnutritive solution group ($p < .05$) in long-term test. Meanwhile groups did not show differences in licking behavior in short-term test ($p > .05$). Group that received both solutions preferred sweet-nutritive solution over sweet-nonnutritive solution in long-term test ($p < .05$) and did not show significant differences on preference in short-term test ($p > .05$).

Conclusions: These findings suggest that time and availability of solutions is determinant on sugar appetite of rats.

Key words: Sugar appetite, licking behavior, rats

PO132

EFFECT OF NUTRITION EDUCATION AND BIWEEKLY IFA SUPPLEMENTATION ON ANAEMIA RELATED KNOWLEDGE AND IRON STATUS OF UNDER-PRIVILEGED ADOLESCENT GIRLS

A. Malhotra¹, A. Tyagi²

¹Department of Food Technology, Lakshmibai College, University of Delhi, Delhi, India

²School of Continuing Education, Indira Gandhi National Open University, Delhi, India

Background and objectives: Biweekly iron and folic acid (IFA) supplementation is an effective strategy for reducing iron deficiency anaemia. This intervention study assessed the effect of nutrition education and biweekly IFA supplementation on anemia-related knowledge and iron status of adolescent girls.

Methods: 140 girls (aged 14-19 years) from outer Delhi were selected randomly. They were divided into - no intervention (control), IFA supplementation (60mg elemental iron + 0.5mg folic acid), IFA supplementation with nutrition education (IFA+NE) and nutrition education (NE) groups. Weight and height were measured to compute BMI and dietary data were gathered by one day 24 hour recall and food frequency questionnaire. Haemoglobin status was assessed by cymethaemoglobin method and a questionnaire was used to assess the knowledge, attitude and practices (KAP) relating to anaemia both at baseline and after 12 weeks of intervention.

Results: The subjects were out-of-school (64%) and from lower castes (48%). Their family occupation was labour (61%) and monthly family earnings were <INR3,000 (86%). Compa-

red to recommended allowances, their cereal-based and monotonous diets were inadequate in terms of energy (50% to 70%), protein (50% to 75%), iron (28% to 36%) and folic acid (28% to 54%) and all other nutrients except fat and vitamin C. Majority of the subjects were normoweight (87%) but anemic (61%). Mean haemoglobin level was 11.58 ± 0.89 , 11.09 ± 1.44 , 11.77 ± 1.07 and 11.64 ± 1.23 g/dL for control, IFA, IFA+NE and NE while KAP scores were 34.31 ± 19.38 , 54.71 ± 15.38 , 40.74 ± 15.46 and 42.65 ± 14.02 percent respectively. Post-intervention, the nutrition education groups (NE and IFA+NE) showed higher increase in KAP score (14.3 and 26.7%, $p < 0.05$) as well as hemoglobin level (0.45 and 0.43 g/dL) respectively.

Conclusions: Nutrition education improved anemia-related KAP and effectiveness of biweekly IFA supplementation in reducing iron deficiency anaemia among underprivileged adolescent girls.

Key words: Iron deficiency anemia, IFA supplementation, nutrition education, adolescent girls.

PO133

POLYMORPHISMS IN THE FATTY ACID DESATURASE GENES AND DIET ARE IMPORTANT DETERMINANTS OF INFANT DOCOSAHEXAENOIC ACID STATUS

L. Lauritzen¹, L. Harsløf¹, L. H. Larsen¹, C. Ritz¹, L. I. Hellgren², K. F. Michaelsen¹, U. Vogel³

¹ Department of Nutrition, Exercise & Sports, University of Copenhagen, Frederiksberg, Denmark

²Department of Systems Biology, Technical University of Denmark, Lyngby, Denmark

³Department of Nanotechnology, The National Research Centre for the Working Environment, Copenhagen, Denmark

Background and objectives: Tissue docosahexaenoic acid (DHA) accretion in early infancy is supported by DHA in breast-milk and may thus decrease once complementary feeding takes over. Endogenous synthesis of DHA from alpha-linolenic acid is low and polymorphisms in the genes that encodes the fatty acid desaturases (FADS) has been shown to have little effect on DHA-status in adults. It is unclear to what extent endogenous DHA-synthesis contributes to infant DHA-status. We aim to investigate the role of diet and FADS-polymorphisms on DHA-status at 9 months and 3 years.

Methods: This cross-sectional study with Danish infants use data from two prospective studies (EFiON and the SKOT-cohort). We measured erythrocyte (RBC) DHA-status at 9 months ($n=409$) and 3 years ($n=176$) and genotyped 4 FADS tagSNPs, rs3834458, rs1535, rs174575 and rs174448 ($n=401$).

Information about breastfeeding was obtained by questionnaires and fish intake was assessed by 7-day pre-coded food diaries.

Results: FADS-genotype, breastfeeding, and fish intake were found to explain 25% of the variation in infant RBC DHA-status (mean±SD: 6.6±1.9% of all fatty acids (FA%)). Breastfeeding was the most important contributor and still being breast-fed at 9 months was associated with 0.8 FA%-points higher DHA vs. no longer breast-fed ($p<0.001$). Two of the examined FADS-SNPs were highly correlated (rs1535 and rs3834458; $r=0.98$). Homozygous carriers of the minor allele of rs1535 had an increase in RBC-DHA of 1.6 FA%-points relative to those with wild type, whereas minor allele carriers of rs174448 and rs174575 had a decrease of 0.9 ($p=0.017$) and 1.9 FA%-points ($p=0.001$), respectively. Each 10 g/d-increment in fish intake was associated with an increase in DHA-status of 0.3 FA%-points. At 3 years, fish intake was the only significant determinant of DHA-status (0.2 FA%-points/10 g).

Conclusions: FADS-genotype and diet are both important determinants of DHA-status in late infancy.

Key words: fish intake, breastfeeding, child nutrition

PO134

DIET IMPACT ON VITAMIN B12 AND FOLIC ACID CONCENTRATION AS AN ELEMENT OF THERAPY IN PERSONS WITH THE LDL-R GENE MUTATION

A. Jarosz¹, J. Kubalska², G. Nowicka³, B. Dauniewska¹

¹Center of Health Promotion, Food and Nutrition Institute, Warsaw, Poland

²Department of Genetics, Institute of Psychiatry and Neurology, Warsaw, Poland

³Pharmaceutical department, Medical University of Warsaw, Warsaw, Poland

Background and objectives: Family hypercholesterolemia (FH) is a disorder inherited as a dominant autosomal trait caused by the mutation of the LDL receptor gene which belong to the most common genetic defects leading to premature coronary heart disease. Heterozygous FH has 76 000 people in Poland. Aim: assessment of vitamin B12 and folic acid intake in persons with FH with the LDL-R gene mutation before and after dietary intervention.

Methods: 14 persons with the LDL-R gene mutation took part in the study. Blood was taken twice, before and after the application of the B12 vitamin and folic acid. Also before and after the intervention a 3 day diet realization assessment interview was conducted. 14 day menus were prepared with different energy intake requirements in mind: 1500 and 1800 kcal. The level intake of folic acid was 400Åµg and vitaminB12-2,4Åµg/day. The intervention lasted for 6 weeks.

Results: The average concentration of the B12 vitamin before the intervention was 464 (Å±35,3) pmol/l. The lowest was 202 pmol/l, highest 635. After intervention the average concentration was 496 (Å±97,5) pmol/l. The lowest was 199 pmol/l, highest 800 pmol/l. In the case of the folic acid the average concentration was 6,61(i,± 2,12) nmol/l before the diet. The lowest was 3,34 nmol/l, highest 10,44. After the diet the average concentration was 9,21 (Å±0,57), lowest was 3,83, highest 9,62.

Conclusions: the proposed diet shows beneficial tendencies especially in the case of folic acid, increasing concentration for all the participants of the study. A significant element is to keep the B12 vitamin level constant even when meat, which was an important source in the diet, consumption is decreased. Even though such persons require pharmacological treatment this diet may be an important element in the therapy especially in reference to homocysteine.

Key words: LDL-R gene mutation, vitamin B12, folic acid

PO136

MALNUTRITION-INFLAMMATION SCORE: A PREDICTOR OF MORTALITY IN HEMODIALYSIS PATIENTS

C. Garagarza¹, P. Matias¹, T. Amaral¹, C. Ferreira¹, C. Jorge¹, C. Gil¹, A. Ferreira^{1,2}

¹Department of Nutrition and Nephrology, Dialverca - Dialysis Unit, Forte da Casa, Lisboa, Portugal

²Department of Nephrology, College of Medical Sciences, Lisbon's Nova University, Portugal

Background and objectives: Hemodialysis (HD) patients with protein-energy malnutrition frequently present high levels of inflammatory markers, both associated with increased morbidity and mortality. Malnutrition-inflammation score (MIS) is a clinical nutrition assessment tool, which includes 7 components of the Subjective Global Assessment, body mass index, serum albumin and transferrin concentrations. The aim of this study was to investigate the usefulness and clinical relevance of MIS to predict mortality in chronic HD patients.

Methods: In this 36-month longitudinal prospective single-center study, baseline patients' characteristics, biochemical parameters and MIS were obtained and correlated with mortality. We studied 85 prevalent HD patients, with a mean age of 65.3±15.7 years, a mean HD time of 43.3±33.0 months, 46% female and 29% diabetics. Univariate, multivariate and survival analysis were performed, and a $p<0.05$ was considered significant.

Results: MIS was positively correlated with age ($r=0.36$, $p=0.001$), nPCR ($r=0.23$, $p=0.04$) and with mortality ($r=0.39$, $p<0.001$) and negatively correlated with serum levels of al-

bumin ($r = -0.40$, $p < 0.001$), creatinine ($r = -0.32$, $p = 0.03$) and phosphorus ($r = -0.27$, $p = 0.013$). Patients that died during the study had significantly lower albumin ($p = 0.001$) and creatinine ($p = 0.04$) and higher MIS ($p < 0.001$) compared with those who didn't die. Patients were divided into 3 groups according to baseline MIS (between 0-4; between 5-7 and ≥ 8). Patients with MIS ≥ 8 had a significant lower survival at the end of the study (log rank = 11.1; $p = 0.004$) compared with the other two groups. After adjustment for baseline characteristics, such as age, diabetes mellitus and HD vintage, MIS was an independent predictor of mortality (HR: 1.32; 95% CI: 1.17-1.49; $p < 0.001$).

Conclusions: According to these results, MIS is a useful predictor of mortality in chronic HD patients. Therefore, assessing MIS is important to routinely monitor malnutrition-inflammation complex syndrome and also to predict these patients' prognosis.

Key words: hemodialysis, nutritional status, mortality.

A PUBLIC HEALTH GENOMICS PERSPECTIVE FOR OBESITY

C. Brettfeld¹, B. Taneri^{2,3}, A. Haslberger¹

¹Department of Nutritional Sciences, University of Vienna, Althanstrasse 14, A-1090 Vienna, Austria

²Department of Biological Sciences, Program of Molecular Biology and Genetics, Eastern Mediterranean University, Famagusta, North Cyprus

³Institute for Public Health Genomics, Cluster of Genetics and Cell Biology, Faculty of Health, Medicine and Life Sciences, Maastricht University, The Netherlands

Background and objectives: It has been repeatedly established that common complex diseases stem from gene-environment interactions (GxE). In light of this experimental evidence, public health measures against common complex diseases should be tailored accordingly. Here we discuss integration of gene-environment data into an existing Public Health Genomics model, namely Public Health Genomics – Common Complex Diseases (PHG-CCD) model [Taneri et al. 2012] in relation to obesity a debilitating public health concern. Obesity is a common complex disease, which has become a major public health burden over the last decades [James et al. 2001]

Methods: We used PHG-CCD, a novel theoretical model developed by Taneri et al. [Taneri et al. 2012], integrating a gene-environment interaction paradigm into public health genomics. In particular, we tailor this model with specific information on GxE implicated in obesity.

Results: We discuss a public health genomics model that in-

corporates gene-environment interactions within the context of obesity, which could potentially be used when managing the prediction, diagnosis and treatment of this disease.

Conclusions: The public health genomics model presented here enables genome-based predictions and evidence-based behavioral interventions, by utilizing GxE data, which is at the core of common complex disorders. Applications of PHG-CCD serve as a valuable public health measure.

Key words: Obesity, genetics, epigenetics, gene-environment interactions (GxE), public health, public health genomics

¹Nutrition Departement, Health Polytechnic of Malang, Indonesia

²Nutrition Departement, Health Polytechnic of Yogyakarta, Indonesia

Background and objectives: Merapi eruption of natural disasters, has resulted in many losses. Losses that occur include the loss of property, damage of environment, decreases community economic. Loss of or damage to property and the environment, especially agricultural land causes family decreases. The food less will result in an increase of protein energy malnutrition (PEM) in children. Based on the cases of nutritional status on the eruption of Merapi mountain, Sleman District, PEM was found in children increased. Children who suffer from PEM at 14.5% and children who otherwise malnutrition 1.3%. Children who suffer from malnutrition due to Mount Merapi disaster if not handled properly can cause the people of Indonesia will be 'lost generation'. The purpose of the research to share knowledge about how to save the children on Merapi mountain from loss generation.

Methods: Preparation the research by using field observation, and interview with Kader Posyandu, and community leaders. Model 'Posyandu Swasembada' is the type of modification Posyandu. Posyandu Swasembada to increase of function Posyandu as community agencies to prevent cases of PEM and malnutrition, child growth monitoring and intervention PEM and malnutrition in the region after the eruption of Merapi mountain. The typical model in Posyandu Swasembada has intervention table. The actions taken at the table of intervention are: nutrition education, supplementary feeding, giving of traditional medicine (herbal medicine) in children is a fussy eater, massage on children, and referral. Model Posyandu Swasembada to save the children from PEM and malnutrition with the

basic are empowerment in community itself.

Key words: Posyandu Swasembada Model, PEM, Lost generation, Merapi Mountain

PO139

THE ASSOCIATION OF SERUM LIPID PROFILE WITH SCD1 DESATURASE INDICES IN RED BLOOD CELL MEMBRANES.

Y. Sone¹, I. Ichi², K. Kawahara³, K. Kawahara^{1,2}, Y. Otsuka^{1,2}, Y. Fujiwara^{1,2}

¹Institute of Environmental Science for Human Life, Ochanomizu University, Bunkyo-ku, Tokyo, Japan

²Graduate School of Humanities and Sciences, Ochanomizu University, Bunkyo-ku, Tokyo, Japan

³Graduate School of Tokyo Medical and Dental University, Bunkyo-ku, Tokyo, Japan

Background and objectives: To investigate the association of the desaturase index (DI) of stearoyl CoA desaturase 1 (SCD1) in red blood cell (RBC) membranes with atherosclerosis indices such as non-high density lipoprotein cholesterol (non HDL-C) level and the ratio of low density lipoprotein cholesterol to high density lipoprotein cholesterol (LDL-C / HDL-C) which are known risk factors of coronary heart disease (CHD) in Japanese men.

Methods: Healthy male subjects of 140 (74 with waist circumference <85 cm and 66 with waist circumference ≥85 cm) were recruited in this study. The serum lipid makers, fatty acid (FA) composition in RBC membranes and genotyping of SCD1 genes of the subjects were measured. The lipid extracts of RBC membranes were methyl esterified with methanol and acetyl chloride. Concentrations of FA methyl esters were detected by GC-FID, and DI of SCD1 was estimated as the ratio of FA product to FA precursor (using C18:1 n-9/C18:0, C16:1 n-7/C16:0). The SNPs of SCD1 gene were genotyped using the TaqMan SNP allelic discrimination method by an ABI 7300 System. Relations between the alleles of SNP and atherosclerosis indices were analyzed by multiple regression analysis to deduct where possible, confounding factors.

Results: We have demonstrated for the first time that the DI of SCD1 is associated with non HDL-C levels and the LDL-C/HDL-C ratio. Moreover, the SNP of the SCD1 gene significantly associated with the DI of SCD1.

Conclusions: The FA composition of RBC membranes is associated with atherosclerosis indices. This suggests that the FA composition of RBC membranes may be an index of CHD risk in Japanese male subject.

Key words: LDL-C / HDL-C ratio, non HDL-C, SCD1.

PO141

EFFECTS OF DIETARY CITRIC ACID ON ENERGY METABOLISM OF THE SKELETAL MUSCLES AND LIVER IN MICE

Y. Hara¹, N. Watanabe²

¹Graduate School of Human Life Sciences, Showa Women's University, Tokyo, Japan

²Department of Food Science and Nutrition, Showa Women's University, Tokyo, Japan

Background and objectives: Dietary citric acid is reported to have many beneficial effects such as anti-fatigue activity. Nevertheless, the mechanism underlying these effects has not been elucidated yet. In this study we aimed to investigate the effect of citric acid intake on the energy metabolism in the skeletal muscles and liver in mice that were fasted without exercise.

Methods: C57BL/6J mice were divided into 2 groups. The control or citric acid groups received distilled water or citric acid solution, respectively. Thirty minutes after the administration, mice were dissected and skeletal muscles or liver were removed. After then, we performed DNA microarray global analysis using those organs.

Results: Expression of the genes involved in the tricarboxylic acid cycle, electron transport system, and β -oxidation of fatty acids were not affected by dietary citric acid. On the other hand, dietary citric acid increased the level of blood glucose and phosphoenolpyruvate carboxykinase gene. In addition, a modest increase of glycogen content in the liver was observed. This increase might be induced via enhancing the expressions of the glucose-6-phosphatase and glucokinase genes and by suppressing the expressions of the phosphofructokinase and pyruvate kinase genes.

Conclusions: These results suggested that dietary citric acid enhanced gluconeogenesis in the liver. These phenomena may explain the beneficial effects such as anti-fatigue of dietary citric acid.

Key words: citric acid, gluconeogenesis, glycogen, DNA microarray, fatigue

PO142**HUMAN AMYLASE GENE COPY NUMBER VARIATION BETWEEN CAUCASIAN AND ASIAN ADULTS**

F. Atkinson¹, D. Hancock², P. Petocz³, G. Denyer², J. Brand-Miller¹

¹Human Nutrition Unit, School of Molecular Bioscience, University of Sydney, NSW, Australia

²School of Molecular Bioscience, University of Sydney, NSW, Australia

³Department of Statistics, Macquarie University, NSW, Australia

Background and objectives: Research has shown that the salivary amylase gene (AMY1) shows wide variation in copy number in the Caucasian American population. Our objective was to investigate the AMY1 copy number variation and salivary α -amylase protein activity in adults from Caucasian and Asian backgrounds.

Methods: Whole blood samples and saliva samples were collected from 150 adults (58 M: 92 F; 105 Caucasians: 45 Asians; age: 29.4 ± 10.4 yr; BMI 23.4 ± 3.4 kg/m²). Genomic DNA was isolated from the blood samples and analyzed using real-time quantitative PCR to determine AMY1 gene copy number relative to a control sample. The salivary α -amylase protein activity was assessed in the saliva samples using a commercial enzymatic assay.

Results: In the population as a whole, AMY1 gene copy number ranged from 2 – 16 copies. The mean AMY1 copy number was significantly higher for the Asian participants (7.8 copies) compared to the Caucasian participants (6.1 copies) ($p < 0.001$). The shape and spread of the distribution curves between the two ethnic groups was significantly different ($p = 0.002$). A significant positive correlation between AMY1 gene copy number and protein activity was observed ($r = 0.59$, $p = 0.0001$).

Conclusions: AMY1 gene copy number varies both within people from the same ethnic background and also between people from different ethnic backgrounds. People from an Asian background were found to have higher average AMY1 copy number, which could help explain higher postprandial glucose responses to starchy foods in this group.

Key words: salivary amylase gene copy number

PO143**INDIVIDUAL CHARACTERISTICS AND ENVIRONMENTAL FACTORS ARE ASSOCIATED WITH SKIPPING BREAKFAST IN JAPANESE MALE UNIVERSITY STUDENTS**

M. Nakade¹, M. Tsubota-Utsugi¹, N. Aiba²

¹Department of Nutritional Epidemiology, National Institute of Health and Nutrition, Tokyo, Japan

²Department of Nutrition and Life Science, Kanagawa Institute of Technology, Kanagawa prefecture, Japan

Background and objectives: Skipping breakfast is most common in men and women in their 20s, including university students. Although some studies have examined the factors related to breakfast skipping in female university students, there have been few reports in male university students. This study aimed to clarify the characteristics of breakfast skippers in male university students.

Methods: A questionnaire survey was conducted in a university in Kanagawa prefecture in 2012. A total of 528 student-mother pairs who completed the questionnaire concerning frequency of eating breakfast, lifestyle and dietary awareness (mothers also answered questions about their socioeconomic states and implementation of dietary education when the students were growing up) were analyzed. The students were classified into either breakfast eater (who eat breakfast 7 days per week) or breakfast skipper and examined the factors related to breakfast skipping by logistic regression analysis.

Results: Sixty-two percent of the students skipped breakfast. A positive relationships between breakfast skipping and several factors were observed independently; the students who living alone (Odds ratio, 95% CI: 2.39, 1.43-4.00), who were smokers (2.30, 1.07-4.96), who had a part-time job (1.64, 1.08-2.50), who thought skipping breakfast was harmless (3.50, 1.89-6.49), who habitually went to bed after 1 am (2.46, 1.64-3.69), whose mother skipped breakfast (2.19, 1.11-4.34) and whose mother did not enjoy cooking (1.89, 1.23-2.84). Conversely, breakfast skipping was less common among the students who took more than an hour to go to university (0.58, 0.35-0.95).

Conclusions: Our results suggested that environmental factors such as living alone, commute time and mother's attitude and individual factors such as unhealthy lifestyle and dietary awareness were contributed to breakfast skipping in university students. Modifying lifestyle and reminding the students and their mothers of the importance of breakfast consumption may help students to eat breakfast.

Key words: Breakfast skipping, university students, Japan, mothers

PO144**PHYSIOLOGICAL BENEFITS OF GLUTAMATE AND DEVELOPMENT OF HANDY GLUTAMATE METER FOR FOOD TASTE MANAGEMENT**

Y. Fujishima¹, Y. Kato¹, T. Mizukoshi¹, S. Koide², S. Ikeda², N. Itoh², H. Miyano¹, H. Uneyama¹

¹Ajinomoto Co., Inc., Japan

²Tanita Corporation, Japan

Background and objectives: Measurement of umami is not only an issue of Japanese people since the importance of umami physiology has been elucidated in recent studies. The benefits of umami compound namely glutamate ranges from saliva secretion, digestive juice secretion, sodium intake reduction, protection of digestive tract or addition of satiety to foods. However, to date, there was no method to measure the glutamate content in foods which was quick and handy. We hence have been developing a prototype handy glutamate meter and evaluating its capabilities.

Methods: Glutamate meter contains a biosensor was created by micro-planar electrochemical sensor fabrication technique. Enzyme electrode of glutamate oxidase was casted with BSA with glutaraldehyde and sandwiched between fluorocarbon hydrophobic restrictive layer and selective permeable layer, placed on surface of platinum and silver /silver chloride electrodes. Linearity of the sensor was evaluated and a variety of food samples were measured.

Results: The dynamic range of the sensor was found to be between 0.05 and 2% w/v glutamate in neutral condition. Application in food was possible in soup, tomato or any food with prior treatment. The measurement time required was less than 10 seconds with accuracy equivalent to commercial amino acid analyzer.

Conclusions: We have succeeded in development of food use glutamate meter. This meter can be used for raw material quality assurance for kombu, tomato, tea, seasoning, production process control at food and fermentation production, product comparison, product development or used as an educational tool.

Key words: Glutamate, meter, sensor, quantification

PO145**SER/TER LPL GENE POLYMORPHISM, ARG158CYS AND CYS112ARG APOE GENE POLYMORPHISMS ARE DIET EFFICIENCY MARKERS IN OBESE PATIENTS**

O. Kirillova, V. Tutelyan, T. Sentsova, I. Vorozhko, K. Gapparova, Y. Chekhonina

Institute of Nutrition RAMS, Moscow, Russian Federation

Background and objectives: Patients with obesity have dyslipidemia. The lipid metabolism is regulated by ApoE and LPL genes that determine lipid levels in blood. Diet therapy is the main treatment for obese patients.

Methods: 108 patients with obesity, 18-66 years old (males – 24, females – 84) were examined. Diagnosis of obesity was based on body mass index (BMI) and bioimpedance body composition analysis. Thirty-nine patients had 1st grade of obesity (BMI=30-35 kg/m²), 27 patients – 2nd grade (BMI=36-40 kg/m²), and 42 patients had 3rd grade of obesity (BMI>40 kg/m²). Serum lipid status was examined by turbidimetric method on spectrophotometer analyzer Konelab 60i. The Ser/Ter polymorphism of LPL gene, the Arg158Cys and the Cys112Arg polymorphisms of ApoE gene were examined by PCR-Real Time analysis.

Results: Significantly difference in cholesterol levels (M±m) after the diet therapy in people with genotype E3/E3 were revealed (5,54±0,22 mmol/l vs 4,54±0,24 mmol/l; r=0,81; p<0,0001). The reduction of triglycerides levels was 1,59±0,18mmol/l vs 1,22±0,07 mmol/l (r=0,79; p<0,0001), the reduction of high density lipoproteins levels (HDL) was 1,40±0,08 mmol/l vs 1,13±0,07 mmol/l (r=0,58; p=0,002), the reduction of low density lipoproteins (LDL) was 3,46±0,19 mmol/l vs 2,91±0,19 mmol/l (r=0,74; p<0,0001). Decreased cholesterol levels in patients with E2/E3 genotype after the diet therapy were revealed (4,61±0,24 mmol/l vs 4,17± 0,17 mmol/l (r=0,97; p=0,012)). LDL levels after the diet therapy were 2,60±0,28 mmol/l vs 2,44±0,15 mmol/l (r=0,96; p=0,021). Patients with $\Delta\Delta$ / $\Delta\Delta$, $\Delta\Delta$ / $\Delta\Delta$, $\Delta\Delta$ / $\Delta\Delta$ and Ser/Ter genotypes did not have any positive dynamics.

Conclusions: The detection of E3/E3 and E2/E3 polymorphisms of ApoE gene is a significant predictor of an effective diet therapy in obese patients.

Key words: polymorphism, obesity, diet therapy.

PO146**COMPARISON OF MACRONUTRIENT AND VITAMIN INTAKE BETWEEN AUSTRIAN VEGETARIAN AND OMNIVORE***K. Wagner*¹¹Institute of Nutritional Sciences, Vienna, Austria

Background and objectives: A vegetarian diet is associated with health benefits. Some micronutrients are only available in animal foods and may therefore be insufficient in a vegetarian diet. The aim of this study was to compare nutrient intake of vegetarian with omnivore adults in Austria and to determine if non omnivore have a higher risk of low nutrient intake.

Methods: The study sample included 419 healthy Austrian adults aged 18 to 64 years. 2.9 % of the sample has been vegetarians, excluding meat and poultry, or even vegans. Food consumption data were collected from October 2010 to February 2012. Dietary intake was measured using two non consecutive 24-h-recalls. Data entry was done with nut.s nutritional software based on BLS 3.01. Under and overreporter were excluded for statistical analysis, results are shown as mean values.

Results: Vegetarians and vegans had a higher intake of sucrose compared to omnivores (13 vs. 10 E %, $p < 0.05$) but no significant difference for dietary fibre intake (30 g vs. 21 g) could be observed. Cholesterol, however was lower in vegetarians and vegans than in omnivores (146 g vs. 308 g, $p < 0.05$). Vegetarians and vegans had a significantly ($p < 0.05$) higher intake of vitamin E (20 mg vs. 14 mg), vitamin K (126 µg vs. 97 µg) and folate (265 µg vs. 210 µg), whereas they had a significantly lower intake of niacin (22 mg vs. 31 mg) and vitamin B12 (1.8 µg vs. 4.6 µg).

Conclusions: Results show that a vegetarian diet provides more of some critical vitamins e.g. folate. Vitamin B12 supply remains a problem in the nutrition of vegetarians.

Key words: nutrient intake, macronutrients, vitamins, vegetarian

PO147**URINARY IODINE EXCRETION LEVEL IS POSITIVELY ASSOCIATED TO PHYSIOLOGICAL STATUS OF FILIPINO WOMEN***M. Serafico*¹, *L. Perlas*¹, *E. Ferrer*¹, *H. Patalen*¹¹Food and Nutrition Research Institute, Department of Science and Technology, Taguig City, Indonesia

Background and objectives: Urinary iodine excretion (UIE) is currently the most practical biomarker for iodine nutrition. For this biomarker, international groups have recommended school-aged children as useful target group for sur-

veillance because of their high vulnerability, easy access and as acceptable proxy for the iodine status of the general population. But the relevance of this group to others, especially among pregnant and lactating women, is not well established. Objective. To assess the association of UIE levels to the physiological status of Filipino women.

Methods: UIE was measured based on the catalytic effect of iodine on the reaction between cerium and arsenic after sample digestion using ammonium persulfate. UIEs of 442 pregnant and 830 lactating women were compared to UIEs of 1272 age- and BMI-matched non-pregnant, non-lactating women covered in the Biochemical Phase of the 7th National Nutrition Survey conducted by FNRI-DOST.

Results: Among pregnant women, median UIE was 100 µg/L (adequate ≥ 150 µg/L) with 26.4% having values < 50 µg/L. Median UIE among non-pregnant women, on the other hand, was 142 µg/L with 17.5% having values < 50 µg/L. Likewise, median UIEs among lactating and non-lactating women were 78 µg/L and 141 µg/L, respectively. Median UIEs for both pregnant and lactating women indicate insufficient iodine status. Further, median UIE levels for the 1st, 2nd and 3rd trimesters of pregnancy were 113, 107 and 89 µg/L, respectively. Iodine nutrition among non-pregnant, non-lactating women was optimal based on median UIE ≥ 100 µg/L) and the percentage ($< 20\%$) of women having UIE < 50 µg/L.

Conclusions: Physiological status such as pregnancy and lactation possibly increase the demand and utilization of iodine. In pregnancy, this may also be true as gestation progresses. To achieve optimal nutrition in these vulnerable groups, an increase in dietary intake is recommended. In addition, iodine supplementation during pregnancy and lactation should be considered.

Key words: iodine, pregnancy, lactation

PO148**FIRST FOOD FOR INFANTS***S. Hernes*¹, *M. Haugen*², *N. Øverby*¹¹Department of Public Health, Sport and Nutrition, University of Agder, Kristiansand, Norway²Department of Food Safety and Nutrition, Norwegian Institute of Public Health, Oslo, Norway

Background and objectives: Weaning foods may play an important role in the child's health. Studies report that infant feeding practices may influence health also later in life with one aspect being the development of preferences for tastes and textures. Studies find that children who are introduced to a variety of tastes early have higher acceptance of foods like fruits and vegetables in later life, reduced risk of food neophobia and reduced risk of developing obesity. We hypothesize that intro-

ducing kitchen-produced foods give greater variety in taste and consistency than industrial produced baby food in jars. The aim of the study First food for infants is to increase parents' knowledge, skills, and awareness regarding tasty and healthy food for infants to improve the children's diet and weight development and prevent food neophobia. Here we present a brief presentation of the study design.

Methods: First food for infants is a randomized controlled trial where parents in the intervention group participate in two cooking courses on how to prepare a variety of baby food. The control group is only given a brochure about infant nutrition. Recruitment of parents is done through the public health care centers. We plan to recruit 80 parents in both the control and intervention group. Questionnaires of feeding practices and food intake are filled in before the intervention (6 months of age) and at 15 months of age.

Results: This project started autumn 2011 and experience from the first four cooking classes show a positive attitude among the parents and they report awareness of food importance and altered feeding practice.

Conclusions: The project will show whether a practical cooking course to parents will increase homemade food practice resulting in a greater variety in food intake, reduce prevalence of neophobia and reduce risk of obesity at toddler's age.

Key words: infant's food

PO149

PROTEOMIC ANALYSIS OF ARGININE METHYLATED PROTEINS IN RAT BRAIN

M. Kimoto¹, H. Hatakenaka¹, T. Suzuki-Yamamoto¹, M. Suzuki¹, A. Ito¹, M. Yokoro¹, H. Yamashita¹, Y. Takahashi¹

¹Department of Nutritional Science, Faculty of Health and Welfare Science Okayama Prefectural University, Japan

Background and objectives: It has been appeared that arginine methylation of histone and non-histone proteins regulates cell-function and is involved in epigenetics. On the other hand, asymmetric dimethylarginine (ADMA), one of free methylated arginines released into body fluid after in vivo protein breakdown serves as an endogenous inhibitor of nitric oxide synthases (NOSs). ADMA is synthesized by protein arginine methyltransferases (PRMTs) and is degraded by dimethylarginine dimethylaminohydrolase 1 (DDAH1). In this study, to demonstrate the physiological significance of the metabolic pathways for methylated arginines in rat brain, in which ADMA was actively metabolized, we examined the localization of the metabolizing enzymes, DDAH1, PRMT1, PRMT5 and identified unknown arginine methylated proteins from rat brain by proteomic analysis.

Methods: standard.

Results: Several histological compartments were prepared from rat brain and subjected to western blot and immunohistochemical analyses. DDAH1, PRMT1, and PRMT5 were ubiquitously expressed in all regions of rat brain. Additionally, colocalization of PRMT1 and DDAH1 in the spinal cord was demonstrated by immunohistochemical analyses. These results suggest that the metabolic pathways implicated in biosynthesis and degradation of ADMA were driven actively in the central nervous system, including the spinal cord. Further, several arginine methylated proteins were detected by western blot analyses using crude extract of rat brain. Of them, fructose biphosphate aldolase C and ribose phosphate pyrophosphokinase 1 were identified as protein containing ADMA residues and SDMA residues, respectively, in the polypeptide.

Conclusions: Fructose biphosphate aldolase C is not only a glycolysis enzyme in brain, but also is known to be involved in the expression of light neurofilament. These findings lead us to further examine the implication of the regulated arginine methylation of these enzymes for neurodegeneration.

Key words: asymmetric dimethylarginine, arginine methylated protein, nitric oxide, fructose biphosphate aldolase C

PO150

FACTORS ASSOCIATED WITH BREASTFEEDING RATES AT BIRTH AND DISCONTINUATION BEFORE ONE MONTH, IN FRANCE IN 2012

B. Salanave¹, C. Guerrisi¹, C. de Launay¹, K. Castetbon¹

¹Institut de Veille Sanitaire, USEN, 74 rue Marcel Cachin, Bobigny, France

Background and objectives: France is one of the European countries where breastfeeding rates are among the lowest. Using data of the national survey Epifane on feeding practices during the first year of life, our objectives were to describe breastfeeding rates at birth and one month, and to identify factors associated with breastfeeding initiation and with early cessation before one month.

Methods: The Epifane survey was carried out using a 2-stage stratified random sample of infants born between the 16th of January and the 5th of April 2012 in 136 maternity wards in mainland France. Detailed information on breastfeeding and formula use was collected during the maternity stay and at one month. Factors associated with breastfeeding initiation and discontinuation were identified using logistic regressions.

Results: Out of 3366 infants included (participation rate: 81%), more than two third (69 %) were breastfed in maternity unit (60 % exclusively, 9 % partially). At one month, half of them (54 %) were breastfed but only 35 % exclusively. Breastfeeding rates were associated with mother's age, marital status,

education, birthplace, body mass index and smoking during pregnancy. Moreover, attending delivery preparation courses, early skin-to-skin contact and partner positive perception of breastfeeding were positively associated with breastfeeding initiation. Among mothers who have initiated breastfeeding at birth and for whom data were available at one month, 20% have stopped nursing their baby before the end of the 4th week. Factors associated with breastfeeding discontinuation were the same plus exclusive/mixed breastfeeding and various complaints such as mastitis.

Conclusions: Targeted programs should be implemented to support prolonged breastfeeding in young mothers and those from low educational level. Actions should also be particularly focused on the sharp fall of breastfeeding rates after home return, which is sizeable as early as at the first week after delivery.

Key words: Breastfeeding, Cohort, Newborns.

PO151

LOWER BETAINE INCREASES THE RISK OF NON-ALCOHOLIC FATTY LIVER DISEASE IN PATIENTS CARRYING THE CC GENOTYPE OF CHDH RS9001

H. Zhu¹, X. Wang¹

¹Department of Nutrition, Sun Yat-Sen University, Guangzhou, Guangdong, China

Background and objectives: The effect of methyl donors and genetic polymorphisms in metabolic enzymes on the risk of non-alcoholic fatty liver disease (NAFLD) is not well understood. The purpose of this study was to investigate the association of homocysteine, choline, betaine levels and the genetic polymorphisms of the related metabolic enzymes with the risk of NAFLD.

Methods: By utilizing a population-based study of 371 NAFLD cases and 699 controls, we used HPLC-MS to determine serum betaine, choline and homocysteine; gene mutations of PEMT, CHDH and BHMT were detected by multiplex SNaP-shot technology.

Results: The highest tertile of betaine level was associated with a lower risk of NAFLD [OR=0.670; 95% CI: 0.517-0.870] compared with the lowest tertile. A putatively functional single nucleotide polymorphisms of choline-metabolizing gene CHDH rs9001 was found to be related to NAFLD risk. Compared with the CC variant genotype, the AA+CA genotype was associated with a decreased risk of NAFLD (OR= 0.817; 95%CI: 0.693-0.962). The BHMT rs3733890 and PEMT rs7946 polymorphisms were also examined but were found not to be associated with NAFLD risk. The CHDH rs9001 CC genotype also had lower betaine concentrations compared with CA+AA genotype (P=0.060), PEMT rs7946 AA genotype had lower choline concentrations compared with GA+GG genotype

(P=0.070). Moreover, the gene-gene interaction analysis revealed a significant interaction of PEMT rs7946 and CHDH rs9001 with NAFLD susceptibility.

Conclusions: Our findings identified the CHDH rs9001 variant was associated with an increased risk of NAFLD and suggest that choline metabolism may play an important role in NAFLD.

Key words: NAFLD; Choline dehydrogenase(CHDH); Genetic polymorphism; Choline; Betaine

PO152

FACTOR ANALYSIS OF PATIENTS' SATISFACTION QUESTIONNAIRE TOWARD HOSPITAL FOODSERVICE IN A GOVERNMENT HOSPITAL IN MALAYSIA

R. Jamaluddin¹, N A. Abd Manan¹, H. Abu Saad¹, M S. Ab Karim¹

¹Universiti Putra Malaysia, Malaysia

Background and objectives: Accurate and reliable questionnaires are important to measure patients' satisfaction with hospital foodservice. However in Malaysia, there is no published evidence that the tool used is valid and reliable for hospital setting in Malaysia. Hence, the main purpose of the study was to investigate the construct validity and reliability of the developed questionnaire in a local setting.

Methods: An interview-administered questionnaire was used on a sample of 277 hospitalized patients in a government hospital. The questionnaire used in the study was adapted and modified from the Acute Care Hospital Foodservice Patient Satisfaction Questionnaire (ACHFSPSQ) by Capra et al., (2005), Hartwell et al., (2007), Hwang et al., (2003), O'Hara et al., (1997) and Dube et al., (1994), in order to suit the local setting, which consisted of 27 statements from 4 dimensions. A factor analysis and reliability analysis was conducted using SPSS version 19.

Results: The principal component of factor analysis revealed that the final questionnaire contained 25 individual statements for four main foodservice dimensions namely food properties, staff and meals service reliability, customisation and physical and social aspects. The reliability analysis also revealed the cronbach alpha value range at 0.55 to 0.84 for the foodservice dimensions. The analysis showed that the alpha value differed from one dimension to another dimension such as food properties $\alpha=0.84$, staff and meals service reliability ($\alpha=0.67$), customisation ($\alpha=0.69$) and physical and social aspects $\alpha=0.55$. The questionnaire on patients' satisfaction toward hospital foodservice was considered accurate and reliable based on the statistical analysis.

Conclusions: The classification of the four dimensions was

able to provide detailed information of the satisfaction level, relationship of the foodservice dimension and influence of dimension which contributed to satisfaction toward hospital foodservice.

Key words: Factor analysis, hospital foodservice, patients' satisfaction, Malaysia

PO153

EFFECTS OF GLUCOSE AND MAGNESIUM IN WATER SOLUTIONS ON WATER ABSORPTION IN THE SMALL INTESTINE

M. Tokunaga¹, M. Miyamoto¹, K. Ito², T. Yamaji², H. Itoh², N. Ota¹, T. Takahashi¹

¹Department of Nutrition and health Science, Fukuoka Women's University, Japan

²Food Science Research Labs, Meiji Co., Ltd., Japan

Background and objectives: The purpose of the present study was to determine effects of glucose and magnesium in water solutions on water absorption in the small intestine.

Methods: We used 8-weeks-old male SD rats (20 and 36 for experiments 1 and 2, respectively). We prepared 5 types of aqueous solutions containing 2 g/L polyethylene glycol 4000 as a non-absorbable marker and supplemented with 0, 96, 193, 289, 385 mmol/L D-glucose. We infused the aqueous solutions into the stomach in the conscious rat using oral sonde after food deprivation for 24 hours and water deprivation for 4 hours. At 10 minutes of the after infusion, we collected the digesta in the small intestinal lumen for measuring of water absorption and the concentration of glucose, cation and osmotic pressure (Experiment 1). We prepared 9 types of aqueous solutions containing 2 g/L polyethylene glycol 4000, 96.0 mmol/L D-glucose, 43.2 mmol/L sodium chloride, 17.3 mmol/L potassium chloride, and supplemented with 0, 0.25, 0.5, 1, 3, 5, 10, 15, 20 mmol/L magnesium chloride. We infused the aqueous solutions into the stomach in the conscious rat using oral sonde as in Experiment 1. After 10 minutes, we collected the digesta in the small intestinal lumen for measuring of water absorption and the concentration of glucose, cation and osmotic pressure (Experiment 2).

Results: The water absorption in the 96 mmol/L glucose solution was highest in the all groups (Quadratic effect; $p < 0.001$, GLM). The water absorption in the 0.5 and 1 mmol/L magnesium solution was highest in the all groups (Quadratic effect; $p < 0.001$, GLM).

Conclusions: The present study suggested the water absorption was increased in 96 mmol/L glucose and 0.5 or 1 mmol/L magnesium in the solutions.

Key words: water absorption, glucose, magnesium

PO154

PUPS OF DAMS FED RESTRICTED DIET DURING LACTATION CONSUME LARGER AMOUNT OF FAT TO ACHIEVE OPTIMAL GROWTH AFTER WEANING

A. Sato¹, A. Ebihara¹, Y. Nakashima¹

¹Department of Human Nutrition, Seitoku University, Matsudo, Chiba, Japan

Background and objectives: To investigate the influence of dietary restriction in dams during pregnancy and during lactation on food choice of their pups after weaning.

Methods: Control and restricted groups of dams were given either free access to AIN-93G (CTG) or restricted diet (60% of that consumed by a control group) during pregnancy (PRG) or during lactation (NRG), respectively. After weaning, all pups were placed on a two-choice diet program of a carbohydrate-protein diet (CPD) and a fat-protein diet (FPD) for 4 weeks (self-selection period).

Results: Although no significant difference in body weight at birth and on day 8 after birth was observed among the three groups, at weaning, the body weight in pups of the NRG was lower than that of the other groups. On day 8 after birth, although the stomach weight in the pups of the NRG was lower than that of the other groups, no significant difference in protein, carbohydrate and total lipid concentrations and PFC ratios in the stomach content were observed among these three groups. The ratio of body weight gain [body weight gain (g)/body weight at weaning (g)] during the self-selection period in the NRG was higher than that of the other groups. The FPD intake ratio [FPD intake (g)/total intake (g)] of the NRG during the self-selection period was also higher than that of the other groups.

Conclusions: It was considered from these results that the pups of the NRG needed a high energy density diet in order to attain a more normal size after weaning. Therefore, they spontaneously consumed a larger amount of the FPD than pups of the other groups.

Key words: dietary restriction, during lactation, self-selection, suckling pups, weaning pups

PO155**THE EFFECTS OF BETA GLUCAN ADMINISTRATION ON IMMEDIATE EARLY GENE IN THE BRAIN DURING EXHAUSTIVE EXERCISE**

J.H. Seo¹, C.J. Kim², H. Hong³

¹Division of Sports Science, Baekseok University, Cheonan, Chungcheongnam-do, Korea

²Department of Physiology, College of Medicine, Kyung Hee University, Seoul, Korea

³NBR Institute, CHA University, Pochon, Gyeonggi-do, Korea

Background and objectives: This study was conducted to investigate the effects of beta glucan on immediate early gene in the brain during exhaustive exercise in rats.

Methods: 60 male Sprague-Dawley rats were divided into six groups: control, exercise, exercise and 50 mg/kg beta glucan, exercise and 100 mg/kg beta glucan, exercise and 200 mg/kg beta glucan, and exercise and caffeine(100 mg/kg caffeine). The rats of the beta glucan-treated groups were administrated orally with the respective doses of beta glucan once a day for 7 days. The treatment was administered 60 min prior to the start of exercise. On the 7th day of the experiment, the time to exhaustion during treadmill running was determined for the exercise groups. The time to exhaustion was defined as the time between the commencement of exercise and the first occurrence of failing to keep up with the treadmill for a period of 3 min or more. The speeds used for determination of the exhaustion time were 10 m/min for 5 min, followed by 16 m/min, 18 m/min, 21 m/min, 24 m/min, 26 m/min, 29 m/min, 32 m/min, 34 m/min, 37 m/min for 3 min each and then 40 m/min until exhaustion.

Results: Treatment with 100 and 200 mg/kg beta glucan led to a significant increase in the time to exhaustion in response to running on a treadmill and a significant decrease in c-Jun and c-Fos expression in the dorsal raphe, the hypothalamus and hippocampal region.

Conclusions: The results of the present study demonstrated that the administration of beta glucan increased endurance exercise performance through inhibition of immediate early gene production in the brain.

Key words: beta glucan, gene, exercise

PO156**FUNCTIONALITY OF MILK FERMENTED DRINKS AT BOSNIA AND HERZEGOVINA MARKET**

Z. Saric¹, T. Dizdarevic¹, E. Kasumovic¹, A. Ibrovic¹, A. Jasarevic¹

¹Department of Food Science, Faculty of Agriculture and Food Sciences, University of Sarajevo, Sarajevo, Bosnia and Herzegovina

Background and objectives: It is well known that fermented milks serves as a good source of GRAS bacteria. Depending on type, viable cells of lactic acid bacteria and especially probiotic bacteria must be found in such products. By this way they can inhabit human colon after consumption and thus cause many benefits for host. Therefore, they have to comply with functionality criteria i.e. they have to contain more than 10⁶ cfu/ml. The aim of the work was to test functionality of fermented milks at Bosnia and Herzegovina market.

Methods: 15 samples of yogurt and probiotic drinks were purchased at the market in capital of Bosnia and Herzegovina, Sarajevo. Total count of viable cells, chemical composition and acidity were measured in chosen samples. In order to check functionality, six samples of fermented milks were stored at 4°C up to 21 day and they are tested to the same parameters. ANOVA with two factors without repetition was done to establish if there are differences among producers and time of storing.

Results: Mean value for total count of viable cells in yogurt samples was 207 x 10¹⁰ cfu/ml and in probiotics 137 x 10¹⁰ cfu/ml and all of them fulfil functionality criteria. At the end of storing at 4°C all samples retained higher count of cells than minimum required except one sample of probiotic. In general, the count was decreasing as the time went by. ANOVA did not show significant influence of storing time (except count of *S. thermophilus* at probiotics) as well as producer (except *L. delbrueckii* ssp. *bulgaricus* at yogurts).

Conclusions: There is real possibility that the count of viable cells decreases below minimum required after expiration of lifetime (25-30 days). Thus, consumers should take care of it during purchase of milk fermented drinks.

Key words: probiotics, functionality, viable cells, yogurt

PO157**LEAN VERSUS OBESE: MOLECULAR INSIGHTS AFTER THE INGESTION OF HIGH-FAT MEALS**

D. Gille¹, K. Kopf-Bolanz¹, F Schwander¹, C. Sonesson², B. Walther¹, G. Vergères¹

¹Federal Department of Economic Affairs, Education and Research EAER, Agroscope Liebefeld-Posieux Research Station ALP, Berne, Berne, Switzerland

²University of Lausanne, Swiss Institute of Bioinformatics, Lausanne, Vaud, Switzerland

Background and objectives: Previous findings in nutrition research indicate that obese people suffer from a metabolic disequilibrium leading to low-grade inflammation and other metabolic disorders whereby the molecular mechanisms are not utterly clarified. Studies that examine postprandially dose-response effects after the consumption of defined composed meals help to provide mechanistic information on these issues. Especially, the comparison of responses from lean and obese subjects should contribute to the understanding of metabolic differences.

Methods: A human intervention study was conducted including seven healthy lean and seven healthy obese volunteers who consumed one high-fat meal in three different caloric doses (500, 1000, 1500 kcal). Besides the determination of classical clinical parameters, also the blood cell transcriptome was measured before and 2h, 4h and 6h after ingestion. Genome wide gene expression was measured using microarray technology.

Results: 45 genes were differently expressed between lean and obese at fasting condition; 16 genes were up-regulated and 29 genes were down-regulated (FDR<0.05). Pathways analysis showed significant differences between the two population groups and included oxidative phosphorylation and other metabolic processes (p<0.001). Geneset enrichment analysis revealed significant caloric dose-dependent changes in gene expression in the lean group, in the obese group and, strikingly, between the two groups reflecting the disability of the obese volunteers to cope with meals of high energy content. Finally, postprandial changes occurred in the lean subjects in a direction that was predictive of the fasting status in the obese volunteers.

Conclusions: A comprehensive analysis of fasting and postprandial parameters comparing the response of lean subjects to the response of subjects with a metabolic deregulation allowed us to identify nutritional health biomarkers that may be used to characterize the interaction between food and the human organism, a strategy that may be of great value to food industry and to medicine.

Key words: obesity, high-fat meal, metabolism

PO158**BENEFICIAL ANTIOXIDANT EFFECTS OF POLYPHENOL-RICH EXTRA-VIRGIN OLIVE OIL IN HEALTHY VOLUNTEERS**

M J. Oliveras Lopez¹, G. Berná^{1,2}, H. López García de la Serrana³, F. Martín^{1,2}

¹Department of Molecular Biology and Biochemical Engineering, University of Pablo de Olavide of Seville, Seville, Spain

²CIBER de Diabetes y Enfermedades Metabólicas Asociadas, Barcelona, Spain

³Department of Nutrition and Food Science, Faculty of Pharmacy, University of Granada, Granada, Spain

Background and objectives: Several studies show that an increased intake of olive oil phenols influences protection against oxidation processes in chronic diseases. The aims were to study the effects of rich-polyphenol extra virgin olive oil (EVOO) in healthy humans, investigating each mechanism of action.

Methods: The 30-days nutritional intervention period involved 45 healthy volunteers, aged 21-45 years, who consumed daily 50 ml of raw EVOO and avoided a high polyphenolic diet, maintaining their physical exercise habits. Phenolic EVOO composition was analyzed by HPLC-DAD-MS. Anthropometric and body composition parameters, biochemical parameters, plasma total antioxidant capacity (TAC), erythrocyte antioxidant enzyme activity and their lymphocyte gene expression were determined. All data were analyzed by the SPSS 17.0 statistical package (SPSS, Inc.) by the t test and the non parametric Wilcoxon test as applicable.

Results: The EVOO used had an appropriate qualitative composition of phenolics. Nutritional, anthropometric, body composition and biochemical parameters did not significantly changed. We observe that EVOO supplementation significantly increased TAC (p<0,001). A significant increase (p<0,01) in CAT and GTPX activity was also observed. No significant difference was observed in SOD activity. EVOO supplementation significantly modified (p<0,05) antioxidant enzyme gene expression. Studies with humans have proved that dietary interventions with rich-phenol foods elevate TAC however, most reported changes in these enzymes have not occurred in healthy people.

Conclusions: Daily consumption of EVOO rich in phenolic compounds, by healthy adults, improved their antioxidant status and modified their antioxidant gene expression levels without modifying any physiological characteristics.

Key words: Extra virgin olive oil; polyphenol; healthy; antioxidant enzyme; gene expression

PO159**IMPROVEMENT OF NUTRITIONAL PROPERTIES IN FRANKFURTERS BY FATTY ACID MODIFICATION**

L. Salcedo-Sandoval¹, S. Cofrades¹, C. Ruiz-Capillas¹, F. Jiménez-Colmenero¹

¹Instituto de Ciencia y Tecnología de Alimentos y Nutrición (ICTAN-CSIC), Madrid, Spain

Background and objectives: Frankfurters have a large market especially among a particular sector of the population. Since their fat (quantitatively and qualitatively) normally diverge from dietary goals, our objective in this work was to develop frankfurters with better lipid composition (reduced fat content and improved lipid profile) by replacement the animal fat with a combination of healthier oils (plant and/or marine origin) stabilized in an oil-in-water emulsion, as a strategy of reformulation.

Methods: Control frankfurter was manufactured with fresh post-rigor pork meat, pork backfat, flavouring and additives. In the reformulated frankfurter the pork backfat was partially replaced by an oil-in-water emulsion prepared with a combination of olive, linseed, and fish oils, and using sodium caseinate as emulsifier. Composition analysis and fatty acid profile were determinate.

Results: Fat content of frankfurter was reduced from 18.88% (control frankfurter) to 10.27% (modified frankfurter). Reformulated frankfurters contained 4.10 g/100 g of the combination of oils providing a significant change in the lipid profile. SFA content was lowered by a 56% while PUFA was increased almost 400%. The modified frankfurter provided 190 mg/100 g of long chain n-3 PUFA and 0.9 g/100 g of alpha linolenic fatty acid.

Conclusions: Based in reformulation strategies, an improved fat content frankfurter was obtained. The changes induced in reformulated product composition are such as to allow carrying different nutritional claims: "reduced fat content" and "high omega 3 fatty acid content", according Regulation (EC) No 1924/2006 and No 116/2010 of the European Parliament and of the Council (2006, 2010). Additionally (pursuant to Commission Regulation No 432/2012), the modified frankfurters may carry some cardiovascular health claims. This research was supported by project AGL2011-29644-C02-01.

Key words: Frankfurter/ Healthier oil combination / Fatty acid profile / Oil-in-water emulsion

PO160**HEALTH BENEFITS OF WHOLE GRAIN WHEAT: INTERVENTION STUDY CLARIFYING UNDERLYING MECHANISMS AND THE ROLE OF POLYPHENOLS BOUND TO DIETARY FIBRE**

V. Fogliano¹, P. Vitaglione¹

¹University of Naples, Naples, Italy

Background and objectives: Epidemiological studies associate whole grain (WG) consumption to reduced CVD risk, body weight and abdominal circumference. Data obtained by intervention studies were not conclusive. Evidence from animal and few human studies indicated that prebiotic dietary fibre ameliorates metabolic syndrome. Whole grain, especially wheat and rye, present a large amount of polyphenols (mainly ferulic acid) bound to dietary fibre. This study aims to assess the role of dietary fiber polyphenols on health benefits of WG.

Methods: A commercial WG product, was selected. Eighty healthy overweight subjects were enrolled. Forty volunteers replaced equicaloric portions of specific foods with 68 g WG/day for 8 weeks; the other half did not change their diets. At baseline, and after 4 and 8 weeks, body weight, waist and hip circumferences, bioimpedance analysis and blood, urine and feces collection was measured. Markers linked to bioavailability of ferulic acid and several polyphenols (by HPLC/MS/MS), to inflammatory status (several cytokines by multiplexed immunometric assay), to lipid and glucose metabolism as well as to the overall nutritional status and appetite, were measured. Metagenomic analysis of feces was run to evaluate the influence of intestinal microflora composition on the health benefit of a WG-enriched diet.

Results: 63 subjects (34 treated with WG and 29 controls) completed the study. Preliminary results indicate different concentration trends for inflammatory cytokines and ferulic acid-related metabolites in blood collected from subjects who consumed WG compared to control subjects over the study period. Data analysis is still ongoing and all final results will be crossed with metagenomic data to ascertain the role of individual microflora on bioavailability of polyphenols bound to WG dietary fiber as well as on health effect.

Conclusions: Consumption of wheat whole grain might improve inflammatory status in overweight subjects

Key words: whole grain, ferulic acid, prebiotic, inflammation

PO161**MAINTAINING CHANGE: WHAT DIFFERENCE DOES PARTICIPATING IN AN INTENSIVE DIETARY INTERVENTION MAKE FIVE YEARS ON?***S L. O'Reilly¹, L. Riddell¹, C. Nowson¹*¹Centre for Physical Activity and Nutrition Research, Deakin University, Australia

Background and objectives: Evidence supports cardiovascular disease (CVD) risk reduction through dietary manipulation, however dietary research interventions typically last under 12 months and require high levels of participant support to achieve change. Given the chronic nature of CVD, the long term health outcomes of intensive interventions in free-living individuals are of particular interest. This study sought to determine if participating in an intensive modified DASH intervention significantly impacted CVD risk biomarkers 5 years after participation, compared to standard healthy eating education.

Methods: 40 adults (n=30 DASH, n=10 standard) participated in this cross-sectional follow-up study. The study collected fasting blood samples, dietary data, blood pressure (BP), body mass index (BMI) and 24h urine collections from all participants 5y after the original intervention. Paired T-tests were conducted to examine the effect of time from follow-up to intervention completion and also to baseline status.

Results: Neither group maintained the level of change achieved during the intervention period. The DASH group's BP increased by 9% systolic and 17.3% diastolic (p<.05) and the standard group increased their BMI, total cholesterol and BP by 6.8%, 15.8%, 9.5% respectively (p<.05) compared to the intervention endpoint. Both groups had raised HDL cholesterol levels (DASH 13.1%, standard 14.7%) (p<.05). However when compared to baseline, only the DASH group's blood lipids were improved (total (9.8%) and LDL cholesterol (14.6%) decreased and HDL cholesterol (7.8%) increased) (p<.05). Neither group had significant weight gain nor BP change compared to baseline. **Conclusions:** Although long-term dietary change appears to be difficult to maintain, some health gains can be achieved through participating in an intensive dietary intervention, with DASH participants having healthier blood lipid profiles. Both groups were weight and BP stable after 5y, which suggests personalised education supports some dietary change maintenance.

Key words: dietary change, CVD, DASH diet

PO162**INTRACELLULAR METABOLISM OF ISOFLAVONES IN HUMAN ENDOTHELIAL CELLS***N. Toro Funes¹, A. Rodríguez Mateos², J P E. Spencer², M T. Veciana Nogués¹, M C. Vidal Carou¹*¹Department of Nutrition and Food Science, Universidad de Barcelona, Santa Coloma de Gramenet, Spain²Department of Food and Nutritional Sciences, University of Reading, Reading, United Kingdom

Background and objectives: Soy isoflavones have received much attention because of their potential benefits as phytoestrogens (Patisaul & Jefferson, 2010). Accumulated evidence suggests that their consumption may have beneficial effects on cardiovascular health, including a favourable effect on blood lipids, inhibition of platelet aggregation and improvement of vascular function (Rimbach et al., 2008). Recent studies have shown that genistein and daidzein are metabolized after absorption by Phase-II-enzymes to form mainly glucuronides and sulfate-metabolites (Hosoda et al., 2010). Their metabolism has been well-reported in cell models of the gastrointestinal tract or in hepatic models, but little attention has been given to the potential intracellular metabolism of isoflavones in human umbilical vein endothelial cells (HUVEC), despite being widely used in vitro models for assessing mechanisms of action of polyphenols in the vascular endothelium (Andrade et al., 2011). Therefore, the aim is to determine whether HUVEC can metabolize isoflavones, using Hep-G2 (liver cell model) and CACO-2 monolayer (small-intestine model) as positive controls.

Methods: Genistein, daidzein and equol (0-10µM) were incubated with HUVEC, Hep-G2 and Caco-2 monolayer cell lines for 2 hours. Supernatants and cell lysates were collected and processed for analysis. Aglycones were determined by liquid chromatography following the method by Toro-Funes et al. (2012). Isoflavone metabolites were identified with mass spectrometry detection.

Results: In HUVEC, aglycones, methyl conjugates of genistein and daidzein, and a genistein-methyl-sulfate were detected in the supernatant and cell lysates. In Hep-G2 cells, aglycones, glucuronides of genistein and daidzein, a genistein-methyl-glucuronide and a genistein-sulfate were found. In Caco-2 monolayer, glucuronides of genistein and daidzein were detected beside the aglycones.

Conclusions: Genistein and daidzein are metabolized into their methyl conjugates in endothelial cells, while equol metabolites were not detected. These findings may have important implications in the investigation of the cardioprotective mechanisms of action of isoflavones.

Key words: endothelial cells, isoflavones, intracellular metabolism.

PO163**CAN PARENTS BE REACHED THROUGH A SCHOOL-BASED FRUIT- AND VEGETABLE INTERVENTION?***M.F. Dalane¹, E. Bere¹*¹Faculty of Health and Sport, University of Agder, Kristiansand, Norway

Background and objectives: Fruit and vegetable consumption is negatively correlated with a number of chronic diseases. One of the greatest nutritional challenges is to increase the consumption of fruit and vegetables in the entire population. Increased consumption of fruit and vegetables contributes to the prevention of most prevalent chronic diseases. The consumption of fruit and vegetables in Norway is generally low. Adults eat about half of the recommended daily intake. Several school-based fruit and vegetable interventions include activities that involve parents, but not much is known about the effectiveness of such a parent component on child and parent intake level.

Methods: This study is part of the intervention study Fruit and Vegetable Make the Marks (FVMM). FVMM aimed at increasing fruit and vegetable consumption among school-children and their parents. The intervention was carried out among 6th and 7th graders from September, 2001 (baseline) to May 2002 (follow-up 1). Six specific newsletters were distributed to the parents during the intervention period. These newsletters aimed at increasing communication between parents and their children concerning fruit and vegetables, and also to stimulate to increased availability of fruit and vegetables at home. The projects were also presented at parents' meetings at school.

Results: A significant effect of the intervention (the newsletters and the parents' meeting) was observed ($p=0.015$). The intake of fruit and vegetables decreased from baseline to follow-up 1 for both groups (intervention and control), but the reduction in the intervention group is lower (-0.27 portions/day) than in the control group (-0.62 portions/day). The effect of the intervention is hence 0.35 portions/day.

Conclusions: We conclude that the parents were reached to a certain extent through the school-based intervention study primarily aimed at pupils. Whether the effect will last over time would demand further study.

Key words: fruit and vegetable, parents, school-intervention

PO164**DIFFERENT SOURCES OF DIETARY LIPIDS: EFFECT ON LIPID PROFILE OF GROWING RATS.***P. Perris¹, I. Fernandez¹, C. Mambrin¹, N. Slobodianik¹, M.S. Feliu¹*¹Nutrition and Food Science, University of Buenos Aires. Faculty of Pharmacy and Biochemistry, Argentina

Background and objectives: The importance of diet in maintaining health is widely accepted and recognized. Diet lipid profile is important to prevent chronic diseases and improve the quality of life of individuals. The objective is to analyze the effect of different sources of dietary lipids with normal and high concentration, on triglycerides (TG), total cholesterol (TC), non-HDL cholesterol and fatty acid profile of growing rats.

Methods: Weanling Wistar rats were fed during 10 days: 15% or 45% dietary fat provided by butter (B15, B45 groups); by olive oil (O15, O45 groups). Control group (C) received normocaloric diet according to AIN'93. Diets fatty acid profiles were determined by gas chromatography (GC); $\omega 6$ and $\omega 3$ and unsaturated/saturated (UFA/SFA) ratios of diets were calculated. Serum levels of TG, TC and chol-noHDL were determined by enzymatic-colorimetric method and fatty acid profile was determined by GC.

Results: $\omega 6$ and $\omega 3$ diets ratio: B=8.7/1; O=15/1; C=9/1; UFA/SFA, B=0.54; O=4.2; C=5.5. Serum (mean \pm SD mg/dL) TG B15=72.2 \pm 24.3, B45=113.0 \pm 31.2*; O15=61.5 \pm 19.4, O45=77.6 \pm 12.1*; C=58.9 \pm 15; TC B15=58.7 \pm 10.3; B45=89.2 \pm 10.1*; O15=66.9 \pm 11.9; O45=73.1 \pm 7.3; C=62.1 \pm 13.9; chol-noHDL B15=28.7 \pm 9.3; B45=52.7 \pm 9.8*; O15=35.1 \pm 10.2; O45=50.9 \pm 8.9*; C=36.1 \pm 10.3. Fatty acid profile (area% \pm SD): Oleic: B15=18.2 \pm 1.6*, B45=19.1 \pm 5.2*; O15=19.4 \pm 3.4*; O45=22.0 \pm 5.1*; C=10.6 \pm 2.0. Linoleic: B15=7.7 \pm 1.9*; B45=8.9 \pm 1.8*; O15=12.4 \pm 1.9*; O45=11.8 \pm 2.8*; C=20.0 \pm 4.7. α -Linolenic: B15=0.4 \pm 0.1*; B45=0.4 \pm 0.11*; O15=0.34 \pm 0.01*; O45=0.5 \pm 0.2*; C=1.0 \pm 0.3. (* p <0.01) TG levels in B45 and O45 were statistically higher compared to C while TC level is only higher in B45. Experimental groups showed higher serum oleic acid levels with lower α -linolenic and linoleic acids levels compared to C.

Conclusions: The administration of these diets provoked changes in serum fatty acid profile levels in response to differences in the sources of dietary lipids used, but not in response to the high fat percentage. This fact would exacerbate the route of the $\omega 9$ family and decrease essential fatty acids.

Key words: diet, lipid profile, rat

PO165**HIGHT FAT LEVEL DIETS: IMPACT ON FATTY ACID COMPOSITION OF SERUM AND THYMUS OF ADULT RATS.**

C. Silva¹, P. Perris¹, I. Fernandez¹, C. Mambrin¹, N. Slobodanik¹, M S. Feliu¹

¹Nutrition and Food Science, University of Buenos Aires, Faculty of Pharmacy and Biochemistry, Argentina

Background and objectives: Diet's fatty acids profile has an essential function as immune regulator. The aim of this study was to analyze the effect of diets containing high levels of fat from different sources, on serum and thymus fatty acid composition of adult rats.

Methods: Wistar rats(50 days of age) divided in 3 groups were fed during 40 days with diets containing 1)50Kcal% fat provided by sunflower oil (group S), 2) 50Kcal% fat provided by butter (group B) and 3) normocaloric diet (group C). All diets had 20% protein and were complete in all other nutrients according to AIN '93. Diets fatty acid profile was determined by gas chromatography(GC) and $\omega 6$ & $\omega 3$ and unsaturated/saturated(U/S) ratios were calculated. At the end of the feeding period, animals were sacrificed and thymus was removed. Serum and thymus fatty acids profile were determined by GC. Anova test was performed.

Results: $\omega 6$ & $\omega 3$ diet's ratio: B: 8.7/1, S: 250/1, C: 9/1; U/S diet's ratio: B: 0.54, S: 9.2, C: 5.0. Fatty acid levels were expressed as %area(X \pm SD). Serum: total saturated: S=29.99 \pm 1.75, B=35.91 \pm 3.13, C=32.88 \pm 1.63; Oleic: S=9.58 \pm 2.00, B=17.71 \pm 2.85, C=10.08 \pm 1.34; Linoleic: S=21.93 \pm 4.15, B=8.38 \pm 0.79, C=16.39 \pm 2.35; Linolenic: S=0.42 \pm 0.09, B=0.43 \pm 0.11, C=0.93 \pm 0.18. Thymus' cells: total saturated: S=26.72 \pm 3.24, B=40.53 \pm 4.6, C=37.56 \pm 2.20; Oleic: S=19.88 \pm 2.96, B=23.68 \pm 9.54, C=24.29 \pm 4.94; Linoleic: S=34.97 \pm 6.73, B=3.84 \pm 0.56, C=12.74 \pm 1.90; Linolenic: S=0.27 \pm 0.07, B=0.39 \pm 0.09, C=0.60 \pm 0.11(*p<0.01). S had lower serum and thymus' cells levels of $\omega 3$ acids and higher linoleic concentration. B showed higher serum oleic acid levels with lower levels of α -linolenic and linoleic compared with control group. Thymus' cells showed lower levels of α -linolenic and linoleic acids.

Conclusions: The differences on fatty acid composition of serum and thymus' cells in adult rats would be a consequence of the differences in diets' fatty acid profile: altered $\omega 6$ & $\omega 3$ ratio in S group and U/S ratio in group B, and the high percentage of fat in each diet.

Key words:Fatty acids-Thymus-Rat

PO166**BENEFITS OF LEGUME PROTEIN HYDROLYZATES AND AEROBIC INTERVALLIC EXERCISE ON VARIOUS PARAMETERS OF METABOLIC SYNDROME**

A. Andrade¹, G. Kapravelou¹, R. Martínez¹, V. Aparicio¹, E. Nebot¹, D. Camiletti¹, L. Bustos¹, P. Aranda¹, M. López-Jurado¹, E J. Bedmar², F. Arrebola³, M. Galisteo⁴, J M. Porres¹

¹Department of Physiology, School of Pharmacy, Institute of Food , Science and Technology, University of Granada, Granada, Spain

²Department of Soil Microbiology and Symbiotic Systems, Estación Experimental del Zaidín, CSIC, Granada, Spain

³Department of Histology, School of Medicine, Institute of Neurosciences, University of Granada, Granada, Spain

⁴Department of Pharmacology, School of Pharmacy, University of Granada , Granada, Spain

Background and objectives: Consumption of protein hydrolyzates from legumes and the regular practice of physical exercise provide important health benefits. This research work aimed to study the influence of consuming crude or hydrolyzed protein from *Vigna radiata* and its interaction with a program of aerobic exercise on various parameters of metabolic syndrome in an experimental animal model of genetic obesity.

Methods: 80 Zucker rats were divided into 2 experimental groups that consumed raw or sprouted *Vigna radiata* diet. These two groups were subdivided into 4 experimental subgroups (n=10) according to genetic (lean vs obese) and lifestyle (sedentary vs exercise) factors. The study lasted for 8 weeks, and regular food intake and body weight controls were performed. The protocol of aerobic interval training took place 5 days a week increasing in intensity and duration along the experimental period.

Results: The characteristic hyperphagia of obese Zucker rats was reflected in higher body weight gain of these animals when compared to the lean groups. Significant hepatomegalia and steatosis was observed among the obese rats, whereas the protocol of intervallic aerobic exercise was effective at improving both conditions. Aerobic intervallic exercise was also an efficient strategy to diminish quadriceps atrophy in obese animals and decrease the weight of abdominal adipose tissue, although the later finding was more evident in lean when compared to obese rats. Oral administration of a glucose overload to obese rats led to a significantly smaller area under the curve in rats that followed the protocol of aerobic intervallic exercise when compared to the obese sedentary animals.

Conclusions: The combination of an aerobic intervallic training protocol with consumption of a legume protein hy-

drolyzate based on sprouted *Vigna radiata* is as an adequate intervention to mitigate the symptoms of metabolic syndrome.

Key words: Metabolic syndrome; protein hydrolyzates; *Vigna radiata*; aerobic intervallic exercise

P167

THE EFFECT OF IRON/ZINC SUPPLEMENTATION AND ITS DISCONTINUATION ON INTESTINE ANTI-OXIDANT STATUS IN RATS FED DEFICIENT DIETS

J. Kaluza¹, D. Madej¹, E. Wierzbicka¹, B. Pietruszka¹

¹Department of Human Nutrition, Warsaw University of Life Sciences – SGGW, Warsaw, Poland

Background and objectives: High doses of iron can initiate the process of hydroxyl radicals production, while zinc as an indirect antioxidant can protect against the damage induced by free radicals. Therefore, the effect of iron or simultaneous iron/zinc supplementation on rat intestine antioxidant status was investigated.

Methods: The study was conducted on 6-week male Wistar rats, in 3 stages: 1) 4-week adaptation to the diets (C - control AIN-93 diet, D - iron deficient or R - with 50% reduction of all vitamins and minerals compared to C-diet); 2) 4-week supplementation with 10-fold more iron (CSFe, DSFe, RSFe) or iron and zinc (CSFeZn, DSFeZn, RSFeZn) compared to C diet; 3) 2-week post-supplementation period (the same diets as during the adaptation stage).

Results: After stage II in the intestine: 1) the iron content in supplemented groups was significantly higher than in corresponding non-supplemented groups (the effect was also observed after stage III); 2) catalase activity in RSFe group was higher than in R and RSFeZn; 3) ceruloplasmin activity was higher in RSFeZn group compared to R and RSFe; 4) thiobarbituric acid-reactive substances concentration was significantly higher in DSFeZn group than in D and DSFe; 5) the level of protein carbonyl groups in RSFeZn rats was higher than in R and RSFe (the effect was also observed after stage III). There was not found the effect of applied treatments on zinc status and superoxide dismutase and glutathione peroxidase activity.

Conclusions: Simultaneous iron/zinc supplementation could have negative impact on intestine antioxidant status. The prolonged effect of applied treatments was observed in intestine on iron content and levels of protein carbonyl groups. There is a need for the further analysis to explain observed relationships.

Key words: iron, zinc, antioxidant status, intestine, supplementation

²National Centre of Biopreparation Bejucal, Mayabeque, Cuba

Background and objectives: Fe-deficiency anaemia is one of the major health problems, therefore it is important to supply Fe with high bioavailability during its recovery. The study was designed to assess the effect of several Fe amounts and sources on haematological parameters, DNA, protein and lipid oxidative damage.

Methods: The rats were placed on a pre-experimental period of 45 days and divided into two groups: control group (n=10) receiving normal-Fe diet (45 mg/kg) and anaemic group (n=30) receiving low-Fe diet (6 mg/kg), to induce Fe-deficiency. Subsequently, the rats were placed on an experimental period of 30 days in which they were fed with three different sources and amounts of Fe: FeSO₄ (F diet) (45 mg Fe/kg), haem Fe (H diet) (2 mg Fe/kg) or FeSO₄ + haem Fe (C diet) (21 mg Fe/kg). DNA damage was assessed using the alkaline comet assay and the brain, liver, erythrocyte and duodenal mucosa lipid peroxidation and protein damage was also assessed.

Results: After supplying the diets, all the haematological parameters were recovered. DNA damage was lower with H diet, compared with F (P <0.001) and C (P <0.05) diet, and similar to the controls. Lipid peroxidation was similar to the controls in all tissues, except in duodenal mucosa, which was lower with H and C diet (P <0.001). The animals fed H and C diets showed lower oxidative protein damage in duodenal mucosa (P <0.01 for H and P <0.001 for C diet) and plasma (P <0.001 for both). Finally, no differences were found in brain.

Conclusions: Fe supplementation with low doses of haem Fe or combined forms of Fe (FeSO₄ + haem Fe) are efficient restoring the impaired haematological parameters and prevents the evoked oxidative stress associated to Fe supplements.

Key words: Oxidative damage; Fe deficiency anaemia; Fe repletion; Haem Fe; Ferrous sulphate

PO169**IRON, COOPER AND ZINC BIOAVAILABILITY DURING IRON DEFICIENCY ANEMIA RECOVERY WITH SEVERAL SOURCES AND AMOUNTS OF IRON**

Y. García¹, J. Díaz-Castro², M I. López-Aliaga², M J M. Alférez², S. Hijano², T. Nestares², M S. Campos², A. Sánchez-Alcover²

¹National Centre of Biopreparation, Bejucal, Mayabeque, Cuba

²Department of Physiology, Faculty of Pharmacy, Institute of Nutrition and Food Technology, University of Granada, Granada, Spain

Background and objectives: In the treatment of the anaemia, several Fe salts traditionally have been used and the combination of haem and non haem Fe increase Fe bioavailability. The aim of this study was to elucidate the effects of different amounts and sources of Fe on the nutritive utilization of Fe, Cu and Zn and on haematological parameters in rats with induced nutritional Fe deficiency.

Methods: The control group received the AIN 93 G diet with normal Fe content, and the anaemic group receiving a low-Fe diet (6 mg/kg) for 40 days, to induce Fe-deficiency. During the experimental period of 30 days the anaemic rats received diets with different sources and amounts of Fe: FeSO₄ (F diet) (45 mg/kg diet), haem Fe (H diet) (2 mg/kg diet) or FeSO₄ + haem Fe (C diet) (21 mg/kg diet).

Results: No differences were found between the three anemic groups in apparent digestibility coefficient and retention/intake of Fe, due to the lower fecal and urinary Fe excretion in the anemic groups fed the H and C diets compared with the group fed the F diet. No differences between the three anemic groups in ADC and R/I of Cu were found. The ADC and R/I of Zn were lower for the anemic rats fed the H diet than for the anemic group fed the F and C diets (P<0.001).

Conclusions: Combined forms of haem/non haem in low doses are efficient restoring the impaired hematological parameters and improve the nutritive utilization of Fe and produce no changes in that of Cu or Zn. These findings could provide a basis for similar Fe supplement therapies in high risk populations and represent a promising novel formulation, minimizing the undesirable effects of high doses of Fe.

PO170**ESTIMATED 24-HOUR SODIUM EXCRETION AMONG DANISH ADULTS AND THE ASSOCIATION WITH HYPERTENSION**

B. Thuesen¹, U. Toft¹, A. Linneberg¹, T. Jørgensen¹

¹Research Centre For Prevention and Health, The Capital Region of Denmark, Denmark

Background and objectives: Recently we developed a model to estimate 24-hour urinary sodium excretion on a population level based on sodium and creatinine measurements in samples of spot urine. The objective of this study was to use the model to estimate the 24-hour sodium excretion and thus the daily salt intake of Danish adults. Also, we aimed to evaluate the association between estimated salt intake and hypertension.

Methods: We included 3294 men and women aged 18-69 years from the population based Danish Health2006 cohort. Estimated 24-hour sodium excretion was calculated from measurements of creatinine and sodium in spot urine. The relation between 24-hour sodium excretion and blood pressure was evaluated by linear and logistic regression models.

Results: The mean estimated 24-hour sodium excretion among men was 4.32g (5%/95% percentiles: 3.06g/5.73g) and among women 2.43g (5%/95% percentiles: 2.43g/3.57g), corresponding to daily salt intakes of 10.80g and 7.52g, respectively. High salt intake was associated with high blood pressure (p<0.0001, linear regression adjusted for confounding by sex and age). The prevalence of hypertension was 46.1% among men and 34.1% among women in the highest quartile of estimated daily salt intake, while the prevalence was 31.4% and 20.5% among men and women, respectively, in the lowest quartile. The effect of salt intake on blood pressure was markedly attenuated when adjusting for BMI. However, obesity and high salt intake are highly correlated and thus BMI may be considered a mediator more than a confounder when evaluating the association between salt and hypertension.

Conclusions: The daily mean intake of salt estimated from measurements of creatinine and sodium in spot urine is 10.80g among men and 7.52g among women. A high daily salt intake is associated with increased blood pressure – however this association is markedly affected by adjustment for BMI.

Key words: Salt, Hypertension, Spot urine, Adults

PO171**GENETIC VARIANTS IN THE TMPRSS6 GENE AND IRON STATUS INDICATORS: A SYSTEMATIC REVIEW WITH META-ANALYSES**

W. Gichohi-Wainaina¹, A. Melse-Boonstra¹, E. J. Feskens¹, G. W. Towers², D. W. Swinkels³, M. B. Zimmermann^{1,4}

¹Division of Human Nutrition, Wageningen University, the Netherlands

²Centre of Excellence for Nutrition, North West-University, Potchefstroom Campus, South Africa

³Laboratory of Genetic, Endocrine and Metabolic Diseases, Department of Laboratory Medicine, Radboud University Medical Center, Nijmegen, the Netherlands

⁴Laboratory of Human Nutrition, ETH, Zurich

Background and objectives: No clear overview of the genetics of iron deficiency, iron deficiency anaemia or anaemia in relation to TMPRSS6 gene variants exists. We conducted a study to systematically review the evidence for the associations between single nucleotide polymorphisms (SNPs) in the TMPRSS6 gene and iron status. Where possible, results were analysed using meta-analyses.

Methods: An electronic literature search was conducted using HuGE Navigator for studies published up till 2012, as well as the PubMed and scopus databases to include manuscripts published prior to 2001. All relevant data was extracted. Forest plots were generated and heterogeneity between studies was investigated. Funnel plots as well as Egger's and Begg's tests were used to check for publication bias.

Results: A total of 14 articles were included in the final review. The majority of the studies were either conducted in subjects of Caucasian (n = 12; 86%) or Asian origin (n = 2; 14%). No study was conducted within the African population. High heterogeneity was observed between studies. Differences in directions of associations, beta values as well as minor allele frequencies were observed between ethnicities. In one of the Asian studies, the iron lowering risk alleles of rs855791 and rs4820268 (as determined in Caucasian populations) were significant genetic risk factors for ID and IDA. In a similar study conducted among Danish blood donors neither of the two SNPs were significant predictors of low serum ferritin levels.

Conclusions: We highlight discrepancies in the associations of genetic variants in the TMPRSS6 gene and iron status between ethnicities. Additionally, a critical knowledge gap exists with regard to the investigations on genetic variants in TMPRSS6 and iron status within the African population.

Key words: TMPRSS6, SNPs, anaemia, iron status, systematic review

PO172**PERIPHERAL BLOOD MONONUCLEAR CELLS (PBMC) AS A SOURCE TO DETECT MARKERS OF INTAKE OF DIETS WITH UNBALANCED PROPORTION OF MACRONUTRIENTS**

R. Díaz-Rúa¹, P. Oliver¹, E. Van Schothorst², A. Caimari³, J. Keijer², A. Palou¹

¹Laboratory of Molecular Biology, Nutrition and Biotechnology (LBNB), University of the Balearic Islands and CIBER Fisiopatología de la Obesidad y Nutrición (CIBERObn), Palma de Mallorca, Spain

²Department of Human and Animal Physiology (HAP), Wageningen University, Wageningen, The Netherlands

³Centre Tecnològic de Nutrició i Salut (CTNS), TECNIO, CEICS, Reus, Spain

Background and objectives: Unbalanced proportion in diet macronutrients is associated to alterations in body weight and/or metabolic parameters, and can be related to different pathologies. In order to find markers of intake of unbalanced diets we analysed gene expression in peripheral blood mononuclear cells (PBMC). PBMC constitute an easy obtainable biological material which use for nutrition studies is increasing as they can reproduce gene expression of other internal tissues and reflect different pathological status.

Methods: Wistar rats were fed for 4 months with a control (70% Kcal from carbohydrates), a high-fat (HF; 60% Kcal from fats) or a high-protein (HP; 45% Kcal from proteins) diet in isocaloric amounts (pair-feeding). PBMC were obtained and gene expression studied by microarray analysis.

Results: Our microarray data showed that 113 and 323 genes of a total of 21,530 probes changed as a result of the intake of a HF and a HP diet, respectively (Student's t test, p<0.05, fold change $\geq \pm 1.2$). Pathways mainly affected by HF diet were: cell cycle, gene expression, immune response, cell communication/signal transduction and energy metabolism. Between genes related to energy metabolism, two key lipolytic genes were affected, Cpt1 and Acox1, whose expression increased as result of the intake of the HF diet. HP diet affected mainly to: cell communication/signal transduction, gene expression and immune response (21 of these genes were related to antigen recognition). Energy metabolism-related genes were also affected by the HP diet, and also in this case an increase was observed in Acox1 expression. Interestingly, 10 genes were simultaneously and equally altered by both unbalanced diets (HF/HP).

Conclusions: Gene expression analysis in PBMC could be useful to detect metabolic deviations of a diet with a proper and equilibrated macronutrient composition.

Key words: PBMC, high-fat diet, high-protein diet

PO173**ELEMENTAL DIETS WITH DIFFERENT FAT COMPOSITION IN EXPERIMENTAL COLITIS**

E. Papada¹, A. Gioxari², Kaliora², A. Papalois³, A. Forbes¹

¹Centre for Gastroenterology and Nutrition, University College London, London, UK

²Department of Science of Dietetics–Nutrition, Harokopio University, Athens, Greece

³Experimental Research Unit, ELPEN-Pharmaceuticals Co. Inc., Pikermi Attikis, Greece

Background and objectives: Inflammatory bowel disease (IBD) is a chronic condition including ulcerative colitis and Crohn's disease. Nutritional therapy seems to be an alternative for intolerant to potent drugs patients. The role of dietary fat in the therapeutic potential of enteral nutrition remains under investigation. The objective of this study was to evaluate the effectiveness of two isoenergetic elemental formulas with different fat content in a rat model of trinitrobenzene sulfonic acid (TNBS) colitis that mimics human IBD.

Methods: Forty five male Wistar rats were assigned into 5 groups: 1) control group, 2) TNBS-colitis group, 3) TNBS-colitis group fed on a long-chain triglycerides (LCT) rich diet, 4) TNBS-colitis group fed on a medium-chain triglycerides (MCT) rich diet, 5) TNBS-colitis group fed on a baseline diet and administered with infliximab. Nutritional management lasted 12 days prior and 4 days next to rectal administration of TNBS. Subsequently, animals were sacrificed and colon tissue samples were collected for histological, inflammation and oxidative stress assessment.

Results: The MCT-rich diet decreased IL-6, IL-8, ICAM-1 and glutathione-S-Transferase (GST) activity, while the LCT-rich diet reduced ICAM-1 and GST activity ($p < 0.05$). None of the elemental formulas affected IL-10. Infliximab reduced IL-8, ICAM-1 and GST activity levels and increased IL-10 levels ($p < 0.05$). No significant differences were detected in malondialdehyde.

Conclusions: A MCT-rich formula seems to exert stronger anti-inflammatory properties than a LCT-rich formula in TNBS-colitis. Further research in humans is necessary to extrapolate the results to human IBD.

Key words: IBD; Elemental Formula; MCT

PO174**CHRONIC MALNUTRITION IN DEVELOPING COUNTRIES: IS THERE A GENETIC DIMENSION?**

J.I. Afolami¹, I.O. Akinyele¹

¹University of Ibadan, Ibadan, Nigeria

Background and objectives: Chronic Malnutrition, also known as stunting, is a serious public health problem affecting 178 million children (32%) under five years in developing countries. It is responsible for 12.6% of total global disease burden in children as measured by disability-adjusted life-years (DALYs). It has been associated with reduced cognitive development, reduced economic productivity and strangely, increased predisposition to cardiovascular diseases in later life stages. Over the years, several interventions to address stunting have not seemed to work, judging by the unchanging prevalence in a country like Nigeria, which is one of the twenty countries responsible for the highest stunting prevalence in the world. Some studies have suggested that genetics might play a role in understanding the mechanism of stunting, which can assist in developing prevention strategies. This paper presents a review of information available in literature, related to chronic malnutrition and genetics.

Methods: A total of 556 journals related to malnutrition and genetics were reviewed using PUBMED. The systematic review was carried out using the following

Results: The review showed that despite the dearth of available information on chronic malnutrition and genetics, some preliminary evidence from different studies suggest that genetics might be involved in chronic malnutrition, especially at critical periods of development.

Conclusions: Mutations in the FTO gene was reported in animal and clinical studies to cause growth retardation, severe psychomotor delay and functional brain deficits, a similar sequelae observed in chronically malnourished children.

Key words: Chronic malnutrition, FTO gene, Genetics, Short Nucleotide Polymorphisms

PO175**RESEARCH ABOUT CHANGES IN NUTRITION AND PHYSICAL ACTIVITY BEHAVIOURS OF IRANIAN STUDENTS WHO LIVES IN ANKARA**

N. Ersoy¹, A. Cakmak¹, F. Tamer¹, K. Simzari¹, G. Ersoy¹

¹Nutrition and Dietetics Department, Health Science Faculty, Hacettepe University, Ankara, Turkey

Background and objectives: The aim of this study was to assess the effect of living away from their country on the dietary habits of a group of Iranian undergraduate University stu-

dents (26 female, 24 males) who lives in Ankara, Turkey.

Methods: A questionnaire form has been filled by the students (age: 25.8 ± 3.5 yrs) in order to determine their personal characteristics and changes in their nutrition and physical activity behaviors.

Results: The mean heights of men and women students were determined as 178.3 ± 0.1 and 162.6 ± 0.1 cm, weights were 76.2 ± 7.5 and 58.2 ± 8.2 kg. The mean BMI values were 24.0 ± 3.1 in men, 22.0 ± 2.3 kg/m² in women. Fifty two percent of the students stated that their nutrition behaviors has changed since they had started to live in Ankara and the most important change (%65.8) has stated to be the decrease in the frequency of meals. Consuming fast foods in two meals, consuming juicy meals with no tomato paste, consuming bread rather than rice, increase in their milk consumption, decrease in the fish consumption, eating meals earlier and having breakfast more regularly have indicated to be the changes in the habits of Iranian students. According to food frequency questionnaire; consumption of milk and dairy products, fresh vegetable and dry fruits and fish consumption of students were low, tea consumption habit and poultry consumption of students were high. Regular exercise ratios of students were 38.0% in Ankara and 64.0% in Iran. Daily energy expenditures of men and women were found to be 3160 and 2316 kcal and exercise durations were found to be 167.6 min/week and 157.8 min/week respectively.

Conclusions: Foreign students may strive to preserve aspects of their original food culture after immigration. Nutrition interventions in this population should be encouraged to promote healthier diets and lifestyles.

Key words: Iranian student, nutrition behavior, physical activity level

(3). Studies on antioxidant supplementation during exercise training have been reporting beneficial, detrimental or no physiological effects (2). Instead of an interventional supply with antioxidants, the current study aimed to verify whether an Ironman triathlon (total race time: $10\text{h}:51\text{min} \pm 1\text{h}:1\text{min}$; mean \pm SD) modified the need for nutritive antioxidants (1). Furthermore, the effects of exercise-induced changes in the plasma concentrations of endogenous and exogenous antioxidants on indices of oxidatively damaged blood lipids, blood cell compounds and lymphocyte DNA were investigated.

Methods: Blood was collected from 42 well-trained male athletes 2 d pre-race, immediately, 1, 5, and 19 d post-race.

Results: Immediately post-race, vitamin C, alpha-tocopherol, and levels of the oxygen radical absorbance capacity (ORAC) assay increased ($P < 0.05$). Exercise-induced changes in the plasma antioxidant capacity were associated with changes in uric acid, bilirubin and vitamin C. ORAC levels and indices of oxidatively damaged DNA correlated inversely ($r = -0.54$; $P < 0.001$) Carotenoids and gamma-tocopherol decreased 1 d post-race ($P < 0.05$).

Conclusions: Results indicate a protective role of the acute antioxidant responses in DNA stability, but an increased need of nutritive antioxidants in the early recovery phase following ultra-endurance exercise. Furthermore, the data suggest that the requirements of nutritive antioxidants to maintain a physiological antioxidant status in endurance athletes in reference to recommendations can be achieved by consumption of a balanced and well-diversified diet.

Key words: endurance exercise, plasma antioxidant defenses, oxidative DNA damage, antioxidant requirements

Background and objectives: Evidence has emerged that reactive species, produced during strenuous exercise, are not only damaging agents, but also act as signaling molecules to initiate exercise adaptations and to regulate muscle function

PO177

HEALTHY AND TASTY MEAT USING MARINADES

U. Kehlet¹, L. Meinert¹, M D. Aaslyng¹

¹Danish Meat Research Institute (DMRI), Roskilde, Denmark

Background and objectives: It is well-known that during heat-treatment of meat, several carcinogens such as heterocyclic aromatic amines (HCAs) may be formed. HCAs are suggested to be one of the mechanisms to explain the association of red meat intake with colorectal cancer. From a health perspective it is important to identify cooking practices that minimize HCA formation in meat. This study examined the effects of marinades with antioxidants and pan-frying temperature on HCA formation and eating quality of pork patties and pork chops.

Methods: As antioxidants, apple puree was added to pork patties, and boneless pork chops were dipped in garlic marinade. The meat was pan-fried (150°C or 220°C) until a core tem-

perature of 70°C was reached. A control without antioxidants was subjected to the same heat treatments. HCAs were analyzed and quantified. A trained sensory panel (n=8) evaluated the meat by descriptive sensory profiling.

Results: Pork patties and pork chops only contained detectable levels of PhiP of all the HCAs measured. The concentration of PhiP was significantly reduced in the pork patties with apple puree (p=0.003) and the pork chops with garlic marinade (p=0.04). In patties, apple puree completely inhibited the formation of PhiP. The content of PhiP increased significantly with higher pan-frying temperature for pork patties (p=0.02) and pork chops (p=0.003). A significant interaction between antioxidants and pan-frying temperature was found for pork patties with apple puree (p=0.02) as a larger reduction of PhiP was found at 220 °C. The eating quality of pork patties and pork chops was affected by the addition of antioxidants and pan-frying temperature.

Conclusions: In an attempt to address the health concerns regarding red meat and cancer risk, the use of antioxidants and a low pan-frying temperature have reducing effects on the formation of carcinogenic compounds.

Key words: Heterocyclic aromatic amines, pork, antioxidants

PO178

DIETARY PATTERNS AND WHOLE GRAIN IN SCANDINAVIA. THE HELGA PROJECT

D. Engeset¹, G. Skeie¹, A. Olsen², L. Nilsson³

¹Department of Community Medicine, University of Tromsø, Norway

²Institute of Cancer Epidemiology, Danish Cancer Society, Copenhagen, Denmark

³Department of Public Health and Clinical Medicine, Umeå University, Sweden

Background and objectives: In the recent years a trend within nutrition epidemiology has been to assess overall dietary quality, often by identifying dietary patterns. The HELGA study population is based on samples of existing cohorts from the three Scandinavian countries. All three cohorts are part of the EPIC study. The aim of this study is to find a typical whole grain pattern in Scandinavia and see if the pattern is similar in the three countries.

Methods: The associations among the variables were investigated by factor analysis.

Results: Both Norway and Sweden had two breakfast patterns and one dinner pattern. Both the countries had a healthy breakfast pattern including food items commonly considered healthy, such as fruit, yoghurt and breakfast cereals. However, coarse bread was the main item in a more traditional pat-

tern for Norway, while it was a part of the healthy pattern in Sweden. The second breakfast pattern in Sweden included unhealthy items like white bread, cakes, sweets, soft drinks and alcohol. The dinner pattern was almost equal in Sweden and Norway. Denmark differed from the other Scandinavian countries concerning dietary patterns. Only one breakfast pattern was found. This pattern had some similarities with the traditional Norwegian pattern, but scored high on all whole grain items while in Norway only wheat had a high score. Two dinner patterns are seen for Denmark, the healthier one includes fruit and vegetables, fish and poultry, the second includes meat and meat products, ice cream and alcohol.

Conclusions: When comparing dietary patterns from the three Scandinavian countries, we find both differences and similarities. The main whole grain item used in Norway and Sweden seems to be wheat, while rye is more dominant in Denmark.

Key words: dietary pattern, whole grain, factor analysis, Scandinavia

PO179

COMBINING FIBRES AND PROTEINS IN A CEREAL PRODUCT REDUCES APPETITE SENSATIONS WITH SOME EFFECTS ON GASTRIC EMPTYING AND GLUCO-INSULINEMIC RESPONSE

A. Lesdema^{1,2}, G. Fromentin², A. Agathe¹, S. Vinoy¹, G. Airinei³, R. Benamouzig³, A. Bado⁴, C. Tomé², A. Marsset-Baglieri²

¹Nutrition Research, Mondelez International, Saclay, France

²UMR914 Nutrition Physiology and Ingestive Behaviour, AgroParisTech, INRA, CNRH-IdF, Paris, France

³Gastroenterology service, Avicenne AHP & CNRH-IdF, University Paris 13, Bobigny, France

⁴Digestive Physiology and Endocrinology, INSERM, UFR Paris Diderot, Paris, France

Background and objectives: There are several data about the effects of single fibres or proteins on satiety but little evidence on their combined effects. The objective of this study was to evaluate the single and combined effects of proteins and fibres in biscuits on appetite sensation, food intake and physiological markers.

Methods: In a crossover randomized design, 56 healthy normal weight women attended the laboratory on 4 days and tested one different biscuit each day at breakfast: control biscuit (C), fibre-enriched biscuit (F), protein-enriched biscuit (P), fibre- and protein-enriched biscuit (FP). Energy intake was evaluated by measuring food consumption during ad libitum

standard lunch, afternoon snack and dinner. They also had to fill in a VAS at regular time intervals in order to evaluate their appetite sensations. Among the 56 volunteers, 16 attended the laboratory on the next day so that different physiological parameters such as gastric emptying, glycemic response and gastrointestinal hormones could be measured.

Results: FP reduced hunger, prospective consumption, desire to eat compared to C, F and/or P. FP reduced the average appetite score vs. P, with a tendency vs. C and F. Moreover, F and FP slowed gastric emptying vs. C. The glycaemia level was lower after FP and P vs. C. Compared to the control, insulinemia after breakfast was lower after FP and F at 90 min and higher after P at 60 min. Active GLP-1 is also increased after P than C.

Conclusions: The interest of combining fibres and proteins in biscuits is shown on satiety feelings, although no effect is observed on gastrointestinal hormones. The mix of fibres and proteins activate mechanisms which are induced by single fibres and proteins. Further work is required to potentially be able to influence food intake reduction.

Key words: combination of fibres and proteins, satiety, physiological markers

PO180

FOOD TAXATION AS A NUTRITION POLICY TOOL – LESSONS FROM THE DANISH CASE OF SUGAR AND FAT TAXES

B. Mikkelsen¹, F.J.A. Perez-Cueto¹, M.S. Jørgensen²

¹Aalborg University, Meal Science and Public Health Nutrition Research Unit (MENU), A.C.Meyers Vænge 15, Copenhagen, Denmark

²Aalborg University, Department of Development and Planning, Center for Design, Innovation and Sustainable Transitions, Copenhagen, Denmark

Background and objectives: With societies reluctant to introduce structural changes in their food environment and with little effective mass strategies, policy makers are left with few alternatives. Existing evidence suggests that food taxation may reduce consumption of unhealthy foods while tax exemption can increase intake of healthier ones. However most studies rely on willingness to pay approaches and other “artificial” designs. Hence, little is known about taxes implemented in real-life cases or the policy processes behind. Denmark is one of these cases. This paper aims at analyzing the policy process leading to the Danish government’s decision to abandon the existing fat tax and to skip the planned sugar tax by January 2013.

Methods: This study evaluates abandoning the saturated fat and sugar taxes (SFST) from a theoretical perspective and gives an account of lessons for future food taxation policies.

Results: The tax on saturated fat was introduced in fall 2011 and was a duty on foods containing more than 2.3 percent saturated fat (dairy, meat and processed foods). The case of abandoning the taxes, introduced in 2011 and 2012 by two Danish Governments has provided insights into the dynamics of food- and nutrition-related policy processes. Food and taxation are hot topics for citizens, politicians, media actors and professional organisations. The case shows that food taxation is highly sensitive, highlights the roles of coalitions, media and storytelling and that scientific evidence is often not enough to inform policy. The influence of strong and weak coalition frameworks plus heavy administrative burden that taxes put on the food industry contributed to the decision of abandoning the taxes.

Conclusions: Future taxations should build on systematic evidence, on broader alliances, involve PHN expertise, be introduced in a “easy-to-administer” way and be followed by well planned evaluation procedures.

Key words: Denmark, Fat tax, Sugar Tax

PO181

VALIDATION AND APPLICATION OF A MICROPLATE METHOD FOR THE DETERMINATION OF FERRIC REDUCING ANTIOXIDANT POWER (FRAP) IN URINE SAMPLES

E. Al-Dujaili¹

¹Dietetics, Nutrition & Biological Sciences, Queen Margaret University, Edinburgh, UK

Background and objectives: The assay of ferric reducing ability of biological fluids as a measure of antioxidant power (FRAP assay) has been extensively used for years(1). The aim of this study was to validate and optimise the FRAP assay onto a 96-well plate in comparison to the published established test tube method and apply it to assess total antioxidant capacity in human urine samples.

Methods: An appropriate 96-well plate was chosen for the FRAP assay. The effects of time of incubation, volume of sample and reagents on assay performance were investigated and optimized. A working reproducible standard curve was obtained (0-1000µmole/L range). The plate assay was then validated for accuracy, reproducibility and correlation with the established FRAP tube method. Subjects (n=32) from Queen Margaret University aged 20-52years were recruited, and asked to provide two 24 hour urine samples at baseline and following intake of 1L cranberry juice. Samples were then analysed by the 2 methods.

Results: An excellent dose response curve was obtained on the 96-well plate with 10µL volume incubated at 37°C for 4 minutes. Intra and inter-assay imprecision data ranged from 0.4-0.7% and 0.5-1.1%CV respectively. Accuracy results were

88-98% over 0.2-0.98mmole Fe(II). Values obtained by the plate method correlated very well with the tube method ($R2 = 0.95$; $p < 0.001$). Also a Bland Altman plot displayed a high agreement between the values obtained. Cranberry juice intake caused an increase in urinary FRAP values but this was not significant ($p=0.08$).

Conclusions: Performing the FRAP assay on the 96-well plate has proved to be a simpler, more convenient, precise, fast and cost effective method for assessing ferric antioxidant power in urine samples.

Key words: FRAP, Antioxidant-power, Plate assay, Methods

EVALUATION OF THE BIOLOGICAL PROTECTIVE EFFECTS OF DURUM AND KAMUT WHOLE GRAIN COOKIES

U. Valli¹, F. Danesi¹, M. Di Nunzio², A. Gianotti¹, R. Quinn³, A. Bordoni¹

¹Department of Agri-Food Sciences and Technologies, University of Bologna, Bologna, Italy

²Interdepartmental Centre for Industrial Agri-Food Research, University of Bologna, Italy

³Quinn Organic Research Center, Big Sandy, Montana, USA

Background and objectives: There is an increased amount of evidence showing that high whole grain intake protects against several diseases. Minor cereals (e.g. Kamut® ancient wheat, barley, spelt, oat) are becoming of nutritional interest because of their better health-related composition in minor components as dietary fiber, vitamins, minerals and phenols (1). In this study the antioxidant protection by cookies made with whole modern grain durum wheat (W) or whole grain Kamut (K) ancient wheat, and fermented using *S. Cerevisiae* (WC, KC) or *S. Cerevisiae* and lactic acid bacteria (WL, KL), was evaluated in cultured cells.

Methods: Cookies were in vitro digested and ultrafiltered in order to supplement HepG2 cells with a mix of compounds whose size was compatible with the intestinal absorption. In vitro total antioxidant capacity (TAC) and phenolic profile of not-digested and digested cookies were assessed. The biological protective effect was evaluated by measuring viability, GSH and ROS intracellular content, cytosolic TAC, LDH release and TBARS content in the media.

Results: Digestion caused chemical and structural modifications releasing new structures with scavenging capacity as indicated by the increase in in vitro TAC. Both W and K cookies effectively protected HepG2 cells from the oxidative damage, without any significant differences due to the cereal type or to the type of fermentation.

Conclusions: Although the use of in vitro digestion and liver cell culture reduced the distance to the physiological situation in humans, results in whole organisms may diverge because of bioavailability and metabolism of ingested phytochemicals. Notwithstanding our results further underline the potential health effects of whole grains.

Key words: whole grain, Kamut brand, ancient wheat, in vitro digestion, antioxidant activity.

³Equipe Alimentation, Squelette et Métabolismes, France

Background and objectives: All industrialised countries face a progressive increase in life expectancy leading to a growing prevalence of chronic age-related metabolic complications, including locomotor dysfunctions. Osteoporotic fractures can result in up to 20% excess mortality within one year. Additionally, up to 50% of patients will be disabled, half of them requiring long term nursing home care, while only one third fully recover from hip fracture. Drug-based osteoporosis treatments have clearly demonstrated side effects while modulating specific target functions in the body, diet can help to achieve optimal health. In this study, we aimed at investigating the impact of fatty acid quality on the age related evolution of the locomotor system and to decipher related aging mechanisms.

Methods: The senescence-accelerated prone mouse (SAMP8) was used to mimic senile osteoporosis rather than post-menopausal osteoporosis. The SAMP8 mouse strain was compared to the SAMR1 control strain. Two months old mice were divided in different groups and subjected to the following diets : (a) standard "growth" diet - (b) "sunflower" diet (high $\omega6/\omega3$ ratio) - (c) "borage" diet (high γ -linolenic acid) - (d) "fish" diet (high in long chain $\omega3$). Mice were fed ad libitum through the whole protocol. At 12 months old, mice were sacrificed and tissues were harvested for bone studies, fat and muscle mass measures, inflammation parameters and bone cells markers expression.

Results: We demonstrated for the first time that while fatty acids from sunflower origin exacerbated osteoporosis features in this original model of progeria, fish oil diets counteracted bone loss. This preservation of bone health was associated with restored bone mineral density and inhibition of inflammatory parameters.

Conclusions: Our data strongly support that nutritional approaches are relevant regarding osteoporosis and offer promising alternatives in the design of new strategies for preventing aged-related locomotor dysfunctions.

LINKING NUTRITION AND FOOD SECURITY IN HUMANITARIAN CONTEXTS: BENEFITS OF INTEGRATING SMART AND HEA AS A TOOL FOR DISASTER MANAGEMENT

E. Rivero¹, L. Cantero¹

¹Acción Contra El Hambre, Departamento de Salud y Nutrición, Madrid, Spain

Background and objectives: Access to food and the maintenance of an appropriate nutritional status are key factors of people's survival in disasters. The Standardized Monitoring and Assessment of Relief and Transition (SMART) methodology for the assessment of nutritional status and the Household Economy Approach (HEA) for assessing food security, are generally carried out separately. Hypothesis: the use of the HEA component developed within SMART ENA delta version provides a better understanding of the causes of malnutrition in crisis situations and improves the decision-making process to plan and implement more effective relief interventions and promote their sustainable impact in a longer term. The objective is to provide supporting evidence of the added value by the integrated nutrition-food security assessment and to suggest SMART ENA delta as a standardized method.

Methods: A systematic review of nutritional and food security assessments was done. The criteria used in order to compose individual case studies were that the indicators could have been estimated using SMART ENA delta. A Food and Nutrition Security Analytical Framework was used for the qualitative analysis of 17 cases.

Results: Based on the framework used for the analysis, it was shown that a more complete picture of the crisis, with its causes and impacts, can be obtained with the integrated assessment SMART-HEA than if both sets of information are collected and analyzed separately.

Conclusions: nutritional data by itself is not enough to interpret and draw conclusions leading to appropriate interven-

tions. It is needed to contextualize the data with other type of information on health, food security and livelihoods. Using SMART ENA delta to conduct an assessment provides useful information without huge additional resources and it is highly suitable for small scale surveys. Further research on case studies directly using this tool is strongly recommended.

BODY IRON STATUS AND RISK OF HEPATOCELLULAR CARCINOMA IN A EUROPEAN PROSPECTIVE CANCER COHORT

M. Jenab¹, V. Fedirko^{1,2}, T. Duarte-Salles¹, M. Stepien¹, I. Romieu¹, C. Bamia³, A. Trichopoulos³

¹International Agency For Research On Cancer (IARC-WHO), Lyon, France

²Rollins School of Public Health, Emory University, Atlanta, GA, USA

³Hellenic Health Foundation, Athens, Greece

Background and objectives: Iron is an essential nutrient but can also act as a catalyst in free radical generation. Higher body iron status may lead to increased oxidative stress, and increased risk of cancer at various sites, particularly the liver which is the main organ of iron storage and metabolism. It has been established that iron overload, e.g. Haemochromatosis, is associated with increased risk of hepatocellular carcinoma (HCC). But, it is unclear to what extent mild or moderate excesses in body iron status contribute to HCC etiology. Since iron is an essential nutrient, it can be hypothesized that very low body status is also cancer promotive. These questions were explored within the European Prospective Investigation into Cancer and Nutrition (EPIC).

Methods: EPIC is a prospective cohort of over 520,000 subjects from 23 centers in 10 Western European countries. In a nested case-control setting, serum iron, ferritin and transferrin were measured in 121 (n men=82; n women=39) HCC cases and 242 control subjects matched by age, sex, study center and date of blood collection. Conditional logistic regression models were used to compute odds ratios based on quartiles of serum analyte levels.

Results: Compared to serum iron levels in the 2nd quartile, a significant increased risk of HCC was observed in subjects in the lowest (OR:2.10,95%CI:1.03-4.28) and highest (OR:4.22,95%CI:2.07-8.56) quartiles. For ferritin, subjects in the highest quartile had a significantly higher HCC risk (OR:3.34,95%CI:1.67-6.68) compared to those in the 2nd. For serum transferrin, a similar pattern of results was observed but was not statistically significant.

Conclusions: These findings indicate that serum iron parameters have a J-shaped relationship with HCC risk, and that higher iron status as indicated by serum iron and ferritin is significantly associated with higher HCC risk in this prospective European cohort.

Key words: Iron, Hepatocellular-Carcinoma

REPLETION OF IRON AND N-3 FATTY ACID DEFICIENT RATS WITH IRON AND ALPHA-LINOLENIC ACID ALONE AFFECTS BRAIN MONOAMINES AND COGNITION DIFFERENTLY THAN COMBINED REPLETION

J. Baumgartner^{1,2}, C M. Smuts¹, L. Malan¹, B K. Yee³, L E. Bianco⁴, R F. Hurrell², M B. Zimmermann²

¹Centre of Excellence for Nutrition, North-West University, Potchefstroom, South Africa

³Laboratory of Behavioural Neurobiology, ETH Zurich, Switzerland

⁴Department of Nutrition Sciences, The Pennsylvania State University, PA, USA

Background and objectives: We recently shown that a combined deficiency of iron (ID) and n-3 fatty acids (n-3 FAD) disrupted brain monoamine metabolism and produced greater memory deficits than ID or n-3 FAD alone. Repleting these double-deficient rats with either iron (Fe) or DHA/EPA alone affected monoamine pathways differently than combined repletion and even exacerbated the cognitive deficits associated with double-deficiency. The objective of this study was to examine whether repletion with Fe and alpha-linolenic acid (ALA), alone or in combination, can correct deficits in brain monoamine metabolism and cognition associated with deficiency.

Methods: Using a 2 x 2 design, male rats with concurrent ID and n-3 FAD (ID+n-3 FAD) were fed an Fe+ALA, Fe+n-3 FAD, ID+ALA, or ID+n-3 FAD diet for 5 weeks (postnatal d 56-91). Biochemical measures and spatial working and reference memory (using the Morris water maze) were compared to age-matched controls.

Results: Provision of ALA in combination with Fe synergistically increased DHA concentrations in the hippocampus (Fe x ALA interaction). Similarly, provision of Fe in combination with ALA resulted in higher Fe concentrations in the olfactory bulb (OB) than the provision of Fe alone ($P < 0.05$). There were significant antagonistic Fe x ALA interactions on 5-HT concentrations in the OB and frontal cortex. Working memory was impaired in ID+ALA rats compared with controls ($P < 0.05$).

However, in the reference memory task, there was a significant effect of ALA for improved memory performance.

Conclusions: Consistent with our previous study providing DHA, feeding either Fe or ALA alone to adult rats with both ID and n-3 FAD affected brain 5-HT concentrations differently than combined repletion, and even exacerbated the working memory deficits associated with combined deficiency. However, in contrast to DHA, ALA had a beneficial effect on reference memory.

³Department of Social Sciences, Wageningen University, Wageningen, NL

⁴Faculty of Nutrition and Food Sciences, University of Porto, Porto, Portugal

⁵School of Agriculture & Food Science, University College Dublin, Dublin, IRL

Background and objectives: Personalised nutrition and nutrigenomics are innovative concepts that identify individual nutritional needs based on phenotypic and genotypic information. The service, however, will only contribute to healthier food consumption if consumers take up such services and end-users are motivated to follow advice (Ronteltap A. and van Trijp H., 2007). The aim of this study was to establish factors determining uptake and compliance with personalised nutrition.

Methods: Focus group discussions (N 16) were apparently healthy, free living adults recruited through a Northern Irish research agency. Efforts were made to recruit equal numbers of males and females from two age groups (18-65 and 30-65 years). Using a standardised interview schedule, discussion was prompted using personalised nutrition scenarios. Discussions (N 2) were recorded, transcribed verbatim and qualitative data thematically content analysed. NVivo9 was used for data storage and retrieval.

Results: Themes identified suggested that uptake of personalised nutrition would be motivated by perceived need to improve health, body morphology and physical performance. Uptake was also dependent upon the perceived credibility of

service providers which could be conveyed through display of professional certificates and testimonials. Motivation, contact and support of service providers were considered important for compliance.

Conclusions: These data imply that a personalised nutrition service should take into consideration not only phenotypic and genetic information but also the perceived motivation of the user. The implications are that different types of support could be required within the personalised nutrition service.

Key words: Personalised Nutrition; Nutrigenomics; Motivation; Qualitative

DIETARY IRON AND OMEGA-3 FATTY ACID DEFICIENCIES INDUCE DIFFERENTIAL GENE EXPRESSION PATTERNS IN RAT HIPPOCAMPUS BOTH INDIVIDUALLY AND IN COMBINATION

J. Baumgartner^{1,2}, M. Boekschoten³, M. Muller³, C M. Smuts¹, L. Malan¹, R F. Hurrell², M B. Zimmermann²

¹Centre of Excellence for Nutrition, North-West University, Potchefstroom, South Africa

²Laboratory of Human Nutrition, Institute of Food, Nutrition and Health, ETH Zurich, Switzerland

³Nutrition, Metabolism and Genomics Group, Division of Human Nutrition, Wageningen University, The Netherlands

Background and objectives: Iron and omega-3 fatty acids (n-3 FAs) are required for normal brain development and functioning. We have previously shown that both, iron deficiency (ID) and n-3 FA deficiency (n-3 FAD) impaired hippocampal-dependent working memory in rats. Furthermore, a combined deficiency produced greater reference memory deficits than a deficiency in iron or n-3 FAs alone. To identify underlying molecular mechanisms, we investigated the effects of iron and n-3 fatty acid depletion, alone and in combination, on gene expression in the rat hippocampus.

Methods: Male rats were fed an ID, n-3 FAD, ID+n-3 FAD or control diet for 5 wks post-weaning, following n-3 FAD induction over 2 generations. The hippocampi of 5 rats/group were dissected for microarray analysis.

Results: Relative to controls, the expression of 138 genes was altered in the ID, compared to only 31 genes in the n-3 FAD group ($p < 0.01$ and fold change [FC] > 1.2). Only 6 genes were commonly affected by ID and n-3 FAD. In the ID+n-3 FAD group, the expression of 139 genes was significantly altered relative to controls. Of these, only the expression of 65 and 7 genes were shared with the ID and n-3 FAD groups, respectively. Four genes were commonly affected in all three experi-

mental groups. Thus, 63 genes were distinct to the ID+n-3 FAD group. The strongest up-regulation was found for the arachidonate 12-lipoxygenase (Alox15) gene in rats receiving ID alone or in combination with n-3 FAD (ID, FC=27.6; ID+n-3 FAD, FC=30.9).

Conclusions: These results suggest that dietary ID and n-3 FAD cause different gene expression patterns in the rat hippocampus, thus, impairing brain development and functioning via different molecular pathways. However, a combined deficiency induced a distinct pattern of gene expression, which may explain the greater cognitive deficits observed in double-deficient rats.

Key words: Alpha-linolenic acid, iron, hippocampus, microarray

BIOLOGICAL EVALUATION OF RAW AND DIFFERENTLY PROCESSED AFRICAN YAM BEAN SEEDS (SPHENOSTYLIS STENOCARPA) USING RATS

F. Igene¹, A. Christopher¹, S. Oboh¹

¹Ambrose Alli University, Nigeria

Background and objectives: The biological values of raw and differently processed African yam bean seeds (AYB) were assessed using albino rats.

Methods: Raw AYB seeds were divided into four parts. Three parts were subjected to different processing methods namely; roasting, boiling and autoclaving, while the fourth was left unprocessed. The seeds were milled and included separately in rat diets. Six experimental diets were formulated. Diets 1 was nitrogen free, diet 2 contained casein (control), while diets 3, 4, 5, 6 contained roasted, boiled, autoclaved, and raw AYB seeds respectively. 24 albino rats in groups of 8 each were respectively assigned to the 6 experimental diets in a completely randomized design. The rats were offered the feeds and water ad libitum for 21 days.

Results: The results obtained indicated that all parameters assessed were significantly affected by treatment effects. The highest feed intake and daily weight gain were observed in the control (18.65±0.57g and 5.91±0.52g) while the raw AYB diet was least (12.56±0.52g and 3.22±0.60g) respectively. Feed conversion ratio ranged from 3.16±0.27 in the standard (casein) diet to 3.90±0.11 in the raw AYB diet. Protein intake ranged from 3.86±0.05g in the raw AYB to 6.64±0.06g in the control casein diet. There was a comparable and significant improvement in the daily weight gain and feed conversion ratio of rats fed boiled AYB and standard casein diets. Final weight, feed gain ratio, apparent digestibility, biological value (BV), net protein utilization (NPU), net protein ratio (NPR) and protein efficiency ratio (PER) were significantly ($P < 0.05$) highest in

rats fed casein diet, but boiled AYB diet competed favourably with the control diet.

Conclusions: It can be concluded that AYB must be boiled before being fed to animal to support growth and health.

Key words: African Yam Bean, Rats, Biological Value.

RECENT SYSTEMATIC REVIEWS INDICATE ADULTS NEED ≥ 800 IU VITAMIN D TO REDUCE RISK OF DISEASE

S. Whiting¹, C. Evans¹, L. Foo²

¹College of Pharmacy and Nutrition, University of Saskatchewan, Saskatoon, SK Canada

²School of Health Sciences, Universiti Sains, Kubang Kerian, Kelantan, Malaysia

Background and objectives: In setting dietary recommendations for vitamin D, it should be expected that actions other than bone-related functions would be considered. Vitamin D has both endocrine and paracrine functions, and levels of 25-hydroxyvitamin D needed for the latter have been shown to be higher than the former. However, in 2010 when the Institute of Medicine (IOM) deliberated on new Recommended Dietary Allowances (RDAs), it stated there was not sufficient evidence to set recommendations for functions not related to bone health. Purpose: Therefore in 2012 we conducted a systematic review of the literature to identify quality studies which were either systematic reviews and/or meta-analyses involving adults (> 17 y, excluding pregnancy and lactation) that examined the effect of vitamin D in any disease or condition.

Methods: Published meta-analysis and systematic review studies related to the effectiveness and efficacy of vitamin D dosages/supplementation on any health outcome measures in adult human participants that were published between January 1 2010 and July 20 2012. Further, key journals were also reviewed through this time period. A total of 18 qualified; studies were found.

Results: Key findings were that vitamin D reduces fall risk at intakes over 400 IU/day, although 800 IU/day is more effective; a positive effect of vitamin D on muscle strength is seen when intakes are over 800 IU/d, especially in those previously deficient; vitamin D has no effect on blood lipids or overall cardiovascular disease risk, but does show a reduction in systolic blood pressure; and with supplement use, mortality was reduced in older adults.

Conclusions: There are health conditions in adults positively impacted by vitamin D supplementation, indicating that that the RDA for adults, especially those over 50 y, should be increased to ≥ 800 IU/day.

Key words: Vitamin D; Recommended Dietary Allowances; falls; muscle strength; systematic review

²Fish Innate Immune System Group, Department of Cell Biology and Histology, Faculty of Biology, University of Murcia, Murcia, Spain

³Department of Plant Biology (Plant Physiology), Faculty of Biology, University of Murcia, Spain

Background and objectives: The flavonoid content of tea (*Camellia sinensis*) has beneficial properties in the prevention of diseases. Mechanisms by which white tea can protect against oxidative stress remain unclear.

Methods: To shed light on this issue, rats were given distilled water (controls), 0.15 mg/d (dose 1) or 0.45 mg/d (dose 2) of solid tea extract/kg body weight for 12 months. All the animals received an injection of adriamycin (ADR) (10 mg/kg body weight), except half of the control group, which were given an injection of saline solution. In the liver, the expression of the nuclear factor E2-related factor 2 (Nrf2), NAD(P)H:quinone oxidoreductase (Nqo1), glutathione-S-transferase (Gst) and heme oxygenase1 (Ho) was analysed by real-time PCR, and the activity of catalase (CAT), superoxide dismutase (SOD) and glutathione reductase (GR) was measured spectrophotometrically.

Results: ADR significantly increased the expression of Nrf2, Gst, Nqo1 and Ho with respect to the control rats and also increased the activity of CAT, SOD and GR.

Conclusions: The intake of white tea increased the expression of Nrf2, Gst1, Nqo1 and Ho1 in the ADR group compared with the control group and decreased the activity of CAT, SOD and GR in a dose-dependent manner.

Key words: Adryamicin; ARE response; Nrf2; Polyphenols; White tea

PO192**ORAL SUPPLEMENTATIONS WITH FREE AND DI-PEPTIDE FORMS OF L-GLUTAMINE: EFFECTS ON GLUTAMINE-GLUTATHIONE AXIS AND HSPS EXPRESSION IN ENDOTOXEMIC MICE**

J. Tirapegui¹, V. Cruzat¹, L. Pantaleão², P I H. Bittencourt³

²Department of Physiology and Biophysics, Institute of Biomedical Sciences, University of São Paulo, São Paulo, Brazil

³Department of Physiology, Institute of Basic Health Sciences, Federal University of Rio Grande do Sul, Rio Grande do Sul, Brazil

Background and objectives: Sepsis is a leading cause of death in ICUs worldwide. The availability of L-glutamine during sepsis modulates the oxidative stress and the Heat shock proteins (HSPs) response. In the present study we investigated the effects of oral supplementation with L-glutamine plus L-alanine (GLN+ALA), both in the free form as compared to L-alanyl-L-glutamine dipeptide (DIP), on glutamine-glutathione (GSH) axis and HSPs expression in mice subjected to endotoxemia.

Methods: B6 mice were subjected to endotoxemia (*Escherichia coli* LPS, 5 mg.kg⁻¹, LPS group) and orally (gavage) supplemented for 48 h with either L-glutamine (1 g.kg⁻¹) plus L-alanine (0.61 g.kg⁻¹) (GLN+ALA-LPS group) or 1.49 g.kg⁻¹ DIP (DIP-LPS group). Glutamine, glutamate, glucose and ammonium were evaluated in plasma. Glutamine, glutamate, GSH, GSH disulfide (GSSG) and Thiobarbituric acid-reactive substances (TBARS) were assessed in skeletal muscle. Muscle HSP70 and HSP27 expression were determined by Western Blot analysis and HSF1 by RT-qPcR.

Results: Endotoxemia depleted plasma (by 71%) and muscle (gastrocnemius, by 44%) glutamine concentrations [relative to control (CTRL) group] which were restored in both GLN+ALA-LPS and DIP-LPS groups (P<0.05). Supplemented groups reestablished GSH content and intracellular redox status (GSSG/GSH ratio). Both supplementations maintained the expression of HSP70 and HSP27 similar to the controls by reducing the mRNA expression of HSF1 in muscle (P<0.05). Tissue lipoperoxidation (TBARS) was 4-fold higher in LPS mice relative to CTRL group, and was remitted by both supplements (P<0.05).

Conclusions: Oral supplementations with GLN+ALA or DIP are effective in reversing LPS-elicited deleterious effects on glutamine-GSH axis by regulating muscle HSPs in mice under endotoxemia. Acknowledgements: São Paulo State Foundation for Research Support (FAPESP) and Brazilian National Council for Scientific and Technological Development (CNPq).

Key words: Glutamine. Sepsis. Oxidative stress. GSH. HSPs

PO193**ORAL SUPPLEMENTATIONS WITH FREE AND DI-PEPTIDE FORMS OF L-GLUTAMINE: EFFECTS ON IMMUNE AND INFLAMMATORY SYSTEM IN MICE UNDER ENDOTOXEMIA**

¹Department of Food Science and Experimental Nutrition, Faculty of Pharmaceutical Sciences, University of São Paulo, São Paulo, Brazil

²Department of Physiology, Institute of Basic Health Sciences, Federal University of Rio Grande do Sul, Rio Grande do Sul, Brazil

³Department of Physiology and Biophysics, Institute of Biomedical Sciences, University of São Paulo, São Paulo, Brazil

Background and objectives: Sepsis is a leading cause of death in ICUs worldwide. Low availability of L-glutamine, the most abundant amino acid in the body, contributes to the uncontrolled inflammatory pathway and suppresses immune response in sepsis. In the present study we investigated the effects of oral supplementation with L-glutamine plus L-alanine (GLN+ALA), both in the free form as compared to L-alanyl-L-glutamine dipeptide (DIP) on immune and inflammatory response, mediated by NF-κB in muscle tissue of mice subjected to endotoxemia.

Methods: B6 mice were subjected to endotoxemia (*Escherichia coli* LPS, 5 mg.kg⁻¹, LPS group) and orally (gavage) supplemented for 48 h with either L-glutamine (1 g.kg⁻¹) plus L-alanine (0.61 g.kg⁻¹) (GLN+ALA-LPS group) or 1.49 g.kg⁻¹ DIP (DIP-LPS group). Blood was collected for plasma concentration of glutamine, glutamate, TNFα, IL-6, IL-1β, IL-10, and T and B lymphocyte proliferation. Gastrocnemius muscle was removed for Western Blot analysis of total NF-κB p65, phosIκB-α/β, and for RT-qPcR of NFKB1 and NFKBIA.

Results: Endotoxemia depleted plasma (by 71%) and muscle (gastrocnemius, by 44%) glutamine concentrations [relative to control (CTRL) group] which were restored in both GLN+ALA-LPS and DIP-LPS groups (P<0.05). Supplemented groups exhibit higher T and B lymphocyte proliferation (p<0.05). Expression of total NF-κB p65, phosIκB-α/β; and pro-inflammatory mRNAs of NFKB1 and NFKBIA were higher in LPS group compared to CTRL, GLN+ALA-LPS and DIP-LPS groups. These effects were accompanied by a raise in plasma concentration of TNF-α, IL-6, IL-1β; and IL-10 in LPS group which was attenuated by the supplements.

Conclusions: Oral supplementations with GLN+ALA or DIP are effective in reversing the lower availability of glutamine, attenuating the inflammatory response and stimulating adaptive immune system under endotoxemia.

Key words: Glutamine. Sepsis. Inflammation. Lymphocytes.

Background and objectives: Polymorphisms in the hepatic lipase gene (LIPC) have been associated with variability in plasma HDL-C concentrations as well as an interaction effect with dietary habits and physical activity (PA). However, hepatic lipase also hydrolyzes fatty acids (FA) of triglycerides and phospholipids. This study assesses whether the 514C/T polymorphism interacts with diet and PA on FA and lipid concentrations.

Methods: The rs1800588 (514C/T) genotype, FA concentrations, triglycerides, cholesterol and lipoproteins were measured in 1155 European adolescents (12.5–17.5 years) from the

HELENA study. 577 adolescents had data on diet and 962 on PA (questionnaire and calculation of VO₂max). Associations between rs1800588 and outcome variables were assessed with linear regression, corrected for age, sex, BMI, center and total energy intake in analyses with diet.

Results: The minor allele of rs1800588 was significantly associated with higher levels of total cholesterol, HDL-C, ApoA1 and stearic acid (C18:0) and lower levels of palmitic acid (C16:0). Monounsaturated FA intake interacted with rs1800588 on HDL-C ($p = 0.07$), triglycerides ($p = 0.08$) and palmitic acid ($p = 0.04$) in an additive model. Furthermore, a direct interaction effect was found with linoleic acid intake for arachidonic acid and palmitic acid ($p = 0.03$; $p = 0.04$, respectively). The interaction effect between rs1800588 and PA showed that carriers of TT who are less active had higher concentrations of LDL-c, ApoB and stearic acid. In contrast, in adolescents who are more active, PA interacts with the polymorphism resulting in higher HDL-c and ApoA1 and lower palmitic acid concentrations. In line, adolescents with a higher VO₂max, carrying the T allele, had higher levels of HDL-c and ApoA1.

Conclusions: These results show that the 514C/T polymorphism in the LIPC gene is associated with serum lipid and fatty acid concentrations, furthermore an interaction effect of diet and PA has been confirmed.

Key words: Hepatic Lipase, Fatty acids, Diet, Physical Activity, Adolescents

PO195**NUTRITIONAL INTERACTION BETWEEN TRANS FATTY ACIDS AND UNSATURATED FATTY ACIDS FROM DIFFERENT SOURCES ON REGULATION OF TRIGLYCERIDE METABOLISM**

M. González¹, J. Saín¹, J. Lavandera¹, C. Bernal¹

¹Bromatología y Nutrición, Facultad de Bioquímica y Ciencias Biológicas, Universidad Nacional del Litoral, Santa Fe, Argentina

Background and objectives: The dietary fat intake modulates the plasma and tissue levels of triglycerides (TG). The aim of this study was to evaluate the effect of diets with different unsaturated fatty acid (UFA) in the presence or absence of trans fatty acids (TFA) on regulation of triglyceride metabolism in mice.

Methods: Male CF1 mice (22 g) were fed (30 days) with a standard diets differing in dietary n-3/n-6/n-9 UFA ratios: Canola (CO: 10.9/19.0/63.2), Maize (MO: 0.9/53.3/31.3) or Olive (OO: 0.8/9.7/76.3) Oils containing 0.75% of TFA (COt, MOt and OOt, respectively) or not. Serum and liver TG content, hepatic TG-pre- α -lipoproteins secretion rate (TGSR), and lipoprotein lipase (LPL) activity from adipose tissue and muscle were determined.

Results: TFA induced hepatic steatosis (+100% OOt vs. OO and COt vs. CO) and increased TGSR in OOt and COt groups (+260% in OOt vs. OO and +160% in COt vs. CO). However, an increasing LPL activity in adipose tissue was observed (+200% in OOt vs. OO and +167% in COt vs. CO), leading to a normal levels of serum TG in these groups. In animals fed MOt, no changes were observed in the evaluated parameters.

Conclusions: TFA altered TG metabolism depending on the type of dietary UFA. Adipose tissue could play a key role in the plasma TG regulation, however the TGSR did not normalize the hepatic TG levels.

Key words: trans fatty acids – unsaturated fatty acids – triglycerides – hepatic metabolism.

PO196

NATURAL AND COMMERCIAL RELATIONS OF CONJUGATED LINOLEIC ACIDS DIFFERENTIALLY AFFECT FATTY ACIDS SYNTHESIS IN LIVER OF MICE

C. Bernal¹, M V. Scalerandi¹, M. González¹, M R. Williner¹, L. Antonacci², G. Gagliostro²

¹Faculty Bioquímica y Cs. Biológicas - U.N.L. Santa Fe, Argentina

²Estación Experimental INTA – Balcarce, Argentina

Background and objectives: c9,t11-CLA (Rumenic Acid-RA-) is the prevailing conjugated linoleic acids (CLA) in dairy fats, while RA and t10,c12-CLA in similar amounts (Mix-CLA) are the major CLA in commercially used supplements. Both CLA have bioactive properties; however, the Mix-CLA, but not RA, produces liver steatosis. The purpose of this study was to compare some mechanisms that might be involved in liver steatosis induced by Mix-CLA in animals fed with different types of dietary fats.

Methods: Male CF1 mice (22.0 ± 0.1g) were fed diets containing 7% olive (O), 7% maize (M), or 7% canola (C) oils, supplemented or not with 1% of RA rich oil (c9,t11-CLA: 60,53%; t10,c12-CLA: 17,85%) (O+RA, M+AR and C+RA) or 1% of Mix-CLA rich oil (c9,t11-CLA: 38,99%; t10,c12-CLA: 38,76%) (O+Mix, M+ Mix and C+Mix). TG secretion rate (TGSR), lipogenic enzymes and FA composition in liver were determined.

Results: Compared to O, M and C groups, O+Mix and M+Mix, but not C+Mix, increased (71%, 33% and 11 % -NS-) the hepatic triacylglycerol (TG) levels. Even FA synthesis measured by FAS and Malic enzyme were raised by both types of CLA in the 3 fat dietary sources (increase; FAS: 48–177%; ME: 19–272%), as well as FA markers of lipogenesis tended to increase, a higher hepatic TGSR in O+AR (91%), M+AR (53%), C+AR (49%) and C+Mix (99%) modulated the hepatic TG levels. Moreover, LC-PUFA biosynthesis was inhibited (30–60%) by AR and Mix-CLA in the 3 different fat sources.

Conclusions: Both CLA increased the FA synthesis; however Mix-CLA, but not RA, induced hepatic steatosis. Steatosis produced by Mix-CLA showed dependency on the dietary fat source. The prevention of hepatic steatosis by RA was due to an increase of the VLDL-TG secretion rate.

Key words: CLA – Rumenic Acid – hepatic steatosis – hepatic metabolism.

PO197

DOES DIET ENERGY DENSITY IS CORRELATED WITH DIET QUALITY?

A. Mendes¹, A. Martins¹, A. Previdelli¹, J. Pereira¹, R. Fisberg¹, D. Marchioni¹

¹Department of Public Health Nutrition, University of São Paulo - USP, São Paulo, SP, Brazil

Background and objectives: Energy density (ED) is hypothesized to be a proxy for nutritional diet quality, since a low ED diet is based on plant and low fat food. Our aim was to investigate the relationship between ED and the Health Eating Index formerly adapted to Brazilian food habits (BHEI-R).

Methods: The sample comprises 1162 individuals: adolescents (n=560), adults (n=585) and elderly (n=517) from the cross-sectional Health Survey of São Paulo (ISA-Capital), conducted in 2008. To assess dietary intake it was collected two non-consecutive 24-hour dietary recalls using the Multiple-Pass Method. ED was calculated using the “foods only” protocol. The Multiple Source Method was applied to provide the usual intake of BHEI-R and its components, and the ED. Multiple linear regression was used to assess the associations between usual ED and the final BHEI-R and their components. This model was adjusted by age, sex, religion, race and education of the head of household.

Results: Usual ED was correlated with BHEI-R (B=-10,93; p <0.01), adjusted by age, sex, religion, race and education of the head of household. The components of BHEI-R that were correlated with ED, adjusted by the same variables were: Whole grains (B=-0.30; p <0.01); Total fruits (B=-1.65; p=0,000); Whole Fruits (B=-1.39; p=0,000); total Vegetables (B= - 0.17; p <0.01); Oils (B=-0.25; p=0,022); Saturated fat (B=-2.70; p <0.01); SoFAAs (calories from solid fat, added sugar, alcohol) (B=-5.08; p <0.01). The other food groups did not show significant correlation with ED.

Conclusions: The ED presented negative and significant relationship with diet quality and maybe used as a surrogate for diet quality.

Key words: Energy density; health eating index; diet

PO198**INCREASED VITAMIN K LEVEL IN LDL-/- AND APOE-/- MICE***N. Kaesler¹, G. Schlipper¹, T. Krüger¹*

¹Medical Clinic II, University Hospital of The RWTH Aachen, Aachen, Germany

Background and objectives: Vitamin K and triglycerides share common metabolic pathways. After absorption, vitamin K can be found in all lipoprotein fractions; vitamin K1 being mainly found in chylomicron remnants and VLDL whereas vitamin K2 is mainly distributed by LDL. Interaction of apolipoprotein E (ApoE) with the LDL receptor mediates cellular uptake. We investigated the cellular uptake of vitamin K in mice deficient of apoE and LDL receptor (LDL-R).

Methods: Male, 8 week old wildtype, ApoE-/- and LDL-R-/- mice were fed a diet supplemented with 5 g/kg vitamin K1 and 500 mg/kg vitamin K2 (MK4) for 4 weeks. After sacrifice, contents of vitamin K1 and MK4 were determined by isocratic reversed-phase HPLC in liver, kidney, aorta and pooled serum.

Results: After 4 weeks of vitamin K diet, vitamin K1 content in liver from wildtype mice was not different to ApoE-/- mice ranging between 11-45 ng/g. Vitamin K1 content significantly increased in LDL-R-/- mice (104.8 ± 10.01 ng/g). Hepatic MK4 content was ranging from 50-848 ng/g independent of the genetic background. LDL-R-/- mice also had significantly higher vitamin K1 concentration in kidney compared to wildtype. Notably, 9-fold increase of tissue content of vitamin K1 and 170-fold of MK4 were found in aortas of ApoE-/- mice (K1: 36.6 ± 12.4 vs 4.0 ± 2.1 ; MK4: 2600 ± 330 vs 125.7 ± 70.3 ng/g). This was paralleled by increased MK4 serum levels in ApoE-/- and increased vitamin K1 serum levels both in ApoE and LDL-R-/- mice.

Conclusions: Despite absence of proteins regarded to be relevant for vitamin K uptake like ApoE and LDL-R, tissue contents of vitamin K isoforms are not reduced but in part even largely increased in knockout mice. The mechanisms leading to these results and functional implications are subject of actual research.

Key words: Vitamin K, Metabolism, lipoproteins, ApoE, LDL-Receptor

PO199**EFFECTS OF TRANS FATTY ACIDS ON BRAIN OXIDATIVE STATUS IN AN EXPERIMENTAL ANIMAL MODEL OF ESSENTIAL FATTY ACIDS DEFICIENCY***M. González¹, E. Latorre¹, A. Fariña¹, C. Bernal¹*

¹Bromatología y Nutrición, Facultad de Bioquímica y Ciencias Biológicas, Universidad Nacional del Litoral, Santa Fe, Argentina

Background and objectives: Partial essential fatty acids deficiency (EFAD) as well as the presence of trans fatty acids (TFA) could alter the balance between the generation of reactive oxygen species and cell content of free radical scavengers. Therefore, EFAD could modify vulnerability of cells to oxidative injury and affect the tissue. Glutathione (GSH) that may be oxidized to glutathione disulfide (GSSG) plays a central role in the defense against oxidative damage and signaling pathways. Concentrations of GSH, GSSG and its molar ratio are indicators of oxidative stress. The objective was to evaluate the effect of TFA on the brain oxidative status in animals with and without EFAD.

Methods: Male Wistar rats were fed (60 days) with a Control (CD), CD+TFA (CDT), EFAD (DD) and DD + TFA (DDT) diets. Fatty acids incorporation into the brain was measured by GC. The brain GSSG and GSH content by capillary electrophoresis with a P/ACE 5010 (Beckman) with UV detection and the lipoperoxidation (LPO) degree by Ohkawa method were determined. Results were expressed as the mean \pm SEM. Data was compared by Two-Way ANOVA, followed by Duncan's test. $p < 0.05$ was considered statistically significant between groups.

Results: TFA showed a low incorporation into the brain ($< 0.5\%$), independently of the EFA status. EFAD, but not the TFA supplementation, altered the brain lipoperoxidation (CD: 70.2 ± 3.8 ; CDT: 60.7 ± 3.8 ; DD: 70.3 ± 1.8 and DDT: 61.0 ± 1.3) and TFA significantly increased the GSH content (CD: 1.46 ± 0.03 ; CDT: 1.24 ± 0.08 ; DD: 1.47 ± 0.02 and DDT: 1.25 ± 0.08).

Conclusions: Even though TFA showed a low incorporation in a short period of exposition, GSH content was altered. A longer exposure of TFA could lead to an increase in the oxidative damage in brain, independently of EFAD.

Key words: Trans Fatty Acids –Essential Fatty Acids Deficiency – Lipoperoxidation – brain.

PO200**BODY COMPOSITION, PHYSICAL ACTIVITY SCORE AND METABOLIC SYNDROME IN URUGUAYAN SCHOOL AGE CHILDREN**

M. Britz¹, A.P. Della Santa¹, E. Umpierrez², A. Aznarez³

¹Departamento de Nutrición Poblacional, Escuela de Nutrición, Universidad de la República, Montevideo, Uruguay

²Facultad de Química, Universidad de la República, Montevideo, Uruguay

³Ministerio de Salud Pública, Montevideo, Uruguay

Background and objectives: The increase in overweight and obesity among children in Uruguay predict that more children are likely to develop Metabolic Syndrome (MS), rising the risk to suffer cardiovascular disease and type2 diabetes mellitus. The objective was to study body composition (%fat mass-%FM), the prevalence of MS components, and physical activity score (PAS) in overweight/obese (OW/O) and normal weight (NW) Uruguayan children.

Methods: Descriptive study of 77 children aged 6-9y of public schools in Montevideo. Measurements: BMI, waist circumference (WC), blood pressure (BP), fasting blood glucose (G), serum lipids, body composition by deuterium oxide dilution, and physical activity (Godard-Score). Diagnostic criteria for MS were: $WC \geq P90$, $BP \geq P90$, triglycerides (TG) ≥ 110 mg/dL, $c\text{-HDL} \leq 40$ mg/dl and $G \geq 100$ mg/dl. It was considered obesity when $BMI/age > +2SD$ and overweight $BMI/age > +1SD \leq +2SD$.

Results: 28 children were OW/O and 49 were NW. Among MS components evaluated, mean values of WC and TG were higher in OW/O vs NW group (9,6 cm higher WC and 27,7mg/dl higher TG; $p < 0.05$). C-HDL was lower in OW/O (51.1 ± 2.2 mg/dl) ($p = 0.00$). The prevalence of MS components altered in OW/O was: BP 39%, WC 36%, TG 32% and c-HDL 21%. The %FM was 28.5 ± 1.2 in OW/O and 21.8 ± 0.9 in NW ($p = 0.00$). Differences in PAS (4.7 in NW, 4.9 in OW/O) were not significant. The prevalence of the presence of one or more components of MS showed a positive trend with BMI/age and %FM. All children with three or more components of MS ($n = 6$) were OW/O and had average %FM 31.2 ± 2.5 (95%CI 26.2;36.1) compared to 22.9 ± 0.4 (95%CI 20.9;24.9) in children without MS components ($n = 49$) ($p = 0.020$).

Conclusions: The prevalence of MS components in children with OW/O is high at school age. MS in these children is associated with OW/O and a fat mass $\geq 26\%$.

Key words: Childhood obesity, metabolic syndrome, body composition, physical activity Partially funded by the IAEA.

PO201**MATERNAL NUTRITION AND ADVERSE BIRTH OUTCOMES IN DEVELOPING COUNTRIES: A SYSTEMATIC REVIEW AND META-ANALYSIS**

V. Mendu¹, R. Athe¹, R.K. KV¹, M.N. K¹

¹National Institute of Nutrition, Indian Council of Medical Research, India

Background and objectives: Maternal nutrition plays a crucial role in influencing fetal growth and birth outcomes. It is a modifiable risk factor of public health importance in the effort to prevent adverse birth outcomes, particularly among developing populations. Deficiencies in micronutrients such as folate, iron, iodine, zinc and vitamins A, B6, B12, C, E and riboflavin are highly prevalent and occur concurrently. Low birth weight (LBW), small-for-gestational age (SGA), preterm birth, stillbirths, neonatal mortality are important adverse outcomes of pregnancy. Therefore there is a need to study the relative efficacy of multiple micronutrient supplementation on pregnancy outcomes. Aim : To systematically review the randomized controlled trials comparing the effect of supplementation with multiple micronutrients on pregnancy outcomes. Specific Objective: 1. To carry out a systematic review/meta analysis of studies that used double micronutrient supplementation vs Multiple Micronutrient (MMN).

Methods: Search Strategies: The strategy includes searching of MEDLINE, ProQuest and the database searches includes PubMed, Cochrane Systematic Reviews. PRISMA was used for conducting and reporting the Meta analysis. Data extraction and quality assessment Data will be extracted on the characteristics of the trials and their participants, which includes randomization, allocation concealment, blinding, completeness of follow-up and compliance. Statistical Analysis: Fixed and Random effects meta analysis was performed by pooling the results for outcomes. Forest plots and funnel plots were generated to view the outcome results and publication bias.

Results: A total of 17 studies was included from 881 based on the PRISMA. Multiple micronutrient supplement was more effective than single/double micronutrient supplementation of increasing the birth weight (weighted mean difference of 47g; 95% CI (3, 91g) and reducing the LBW (RR: 0.87; 95% CI(0.83, 0.92), SGA (RR: 0.88; 95% CI (0.79, 0.97)). However, Pre-term birth, still births and neo-natal deaths did not show difference between the groups.

Conclusions: Micronutrient supplementation had little or no effect on adverse birth outcomes.

Key words: Meta Analysis, LBW, SGA

PO202**EXPOSURE VS. SENSORY EDUCATION: THEIR EFFECTIVENESS IN INTRODUCING NOVEL VEGETABLES TO PRESCHOOL CHILDREN'S DIETS? PRELIMINARY RESULTS OF A DANISH INTERVENTION**

M V. Mikkelsen¹, F J A. Perez-Cueto¹, B E. Mikkelsen¹

¹Research Group for Meal science and Public Health Nutrition, University of Aalborg (Campus Copenhagen), Copenhagen, Denmark

Background and objectives: Developing positive eating habits begins in childhood and involves establishing good food practice. Generally, vegetables are difficult to introduce into a diet, although they are specifically addressed by all recommendations. Ways to achieve healthy eating goals include developing food experiences, conducting to accept different tastes and textures. Healthy eating interventions in kindergartens have shown promising results using different strategies including exposure to novel vegetables and sensory education. Aim The LOL (Learning over Lunch) project investigates whether preschool children's vegetable preferences are improved by sustained exposure to novel vegetables alone or by combining sensory education with exposure to novel vegetables.

Methods: A controlled intervention study was carried out in 4 Danish kindergartens, covering in total 246 children (mean age: 4,4 years; boys: 57%; girls: 43%). Three preschools received three novel vegetables that were included in the lunch service for a period of 20 weeks. One of the kindergartens received sensory education and other food-related activities during the intervention. Data on prior exposure of vegetables, knowledge, liking and willingness to try was collected using a picture-based questionnaire for children, questionnaire data from parents and food service personnel. Numeric data were analysed with SPSS v.20, visual data were analysed using Face-reader[®] and Observer XT[®].

Results: Preliminary follow-up results show that the largest effect on children liking and eating novel vegetables is achieved by a systematic and sustained exposure through provided meals, and addition of sensory education and food-related activities seem not to affect this outcome.

Conclusions: The project suggests that preschool food service is a key player in influencing children preferences for unfamiliar vegetables and in implementing strategies to improve children's eating habits. Sustained exposure to vegetables appears to be an important tool to achieve consumption and liking of vegetables.

Key words: Vegetables, preschool children, food service in preschools

PO203**PLASMA LEVELS OF CLA ISOMERS AFTER SINGLE ORAL ADMINISTRATION OF TONALIN OIL TO RATS**

L M. Rodriguez-Alcalá¹, J. Fontecha¹, M. Juárez¹, A. Anadón², M A. Martínez², I. Ares², M R. Martínez-Larrañaga²

¹Instituto de Investigación en Ciencias de la Alimentación (CIAL, CSIC-UAM), Bioactividad y Análisis de los Alimentos, Madrid, Spain

²Universidad Complutense de Madrid, Faculty of Veterinary Medicine, Department of Pharmacology and Toxicology, Madrid, Spain

Background and objectives: The two principal CLA isomers: Rumenic acid (RA; C18:2 cis9, trans11), associated to anticarcinogenic, antiatherogenic, antioxidative and immune system stimulation, and the C18:2 trans10, cis12 isomer related with reduction of body fat activities, are present within a concentration of 80g/100g oil and a 1:1 ratio in the synthetic commercially available Tonalin TG 80 oil. Previous data from animal experimentations stated that the effective dose in humans to obtain healthy biological effects could be between 3-6 g CLA/day. However, of the Tonalin oil no data are available on their absorption, distribution and elimination characteristics. The aim of this study was to characterize the absorption grade of Tonalin administered intragastrically as a single dose in rats.

Methods: Tonalin oil was administered orally by gavage (3000 mg/kg bw. corresponding to 1200 mg C18:2 cis9, trans11/kg bw and 1200 mg C18:2 trans10, cis12/kg bw.) to male Wistar rats. Serial blood samples were collected after oral administration. Plasma concentrations of the two active conjugated linoleic acid isomers were determined by GC/MS.

Results: The active conjugated linoleic acid isomers were rapidly and partially absorbed. Maximum plasma concentration was about 7 µg/mL for each of the two isomers after 2h of oral administration. Isomer concentrations in plasma after 1 h were about 2 µg/mL, and exceeded 1 µg/mL after 12 and 24 hours respectively.

Conclusions: The present study showed that after oral administration of Tonalin oil, low concentrations of the active conjugated linoleic acid isomers (C18:2 cis9, trans11 and C18:2 trans10, cis12) reached the blood circulation intact. Tonalin plasma disposition characteristics should be considered in choosing dosage regimens that maximize efficacy of Tonalin for use in functional food and dietary supplements.

Key words: CLA isomers, Oral absorption, Plasma concentrations.

PO204**EVALUATION OF THE LIPID AND GLYCEMIC PROFILE OF RATS WITH DIET SUPPLEMENTED WITH CHEESE WHEY PROTEINS AND THEIR HYDROLYSATES**

O. Barbosa¹, A L M. Nasser¹, J.C. Bassan¹, T.M.S. Bezerra², M. Monti³, C M J. Miranda³, A J. Goulart¹, R. Monti¹

¹Faculdade de Ciências Farmacêuticas, UNESP Univ Estadual Paulista, Brazil

²Instituto de Química, UNESP University Estadual Paulista, Brazil

³Faculdade de Ciências Agrárias e Veterinárias, UNESP Univ Estadual Paulista, Brazil

Background and objectives: Cheese whey, a by-product of the manufacture of cheeses, has a high nutritional value and bioactive peptides. The objective of this work was to evaluate the lipid and glycemic profile of Wistar rats with diet supplemented with integral and hydrolyzed whey proteins.

Methods: Forty young animals were used in 4 groups: control (C), integral proteins (NH), with low degree of hydrolysis (LDH) and high degree of hydrolysis (HDH), treated during 43 days with 20 g/animal/day of diet AIN 93 M. The nutritional supplement given to NH, LDH and HDH (110mg prot/animal/day) was produced using the enzymes pepsin, trypsin, chymotrypsin and carboxipeptidase-A. To obtain the hydrolyzed LDH, enzymes were added together at the same reaction time, and to obtain HDH they were added sequentially every 10min. Total reaction time was 100min to LDH and 120min to HDH. The lipid and glycemic profile were analyzed by quantification of blood HDL, triglycerides, total cholesterol, and glucose.

Results: The results showed that, after the period of supplementation, HDL cholesterol increased by around 50% in group LDH; in the same group total cholesterol was about 29% higher; in the other groups these parameters were not altered. Also there was no difference in the concentration of triglycerides. For fasting glycemia groups LHD and HDH presented lower concentration (18% and 20% respectively), in relation to control and NH groups. In the control group the glucose concentration was the highest in relation to the supplemented groups.

Conclusions: We conclude that the LHD hydrolyzate was efficient in HDL cholesterol increasing and glycemia reduction, which was also reduced by HDH hydrolyzate. There was no difference in triglycerides of the supplemented groups compared to control. The increase in total cholesterol of LDH may be due to the increase in HDL cholesterol.

Key words: whey proteins, enzymatic hydrolysis, hydrolysates, protein supplementation

PO205**DEVELOPMENT OF A HIGH THROUGHPUT ASSAY FOR THE QUANTIFICATION OF MULTIPLE PLANT POLYPHENOLS IN HUMAN PLASMA**

D. Mawson¹, K. Jeffrey¹, P. Teale¹, P. Grace¹

¹LGC Health Sciences, Fordham, UK

Background and objectives: Catechins represent a class of polyphenols found in a variety of foodstuffs including dark chocolate and green tea. Studies have linked lower instances of chronic diseases with populations whose diets are high in foods containing these compounds. The analysis of these compounds from biological samples is complicated due to the number of active components, including isomers and disparate structures, poor stability, lack of commercially available internal standards, metabolites and relative concentrations of the different catechins. The objective of this experimental work was to develop a robust assay for the quantification of green-tea derived polyphenols from plasma samples which could cope with these issues.

Methods: Extraction of catechins from human plasma has been achieved using a protein precipitation – based process. A deuterated internal standard was synthesised in the laboratory and used in combination with commercially available internal standards to correctly model and compensate for extraction losses of the eight catechins quantified. Separations of catechins and monitored metabolites were achieved using a Waters Acquity UPLC Quattro Premier LC-MS.

Results: The simple extraction process together with relatively rapid LC-MS/MS method allows for the quantification of the eight catechins in high sample number studies. Additionally, the rapid analysis circumvents the stability issues commonly associated with the analysis of this class of compounds. In addition to stability testing, assay performance has been confirmed through a comprehensive validation including sensitivity, precision and accuracy, selectivity, matrix effects and recovery testing. In all cases, acceptance criteria of inter- / intra- CVs and REs of less than 15% (20% at the LLOQ) is met.

Conclusions: An assay has been developed which is capable of simultaneous quantification of green-tea derived catechins from plasma samples. This assay circumvents common pitfalls associated with the analysis of these compounds.

Key words: Catechins, Quantification, LC-MS/MS, polyphenols, green tea.

PO206**DEVELOPMENT OF HIGH THROUGHPUT LC-MS/MS ASSAYS FOR NUTRITIONAL BIOMARKER QUANTIFICATION***D. Mawson¹, K. Marrs¹, P. Teale¹, P. Grace¹*¹LGC Health Sciences, Fordham, UK

Background and objectives: Increasingly, quantification of nutritional biomarkers from biological samples is being seen as the gold standard methodology for dietary assessment. Such assessments are not without issues; the samples required for large population studies can prove logistically challenging if sample extraction and analysis run times are lengthy. Additionally, depending on the nature of the biomarker use of ELISA may not be possible, or may incur poor selectivity leading to misinterpretation of results. Liquid chromatography – mass spectrometry can address some of the issues. Here, the development of two chromatographic

Methods: One of the quantification of phytoestrogens and the other for 25-hydroxyvitamin D and steroids will be discussed. Methods LC-MS/MS: Methods have been developed using a Waters Acquity system coupled to a Sciex 5500 Qtrap. Selective MRM transitions have been found for each analyte and chromatographic separations developed using both Waters Acquity and Phenomenex Kintetex columns.

Results: A chromatographic method suitable for the simultaneous quantification of nine phytoestrogens from human urine has been developed. The analysis of a single sample is achieved within a 5 minute run time with excellent column longevity exhibited when utilised with an in-house developed extraction method. A UPLC based chromatographic method has also been designed where 4 steroids and hydroxyvitamin D2 / D3 can be separated and analysed within a 4 minute run time.

Conclusions: Chromatographic methods have been developed for the quantification of multiple phytoestrogens and hydroxyvitamin D2 and D3 together with steroids. Both methods are reliable, robust and would be suitable for use for high sample volume population studies.

Key words: 25-Hydroxyvitamin D, steroids, phytoestrogens, LC-MS/MS

PO207**URINARY ENTEROLACTONE AND ENTERODIOL CONCENTRATIONS CORRELATE WITH TOTAL FIBER INTAKE AND SHOWED A MODERATE TO HIGH REPRODUCIBILITY IN A SPANISH POPULATION***B. Moreno-Franco¹, A. García-González², A M. Montero-Bravo², E. Iglesias-Gutiérrez², N. Úbeda², H. Adlercreutz³, J.L. Peñalvo⁴*¹Department of Medicine, Psichiatry and Dermatology. University of Zaragoza, Zaragoza, Spain²Department of Pharmaceutical and Food Sciences, University CEU San Pablo, Madrid, Spain³Institute for Preventive Medicine, Nutrition and Cancer, Folkhalsan Research Center and Division of Clinical Chemistry, Biomedicum University of Helsinki, Helsinki, Finland⁴Department of Epidemiology, Atherothrombosis and Imaging, National Center for Cardiovascular Research, CNIC, Madrid, Spain

Background and objectives: Lignans (LG) are diphenolic compounds widely distributed in the diet as part of the dietary fiber (DF) complex. Once ingested, LG may be directly absorbed, or undergo an extensive metabolism by the gut microflora leading to the formation of the so called enterolignans (enterolactone and enterodiols), that can be detected in human biological fluids. When these metabolites were discovered, it was found that their urinary levels correlated with DF intake, and could play an important role in the prevention of certain diseases like cancer. The aim of this study was to examine the validity of using urinary enterolactone and enterodiols concentrations as biomarkers of DF intake and to assess their short-term reproducibility in a ninety-nine Spanish population.

Methods: To study LG exposure and its relation with reported dietary intake, dietary habits were assessed by means of a FFQ previously validated in Spain, capturing long-term intake during 3 months preceding inclusion into the study and by 3-day registry, capturing immediate intake. Participants provided a first morning sample after overnight fasting, 2 times on a 3-month interval from the study starting point. Urinary enterolactone and enterodiols were measured by HPLC-couluarray detection.

Results: Urinary enterolactone and enterodiols concentrations correlated with DF intake in both first ($r=0.22$; $P<0.05$) and second ($r=0.36$; $P<0.01$) visit after adjusting for age, BMI and energy intake. The intra-class correlation coefficient was 0.79 (95% CI: 0.69-0.86) for total DF intake and 0.64 (95% CI: 0.45-0.76) for enterolactone and enterodiols showing a moderate to high reproducibility.

Conclusions: These results indicate that LG metabolites may be used as DF intake biomarkers and could be used to

assess DF intake in epidemiological studies in free living populations.

Key words: Lignans; Enterolactone; Enterodiol; Dietary fiber

PO208

INDIVIDUAL AND FAMILIAL DIETARY PREDICTORS OF OBESITY AMONG HISPANIC CHILDREN FROM AN URBAN COMMUNITY IN THE US

⁴Pediatrics, University of Wisconsin-Madison, Madison, WI, USA

⁵Institute for Health Promotion and Disease Prevention Research (IPR), University of Southern California, Alhambra, CA, USA

⁶Department of Veteran Affairs Rehabilitation Outcomes Research Center (RORC), Gainesville, FL, USA

Background and objectives: Although not without controversy, a growing body of evidence suggests that a high intake of added sugars, especially those in sugar-sweetened beverages (SSB), have contributed to the pediatric obesity epidemic. We examined the diet of Hispanic children in relation to body mass index (BMI) and determined the relationships between home food environment and familial dietary habits with children's intake of added sugars and SSB.

Methods: A food frequency questionnaire was administered to 187 children (aged 10 to 14 years) and height and weight were measured. Parents self-reported on home food environment, familial dietary habits, and their height and weight through questionnaires.

Results: The prevalence of childhood overweight and obesity were 24.7% and 28.1%, respectively. Reported intake of total sugars and SSB were identified as significant correlates of childhood overweight and obesity ($r = 0.24, 0.17$; $P < 0.05$). Home availability of SSB, parental intake of SSB, and children's time spent watching television (TV) were associated with higher intake of added sugars ($r = 0.35, 0.30, 0.26$; $P < 0.05$) and SSB ($r = 0.28, 0.26, 0.24$; $P < 0.05$). The presence of a TV in the children's bedroom was positively associated with children's

BMI ($r = 0.17$; $P = 0.02$), and surprisingly family meals were inversely associated with children's BMI ($r = -0.17$; $P = 0.04$) and intake of added sugars ($r = -0.26$; $P = 0.05$).

Conclusions: Our results suggest that SSB intake in Hispanic children is associated with BMI status and that home food availability and familial dietary habits play a role in children's intake of added sugars and SSB. Interventions that target these modifiable risk factors and that have a parental component could have a positive effect on the risk for obesity and diabetes in this community.

Key words: Obesity, sugar-sweetened beverages, home food environment, Hispanic children

¹University of Murcia, Murcia, Spain

²Miguel Hernández University, Eche, Alicante, Spain

³Mediterranean Salad Company, S. Coop. The Raal, Murcia, Spain

Background and objectives: There is an increasing research trend in the use of fructooligosaccharides as prebiotic for food nutritional improvement. Artichoke flour (AF) has a high potential as a functional ingredient becoming a source of inulin and its colour is important in different food formulations. The objective of the research is the optimization of AF colour through the chlorophyll extraction minimizing the use of ethanol.

Methods: The chlorophyll of the AF obtained from industry by-products (mainly bracts and stems) was extracted with different proportions (% w/v) of flour / ethanol (20%, 10%, 7%, 5%, 4% y 3%) for the optimization of the amount of solvent used on the extraction process. After the extraction, the CIEL*a*b* colour coordinates were measured with a Minolta CR-300 colorimeter (Minolta Camera Co. Osaka, Japan). The colour parameters Chroma (C*) and Hue angle (h) were also calculated.

Results: L* was significantly higher in the samples with 4% and 3%. The value of the red - green (a*) coordinate showed lower values in the control and 20% samples, indicating a greener colour, and therefore a lower chlorophyll extraction, respect to those with higher solvent proportions. From the 10% any differences were observed with increasing solvent amount. The yellow-blue (b*) value shows yellowish samples from the 10%, without significant increases from this proportion. The

C* was lower in the control and 20% samples. The result found for hue angle in control samples was significantly higher respect to the samples after extraction.

Conclusions: The optimum colour was obtained from the 10%. Higher ethanol amounts are not needed for obtaining the extracted AF, with the adequate colour for being used as a functional ingredient.

Key words: Colour, fructooligosaccharides, artichoke, by-products.

PO210

SERUM N-6 AND N-3 POLYUNSATURATED FATTY ACIDS AS BIOMARKERS OF DIETARY INTAKE IN EARLY PREGNANCY ACCORDING TO BODY MASS INDEX

J. Lepsch¹, J. Vaz¹, M. Schlussek¹, G. Kac¹

¹Nutritional Epidemiology Observatory, Federal University of Rio de Janeiro, Brazil

Background and objectives: Few studies have evaluated dietary report of essential fatty acids in pregnancy against biomarkers. However, overweight subjects may underreport their intake. Thus, we investigated whether serum essential fatty acid composition in early pregnancy may be used as biomarker of corresponding dietary intake and if correlations are affected by body mass index (BMI; kg/m²).

Methods: This study was nested within a prospective cohort in Rio de Janeiro/Brazil. The present sample was comprised of 252 women, aged 20-40 years, between 6th and the 13th weeks' gestation. Dietary intake was assessed using a validated food frequency questionnaire (FFQ). Fatty acid compositions were determined in fasting serum samples, utilizing a high-throughput robotic direct methylation coupled with fast gas-liquid chromatography. Spearman correlation (rs) was used to assess the relationship between fatty acid intake and corresponding serum composition. Women were classified according to pre-pregnancy BMI as under/normal weight (BMI<25; n=141) or overweight (BMI≥25; n=111).

Results: In the total sample, dietary report was significantly correlated with serum composition of total polyunsaturated fatty acids (PUFA; rs=0.23, p<0.001), linoleic acid (LA, 18:2n-6; rs=0.27, p<0.001), eicosapentaenoic acid (EPA, 20:5n-3; rs=0.27, p<0.001) and docosahexaenoic acid (DHA, 22:6n-3; rs=0.20, p<0.001). When analyses were stratified by BMI, significant correlations between diet and serum composition among under/normal weight women were observed for total PUFA (rs=0.35, p<0.001), LA (rs=0.35, p<0.001), EPA (rs=0.32, p<0.001), DHA (rs=0.17, p=0.038). In contrast, among overweight women significant correlations were observed only for linolenic acid (18:3n-3; rs=0.22, p=0.018) and

DHA (rs=0.23, p=0.016). The reported means of fatty acids in FFQ were not significantly different between pre-pregnancy BMI groups.

Conclusions: Serum fatty acid composition in early pregnancy may be used as biomarker of dietary intake of essential fatty acids. However, caution should be taken when analyzing the dietary report of overweight pregnant women.

Key words: Biomarkers; Fatty Acids; Diet

APPLICATION OF DIET QUALITY INDEX REVIEWED BEFORE AND AFTER NUTRITIONAL GUIDANCE

S.J. Papini¹, M.C. Oliveira², I. Calahani², M.B. Malta³, A.N. Previdelli⁴, J.E. Corrente⁵

¹Departamento de Enfermagem, Faculdade de Medicina de Botucatu UNESP, Botucatu, São Paulo, Brasil

²Curso de Nutrição, Instituto de Biociências de Botucatu UNESP, Botucatu, São Paulo, Brasil

³Departamento de Saúde Pública, Faculdade de Medicina de Botucatu UNESP, Botucatu, São Paulo, Brasil

⁴Departamento de Nutrição, Faculdade de Saúde Pública USP, São Paulo, São Paulo, Brasil

⁵Departamento de Bioestatística, Instituto de Biociências de Botucatu UNESP, Botucatu, São Paulo, Brasil

Background and objectives: Due to early diagnosis of chronic diseases and the recognition of food over its development and progression, the aim of this study was to evaluate the effect of individual nutritional counseling on changes in food practices in patients attended in ambulatory.

Methods: Two 24-hour recalls were applied before and after the orientation to calculate the Revised Diet Quality Index (RDQI). The RDQI is an instrument for evaluating the overall diet quality, and may be associated with gradients of risk for chronic diseases related to diet.

Results: Thirty patients were evaluated and submitted to individual nutritional guidance in an auxiliary unit of Medicine Faculty, UNESP, Botucatu, São Paulo, Brazil. The average score of RDQI before the intervention was 61.9 points, ranging from 34.7 to 82.6 points of a maximum 100 points total and, after nutritional guidance was for 70.2, ranging from 40.8 to 85.24 points (p=0.02). The consumption of dairy products, whole grains, fruits and vegetables were reported more frequently in the second query, as well as the lower consumption of solid fat, trans, alcohol, sugar and salt. The consumption of meats, eggs and vegetables remained the same in both interviews. Lower

scores, from 30 to 50 points, were obtained by three patients in the first interview and just one in the second. Scores considered high, from 61 to 90 points were obtained by 13 patients in the first query and by 22 in the second.

Conclusions: Thus, it was observed that 76.7% of the patients reached higher RDQI in the second query, demonstrating that the nutritional guidelines were followed by these individuals, thus improving the quality of the diet index.

Key words: diet quality index reviewed, overall diet quality, nutritional guidance, chronic diseases, nutrition.

RELATIONSHIP BETWEEN UNCOUPLING PROTEIN-2 ALA55VAL GENE POLYMORPHISM AND INDICATORS OF METABOLIC SYNDROME IN MEXICAN SCHOOL CHILDREN.

G. López¹, M. Galván¹, A. Estrada¹

¹Laboratorio de Nutrición Molecular, Universidad Autónoma del Estado de Hidalgo, Pachuca Hidalgo, México

Background and objectives: Obesity is associated with metabolic syndrome (MS) however MS is seen among eutrophic children. Identify genotypes associated with metabolic syndrome indicators in children of state of Hidalgo.

Methods: In a random sample of 750 school children of public, private and indigenous centers we measured weight and height using standardized techniques, it was considered that a child had metabolic syndrome indicators (ISM) when the children in fasting had any of the following criteria: triglycerides >150mg/dL, HDL cholesterol <40mg/dL, fasting glucose >110mg/dl, systolic and diastolic blood pressure >90th percentile for age and sex, and waist circumference ≥90th percentile for age and sex. To identify the variant rs660339 (Ala55Val) in UCP2 gen we used TaqMan® PCR GeneAmp® 9700.

Results: The proportion of children with ≥2 ISM was of 67.7% in Ob children, 20.7% in SP children and 7.9% with NP children. NP children who had ≥2 ISM showed higher frequencies of GG genotype (11.7%) and less than AA (2.9%) (p = 0.03), this trends were observed too in children with SP but not in the Ob children.

Conclusions: The GG genotype of rs660339 polymorphism in the UCP2 gene is more frequently in children with normal weight that had ISM. This can serve as an early indicator of risk to predict the development of metabolic syndrome in the age adult.

Key words: UCP2 polymorphism, Metabolic syndrome, School children

PO213

EFFECT OF DIFFERENT RESTRICTION LEVELS ON FOOD INTAKE AND BODY WEIGHT IN ALBINO RATS.

R. Mancilla-González¹, A. López-Espinoza¹, A. Martínez¹, C. Llanes-Canedo¹, A. Espinoza¹

¹Behavioral Feeding and Nutrition Research Center, CUSur, University of Guadalajara, México

Background and objectives: Experimental evidence shows that when an organism is exposed to food restriction shows changes in food and water intake and body weight. Restriction of food has been associated with eating disorders such as obesity, nervous anorexia and bulimia. However, the role of level of restriction over such changes is not yet clear. Objectives. In order to analyze this relation, an experiment was performed in which the effects of different percentages of restriction over food intake and body weight in albino rats were evaluated.

Methods: Thirty two experimentally naive Wistar albino rats of three months of age at the beginning of the experiment were used, they were separated in four different groups, three experimental and a control. The experiment consisted of nine phases of five days each. Phases 1,3,5,7 and 9 were ad libitum as long that phases 2, 4, 6 and 8 were restriction periods. The first group was exposed to a food restriction of 25 %, the second to a 50% and the third was restricted to a 75% compared to average consumption on base line period. Food intake and body weight were recorded every day.

Results: Results showed that group with a 75% restriction had a food intake higher when compared to the 50 and 25% restriction groups. Loss body weight was proportional to restriction level, as long that in phases with food ad libitum subjects showed a weight recovery over levels registered in base line.

Conclusions: Data collected demonstrated existence of a relation between food restriction level and changes on food intake and body weight.

Key words: restriction level, food intake, body weight, rats

PO214**FOOD SELECTION IN RECREATIONAL FACILITIES: DO PARENTS AND CHILDREN MAKE HEALTHY CHOICES?**

D L. Olstad^{1,2}, K D. Raine², L J. McCargar¹, L A. Goonewardene^{1,3}

¹Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Alberta, Canada

²Centre for Health Promotion Studies, University of Alberta, Edmonton, Alberta, Canada

³Alberta Agriculture and Rural Development, Government of Alberta, Edmonton, Alberta, Canada

Background and objectives: Concern over childhood obesity has prompted debate regarding whether children's food choices should be constrained, particularly in settings such as recreational facilities where children are mainly, but not exclusively present. This study assessed the food purchasing behaviors of adults and children at a recreational swimming pool and examined whether food selection could be improved through three interventions.

Methods: A baseline phase was followed by three successive and additive interventions that promoted sales of healthy foods through descriptive menu labels, free samples, and 30% price reductions. Researchers observed patrons and their food purchases in an unobtrusive manner for 5h/d for 17d during the 40d study period. A chi-square analysis was performed with the rating of menu items (healthy/unhealthy) as the dependent variable.

Results: Overall, 41% of items sold (n=2650) were healthy, mirroring their availability (46%). The proportion of healthy items sold differed according to who was present during the purchase ($p < 0.01$). When only adults were present, 44% of items purchased were healthy, whereas when both adults and children, or only children were present healthy items represented 39% and 37% of items purchased, respectively. The population of adults consisted primarily of parents. The first, second and third interventions increased selection of healthier items by 16%, 29% and 37%, respectively, across all groups ($p = 0.03$).

Conclusions: The proportion of healthy items purchased was highest when adults/parents purchased items alone. Food selection improved during the interventions, although the majority of purchases remained unhealthy across all groups. Parents and children may not always consider the health implications of dietary choices made for themselves and for others. Policy makers should consider limiting the availability of unhealthy foods in a variety of settings where children are present.

Key words: childhood obesity, food availability, healthy foods, policy, recreational facility

PO215**PARTICIPATION IN AN INTEGRATED HOMESTEAD FOOD PRODUCTION AND NUTRITION AND HEALTH-RELATED EDUCATION PROGRAM INCREASED CHILDREN'S HEMOGLOBIN LEVELS IN BURKINA FASO**

D K. Olney¹, A. Pedehombga², M. Ruel¹, A. Dillon³

¹International Food Policy Research Institute, Washington, DC, USA

²Helen Keller International, Ouagadougou, Burkina Faso

³Michigan State University, East Lansing, Michigan, USA

Background and objectives: Anemia is nearly universal among young children in Burkina Faso and is likely caused by multiple factors including suboptimal infant and young child feeding (IYCF) and care practices, illness, and limited access to nutrient-rich foods and health care.

Methods: We conducted a cluster randomized control trial, of Burkinabe children aged 3-12 months. Forty-five villages were randomly assigned to a control group or one of two treatment groups. Both treatment groups participated in a two-year program that included homestead food production (HFP) to increase production of nutrient-rich foods and a behavior change communication (BCC) intervention to improve knowledge and adoption of optimal IYCF and care practices delivered by older women leaders or village health committee members (HC villages).

Results: After two years of program implementation, children in HC villages had a greater increase in mean hemoglobin concentration of 0.46 g/dL (double difference estimates; 95% CI -0.07 – 1.0, $p = 0.089$), compared to those in control villages. This difference was greater and statistically significant among younger children (3-5.9 months of age at baseline) in HC villages relative to those in control villages (difference = 0.73 g/dL (95% CI 0.12 – 1.33, $p = 0.02$)). Supporting this finding, we also found greater gains in women's home production of foods in the lean agricultural season and knowledge of key IYCF and care practices among women in HC compared to control villages.

Conclusions: Participation in a program that increases home production of nutrient-rich foods and provides nutrition and health related education through a well-developed BCC strategy can improve children's hemoglobin concentrations by increasing access to nutrient-rich foods and enhancing knowledge related to optimal IYCF and care practices. This is the first cluster-randomized control trial of a HFP program that has demonstrated a significant positive effect on increasing children's hemoglobin concentrations.

Key words: children, hemoglobin, Burkina Faso

PO216**EMERGING DISEASE BURDEN TRANSITION IN DEVELOPING COUNTRIES: THE CASE OF BANGLADESH**

M. Kothari¹, S. Poedjastoeti², T. Croft², D. Garrett¹, P. Ametepi³

¹Demographic Health Survey, PATH, Washington DC, USA

²Demographic Health Survey, ICF International, Beltsville MD, USA

³Demographic Health Survey, JHU, Beltsville MD, USA

Background and objectives: Evidence is growing that risk factors for disease burden are shifting globally from communicable diseases to non-communicable diseases (NCDs) (Lim, S. Stephen, 2012). This shift is also taking place in Bangladesh. Blood pressure (BP) and Fasting Blood Glucose (FBG) values were collected from women and men age 35+ in the 2011 Bangladesh Demographic and Health Survey (BDHS). The current study investigates the prevalence and determinants of BP/FBG in this population.

Methods: The 2011 BDHS is a nationally-representative sample of 18,000 households. BP and FBG values, hemoglobin, and height/weight measurements were obtained from 4,311 women and 4,524 men age 35 + in one third of the selected households. Bivariate tables were run to analyze the preliminary results, which were weighted to represent a national estimate. Logistic regression models will be applied to the data to identify the determinants of BP and FBG. The potential variables identified to be included in the model are age, urban-rural residence, region, education, household wealth, and BMI.

Results: The preliminary results indicate that 32% of women and 19% of men age 35+ have higher-than-normal blood pressure or are taking medication to lower the BP. Further, 45% of women and 57% of men were not aware of the condition. Eleven percent of women and men age 35 + are diabetic or are taking medication for diabetes. More than half of these men and women were not aware of their condition. We expect to measure the likelihood of propensity towards hypertension and diabetes based on BMI.

Conclusions: NCDs in Bangladesh could be on a rise, but the awareness about it is low. Knowledge about the prevalence of hypertension and diabetes, as well as information about their intermediate risk factors are important for the disease prevention and control.

Key words: Bangladesh, BP, Blood glucose, BMI, DHS

PO217**EXCESS DIETARY ENERGY INTAKE AND ESTROGEN-DEPRIVATION MODULATE ADIPOSITY-RELATED PROINFLAMMATORY EVENTS AND MUSCLE LOSS.**

J. Kim¹, Y.H. Lee¹, M.K. Sung¹

¹Sookmyung Women's University, Seoul, South Korea

Background and objectives: Postmenopausal weight gain is a known risk factor for breast cancer while postmenopausal women experience lower fat to lean tissue ratio. The objective of this study was to investigate the effects of excess fat accumulation and/or estrogen deprivation on adiposity related proinflammatory events and muscle tissue loss.

Methods: C57BL/6J female mice ovariectomized (OVX) or sham-operated (SHAM) at 5 wk age were fed with normal diet (ND, 15% fat as calorie) or high fat diet (HD, 45% fat as calorie) for 12 wk. Blood and tissue inflammatory molecules were measured to determine the effects of OVX and dietary fat content on inflammatory events. C2C12 skeletal myotubes were also used to examine the effects of 17 β -estradiol, insulin, and leptin on muscle degradation.

Results: Body and adipose tissue weight were significantly higher in OVX mice compared to SHAM mice. HD significantly increased the level of circulating insulin while adiponectin level was decreased. OVX animals exhibited significantly higher blood level of leptin. There was no significant difference in the expression of PPAR- α and SREBP1c mRNA in the liver. However, the expression of muscle Akt, phosphorylated Akt, and FoxO1 was higher in OVX+HD mice indicating possible muscle protein degradation. Adipose tissue leptin, IL-6, and TNF α mRNA expression were increased in OVX+HD mice. Skeletal myotubes study indicated that lower level of 17 β -estradiol increased the expression of MuRF1 and FoxO1 while mTOR expression was decreased. Leptin and insulin treatment increased the expression of MuRF1. Interaction between estrogen and insulin/leptin was observed for FoxO1.

Conclusions: These results suggest that both estrogen deficiency and excess fat intake regulate systemic inflammation by modulating the production of major adipokines in metabolic tissues including adipose tissue, liver and muscle.

Key words: ovariectomy, adipose tissue, estrogen

PO218**ABSORPTION AND GASTROINTESTINAL OXIDATIVE INJURY IN KM MALE RATS FED OXIDIZED CASIN**

S. Y^{1,2}, L. Z², L. G^{1,2}, W. L²

¹The State Key Laboratory of Food Science and Technology, Jiang Nan University, Wuxi, China

²Institute of Food Nutrition and Functional Factor, School of Food Science and Technology, JiangNan University, Wuxi, China

Background and objectives: Protein oxidation is one of the important causes of many degenerative diseases. Protein oxidation in food process is of frequent occurrence. However, the health impacts of oxidized products of food proteins in vivo have been unexplored. The aim of this study was to determine whether oxidized casein products can enter blood circulation, and to evaluate oxidative effects on the digestive organs of rats.

Methods: Westar male rats were administered orally with origin casein (control-C) and casein oxidized by H₂O₂ (0.4mmol/g prot) combined with Cu (H₂O₂-Cu) and HClO (0.4mmol/g prot). The chyme of intestine, blood of portal and peripheral vascular were taken for determination after 0.5, 1.0, 1.5, 2 hr.

Results: Advanced oxidation protein products (AOPPs), dityrosine (Dtyr) and carbonyls were significantly ($p < 0.05$) increased in rats administered with oxidized casein, while thiol content decreased. Reactive oxygen species (ROS) levels in blood were also higher than in controls 0.5~2 h after perfusion, levels of AOPPs, Dtyr, carbonyl, and thiol in blood exhibited strong correlations with those in casein samples. Furthermore, analysis of chyme-plasma of portal and peripheral vascular via HPLC-MS demonstrated the absorption of oxidized-casein products including Dtyr and peptide carbonyls. ROS, malonyldehyde and protein carbonyls in blood, liver, duodenum and jejunum were significantly ($p < 0.05$) elevated. Total anti-oxidants and activities of superoxide dismutase, catalase and glutathione peroxidase were decreased.

Conclusions: Oxidized casein products could be absorbed and possibility causing oxidative damage to digestive organs in rats.

Key words: Oxidized-casein; HPLC-MS; digestive organs; oxidative damage

PO219**THE CONTRIBUTION OF BREASTFEEDING TO ACHIEVING MILLENNIUM DEVELOPMENT GOAL FOUR IN THE ASIA PACIFIC REGION**

M. Lee¹, C. Binns², M. Inoue²

¹School of Health Professions, Murdoch University, Perth, Western Australia, Australia

²School of Public Health, Curtin University, Perth, Western Australia, Australia

Background and objectives: Millennium Development Goal4 includes the target to reduce the under-five mortality by two thirds between 1990 and 2015. Despite population growth, the number of under-five deaths worldwide fell from more than 12 million in 1990 to 7.6 million in 2010. Within the Asia Pacific Region there are still 10 countries (of 48) with infant mortality rates above 50 deaths/1000 births and the region accounts for about 40% of all infant and child deaths globally. The proportion of deaths in the neonatal period is increasing and is now 54% in the Western Pacific Region. Neonatal deaths are falling at a slower rate (1.7%) than is required to achieve the target (4.4%) and it is estimated that 25% of these deaths are preventable by following recommended infant feeding procedures, including early breastfeeding and use of inappropriate prelacteal feeds. The objective is to document early breastfeeding rates and use of prelacteal feeds in the region.

Methods: Cohort studies of breastfeeding were undertaken using the same questionnaires and

Methods in the Asia Pacific Region in China (three locations), Vietnam, Japan, Nepal, Malaysia, the Maldives, Japan, Australia and Papua New Guinea. The sample sizes ranged from 281 to 1612.

Results: In many countries there was a delay in the time until the baby received its first breastfeed. In China the high rate of caesarean sections (77% in our Hangzhou study), leads to a delay in the first feed beyond the one hour recommended by WHO. In Sichuan 93% of infants received a first feed other than breastmilk, whereas in Sabah the rate was 4.4%.

Conclusions: There are many preventable neonatal deaths in the region. Early breastfeeding and not giving prelacteal feeds has the potential to reduce these deaths by as much as 20%.

Key words: Millennium Development, Asia Pacific, Infant mortality, breastfeeding

PO221**MICROSTRUCTURAL ANALYSIS OF BINGE EATING**

A. López-Espinoza¹, A. Martínez¹, V. Aguilera¹, A. Espinoza¹, P. Zepeda¹, F. Santoyo¹

¹Behavioral Feeding and Nutrition Research Center, CUSur, University of Guadalajara, México

Background and objectives: The use of the microstructural analysis has traditionally been limited to evaluated effects of drugs on feeding behavior, this peculiarity to limited characterization of multiple food phenomena. A phenomenon that requires an appropriate characterization by its relationship to feeding pathologies development is binge eating. Experimental models based on deprivation, stress, cycles of dieting and overeating, among others have been used for their study, however, description of its microstructural behavior not yet reported. Objective of this study was to describe microstructural characteristics of binge eating using a food deprivation model in rats.

Methods: Seven male albino rats 5-month-old at the beginning of the experiment lived in the microstructural feeding analysis system enclosures continuously. Were exposed to fifteen days of free access to water and food (base line), followed by 3 days of food deprivation. On the next fifty days, water and food again were freely available. Cycle deprivation-refeeding was repeated five times.

Results: Data collected demonstrated that all subjects presented binge eating episodes after deprivation period. Meal microstructural showed differences between base line and refeeding periods. During refeeding periods, number of meals, meal size (g), meal time (s), feed rate (g/s) and returns increased, on the other hand Interval between meals (s) decreased in comparison with data collected in base line.

Conclusions: These results provide a characterization of binge eating.

Key words: Microstructural analysis, binge eating, deprivation, rats

PO222**THE MINOR ALLELE OF THE FADS1 GENE POLYMORPHISM IS ASSOCIATED WITH LOWER EICOSAPENTAENOIC ACID IN BREAST MILK OF CHINESE WOMEN**

L. Xie¹, G. Liu², Z. Gan², J. Yang¹, J. Deng¹, C. He¹

¹Department of Nutrition and Food Hygiene, Jilin University, China

²Experimental Center of Prevention, Jilin University, China

Background and objectives: The enzyme encoded by fatty acid desaturase gene 1 (FADS1) is the rate limiting enzyme

in the synthesis of long chain polyunsaturated acids (PUFAs). During the early neonatal period, rapid synthesis of brain tissue, with cellular differentiation and active synaptogenesis, has a special need for docosahexaenoic (DHA, 22:6n-3), eicosapentaenoic (EPA, 20:5n-3) and arachidonic (ARA, 20:4n-6) acids. Minor alleles of FADS1 gene polymorphisms are associated with lower ARA and EPA of breast milk in Caucasian women. We aimed to determine if SNP rs174556 (C major allele; T minor allele) in FADS1 is associated with differences in n-6 and n-3 fatty acids in breast milk of Chinese lactating women.

Methods: The subjects were 92 healthy Chinese lactating women from Changchun. Fatty acid intakes were estimated by 24 hour diet recall, and breast milk samples were collected in the postpartum 20+3 day. Fatty acid composition of breast milk was detected with gas chromatography. Rs174556 in FADS1 of lactating women was genotyped using PCR ¹³C Restriction Fragment length Polymorphism method.

Results: 92 Women had mean (±SD) concentrations of ARA (0.277±0.181 mg/ml), DHA (0.184±0.129 mg/ml), and Median (±Q) concentration of EPA (0.034±0.025 mg/ml) in breast milk. The dietary intakes of PUFAs didn't differ among the women grouped by the polymorphism rs174556. The content of EPA in breast milk was the lowest in minor allele homozygotes of rs174556 TT (P=0.047). The content of other PUFAs in breast milk didn't have significant differences among the women grouped by rs174556.

Conclusions: The minor allele TT homozygotes of the FADS1 gene polymorphism rs174556 are associated with lower EPA status of breast milk in Chinese lactating women. Supported by NSFC (81102115).

Key words: FADS1, PUFA, Breast milk, Gene polymorphism

PO223**COMPARISON OF FERMENTATION LEVELS IN LARGE INTESTINE OF RATS FED DIFFERENT CARBOHYDRATE-SOURCE DIETS BY ANALYZING FECES USING LC/MS**

M. Hagio¹, M. Matsumoto², A. Shinoki¹, A. Yokota¹, S. Ishizuka¹

¹Research Faculty of Agriculture, Hokkaido University, Japan

²Department of Physical Education, Nihon University, Japan

Background and objectives: To acquire exact condition of fermentation in large intestine, timing of taking intestinal contents is very important. However, it's difficult to investigate real-time degree of fermentation. The aim of this study is to establish the easy-to-use and rapid method of monitoring fer-

mentation by analyzing feces in rat using LC-MS, and compare fermentation pattern in rats fed different carbohydrate-source diets.

Methods: Wistar/ST rats (11-week-old) were divided into 3 dietary groups which were made from different source of carbohydrate (cornstarch, dextrin and sucrose). After acclimatization of three days, the training of 2 hour-feeding was started. At the fourth day of feeding restriction, feces were collected at 0, 3, 6, 9, 12 and 24 hours after 2 hour-feeding. Then, the concentrations of short chain fatty acids (SCFAs) which were composed of acetate, propionate and butyrate were measured by LC/MS.

Results: The total concentrations of three SCFAs in feces reached a peak at 6 hours after feeding in dextrin group and at 12 hours in sucrose group. However, in cornstarch group, the concentrations continued to rise until 24 hours after feeding. When SCFA concentrations were compared among contents of cecum, proximal colon, distal colon and rectum, SCFAs balance was almost same.

Conclusions: These results showed that difference of carbohydrate source changed a peak of fermentation. Although these results from analyzing feces may not reflect on real-time fermentation in large intestine, analyzing feces is easily-handled and capable of monitoring SCFAs balance. This method is thought to be useful for investigating the continuous change of fermentation in various conditions.

Key words: LC/MS, rat, fermentation, carbohydrate, short chain fatty acid

ced typical consecutive-reaction kinetics. Apparent K_m and k_{cat} values of hLSD1 for the first demethylation reaction were found to be in the range of previously reported values. Tranylcypromine was shown to inhibit LSD1 activity with an IC_{50} of 2.3 μM for the first demethylation reaction in the presence of 20 μM H3K4me2. FI-TOF/MS newly provided apparent K_m and K_{cat} values of hLSD1 for the second demethylation reaction, indicating more efficient demethylation reaction than the first reaction. Without using the recombinant enzyme, this FI-TOF/MS method was applied to detect endogenous LSD1 activity in a crude nuclei fraction of human neuroblastoma-derived SH-SY5Y cells.

Conclusions: A simple FI-TOF/MS assay is presented to efficiently and easily measure LSD1 enzyme activity. It is useful to measure the endogenous LSD1 activity in cultured cells.

Key words: H3K4me3, LSD1, TOF/MS, neuroblastoma, consecutive-reaction

FLOW INJECTION ASSAY FOR MEASURING LYSINE-SPECIFIC DEMETHYLASE-1 (LSD1) ACTIVITY BY TIME-OF-FLIGHT MASS SPECTROMETRY

Y. Shidoji¹, C. Sakane¹, H. Ohta²

¹Molecular and Cellular Biology, Graduate School of Human Health Science, University of Nagasaki, Nagayo, Nagasaki, Japan

²University of Nagasaki, Sasebo, Nagasaki, Japan

Background and objectives: Lysine-specific demethylase 1 (LSD1), a histone-modifying enzyme, is upregulated in many cancers, especially in neuroblastoma, breast cancer and hepatoma. We set out to establish a simple method to measure LSD1 activity using a synthetic N-terminal 21-mer peptide of histone H3, which is dimethylated at Lys-4 (H3K4me2).

Methods: After the enzyme reaction, a substrate of either H3K4me2 or H3K4me1 and two demethylated products, H3K4me1 and H3K4me0, were quantitatively determined by flow injection time-of-flight mass spectrometry (FI-TOF/MS).

Results: By using recombinant human LSD1, a nonlinear fitting simulation of the data obtained by FI-TOF/MS produ-

PO225

TIME TRENDS IN DIET AND NUTRITIONAL STATUS OF RURAL AND TRIBAL POPULATION IN INDIA: A LONGITUDINAL NATIONAL NUTRITION NNMB SURVEYS

A. Laxmaiah¹, N. Arlappa¹, I. Mesharam¹, N. Balakrishna¹, K. Mallikharjuna Rao¹, C. Galreddy¹, S. Kumar¹, M. Ravindranath¹

¹National Institute of Nutrition, ICMR, India

Background and objectives: Undernutrition is one of the major public health problems in India, affecting mostly children, adolescents and reproductive age women. It may result by multiple overlapping and interacting factors, which are in dynamic in nature. For the purpose, National Nutrition Monitoring Bureau was established by the ICMR in 1972, to monitor diet and nutritional status of population groups in India.

Methods: The study was a community based longitudinal and adopted multistage sampling. The repeat surveys were carried out in 1979, 1990, 1997 (N 60,601) and 2012 (N 86,754) among rural population and similar surveys were carried out in 1987 (N 41,576), 1999 (N 90,885) and 2009 (N 1,15,113) among tribal population from 1200 selected villages in 8-10 major states in India to assess nutrition time trends.

Results: Despite no change in food and nutrient intakes over a period of 4 decades, the prevalence of severe underweight (<Median-3SD) was significantly ($p < 0.001$) declined from 42.2% in 1979 to 15.9% in 2012. The prevalence of severe stunting (<Median-3SD) was also significantly ($p < 0.0001$) declined from 57.8% to 22.2% in the same period. In case of tribal children, the prevalence of severe underweight was significantly ($p < 0.001$) declined from 22.9% in 1999 to 20% in 2009 and

severe stunting was also significantly ($p < 0.001$) declined from 30.8% to 25.7% in same period. In case of adults, the prevalence of chronic energy deficiency ($BMI < 18.5$) was significantly declined from 50% in 1999 to 40% in 2009 and concomitantly, overweight and obesity was ($p < 0.01$) increased.

Conclusions: The study revealed, there was significant reduction in prevalence of severe undernutrition and increase in overweight and obesity over a period of 4 decades, despite no change in the diet and it could be due to physical inactivity, which needs to be explored.

Key words: Underweight, Stunting, time trends, overweight, rural

⁵Economics Department, Latvia University of Agriculture, Jelgava, Latvia

Background and objectives: Results of the European Nutrition and Health Report 2009 [ELMADFA I, 2009] show that children aged three to six years have unfavorable nutrition behaviors. To improve these habits a guidebook for nutrition education in kindergarten was developed through collaboration between different academics (nutritionists, home economists, pediatricians, educationists, psychologists) across five countries (Austria, Germany, Latvia, Romania, Turkey) within the Lifelong-Learning-project NUTGECS.

Methods: A stakeholder analysis according to Hughes and Margetts [2011], researches concerning the nutritional status of children aged three to six years, investigation of nutrition training of kindergarten teachers, of the current situation of early childhood nutrition education, impact of community nutrition, and the legislative framework for kindergartens have been conducted in all participating countries.

Results: Based on the stakeholder analysis kindergarten

teachers were chosen as the target group for the guidebook. Kindergarten teachers have a multiplier effect, are persons of trusts, important role models and have contact to other relevant stakeholders. The analysis concerning the nutritional status show that early childhood nutrition is a major health issue in all countries although problems vary. However, in all states children consume too many sweets and too less fruit, vegetables, dairy products and carbohydrate rich food, which results in a deficient intake of vitamin D, folate, iodine, and protein. Therefore, the theoretical part of the guide focused on these food items and nutrients. The practical part presents child-appropriate nutrition education examples and parental involvement strategies.

Conclusions: The established Nutrition Guide for Early Childhood Active Stakeholders (free download: www.nutgecs.eu) offers scientific information and practical approaches. Through this comprehensive approach the guidebook is a sustainable way to support kindergarten teachers in nutrition education.

Key words: nutrition education, kindergarten, guidebook

PO227

IMPACT OF SOCIO-ECONOMIC STATUS ON BODY WEIGHT OF AUSTRIAN KINDERGARTEN CHILDREN

P. Rust¹, E. Höld¹, P. Bayaty¹, K. Wagner-Sahl¹

¹Department of Nutritional Sciences, University of Vienna, Vienna, Austria

Background and objectives: In public opinion overweight and obesity are increasing problems in Austrian children, although data show that the number of children with too high body weight is almost constant during the last years [ELMADFA et al., 2003; 2008; 2012]. However, increasing percentages of overweight/obesity are going along with rising age and a variety of other determinants especially socio-economic status.

Methods: Within the framework of the Austrian kindergarten nutrition intervention project MOGI anthropometric measurements have been conducted in 183 3-to 6-year old children. BMI-Classification has been done according to percentile curves of Kromeyer-Hauschild [2001]. Participating families were randomized into socially disadvantaged and not disadvantaged by the Family Affluence Scale (=FAS) [BOYCE et al., 2006].

Results: 41.0 % of all participating children were socially disadvantaged. The majority of all children were normal weight (79.2%), 10.9% were overweight, 4.4% obese and 5.4% underweight. These outcomes are similar to the results of the Austrian Nutrition Report 2003 [ELMADFA et al., 2003]. Social background didn't influence the children's BMI ($p > 0.050$). Although, parents of socially disadvantaged children are less

informed about healthy nutrition than not disadvantaged ($p < 0.001$), children of both groups consume comparable amounts of fruit and vegetables ($p = 0.078$).

Conclusions: Data of the MOGI-project indicate that the BMI of the majority of Austrian kindergarten children is within the normal range and stable over the last ten years. Although social background determines parental nutrition knowledge their childrens' eating habits and body weight are not different in between social advantaged and disadvantaged children at that point of life. This might be due to the needless behavior of children and the compensatory influence of kindergarten teachers as important role models. These results underline the importance of nutrition education in kindergarten to sharpen personal responsibility of children.

Key words: kindergarten children, body weight, socio-economic status

PO228

A STUDY ON THE EFFECTS OF LOW PROTEIN DIET ON HEPATIC MIRNA AND ITS TARGET GENES BY MICROARRAY ANALYSIS

K. Takahashi¹, K. Saito², S. Takahashi¹, H. Kato²

¹Department of Applied Biological Chemistry, The University of Tokyo, Tokyo, Japan

²Organization for Interdisciplinary Research Program 'Food for Life', The University of Tokyo, Tokyo, Japan

Background and objectives: microRNA (miRNA) is a small non-coding RNA which regulates gene expression by repressing transcription or cleaving mRNA of target genes. In this study, we aimed to examine the effect of nutrition on the expression of miRNA, which has remained to be a target of nutritional science. In addition, we investigated the influence of nutritional condition on the regulation of miRNA on mRNA expression which might result in physiological changes.

Methods: six week male Wistar rats were divided into Control (C) group and Low Protein (LP) group. C group was fed a 20% casein diet and LP group was fed a 5% casein diet for 2 weeks. Total RNA were extracted from the livers and used for microarray analysis of miRNA (GeneChip® miRNA 2.0 Array, Affymetrix) and mRNA (GeneChip® Rat Genome 230 2.0 Array, Affymetrix). HepG2 cells were transfected with synthetic miRNA as well as its antisense inhibitor. The expression of the putative target genes were then validated by qRT-PCR.

Results: The miRNA array analysis revealed that miR-203 was down-regulated by the LP diet. mRNA expression analysis showed an up-regulation of Hadhb, which is a putative target gene of miR-203 and a gene encoding an enzyme for fatty acid beta-oxidation. In HepG2 cells, overexpression of miRNA cau-

sed a down-regulation of Hadhb, which was up-regulated by the introduction of the antisense inhibitor.

Conclusions: In this study, we have shown that low protein diet up-regulates the expression of Hadhb through the down-regulation of miR-203. This is the first research exemplifying the effective practical application of the combination of miRNA array analysis with mRNA expression analysis in nutritional science.

Key words: miRNA, microarray, protein nutrition, miR-203

STUDY ON VITAMIN D RECEPTOR GENE FOK1 POLYMORPHISM WITH PIG'S MYOFIBER PROLIFERATION

B. Jin¹, Y. Zhu¹, L. Gong¹, X X. Zhang², X. Zhou¹, Y G. Yuan², Q. Yin¹

¹Department of Food Science and Nutrition, Nanjing Normal University, Nanjing, China

²Nanjing Institute of Animal and Poultry Sciences, Nanjing, China

Background and objectives: In this research the expression and polymorphism of vitamin D receptor (VDR) gene and its Fok1 locus (located in exon 2 start codon region) was studied for myofiber proliferation via protein translation in pig's *Longissimus dorsi* (LD).

Methods: 101 LD samples was collected from 12 breeds and used to test meat shear force, VDR gene expression and Fok1 locus polymorphism by RT-PCR, PCR-RFLP and sequencing technology.

Results: Expression of VDR gene was $0.68 \pm 0.01 - 0.81 \pm 0.01$ in LD of all breeds, significantly ($P < 0.05$). Fok1 locus had three genotypes such as f (wide), fF (heterozygote) or F (mutant) in pig's skeletal muscle (LD). For VDR Fok1 locus genotype frequency analysis, T and C alleled frequency of 40.10% and 59.90%, respectively. When the base T at GGATG was replaced by C on Fok1 locus, the genotype f would be mutated to F as GGACG. It was found that there were three genotypes in LD of Shanzhu who is the special China dark pig with thin myofiber and less meat shear force, while Landrace or Yorkshire had no genotype f with bigger size and meat shear force. If Shanzhu or other China pigs were hybridized with lean-pigs as Yorkshire, genotype f and fF of Fok1 locus in LD was increased with F decrease, significantly ($P < 0.05$). The association of VDR Fok1 genotypes with meat shear force was analyzed by GLM model. It was verified that genotypes of VDR Fok1 locus was correlated with meat shear force, significantly ($P < 0.05$). The influence of genotypes f and F at VDR Fok1 locus on meat shear force was up to $P < 0.01$ as $F > fF > f$.

Conclusions: This meant that the higher expression of genotype F at VDR Fok1 locus could induce the myofiber proliferation in skeletal muscle. It was indicated that VDR Fok1 locus polymorphism is a major factor for meat tenderness.

Key words: VDR, Fok1, locus polymorphism, myofiber proliferation, meat shear force, pigs

PO230

RELATIONSHIP OF PPAR γ 2 BSR1 LOCUS POLYMORPHISM AND LIPIDS METABOLISM IN LONGISSIMUS DORSI

B. Jin¹, Y. Zhu¹, L. Gong¹, Q. Yin¹, X. Zhou¹, X X. Zhang², Y G. Yuan²

¹Department of Food Science and Nutrition, Nanjing Normal University, Nanjing China

²Nanjing Institute of Animal and Poultry Sciences, Nanjing China

Background and objectives: The expression and polymorphism of PPAR γ 2 gene and its Bsr1 locus, located in the coding region of the first promoter, was studied the relationship of lipids metabolism in pig's Longissimus dorsi (LD).

Methods: 101 LDs as muscle samples were to analyze its intramuscular fat (IMF) and prepared cDNA to test PPAR γ 2 expression in LD, Bsr1 locus polymorphism and sequences.

Results: The expression of PPAR γ 2 gene in pig's LD was between 0.35±0.07- 0.58±0.07 in 12 breeds ($p < 0.05$ or $p < 0.01$, $YIMF = 4.04X + 0.68$, $R = 0.22$). Bsr1 locus had three genotypes such as b (wide), bB (heterozygote) or B (mutant) in pig's skeletal muscle (LD). The average frequency of three genotypes was 15.49% b, 23.95% Bb and 60.56% B respectively. When the base G on Bsr1 locus (CCAGT) was replaced by A as CCAAT, wide genotype b was mutated to genotype B. Bsr1 locus genotypes in LD of China dark pig as Shanzhu contained all of three (b, bB and B), in which type b was expressing up to 50.00%. In contrast, Bsr1 locus in Landrace and Yorkshire LD was lack of type b. If China pigs were hybridized with Landrace, type bB would express highly in these breeds. So a mathematical model (GLM, $Y = \mu + G + X + S + e$, Y as apparent characters; μ as means of apparent characters; G as genotype; X as breeds; S as sex; e as residuals) was built a relationship of Bsr1 locus genotypes and lipids metabolism. It was found that the higher type b, the more content IMF, significantly ($P < 0.05$). There were $b > Bb > B$, respectively.

Conclusions: This suggested that the high expression of type b contributed to adipose differentiation, deposition and appropriate meat tenderness. It also means PPAR γ 2 gene can be the meat target gene.

Key words: PPAR γ 2; Bsr1 locus polymorphism; lipids metabolism; intramuscular fat; pigs

QR-CODES IN FOOD LABELING: OUTLOOK FOR FOOD SCIENCE AND NUTRITION

J. Sanz-Valero^{1,2,7}, L M. Álvarez Sabucedo³, C. Wanden-Berghe^{4,5,7}, E. Martínez de Victoria^{6,7}

¹Department of Public Health and History of Science, Miguel Hernández University, Elche, Spain

²Department of Public Health and History of Science, University of Alicante, Alicante, Spain

³Telematics Engineering Department, University of Vigo, Vigo, Spain

⁴Department of Pharmacy, CEU Cardenal Herrera University, Elche, Spain

⁵Home Care Unit, General University Hospital of Alicante, Alicante, Spain

⁶INYTA, University of Granada, Granada, Spain

⁷Communication and Scientific Documentation in Nutrition Group (CDC – Nut SENPE), Madrid, Spain

Background and objectives: Although the use of QR-codes (Quick Response codes) has not been broadly adopted in the domain of food science/nutrition, it is possible to find it increasingly as a complement for labelling. The aim is to explore and show proposals for using QR-codes in the domain. The final goal is to describe how the applications of QR-codes can largely benefit the food science/nutrition.

Methods: From the evaluation of QR-codes use cases in the context of the industry, it is possible to derive new applications to the nutrition domain. The goal is to design Web-based systems to enable the provision of advanced services that already are supported in the present in many contexts of the daily-life but with better performance.

Results: Some proposals about the use of QR-codes:

- Basic research:
 - Advanced tagging of laboratory samples.
- Food security:
 - Comprehensive information about nutritional composition.
 - Advanced features to avoid falsifications and food fraud.
 - Control of technological processes and determination of the HACCPs (Hazard Analysis and Critical Control Points).
 - Application to food traceability.
- Community nutrition:
 - Use for patient education.
 - Reduced time and costs in investigating food poisoning.
- Clinical nutrition:
 - Based on the patient profile, reporting food suitability in certain metabolic diseases.
 - Providing information on food-drug interactions.

-In home care, the QR-codes will facilitate the exchange of information between caregivers and medical equipment.

Conclusions: The possibilities of QR-codes are countless, almost anything you want to imagine. Therefore, sooner or later, this technology will achieve a role of the paramount relevance in our context. This seems to be the right time to actively seek for the best ways to make the most of this promising technology tools.

EFFECTS OF NON-DIGESTIBLE POLYSACCHARIDES ON FOOD TASTES

K. Makishima¹, T. Yasui¹, W. Suyotha¹, M. Umekawa¹, S. Yano², M. Wakayama¹

¹Department of Biotechnology, College of Life Sciences, Ritsumeikan University, Japan

²Department of Biochemical Engineering, Graduate School of Yamagata University, Japan

Background and objectives: Non-digestible polysaccharides such as chitin, chitosan, f_{β} -1,3-glucan and f_{α} -1,4-glucan are not subjected to degradation by digestive enzymes of human beings, and commonly called dietary fiber. Non-digestible polysaccharides contribute to prevention of myocardial infarction, obesity, diabetes, and therefore such substances are of critical importance. However, it is difficult to ingest adequate non-digestible polysaccharides. Accordingly, it is desirable to ingest non-digestible polysaccharides easily. Meanwhile, at present, no studies on effect of non-digestible polysaccharides on tastes have been reported. We have focused on interaction between non-digestible polysaccharides and taste components. If non-digestible polysaccharides have favorable effects on tastes, they can be applied to new flavoring agents or food additives. Here we report effects of non-digestible polysaccharides on food tastes.

Methods: As non-digestible polysaccharides, f_{β} -1,3 or 1,6-glucan, f_{β} -1,3-glucan, chitin, chitosan were used. f_{β} -1,3 or 1,6-glucan and f_{β} -1,3-glucan were prepared in our laboratory. As taste components, sodium chloride, glucose, fructose, monosodium glutamate and sodium inosinate were used. Each non-digestible polysaccharide was mixed with each taste component and incubated. After incubation, the non-digestible polysaccharide was precipitated by centrifugal separation or standing, and then supernatant concentration of taste component was analyzed. Sodium chloride concentration was measured by salinometer. Glucose and fructose concentrations were determined by 3, 5-dinitro salicylic acid method. Monosodium

glutamate used by glutamate dehydrogenase method. Sodium inosinate was determined by absorption spectrum.

Results: Significant interactions between f_{β} -1,3 or 1,6-glucan and fructose, f_{β} -1,3 or 1,6-glucan and monosodium glutamate, f_{β} -1,3-glucan and monosodium glutamate were observed. Each maximum interaction rates were about 64%, 75% and 49%, respectively.

Conclusions: Significant interactions were found between f_{β} -1,3 or 1,6-glucan and fructose, f_{β} -1,3 or 1,6-glucan and monosodium glutamate, f_{β} -1,3-glucan and monosodium glutamate.

Key words: non-digestible polysaccharide, taste, interaction

PO233

EFFECTIVE DOSAGE OF S-EQOL FOR MANAGEMENT OF MENOPAUSAL SYMPTOMS

S. Uchiyama¹, T. Ueno¹, S. Iwashita²

¹Otsuka Pharmaceutical Co., Ltd., Saga Nutraceuticals Research Institute, Japan

²Pharmavite, LLC, Japan

Background and objectives: We have developed a dietary supplement with S-equol, a fermented soygerm by lactic acid bacterium *Lactococcus* 20-92. This research investigated the dosage of S-equol needed to alleviate menopausal symptoms. Two double blind placebo controlled studies were conducted with Japanese postmenopausal equol non-producing women.

Methods: One hundred five subjects (40-60yrs) were randomly assigned to either 2mg/d (EQ-2), 6mg/d (EQ-6) or 10mg/d (EQ-10) equol supplement groups or placebo (P) for 12 wks. Subjects completed the simplified menopausal index (SMI), which is a rating scale for menopausal symptoms at 0, 6 and 12 wks. Since treatment of menopausal symptoms have many placebo effects, over 50% placebo responders in SMI during the 4 wks of screening period were excluded from the treatment period in the confirmation study. One hundred sixty subjects (45-60yrs), who were more than 25 in SMI and 1/day in hot flushes (HF), were assigned either P or EQ-10 group for 12 wks. Menopausal symptoms were assessed by multiple instruments including HF frequency record.

Results: The changes in SMI score at 12 wks were -49.3% in P, -54.1% in EQ-2, -52.8% in EQ-6 and -68% in EQ-10. Reduction of shoulder stiffness showed EQ dose dependency, with a difference between P vs. EQ-10 for 6 wks (0.0+/-0.4 vs -0.5+/-0.7, $p<0.05$) and for 12 wks (-0.3+/-0.4 vs -1.0+/-0.9, $p=0.06$). Thus, EQ-10 was decided to be used as the dosage for the confirmation study. In the confirmation study, both severity of HF and neck and muscle stiffness were significantly improved in EQ-10 vs in P at 12 wks. HF frequency was reduced in EQ-10 than P (-58.7% vs -34.5%, $p<0.01$).

Conclusions: These results suggest that 10mg/day EQ supplement alleviates menopausal symptoms, especially in HF and neck/shoulder and muscle stiffness, in EQ non-producing post menopausal Japanese women.

Key words: equol, soy, menopausal symptoms

PO234

CIRCADIAN RHYTHMICITY AS A PREDICTOR OF WEIGHT LOSS

M C. Bandin Saura¹, A. Martinez-Nicolas¹, J A. Madrid¹, M. Garaulet¹

¹Departamento de Fisiología, Universidad de Murcia, Murcia, Spain

Background and objectives: One of the objectives in the treatment of obesity is to identify which are the best predictors of weight loss success. Circadian rhythmicity, previously associated with obesity, could be a good marker of the effectiveness of the treatments. The aim of this work was to study the potential relationship between circadian rhythms and total weight loss in women undergoing a behavioral therapy treatment based on Mediterranean Diet.

Methods: We selected 85 overweight women (BMI: 28.59±4.30), subjected to a weight-reduction program. Efficacy of the treatment was defined as the total weight loss, percentage of initial weight and weekly weight loss rate of the studied population. To study circadian rhythmicity, distal wrist temperature (WT), motor activity and position were analyzed.

Results: Pearson's correlation analyses showed significant association between the efficacy of the treatment and different circadian rhythmicity variables. Lower weight loss was related with worse WT circadian rhythmicity determined by means of Circadian Function Index ($r=0.228$, $p=0.038$) and a more flattened pattern measured as amplitude from cosinor ($r=0.235$, $p=0.032$). This correlation was inverse for the intradaily variability ($r=-0.339$, $p=0.002$), which suggests a higher fragmentation of rhythms. Moreover, the group of women ($n=10$) who lost less weight displayed lower relative amplitude ($0.71±0.36$ vs $1.24±0.62$, $p=0.036$) and higher intradaily variability ($0.24±0.11$ vs $0.15±0.07$, $p=0.043$) than those who achieved the highest weight loss ($n=10$). With respect to position, other marker of circadian rhythmicity, women who lost more weight were in general presents position less lying during the day (higher positions) than those with lower weight loss ($39.12±3.79$ vs $35.31±2.53$, $p=0.011$).

Conclusions: The study of the circadian pattern at the beginning of the treatment may be a good predictor of future weight loss. Further treatment should consider chronobiological aspects to diagnose obesity and effectiveness of treatments.

Key words: Circadian Rhythm, Weight Loss, Treatment Efficacy.

PO235

DIVERSE SIGNALING PATHWAYS OF AMINO ACIDS FOR AUTOPHAGY CONTROL

A. Angcajas¹, K. Kaneshiro¹, N. Hirai¹, S. Fujimura¹, M. Kadowaki¹

¹Department of Applied Biological Chemistry, Graduate School of Science and Technology, Niigata University, Niigata, Japan

Background and objectives: Amino acid (AA) is a well-known autophagy regulator. mTOR is considered as the main signaling pathway of physiological regulation for autophagy. Additionally, reactive oxygen species (ROS) modulates autophagy in response to various cellular stresses, such as starvation, and is also considered as a signaling molecule in autophagy. To explore the relevance of ROS production to AAs effect on autophagy, we analyzed the effects of individual AA on the intracellular ROS level and autophagy in H4IIE cells.

Methods: DCFDA was used as fluorescent probe during ROS measurement. The cytosolic LC3 ratio (LC3-II/LC3-I) was employed as a suitable autophagic index. LC3 signals were detected by Western blotting.

Results: Separate treatments of complete (CAA), regulatory (RegAA), and nonregulatory (nonRegAA) amino acids in H4IIE cells resulted to suppression of autophagy by 42%, 22%, and 18%, respectively. Significant suppression in intracellular ROS production was observed with CAA and RegAA. Interestingly, individual AA showed various stimulating or suppressive effects on ROS level. The profile did not correspond with that of autophagic suppression by individual AAs. The response of autophagy to tryptophan, alanine, glutamine, and tyrosine fit with the suppression of ROS production. Cysteine showed remarkable suppression on ROS production, in contrast with cystine, but both showed minimal effects on autophagy. Furthermore, arginine resulted in 35% autophagic suppression, but its ROS production was stimulated. During inhibitor study of NO pathway, aminoguanidine, L-NMMA, and rapamycin treatments suggested that NO signaling pathway, but not mTOR pathway, was involved in arginine regulation on autophagy.

Conclusions: These results strongly indicate diverse and unique signaling pathways for individual AA, as manifested by lack of correlation between ROS production and autophagy regulation. The involvement of NO signaling for arginine is an evidence that mTOR is not the only signaling pathway possible for autophagy regulation by AA.

Key words: Autophagy, ROS, Amino acid

PO236**A NEW FERMENTED MILK SAUCE G LACTOSHOH USING A MONASCUS KOJI**

S. Fujimoto¹, Y. Ishitani¹, M. Umekawa¹, S. Yano², M. Wakayama¹

¹Department of Biotechnology, College of Life Sciences, Ritsumeikan University, , 1-1-1 Nojihigashi, Kusatsu, Shiga, Japan

²Department of Biochemical Engineering, Graduate school of Yamagata University, 4-3-16, zyouunan, yonezawa, Yamagata, Japan

Background and objectives: Cow's milk is used for drink and food all over the world because of its high nutritive value. However, the difficulty of production adjustment and decrease of consumption have caused the problem of mass disposal of cow's milk. Lactosho was developed for the method of effective utilization of cow's milk. Lactosho is the new fermented seasoning which is produced from milk protein by referring soy sauce fermentation process. In this study the fungus *Monascus* is used as major koji mold instead of *Aspergillus oryzae*. Since monakolin K which is the secondary metabolite of *Monascus* has hypocholesterolemic activity, it is expected to add functionality to Lactosho by using *Monascus*. Here are report Lactosho fermentation using *Monascus* as major koji mold and evaluation of the product.

Methods: *Monascus pilosus*, *Monascus purpureus* and *Aspergillus sojae* were used for koji mold. Skim milk powder and flour were used for raw materials of koji. Several combinations of koji mold were applied to Lactosho fermentation in this study. Lactosho fermentation was conducted for 90 days. Enzyme activities (protease, f_2 -amylase, glucoamylase, $f\hat{A}$ -galactosidase) were monitored during fermentation. Amino acid analysis of fermentation samples were performed by HPLC. Sensory test of fermentation products was conducted by lab members.

Results: The Lactosho made *Monascus* and *A. sojae* koji mixed showed relatively high enzyme activities (protease, f_2 -amylase, and glucoamylase) and quantity of amino acids compared with other samples. On the other hand, $f\hat{A}$ -galactosidase activity was low in all samples. The taste of Lctosho made by *Monascus purpureus* koji was more high evaluation than *Monascus pilosus*.

Conclusions: Combination of *Monascus* koji and *A. sojae* koji gave a good properties to Lactosho, high enzyme activities (protease, f_2 -amylase, glucoamylase) and high quantity of amino acid.

Key words: Cow's milk, Lactosho, *Monascus pilosus*, *Monascus purpureus*, *Aspergillus sojae*

PO237**OLIGOSACCHARIDE DERIVED FROM LEUCONOSTOC MESENEROIDES SUPPRESS GLUCOSYLTRANSFERASE I FROM STREPTOCOCCUS MUTANS**

K. Ishihara¹, W. Suyotha¹, S. Yano², M. Umekawa¹, M. Wakayama¹

¹Department of Biotechnology, Collage of Life Science, Ritsumeikan University, Kusatsu, Shiga, Japan

²Department of Biochemical Engineering, Graduate School of Yamagata University, Yonezawa, Yamagata, Japan

Background and objectives: *Streptococcus mutans* causes dental caries, since it adheres to the tooth and secretes lactic acid which can dissolve tooth enamel. The adhesion of *S. mutans* is supported by its extracellular polysaccharide (a-1,3-glucan, also called mutan), synthesized by glucosyltransferase I (GTF-I). Mukasa et al. reported that activity of GTF-I from *S. sobrinus* was decreased by addition of nigerooligosaccharide, considering that a-1,3-or-1,6-glucan oligomer can serve as GTF-I inhibitor. *Leuconostoc mesenteroides* synthesizes water-insoluble glucan which has a-1,3- and a-1,6-linkage, also called alternan. Because lactic acid bacteria have been extensively applied in the food industry, their glucans are interesting for the additives used in the production of foods. This study investigated the suppressive effect of a-1,3-or-1,6-glucan oligomers from *L. mesenteroides* on activity of GTF-I from *S. mutans*.

Methods: Alternan was synthesized by *L. mesenteroides* NBRC 100496 using sucrose as a substrate. Oligosaccharides were prepared by partial hydrolysis of alternan, using mutanase or/and dextranase, for 15, 30, 60, and 90 min at 30 °C. The preparations were subjected to evaluation of their inhibitory effect on GTF-I from *S. mutans*. Inhibitory activity was evaluated by measuring the turbidity of synthesized mutan in glass tube. The preparation that showed high inhibitory activity was analyzed by gel filtration chromatography (Bio-Gel P6), thin layer chromatography, and ultrafiltration (10,000-M.W. cutoff).

Results: The preparation with highest inhibitory activity was obtained by hydrolysis of alternan for 30 min with dextranase. It showed 65 % suppression of GTF-I from *S. mutans* when it was added to the reaction solution at a concentration of 0.092 mM (glucose equivalent). Molecular size of oligosaccharides was estimated under 10,000 and their backbone was a-1,6-linkage.

Conclusions: a-1,3-or-1,6-glucan oligomers derived from *L. mesenteroides* can be used as new anticariogenic oligosaccharides because of their suppression of GTF-I from *S. mutans*.

Key words: oligosaccharide, glucosyltransferase, *Streptococcus mutans*, *Leuconostoc mesenteroides*

PO238**THE USE OF FOOD FREQUENCY QUESTIONNAIRE AS A TOOL FOR BEHAVIOR MODIFICATION**

T. Tangsermwong¹, T. Lapananon², S. Meewan², S. Kominadr²

¹Division of Nutrition and Dietetics, Faculty of Medicine, Ramathibodi Hospital, Mahidol University, Bangkok, Thailand

²Division of Nutrition and Biochemical Medicine, Department of Medicine, Faculty of Medicine, Ramathibodi Hospital, Mahidol University, Bangkok, Thailand

Background and objectives: Obesity is a difficult-to-treat disease. In most instances, it is also a behavior problem as well as the eating awareness. A self-check questionnaire of high-risk food items can be a good behavior-modifying tool for the obese. It is easy and takes only little time to fill out.

Methods: Twenty-nine items of high risk food affecting weight were chosen to create a short semi-quantitative questionnaire. Its content consisted of the frequency and also the amount of food ingested during the past week. Participants who wanted to lose weight were taught to modify their behavior based on self awareness, energy calculation, food exchange and exercise. The short semi-quantitative food frequency questionnaire was used as one of the several evaluating forms which subjects must answer following through the program. The behavior was checked at the first visit before starting the protocol, and during staying in the study.

Results: Forty-nine cases completed the questionnaire. Compare with the first visit the frequency and amount of high risk food items eaten by the participants, during subsequent visits were fruit cooked in concentrated syrup, Fast foods, sweeten milk, curry in coconut milk, Thai dessert, Potato chip, dried crunchy meat were being consumed less and the reduction were 26.5, 20.4, 20.4, 18.4, 16.3, 16.3, 16.3%, respectively. Two weight-influence food items being consumed by most participants during the last follow up at 8 weeks were iced coffee and tea and fruit juice.

Conclusions: The short and appropriate itemized food-questionnaire is an interesting monitoring-tool for making awareness and gradually modifying the unhealthy food behavior of the subjects. Adding more items of the high risk food to the questionnaires as well as keeping regular recording of the questionnaires should provide more benefit for individualized weight reduction.

Key words: Food frequency questionnaire, Behavior modification, Self awareness

PO239**REGULATION OF AUTOPHAGY BY ANTIOXIDANTS IN RAT ISOLATED HEPATOCYTES**

Y. Horii¹, R. Karim¹, H. Rokeya¹, M. Kubota², S. Fujimura^{1,2}, M. Kadowaki^{1,2}

¹Department of Applied Biological Chemistry, Graduate School of Science and Technology, Niigata University

²Center for Transdisciplinary Research, Niigata University

Background and objectives: In eukaryotes, autophagy is an indispensable intracellular mechanism of bulk protein degradation that is induced by starvation, and also regulated by nutrients and hormones. In recent years, we have focused on the effect of antioxidants on autophagy. Physiological levels of vitamin C and vitamin E enhanced autophagy. Enhancer of autophagy is considered to be beneficial for anti-aging. Then, we further attempt to clarify the effect of typical antioxidants, N-acetylcysteine (NAC), alpha-lipoic acid (LA), and epigallocatechin gallate (EGCG) on autophagy in rat isolated hepatocytes. EGCG is a main component of green tea catechins.

Methods: Fresh hepatocytes were isolated from male Wistar/ST rats by collagenase method. Autophagy was assessed by cytosolic LC3 ratio method*. All nutritional signals of autophagy are believed to get to LC3, a specific autophagy marker protein.

Results: Autophagy was suppressed by 5mM NAC, and 1 and 5mM LA. However, the effect of EGCG was biphasic, stimulated autophagy at 50fÊM (physiological dose) and suppressed it at 200fÊM.

Conclusions: These results suggest that, in rat isolated hepatocytes, the effects of these antioxidants on autophagy are not uniform. The reason may be dependent on the specificity of the antioxidants and on their concentrations, i.e., physiological or pharmacological.

Key words: Autophagy, Antioxidants, EGCG, Rat isolated hepatocytes, Cytosolic LC3 ratio method

PO240**THE ETHNO-BOTANY OF WILD EDIBLE FRUIT TREES IN GULU, UGANDA AND ASSOCIATED CONSERVATION THREATS**

*C. Oryema*¹, *H. Oryem-Origa*², *J. Tabuti*², *N. Roos*³

¹Gulu University, Uganda

²Makerere University, Uganda

³University of Copenhagen, Denmark

Background and objectives: Edible wild fruits are recognised in diets and livelihood strategies of rural communities resettled after civil wars in Northern Uganda. However, the contribution is unknown. The study objectives were to document: 1) the products and services obtained from most preferred wild edible fruit trees in Gulu District, and their modes of harvest, 2) to determine threats against these species, and 3) to establish existing constraints and conservation strategies.

Methods: A survey was conducted in 2010-2011 and included 350 respondents from six sub-counties. Quantitative data were collected using questionnaires with households. The respondents were selected in a cluster sampling procedures. Qualitative data were collected using field and home observational studies.

Results: The five top ranked fruit tree species preferred for their fruits were identified in the survey, and selected for detailed investigations. These included: *Vitellaria paradoxa* Gaertn, *Vitex doniana* Sweet, *Borassus aethiopum* Mart, *Tamarindus indica* L. and *Annona senegalensis* Oliv. Both direct and indirect uses and services of the fruit trees were mapped. These included: fuel-wood, charcoal, medicinal, timber, construction materials, crafts and ecological services. Modes of harvests varied for the different products, consequently impacting differently on the tree populations and diversity. The main constraints for sustainable future utilisation included perception that these trees were still in plenty and cannot be transplanted from their original environment (62%), and lack of knowledge on nutritional contribution (15%). Majority of the respondents (66%) preferred to retain the trees in their gardens, rather than to replant them.

Conclusions: Edible fruit trees provide extensive benefits to the rural livelihoods, but they are highly threatened due to unsustainable exploitation. Collaborative actions among different stakeholders that enhance conservation and provisions of such trees are recommended.

Key words: Wild Fruit uses, Gulu, Uganda

PO241**OREXIGENIC HYPOTHALAMIC ACTIVATION DETERMINED WITH FUNCTIONAL DIFFUSION WEIGHTED IMAGING (fDWI) DIFFERS AMONG OBESE AND LEAN ANIMALS DURING FASTING**

*M. Tabernero*¹, *B. Lizarbe*², *V. Caz*¹, *P. López-Larrubia*², *S. Cerdan*², *C. Largo*¹

¹Experimental Surgery Department, Hospital La Paz Health Research Institute, Madrid, Spain

²Department of Experimental Models of Human Diseases, Instituto de Investigaciones Biomédicas, Madrid, Spain

Background and objectives: the outcome of adaptive responses mediated by hypothalamus during fasting is the reduction of energy expenditure and the promotion of food intake. Therefore, understanding its regulation is key in appetite management. Our aim was to compare hypothalamic activation in spontaneous lean, normal and obese animal under fed and fasting conditions using fDWI.

Methods: 16 male wistar rats were fed ad libitum during 6 months with high-fat diet. After 18 weeks animals were distributed according its body weight (bw) into obese (n=3; bw > 600g), normal (n=10 bw between 450 and 550g) and lean (n=3; bw < 430g). Functional Diffusion weighted imaging (fDWI) was applied to fed and overnight fasted rats in a 7T magnet. Data was analyzed in the Dorsomedial, Ventromedial and Arcuate Nucleus (DMN, VMN and ARC, respectively) and fitted to a biexponential model with slow (SDP) and fast (FDP) diffusion phases and slow (Dslow) and fast (Dfast) diffusion coefficients. Plasmatic biochemical parameters were assessed enzymatically, while hormone and plasma adipose cytokines were determined by ELISA.

Results: Obese animals presented larger adipose depots and worse lipid profile than the normal and lean group. Not significant differences were observed in the plasmatic glucose, hormones and cytokines concentrations among groups. Obese and normal rats showed similar fDWI responses to fasting, with significant increments of SDP and Dslow in the orexigenic ARC and VMN nuclei, reflecting activation-induced astrocytic swelling. In contrast, SDP and Dslow decreased in the DMN of non-obese rats upon fasting.

Conclusions: Animals that spontaneously did not develop obesity following a high fat diet showed a different hypothalamic response to fasting than animals that developed obesity. Under energy restriction hypothalamic nuclei activation follows similar patterns in obese and normal animals, which activate orexigenic signals in contrast with those observed in lean group.

Key words: hypothalamus, appetite, obesity

PO242**BODY MASS INDEX AND BLOOD PRESSURE OF UNDERGRADUATES STUDENTS IN SOUTH WEST NIGERIA***S. Nupo¹, J. Akinlotan¹, O. Akinlua¹*¹Moshood Abiola Polytechnic Ojere Abeokuta, Nigeria

Background and objectives: The study was carried out to determine the prevalence of overweight and the blood pressure of undergraduates in South west Nigeria. A total number of five hundred (500) students were randomly-selected.

Methods: A representative sample of five hundred (500) students was surveyed from south west Nigeria pretested interview guide was used to collect information on personal data, and socio demographic characteristics of the subjects. Information on dietary diversity was obtained using Food and Nutrition Technical Assistance Project questionnaire (FANTA). Body mass indexes (BMI), waist-hip ratio (WHR) were used in classifying obesity. Information on food intake was obtained from 24- hour dietary recall techniques. Fasting Blood samples were collected from the students to determine their lipid profile. Automatic sphygmomanometer was used to measure the blood pressure, dietary diversity score (DDS) was computed and the nutritional status was assessed. Data were analyzed using descriptive statistics; SPSS software package version 16.0.

Results: The result of the blood pressure revealed that 36% of the female had normal blood pressure, 22% had pre-hypertension, 6% had stage 1 hypertension while 2% had stage 11 hypertension. Also, 14% of male had normal blood pressure, 15% had pre-hypertension, 4% had stage 1 hypertension, 2% had stage 11 hypertension. The result of BMI shows that 7% of the female were overweight, 2% had obesity grade 1 while 0.3% had obesity grade 11. Only 2% of male were overweight. The result reveals that 10% of female had chronic energy deficiency while 1.3% of male had chronic energy deficiency. The dietary diversity score of the students were low (3.22± 20 and 3.31± 22 for male and female respectively).

Conclusions: The protein intake of the subjects was low. The nutritional status of the student must be improved.

Key words: BMI, protein intake, blood pressure

PO243**REDUCTION OF INFLAMMATION-RELATED CVD RISK FACTORS IN PERIPHERAL TISSUES BY SUPPRESSION OF POSTPRANDIAL HYPERGLYCEMIA IN TYPE 2 DIABETIC OLETF RATS***C. Imai¹, T. Harasaki¹, K. Mochizuki², T. Goda¹*¹Graduate School of Integrated Pharmaceutical and Nutritional Sciences, University of Shizuoka, Shizuoka, Japan²Faculty of Life and Environmental Sciences, University of Yamanashi, Kofu, Japan

Background and objectives: Postprandial hyperglycemia is reportedly related to risks for cardiovascular diseases (CVD), but the underlying mechanisms are unclear. In this study, we examined whether suppression of postprandial hyperglycemia by supplementation with alpha-glucosidase inhibitor miglitol leads to alterations in the expressions of inflammatory cytokines and adhesion molecules in peripheral tissues including leukocytes, aorta and skeletal muscle.

Methods: Thirteen-week-old male Otsuka Long-Evans Tokushima Fatty (OLETF) rats, an animal model of type 2 diabetes, were fed a control diet or a diet containing 600 mg/kg miglitol for 47 weeks. Blood, skeletal muscle and the aorta were collected, and total RNA was subjected to real-time RT-PCR analysis of the mRNA levels of inflammatory cytokines and adhesion molecules. Concentrations of adhesion molecules in arterial blood were determined using antibody-immobilized beads by MILLIPLEX system.

Results: Oral glucose tolerance tests showed that OLETF rats fed a diet containing miglitol showed a decrease in postprandial glucose levels, along with preserved postprandial insulin response. Real-time RT-PCR analysis of the genes in peripheral leukocytes showed that rats fed a diet containing miglitol had reduced expressions of the genes coding inflammatory cytokines (IL-1beta, TNF-alpha, S100 a11) and E-selectin, an adhesion molecule which enhances attachment of leukocytes with vascular endothelium. In OLETF rats fed a diet containing miglitol, mRNA levels of IL-1beta and CD11c integrin were reduced in the skeletal muscle, and those of E-selectin were reduced in the aorta, which was accompanied by a reduction in the serum sE-selectin and sICAM-1 levels.

Conclusions: These results suggest that suppression of postprandial hyperglycemia leads to a reduction in the expressions of inflammation-related CVD risk factors in various tissues including peripheral leukocytes, aorta and skeletal muscle.

Key words: postprandial hyperglycemia, inflammation, leukocyte, adhesion molecule, diabetes

PO244**DIETARY DIVERSITY SCORE, LIPID PROFILE AND NUTRITIONAL STATUS OF UNDERGRADUATES IN SOUTHWEST NIGERIA**

N. Sunday¹, A. Jokodola¹, O. Segun¹

¹Moshood Abiola Polytechnic Ojere Abeokuta, Uganda

Background and objectives: This study was carried out to determine the Dietary Diversity score, lipid profile and nutritional status of undergraduates in South west Nigeria.

Methods: A representative sample of five hundred (500) students was surveyed from Moshood Abiola Polytechnic and Lagos state Polytechnic using simple random technique. A pretested interview guide was used to collect information on personal data, and socio demographic characteristics of the subjects. Information on dietary diversity was obtained using Food and Nutrition Technical Assistance Project questionnaire (FANTA). Body mass index (BMI), waist-hip ratio (WHR) and skin fold thickness were used in classifying obesity. Information on food intake was obtained from 24- hour dietary recall techniques. Fasting Blood samples were collected from the students to determine their lipid profile. Dietary diversity score (DDS) was computed and the nutritional status was assessed. Data were analyzed using descriptive statistics; SPSS software package version 16.0.

Results: The results revealed that majority (97.7%) of the students were within the age range of 18-15 years, more than half (59%) were female. The results of the dietary diversity score showed that starch received the highest score 0.70 ± 2.91 while cereal/ grain received the lowest score (0.30 ± 3.37). The result of the lipid profile showed that 7% male were below optimal level of low level lipoprotein (LDL), 7% were near optimal, 10% had normal triglycerides. The result of body mass index showed that 6% had chronic energy deficiency, 3% were obese while others had normal body weight.

Conclusions: The dietary diversity score of the students were low and it had influence on their nutritional status.

Key words: Diversity, nutritional, dietary

PO245**NUTRITIONAL EXTREMES AMONG RURAL CHILDREN AGED 7-15 INHABITING POMERANIA REGION IN THE LIGHT OF THE ECONOMIC TRANSITION IN POLAND.**

J. Roznowski¹, L. Cymek², A. Roznowska³

¹Nzoz Twoj Lekarz, Chelmino, Polonia

²Departament of Population Biology, Institute of Biology and Environmental Protection, Pomeranian University in Supsk, Poland

³Student at Medical University of Gdańsk, Poland

Background and objectives: The aim of this study is to examine the prevalence of underweight, overweight and obesity, using International Obesity Task Force (IOTF) criteria, in four rural children living in Pomerania Region cohorts in different economic eras: communist economy (1976/1983), crisis of the 1980s (1988/1991), political transformation (1996/2001) and free market economy (2006/2010), when the living conditions of majority of the Polish population changed.

Methods: The study included 11,780 records (5,818 boys and 5,962 girls) for children aged 7-15. The Chi-Square test was used for statistical analysis of the prevalence of over- and underweight in boys and girls during the subsequent decades and in the groups with different SES. Logistic regression models was applied for underweight/overweight risk assessment (odds ratio-OR) vs. the analysed variables

Results: Children were characterised by a statistically significant ($p < 0.0001$) differentiation of the prevalence of body mass deficit and excess in particular periods of the study. Almost each period –excluding 2006-2010 demonstrated both a high prevalence of overweight and thinness among girls ($p < 0.0001$). The highest prevalence of thinness in girls and boys was noted in the third period of the study (16.38% and 12.24% respectively). In the years 2006-2010 both girls and boys presented the highest prevalence of overweight and obesity (15.9% and 16.03%). Social factors such as mother's or father's education were moderately associated with under- or overweight ([odds ratio] OR fluctuated from 1.55 to 3.23). High association in density of households per room (equivalent of low income) with both under- and overweight noted over all four past decades ($p < 0.00001$).

Conclusions: While overweight and obesity was significantly spreading, malnutrition still remained a serious problem. The coexistence of children representing opposite sides of the energy balance equation presents a unique challenge for policy and interventions.

Key words: rural children, body mass index, SES

PO246**THE REGULAR INTAKE OF LACTOBACILLUS PLANTARUM 3547 IMPROVES THE INFLAMMATORY PROFILE MEASURED IN PLASMA OF PEOPLE WITH OVERWEIGHT AND OBESITY.**

B. López-Plaza¹, A. Fernández², L M. Bermejo¹, T K. Weber¹, M. Varero-Pérez¹, S. Palma-Milla¹, A. Lisbona-Catalán¹, C. Gómez-Candela¹

¹Department of Clinical Nutrition and Dietetic, Hospital La Paz Institute For Health Research (IdiPAZ), Madrid, Spain

²CARINSA Group, Sant Quirze del Vallès, Barcelona, Spain

Background and objectives: Overweight and obesity are characterized by a mild but chronic state of inflammation. Probiotics have showed to strengthen the beneficial microbiota modulating inflammatory process. Main objective has been to evaluate the effect of regular intake of probiotic *Lactobacillus plantarum* 3547 (Lp3547) on markers of inflammation measured in plasma of people with overweight and obesity.

Methods: A randomized, double-blind, placebo-controlled clinical trial was carried out during 10 weeks in 22 healthy volunteers of both genders with overweight/obesity (BMI ≥ 27 - <35 kg/m²); 40-50 years old, without chronic diseases and without pharmacologic treatment. Before 2 weeks of diet stabilization and fermented foods suppression participants were randomized into 2 groups: Probiotic Group (LpG, n=11) that consumed a daily capsule of Lp3547 (10x10⁹cfu) and Placebo group (PG, n=11) with a capsule containing maltodextrin. Both groups maintained the habitual pattern of physical activity and diet. At the beginning and end of the intervention, blood samples were collected to determine the inflammatory profile by ELISA. Anthropometric and diet were evaluated.

Results: At the beginning of the intervention both groups had similar values of cytokines in plasma. After the intervention the participants who belonged to LpG showed a significantly decreased of INF- γ ; compared with those belonging to GP (-2.9 \pm 1.1 vs. -0.01 \pm 0.06pg/ml)($p<0.05$). Other cytokines such as TNF α ; levels showed a tendency to decrease in LpG participants between the beginning and end of the intervention (8.6 \pm 9.3 vs 7.4 \pm 4.2pg/ml) ($p<0.1$) while those participants belonging to PG remained stable (4.4 \pm 2.9 vs 5.23 \pm 3.5pg/ml). The other cytokines had no significant changes.

Conclusions: regular consumption of the probiotic Lp3547 for 8 weeks improves the inflammatory profile from plasma to decreasing the INF- γ levels and improving slightly the TNF- α levels in people with overweight and obesity.

Key words: Probiotics, Overweigh/Obesity, Cytokines.

PO247**UTILIZATION OF MATERNAL HEALTH SERVICES AND APPROPRIATE FEEDING PRACTICES TO IMPROVE NUTRITIONAL STATUS OF INFANTS AND YOUNG CHILDREN IN NEPAL**

K N. Pokhrel¹, M. Jimba¹, J. Yasuoka¹, K. Otsuka¹, N. Pokhrel²

¹Department of Community and Global Health, The University of Tokyo, Japan

²Integrated Development Foundation Nepal, Nepal

Background and objectives: In some developing countries, including Nepal, mothers receive nutrition education covering infant and young child feeding (IYCF) practices while attending maternal antenatal care (ANC) and postnatal care (PNC) visits. However, the relationship between maternal health service utilization and child undernutrition remains unknown. Moreover, few studies indicated the relationship between a summary of comprehensive IYCF practices and undernutrition. This study aimed to examine the relationship between maternal health service utilization and undernutrition, and that between IYCF and undernutrition.

Methods: A cross-sectional study was performed with 400 mothers who had children aged 6-23 months in Makawanpur district, Nepal. Information on sociodemographic backgrounds, household food insecurity, utilization of maternal health services, feeding practices and children anthropometrics were collected. To measure summary of comprehensive IYCF covering breastfeeding, meal frequency, dietary diversity, and food variety, an infant and child feeding index (ICFI) was used. Multivariate logistic regression analysis was applied to examine the association of exposure variables with underweight and stunting.

Results: Approximately 50% of children were stunted and 22% of them were underweight. Maternal ANC visit was negatively associated with underweight (AOR: 3.5; 95% CI: 2.86-13.82; $p=0.040$) and stunting (AOR: 3.1; 95% CI: 1.58-13.40; $p=0.009$). Also, maternal PNC visit was negatively associated with underweight (AOR: 3.9; 95% CI: 1.63-9.15; $p=0.002$). Low ICFI score was positively associated with underweight (AOR: 2.8; 95% CI: 1.00-7.87; $p=0.042$) and stunting (AOR: 4.0; 95% CI: 1.40-11.38; $p=0.009$) among the children.

Conclusions: Maternal ANC and PNC visits were negatively associated with underweight and stunting. Additionally, inappropriate feeding practice had positive association with underweight and stunting. Increase in coverage of ANC and PNC visits is recommended along with nutrition education, that target mothers to improve feeding practices and thus to improve nutrition status of children.

Key words: Breastfeeding; infant and child feeding; undernutrition; antenatal care; postnatal care; Nepal

PO248**FABP4 AND TNF-ALPHA METHYLATION LEVELS ARE ASSOCIATED WITH WEIGHT LOSS IN SPANISH ADOLESCENTS: THE EVASYON STUDY**

A. Molerés¹, J. Campion^{1,2}, F.I. Milagro^{1,2}, C. Campoy³, J.M. Garagorri⁴, A. Marcos⁵, J.A. Martínez^{1,2}, M.C. Azcona-Sanjulian⁶, A. Martí^{1,2}

¹Department of Nutrition, Food Science and Physiology, University of Navarra, Navarra, Spain

²CIBER Fisiopatología Obesidad y Nutrición (CIBEROBn), Instituto de Salud Carlos III, Spain

³Pediatric Department, Medicine School, Universidad de Granada, Spain

⁴Department of Paediatrics, Radiology and Physical Medicine, Universidad de Zaragoza, Spain

⁵Immunonutrition Research Group, Department of Metabolism and Nutrition, Institute of Food Science, Technology and Nutrition (ICTAN, CSIC), Madrid, Spain

⁶Paediatric Endocrinology Unit, Department of Pediatrics, University of Navarra Clinic, Spain

Background and objectives: FABP4 and TNF- α are predominantly expressed in adipose tissue and its circulating levels have been linked to obesity. However, there is very scarce information of whether epigenetic patterns of these genes could influence individual weight loss response. Therefore, the aim of our study was to analyze whether methylation levels of two CpGs sites in FABP4 and TNF- α genes could predict weight loss response to a lifestyle intervention programme in overweight/obese (OW/OB) Spanish adolescents.

Methods: Twenty four OB/OW adolescents (12-16 years old; 42% males) undergoing 10 weeks of a multidisciplinary intervention for weight loss (EVASYON study) were assigned as high (n=12; BMI-SDS loss >1.0) or low (n=12; BMI-SDS loss < 0.4) responders to the treatment. Baseline methylation levels of CpGs located in FABP4 and TNF- α genes were measured using the genome-wide Illumina Infinium HumanMethylation27 BeadChip array.

Results: We found a sex-response interaction ($p=5.8 \times 10^{-4}$) for FABP4 (cg10062803) methylation levels. Male low responders to the weight loss intervention programme had significantly higher basal methylation levels ($p=6 \times 10^{-4}$) for the studied CpG, while in females this site was hypomethylated in low responders compared to high responders ($p=0.008$). Concerning TNF- α (cg04425624), basal hypermethylation predicted a greater weight loss after the intervention both in males ($p=0.002$) and females ($p=0.04$).

Conclusions: Methylation levels of two CpGs in the FABP4 and TNF- α genes are associated with the weight loss response and could therefore be used as putative epigenetic biomarkers

to predict the susceptibility to lose weight after a multidisciplinary lifestyle intervention in OW/OB adolescents.

Key words: weight loss intervention, epigenetics, genes, biomarker.

PO249**EFFECT OF A FOS-LACTOBACILLUS FERMENTUM SYMBIOTIC ON HEPATIC AND ADIPOSE TISSUE TRANSCRIPTOME IN OBESE ZUCKER RATS**

B. Rivero², O. Martínez-Augustín¹, A. Zarzuelo¹, F. Sánchez de Medina¹

¹University of Granada / CIBERehd, Granada, Spain

²University of Granada, Granada, Spain

Background and objectives: Modulation of the intestinal microbiota may play a role in the management of metabolic syndrome. Here we examine the impact of a beneficial symbiotic on adipose and hepatic tissue at the genomic level.

Methods: obese Zucker rats were treated with FOS (5% diet) and 1.25-E11 UFC/L of *Lactobacillus fermentum* for 10 weeks. RNA was isolated from the liver and visceral adipose tissue and analyzed with SurePrint G3 Rat Gene Expression Microarray (Agilent Technologies). Experimental groups: lean Zucker (control) rats, untreated obese Zucker, treated rats.

Results: obesity had a major impact on the transcriptome of both hepatic and especially adipose tissue, with 3584 and 7036 sequences differentially expressed compared with the lean controls. The adipose tissue of symbiotic treated rats showed only 52 sequences upregulated and 88 downregulated compared with that of obese controls. The general effect of the symbiotic was that of normalization, i.e. treatment tends to augment obesity-repressed genes and viceversa. The exceptions were *Arntl*, which is lowered by obesity and further downregulated by the symbiotic, and *Mt1a*, *Tef*, *Bhlhe41*, *Pik3ip1* and *Hspb7*, which show the opposite behaviour. The transcriptome of hepatic tissue showed 2612 sequences differentially modulated by the symbiotic compared with obese controls. Only 1335 of these correspond to genes modulated by obesity, i.e. half of the changes in the transcriptome affect genes whose expression is not changed by obesity. Furthermore, the profile was very different from that observed with adipose tissue, in that there are many genes showing changes of expression in the same direction i.e. upregulated by both obesity and symbiotic, and viceversa.

Conclusions: symbiotic treatment of obese Zucker rats has a major effect on hepatic gene expression, which may be related to its beneficial impact in metabolic syndrome.

Key words: genomics, symbiotic, metabolic syndrome, transcriptome

PO250**HIGHER TELOMERE LENGTH IS ASSOCIATED WITH A DECREASE IN OBESITY RISK IN AN INTERVENTION WITH MEDITERRANEAN DIET: THE PREDIMED-NAVARRA TRIAL**

⁷Department of Biochemistry and Molecular Biology, University of Navarra, Navarra, Spain

Background and objectives: Shorter telomere length (TL) is associated with some age-related human disorders, but its relationship with obesity or adiposity parameters remains unclear. The aim of this study was to assess the relationship between TL and changes in adiposity indexes after a 5-year nutritional intervention. Subjects and

Methods: TL was measured by quantitative real-time PCR in 521 subjects (55-80 years, 55% women). Participants were randomly selected from the PREDIMED-NAVARRA center after they completed a 5-year intervention program. Anthropometric parameters and TL were measured and assessed at baseline and after 5-year intervention.

Results: Higher baseline TL significantly predicted a greater decrease in body weight (B= -1.09 kg, 95%CI: -2.01;-0.16 kg), BMI (B= -0.47 kg/m², 95%CI: -0.83;-0.11 kg/m²), waist circumference (B= -1.15 cm, 95%CI: -2.28;-0.01 cm) and waist to height ratio (B= -0.008, 95%CI: -0.010; -0.001) in multiple-adjusted models. In addition, the reduction in adiposity indexes during the intervention was associated with increasing TL and was even higher among subjects with the longest telomeres at baseline. Logistic regression analysis showed that the risk of remaining obese after 5 years was lower in those participants who initially had the longest telomeres and increased their TL after the intervention.

Conclusions: Our research suggests that TL is inversely associated with changes in obesity markers. The assessment of TL can provide further insights for biological pathways leading to

adiposity. We show for the first time that a decrease in obesity risk is linked to higher TL after a 5-year Mediterranean diet intervention.

Key words: Telomere length, adiposity, aging, nutritional intervention.

Background and objectives: DNA methylation that may be modified by obesity and stroke is one of the epigenetic mechanisms that regulates gene expression. The objective of the present study was the search of epigenetic changes related to cerebral infarction, and whether these modifications depend on the obese state.

Methods: DNA isolated from white blood cells of 6 non-obese patients without stroke (BMI 22.5±2.0 kg/m²; Waist circumference (WC) 83.3±12.5), 6 non-obese with ischemic stroke (BMI 22.5±1.6 kg/m²; WC 84.5±4.1), 6 obese without stroke (BMI 36.6±3.4 kg/m²; WC 111.3±9.3), and 6 obese with ischemic stroke (BMI 33.7±1.1 kg/m²; WC 117.6±12.5) was bisulfite treated and hybridized on a Human Methylation27BeadChip array (Illumina). Selected genomic regions of the KCNQ1 and C5AR1 genes were subsequently analyzed by Sequenom EpiTYPER, and RT-PCR was applied to determine changes in their expression.

Results: Array analysis showed more than 97 CpGs differentially methylated (p<0.05 and Δmethylation>5%) between obese and non-obese subjects (i.e., KCNQ1). 80 CpGs were

modified in stroke patients and 27 CpGs showed interactions between groups (i.e., C5AR1). EpiTYPER approach showed that two CpG sites of KCNQ1 were hypermethylated ($p < 0.05$) in obese in comparison with lean patients. Concerning C5AR1, the whole promoter region was hypomethylated ($p < 0.05$) in stroke patients and hypermethylated ($p < 0.05$) in obese subjects. Obese patients showed significantly lower ($p < 0.05$) expression of both genes, whereas stroke patients showed lower ($p < 0.05$) KCNQ1 mRNA levels.

Conclusions: The DNA Methylation pattern of white blood cells was modified by ischemic stroke and obesity status. Moreover, DNA hypermethylation in obese status was reflected in a decrease of gene expression of KCNQ1 and C5AR1. These results suggest the potential use of gene expression and/or epigenetic biomarkers in clinical diagnosis and prognosis of obesity comorbidities.

Key words: cerebral infarction, epigenetic, mRNA

EFFECTS OF CARDIOTROPHIN-1 ON HSL AND ATGL PROTEIN LEVELS IN ADIPOSE TISSUE OF OB/OB MICE

M. Lopez-Yoldi¹, M.J. Moreno-Aliaga^{1,3}, J.A. Martinez^{1,3}, J. Prieto², M. Bustos²

¹Department of Nutrition, Food Science and Physiology. University of Navarra. Spain

²Area of Hepatology and Gene Therapy. Center for Applied Medical Research (CIMA), University of Navarra, Spain

³CIBER Fisiopatología Obesidad y Nutrición (CIBEROBn) Instituto de Salud Carlos III. Spain

Background and objectives: Cardiostrophin-1 (CT-1) is a member of the IL-6 family of cytokines. A recent study of our group has revealed that CT-1 is a key regulator of glucose and lipid metabolism. The aim of this study was to analyze the effects of recombinant CT-1 (rCT-1) on protein levels of adipose triglyceride lipase (ATGL), hormone-sensitive lipase (HSL) and perilipin, the key enzymes of lipolysis, in mouse epididymal white adipose tissue.

Methods: Effects of rCT-1 treatment were evaluated in eight weeks-old male ob/ob mice. Animals were treated intravenously with rCT-1 (0.2 mg/kg of body weight) and sacrificed 30 minutes after administration. Control mice were administered vehicle (saline). Total protein content of perilipin and the main lipases ATGL and HSL, as well as the phosphorylation levels of perilipin and HSL at Ser563, Ser565 and Ser660 were analyzed by Western Blot in epididymal fat lysates.

Results: rCT-1 treatment induced a marked increase in PKA mediated phosphorylation of perilipin and HSL at Ser660

and Ser563. However, AMPK mediated phosphorylation of HSL on Ser 565 was significantly decreased. Moreover, a significant increase on ATGL protein levels was observed in mice adipose tissue after 30 min of rCT-1 treatment compared with that from control ob/ob mice.

Conclusions: The present data suggest a lipolytic action of rCT-1 in adipose tissue of ob/ob mice mainly mediated by activation of the main lipases, HSL and ATGL, involved in the lipolytic process.

Key words: Cardiostrophin-1, lipolysis, ATGL, HSL, perilipin

DIETARY ALPHA-LIPOIC ACID SUPPLEMENTATION DECREASES CHEMERIN IN HIGH FAT-FED RATS

P. Prieto-Hontoria^{1,2}, M. Fernandez-Galilea¹, P. Perez-Matute^{1,3}, J.A. Martinez^{1,2}, M.J. Moreno-Aliaga^{1,2}

¹Department of Nutrition, Food Science and Physiology, University of Navarra, Pamplona, Spain

²CIBER Fisiopatología Obesidad y Nutrición (CIBEROBn), Instituto de Salud Carlos III, Pamplona, Spain

³Infectious Diseases Area, Center for Biomedical Research (CIBIR), Logroño, Spain

Background and objectives: Chemerin is a novel adipokine highly expressed in white adipose tissue. Serum chemerin levels are elevated in obese compared with lean both in animals and humans. Serum chemerin levels are strongly associated with markers of inflammation and components of the metabolic syndrome. α -Lipoic acid (α -LA) has been shown to exert beneficial properties on diabetes and obesity. So, the aim of this study was to investigate the effects of supplementation of high fat diet with α -LA on chemerin circulating levels in rats.

Methods: Control and high fat-fed male Wistar rats were assigned into two subgroups; in one of them the diet was supplemented with α -LA (0.25 wt/100 wt of diet) during 8 weeks. Two Pair-Fed (PF) groups were also included in order to evaluate if α -LA actions are secondary to its inhibitory effects on food intake. Serum chemerin levels were determined by ELISA.

Results: Chemerin circulating levels were significantly higher in the obese high fat-fed group in comparison with the control group. Supplementation of the diet with α -LA was able to reduce the overproduction of chemerin induced by the high fat feeding. α -LA also reduced chemerin levels in control-chow fed animals. A decrease in circulating chemerin was also observed in the PF group fed on a high fat diet, suggesting that the effects of α -LA on chemerin are in part secondary to its anorexigenic and body weight lowering properties.

Conclusions: These results suggest that the reduction of chemerin could also contribute to the beneficial effects of dietary supplementation with α -LA on obesity-related metabolic disorders.

Key words: Lipoic Acid, Obesity, Chemerin

PO254

FEATURES OF A POPULATION INTERESTED IN PERSONALIZED NUTRITION BASED ON GENOTYPE: APPLICATION OF A SNP GENOTYPING KIT

R. San-Cristobal¹, L. Goni¹, F. Milagro^{1,2}, M. Cuervo^{1,2}, A. Ibanez¹, M. Hernandez¹, J.A. Martinez^{1,2}

¹Department of Nutrition, Food Science and Physiology, University of Navarra, Spain

²CIBER Fisiopatologia Obesidad y Nutricion (CIBEROBn), Instituto de Salud Carlos III, Spain

Background and objectives: Personalized nutrition is starting to be based on genetic variance, which is enabling to prescribing a customized dietary pattern to prevent or treat nutritionally-related diseases through specific genetic risk scores (GRS) and SNP screening tools. The aim of the present study was to describe the features of a population which have required a nutrigenetic service.

Methods: The interactions between food intake or dietary pattern with genetics was assessed by screening of 24 specific SNPs previously reported in GWAS studies and meta-analyses for obesity, type 2 diabetes, lipid profile, cardiovascular risk and metabolism of specific nutrients by Luminex based SNP genotyping using DNA Zip Coded beads. Furthermore, medical/family history, habitual dietary habits, lifestyle behaviors, anthropometric and biochemical data were collected between September 2012 and January 2013 from the first three hundred users seeking for a nutrigenetic advice. Genetic samples (isolated from oral epithelial cells) allowed calculating a GRS related to the risk to develop 14 metabolic associated disorders and micronutrient alterations.

Results: About 23% of the users were male (n=70) and 77% were female (n=230), while 152 users were <50 y.o. and 148 were \geq 50 y.o. The more prevalent diseases among of subjects seeking for a nutrigenetic advice were obesity (41%) and related disorders such as hypercholesterolemia (24%) and hypertension (21%). According to the GRS, 59% of the subjects with BMI>30kg/m² presented genetic predisposition for obesity. Similarly, 25% of the diabetic, 22% of the hypercholesterolemic and 38% of the hypertriglyceridemia subjects showed genetic predisposition according to the GRS for each disease.

Conclusions: The user profile of this nutrigenetic service are a 50 y.o. obese woman. This nutrigenetic approach will

allow personalizing the management of obesity and related disorders through genotype assessment.

Key words: Personalized nutrition, Nutrigenetic service, Metabolic diseases

PO255

EFFECT OF METHYLATING AGENTS ON ADIPOCYTE DIFFERENTIATION: CHANGES IN CAVEOLIN-1 METHYLATION AND EXPRESSION

S. Palacios-Ortega¹, F. Milagro^{2,3}, M. Varela¹, J.A. Martinez^{2,3}, C. de Miguel^{1,3}

¹Department of Biochemistry and Genetics, University of Navarra, Spain

²Department of Nutrition, Food Science and Physiology, University of Navarra, Spain

³CIBER Fisiopatologia Obesidad y Nutricion (CIBEROBn) Instituto de Salud Carlos III. Spain

Background and objectives: Obesity is a metabolic disease in which regulation of gene expression by epigenetic mechanisms may play a critical role. Caveolin-1 (Cav-1) is a gene highly expressed in adipocytes that plays a key role in the regulation of insulin signalling. The aim of this study was to determine whether high concentrations of methylating agents might cause alterations in the adipogenic process and if these modifications might be associated with changes in the methylation pattern of the Cav-1 gene and its expression.

Methods: 3T3-L1 cells were differentiated during 21 days in the presence or absence of a methylating cocktail composed of choline 70 μ M, betaine 1400 μ M, vitamin B12 0.074 μ M and folic acid 0.09 μ M. Adipocyte differentiation stage was monitored by Oil Red O staining. The region of Cav-1 studied (from 619 bp 5' to 1333 bp 3' of the ATG codon) includes two CpG islands located in the proximal promoter and the first intron of the gene. Methylation percentage of CpG dinucleotides was determined by MassArray EpiTyper. Cav-1 expression was measured by RT-PCR and protein level by western blotting.

Results: The treatment of 3T3-L1 cells with the methylating agents for 21 days produced a slight but significant delay in the differentiation process. The pro-methylating environment induced a significant increase in the methylation of most of the CpG sites of the analyzed Cav-1 region. The expression of the Cav-1 gene was also affected by the methylating agents.

Conclusions: The current study demonstrates that a milieu rich in methylating agents could affect the adipogenic process and induce changes in the expression of key genes involved in the regulation of insulin signalling through epigenetic mechanisms.

Key words: Caveolin-1, adipocyte differentiation, epigenetics, insulin signalling.

PO256**TRANSCRIPTOME ANALYSIS IDENTIFIED A POTENTIAL NOVEL FUNCTION OF CORIANDER IN SUPPRESSION OF COLITIS**

H. Jia¹, M. Hanate^{1,2}, W. Aw^{1,3}, K. Saito¹, H. Kato^{1,2}

¹Corporate Sponsored Research Program Food for Life, Organization for Interdisciplinary Research Projects, The University of Tokyo, Tokyo, Japan

²Department of Applied Biological Chemistry, The University of Tokyo, Tokyo, Japan

³Graduate School of Biomedical Science, Tokyo Medical and Dental University, Tokyo, Japan

Background and objectives: Coriander (*Coriandrum sativum* L.), a widely consumed spice, has been reported to have antioxidant, antimicrobial and carminative properties. In this study, transcriptome analysis was first performed in normal rats fed coriander to explore its new functions. Thereafter the predicted impacts and underlying mechanisms of coriander on colitis were investigated in DSS-induced mice colitis.

Methods: Six-week-old male Wistar rats were fed either AIN-93G diet or AIN-93G-based diet with 0.5% of coriander powder for 4 weeks. Hepatic gene expression profile was obtained using DNA microarray analysis (Rat Genome 230 v2.0, Affymetrix). Functional categorizing was assigned using Ingenuity Pathway Analysis. Experimental colitis was induced in seven-week-old male C57BL/6J mice by adding 1% DSS in drinking water for 9 days. Mice were fed either AIN-93G diet or 2% coriander diet. Severity of colitis was estimated as disease activity index (DAI). Plasma TNF- α levels and colonic gene expression of pro-inflammatory cytokines were also measured.

Results: Top “bio” Function involved in Diseases and Disorders in rats fed coriander was Inflammatory disease. The highest ranked functions involved in this were Inflammatory bowel disease (IBD), Crohn’s disease, Asthma and rheumatic arthritis, of which the latter two are main extraintestinal manifestations of IBD. These results indicate that coriander may have a potential beneficial role for the management of IBD. In mice, COR significantly suppressed the elevation of DAI and plasma TNF- α levels. Gene expression of pro-inflammatory markers such as IL-6, MIP2, IL-1 β , COX-2 and CCL2 were down-regulated, whereas IL-10, which reduces the production of inflammatory cytokines, was up-regulated in COR group.

Conclusions: The transcriptomics analysis uncovered new beneficial functions of coriander. Coriander improved colitis symptoms and suppressed pro-inflammatory cytokine responses in experimental colitis, which might be involved in the mechanisms underlying the cytoprotective function of coriander in colon.

Key words: coriander, DNA microarray, rat liver, mice colon

PO257**ESTIMATING THE ADEQUACY OF NUTRIENT AVAILABILITY OF UGANDAN FARMING HOUSEHOLDS’ FOOD PRODUCTION**

J. Fiedler¹, J. Kalibbala Sekandi²

¹International Food Policy Research Institute (IFPRI)

²Planning and Strategic Information Management Unit, UNICEF, Kampala and the Centre for Performance Management and Evaluative Research, Plot 89/91, Buganda Road P. O. Box 33027, Kampala, Uganda

Background and objectives: There has been increasing discourse about the optimal mix of nutrition programs. However, few empirical studies examine this important issue. The objective was to examine Zambia’s micronutrient program portfolio and discuss the optimal mix based on costs, coverage, impact and cost-effectiveness.

Methods: We used household consumption and acquisition data from the 2006 Living Conditions Monitoring Survey with a Zambian food composition table to estimate usual intakes of calories and key micronutrients and estimated the prevalence of inadequate intake. Using purchases of fortified sugar and three other potentially fortifiable staples, we modeled the additional intake of nutrients due to each vehicle. We also modeled biofortification of a high pro-vitamin A maize and empirically identified the key characteristics of the maize market. Finally we analyzed vitamin A supplementation through Child Health Week. For each intervention independently and all combinations, we analyzed the cost, coverage and impact including the change in the prevalence of inadequate intake and the total number of disability-adjusted life years (DALYs) saved. We used IFPRI’s IMPACT Model to predict changes in food production and consumption patterns through 2042 and used alternative objective criteria to optimize the micronutrient program portfolio mix over 30 years.

Results: Oil and sugar offer the greatest coverage (67%-69%) while biofortification can reach greater than 50%. Supplementation and sugar and oil fortification produce the greatest impacts. The most cost-effective 1, 2, and 3-package interventions were oil fortification alone; oil plus biofortification; and oil plus biofortification and supplementation. The sequencing of combinations affected these results.

Conclusions: Each intervention plays a significant role in combating micronutrient deficiency in Zambia. However, the choice of vehicles and the order of implementation sequencing of the interventions is crucial to optimizing overall impact and cost-effectiveness.

Key Words: Biofortification, fortification, supplementation, impact, cost-effectiveness

PO258**EFFECT OF FATTY ACIDS ON THE INFLAMMATORY CASCADE IN THP-1 DERIVED MACROPHAGES***C. Paras Chavez¹, P. Noakes¹, P. Calder¹*

¹Institute of Human Nutrition and Human Development and Health, Faculty of Medicine, University of Southampton, Southampton, UK

Background and objectives: A long-lasting inflammatory response has been related to the development of chronic-degenerative diseases. Fatty acids from the diet are incorporated into inflammatory cell membranes and give rise to bioactive compounds determining the duration and intensity of an inflammatory process. Macrophages are key players in the regulation of inflammation. Nevertheless, the signalling pathways coordinating the production of newly characterized lipid mediators and the role of fatty acids in this network are not fully understood. We aimed to study the synergy between the elements involved in the inflammatory signalling cascade in macrophages and to evaluate the effect of different fatty acids on these.

Methods: THP-1 monocytes were differentiated to macrophages using PMA. Macrophage phenotype was confirmed by evaluating cell morphology and cell surface expression of CD11c, CD14 and CD68 by flow cytometry and immunohistochemistry. THP-1 derived macrophages were incubated with LPS or fatty acids. Cell pellets were collected for analysis of gene and protein expression. Lipid mediators and cytokines were evaluated by mass spectrometry and flow cytometry, respectively.

Results: PMA induced changes in cell morphology and macrophage features in THP-1 monocytes. CD11c and CD14 expression were increased and THP-1 derived macrophages were positively stained for CD68. LPS incubation resulted in a dose- and time- dependent increment of inflammatory cytokines and lipid mediators. The NFκB pathway was activated following LPS treatment as evidenced by the decrease of IκB in the cytosol and the increment of nuclear p65 at early time points. Fatty acid treatment altered COX protein and gene expression.

Conclusions: The upregulated production of some cytokines and lipid mediators is linked to the activation of the NFκB pathway. Fatty acids may modulate the course of the inflammatory response by inducing changes in this signaling pathway. We are grateful with Dr Mojgan Masoodi for assistance with mass spectrometry.

Key words: Macrophage, inflammation, fatty-acids.

PO259**INTRODUCING MIRONUTRIENT POWDER AS A POTENTIAL COMPLEMENTARY STRATEGY FOR ALLEVIATING PERSISTING MICRONUTRIENT DEFICIENCIES AMONG CHILDREN IN TANZANIA***G. Mulokozi¹, J. Kaganda², A. Mugabiro¹, W. Lorri³*

¹Feed The Future, Tuboreshe Chakula Project, Dar es Salaam, Tanzania

²Tanzania Food and Nutrition Centre, Dar es salaam, Tanzania

³Office of the President, Dar es Salaam, Tanzania

Background and objectives: Micronutrients deficiencies are public health problems in Tanzania affecting mostly children and women of reproductive age. Ongoing interventions include twice-yearly vitamin A supplementation among children, salt iodation and nutrition education to promote appropriate complementary feeding and dietary diversification. Food fortification of maize flour and edible oil and home fortification with micronutrient powder (MNP) for foods consumed by children aged 6 – 59 months is being introduced in the country as a complementary intervention.

Methods: Micronutrient deficiencies among children aged 6-59 months was assessed in a cross-sectional study of Tanzania Demographic and Health Survey of 2010 in which dried blood spot samples obtained from children aged 6-59 months were tested for vitamin A (retinol binding protein) and Iron (soluble transferrin receptor). A sample of household salt was collected and tested using a quantitative method. Coverage of vitamin A supplementation was assessed by asking women if their children had received vitamin A supplements. Current infection and or inflammation were assessed by testing C-reactive protein. Market-based micronutrient powder to fortify foods intended for children aged 6-59 months is being introduced in 8 districts of Tanzania.

Results: After adjusting for current infection and/or inflammation, 33% of children aged 6-59 months had vitamin A deficiency, 59% had anaemia and 35% were iron deficient. About 47% of households were using salt that is adequately iodized. Vitamin A supplementation coverage was 61% among children; yet there was no significant reduction of vitamin A deficiency. Recent introduction of MNP with social marketing and behavioral change communication strategy in place is a key component of the intervention and expected to result in increased consumption of MNP by children.

Conclusions: MNP intervention has a great potential for complementing supplementation and other interventions to alleviate micronutrient deficiencies among children in Tanzania.

Key words: Micronutrients deficiencies, Micronutrient powder, Tanzania

PO260**MATERNAL STRESS AND DISTRESS AND CHILD NUTRITIONAL STATUS**

P. Rondó¹, G. Rezende¹, J. Lemos¹, J. Pereira²

¹School of Public Health, University of São Paulo, Avenida Dr Arnaldo 715, São Paulo, Brazil

²Federal University of Piauí, Campus Senador Helvídio Nunes de Barros, Rua Cícero Eduardo s/n, Bairro Junco, Picos, Brazil

Background and objectives: Malnutrition and overweight/obesity seem to be more likely to occur in children of mothers with stress and distress. This study assessed the relationship between maternal stress and distress in pregnancy and 5-8 years postpartum and child nutritional status.

Methods: Longitudinal cohort study carried out in Jundiaí city, Southeast Brazil involving 409 women followed throughout pregnancy to 5-8 years postpartum, and respective children. Measures of stress and distress were obtained three times in pregnancy (at gestational ages lower than 16 weeks, from 20 to 26 weeks and from 30 to 36 weeks) and 5-8 years postpartum by the Perceived Stress Scale-PSS, General Health Questionnaire-GHQ, and the State Trait Anxiety Inventories-STAI. The nutritional status of the children was assessed by the WHO body mass index-BMI z-score for age. The relationship between child BMI z-score for age and scores of the PSS, GHQ and STAI, was evaluated by multivariate linear regression, controlling for confounding variables.

Results: BMI z-score for age of the children was negatively associated with maternal scores of the PSS 5-8 years postpartum and scores of the GHQ in the second trimester of pregnancy. BMI of the children was positively associated with maternal BMI and birthweight ($R^2=0.13$). There were 0.04 ($CI=0.07-0.9 \times 10^{-2}$) decrease in child BMI per score unit of the PSS increase, and 0.09 ($CI=0.18-0.6 \times 10^{-3}$) decrease in child BMI per score unit of the GHQ increase.

Conclusions: This study detected a relationship between maternal mental and nutritional status and child nutritional status, implying that if the mother is not physically or mentally well, her capacity for caring for her child may be impaired.

Key words: maternal stress, maternal distress, child nutritional status, birthweight.

PO261**PNPLA3 RS738409 POLYMORPHISM IN ASSOCIATION WITH THE SUSCEPTIBILITY OF ALCOHOLIC LIVER DISEASE: A META-ANALYSIS**

Z. Wang¹, S. Rong¹, Y. yang¹, X. Xiang¹

¹Department of Food Nutrition Assessment, Institute of Nutrition and Food Safety, Chinese Center for Disease Control and Prevention, China

Background and objectives: Emerging evidence suggests an association between rs738409 polymorphism in the patatin-like phospholipase domain containing 3 (PNPLA3) gene and the susceptibility to alcoholic liver disease (ALD). This study was to integrate previous findings and quantitatively summarize the association through a meta-analysis.

Methods: Electronic literature search was performed in the PubMed/MEDLINE and EMBASE databases through December 2012. Case-control and cohort studies that reported data about the association between the PNPLA3 rs738409 with ALD risk were eligible for inclusion. A meta-analysis was conducted in a random-effects model.

Results: Of the 85 potentially relevant articles, six articles comprising 6808 subjects (3220 ALD cases and 3588 controls) were included in the meta-analysis. A significantly increased risk for ALD, in particular cirrhotic ALD, was observed in individuals with the rs738409 G allele as compared with those with the C allele; the pooled odds ratios (ORs) and 95% confidence intervals (CIs) were 1.80 (1.49-2.16) for overall ALD and 2.07 (1.81-2.37) for cirrhotic ALD (both $P < 0.001$). Furthermore, the pooled ORs and 95% CIs for overall ALD and cirrhotic ALD among individuals with the GG genotype versus those with the CC genotype were 3.59 (2.37-5.43) and 4.37 (3.06-6.26), respectively (both $P < 0.001$).

Conclusions: Alcohol consumers carrying the rs738409 G allele in the PNPLA3 gene may have a higher risk of ALD, in particular cirrhotic ALD, than those carrying the C allele. Further studies are warranted to demonstrate the detailed molecular mechanism and the clinical utility of these findings.

Key words: PNPLA3; ALD; cirrhosis; meta-analysis; susceptibility

PO262**NUTRITIONAL STATUS AND COGNITIVE DEVELOPMENT OF CHILDREN (6-24 MONTHS OLD) IN ISOKAN LOCAL GOVERNMENT AREA, OSUN STATE, NIGERIA.**

J. Ajisekola¹, I O. Akinyele¹

¹Department of Human Nutrition, University of Ibadan, Nigeria

Background and objectives: Studies have shown that a child's learning capacity seems to be partially determined by parental investments in nutrition during infancy. The main objective of this study was to assess the nutritional status and cognitive development of 6-24 months old children.

Methods: A cross-sectional survey was conducted among 403 children (6-24 months) randomly selected from most patronized four comprehensive Primary Health Centers (PHC). Semi-structured questionnaire was used to collect information on mother's socio-demographic characteristics and child feeding practises. Child's length and weight were measured, HAZ, WAZ and WHZ z-scores were also determined. Malawi Developmental Assessment Tools consisting of 42 questions (of 90% pass assurance) in Gross motor, fine motor, social and language domains were used to test for cognitive development of the children.

Results: The results shows that 86.8% of the mothers were employed; out of which 42.4% were petty traders. Most of the mothers (66.0%), earned less than N10,000 per month. Of the mothers, 72.9% initiated breastfeeding within 1hour but only 15.1% practiced exclusive breastfeeding. Only 42.7% of the children were introduced to complementary foods at 6 months and 45.2% of all ate three times daily. Result also showed that 21.8%, 36.5%, 15.4% of the children were wasted, stunted and underweight, respectively. Sixty three percent (61.3%) of children had adequate cognitive development while 38.7% were inadequate. There was significant association between mother's occupation and income, feeding baby with colostrum, complementary feeding practices and cognitive development of children. The duration of breast feeding was not associated with cognitive development. Wasting status (WHZ) was strongly associated with cognitive development of children but there was no association with underweight and stunting.

Conclusions: This study showed that childhood malnutrition and inadequate cognitive development starts early in life and often coincides with mothers' economic status and child feeding practices.

Key words: Nutritional status, Cognitive Development, child feeding practices.

PO263**DIVERSITY AND NUTRITION QUALITY OF SOME SORGHUM GRAIN AND GERMINATED SORGHUM (SORGHUM BICOLOR) GRAIN VARIETIES GROWN IN KENYA**

A. Makokha¹, P. Kahenya¹

¹Jomo Kenyatta University of Agriculture and Technology, Kenya

Background and objectives: Sorghum grain is an important traditional food staple in many African countries. There are different varieties of sorghum grown in Kenya that differ in their nutritional value. The nutritional value can be improved by germination, which reduces the tannin content. The objective of this study was to determine the nitrogen and tannin content of different varieties of sorghum grain grown in Kenya, and the characteristics of the germinated and dried grain.

Methods: Physical characteristics of 10 varieties of sorghum grain were assessed by determining colour, kernel weight testa presence, and endosperm texture. Nitrogen and tannin content were also determined. The characteristics of the germinated grain was assessed by determining diastatic power (DP), and free amino nitrogen (FAN).

Results: The crude protein levels ranged from 9.7% to 14.6%, respectively. Six of the sorghum grain samples had high tannin content of more than 1.0% Catechin Equivalents (CE), while four were low tannin samples, with CE less than 0.2%. The diastatic power of the grain after 48, 72, 96 and 120 hours of germination ranged between 5.4 to 15.8, 8.1 to 24.8, 10.9 to 27.7 and 13.5 to 28.5 Sorghum Diastatic Units (SDU), respectively. The corresponding alpha amylase activity ranged between 2.5 to 16.6, 3.3 to 23.9, 5.4 to 25.5, and 7.4 to 29.1 SDU, respectively. Beta amylase activity for the same periods ranged between 0.1 to 6.5, 2.2 to 7.5, 1.9 to 7.5, and 2.1 to 10.6, SDU, respectively.

Conclusions: There was wide variations among the sorghum varieties in the physical characteristics, nitrogen and tannin content. There was also wide variation in the characteristics of germinated grain. There is good potential for using these differences to improve the utilization of sorghum grain for various foods.

Key words: Sorghum, Varieties, Characteristics, Utilization, Germination.

PO264**CORIANDRUM SATIVUM L. ETHANOL EXTRACT UP-REGULATE THE EXPRESSION OF THE fà CLASS OF GLUTATHIONE S-TRANSFERASE AND NAD(P)H: QUINONE OXIDOREDUCTASE 1 AS WELL AS NRF2 ACTIVATION***KL. Liu¹, TC Liu*¹Department of Nutrition, Chung Shan Medical University, Taiwan

Background and objectives: Coriandrum sativum L. is used not only as spice, but also as folklore medicine in many countries. To explore the chemopreventive action of Coriandrum sativum the effect of Coriandrum sativum ethanol extract on glutathione level and expression of fà class of glutathione S-transferase (GSTP) and NAD(P)H: quinone oxidoreductase 1 (NQO1) was investigated.

Methods: PCR, Western blot, molecular biology analysis.

Results: Real-time PCR analysis and immunoblotting analysis revealed that ethanol extract of Coriandrum sativum significantly increased protein and mRNA expression of GSTP and NQO1 in rat Clone 9 liver cells. Moreover, Coriandrum sativum extract up-regulated GSTP promoter activity and nuclear accumulation of nuclear factor erythroid 2-related factor 2 (Nrf2) as well as Nrf2 with GSTP enhancer I binding affinity and Nrf2 transcriptional activity.

Conclusions: The efficacy of Coriandrum sativum ethanol extract in induction of GSTP and NQO-1 expression as well as Nrf2 activation implies that Coriandrum sativum could be considered as a potential chemopreventive agent.

Key words: Coriandrum sativum, GSTP, NQO-1, Nrf2

PO265**MATERNAL AND CHILD NUTRITIONAL STATUS IN RURAL AND URBAN COMMUNITIES OF LAGOS STATE, NIGERIA***I. Senbanjo¹, I. Olayiwola¹, W. Afolabi¹, C. Senbanjo¹*¹Department of Paediatrics and Child Health, Lagos State University College of Medicine, Ikeja, Lagos State, Nigeria

Background and objectives: The quality of food intake is an important factor in the determination of the nutritional status of people in any community. This study was carried out to determine the nutritional status of mothers and children and to compare the nutritional status of mothers and children in rural and urban communities of Lagos, Nigeria.

Methods: The study was cross-sectional and structured questionnaire was used to collect data using a multistage random sampling technique. A total of 300 mother-child pair were selected to participate in the study. Data collected include demographics and socio-economic characteristics. Nutritional status was assessed using 24-hour dietary recall and anthropometry.

Results: The calorie intake of mothers in rural communities was 11.3 + 2.9 MJ and this was significantly higher than 8.7 + 1.8 MJ obtained for urban mothers ($p < 0.001$). However, the intake of proteins (31.1 + 8.1g), calcium (685.0 + 206.7mg), iron (21.8 + 6.9mg), (zinc 4.7 + 2.1mg), vitamin A (259.2 + 57.7 microgRE), and vitamin C (25.5 + 9.3mg) among mothers from rural communities were lower than corresponding values of 43.3 + 10.8g, 694.7 + 157.3mg, 24.4 + 6.4mg, 5.3 + 2.1mg, 306.7 + 92.6 microgRE, 31.3 + 10.9mg obtained for urban mothers. The prevalence of maternal under-nutrition was significantly higher among mothers from rural compared with those from urban communities (10.7% vs. 2.7%, $p = 0.022$). The complementary foods given to children from rural and urban communities were mainly cereals. The prevalence of underweight and stunting among the children were significantly higher in rural than urban communities (19.4% vs. 9.3%, $p = 0.025$) and (43.3% and 12.6%, $p = 0.001$), respectively.

Conclusions: This study had established a high prevalence of under-nutrition among mothers and children living in rural and urban areas in Lagos, Nigeria

Key words: Mothers; children; nutritional status, rural; urban

PO266**THREE-DIMENSIONAL ANALYSIS OF THE ONSET OF REGIONAL HETEROGENEITY OF HEPATOCYTES AND MICROVASCULAR ARCHITECTURE IN SHREW HEPATIC LOBULES***T. Ishikawa¹, Y. Sone¹, M. Sonoda², K. Yamashita³, Y. Fujiiwara²*¹Institute of General Research for SHOKUIKU, Ochanomizu University, Tokyo, Japan²Dept. of Nutrition and Food Science, Ochanomizu University, Tokyo, Japan³Dept. of Anatomy, Nippon Medical School, Tokyo, Japan

Background and objectives: Morphological and functional heterogeneity of hepatocytes are closely related to nutritional status. We previously reported that, in diabetic house musk shrews (*Suncus murinus*), typical lipid deposition begins in pericentral hepatocytes and extends the whole of the hepatic

lobes. Herein, we decided three-dimensionally (3D-ly) and morphometrically to elucidate the onset of the hepatocellular heterogeneity and the development of liver cell cords and microvasculature using normal prenatal, early postnatal and adult shrews.

Methods: The livers were fixed and embedded in epoxy resin. The semi-thin serial sections were served for light microscopy. The contours of hepatocytes, portal and central veins, and sinusoids were traced by an imaging software, and their three-dimensional reconstructions were performed with geometric and volume rendering methods. Besides, confocal microscopic observations were also performed with fluorescent substance-casted hepatic vessels.

Results: Hepatocytes surrounded wholly a straight course of a sinusoid from a portal venous side to a central vein was 3D-ly reconstructed. The regional heterogeneity of hepatocytes in size appeared from 4th day after birth and became conspicuous by 16th day. The sinusoids in adult lobules branched out from a portal venous side, ran radially to the central vein with a few ramifications, and then anastomosed each other to make a unique mesh sheet around the central vein. This characteristic microvascular architecture seemed to intimately relate to the obvious intralobular heterogeneity of hepatocytes.

Conclusions: These spatial visualization and analysis have yielded many interesting findings which are available for explanation of several region-specific events in livers induced by NAFLD, NASH and other nutritional status.

Key words: hepatocytes, lipid deposition, heterogeneity, microvascular architecture

PO267

ABNORMALITIES OF HEMOGLOBIN, IRON, VITAMIN B12 AND 25(OH)D STATUS IN A CONVENIENCE-SAMPLE OF PRESCHOOLERS ATTENDING A DAY-CARE CENTER IN GUATEMALA

S. Salguero¹, L. Hernández¹, L. Armas², L. Paul³, J. Selhub³, M J L. Bonorden⁴, K L. Sheldon⁴, R M. Herreid⁴, N W. Solomons¹

¹Center for Studies of Sensory Impairment, Aging and Metabolism (CeSSIAM), Guatemala City, Guatemala

²Osteoporosis Research Center, Creighton University, Omaha, USA

³Vitamin Metabolism Laboratory, Jean Mayer USDA, HNRCA, Tufts University, Boston, USA

⁴Hormel Food Corporation, Austin, USA

Background and objectives: Vitamin D, known as the “sunshine” vitamin, can be synthesized in the skin by exposure to solar ultraviolet energy. Little concern has been expressed

for the nutritional status of this vitamin in the tropics. Vitamin B12 has been identified as a problem nutrient in Guatemala. Our objective was to assess the prevalence of abnormal status of these two vitamins along with hemoglobin and iron in preschoolers from a peri-urban area of Guatemala-City.

Methods: 165 day-care children (aged 3-6 years) at Fe y Alegria in Peronia, 18 km from Guatemala-City, participated. Anemia was assessed by altitude-adjusted hemoglobin criteria. For iron status, ferritin of <20 g/dL signified deficiency. Circulating levels of vitamin B12 were measured in Boston, MA by an Immulite 1000 method (Siemens, IL), using cutoff-criteria for deficient and marginal of <200 pg/mL and 200-299 ng/mL, respectively. Serum 25(OH)D was measured in Omaha, NE on a Liaison instrument (DiaSorin, Inc., Stillwater, MN), using cutoff-criteria for deficient and insufficient of <20 and 20-29 ng/mL, respectively.

Results: The average hemoglobin (g/dL) was 12.6±0.7 (median:12.6). Median ferritin (ng/mL) was 30.2, with 19% of values <20 g/dL. Overall mean vitamin B12 concentration (pg/mL) was 539±298 (median: 454; range:118-2012); globally, 4% had deficient and 15% marginal values, for a 19% abnormal prevalence. The mean 25(OH)D concentration (ng/mL) was 29±7 (median: 28; range:17-76); globally, 5% had deficient values and 54% insufficient, for a 59% abnormality rate.

Conclusions: ~1/5 of the preschoolers presented abnormal status regarding iron and vitamin B12. 3 in 5 children were deficient/insufficient in their vitamin D status. With these findings, we add another segment of the Guatemalan population to the groups vulnerable for under-explored vitamins.

Key words: Hemoglobin, iron, vitamin B12, 25(OH)D, Guatemala

PO268

DIETARY LACTOFERRIN SUPPLEMENTATION PROTECTS THE NEWBORN PIGLETS FROM EARLY WEANING DIARRHEA

C W. Yang¹, Y. Chen¹, H X. Gan¹, X. Zhu¹, N. Liu¹, B. Wang^{1,2}

¹School of Medicine, Xiamen University, Xiamen, Fujian Province, China

²School of Animal and Veterinary Science, Charles Sturt University, Wagga Wagga NSW 2678, Australia

Background and objectives: Lactoferrin is a natural rich compound in the milk of mammals that has shown to play many biological functions in infants including regulation of immune response and protection against microbial infection. Objective: To investigate the effects of dietary supplementation of lactoferrin on intestinal micro-flora and early weaning diarrhea in newborn piglets.

Methods: 3 days old male piglets (*Sus scrofa* Landrace; Large White F1, n=54) were randomized to 3 feeding groups fed milk supplemented with lactoferrin for 5 weeks at dose level of 0.05g/L (group 1, control), 0.5g/L (group 2) and 1g/L (group 3). At 38 days old, the jejunum tissue and the descending colonic contents were collected for colonic bacterial community using qPCR. The faecal consistency score of piglet was monitored daily throughout 5 weeks.

Results: Our results showed that the piglet administered with lactoferrin significantly delayed the onset of food transition diarrhea; reduced the frequency of diarrhea; reduced the duration of diarrhea with a dose response relationship ($p < 0.05$). The incidence of diarrhea in lactoferrin groups decreased marginally significant than that of the control group ($p = 0.058$). There was no difference in 16S rDNA copies of total bacteria, Bifidobacteria and Lactobacillus per gram of colonic contents among the groups, however, the *E. coli* levels tended to be lower in lactoferrin groups.

Conclusions: Dietary lactoferrin supplementation improved gut comfort and alleviated early weaning diarrheal symptoms. This benefit may result from the well-known immune-boosting activity of lactoferrin.

Key words: lactoferrin, diarrhea, piglet, colonic-flora This study was supported by a research grant from the School of Medicine of Xiamen University and Nestle Research Center.

PO269

ASSESSMENT OF HEALTH PROFESSIONAL CURRICULAR FOCUS ON NUTRITION IN INDIA

S. Pati¹

¹Indian Institute of Public Health-Bhubaneswar, Public Health Foundation of India, India

Background and objectives: Despite the fact that nutrition constitutes an integral part in prevention and treatment of all major chronic and communicable diseases, commensurate directives for its appropriate education to future health care providers is much left to be desired. In western countries, efforts are already underway to collaboratively accommodate nutrition education into health professional training. However, the same is yet to be initiated in India where both under and over nutrition are the prime causes of morbidity and mortality and pose considerable public health challenge. Present work attempted to identify the nutritional content of different health profession curricula in India and assess its quality and quantity. This mapping of curricular components would lead to designing a nutritional curriculum that can be effectively and efficiently integrated in traditional health professional education without additional elongation.

Methods: Curricula of medicine, dentistry, nursing, physiotherapy, occupational therapy and pharmacy were analyzed in detail to identify elements relating to nutrition teaching imparted throughout the pre and clinical years. The time allotted and the mode of teaching was also assessed in depth.

Results: In under graduate curriculum, nutrition related content is taught under biochemistry, physiology, pathology, pharmacology, medicine, and community medicine. There is no teaching of nutrition in the context of disease prevention and health promotion. Learning of nutritional counseling skills is starkly missing.

Conclusions: Future physicians, nurses and health care givers should possess adequate knowledge base and inculcate specific patient-centered nutrition counseling skills during the formative years. Appropriate integration of nutrition into various health profession courses appears to be deficient and necessitates urgent academic intervention. Curriculum designers first need to be sensitized in this regard. The respective apex councils and national associations should consider prioritizing nutrition in their education and promoting a culture that builds competency in nutrition education.

Key words: nutrition, curriculum, education, India

PO270

FEEDING PRACTICES AND NUTRITIONAL STATUS OF UNDER FIVE TWINS AND SINGLETONS IN IGBOORA COMMUNITY, NIGERIA

O O. Leshi¹, O T. Adepoju¹

¹Department of Human Nutrition, University of Ibadan, Nigeria

Background and objectives: Several studies have been done on the IYCF and nutritional status of under-five children in Nigeria but few have focussed on twins. The objective of this study was to comparatively assess feeding practices and nutritional status of twins and singletons below five years of age in Igboora.

Methods: A cross sectional study was purposively carried out in Igboora, a community reported to record the highest prevalence of twinning in the world. Eighty two mothers of Twins and 83 mothers of singletons were selected through snow ball and systematic sampling techniques respectively. Anthropometric measurements were conducted to assess for the nutritional status while structured questionnaire was used to assess child feeding practices.

Results: Early initiation of breastfeeding was practiced by 45% of mothers with singleton while 42% of mothers with twins reported the practice. The rate of exclusive breastfeeding among mothers of singleton was 15.7% while it was 7.3% among mothers of twins. Majority of the mothers of singletons

and twins continued breastfeeding beyond one year. Introduction of complementary foods before six months was observed among 34.9% and 58.5% of mothers with singleton and twins respectively. While 23% of singletons were fed with minimum acceptable diet, 30.4% of twins had minimum acceptable diet. The prevalence of wasting, stunting and underweight among singletons were found to be 14.5%, 36.1% and 19.3% respectively while twins were found to have higher prevalence: 25.6%, 45.1% and 39.6% respectively. The twins were two times more likely to be wasted (OR=2.04), stunted (OR= 1.45) and underweight (OR=2.75) than singleton.

Conclusions: From this study, adequate Infant and Young Child Feeding were more likely to be practised by mothers of singletons than mothers of Twins and twins were found to be two times more likely to be malnourished than the singletons.

Key words: IYCF practices, nutritional status, twins

PO271

FOOD SECTOR APPROACH IN REDUCING SALT INTAKE IN THE NETHERLANDS: BREAD AND MEAT PRODUCTS SECTORS AS EXAMPLES

J. van Raaij¹, M. Hendriksen¹, L. Temme¹, M. Noort², T. Verkleij², A. Jansen³, K. den Uijl⁴, P. Sakkers⁴

¹RIVM, National Institute for Public Health and the Environment

²TNO, Netherlands Organisation for Applied Scientific Research

³WUR, Wageningen University and Research Center

⁴FND, Food and Nutrition Delta

Background and objectives: Elevated salt intake is associated with a number of noncommunicable diseases (NCDs) including hypertension, cardiovascular disease and stroke. Decreasing salt intake may reduce blood pressure and the risk of associated NCDs. Since in the Netherlands about 80% of daily salt intake comes from processed foods, food sectors should play a major role in salt reduction.

Methods: A unique cooperation on food reformulation between ministries, research institutions and a university resulted in an overview on to what level sodium reduction in foods would be technologically possible, maintaining safety and integrity of the product and acceptability to the consumer. Since bread and meat products (as sandwich filling) are main contributors to daily salt intake in the Netherlands (26% and 10%, respectively), the findings on these two food groups were discussed in detail with the concerning food sector through workshops. Food producers, retailers and caterers were all involved.

Results: For Dutch men aged 19-69 yr salt intake from processed foods is 7.8 g/d and for Dutch women 6.0 g/d. Salt in-

take from bread is 2.0 and 1.4 g/d respectively. Technologically reductions are possible to 1.0 and 0.7 g/d, respectively. Salt intake from meat products (as sandwich filling) is 0.78 and 0.60 g/d, respectively. Technologically reductions are possible to 0.32 and 0.25 g/d, respectively. Both workshops revealed that sectors consider the discussed options in general as feasible. The bread sector is already quite far in implementing salt reduction, the meat product sector considers the targets as feasible providing sufficient time is given to realize technological modifications.

Conclusions: Food sectors may contribute substantially to lowering daily salt intake. Food sectors are willing to contribute, providing that all sectors contribute simultaneously. Sector-organized workshops with all involved stakeholders seem to be a valuable instrument.

Key words: Salt reduction, food sectors, bread, meat products

PO272

HDL SIZE IN OBESE ADOLESCENTS

M C P. Freitas¹, N R T. Damasceno¹

¹School of Public Health University of Sao Paulo, Sao Paulo, Brazil

Background and objectives: Obesity exerts negative impact in many classical cardiovascular risk factors, and adolescents are a vulnerable group to development obesity. In this fashion, it is probably that obesity in adolescents show significant and early changes in lipid metabolism. The goal of this study was to analyze the possible association between HDL size and other lipid parameters in obese adolescents.

Methods: Adolescents (n=237), both sexes and aged 10 to 19 years were included in this protocol. Socio-demographic, clinical, physical activity and dietetic habits were evaluated. After fasting (12h) blood samples were collected and from plasma/serum were analyzed: lipid profile, Apo AI, Apo B, CETP, HDL size and PON-1.

Results: Linear trend analysis showed that higher tercis of HDL size was associated to higher tercis of TC, LDL-C and non-HDL, while the inverse relationship was observed to apo AI, HDL, waist circumference, body mass index and percentage of fat mass had a size inversely proportional variation.

Conclusions: Obesity promotes multiple and negative effects on HDL particle in adolescents.

Key words: Size HDL, Obesity, Adolescents

PO273**BREAST CANCER SURVIVORS AND THE ROLE OF NUTRITION**

N. Bader¹, M. Billinger¹, K. Kremer¹, K. Pfeiffer¹, J. Schneider¹, A. Seidensal¹, S. Voigt¹, K. Kohlenberg-Mueller¹

¹Department of Nutritional, Food and Consumer Sciences, University of Applied Sciences, Fulda, Germany

Background and objectives: Evidence-based nutritional guidelines are published for cancer survivors. Limited information is available however regarding patients' nutritional status, eating patterns, and quality of life (QOL).

The studies objective was to sample a pool of breast cancer survivors to garner information concerning nutritional status, QOL, and their interest in nutritional intervention.

Methods: Breast cancer survivors within Germany, at self-help groups and gynecological practices, were asked to anonymously complete a standardized questionnaire.

Results:

1. Study included 236 women; all voluntary participants. of those surveyed:

30.9% were aged 50-59 years

44.5% were aged 60-69 years

14.4% were aged ≥ 70 years.

Of these, 75% received their cancer diagnosis over 4 years ago, while 78% of all participants reported no relapse.

2. BMI was calculated in Kilograms (weight) / meters (height) squared.

Average BMI among participants was 27 ± 5.5 kg/m².

45.3% were overweight

17.8% were obese

0.4% were underweight

49.6% reported a weight gain of 8.6 ± 6.1 kg

14.8% reported a weight loss of 8.5 ± 4.8 kg

44.1% of participants reported two or more hours of exercise per week.

3. Post treatment, 56.4% of participants modified their eating habits.

Higher consumption of vegetables (30.8%), fruits (27.2%) and fish (8.7%) were reported in addition to a 39.2% decrease in meat and meat products.

4. Participants QOL was estimated as "generally good."

5. Of 27.1% of patients offered nutrition or dietetic counseling, 87.5% participated.

Conclusions: The study demonstrated the need for more attention to be placed on nutrition concerning survivors of breast cancer. It emphasizes the need for nutrition to become an integral part of follow-up care, with a focus on maintaining healthy weight, and information concerning portioning and nutritional quality of dietary choices.

Key Words: Cancer survivors, breast cancer, nutrition, BMI, food choice

PO274**DIETARY GLYCEMIC INDEX AND GLYCEMIC LOAD ACCORDING TO MEDITERRANEAN DIET ADHERENCE: THE PREDIMED STUDY**

A. Rodríguez-Rejón¹, I. Castro-Quezada¹, C. Ruano^{1,2}, M D. Ruiz-López³, R. Artacho³, R. Estruch², J. Salas-Salvadó², M I. Covas², D. Corella², E. Gómez-Gracia², J. Lape-tra², X. Pintó², F. Arós², M. Fiol², R M. Lamuela-Raventós², M A. Martínez-González², L I. Serra-Majem^{1,2}

¹Department of Clinical Sciences. University of Las Palmas de Gran Canaria, Spain

²Ciber Fisiopatología Obesidad y Nutrición (CIBERO-BN, CB06/03), Instituto de Salud Carlos III, Spain

³Department of Nutrition and Food Science. University of Granada, Spain

Background and objectives: Low dietary glycemic index (GI) and glycemic load (GL) have been related with a decreased risk of chronic degenerative diseases. However, the relationship between GI/GL and Mediterranean diet adherence is unclear. Objective: To assess the GI and GL according to the Mediterranean diet adherence in the PREDIMED study, a nutrition intervention trial for primary cardiovascular prevention in a high- risk cohort.

Methods: We measured GI and GL among 2880 non diabetic subjects. Diet was assessed with the use of a validated 137-semiquantitative FFQ. Mediterranean diet adherence was determined using a 14-point score validated tool. GI and GL of each item of the FFQ were assigned by a 5 step methodology using the International Tables of Glycemic Index and Glycemic Load Values. Participants were classified according to quartiles of Mediterranean diet adherence. Dietary variables were energy adjusted by the residual method. Generalized linear models were fitted to assess the regression coefficients (95% CI) for the association between the Mediterranean diet adherence and GI and GL using the lower category as the reference.

Results: On the studied population, mean (SD) for dietary GI was 56.97 (4.72) and for dietary GL was 112.85 (22.99). The multivariate-adjusted models revealed a significant inverse association between GI or GL and the level of Mediterranean diet adherence. For GI: the regression coefficient for the upper category of adherence versus the lowest was $\beta = -1.83$ (-2.27 to -1.39) in the adjusted model. We also found statistical inverse relationship for GL, $\beta = -13.10$ (-15.27 to -10.93) upper category vs. lowest category.

Conclusions: An Inverse association between GI or GL and the level of Mediterranean diet adherence was found.

Key words: Glycemic Index, Glycemic Load, Mediterranean Diet.

PO275**ZINC STATUS AND METALLOTHIONEIN 1F AND 2A GENE EXPRESSION IN ATHEROSCLEROSIS PATIENTS TREATED WITH ROSUVASTATIN AND ZINC SUPPLEMENTATION**

P. Dias¹, D. Ferreira¹, K. Sena-Evangelista², M. Paiva³, A. Rezende⁴, D. Abdalla⁵, L. Pedrosa²

¹Post-Graduate Program in Pharmaceutical Sciences, Federal University of Rio Grande do Norte, Natal, Brazil

²Department of Nutrition, Federal University of Rio Grande do Norte, Natal, Brazil

³Onofre Lopes University Hospital, Federal University of Rio Grande do Norte, Natal, Brazil

⁴Department of Clinical and Toxicological Analysis, Federal University of Rio Grande do Norte, Natal, Brazil

⁵Department of Clinical and Toxicological Analysis, Faculty of Pharmaceutical Sciences, University of São Paulo, São Paulo, Brazil

Background and objectives: Given that reduced zinc concentrations have been attributed to the use of statins, it is important to determine zinc flow in patients with atherosclerosis and assess the need for supplementation. The study aimed at evaluating the effects of zinc supplementation on zinc status and metallothionein (MT) 1F and 2A gene expression in patients with atherosclerosis treated with rosuvastatin.

Methods: Fifty-four patients that took part in the original study (Clinicaltrials.gov I.D NCT01547377) were enrolled in Natal, Northeast Brazil. We conducted a double-blind randomized clinical trial in which patients were treated with 10 mg of rosuvastatin for 4 months and a zinc (30 mg/d) supplement (n=27), or placebo (n = 27). The following parameters were analyzed both before and after the intervention: diet, lipid profiles, hs-CRP (high-sensitivity reactive protein), plasma and erythrocyte zinc concentration, erythrocyte SOD activity and metallothionein (MT)1F and 2A gene expression.

Results: Rosuvastatin therapy was efficient in reducing LDL and non-HDL total cholesterol, triglycerides and hs-CRP irrespective of zinc supplementation. No differences were observed in plasma (p>0.671) or erythrocyte (p>0.123) zinc concentrations. The SOD antioxidant enzyme was unchanged by zinc treatment (p=0.201); however, comparison between pre- and post-treatment values shows that its activity increased significantly in the placebo group (p=0.021). The pattern of MT1F and MT2A gene expression was not significantly altered by zinc treatment (p=0.088; p=0.229), even though intra-group comparison demonstrated that the placebo group displayed a significant decline in the pattern of MT1F expression (p=0.043), suggesting a likely effect related to the need to supply the organic demands of oxidative stress with lower zinc intake.

Conclusions: Treatment with rosuvastatin did not have a significant impact on zinc status. Further, the zinc doses used here did not influence zinc biomarkers or the pattern of MT 1F and 2A gene expression.

Key words: zinc, rosuvastatin, metallothioneins.

PO276**NUTRITION GOVERNANCE: FIVE CRUCIAL BUILDING BLOCKS AND AN APPLICATION OF THESE BUILDING BLOCKS INTO SPECIFIC COUNTRY CONTEXTS**

M. Colnar¹, S. De², H M. Leung³, M. Wang⁴, J. Fanzo⁵, G. Denning⁶

¹Fintrac, St. Thomas, US Virgin Islands, USA

²nonprofit-share, New York City, NY, USA

³B Lab, New York City, NY, USA

⁴Booz & Company, Sydney, Australia

⁵The Institute of Human Nutrition, Columbia University, New York City, NY, USA

⁶School of International and Public Affairs, Columbia University, New York City, NY, USA

Background and objectives: Enjoying unprecedented momentum in the international agenda, nutrition policies and programs have become a leading priority for actors at the international, national and local levels. The change in global sentiment toward nutrition is largely due to successful high-level nutrition-based policy campaigns such as Scaling Up Nutrition (SUN) and the 1,000 Days Initiative. The institutional architecture for addressing nutrition, however, has been largely lacking and in need of renovation.

Methods: This work examines the concept of nutrition governance and its relatively new appearance on the global stage. A review of the existing literature reveals five key concepts as being fundamental to good nutrition governance: political commitment, consensus building and coordination, financing, service delivery capacity, and transparency and accountability. The paper explores these concepts and demonstrates how they are necessary to implement meaningful nutrition policies and programs at the national level. These five building blocks are examined through the lens of six country case studies that illustrate good nutrition governance. The country stories of Peru, Brazil, Bangladesh, Tanzania, Vietnam and Thailand are highlighted because each country illustrates a different path in its nutritional programming and each demonstrates declines in nutrition-related deficiencies.

Results: This literature review and country context research gave rise to two main observations. The first is the interdependent nature of the five building blocks as a basis for effective nutrition governance; effective program implementation relies

on all of the building blocks to be engaged at some level. The second is that while the building blocks are broadly applicable across different countries, how the specific processes and activities within each block manifest themselves depends on the country context.

Conclusions: The purpose of this analysis is to further develop the current thinking on nutrition governance in the interests of strengthening the SUN movement and related efforts to combat malnutrition globally.

Key words: Governance, policy, financing, capacity, transparency

PO277

THE IN VITRO FUNCTIONAL EFFICACY OF PROBIOTIC COMBINATIONS IN FERMENTED GOAT'S MILK

C. Ranadheera^{1,2}, C. Evans², M. Adams², S. Baines²

¹Department of Agricultural Systems, Faculty of Agriculture, Rajarata University of Sri Lanka

²School of Environmental and Life Sciences, University of Newcastle, Australia

Background and objectives: Resistance to gastrointestinal condition, adhesion to intestinal epithelium and immunomodulation are critical factors in maintaining probiotic efficacy. Most of the studies evaluating these characteristics in vitro have been conducted without considering the protective and synergistic effects of carrier food matrices towards these characteristics. This study evaluates the in vitro functional properties of various probiotic combinations in fermented goat's milk including tolerance to simulated gastrointestinal juices, cellular adhesion and immune-stimulation of intestinal cell cultures.

Methods: Seven different types of fermented drinking milk were made from goat's milk using various culture compositions of three probiotics: *Lactobacillus acidophilus* LA-5, *Bifidobacterium animalis* subsp. *lactis* BB-12 and *Propionibacterium jensenii* 702 and stored at 4°C for 3 weeks. In vitro gastrointestinal tolerance (using simulated gastric juice, pH 2 and intestinal juice, pH 8 with or without 0.3% bile salts), adhesion ability (using a Caco-2 cell model) and immunomodulation aspects (by measuring stimulation of IL-6 and TNF- α production from Caco-2 cells) of these probiotics were evaluated.

Results: All three probiotics and combinations in fermented goat's milk have demonstrated significantly lower viability after exposure to simulated gastric and intestinal (with 0.3% bile) fluids in vitro ($p < 0.05$). The ability of these probiotics to adhere to Caco-2 cells appeared to be influenced by the specific probiotic strains with which they were combined in the manufacturing of fermented goat's milk. *P. jensenii* 702 was unable to induce IL-6 and TNF- α ; production from Caco-2 cells either in monoculture or co-cultures with other probio-

tics, while the monocultures of *L. acidophilus* LA-5 and *B. animalis* subsp. *lactis* BB-12 and the co-culture of those two probiotics were able to induce low levels of IL-6 and TNF- α ; production ($< 4.17 \pm 1.25$ pg/ml) respectively.

Conclusions: Probiotic combinations as well as food matrix may affect the functional properties of probiotics.

Key words: Probiotics, gastrointestinal-tolerance, adhesion

PO278

THE FATTY ACID COMPOSITION AND MAIN FOOD SOURCES OF FATTY ACIDS IN THE DUTCH DIET

M. Ocke¹, C. van Rossum¹, J. Verkaik-Kloosterman¹, E. Buurma-Rethans¹, E. de Boer¹

¹RIVM, National Institute for Public Health and the Environment, Bilthoven, The Netherlands

Background and objectives: The fatty-acid composition of the diet is an important determinant of cardiovascular disease risk. Decreasing the intake of saturated and trans unsaturated fatty acids, and increasing the intake of fish fatty acids (EPA&DHA) lowers cardiovascular risk. The development of atherosclerosis starts in childhood. Therefore, insight in the fatty acid composition of the diet is needed across all ages. **Objectives:** To provide estimates of intakes and main food sources of saturated and trans unsaturated fatty acids, and EPA&DHA in Dutch children and adults and to analyse compliance with dietary recommendations.

Methods: In 2007-2010, a Dutch national food consumption survey among 3819 participants aged 7-69 years was conducted. Two non-consecutive 24-hour dietary recalls with the software EPIC-Soft[®] were collected. Habitual nutrient intake was calculated using the Dutch Food Composition Database2011 and SPADE. Intake distributions were compared with dietary reference values set by the Dutch Health Council.

Results: About one third of consumed energy was derived from fat. In this population, 85% and <5% exceeded the advised maximum intakes of 10% saturated fat and 1% trans unsaturated fatty acids, respectively. The main sources of saturated fatty acids were dairy products, meat products, added fats, and cakes. Median intake of EPA&DHA increased with age, but was below the adequate intake for all age groups. Meat, fish, and eggs were the main sources of EPA&DHA; dietary supplements contributed 6%.

Conclusions: For the prevention of cardiovascular diseases, the Dutch diet could be improved through consumption of less or less-fatty choices of dairy, meat, added fats, and cakes, and increased consumption of fatty fish. In contrast to the past, intake of trans fatty acids is at an acceptable level. Food consumption surveys facilitate to identify where dietary targets are not being achieved and how they can be improved.

Key words: fatty acids, dietary monitoring

PO279**A STUDY ON BODYWEIGHT PERCEPTION, FUTURE INTENTION AND WEIGHT MANAGEMENT BEHAVIOUR AMONG NORMAL WEIGHT, OVERWEIGHT AND OBESE WOMEN IN INDIA***P K. Agrawal¹*¹Population Council

Background and objectives: Inaccurate body weight perception is threat to healthy weight management behaviour. Although body weight perception studies are abundant in developed countries to form basis for weight management programmes, in developing country such as India, where obesity is rising, body weight perception and weight management behaviour have been hardly studied. We studied the socio-economic differential in the self perception of body weight, future intention for weight management and actual weight management behaviour among overweight and obese women in India.

Methods: A follow-up survey was conducted from sampled women of 2nd National Family Health Survey after four years in 2003 and 325 adult women years were interviewed in national capital territory of Delhi. Information on their own weight perception, intention of weight management and actual weight management behaviour were collected through personal interview along with anthropometric measurements for BMI. Descriptive statistics and multivariate logistic regression are used for data analysis.

Results: Discrepancy between self perceived body weight and women's actual body weight was reported. One quarter overweight women and one in ten obese women perceived themselves as normal. A significant proportion of overweight (one in four) and 4% obese women also wanted to maintain their weight as it is. Only one in three overweight and one in four obese women were performing any physical activity to reduce their weight. Women daily exposed with media were significantly more likely to perceive their weight accurately (aOR: 8.78;95%CI:2.15-37.97) and also had intention to reduce weight (aOR:16.38;95%CI:2.04-25.26) than who were not exposed.

Conclusions: These findings are important for public health interventions in obesity care. Implementation of health promotion and health education in the community should use effective mass media to raise awareness of accurate body weight to combat the growing level of obesity among Indian women.

Key words: obesity; self-perception; weight-management; women; India

PO280**PROGRAMMING THE METABOLIC GENE EXPRESSION IN ZEBRAFISH JUVENILES (DANIO RERIO) BY SUPRA-PHYSIOLOGICAL GLUCOSE LEVEL DURING EMBRYOGENESIS***F. Rocha¹, J. Dias¹, S. Engrola¹, P.J. Gavaia¹, I. Geurden², M.T. Dinis¹, S. Panserat²*¹Center of Marine Science (CIMAR LA/CCMAR), University of Algarve, Faro, Portugal²UR1067 Nutrition Metabolism Aquaculture, Pôle d'Hydrobiologie, Institut National de la Recherche Agronomique (INRA), Saint-Pée-sur-Nivelle, France

Background and objectives: Fish show a low ability to use dietary carbohydrates. Knowledge on the role of early nutritional stimuli as triggers of metabolic pathways (metabolic programming) in fish is extremely scarce. A series of studies were undertaken with zebrafish, as model organism, to assess the effect of supra-physiological levels of glucose during early embryonic stages as a lifelong modulator of metabolic pathways.

Methods: Molecular ontogeny of metabolic pathways during zebrafish embryogenesis was analysed by real-time PCR. Embryos at 0.2 days post fertilization (dpf) were enriched with glucose solution by means of microinjection. Acute effects of glucose injection on gene expression were assessed in larvae up to 10 dpf, while the programming concept was evaluated in juveniles (41 dpf) challenged with a hyperglucidic diet.

Results: Data on molecular ontogeny showed that genes related to carbohydrate metabolism, transport and digestion have low expression levels at 0.2 dpf, yet are activated at endogenous feeding period (4 dpf). By microinjecting zebrafish eggs, a 43-fold increase of basal levels of glucose was achieved, without compromising survival. Larvae from glucose-enriched eggs (4 dpf) showed a down-regulation of several genes related to glycolysis, glycogenolysis, lipogenesis and carbohydrate digestion in comparison with control (saline injected). This inhibitory regulation was suppressed after 10 dpf. At juvenile stage and upon switching from a low to a high carbohydrate diet, early glucose enrichment did not lead to marked benefits on the metabolic abilities of zebrafish. However, fish exposed to early glucose stimulus showed an improved capacity for glucose storage in muscle and lower glucose production and transport in viscera.

Conclusions: Early yolk supplementation with glucose caused both acute and chronic changes on the expression pattern of several genes that may permanently influence carbohydrate metabolism. This study suggests that early nutritional stimuli have the potential to modulate the metabolism of zebrafish at later stages.

Key words: Glucose; Programming; Gene expression, Zebrafish.

PO281**THE LEVEL OF KNOWLEDGE OF MOTHER IS A COMMON DETERMINANT RELATIONSHIP WITH MOTOR AND MENTAL DEVELOPMENT OF STUNTING INFANTS IN WEST SUMATRA PROVINCE INDONESIA**

H. Zulkarnain^{1,2}, H. Rina, L. Indrawaty, J. Fasli

¹Faculty of Public Health Andalas University Padang, Indonesia

²Politechnic of Health Ministry of Health Padang, Indonesia

³Faculty of Medicine Andalas University Padang, Indonesia

⁴Faculty of Medicine Andalas University Padang, Indonesia

Background and objectives: Stunting can have long-term effects on cognitive development, school achievement, economic productivity in adulthood and maternal reproductive outcomes. This study aims to determine the relationship of nutrition knowledge of mothers, health status, parenting and psychosocial stimulation of children with levels of motor and mental development of stunting infants 6 to 12 months of age in West Sumatra Province Indonesia.

Methods: It was a cross sectional study conducted at Tanah Datar regency in West Sumatra Province Indonesia from April to August 2012. Among 265 infants from 11 villages in Tanah Datar regency were assessed for nutritional status and stunting according to standard (WHO, 2006). The qualitative approaches also used for enrich analyses from informants consisting midwives, cadres and mothers of stunting infants. Sampling was carried out with Multistage Random Sampling technique. The collected data was analyzed by Statistical Program SPSS version 15. Frequencies and percentages were computed to present all categorical variables Quantitative variables such as age, nutritional status was presented by mean \pm SD. Data analysis was performed with a statistical test as Multiple Logistic Regression.

Results: The quantitatively data was found an association with maternal nutrition knowledge of motor and mental development of stunting infants with p value 0.02. While the incidence of diarrhea, respiratory events, parenting and psychosocial stimulation did not significantly associated with motor and mental development of stunting infants. Maternal nutrition knowledge was the most common related to motor development of stunting infants is with respective OR 2.837 (95% CI 1.134 to 7.095).

Conclusions: It was found relationship low knowledge nutrition of mother with delay motor and mental development of stunting infants 6 to 12 month of ages in West Sumatra Province.

Key words: stunting, motor, and mental development, infants.

PO282**EFFECT OF ANIMAL SOURCE FOOD (ASF) PROVISION ON THE GROWTH OF MALNOURISHED CHILDREN IN KELANTAN, MALAYSIA: A RANDOMIZED CONTROLLED TRIAL**

R. Jalil^{1,2}, I. Naser¹, W M. Wan Muda², W S. Wan Nik², Z. Shariff³, M R. Abdullah¹

¹Department of Community Medicine, School of Medical Sciences, Universiti Sains Malaysia, Health Campus, 16150, Kubang Kerian, Kelantan, Malaysia

²Program of Nutrition & Dietetics, School of Health Sciences, Universiti Sains Malaysia, Health Campus, 16150, Kubang Kerian, Kelantan, Malaysia

³Department of Nutrition and Dietetics, Faculty of Medicine and Health Sciences, Universiti Putra Malaysia, Serdang 43400 Selangor, Malaysia

Background and objectives: It is well established that animal source foods (ASF) is a major contribution to the diet, yet parents who never serve eggs and red meat are keeping children away from the most concentrated sources of proteins, vitamins and minerals that promote the growth and enhance child's immunity. The objective of this study was to evaluate the effect of Animal Source Food (ASF) on the growth of malnourished children in Kelantan, Malaysia.

Methods: A six months of ASF intervention trial was carried out in 90 malnourished children of food insecure households in a rural area of Malaysia. Children were randomized into three groups: 30 children was assigned to Milk group (M) who consumed two carton of 250 ml milk daily over the study period; in Egg group (E), 30 children consumed two eggs daily and Control group (C) (n=30). Anthropometric data were collected at baseline, at 3 and 6 months of the trial.

Results: Over the study period there was a significant increase in height, weight and Mid Upper Arm Circumference (MUAC) when One-way repeated measures ANOVA was performed. However, there was no significant differences of increments in height, weight and MUAC were observed between the groups.

Conclusions: The provision of ASF trial improved weight, height and MUAC among malnourished children.

Key words: Milk, egg, malnutrition, weight, height

PO283**ASSOCIATION OF THE ANXIETY WITH THE NUTRITIOUS CONDITION IN ADOLESCENTS, AGES 11 TO 13 YEARS IN MEXICO CITY**

C. Radilla¹, S. Vega², R. Gutiérrez², M. Radilla³, M. Coronado²

¹Student of the Doctorate of Biological Sciences and of the Health. Autonomous Metropolitan University Campus Xochimilco

²Department of Agricultural and Animal Production, Division of Biological Sciences and of the Health, Autonomous Metropolitan University, Campus Xochimilco, Calzada del Hueso 1100, Colonia. Villa Quietud Delegación Coyoacán, CP 04960 Mexico City

³Independent Consultant

Background and objectives: Nowadays is more frequent than the adolescents present problems of anxiety, due to multiple stressful events to which find them exposed day after day, since they can be an adverse economic situation, school exigency, parents divorce, school bullying, which together with their own development changes, it does that they experience dread, worry or be concerned, and that feelings interferes in his food habits and ways of life. The aim of present study was to know the prevalence of anxiety disorders in adolescent students of middle schools in Mexico City and, in its case evaluate if some relation exists with they nutritious condition.

Methods: The study sample was constituted by 142 students (72 women/70 men), with age from 11 to 13 years, of 8 secondary schools public of Mexico City. Through the application of the 'scale HAD insole anxiety', which contains 7 items and the use of Who Anthro Plus program, the conditions of anxiety and nutritious status were obtained, respectively.

Results: We establish that the percentage of adolescents without anxiety was 60 % (women 29% and men 31%), the percentage of adolescents with probable anxiety was 13.3% (women 7% and men 6.3%) and finally with significant anxiety 26.7% (women 14.7% and men 12%). With regard to the nutritious condition we establish that 1.4% presented thinness (women 1.4%), 57.7% normal weight (women 34.5% and men 23.2%), 27.5% overweight (women 10.5% and men 17%) and 13.4% obesity (women 4.2% and men 9.2%). The statistical analysis (test chi² de Pearson) did not find significant association ($p > /0.05$) between the anxiety and the nutritious condition.

Conclusions: We recommend to extend the study to identify the factors that predispose the anxiety and its relation with the increase of weight in the adolescents of middle school in Mexico City.

Key words: anxiety, adolescent, middle school, nutritious condition, Mexico

PO284**HIBISCUS SABDARIFFA POLYPHENOLS PREVENT INFLAMMATORY-RELATED PATHOLOGIES THROUGH EPIGENETIC REGULATION**

M. Herranz López¹, S. Fernández-Arroyo², R. Beltrán-Debón³, E. Barrajon-Catalán¹, A. Segura-Carretero², J. Joven³, V. Micol¹

¹Institute of Molecular and Cell Biology, Miguel Hernández University, Elche, Alicante, Spain

²Department of Analytical Chemistry, Faculty of Sciences, University of Granada, Granada, Spain

³Centre de Recerca Biomèdica, Hospital Universitari de Sant Joan, IISPV, Universitat Rovira i Virgili, Reus, Spain

Background and objectives: The low-grade chronic inflammation pathology matches as seemingly disparate as cancer or obesity, which share energy metabolism as pathogenic scene. The potential of *Hibiscus sabdariffa* L. to protect against inflammatory metabolic disturbances has been previously reported.

Methods: In this study, we have evaluated the effect of the phenolic extract from HS (PEHS) on triglyceride accumulation, oxidative stress and adipokine secretion in hypertrophic adipocytes. A bioavailability study was performed in rats, determining the PEHS major metabolites. Finally, we assessed the ability of HS polyphenols to modulate hepatic metabolism and microRNA expression in diet-induced fatty liver disease in hyperlipidemic mice model.

Results: PEHS showed a decreased triglyceride accumulation, adipocyte size, ROS generation and adipokines, especially MCP-1 and leptin in hypertrophic/insulin-resistant adipocytes grown in high glucose conditions. Increased expression of MCP-1 in adipocytes transfected with an MCP-1 enhancer and stimulated with TNF-alpha was regulated by PEHS. Seventeen polyphenols and metabolites were detected in plasma samples rats, after oral acute administration of PEHS. Flavonol-conjugated forms were the most representative as measured by HPLC-ESI-TOF-MS. Experiments performed in hyperlipidemic mice model shown that quercetin 3-O-beta-D-glucuronide accumulated in small intestine, liver immune cells and hepatic lipid droplets through immunohistochemistry. The allocation of these metabolites in cells associated with the immune and inflammatory functions suggests that macrophages may be a specific goal of polyphenols and also a link with its antioxidant and anti-inflammatory actions. In this model, HS polyphenols decreased postprandial glucose level and hepatic lipids together with a significant increase in PPAR-alpha mRNA expression. The high-fat diet induced overexpression of miR-103 and miR-107 was totally reversed by the continuous administration of polyphenols.

Conclusions: Plant-derived polyphenols may prevent and/or attenuate the metabolic effects of high fat diet. The use of plant-derived polyphenols might open preventive measures against management of inflammatory diseases, using simple dietary recommendations.

Key words: flavonoids, epigenetics, MCP-1

PO285

EFFECTS OF VITAMIN C SUPPLEMENTATION ON SICKLE CELL DISEASE: A DOUBLE BLIND PLACEBO-CONTROLLED STUDY

F. Adiiboka¹, E. Asibey-Berko¹, I V Y. Ekem²

¹Department of Nutrition and Food Science, University of Ghana, Accra, Ghana

²Department of Haematology, Korle-bu Teaching Hospital, Accra, Ghana

Background and objectives: In West African countries, sickle cell disease contributes the equivalent of 5% of under-five mortality. This rate can be reduced if more efforts are made to improve the general nutritional status of sickle cell patients. Fortunately, Vitamin C has been found to be very vital in improving and sustaining health. However, the vitamin C status of sickle cell patients has been found to be low. Objectives: To determine the effects of vitamin C supplementation on the blood pressure, body mass index and some blood count parameters in sickle cell patients.

Methods: A randomized double blind, placebo –controlled study. The treatment group was supplemented with 300mg of vitamin C per day and the control group was supplemented with placebo. Supplementation was for 3 months. The data of 30 subjects in the vitamin C group (18 SS and 12 SC genotypes) and 30 subjects in control group (18 SS and 12 SC genotypes) were analysed and discussed.

Results: There was a statistically significant increase in the mean MCHC of the subjects with SC genotype on vitamin C (from 29.61 to 31.32 g/dl) compared to those on placebo (from 30.44 to 28.5 g/dl) ($P=0.01$). There was also a statistically significant reduction of the lymphocyte count of the subjects with SS genotype on vitamin C supplementation (from 4.2 to $3.0 \times 10^9/L$) by the end of the 3 months of supplementation ($p=0.024$).

Conclusions: Vitamin C supplementation therefore has some beneficial effects on some full blood count parameters of sickle cell patients. It is recommended that sickle cell patients are supplemented with at least 300mg of vitamin C in addition to other nutrient supplements.

Key words: Sickle cell disease, Vitamin C, Double blind, Placebo-controlled

PO286

IMPACT OF INTERVENTIONS BY CONSORTIUM FOR IMPROVING AGRICULTURE-BASED LIVELIHOODS IN CENTRAL AFRICA (CIALCA) ON FOOD AND NUTRIENT SECURITY OF FARMER-HOUSEHOLDS

B. Ekesa-Onyango¹, M. Van Schagen², E. Ouma³, H. Garming¹, E. Birachi⁴, P. Van Asten³, B. Van-Lauwe⁴, G. Blomme¹

¹Bioversity International, Uganda

²CIALCA Bujumbura, Burundi

³International Institute of Tropical Agriculture (IITA)

⁴Tropical Soil Biology and Fertility Institute of the International Centre for Tropical Agriculture (TSBF-CIAT)

Background and objectives: In the past decades Democratic Republic of Congo (DRC), Rwanda and Burundi, were characterized by political instability, civil conflict and widespread poverty. This has interfered with the countries' food production and economic activities resulting in high levels of food and nutrient insecurity.

Methods: This was a cross-sectional survey to establish the impact of adopting products promoted by the Consortium for Improving Agriculture-based livelihoods in Central Africa (CIALCA) project on food and nutrient security. Multi-stage sampling was used to select 7 project mandate areas, 5 villages per mandate area (stratified into action, satellite and control sites) and 913 households. Structured questionnaires were administered and analysis of impact was based on comparison between strata. Differences in means were tested by analysis of variance and significance of difference obtained by Tukey's HSD multiple rank tests.

Results: A majority of the households indicated consuming a sufficient quantity of food, although not of the desired type. Overall, the perception of adequate household food sufficiency received a higher rating in the action and satellite sites compared to the control sites. The dominant factor reported for improved food security was use of improved agricultural technologies. For the households that indicated worsened food security, majority (>60%) stated that this was due to climatic conditions. Although the proportion of households meeting their calorie RDIs in DRC and Burundi was higher in the action and satellite sites as compared to the control sites the difference was statistically insignificant. In Rwanda action and satellite sites had a lower proportion of households meeting their daily calorie RDIs but again this difference insignificant.

Conclusions: Overall, majority (53%) of respondents in the control sites indicated a decrease in intake of protein rich foods over the past three years, which was significantly higher than the proportion of households in the action (46%) and satellite (41%) sites.

Key words: food intake, food security

PO288**SOLAR-POWERED DRIP IRRIGATION CONTRIBUTES TO IMPROVED HOUSEHOLD FOOD PRODUCTION AND CONSUMPTION, AND FEMALE EMPOWERMENT**

H. Alaofè¹, J. Burney², D. Taren¹

¹University of Arizona, College of Public Health, USA

²University of California, San Diego, International Relations, Pacific Studies, USA

Background and objectives: Food insecurity is in about 29% of rural households in Benin and malnutrition particularly micronutrient deficiencies contributes significantly to high rates of maternal and child mortality. This study measured the impact of solar-powered drip irrigation (PVDI) systems on household food production and consumption, and women empowerment in the Kalalé district.

Methods: In 2007 PVDI systems were installed with local women's agricultural groups engaged in horticulture as a strategy to increase and ensure year-round availability and for enhancing food security. Results were compared with other women groups in other villages and random samples of households in the same villages. Household surveys were conducted before and 1-year after implementation to evaluate the impact of the PVDI systems in 244 and 286 households respectively.

Results: The percentage of households who grew vegetables and fruit increased, 14% and 200%, respectively, when they had access to PVDI compared with other households in the same villages (-20% for vegetables and 55% for fruit). Daily consumption of vegetables and fruits during the hunger season (dry season) also increased by 42% in women groups who used PVDI systems compared with a decrease in daily consumption in other women's groups and households. Women empowerment in household spending and purchasing improved: 77% of PVDI women's groups used most of their income on food and household expenses at baseline. Afterwards, 62% of women in PVDI households had access to the income and 80% used this income on health care, education, livestock, and microenterprises.

Conclusions: The study indicated that PVDI has the potential to improve household food production and consumption and consequently to enhance household food security of all household members. These changes occurred with minimal nutrition education which could further enhance consumption and decrease food insecurity.

Key words: solar-power drip irrigation, food production, consumption, food insecurity, women empowerment.

PO289**PROGRAMMING OF LIVER GENE EXPRESSION BY GESTATIONAL EXPOSURE TO FOLIC ACID /VITAMIN B12 IMBALANCE**

²Department of Pathology and Laboratory Medicine, Child and Family Research Institute, University of British Columbia, Vancouver, Canada

³Department of Pediatrics, Child and Family Research Institute, University of British Columbia, Vancouver, Canada

Background and objectives: Developmental programming suggests that changes in environment during development can program metabolic response later in life and increase risk for chronic disease. Food fortification with folic acid has increased folate intakes of Canadians, however there is concern regarding vitamin B12 status. Around 5% of Canadian women are vitamin B12 deficient. This is concerning because an association between gestational exposure to high maternal folate and low vitamin B12 status with greater adiposity and insulin resistance in children has been reported. We examined the effect of gestational exposure to maternal folic acid/vitamin B12 imbalance on programming of liver gene expression.

Methods: Female C57BL/6 mice were fed a high folic acid/adequate vitamin B12 (HFA+B12), high folic acid/no vitamin B12 (HFA-B12), or control (adequate folic acid/vitamin B12) diet 6 weeks prior to mating and through pregnancy and lactation (n=6-8 mice/group). At weaning, the offspring mice were randomly assigned to receive the control diet or a Western diet (45% fat, 35% carbohydrate) for 20 weeks (n=5-6 mice/group). We quantified mRNA expression by real-time PCR of key enzymes in methyl nutrient metabolism in liver from adult male offspring: Mtr (encodes methionine synthase), Mat1a (encodes methionine adenosyltransferase) and Cbs (encodes cystathionine β -synthase). Data were analyzed by two-way ANOVA.

Results: Offspring mice with gestational exposure to maternal HFA-B12 had lower Cbs mRNA expression (P<0.05) and this was unaffected by postweaning diet. Offspring mice fed the Western diet had higher Mtr mRNA expression (P<0.05) compared to control-fed mice, regardless of gestational maternal diet. No effect of gestational and postweaning diet on Mat1a expression was observed.

Conclusions: Our findings suggest that gestational exposure to maternal folic acid/vitamin B12 imbalance programs Cbs mRNA expression in liver of adult male offspring.

Key words: Folic acid; Vitamin B12; Developmental programming; Cystathionine β -synthase; Methionine synthase.

PO290**INFLUENCE OF FEEDING, PARENTAL ANTHROPOMETRY, SOCIO-CULTURAL AND PERINATAL ASPECTS ON INFANT BODY SIZE IN SPAIN**

B. Oves¹, G. Rodríguez^{1,2}, L. Escartín², M.P. Samper², M.L. Álvarez¹, I. Labayen³, L.A. Moreno¹

¹Growth, Exercise, NUTrition and Development (GENUD) Research Group, University of Zaragoza, Spain

²Department of Pediatrics, Radiology and Physical Medicine, University of Zaragoza, Spain

³Department of Nutrition and Food Science, University of the Basque Country, Spain

Background and objectives: Infant growth during the first months of life is a sensitive indicator of early health status, as a result of the continuous interaction between heredity and environment, and it may be also a predictor of long-term outcome. We aimed to study the influence of nutritional, socio-cultural and perinatal aspects on infant body size at 12 months of age in Spain.

Methods: The sample included a cohort of 1.602 infants (48.3% females) born in Northern Spain during 2009. Multivariate regression analyses were used to determine the variables associated with child anthropometry at 12 months of age. Five levels were selected for the analyses: Level 1 (smoking during pregnancy), level 2 (parity, maternal age, maternal educational level and maternal origin), level 3 (paternal BMI, maternal BMI and maternal weight gain during pregnancy), level 4 (gestational age, sex, length and birth weight) and level 5 (breast-feeding during first 4 months).

Results: Adjusted for gestational age and sex, the factors significantly associated with higher weight and length at one year of age were: to be born to immigrant mother (315.20 g and 0.73 cm; $p=0.002$), higher maternal weight gain during pregnancy ($p<0.01$), formula feeding (compared with exclusively breastfeeding during the first 4 months) (142.19 g and 0.46 cm; $p<0.05$) and higher newborn length ($p<0.001$). Variables like newborn weight, maternal BMI and maternal educational level were also associated with infant weight at 12 months of age.

Conclusions: Maternal education level, maternal origin, maternal BMI, maternal weight gain during pregnancy, newborn anthropometry and infant feeding are all factors that independently influence infant body size in Northern Spain at the end of the first year of life.

Key words: Growth, infant, breastfeeding.

PO291**VALUE CHAIN ANALYSIS FOR NUTRITION: A METHODOLOGICAL CASE STUDY OF THE FRUIT AND VEGETABLE SECTOR IN FIJI**

⁴WHO Collaborating Centre for Obesity Prevention, Deakin University, Melbourne, Victoria, Australia

⁵Fiji School of Medicine, College of Medicine, Nursing and Health Sciences, Fiji National University, Suva, Fiji

⁶National Food and Nutrition Centre, Suva, Fiji

Background and objectives: Low quality diets among the poor are a major challenge to both health and development and are driven by lack of access to a diverse, nutrient-rich, and acceptable food supply. Value chain analysis (VCA) has been proposed to support the identification of solutions to food supply problems, however little evidence of its utility for this purpose exists. The objectives of this case study were to determine how fruit and vegetable value chains in Fiji – where poor diets and high rates of diet-related disease have been identified – contribute to product accessibility and acceptability in urban areas and to assess the benefit of VCA in identifying opportunities for intervention.

Methods: Eight focus groups with urban consumers established what attributes are valued in fruit and vegetables and four workshops with chain actors and stakeholders were facilitated to map three exemplar value chains. The performance of these chains in respect to their ability to deliver consumer-defined value was then explored through observations and interviews with chain actors. Data were collected in English, Fijian, and Hindi and analysed in Nvivo using thematic analysis.

Results: Urban consumers are highly motivated to consume fresh, local fruits and vegetables, but find the supply to be poor quality and often unaffordable. A number of value chain characteristics contribute to these supply challenges, particularly poor infrastructure (e.g. roads and water supplies), strained relationships between chain actors, sub-optimal post-harvest handling and storage, and limited access to agricultural inputs. The extent of these challenges was found to vary by chain type: short-length, medium-length, and export-oriented.

Conclusions: This case study identified multiple points in the exemplar chains where targeted intervention could lead to increased accessibility and acceptability. In doing so, the findings suggest VCA as a beneficial tool for identifying solutions to poor quality diets.

Key words: Value chain analysis

PO292

ASSOCIATION BETWEEN MEDITERRANEAN DIET QUALITY INDEX (MDQI) AND SERUM LIPID PROFILE IN CROATIAN WOMEN

I. Rumora Samarin¹, I. Rumbak¹, I. Keser¹, I. Višekruna¹, I. Colić Barić¹

¹Department of Food Quality Control and Nutrition, Faculty of Food Technology and Biotechnology, University of Zagreb

Background and objectives: Potential positive effect on plasma lipid profile could be one of the benefits of following Mediterranean diet (MD). Therefore, the objective was to evaluate diet by Mediterranean Diet Quality Index (MDQI) and correlate it with the serum lipid profile (triglycerides, total cholesterol, LDL and HDL cholesterol) in women from the continental part of the Croatia.

Methods: MDQI, a qualitative method to evaluate MD, was computed using dietary data collected from 237 women aged 30-70. The dietary method used was 24-hour recall carried out in three different seasons during one year. Anthropometric parameters and serum lipid profile were assessed by a standard laboratory method.

Results: There was no observed significant difference in total MDQI score between groups, but was observed in some of the MDQI categories: cereal ($p=0,041$) and cholesterol ($p=0,003$) intake. More than 50% of the women in both group (67,7% fertile and 66% menopausal) are categorised in medium-poor group (MDQI score 8-10). Positive correlation was obtained between triglycerides and fish intake ($p=0,026$); cholesterol and meat intake ($p=0,001$), and BMI and fish intake ($p=0,030$) within fertile women group. Within group of menopausal women significant positive correlation was observed between HDL and cereal intake ($p=0,037$), and negative between HDL and intake of fruit and vegetables ($p=0,022$).

Conclusions: Correlation between MDQI total score and lipid profile parameters were not established in observed population. The difference between participants age and menopausal status may be one of the reasons for this result. The influence of estrogen status of the women in this sample could have significant impact on the serum lipid profile, although exclusion criteria for participants were diseases that could affect

lipid profile. For the future study more uniform sample according the age and menopausal status should be included.

Key words: women, Mediterranean Diet Quality Index (MDQI), serum lipid profile

PO293

PREDICTORS OF TOLERANCE TO ENTERAL FEEDING IN CRITICALLY ILL PATIENTS

M. Cruz², J. Fonseca¹

¹Nutrición Clínica, Instituto Nacional de Ciencias Médicas Y Nutrición Salvador Zubiran, México, Distrito Federal, México

²Licenciatura en nutrición, Universidad Autónoma de Querétaro, Querétaro, Querétaro, México

Background and objectives: Patients in the critical care units are under acute stress having metabolic changes and increasing their energy demands, that is why specialized nutritional support is required in order to cover the different energy demands in this stage, and it's known that enteral nutrition support is the first option as long as there is no contraindication for its prescription. The use of indicators that will help identify patients who will not tolerate enteral feeding before it's started might be a strategy which will reduce the time needed to reach energy goals and maintain the nutritional status.

Methods: Tolerance to enteral feeding was measured in 38 patients in this study, 20 patients were intolerant and 18 tolerated diet well, demographic, biochemical, hemodynamic and metabolic variables were used in order to predict the intolerance. Positive likelihood ratios were used, 4 variables were statistically significant for the prediction of intolerance to enteral feeding, these were: the diagnosis of sepsis, risk of refeeding syndrome, PEEP (Positive End Expiratory Pressure) >10 cm and serum glucose >200 mg/dl;

Results: the probability posttest increase from a 40% in the pretest to 65% for sepsis diagnosis, 50% for risk of refeeding syndrome, 78% for PEEP >10 cm and 72% for serum glucose >200 mg/dl in the posttest. Being PEEP >10 cm and Serum Glucose >200 mg/dl the variables with the highest statistical power.

Conclusions: Sensitivity was 70% and specificity was 94% for PEEP > 10 cm while a sensitivity of 80% and specificity of 94% to serum glucose > 200 mg/dl, making these two variables great predictors to enteral feeding tolerance in UCI patients.

Key words: critical illness, enteral nutrition, nutrition tolerance

PO294**MAPPING BIODIVERSITY FOR FOOD SECURITY IN RUDEWA MBUYUNI VILLAGE KILOSA DISTRICT, TANZANIA**

¹Department of Food Science and Technology
Sokoine University of Agriculture, Tanzania

²Department of Crop Science and Production
Sokoine University of Agriculture, Tanzania

³University of Dodoma, Tanzania

⁴Tanzania Food and Nutrition Centre, Tanzania

Background and objectives: The number and variability of living organisms in an ecosystem contribute to many constituents of human well being including food, water, medicine and oxygen. The biodiversity of natural systems provide safety net and benefits to poor rural communities in terms of food and nutrition security and access to medicinal products. Do we know how many food plants species are available in a given area? Objective: to identify and map out various species of plants, trees, animal, birds and insects that are of food value in Rudewa Mbuyuni village in Kilosa district, Tanzania.

Methods: mapping plots were laid systematically in an interval of 250m between plots. Geo-referenced top map of the village and geographic coordinates in LTM system were selected randomly at an interval of 250m apart forming a square matrix of 250m inter plot distance and 250m intra-transect distance, hence a sampling intensity and a transect of 20m x 20m was established. All plants and animal species were identified and both scientific and local names listed by researchers and local facilitators, including information about local uses and economic importance of species was recorded.

Results: a total of 257 plant species belonging to 61 families were identified an indication that the area is rich and diverse in plants and animals. Out of the 257 species, 98 species are edible. A total of 46 insect species from 19 different families were observed. Also 102 species of birds from 45 different families were identified, indicating a high diversity of birds.

Conclusions: There is a diverse of plants and animals in the study area and most of them are edible but underutilized. Hence there is potential for improving food security in the area through the utilization of the available of species of plants and animals.

Key words: mapping biodiversity species food security

PO295**INTERACTIONS BETWEEN ZN, FE AND MG IN CRITICAL CARE PATIENT**

J. Molina¹, M. Navarro¹, D. Florea¹, A. Trigo¹, G. Lobo², A. Pérez de la Cruz², E. Planells¹

¹Department of Physiology, Institute of Nutrition and Food Technology, University of Granada, Granada, Spain

²Unit of Nutrition, Virgen de la Nieves Hospital, Granada, Spain

Background and objectives: Minerals like Zn, Fe and Mg are essential nutrients for the cellular integrity. The lack of one or more of them may determine the big disorder on cell metabolism all this inducing dysfunction of multiples organs which is common in hypercatabolic critically ill patient. Objective: To assess the status of Zn, Fe and Mg in a group of ICU patients.

Methods: Multicentre observational study of 40 critically ill subjects, with mean age 58 from Granada area, Spain. Zn, Fe and Mg were analyzed by AAS in blood cells samples which were previously wet mineralized.

Results: Zinc intake is 7.8 ± 4.9 , Mg 172.5 ± 110.2 , Fe 7.74 ± 6.3 (mg/d). Mean of Zn in whole blood was 0.43 ± 0.17 mg/dL in final of ICU period. In case of cellular Mg and Fe after 7 days of ICU period the mean values is 2.5 ± 2.1 mg/dL, 59.7 ± 30.3 mg/dL respectively. The results show statistical significance according whit Mg levels in blood cells at the end of the period monitored in critically ill patients ($p = 0.033$), showing that patients with Mg deficiency, have 5.5 times more risk to suffer zinc deficiency.

Conclusions: According to the results, the patients have no sufficient intake of Mg being necessary a nutritional assessment during ICU stay to know the status of minerals such as Zn, Fe and Mg which are key for critical ill patients avoiding gaps that may worsen their evolution.

Key words: Magnesium, Zinc, Iron. Mineral status, Critical Care Patient.

PO296**ANEMIA REDUCTION IN CHILDREN LIVING IN A MALARIA-ENDEMIC REGION OF TANZANIA**

T. Mosha¹, H. Laswi¹, M. Bennink²

¹Sokoine University of Agriculture, Food Science and Technology, Morogoro, Tanzania

²Michigan State University, Food Science and Human Nutrition, East Lansing, USA

Background and objectives: If iron containing supplements are distributed in malaria endemic areas, the WHO recommends that malaria monitoring and treatment accompany supplement distribution. Hypothesis: Education regarding prompt treatment for malaria and malaria screening will allow safe supplementation with iron. The objectives of two studies were to determine if an iron-containing supplement could reduce anemia without increasing malaria in rural areas with basic medical care.

Methods: The first study determined whether 2.5 mg of iron as ferric EDTA and 2.5 mg of iron as ferrous lactate was as effective in correcting anemia as 10 mg of iron as ferrous lactate. Moderately anemic children 6 - 36 mo (N = 69 and 70) had baseline hemoglobins (Hb) of 7.0 - 9.1 g Hb/dl and received one of two micronutrient supplements differing only in iron content and source.

Results: Both supplements improved Hb status ($p < 0.05$) equally ($p > 0.95$) and the average Hb concentration improved from 8.30 ± 0.60 g/dl to 11.08 ± 1.25 g/dl upon consumption of the supplements for 60 days. Malaria incidence (10.0 to 10.4%) did not change with iron supplementation. The second study provided the low-dose iron supplement to > 4,000 children. Only 10% of the children (453) were monitored for changes in Hb and malaria. The baseline Hb was 9.72 ± 0.93 g/dl and after consuming the supplement for 60 days, the average Hb concentration increased to 10.96 ± 0.88 g/dl ($p < 0.05$). Malaria incidence (10.4 to 10.6%) did not change.

Conclusions: iron containing supplements can be safely utilized in malaria endemic areas to alleviate anemia and other "hidden, sub-clinical nutrient deficiencies" if village health attendants and parent's are educated regarding the importance of malaria monitoring and treatment. The Heinz Company Foundation provided the micronutrient supplements and funds for the studies.

Key words: anemia, malaria, ferric-EDTA

⁵Healthy Lifestyle in Europe by Nutrition in Adolescence Study Group

Background and objectives: Previous research showed that vitamins status may be involved in the early stages of many chronic diseases development, like hypertension. The objective is to analyze the potential association between vitamins (antioxidant vitamins, hydrosoluble vitamins and vitamin D) serum concentrations and blood pressure (BP) in European adolescents. Patients and

Methods: Participants from the Healthy Lifestyle in Europe by Nutrition in Adolescence cross-sectional study (HELENA-CSS) (n = 1,089; 12.5-17.5 yr; 580 girls) were selected by complex sampling. The associations between vitamins serum concentrations (vitamin A, vitamin B6, vitamin B9, vitamin B12, vitamin C, vitamin D) and BP were examined by multi-level linear regression models (school as context variable), the analysis were stratified by sex and adjusted by contextual and individual potential confounders.

Results: In girls, we found a positive association between red blood cell folate concentration and systolic BP ($\beta = 3.19$; CI 95% = 0.61 - 5.77), although no association between the vitamins serum concentration biomarkers and diastolic BP was found. In boys, retinol was positively associated with diastolic BP ($\beta = 3.84$; CI 95% = 0.51 - 7.17) and vitamin B6 was positively associated with systolic BP ($\beta = 3.82$; CI 95% = 1.46 - 6.18). In contrast, holo-transcobalamin was inversely associated with systolic BP ($\beta = -3.74$; CI 95% = -7.28 - -0.21).

Conclusions: RBC-folate and vitamin B6 serum concentrations may impact BP in adolescents. Programs aiming to prevent high blood pressure levels should promote consumption

of vegetable proteins and foods rich in vitamin B12 i.e. white meat and eggs, which may help to blood pressure control in adolescents.

Key words: iron; vitamins; blood pressure; adolescents; multilevel analysis.

PO298

HEALTH ECONOMIC MODEL FOR ASSESSING THE IMPACT OF HIGH BIRTH WEIGHT ON PUBLIC HEALTH

I. Lenoir-Wijnkoop¹, M. Nuijten², R. Uauy³

¹Departement of Pharmaceutical Sciences, University of Utrecht, Utrecht, The Netherlands

²Ars Accessus Medica, Amsterdam, The Netherlands

³Institute of Nutrition INTA, University of Chile, Santiago, Chile

Background and objectives: In spite of the general interest in the impact of overweight and obesity on public health, little is known about the impact of being large for gestational age (LGA, >90th centile), or being macrosomic (birth weight >4,000g); both conditions are related to maternal obesity and/or gestational diabetes and associated with increased morbidity for mother and child. Macrosomic infants have a higher risk of developing obesity and type 2 diabetes mellitus (T2DM) in later life. The objective of our study is to assess the health-economic impact of macrosomia.

Methods: A decision analytical model was designed to estimate the health-economic impact of macrosomia, including both short- and long-term consequences. Options for performing different base-case analyses and various scenario analyses are incorporated.

Results: Maternal obesity, excessive maternal weight gain and poorly controlled diabetes during pregnancy are associated with intermittent periods of fetal exposure to hyperglycemia and subsequent hyperinsulinemia. This acts as a fetal growth hormone, particularly leading to increased body adiposity and glycogen storage in the liver. This first analysis shows the health-economic consequences of macrosomia. Details of cost per case and outcomes of a budget impact analysis will be presented.

Conclusions: Overweight and obesity are of concern in the general population, affecting increasing numbers of women of child-bearing age. Subsequent macrosomia and associated complications for mother and child are included in our model, considering both short- and long-term consequences. It allows for the mapping of the related health-economic burden and indicates that the annual budgetary impact of macrosomia could be substantial. The current core-model offers a template for further health technology assessments to determine the cost-

effectiveness of preventive educational interventions on life style, diet and physical activity to reduce the short- and long-term public health consequences of macrosomia.

Key words: macrosomia, overweight, health economic modeling, healthcare costs

PO299

BODY MASS INDEX AND WAIST CIRCUMFERENCES: HOW EFFECTS THE DISEASE RISK OF NORTHERN CYPRUS ADULTS?

C. Gezer¹, S. Dal¹, E. Özer¹, S. Yücecan¹

¹Near East University, Faculty of Health Sciences, Department of Nutrition and Dietetics, Turkey

Background and objectives: All overweight and obese adults considered at risk for diseases such as hypertension, type 2 diabetes, cardiovascular disease. This study was planned to observe the risk of these diseases according to body mass index (BMI) and waist circumferences of people living in Turkish Republic of Northern Cyprus (TRNC)

Methods: The study involved 1740 subjects (738 male, 1002 female) from 19 to 65 years old, who were selected to constitute a representative TRNC population as a whole between June-July 2012. Anthropometric measurements (BMI and waist circumference) were obtained using standardized techniques and equipment. Abdominal obesity (AO) was considered a waist circumference of >102 cm in men and >88 cm in women. Disease risk was evaluated according to classification of BMI and waist circumferences which has been defined by World Health Organization.

Results: Mean waist circumferences were 96.7±14.1 cm in men and 87.6±15.1 cm in women. In addition, the percentages of AO were assessed 36.6% for total, 31.0% for males and 45.1% for females. When disease risk was determined according to BMI and waist circumferences, percentages of the population who had increase, high, very high and extremely high disease risk were 20.6%, 15.9%, 20.8% and 2.5%, respectively. While 30.9% of males had increase, 34.4% had the sum of high, very high and extremely high disease risk. Also, 13.1% of females had increase and 43.0% had high disease risk. It was determined that males (65.3%) were under higher disease risk than females (56.1%).

Conclusions: Consequently, approximately 1/3 of TRNC population are under the disease risk due to overweight, obesity, abdominal obesity and this risk increases rapidly for men day by day. Therefore, to prevent obesity and its comorbidities national nutritional programs should be improved and males attendance these programs could be more beneficial.

Key words: body mass index, abdominal obesity

PO300**THE FAMILY AS AN AGENT FOR CHANGE IN EATING HABITS AND OBESITY IN GRADE 2-3 SCHOOLCHILDREN**

T. Goldstein¹, J. Kark²

¹Department of Human Nutrition and Metabolism, Hebrew University-Hadassah Faculty of Medicine, Jerusalem, Israel

²Epidemiology Unit, Hebrew University-Hadassah School of Public Health and Community Medicine, Jerusalem, Israel

Background and objectives: The prevalence of obesity is increasing worldwide and in Israel. Our study tests a new educational approach through a controlled school-based trial to achieve an improvement in eating habits and reduced obesity in Grades 2-3.

Methods: A cluster randomized controlled trial allocated 4 elementary schools to intervention or control groups. This allocation was switched with the next cohort of children. Recruitment was in first grade, randomization at the beginning of second grade, evaluation of

Methods: end of second grade and the beginning of third grade Intervention: 5 joint parent-children classroom activities on nutritional topics and 5 educational workshops for parents only. Alfred Adler's concepts were the guiding principles. Subjects: of 743 children in 23 second grade classes, parents provided informed consent for 508 (68%), and for the third grade follow-up 432 (58%).

Results: At the end of 2nd grade, the intervention group compared with the control group reported significantly increased intake of fruits, vegetables and high protein foods, and reduced sweets and munched snacks. By the 3rd grade the variety of protein-rich foods had increased in the intervention classes, and sweets and munched snacks declined. No differences in meal patterns were noted except for eating breakfast. From individual observations of food brought for the ten o'clock snack at the end of the 2nd grade, the intervention group showed a significantly higher intake of water, whole-wheat bread sandwiches, protein-rich spreads, vegetables, and a decline in candy snacks and sweetened sandwich spreads. The intervention group showed better height and BMI measures at the end of second grade and waist circumference in the 3rd grade.

Conclusions: There were encouraging changes in eating habits and in anthropometric measurements. To maintain changes over longer periods, refreshing these nutrition themes annually in school using the model is required

Key words: childhood obesity, nutrition intervention.

PO301**PHYSICAL FITNESS REFERENCE STANDARD IN EUROPEAN CHILDREN: THE IDEFICS STUDY**

¹¹Epidemiology & Population Genetics, Institute of Food Sciences, CNR, Italy

¹²Department of Public Health, Ghent University, Ghent, Belgium

¹³College of Medical, Veterinary and Life Sciences, University of Glasgow, Glasgow, Scotland

Background and objectives: Reference standards of physical fitness in European adolescents have been published (HELENA study; 12.5-17.5 yrs). However, there are no data on children from large and representative samples. The IDEFICS study provides a golden opportunity to establish normative values of a large set of fitness components from eight European countries using common and well-standardized methods of measurement. We aim to report sex- and- age specific fitness levels in European children aged 6-9 yrs.

Methods: A cohort of 16,224 children aged 2-9 yrs. met the IDEFICS inclusion criteria: complete data on weight, height and age. Fitness was measured in children 6-9 yrs (N= 7,385; 50.5 % girls). Cardiorespiratory fitness [20m shuttle run (stage)], coordination/equilibrium [flamingo balance (attempts/min)], flexibility [back-saver sit and reach (cm)], speed [40m

sprint (sec)] and strength [handgrip (kg), standing long jump (cm)] were measured. Sex -and age- specific normative values for physical fitness in European children were derived by using the LMS statistical method as tabulated percentiles from 10 to 100 and as smoothed centile curves (P5, P25, P50, P75 and P95).

Results: The results (showed as mean values, boys \ girls) showed that boys performed better in cardiorespiratory fitness (2.8 \ 2.4), strength (handgrip: 11.7 \ 10.5; standing long jump: 111.0 \ 102.3) and speed (9.2 \ 9.5), while females performed better in coordination/equilibrium (9 \ 7) and flexibility (19.0 \ 21.4). A trend towards increased physical fitness with age in both sexes was observed, except for the flexibility test (in boys remained stable and in girls it decreased with age). Sex-and-age specific tabulated percentile values and centile curves were provided to be used as reference values for this population.

Conclusions: The present data will enable evaluation and correct interpretation of European children's fitness status from 6 to 9 yrs.

Key words: fitness, childhood, percentiles

PO302

COMMUNITY BASED INTERVENTION IMPROVES INFANT FEEDING PRACTICES IN BETHLEHEM VILLAGES

H. Rabadi^{1,2}, N. Al Sharif²

¹World Vision, Bethlehem , Palestine

²School of Public Health , Al Quds university, Palestine

Background and objectives: Infant feeding practices are critically important for children's growth and development. Sub-optimal feeding practices are known to be prevalent in Bethlehem villages. The objectives of this study were to assess mothers' knowledge and practices regarding infant feeding and to evaluate the effectiveness of Timed , Targeted Counseling (TTC) in improving these practices.

Methods: An intervention study was carried out in four villages surrounding Bethlehem. All mothers (n=118) of infants born during March , April 2011 were identified by Community Health Workers (CHWs) and randomly assigned to intervention (n=66) and comparison (n=52) groups. The CHWs targeted the intervention group with key messages and support for positive infant feeding practices during home-visits (TTC) throughout 16 month. The comparison group were not exposed to any messages but were visited only for data collection such as disease incidence. Baseline and end-line data were collected from both groups through household interviews .

Results: Infant feeding practices were significantly improved in the intervention group after the intervention; exclusive

breastfeeding until 6 months increased from 27.3% to 69.7% (P <0.001), duration of breastfeeding above 1 year increased from 56.1 to 83.3% (P <0.001), timely introduction of the complementary meals increased from 38.5% 66.7% (P <0.001) and offering the minimum meal diversity increased from 16.7% to 22.7%. No significant changes were seen among the comparison group. During the study period there were fewer reported disease episodes in the intervention versus comparison group for diarrhea (10 vs. 25 cases), respiratory illness (15 vs. 33), common cold (39 vs. 50), fever (20 vs. 31) and ear infections (7 vs. 32).

Conclusions: The TTC approach has positively influenced infant feeding practices in Bethlehem villages. Scale up plans for TTC, integrated with early childhood stimulation component, is envisioned.

Key words: Timed and targeted counseling, Community health workers, Infant feeding practices.

PO303

PACIFIC KIDS DASH FOR HEALTH (PACDASH) TAILORED MULTILEVEL INTERVENTION FOR PREVENTION OF OBESITY AND ELEVATED BLOOD PRESSURE AMONG MULTIETHNIC CHILDREN.

R. Novotny^{1,2}, C. Nigg¹, F Li¹, G. Renda², L. Wilkens¹

¹University of Hawaii At Manoa, USA

²Kaiser Permanente, Center for Health Research Hawaii, USA

Background and objectives: The PacDASH intervention program provided tailored information to children according to stage of readiness to change and self-efficacy in order to improve fruit and vegetable intake and physical activity level, and to prevent obesity and elevated blood pressure.

Methods: The randomized two-arm program (intervention, n=41; and usual care, n=44) was given to children (BMI from the 50-99th percentile according to CDC reference data) from a health care maintenance organization (intervention, n=41; usual care, n=44). Targeted recommendations were provided to child, parent and health care provider (latter at baseline only) at baseline, 3, 6 and 9 months, along with monthly supportive mailings and tested for effect on BMI, DXA body composition, and blood pressure.

Results: Child (n=85; 62.3% female; mean age=7.1, SD=0.95; 43.5% Asian, 28.2% Native Hawaiian or Other Pacific Islander, 21.2% White, and 7.1% Other ethnicity) outcomes were modeled across 9 months (62 children at endpoint, 33 intervention, 29 usual care) using mixed linear regression, adjusted for age, sex and ethnicity. All children in the program experienced a constant BMI z-score of 1.30 (SD=0.72) from baseline to 9 months (p=0.97). Diastolic blood pressure percentile increa-

sed in both study groups, to a greater degree in the usual care group, with a 12 percentile point difference in change between groups by 9 months ($p=0.01$). There was no change in systolic blood pressure percentile (mean=31, SD=23).

Conclusions: The intervention had a protective effect on diastolic blood pressure, and held expected weight gain constant across the 9 month study time period.

Key words: child obesity blood pressure ethnicity intervention

PO304

NEW ZEALAND GREEN-LIPPED MUSSELS (*PERNA CANALICULUS*) ENHANCE NON-HAEM IRON ABSORPTION WHEN PROVIDED AS A SINGLE DOSE IN MICE

R. Stewart¹, J. Coad¹, G. Reynolds¹, K. Pedley¹

¹Institute of Food, Nutrition and Human Health, Massey University Palmerston North, New Zealand

Background and objectives: Non-haem iron bioavailability is affected by the nutritional composition of a meal. Like red meat, New Zealand green-lipped mussels (NZGLM) have been reported to improve non-haem iron absorption from a second dietary iron source in vitro. Objectives: To investigate whether NZGLM enhance non-haem iron absorption compared to egg albumin, (a negative control) or ascorbic acid (a positive control) in iron-deficient mice, and to investigate the effects of repeated exposure to NZGLM extract on iron uptake from a single iron dose.

Methods: 6 week-old male Swiss mice were maintained on a low-iron diet (5ppm) supplemented with or without NZGLM extract (3.3% w/w) ad libitum for 2 weeks. Fasted mice were provided with a single dose of ascorbic acid, NZGLM or egg albumin combined with ⁵⁹FeCl₂ radionuclide and ⁵⁶FeCl₂ by gavage after a 12 hour fast. Control and NZGLM-supplemented diets were re-introduced ad libitum for 4 days. Iron loading was determined by measuring the incorporation of radiolabelled iron into whole blood and the small intestine.

Results: Ascorbic acid enhanced blood and small intestinal iron loading by 140% ($P=0.01$) and 144% ($P=0.0005$) respectively compared to egg albumin. NZGLM enhanced blood and small intestinal iron loading by 148% ($P=0.002$) and 128% ($P=0.035$) respectively compared to egg albumin in mice raised on the NZGLM-free diet. Blood iron loading and small intestinal iron loading were reduced by 22% ($P=0.009$) and 25% ($P=0.015$) respectively in mice repeatedly exposed to the NZGLM extract compared to mice maintained on the control diet.

Conclusions: NZGLM enhance blood and small intestinal iron loading with a similar magnitude to ascorbic acid when provided as a single dose to iron deficient mice. This result is

similar to that reported in vitro. Repeated exposure to NZGLM extract for 18 days significantly reduces iron uptake from a single iron dose.

Key words: Iron, meat, mussel

PO305

NUTRITION OUTREACH THROUGH COMMUNITY EVENTS IN THE BLOGOSPHERE: THE NUTRITION CARNIVAL EXPERIENCE

A. Sánchez García¹, D. Giménez Monzó², J. Farré Moya³, H. López García de la Serrana⁴

¹Nutrition and Bromatology Department, University of Granada, Granada, Spain

²Public Health Department, University Miguel Hernández-Elche, Alicante, Spain

³Alimmenta S.L, Barcelona, Spain

⁴Nutrition and Bromatology Department, University of Granada, Granada, Spain

Background and objectives: During 2012 there was an outreach initiative based on collaboration between Health and Nutrition blogs. This kind of community event is known in the blogosphere as 'Carnival', has been common in other scientific disciplines such as Physics (38th edition), Chemistry (22th edition) and Biology (20th edition). Two Nutrition Carnival editions were held (May and October 2012). In this events different bloggers analyze and propose their visions of a predefined theme. This study analyzes the content and impact of the event in order to find out if it is a good outreach tool in Health and Nutrition sciences.

Methods: Descriptive study of the texts generated, a review was conducted of participants post and a statistical analysis of the impact of the event.

Results: 72 post were analyzed. The topics covered were 'Children's food education' and 'Nutrition Myths'. According to the writers are essential in food education factors as: family (88.2%), school (26.5%) school meals (14.7%) and play an essential role: family (41.2%), dietitians (20.6%) and medical personnel (17.6%). The most common nutritional myths were the properties of specific foods (50%) and weight loss information (36.8%). The two host blogs registered 71,301 visits during the month of celebration, and the official pages of both editions have 3,556 registered outbound links. The participants articles have been shared on social networks 3714 times until January 2013. There were a total of 589 comments, visitors shared personal experiences and asked questions reflecting the importance and usefulness of the event.

Conclusions: Outreach events in the blogosphere conducted by professionals can be a great alternative to broadcast

scientific evidence and to bring information to the population, promoting healthy practices, preventing unhealthy habits, generating discussion areas and resolving the gap between theory and practice.

Key words: Nutrition, Dietetics, Public health, food education, Internet.

PO306

UNVEILING THE PROPORTIONAL MORTALITY OF FOOD-RELATED AND NUTRITION-RELATED DISEASES. VENEZUELA: 1938-1998

M. Araujo-Yaselli^{1,2}, P. Pereyra-Zamora¹

¹Department of Preventive Medicine and Public Health (History of Science), University Complutense of Madrid, Madrid, Spain

²Department of Community Nursing, Preventive Medicine, Public Health and History of Science, University of Alicante, Alicante, Spain

Background and objectives: Abundant epidemiological evidence has been accumulated on the direct association between food, nutrition and development of communicable and non-communicable diseases. However, this would be the first study to analyze the proportional mortality related with food and nutrition (PMFN) in a long-term trend for a developing country.

Methods: Data from national registry is collected and analyzed in order to show PMFN of the top 5, 25 and 27 causes of death in Venezuela since 1938 to 1998 and the principal causes by sex since 1950 to 1998.

Results: PMFN was increasing rapidly: 10.63% in 1938 (top 5), 28.38% in 1950 (top 27) and 62.43% in 1998 (top 25). The top three causes were changing from diarrhoea and gastroenteritis of presumed infectious origin (ICD-10: A09), tuberculosis (A15-A19) and pneumonia (J12-J18) in 1938 to A09, A15-A19 and certain conditions originating in perinatal period (P00-P96) in 1950 and finally, heart diseases (I05-I09, I11, I13, I21-I51), neoplasms (C00-D48) and accidents (V01-X59) in 1998. Between men and women order and speed of movement of causes were different. Male: 22.52% to 52.81% for 1950 and 1998 (top 10), went on to die of A09, P00-P96 and tuberculosis to heart diseases, neoplasms and accidents. Female: 24.54% to 65.62% for 1950 and 1998 (top 10) went on to die of A09, tuberculosis and neoplasms to heart diseases, neoplasms and cerebrovascular diseases (I60-I69). A considerable proportion of deaths could be related to PMFN, however, percentage that those deaths represent is still to be determined and also their real weight.

Conclusions: Study of mortality related to food and nutrition should not be limited only to what is contemplated in subgroup nutritional deficiencies (E40-E64) or diabetes (E10-

E14) for example, since it would incur in underestimation of impact of food-nutrition on disease development.

Key words: Nutrition; mortality; Venezuela.

PO307

BIOACTIVE COMPOUND AND FIBER AND CAROTENOIDS IN FLOUR LEAVES OF MORINGA OLEIFERA LAM

E M. Borges Teixeira¹, M R. Barbieri de Carvalho², L. Arantes Pereira¹

¹Instituto Federal do Triângulo Mineiro, IFTM, Setor de Agroindústria, Campus, Uberaba, Brasil

²Faculty of Agriculture and Veterinary Sciences, UNESP, Jaboticabal, Brazil

Background and objectives: The Moringa oleifera Lam belongs to the family of Moringaceae, is native to northern India and grows in many countries of the tropics. With representative amounts of nutrients and countless popular uses due to its nutritional and pharmacological applications. The study of their physical and chemical characteristics allows its application in various food products and verification of its behavior toward various treatments used in processing is certainly an important aspect, however do not have well-known anti-nutritional characteristics, since these substances could alter the composition or its nutrients become unavailable, and cause adverse physiological effects. Objective - To determine the anti-nutritional substances flour leaves of Moringa, with emphasis on tannins, cyanogenic compounds, trypsin inhibitors, nitrate and oxalic acid, its crude fiber and determine the carotenóides.

Methods: For determination of tannins was the spectrophotometric (JOSLYN, 1990). The presence of compounds was assessed by testing cianogêncios Guignard (Montgomery 1969). Nitrates were determined by the colorimetric method of Cataldo et al. (1975) and oxalic acid titration method was used as described by AOAC (1990). The activity of trypsin inhibitors was determined by the method of Kakade et al. (1969), using BAPA (benzoyl-DL-arginine-p-nitroanilide) as a substrate. The determination of dietary fiber as AOAC (1990). Carotenoids as described by Rodriguez-Amaya (1999).

Results: In the analysis of antinutritional compounds were observed: tannins (20.69 mg / g), cyanogen (no), trypsin inhibitor (UTI 1.45 / mg), nitrate (17mg / g) and oxalic acid (10 5 mg / g), crude fiber content (10.99%), carotenoids were identified β -carotene and lutein, with concentrations of 161.0 and 47.0 respectively ?g.g-1 leaf.

Conclusions: These results suggest it becomes possible applicability of flour jug sheet feeding by low toxicity and significant amount of fiber and carotenoids.

Key words: Moringa oleifera, antinutrients, feeding, fibers and carotenoids.

PO308**EFFECTS OF CALCIUM AND VITAMIN D ON THE SERUM PTH AND ADIPONECTIN LEVELS IN GROWING RATS**

S.S. Lee¹, Y.J. Lee¹, S.M. Lee¹, K.M. Lee¹, E.S. Won²

¹Department of Food and Nutrition, College of Human Ecology, Hanyang University, Korea

²R&D Planning Team, R&D Center, Seoul Dairy Co, Korea

Background and objectives: Calcium and vitamin D deficiency are reported to associate with obesity and to induce inflammatory reactions as parathyroid hormone (PTH) increase. This study was conducted to investigate the effects of different levels of calcium and vitamin D intake on the serum PTH and adiponectin levels in growing rats.

Methods: Fifty six 5-week-old Sprague-Dawley male rats were divided into 7 groups and fed for 6 weeks: control (0.5% Ca, 1000IU VD), LCLD (0.05% Ca, 10IU VD), LCND (0.05% Ca, 1000IU VD), LCHD (0.05% Ca, 5000IU VD), HCLD (1.00% Ca, 10IU VD), HCND (1.00% Ca, 1000IU VD), HCHD (1.00% Ca, 5000IU VD). Serum intact parathyroid hormone (iPTH) and adiponectin were analyzed, and then the effects of Ca and vitamin D on each group were evaluated by two-way ANOVA.

Results: The concentrations of serum Ca were not significantly different among seven-groups, but the levels of serum 25(OH)D3 were higher in high vitamin D groups than the other groups ($p < 0.001$). The serum adiponectin levels in high Ca or vitamin D groups were not significantly different compared with control and low groups. However, the serum iPTH in LCLD was the highest level among the other groups ($p < 0.05$). The amount of internal fat and abdominal fat in the low calcium groups were higher than control and high calcium groups ($p = 0.001$, $p < 0.001$), moreover those fat amount was the highest in LCLD group. The amount of body fat was affected by calcium intake rather than vitamin D intake when analyzed by two-way ANOVA.

Conclusions: Low calcium intake may contribute to increase the serum iPTH level and body fat amount. However, vitamin D intake was showed low effect on the serum adiponectin level for 6 weeks.

Key words: calcium, 25(OH)D3, iPTH, adiponectin, body fat

PO309**CONSUMER BEHAVIOR REGARDING FOOD LABELLING INFORMATION IN THE CITY OF PETRÓPOLIS (RJ)**

A. Esteves¹, U. Pombo¹, M.H. da Silva¹

¹Faculdade Arthur Sa Earp, Curso de Nutrição, Petrópolis, Rio de Janeiro, Brasil

Background and objectives: The nutrition labelling on foods for the promotion of healthy food is fundamental. The consumers get more information about what they are consuming through the product labels. Objective: To verify if the consumers have the habit to read and to know the information contained on the products labels.

Methods: transversal, observational, quantitative and descriptive study type. The consumers (154) were interviewed during shopping in supermarkets located in the Petrópolis through a questionnaire where the answers were related to the habit of reading labels and also according to sociodemographic variables.

Results: the majority of consumers were female and only 46% interviewed had the habit of reading labels. It should that the older and more educated the consumers were, the interest for information increased. The most consulted items were the expiration date (39%) and price (27.8%). The nutritional information more consulted were the caloric value (28.1%) and sodium contents (26.7%). It was observed that the price also influences on the choice of products (35%), followed by the brand (28%). The most common reasons for not consulting the labels were lack of interest (44.3%) followed by the letter size on the label. (40.8%). The results showed that most consumers interviewed (84.4%) did not know the correct meaning of the terms light and diet.

Conclusions: This study showed the necessity to find a most clear form to present nutrition information to consumers enabling them to understand and make healthier decisions when choosing their products. It reinforced the need of nutrition education programs including food labelling, in order to enlighten and educate consumers about the importance of nutritional information contained on labels to avoid any misinterpretations about the products.

Key words: nutritional Information, food labeling, Light and Diet.

PO310**THE ROLE OF BILIRUBIN IN HUMAN HEALTH: IMPLICATIONS FOR OXIDATIVE STRESS-MEDIATED DISEASES**

C. Mölzer¹, M. Wallner¹, A. Bulmer², K-H Wagner^{1,2}

¹University of Vienna, Department of Nutritional Sciences, Australia

²Heart Foundation Research, Griffith University, Australia

Background and objectives: Bilirubin is the primary bile pigment which is formed during haem catabolism within the reticulo-endothelial system. Mostly unconjugated bilirubin (UCB) circulates in the plasma, the majority of which tightly bound to albumin, and is excreted by the liver to eventually enter the intestine. Epidemiological studies report a negative association between circulating UCB concentrations and the risk for cancer, cardiovascular and metabolic diseases. To further explore physiological effects of UCB, a human and an animal trial, along with a series of in vitro experiments were performed. The overall aim of this project was to investigate whether lower levels of oxidatively damaged DNA and chromosomal aberrations in hyperbilirubinemic humans and animals can be observed.

Methods: 76 age- and gender-matched individuals were allocated into Gilbert's syndrome (GS; UCB \geq 17 μ M; n=38) or controls groups (n=38). A hyperbilirubinemic rat model (Gunn rats) was selected to support the human trial, and included 40 rodents in total. Applied methods included the comet and micronucleus assay. In vitro experiments were performed to investigate anti-mutagenic and antioxidant properties of bile pigments and derivatives in the Salmonella reverse mutation assay, and DNA-damaging effects in human cancer cell lines in the comet assay. To obtain assistive mechanistic data, flow cytometry parameters were analyzed.

Results: The findings suggest DNA protection in epithelial tissue of older hyperbilirubinemic individuals. The significantly lower BMI found in the GS group might contribute to the prevention of cardiovascular diseases and could improve the health status in metabolic diseases. In vitro data suggest anti-mutagenic effects of bilirubin derivatives in the applied bacterial model, and DNA strand-breaks in human cancer cells.

Conclusions: This study suggests an indirect effect of elevated plasma UCB levels in protecting against metabolic diseases, and implies manifold beneficial in vitro properties of bile pigments.

Key words: Bilirubin, DNA damage, micronuclei, CVD

PO311**CLINICAL TRIAL FOR THE EVALUATION OF ANTI-HYPERTENSIVE EFFECTS OF SOLAR SALT PRODUCED IN KOREA**

B. Lee¹, A.R. Yang¹, M.Y. Kim¹, H.G. Kim²

¹Dept. of Food and Nutrition, Chung-Ang University, Anseong, Gyeonggi, Republic of Korea

²Dept. of Pharmacology, Dankook University, Cheonan, Choongnam, Republic of Korea

Background and objectives: The study was performed for evaluating blood pressure (BP) and its biomarkers when Korean solar (sun-dried) salt (86% NaCl, SS) were administered as a daily condiment compared with refined salt (99% NaCl, RS) for 12 weeks.

Methods: Twenty-three female (20–65 yrs) volunteers were given SS (n=12) or RS (n=11) group. The subjects must consume at least 15 meals a week cooking with either salt. BP was checked morning and evening everyday for 12 weeks. Biomarkers measured at day 1, 4th and 12th week were electrolytes (Na⁺, K⁺, Cl⁻, Mg²⁺, Ca²⁺), aldosterone, renin and catecholamines in blood and urine.

Results: The morning systolic BP (SBP) in SS group tended to be lower than RS group without statistical significance. The evening SBP was slightly increased in both groups. The serum electrolytes did not change except for Ca⁺ level, which was increased in both groups at 12th week (p<0.05). The urinary electrolytes showed similar tendency to blood, except that urinary Ca⁺ and K⁺ levels of SS group tended to be lower. Plasma aldosterone of both groups at 4th week were increased (p<0.05), but plasma rennin level did not change. Plasma norepinephrine level of RS group at 4th week was increased than that of day 1 (p<0.001) and epinephrine level of both groups were also increased at 4th week (p<0.05). However, SS group of norepinephrine and epinephrine levels tended to be lower than RS group. Urinary norepinephrine, epinephrine and dopamine levels were decreased in both groups after 12 weeks (p<0.05), but there were no significant differences between the groups.

Conclusions: Two types of salts exerted differently on blood pressure and its biomarkers. From the findings, it would be worthy to conduct more controlled clinical study since several biomarkers as well as blood pressure were compromised.

Key words: solar salt, refined salt, blood pressure, human clinical trial

PO312**PEN - THE GLOBAL RESOURCE FOR NUTRITION KNOWLEDGE TRANSLATION**

B. Amour¹, A. Byron², S. Kellie³, B. Murray², J. Thirsk¹

¹Dietitians of Canada, Toronto, Ontario, Canada

²Dietitians Association of Australia, Deakin, Australian Capital Territory, Australia

³British Dietetic Association, Birmingham, UK

Background and objectives: Dietitians translate research into practice when applying the science of nutrition to the feeding and education of individuals or groups in health and disease. Maintaining currency is challenging when knowledge is constantly expanding. In 2005 Dietitians of Canada launched a dynamic knowledge translation subscription service called Practice-based Evidence in Nutrition (PEN) as a resource for dietitians, including those working in two Canadian provincial government call centres. Establishing international partnerships required modifying PEN processes of knowledge translation.

Methods: Collaborating authors from each global partner use protocols to identify, analyse and synthesise the evidence to create new or update existing practice questions, guidance summaries and client resources, the key components of PEN. While the evidence to develop these components comes from the international literature, global partners have customised PEN to take into account national reference documents e.g. nutrient reference values and dietary guidelines. Additional partners have meant enrichment in knowledge pathway content and usage data is helping to prioritise pathways for revision or development. Partners have used online tutorials, webinars and conference workshops to build capacity and maximise use by practitioners, and to encourage contribution to the PEN knowledge pool.

Results: As of February 2013 there were 169 knowledge pathways, 1044 practice questions and 3341 resources. Usage data indicates that client handouts are often accessed more than practice questions. Social media confirms the popularity of PEN with distribution to 10,000 first year PEN eNews subscribers and greater than 1000 followers on each of Facebook and Twitter. Universities report PEN as a tool to support student studies and for students to gain recognition by contributing to the global knowledge pool.

Conclusions: Problem solving and cooperation within the global partnership has enabled the development of PEN as a valuable international resource for practitioners.

Key words: research, social media, knowledge translation, partnerships

PO313**THE EFFECT OF AGE ON ATTITUDES OF POLISH GIRLS TO NUTRITION AND HEALTH. THE GEBA-HEALTH PROJECT**

J. Czarnocinska¹, L. Wadolowska², J. Kowalkowska², E. Babicz-Zielinska^{3,4}, M. Jezewska-Zychowicz⁵, K. Sobas², W. Kozirok^{3,4}

²Department of Human Nutrition, University of Warmia and Mazury in Olsztyn, Poland

³Department of Trade and Services, Gdynia Maritime University, Poland

⁴Eating Behaviour Research Group

⁵Department of Organization and Consumption Economics, Warsaw University of Life Sciences, Poland

Background and objectives: Individual attitudes change with age. No studies have been conducted to determine whether and to what extent attitudes towards nutrition and health presented by Polish girls change in adolescence and at maturity. The study aim was to analyze the effect of age on attitudes to nutrition and health presented by girls.

Methods: The research involved 232 girls aged 13-21 years. Attitudes to nutrition and health were assessed using the Health Concern Scale (HCS) and the Health Taste Attitude Scale (HTAS).

Results: In HCS neutral attitudes (score of 30-50points) were identified in 72% girls, negative attitudes (10-29points) in 19% girls, positive attitudes (51-70points) in 10% girls. In HTAS neutral attitudes (114-190points) were found in 93% girls, positive attitudes (191-266points) in 6% girls. No girl showed a negative attitude (38-113points). In girls aged 19-21 the odds ratio for attitudes classified in the upper-positive tercile for the subscales HTAS-1:interest-in-health was 2.97 (95%CI 1.24; 7.11), HTAS-3:natural-product was 2.91 (95%CI 1.28; 6.62), HTAS-6:pleasure was 3.60 (95%CI 1.56; 8.30), while in HTAS it was 4.31 (95%CI 1.87; 9.92) in comparison to girls aged 13-15 (OR=1.00). In girls aged 19-21 the odds ratio for attitudes classified in the lower-negative tercile of the subscales HTAS-2:light-food was 2.74 (95%CI 1.19; 6.31) in comparison to girls aged 13-15 (OR=1.00). The relation between age and attitudes of girls measured in HCS and subscales HTAS-4:sweets and HTAS-5:food-as-a-reward was non-significant.

Conclusions: With age in girls an increase was observed for interest in health and positive attitudes to natural products and nutrition as well as negative attitudes to light food. Changes in attitudes were most evident in girls aged 19-21 years. Age of girls did not influence their attitudes to sweets or perception of food as a reward.

Key words: age, attitude, girls, health, nutrition

PROTECTIVE EFFECTS OF ERGOTHIONEINE AGAINST METHYLGIOXAL-INDUCED NEURON CELLS INJURIES AND ITS POSSIBLE MECHANISM

T.Y. Song¹, C. Chen¹, H.C. Lin¹, Y.S. Jhan¹, W.H. Chang¹, S.J. Huang¹

¹Department of Health Food, Chung Chou University of Science and Technology, Taiwan

Background and objectives: Patients with long-standing diabetes commonly develop diabetic encephalopathy, which is characterized by cognitive impairment and dementia. Methylglyoxal (MGO) is a toxic precursor of advanced glycated end-products (AGE) that are responsible for protein glycation. Ergothioneine (EGT) is an antioxidant components of many mushrooms especially *Lentinus edodes*. In this study we investigated whether EGT protects against MGO-induced neuronal cell damage.

Methods: murine pheochromocytoma (PC12) cells were incubated with MGO with or without EGT. Levels of protein carbonyl, reactive oxygen species (ROS) and the expression of AGE, AGE receptor (RAGE), and nuclear factor kappa-B (NF-kB) were analyzed.

Results: cell viability of PC12 cells treated with 30 μ M MGO for 72 h was decreased to 64%. Co-incubation with EGT (2 μ M) for 72 h significantly restored the viability. MGO markedly increased protein carbonyl and ROS production, which was strongly reduced by EGT (71% and 64%, respectively). These effects of EGT were equal to 100 nM aminoguanidine (an AGE inhibitor) and 10 μ M Epalrestat (an aldose reductase inhibitor). AGE, RAGE and NF-kB expression was increased 3.2-, 4.5- and 2.4-fold, respectively, by MGO, but was significantly attenuated by EGT co-treatment.

Conclusions: the neuroprotective effect of EGT is likely attributed to a decrease of ROS production by inhibition of the AGEs/RAGE signaling pathway.

Key words: Ergothioneine, methylglyoxal, neuron cells, advanced glycated end-products

EFFICACIOUS OF SYNBIOTIC AND NUTRIENTS SUPPLEMENT ON STIMULATED OF SECRETORY IMMUNOGLOBULIN A (SIGA) IN TREATED PULMONARY TUBERCULOSIS PATIENTS

S. Samsidi¹, H. Ridwan², C.M. Kusharto², A. Sulaeman², B. Alisjahbana³

¹Health Polytechnic of Bandung, Indonesia

²Faculty of Human Ecology, Bogor Agriculture University, Indonesia

³Faculty of Medicine, University of Padjadjaran Bandung, Indonesia

Background and objectives: Administrations of Tuberculosis chemotherapy probably disturbed of normal microflora balance, therefore it decreased mucosal defense system. The study objective was to analyze the efficacy of milk based protein supplement (MBP) with synbiotic and micronutrients on improving microflora balance and secretory IgA among treated adult PTB patients.

Methods: A double-blind randomized treatment-control trial design was applied in this study. Ninety four new cases of PTB aged 20-45 years old were selected and divided into two groups; the treatment group was treated daily supplement with MBP (13.9 g protein), synbiotic (35x10 log₁₀ cfu of *Lactobacillus acidophilus* and 5x10 log₁₀ cfu of *Bifidobacterium longum* and 120 mg fructo-oligosaccharides) and micronutrients (5,000 IU vitamin A and 15 mg zinc); and the control group was treated daily with MBP only during 2 months intervention. All patients received a standard TB chemotherapy. Parameters of gut microflora and titer sIgA were collected at baseline, after 1, 2 and 6 months of intervention. Population of *Lactobacillus* sp in fecal was counted using plate count method and population of *Bifidobacterium* sp in fecal was counted using direct count method and counting chambers. Titer of sIgA was measured using ELISA method.

Results: After first month intervention total colony of *Lactobacillus* sp and *Bifidobacterium* sp were higher in treatment group than control groups ($p < 0.05$). In addition titer of sIgA was also higher in treatment group than control group ($p < 0.05$).

Conclusions: There was positive effect of these supplements to maintain balance of gut microflora and stimulating sIgA secretion during TB chemotherapy.

Key words: protein, synbiotic, vitamin A, zinc, sIgA.

PO316**THE ASSOCIATION OF THE FTO GENE SNP RS 9939609 WITH DIETARY ENERGY INTAKE AMONG BEIJING HAN CHILDREN***H. Fang¹, Y. Li¹, X. Hu¹, Q. Zhang¹, A. Liu¹, G. Ma¹*

¹National Institute For Nutrition and Food Safety, Chinese Center For Disease Control and Prevention, China

Background and objectives: Fat-mass and obesity-associated (FTO) gene is a gene located in chromosome region 16q12.2. Genetic variants in FTO are associated with the obesity phenotype in European and Hispanic populations. This association was also confirmed among Chinese children. However, the role of FTO variants in the regulation of energy balance is unknown. We aimed to test the role of FTO genetic variants on dietary energy intake.

Methods: We genotyped FTO variants rs9939609 in 670 children (332 girls and 338 boys) aged 8-11 years living in Beijing, and analyzed the role of FTO genetic variants in modulating of energy intake.

Results: Compared with the TT genotype, we found marginally increasing level of dietary energy intake in the AA/AT genotype subjects ($P=0.095$). The consumption of fat, energy from fat and the percentage from fat were also found obviously higher.

Conclusions: Influence on the energy intake of dietary is one of the ways of FTO gene affects energy balance.

Key words: FTO; child; Chinese; obesity; dietary energy intake

PO317**USE OF LOCAL NUTRIENT-RICH FISH IN DEVELOPING A COMPLEMENTARY FOOD AND ITS CONTRIBUTION TO RECOMMENDED NUTRIENT INTAKES OF INFANTS***J.R. Bogard¹, S.H. Thilsted¹, H.J. Keus¹, M. Karim¹*

¹WorldFish, Bangladesh

Background and objectives: Timely introduction of nutrient-rich complementary foods among infants aged 6-23 months, when breastmilk is no longer sufficient to meet energy and nutrient requirements is essential for optimal child growth and development. In developing countries, complementary foods are often low in macro- and micronutrients, contributing to low nutrient intake and resulting in undernutrition in infants. Processing and combining local foods to optimize nutritional value in production of a pre-prepared complementary

food could be an important food-based strategy to improve nutrient intakes of infants aged 6-23 months.

Methods: Based on nutrient composition, small fish, rich in iron and zinc; and orange flesh sweet potato, rich in vitamin A were selected along with the staple food, rice for product development. These foods were dried and combined to: optimize nutrient content, minimize anti-nutrient content and ensure an acceptable product. Nutrient content of the product was estimated and compared to recommended nutrient intakes (RNIs) for infants, and nutrient composition of two fortified blended complementary foods used in Bangladesh.

Results: Two serves per day of the complementary food meet: 80% (infants 6-12 months) and 129% (1-2 years) of iron RNI; 81% of zinc RNI (6 months - 2 years); 99% (6-12 months) and 79% (1-2 years) of calcium RNI; and 52% of vitamin A RNI (6 months - 2 years). In comparison to the two fortified complementary foods, the product developed is similar in macronutrient and higher in iron, zinc and calcium content.

Conclusions: Local nutrient-rich foods, particularly small fish, incorporated in a pre-prepared complementary food can contribute significantly to the RNIs of infants, 6-23 months. This product is particularly suitable for use during initiation of complementary feeding, and as a food-based strategy for prevention and treatment of undernutrition in infants and young children.

Key words: complementary food, small fish, food-based strategy, Bangladesh

PO318**VARIANTS IN THE C-TERMINAL REGION OF PCSK9 AFFECT LDL-C LEVELS IN A BLACK SOUTH AFRICAN POPULATION (THE PURE STUDY)***T. Van Zyl¹, K.R. Conradie¹, J.C. Jerling¹, G.W. Towers¹*

¹Centre of Excellence for Nutrition, North-West University, Potchefstroom, North West, South Africa

Background and objectives: PCSK9 is a serine protease that promotes the degradation of the LDL receptor. Mutations in the PCSK9 gene that affect the C-terminal domain of the protein have been associated with LDL-c levels. Variants A443T and C679X are loss-of-function mutations and have been associated with lower LDL-c levels. Variant H553R is a gain-of-function mutation associated with increased LDL-c levels. The aim of this study was to investigate the genotypic distribution of variants A443T, C679X, H553R and A594D (a novel variant) in the PCSK9 gene and determine their association with LDL-c in a black South African cohort.

Methods: A cross-sectional, observational study within the PURE study was conducted on 1600 randomly chosen; apparently healthy subjects aged 35 to 60 years. LDL-c levels were

determined by means of the Friedewald formula. Screening of these SNPs was achieved by the use of the Illumina's VeraCode™ Golden Gate Genotyping Assay on a BeadXpress™ Reader system. The SNPs were tested for adherence to HWE. Univariate analyses were used to determine if associations were present between the different genotypes and LDL-c levels.

Results: All four of the variants were detected in the study population with minor allele frequencies of 0.04, 0.03, 0.04 and 0.05 for A443T, C679X, H553R and A594D, respectively. All variants adhered to the assumptions of HWE. Both A443T ($p=0.04$) and C679X ($p<0.01$) were significantly associated with lower LDL-c levels. H553R ($p=0.09$) and A594D ($p=0.10$) were not significantly associated with LDL-c levels.

Conclusions: Even though these variants are present at low frequencies they do contribute to the inter-individual differences of LDL-c levels in the study population. These mutations may be indicative of the as yet undetermined genetic architecture responsible for the lowered cardiovascular disease risk encountered in the black South African population.

Key words: LDL, LDL receptor, PCSK9

PO319

EFFECTS OF SPIRULINA PLATENSIS ON APOPTOTIC GENE EXPRESSION IN AGE-RELATED HEARING LOSS

Y.C. Chan², J.H. Hwang¹, M.H. Lin², M.F. Wang²

¹Department of Otolaryngology, Buddhist Dalin Tzu-Chi General Hospital, Chiayi, and School of Medicine, Tzu Chi University, Hualien, Taiwan

²Department of Food and Nutrition, Providence University, Taichung, Taiwan

Background and objectives: *Spirulina platensis* was demonstrated to be effective in treating hyperlipidemia, immune-deficiency, and inflammatory processes. However, the effects and related mechanisms of *Spirulina platensis* on degenerated disease are still unclear. This study was aimed to examine the effects of *Spirulina platensis* on age-related hearing loss.

Methods: Eleven-month old SAM mice were randomly divided into Senescence-accelerated-resistant (SAMR1) normal control, senescence-accelerated prone-8 (SAMP8) normal control, and *Spirulina platensis* (400 mg/Kg BW) SAMP8 groups, respectively, and fed with the experimental diets for six weeks. The auditory brainstem response (ABR) test was performed at the baseline and the end of experiment. After sacrificed, the poly ADP-ribose polymerase-1 (PARP-1) and apoptosis inducing factor (AIF) protein expressions of brain stem and cochlear were analyzed.

Results: *Spirulina platensis* could lower the ABR threshold and hearing degeneration in SAMP8 mice. *Spirulina platensis*

supplementations significantly decreased the cleaved-PARP1 expression in brain stem, and reduced the PARP-1 expression in spiral ganglion neurons and hair cell of cochlear. The AIF expression of brain stem and cochlear in *Spirulina platensis* diet group were also lower than the SAMP8 control group.

Conclusions: Our results indicated that the *Spirulina platensis* could retard the age-related hearing loss, which might due to moderate the apoptosis related gene expression in aged SAMP8 mice.

Key words: *Spirulina platensis*, age-related hearing loss, poly ADP-ribose polymerase-1, apoptosis inducing factor

PO320

EFFECT OF VANADIUM ON THE OXIDATIVE STATUS OF DIABETIC RATS

C. Lopez-Chaves¹, C. Sanchez-Gonzalez¹, C E. Trenzado², L. Vera³, P. Aranda¹, M. Montes-Bayon⁴, A. Sanz-Medel⁴, J. Llopis¹

¹Department of Physiology, University of Granada, Granada, Spain

²Department of Animal Biology, University of Granada, Granada, Spain

³GENYO, University of Granada, Granada, Spain

⁴Department of Analytical Chemistry, University of Oviedo, Oviedo, Spain

Background and objectives: Due to growing exposition of the population to vanadium compounds, the study of the metabolism of this trace element is an important area of current investigation. Vanadium is an essential element for some living organisms although there are controversies about its essentiality in the human body. There is an increasing use of nutritional supplements of vanadium as an anabolic agent by body builders and athletes. V also showed hypoglycaemic effects and is being investigated for the treatment of diabetes. There are many aspects that remain to be determined like digestive and metabolic interactions with other elements involved in the antioxidant defence.

Methods: Four study groups were examined: Control; Diabetic; Diabetic treated with 1mgV/day (DMV); and Diabetic treated with 3mgV/day (DMVH). The vanadium was supplied in drinking water as bis(maltolato) oxovanadium (IV)(BMOV). The experiment had a duration of five weeks. Superoxide dismutase (SOD), catalase (CAT), NAD(P)H:quinine-oxidoreductase1 (NQO1) activity, protein carbonyl groups levels and malondialdehyde (MDA) levels in the liver were determined.

Results: In the diabetic animals, we recorded higher protein carbonyl groups levels and NQO1 activity, together with decreased CAT activity, in comparison with the control rats. In

DMVH, there was a significant decrease in NQO1 activity, and increased CAT activity and MDA levels, in comparison with the diabetic rats.

Conclusions: Treatment with 3mgV/day provokes a deterioration of antioxidant defences in the tissues.

Key words: Pathology, antioxidant defence

PO321

RAMA PEDIATRIC BLENDERIZED FORMULA

P. Hongto¹, T. Tangsermwong², U. Suthutvorawut², N. Chongviriyaphan²

¹Nutrition&Dietetics Division, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Thailand

Background and objectives: To develop the Pediatric Blenderized tube feeding formula with optimum viscosity for tube feeding containing 10 % protein, 30 % fat, and 60% carbohydrate. The recommended dietary allowance for nutrients, vitamins and minerals were also added.

Methods: Calculate the Blenderized Formula that the percentages of total weight for protein, fat, and carbohydrate is 10%, 30%, and 60%, respectively. The raw material used for the preparation are chicken liver, eggs, chicken meat, rice, cane sugar, banana, dextrin and soybean oil. The nutrition value was calculated based on the nutrition database from Food Table Composition using Microsoft Excel. Some nutrients, vitamins and minerals in medication form were added if necessary. Concerning the recommended dietary allowance for children, We developed 9 formulas. Then the pediatrician team selected 1 formula from 9 formulas.

Results: The Pediatric Blenderized Formula was able to flow continuously through the 14 French feeding tube in the simulation scenario. When we fed the patients through feeding tube in the pediatric ward, We found that flow rate is slower and sometimes feeding tube obstruction was occurred and bag shaking is needed. Therefore, the type and portion of raw material has modified without changing the nutrient value. The optimum formula for preparing blenderized diet was then published.

Conclusions: We developed the blenderized diet for the pediatric patients called "Ramathibodi Pediatric Blenderized Formula" available for the patients admitted in Ramathibodi hospital. This formula can be ordered through the Ramathibodi hospital diet ordering program by using code "Pediatric BD".

Key words: Blenderized formula, Tube feeding, Pediatric BD

PO322

EXAMINATION OF THE IMPACT OF USING GENERIC NUTRITIONAL COMPOSITION DATA, ON NUTRIENT INTAKE ESTIMATION AT MEAL AND DAILY FOOD-INTAKE LEVELS

C. Woolhead, M.J. Gibney¹, M. Walsh¹, L. Brennan¹, E.R. Gibney¹

¹Institute of Food and Health, University College Dublin, Dublin, Ireland

Background and objectives: Currently dietary data, using food diaries or recalls, is collected and analysed at an individual food item level, seeking specifics such as brand, food weight and time of consumption, which can be time consuming and cumbersome. It remains to be seen whether such detail is required and how generic information application impacts on nutrient intake.

Methods: Dietary data, based on 4-day semi-weighed food diaries from the Irish National Adult Nutrition Survey (NANS) was used for this analysis. The data contained 133,068 food occasions and 2552 food items. Each food item had details including meal code, study day and food-weight amongst others. Meal-type "Breakfast" was selected consisting of 683 food items. These were coded into 21 food groups e.g. "Breads", "Milks". Dietary intake modelling was performed by substituting generic nutritional compositions of specific foods/food groups and the impact of altered compositions was assessed at meal and daily mean intake levels. Food groups examined included "Milk", "Fruit", "Bread" and "Cereal".

Results: Dietary intake modelling demonstrated no significant differences in mean nutrient intake when substituting "Breads" or "Fruits" with generic compositions at both mean daily and meal intake levels. Using generic compositional data within the food group "Milks", there were no significant differences for the majority of nutrients, except phosphorus ($p \leq 0.001$) and saturated fat ($p \leq 0.05$). "Cereals" (split), at a daily level, produced no significant differences for most nutrients, other than calcium ($p \leq 0.001$) and NSP ($p \leq 0.05$). However, for cereals, many significant differences were found at a meal level ($p \leq 0.001$).

Conclusions: For many food groups at breakfast, a generic nutritional composition may be adequate when examining nutrient intakes in the population, giving promise to the idea of meal assessment in the future.

Key words: Meal, Meal variability.

PO323**GENOMIC PROFILING IN SUBJECTS WITH COMMON OBESITY IN BULGARIAN POPULATION**

*M. Nikolova, D. Popova*²

¹Department of Hygiene, Medical Ecology and Nutrition, Medical University of Sofia, Sofia, Bulgaria

²Clinic of Metabolic Diseases and Dietetics, University Hospital 'Tzaritsa Yoanna - ISUL', Sofia, Bulgaria

Background and objectives: Obesity is an important factor contributing the global burden of morbidity and mortality. Data from the national nutrition survey in Bulgaria from 2004 showed the prevalence of overweight (BMI 25 - 29.99) among the adult population from 34% to 40% and obesity rate (BMI > 30) was from 16.7% to 21.3%. For the past 15 years, candidate gene and genome-wide linkage studies have been the main genetic epidemiological approaches to identify genetic loci for obesity, while in last four years, 52 genetic loci were identified to be unequivocally associated with genes for common obesity and related traits as a result of development of genome-wide association studies (GWAS).

Methods: For the purpose of the study will be used clinical methods (assessment of nutritional status by anthropometric, laboratory tests, BIA) and genetic methods (target next-generation sequencing of 12 genes associated with the regulation of body weight, body composition, BMR, lipid metabolism). From the found associations, 12 genes are repeated constantly in ten or more studies: ADIPOQ, FTO, ADRB3, GNB3, HTR2C, NR3C1, LEP, LEPR, PPARG, UCP1, near-MC4R, NRXN3.

Results: The study aims to investigate genetic variants in a panel of 12 genes associated with the regulation of body weight in 200 patients (well phenotyping) with common obesity and compared with a 100 healthy controls: to find new variants of defined genes and their frequency distribution in the Bulgarian population, as the influence of environmental factors on their clinical manifestation; to establish clinical and genetic algorithm for the prevention and control of obesity.

Conclusions: It is expected that new data will enrich scientific knowledge about frequency and diversity of risk gene pool for common obesity in the Bulgarian population and contribute to the creation of multigenous panel for early diagnosis and prevention of obesity.

Key words: Common obesity, genetics, gene - environment interactions

PO324**A DIET ENRICHED WITH SULFUR-CONTAINING ANTIOXIDANTS IMPROVES NK ACTIVITY AND DIGESTION OF PERITONEAL LEUKOCYTES IN DOUBLE-TRANSGENIC MICE FOR ALZHEIMER'S DISEASE**

L. Marin¹, O. Hernandez¹, M. de la Fuente¹

¹Department of Physiology, Faculty of Biology, Complutense University of Madrid. 28040 Madrid, Spain

Background and objectives: Previous studies have shown in triple-transgenic mice for Alzheimer's disease (AD) a premature immunosenescence in comparison to non transgenic animals (NTgAD). In addition, they have proposed the analysis of the functional state of peripheral immune cells as a useful tool for measuring the progression of AD. Since the ingestion of diets enriched with sulfur-containing antioxidants have been shown to slow down immunosenescence and improve longevity, the aim of the present work was to study the effect of an ingestion of these antioxidants in several relevant functions of immune cells from double-transgenic mice for AD (2xTgAD), a model in which the possible presence of a premature ageing of the immune cell functions have not been studied.

Methods: Female (4 months of age) 2xTgAD and control (NTgAD) mice were used. The 2xTgAD were divided in two groups. One group of animals was fed a diet supplemented with N-acetylcysteine + thioproline (0.1% w/w) (2xTgADA) and the other a standard diet (Panlab A04) (2xTgADC). After 2 and 8 months, the peritoneal leukocytes were obtained and two key immune functions were studied, i.e.: natural killer (NK) activity and digestion capacity measured by tumor cell lysis and intracellular superoxide anion levels, respectively.

Results: The functions studied were decreased in 2xTgADC in comparison to NTgADC and the ingestion of antioxidants increased the values of these functions bringing them close to those in the NTgADC group.

Conclusions: 2xTgAD mice show a premature immunosenescence. Moreover, since the immune system is a marker of health and a predictor of longevity, an adequate treatment with sulfur-containing antioxidants could be useful in these animals to slow down the effects of the aging process and the progress of AD.

Key words: Antioxidants. Alzheimer's disease. Leukocyte functions. Mice

PO325**UNIDIRECTIONAL FLOW TECHNIQUE USING TRACERS FOR RESEARCH NEW NUTRIENTS-METABOLITES BIOMARKERS IN EARLY STAGES OF THE DISEASE**

*F. Sanchez-Jimenez*¹

¹Area Dietetica/Colegio Oficial de Tecnicos Superiores Sanitarios de Valencia, Alicante, Comunidad Autonoma Valenciana, Valencia, Spain

Background and objectives: Biomarkers with higher sensitivity, specificity and predictive value than those used so far is of vital importance in decisions about health spending. Diagnostic in the accounts represents 1-2% of health care costs, the decisions made up 70% of health care. Current

Methods to detect levels of biomarkers that reflect the final stages of the disease when treatment options are limited.

Methods: Comparing Nuclear Magnetic Resonance Spectroscopy [NMR] Mass spectrometry [MS] (refined by chromatographic techniques) with unidirectional flow technique perfused using paired cultures tracers [UFTTP] modified by Peran y MacGee for analyzing metabolites-nutrients and other biological molecules. UFTTP involves the absorption kinetics in the range of seconds, the absorption is measured by comparing the concentrations output profiles of [14C]-D-mannitol (extracellular tracer) either with [3H]-Nutrient-Metabolit s, following a bolus infusion liquid containing intrainput [14C]-D-mannitol and [3H]-Nutrient-Metabolit.

Results: The relative levels of pathophysiological concentration of these compounds are in the ultra trace interval (picomolar or less) at millimolar levels or even higher. These conditions are satisfied either by NMR, MS and UFTTP. The dietary manipulation is possible because the nutrients-metabolites are contained in foods. NMR and MS must still find significant correlations between metabolomes, its sensitivity is so high that it is able to identify the compounds detected which requires a subsequent stage for validation. UFTTP directly addresses the possible treatments and nutritional adjustments applied (dietetics plan).

Conclusions: UFTTP technique is practiced under patho and/or physiological conditions in the range of seconds and give results of the absorption kinetics and competitive inhibition. This also provides a new technique suitable for discovering new biomarkers, design of new drugs, therapeutic techniques and dietetic plans to nutrient content adjusted to prevent, treat or mitigate disease.

Key words: biomarkers, nutrients, dietetic, phase, early.

PO326**DIETARY HABITS OF POSTPARTUM MOTHERS DURING BREASTFEEDING**

*L. Alouane*¹, *A. Ghrissi*², *I. Benkhaled*²

¹National Nutrition Institute, Department of training-information, INNTA, Tunisia.

²High health and technology school. Department of Nutrition. BP 176 Bab Suika- 1006 Tunis TUNISIE

Background and objectives: The main purpose of the study was to identify the changes postpartum mothers of infants aged 0-2 months made in their nutrition with the aim of increasing their milk production.

Methods: The 120 postpartum mothers enrolled in this study came to the care center base at Ariana city. Dietary data were collected from the mothers via a questionnaire prepared by the researchers to elicit details about what kind of foods or nutrition supplements women added, avoided or were recommended to avoid or add to their diets and why.

Results: All the mothers made changes in their diets while breastfeeding. The number one change that mothers made in their diet in order to increase milk production was to increase their fluid intake (64%) while the second was to increase their consumption of dried legumes, grains and nuts (27%). Increased consumption of milk and milk products is mentioned by only 8% of mothers. The main type of food mothers were advised to avoid were vegetables (30%). The most important reason for this was the belief that they increased the chance of newborn colic (75%). The main source for information was their mother (58%) and mother in law (17%). Nutritional advice for health workers are not followed (4%). There were not statistically significant differences between foods avoided by breastfeeding mothers related to their age, education and socioeconomic level.

Conclusions: All of the mothers adapted specific practices, and had been given recommendations by others about their nutrition while breastfeeding. Mothers need another form of education by health workers to better monitor nutritional advice.

Key words: Nutritional habits – breastfeeding – food intake - nutritional information.

PO327**DEVELOPMENT OF A NEW SOFTWARE SPECIALIZED IN NUTRITION RESEARCH (FIRST PHASE: OBTAINING INFORMATION)**

B. López-Plaza¹, A. Moreno-Fernández de Leceta², O. Alonso-Usun², S. Palma-Milla¹, C. Gómez-Candela¹

¹Clinical Nutrition Department, University Hospital La Paz. La Paz Institute For Health Research (IdiPAZ). Madrid, Spain

²Ibermática Innovation Institute, Miñano, Álava, Spain

Background and objectives: New technologies must be part of the development of science and should be user-friendly to allow the researcher streamline and optimize their work. Currently there is no tool that meets with these characteristics in the field of nutrition, so it is being developed a computer application (CA) that incorporates all the processes through which knowledge is generated.

Methods: The different stages of information search have been integrated into the CA: the software is able to obtain and process the information from the variables of interest to the researcher. The CA works with one or several questions simultaneously, in ordinary language, which is then translated into controlled vocabulary (MeSH, Thesaurus ...) for your search in specialized databases (MEDLINE, Cochrane ...). The CA organizes this information and integrates concepts of evidence-based medicine and CONSORT criteria that allow assessing the power and quality of information. At the same time this tool incorporates a system of alerts about the existence of new information on the net. The browser is also able to identify and assess related images.

Results: In the first phase of its development, the software has shown good results when it is compared with the usual practice of seeking information. The speed of finding information with CA is better, and the assessment of the quality of the information is appropriate.

Conclusions: This new software for support of scientific research will streamline and optimize the work of the researcher in the nutrition area, improving the quality of the process and the results of the search for new knowledge.

Key words: Software, Nutrition Research

PO328**MEAL CONSUMPTION, DIETARY PATTERNS, PHYSICAL ACTIVITY AND COGNITIVE ABILITY AMONG MALAYSIAN ADOLESCENTS**

M T. Mohd Nasir¹, A R. Nurliyana¹, M S. Zaililah¹, A. Rohani¹

¹Universiti Putra Malaysia, Malaysia

Background and objectives: Adolescence is a transitional period where the brain matures to achieve its adult structure and functions. Many factors tend to influence cognition in a multidirectional manner. This cross-sectional study aimed to determine meal consumption, dietary patterns, physical activity and cognitive ability among Malaysian adolescents aged 12 to 13 year-old (N=416).

Methods: Adolescents were randomly recruited from five public schools in an urban area of Selangor, Malaysia. Socio-demographic background was obtained from parents. Height and weight were measured, and body mass index was calculated. A questionnaire on meal consumption and physical activity was administered in class. A semi-quantitative food frequency questionnaire (S-FFQ) was used to determine habitual dietary intake. Dietary patterns were constructed using principal component analysis based on servings per day intake of the food items in the S-FFQ. Cognitive ability was assessed using Wechsler Nonverbal Scale of Ability (WNV) in a one-to-one manner.

Results: Adolescents who consumed dinner at least five days a week (M=103.5, SD=12.0) had higher scores on the cognitive test compared to those who consumed dinner less than 5 days a week (M=98.0, SD=12.5). Four major dietary patterns were identified and labelled as refined-grain pattern, snack-food pattern, plant-based food pattern and high-energy food pattern. The high-energy food pattern was found to be negatively associated with cognitive ability ($r=-0.15$, $p<0.01$). There was a significant positive association between physical activity and cognitive ability ($r=0.10$, $p<0.05$). Consumption of dinner, high-energy food pattern and physical activity were found to contribute significantly towards cognitive ability after controlling for socio-economic status as indicated by monthly household income and parents' educational attainment.

Conclusions: Adolescents should be encouraged to consume dinner regularly, decrease intake of high-energy foods and increase physical activity level to enhance their cognitive ability.

Key words: Cognitive ability; dietary patterns; physical activity

PO329**THE ROLE OF FORESTS, TREES AND BIODIVERSITY IN NUTRITION-SENSITIVE FOOD AND AGRICULTURE SYSTEMS**

B. Powell¹, A. Ickowitz¹, R. Jamnadass², S. McMullin², R. Nasi¹, C. Padoch¹, M. Pinedo-Vasquez¹, T. Sunderland¹

¹Centre For International Forestry Research (CIFOR), Bogor, Indonesia

²The World Agroforestry Centre (ICRAF), Nairobi, Kenya

Background and objectives: Experts note that improving global nutrition will require conscious and sustained efforts in health, education, economics and agriculture (Pinstrup-Andersen 2009; Swaminathan 2012). Forests and conservation have often been overlooked in these calls for cross-cutting attention to nutrition, despite their significant influence over land use planning and policy.

Methods: Review emerging literature.

Results: Recently, researchers have investigated ways that forests contribute to nutrition (in addition to contributions to income, safety-nets and sustainability). Wild foods make important contributions to dietary diversity, often increase nutrient-density of local diets, and are culturally important in many traditional food systems. Although less important for staple crop production, forests and tree-based agricultural systems provide many under-consumed and nutritionally-important foods (fruits, vegetables and meat). An emerging body of research shows links between tree cover and fruit and vegetable consumption (Ickowitz et al. in preparation; Powell 2012), adding to previous research asserting their importance for fruit production (Jamnadass et al. 2011) and improved micronutrient intake (Jones et al. 2005). Agricultural landscapes that include significant tree cover frequently provide bush-meat. Forests provide fuelwood, an essential component of many food systems. Some ecosystem services that forests supply are particularly important to nutrition: loss of genetic resources found in crop varieties and crop wild-relatives could have repercussions for bio-fortification. Fruit and vegetable crops (among the most nutritionally important foods) are more sensitive to loss of pollination services (Eilers et al. 2011; Gallai et al. 2009).

Conclusions: Overcoming global malnutrition will require food systems that are simultaneously productive, sustainable and nutrition-sensitive, through management of complex landscapes for optimized nutrition, not just agricultural production and biodiversity conservation. Trees and forests not only contribute to biodiversity conservation and sustainability of agricultural systems, but also to enhanced nutrition-sensitivity of food systems.

Key words: Forests, trees, agricultural systems, nutrition-sensitive, review

PO3297**ROLE OF SLOW DIGESTING CARBOHYDRATES DURING PREGNANCY FOR IMPROVING BONE HEALTH IN OFFSPRING OF OBESE RATS. (NIGO-HEALTH STUDY)**

T. Bueno-Vargas¹, J. López-Pedrosa¹, R. Rueda¹, M. Manzano¹

¹Discovery R&D, Abbott Nutrition, Granada, Spain

Background and objectives: Maternal obesity and accompanying obesogenic dietary intake prior to and throughout pregnancy and lactation program offspring physiological system predisposing not only to a higher risk of developing metabolic syndrome, but also to be at increased risk of low bone mass and fracture development later in life. We examined the effects of two mixtures of carbohydrates (CHO) consumed by pregnant rats, exposed to high fat diet, on bone architecture of adolescent offspring.

Methods: Virgin rats were assigned to one of three experimental groups: control (C) dams fed a standard rodent diet before mating and throughout pregnancy; dams fed a high fat 6 weeks before mating and then fed a HF diet containing either CHO with high (HF/HC) or low (HF/LC) digestion rate throughout pregnancy. At delivery all the animals were fed with the standard rodent diet for the remainder of the study (13 weeks). At adolescence, bones were isolated and analyzed by Micro-CT technology.

Results: Micro-CT analysis of bone showed that maternal HF/HC diet induced alterations in the trabecular architecture of femur of male offspring. HF/LC offspring had significantly improved bone mechanical properties as it is showed with the increase of bone volume fraction and trabecular thickness parameters and the decrease in bone surface-bone volume ratio and Structure model index parameters (t-test; $p < 0.1$ vs HF/HC).

Conclusions: Data show that nutritional intervention with a slow digesting carbohydrate system during gestational period, results in improved bone architecture and bone strength of their progeny. This improvement on offspring trabecular bone must be a key determinant for preventing bone fragility later in life.

Key words: Early programming, dietary carbohydrate, bone

PO330**EFFECTS OF CRYSTALLINE CELLULOSE AND PECTIN IN DIGESTA ON THE BEHAVIOR OF GLUCOSE IN THE INTESTINAL LUMEN**

T. Takahashi¹, N. Ota¹, M. Miyamoto¹, M. Tokunaga¹, M. Furuse², S. Yasuo², D. Oikawa³

¹Fukuoka Women's University, Japan

²Kyushu University, Japan

³Nagasaki University, Japan

Background and objectives: Our mathematical simulation in flow behavior in the gastrointestinal suggested absence of turbulence, which might suggest poor mixing in the molecular levels in the intestine. In poor mixing condition, the diffusion rate of glucose in the digesta should be the rate-limiting factor for the overall glucose absorption. If the condition is valid, greater digesta viscosity should make the glucose gradient steeper in the lumen because the diffusion should depend negatively on the viscosity of the digesta. Therefore, we observed the glucose gradient in the intestinal lumen along the radial axis in artificial digesta including crystalline cellulose and pectin in the suncus.

Methods: We prepared 4 types of artificial digesta containing 20g/L CMC, 100g/L glucose in phosphate buffer and supplemented with both 100g/L crystalline cellulose and 13g/L pectin, 100g/L crystalline cellulose, 13g/L pectin, or containing no additives (control). The viscosity of the artificial digesta were in the order of of the control < crystalline cellulose additive = pectin additive < both cellulose and pectin additive. We infused the artificial digesta into the suncus duodenum via the stomach after hemostasis. After 15 min, the intestine was sampled and froze on dry ice, and then cross section of the intestine was made using a cryostat.

Results: Glucose on the center and peripheral site was sampled and measured the concentration of glucose. The glucose level in the centre of the lumen of cross-section of the small intestine was in the order of the control < either crystalline cellulose or pectin additive < both cellulose and pectin additive.

Conclusions: Glucose gradients should suggest the predominance of glucose diffusion in digesta in overall glucose absorption. Crystalline cellulose and pectin should reduce glucose absorption rate by decreasing the diffusion of glucose on the radial axis of the intestinal lumen.

Key words: cellulose, pectin, viscosity, digesta, diffusion

PO331**PROTEIN-ENERGY WASTING MODIFIES THE ASSOCIATION OF PLASMA LEPTIN WITH INFLAMMATION IN HAEMODIALYSIS PATIENTS**

M. Ruperto¹, G. Barril², S. Bastida¹, F.J. Sánchez-Muniz¹

¹Universidad Complutense de Madrid, Madrid, Spain

²Hospital Universitario La Princesa, Madrid, Spain

Background and objectives: Plasma leptin concentrations may contribute to anorexia and the pathogenesis of protein energy wasting (PEW) in hemodialysis patients (HD). The aim of this study was to investigate the interaction between PEW, systemic inflammation, and plasma leptin concentrations in HD patients and to analyze whether these factors were associated with clinical outcome.

Methods: Cross-sectional study of 45 HD patients (25 males, 55.6%) aged of 68.1 ± 14.5 y. and mean time on HD: 57.2 ± 37.4 months. Clinical PEW assessment, leptin and interleukin-6 (IL-6) were evaluated. Plasma leptin concentrations were stratified into tertiles (lower tertile, T1; medium tertile, T2; higher tertile, T3). Results were tested using the SPSS statistical packet.

Results: PEW was present in 35.6 % of HD patients. PEW was more prevalent in T1 and T2 vs. T3. Multivariate analysis of variance adjusted by gender showed interaction of IL-6, waist circumference (WC), percentage of fat body mass (%FBM) and Charlson comorbidity index (all, $p < 0.01$) with tertiles of plasma leptin. PEW patients in T3 were overweight and had abnormally higher plasma leptin concentration and comorbidities compared to well-nourished patients when both, nutritional status and tertiles of plasma leptin concentration were studied. Significant interactions were found between Plasma leptin tertiles and nutritional status on BMI, WC, IL-6, %FBM and comorbidities values (all, $p < 0.01$).

Conclusions: Plasma leptin concentrations are influenced by nutritional and inflammation status. Results suggest that plasma leptinemia should be analyzed and discussed in the context of PEW and systemic inflammation in HD patients.

Key words: Plasma leptin, protein-energy wasting, inflammation, hemodialysis

PO332**NEW APPROACH OF ESTIMATING THE RISK OF TYPE-2 DIABETES USING OVERWEIGHT-YEARS METRIC**

A. Abdullah¹, F Ali Amin², F Hanum¹, A. Peeters³

¹Department Biostatistics and Population Health, Faculty of Public Health, University Muhammadiyah Aceh, Banda Aceh, Indonesia

²Department Public Health Nutrition, Faculty of Public Health, University Muhammadiyah Aceh, Banda Aceh, Indonesia

³Department Biostatistics and Population Health, Faculty of Public Health, University Muhammadiyah Aceh, Banda Aceh, Indonesia

⁴Baker IDI Heart and Diabetes Institute & Department of Epidemiology and Preventive Medicine, School of Public Health and Preventive Medicine, Monash University, Australia

Background and objectives: Recent study reported that combined the severity and the duration of obesity into a single measure of obese-years was a better predictor of the risk of type-2 diabetes than using the intensity or the duration of obesity alone. However, the analysis, the notion that obese-years was only “switched on” when BMI reaches 30 Kg/m², ignored the effect of overweight - BMI from 25 Kg/m². This study aimed to examine the total impact of “overweight-years” metric – combining the severity of bodyweight and number of years lived with BMI above 25 kg/m² on the risk of type-2 diabetes.

Methods: 5036 participants of the Framingham Heart Study were examined. The severity and the duration of each participant lived with overweight were measured every two years for up to 48 years. Overweight-years was defined and its relationship with the risk of type-2 diabetes was modelled using time-dependent cox regression and compared using the Akaike's information criterion.

Results: The study found that adjusted hazard ratios of type-2 diabetes increased significantly as overweight-years increase and a dose response relationship was clear. hazard ratios for the categories of 0, 1–24.9, 25–49.9, 50–74.9, and ≥75 overweight-years were 2.38 (95% CI:1.73-3.29), 2.79 (95% CI:1.97-3.94), 3.45 (95% CI:2.41-4.94) and 6.00 (95% CI:4.44-8.10) respectively. The risk of type-2 diabetes increased by 6% (95% CI:5%-7%) per additional 10 overweight-years. AIC values indicated overweight-years model was better predictor than the intensity and the duration of overweight alone. Compared with the current model of obese-years, overweight-years model provided a slightly better risk of type-2 diabetes.

Conclusions: Overweight-years is more concisely estimate the risk of type-2 diabetes and it is suggested to consider as an alternative model in estimating the population health burden related with total effect of obesity.

Key words: Overweight, overweight-years, Risk factor, type-2 diabetes

PO333**DIETARY METHIONINE REGULATES THE EXPRESSION OF ASPARAGINE SYNTHETASE AND 3-PHOSPHOGLYCERATE DEHYDROGENASE IN RAT LIVER**

¹Laboratory of Molecular Nutrition, Kyoto Prefectural University, Japan

²Division of Food Science and Biotechnology, Graduate School of Agriculture, Kyoto University, Japan

³Research Unit for Physiological Chemistry, C-PIER, Kyoto University, Japan

Background and objectives: We found that the expressions of Asparagine synthetase (AS) and 3-phosphoglycerate dehydrogenase (PHGDH), a late-limiting enzyme for Ser biosynthesis were changed in response to protein requirement in rat liver. Since the change occurred immediately after dietary shift and depended on protein content in diet, we hypothesized that some amino acids regulate the gene expression. In the present study, we examined the hypothesis to feed rats amino acids mixture lacking in a single amino acid.

Methods: Male SD rats (500–600 g B.W.) were fed protein free diet for several days to induce the expression of AS and PHGDH. The diet was removed at 8 AM and re-feeding was started at 8 PM with the diet contained 12% amino acids mixture based on the amino acids composition of casein, or the mixture lacking in any one of amino acids. Then rats were killed 12 h after re-feeding and the gene expression was determined. In contrast, we maintained rats on amino acids mixture for 4 days to examine whether the gene expression was induced by lack of any one of amino acids.

Results: Protein free diet induced the expression of AS and PHGDH significantly and the diet contained amino acids mixture reduced the expression rapidly to the basal level within 12h after dietary shift. Among amino acids mixtures examined, only the mixture lacking in Met did not showed such decrease. On the other hand, the expression of these enzymes was induced when rats were maintained on the diet lacking in Met but not other single amino acids.

Conclusions: These results suggested that dietary Met regulates the expressions of AS and PHGDH. In addition, our results also showed very similar response of AS and PHGDH gene expression to protein/amino acid nutrition.

²Functional Food Research and Development Centre (CIDAF), Health Science Technological Park, Avda del Conocimiento 3, 18100, Armilla (Granada), Spain

³Inter-Departmental Centre for Agri-Food Industrial Research (CIRI Agroalimentare), University of Bologna, Cesena (FC), Italy

⁴Department of Agro-Food Sciences and Technologies, Alma Mater Studiorum - Università di Bologna, Cesena (FC), Italy

Background and objectives: Cherimoya is a tropical fruit. Nowadays, cherimoya is consumed as fresh fruit, although its industrial use is being currently evaluated. Recently, the number of studies related to economic exploitation of seeds and other by-products proceeding from new oleaginous vegetable sources has increased. Therefore, the aim of this work was the characterization of lipidic fraction of the edible portion of the cherimoya and their by-products.

Methods: Pulp, seed and skin of two different varieties of cherimoya were crushed, liophilized, and lipids were extracted with the Folch procedure. Several chromatographic techniques were used to determine fatty acid, tocopherol, sterol and phospholipid composition.

Results: Different fatty acid compounds were identified in pulp, seed and skin. The major fatty acids were palmitic, oleic, linoleic and linolenic acid. Appreciable differences were detected in pulp, skin and seed fatty acid composition; seed reported as principal fatty acids oleic, linoleic n6 and palmitic acid, respectively. Skin and pulp contained higher content of linoleic n3 fatty acid. alpha-tocopherol and delta-tocopherol were identified only in seeds; moreover alpha-tocopherol was also detected in skin. No tocopherols were quantified in pulp. Three different phospholipid, as phosphatidylethanolamine, phosphatidylinositol and phosphatidylcholine, were identified. Total phospholipid content varied between 8.2 and 184 mg/g of fat. As expected the major content was found in pulpa and skin. Finally, sterols were determined in all samples. Beta-sitosterol was the first sterol in all samples. Surprisingly, gamma-sitosterol was detected only in pulp and skin of Fino de Jete cultivar.

Conclusions: The results obtained confirmed that the lipid distribution depends on the cultivar and, in the same cultivar, it varied in the different zones of the fruit. These preliminary

results suggested that gamma-sitosterol can be used as marker of Fino de Jete cultivar. However further investigations are needed.

Key words: Cherimoya, fatty acids, tocopherols, phospholipids, sterols.

¹⁰Energy Metabolism and Body Composition Laboratory, Institute of Nutrition and Food Technology, University of Chile, Santiago, Chile

Background and objectives: B-vitamins are key adolescence health nutrients. The association between food consumption

and vitamin B6, folate, and B12 intakes and biomarkers was examined in healthy adolescents participating in the HELENA (Healthy Lifestyle in Europe by Nutrition in Adolescence) cross-sectional study.

Methods: 1,664 individuals met the eligibility criteria for analysis of food and vitamin intakes and 494 for biomarker analysis (47% males for both). Foods and vitamin intakes were assessed by two non-consecutive 24-h recalls. Biomarker concentrations were measured by chromatography and immunoassay. Discriminant analysis, expressed as canonical coefficients (from 31 food groups best discriminating individuals in extreme tertiles of intakes and biomarker levels), and linear regression models adjusted for body mass index, maternal education (obtained by self-administered questionnaire), age and total energy intakes, were performed.

Results: Canonical coefficients (males and females) indicated that, apart from typical sources, fruits (0.437 and 0.398), fruit & vegetable juices (0.344 & 0.400), starch roots and potatoes (0.511 and 0.502), vegetables (0.304 for females), and oily fruits (-0.584 for females) for vitamin B6; bread & rolls (0.450 for females), starch roots & potatoes (0.312 for males), fish products (0.588 for females), soft drinks (0.489 for males), and soups (-0.604 for females) for folate; and fruit & vegetable juices (0.505 for females), snacks (1.0 for males), cakes (-0.514 for males), and vegetable oils (0.901 and 0.710) for vitamin B12; were by far the food groups which best discriminated individuals in the lowest and highest tertile of the distribution of vitamins both intakes and biomarkers. Linear regression analysis confirmed these associations between food groups and B-vitamins, intakes or biomarkers.

Conclusions: Some food groups, like snacks in relation to vitamin B12, and not only of their major sources, discriminated individuals by tertiles of the distribution of vitamin B intakes and biomarkers.

Key words: Food groups, B-vitamins, adolescents

PO336

METABOLIC AND CARDIOVASCULAR RISKS AFTER PEDIATRIC LIVER TRANSPLANTATION

M. Araujo¹, Y. Camiser¹, C. Cambaceres¹, C. Mazza¹, O. Inventarza¹

¹Hospital Nacional de Pediatría J P Garrahan, Buenos Aires, Argentina

Background and objectives: More than 500 pediatric liver transplants (LT) have been performed in our hospital since the beginning of the program. Patients with LT adults show an increased prevalence of premature cardiovascular disease (PCVD), but studies in the pediatric population are scarce. The objective was to study the prevalence of cardiovascular risk factors in children with LT treated at a pediatric hospital.

Methods: A descriptive, prospective, cross-sectional. Consecutive patients with LT, more than 5 y age, 1 year or more post transplant, since June 2009-June 2010 were included. Variables related to transplantation, clinical, laboratory including OGTT and carotid thickness intima-media were analyzed. Results are expressed as mean and standard deviation for normally distributed variables. t test, Pearson chi square, multiple regression were used.

Results: 133 pediatric LT patients were studied. Mean age at study 12.8(4.4SD) years, mean age at transplant 5.2(4.2SD) years. Mean time after transplant 7.7(3.6SD) years. All received corticoids. At study 12 p were receiving corticosteroids, 85 cyclosporine, 27 FK, sirolimus 25 p and mycophenolate 71 p. Mean BMI Zscore -0.27(0.9SD). Mean Height Zscore 0.02 and mean weight Zscore -0.3. 6 p were stunted, 36 p low weight for height, 4 p obese, 12 p overweight. 80 p normal weight / height. The mean basal glucose 79.9 mg%(12.8SD). Basal insulin 9.5 U/ml(12.4SD). The insulin resistance (HOMA IR) 2.1(5SD). Mean total cholesterol was 145 mg%(54.8SD), and triglycerides 94mg%(43.3SD) for obesity, 9% of overweight, the prevalence of impaired fasting glucose 3.9%, the prevalence of diabetes 1.6%.

Conclusions: Prevalence of abnormal glucose metabolism 13.4%. There was strong statistically significant association between alterations in glucose metabolism and insulin resistance. No association was found between different immunosuppressive regimens.

Key words: Liver transplantation, risk factor cardiovascular disease

PO337

ULTRAFILTRATION AS MILK CONCENTRATION METHOD FOR THE ELABORATION OF A PROBIOTIC FERMENTED GOAT'S MILK

M. Moreno-Montoro¹, T. Bergillos-Meca¹, M. Navarro¹, M. Olalla¹, R. Giménez¹, R. Artacho¹, C. Cabrera¹, A. Sampedro², J. Rodríguez-Granger², M D. Ruiz-López¹

¹Department of Nutrition and Food Sciences, University of Granada, Granada Spain

²Department of Microbiology, University Hospital Virgen de las Nieves, Granada, Spain

³Institute of Nutrition and Food Technology, University of Granada, Granada, Spain

Background and objectives: Our aim was to improve the whey retention and rheology of a probiotic fermented goat's milk by using ultrafiltration rather than other traditional concentration Methods such as the addition of powdered milk.

Methods: We measured synaeresis, rheology and pH in the following experimental fermented goat's milks: control (skim-

med goat's milk + starter culture), A (skimmed goat's milk + 2% powdered goat's milk + starter culture), B (skimmed goat's milk + 4% powdered goat's milk + starter culture), C (skimmed ultrafiltered goat's milk + starter culture) and D (skimmed ultrafiltered goat's milk + starter culture + *Lactobacillus plantarum* strain C4). 50 KDa ultrafiltration membrane was used and the fermentation process was stopped at pH 4.7 and 4.2.

Results: Dry extract = 9.94 (control), 11.4 (A), 13.67 (B), 12.5 (C) and 13.38 (D). Least syneresis was found in C and D (0%), which may be due to the fact that caseins, which are responsible for the coagulum formation, are more concentrated in ultrafiltered milk. In fact, caseins remain unaltered by ultrafiltration, unlike when subject to desiccation processes. As far as control, A and B fermented goat's milks are concerned, syneresis decreases concomitantly with the addition of powdered milk (14%: control; 5% in A and B samples) and with pH 4.2 (5% in the control yoghurt, 2% in A and B). This may be due to the higher quantity of casein coagulated, the isoelectric point of caprine proteins being 4.2, leading to an improvement in whey retention. Finally, the fermented goat's milk at pH 4.2 showed the best rheology performance.

Conclusions: We consider that ultrafiltration is a better way of concentrating fermented goat's milk than the addition of powdered milk because it affords an improvement in whey retention and higher protein quality in the final product.
