Methods: A total of 407 undergraduates (206 males and 201 females) were selected from four male and three female halls of residence in the University using non probability sampling technique. A pre-tested, interviewer administered semi-structured questionnaire was used to obtain information on demographic, knowledge of nutrition and risk factor of cancer (20 points), lifestyle, dietary pattern, and anthropometric indices were taken. Nutritional status was determined using the World Health Organization growth standard. Descriptive statistics and Chi-square test were performed on data at 5% level of significance.

Results: Mean age of respondents was 21.42 ± 2.58 (male) and 20.44 ± 2.36 (female). Mean nutrition knowledge score in relation to risk of cancer was 10.72 ± 4.34 and 11.77 ± 4.75 male and female respectively ($p < 0.05$). No significant difference existed in awareness of risk factors of cancer between male and female. Respondents' physical activities were moderate: 19.4% daily, 8.1% 4-6 times/week, 21.6% 2-4 times/week and 50.9% less than 2 times/week. Mean BMI was 22.16 ± 3.13 (male) and 22.60 ± 3.52 (female). 35.7% and 64.3% male and female were obese ($p < 0.05$). Fried foods, smoked fish, cured meat consumption was high while consumption of fruits and vegetables was low.

Conclusions: Health promotion activities that aim to enhance student's awareness of good nutrition and risk factors of cancer should be promoted among the undergraduates.

Key words: nutrition knowledge, lifestyle, dietary pattern, cancer.

PO2097

GENDER MODERATES THE RELATIONSHIP BETWEEN PSYCHOLOGICAL DISTRESS AND DISORDERED EATING AMONG MALAYSIAN UNIVERSITY STUDENTS

W.Y. Gan¹, M.T. Mohd Nasir¹, M.S. Zalilah¹, A.S. Hazizi¹

¹Department of Nutrition and Dietetics, Universiti Putra Malaysia, Serdang, Selangor, Malaysia

Background and objectives: Recent studies have shown that Asian students are at higher risk of developing disordered eating than previously believed. This cross-sectional study aimed to examine gender differences in the relationship between psychological distress and disordered eating among Malaysian university students.

Methods: A total of 584 university students (59.4% females and 40.6% males) completed a self-administered questionnaire on the Eating Attitudes Test-26 (EAT-26) and Depression, Anxiety and Stress Scale-21 (DASS-21). A multi-group analysis in Structural Equation Modeling which was the simultaneous analysis on both male and female students was performed to examine if the model was statistically equivalent across gender by comparing the unconstrained model, which allowed the path between psychological distress and disordered eating to vary across genders with another model, which constrained the path between genders to be equal. The model fit statistics with and without such constraints were compared.

Results: The fit indices for the unconstrained model were $F = 49.90$, $df = 37$, $CFI = 0.995$, $SRMR = 0.035$, $RMSEA = 0.017$ (90% CI = 0.009–0.027); while the fit indices for the constrained model were $F = 65.70$, $df = 44$, $CFI = 0.991$, $SRMR = 0.045$, $RMSEA = 0.021$ (90% CI = 0.009–0.030). Results showed that

there was a significant difference in the fit for the two models ($F= 15.8$, $p<0.05$), indicating that the path between psychological distress and disordered eating differed by gender. Gender was a moderator in this relationship, in which the relationship was stronger in females ($P = 0.82$) than in males ($P = 0.61$).

Conclusions: Interventions related to psychological distress targeted at preventing disordered eating should be planned differently for both genders.

Key words: Psychological distress, disordered eating, gender, moderator

PO2098

NATURAL KILLER T CELLS IN OBESITY -RELATED LIVER DISEASE

R R. Mabrouk¹, A. Yassin, R. Elkabarity, H. Zayed

¹Faculty of Medicine, Ain Shams University, Cairo, Egypt.

Background and objectives: Liver involvement in obesity falls within a clinical entity called NAFLD. Potential steps involved in the pathogenesis of NAFLD include abnormal patterns of cytokine production among other inflammatory and lipid abnormalities. Although studies suggested that NKT cells may have a protective role in animal models of NAFLD, yet results have been reported to be controversial. NKT cells were reported to be correlated negatively to disease severity and in other studies being increased promoting the liver injury. The objective of this work was to determine the obesity related complication markers and the percentages of NKT cells in the peripheral blood of obesity related liver disease.

Methods: The study was conducted at the outpatient clinic in Ain Shams University on 30 patients with NAFLD along with 20 healthy controls. They were subjected to thorough clinical examination, anthropometric measurements, blood glucose level, hs-CRP, HOMA-IR and percentages of NKT cells by flow cytometry.

Results: This study revealed a statistically significant elevation of the mean FBS, HOMA, hs-CRP and lipid profile in patients group when compared to normal healthy controls. The median percentage of NKT cells [CD3+/CD56+] was significantly lower in patients group when compared to control group. A negative statistical significant correlation was found between the NKT cells and the fasting blood glucose.

Conclusions: This study concluded that NAFLD was associated not only with the obesity related complications markers but also with significant decrease of NKT cells.

Key words: NAFLD: Nonalcoholic fatty liver disease NKT cells: Natural Killer T cells, HOMA-IR: Homeostasis model assessment of insulin resistance.

PO2099

POTENTIAL IMPACTS ON NUTRITIONAL MANAGEMENT IN CANCER: COMPLEMENTARY AND ALTERNATIVE THERAPY USAGE IN A SCOTTISH PEDIATRIC COHORT

R. Revuelta Iniesta¹, M L. Wilson², K. White³, L. Stewart², J M. McKenzie¹, D C. Wilson²

¹Dietetics, Nutrition and Biological Health Sciences, Queen Margaret University, Edinburgh, UK

²Department of Child Life and Health, University of Edinburgh, Edinburgh, UK

³Department of Haematology and Oncology, Royal Hospital for Sick Children, Edinburgh, UK

Background and objectives: The use of complementary and alternative therapies (CAT) in paediatric oncology patients is popular worldwide, yet data from the UK is scarce. CAT which are biological in origin can interact with conventional cancer treatment. Our objectives were to determine the usage of CAT in the paediatric oncology population of SE Scotland and to establish both the reasons for its use and perceived benefits.

Methods: A retrospective survey was performed using a previously piloted questionnaire, which was distributed between 2006-2009. Eligibility criteria included children aged <18 years, diagnosed with a first time cancer and managed by the SE Scotland paediatric service. Demographic and clinical data were collected and descriptive statistics were employed to establish frequencies. Univariate associations were established by means of χ^2 -test.

Results: 169 families were approached and 74 (43.7%) returned completed questionnaires. Of these, 41 (55.4%) reported having used CAT whilst their children were receiving conventional cancer treatment. Higher socioeconomic status was significantly associated with an increased use of CAT ($\chi^2 = 46.718$, $p < 0.001$). Of the biological CAT, the most popular were vitamin and mineral supplements ($n=22$; 52.6%) followed by fish oils ($n=12$; 29.2%) and herbal remedies ($n=11$; 26.8%). 72% of families perceived CAT to be beneficial and the most common reasons for CAT use were to improve quality of life ($n=15$; 36.5%) and to reduce both stress and side effects ($n=10$; 24.4%).

Conclusions: The use of CAT is highly prevalent in this cohort. Although, this is the largest retrospective study in the UK, more epidemiological and high quality interventional studies are required to provide clinicians with evidence based guidance on the safety and efficacy of different CAT, particularly the effects of biological based therapies and their potential interactions with conventional treatments.

Key words: complementary therapy, children, cancer

PO2100**THE LONG-TERM GREEN OR BLACK TEA DECOCTION CONSUMPTION IMPROVED OMEGA N-3 FATTY ACIDS COMPOSITION OF PLASMA AND LIVER IN RATS***C. Snoussi¹, M H. Hamdaoui¹*¹Research Unit, High School of Health Sciences, Tunis EL Manar University, Tunisia

Background and objectives: The effect of green or black tea decoction (GTD, BTD) on dietary omega n-3 polyunsaturated fatty acids (EPA and DHA), known by their high cardiovascular disease protect is still unknown. Our objective was to study the influence of the long-term GTD and BTD consumption on the omega-3 fatty acids composition of plasma and liver in rats fed high-fat diet (HFD) containing omega n-3 (7% of total PUFA).

Methods: Male Wistar rats were used during 10 weeks. The rats of the group 1 received the HFD+ distilled water (CGr), the group 2 received the HFD +GTD (GTGr) and the group 3 received the HFD+BTB prepared from 50g/L (BTGr). At the end of the experimental period, blood was collected for determination of plasma lipids. The liver was removed, weighed and conserved. The extraction of lipids from the HFD, the plasma and the liver was determined using Folch method. The fatty acid methyl esters were analyzed on a Gas Chromatograph with a flame ionization detector and a capillary column. Values are means of triplicates analyzes for each sample±S.E.M. Results are expressed in % of total fatty acids and compared by ANOVA.

Results: After 10 weeks treatment, GTD and BTB significantly increased plasma polyphenols (CGr: 31±3.3 vs GTGr: 101.3±6 and BTGr: 76.6±9.4 µg/mL, $p < 0.05$). Additionally, they increased plasma EPA + DHA (CGr: 8.4±0.5 vs GTGr: 23.5±0.5 and BTGr: 27.2±0.4 %, $p < 0.05$) and liver EPA + DHA (CGr: 9.9±0.6 vs GTGr: 16.5±0.6 and BTGr: 21.2±0.4 %, $p < 0.05$).

Conclusions: Taking long-term GTD or BTB significantly improved the profile of plasma and liver EPA+DHA composition which could be an effective way to reinforce the protect against cardiovascular diseases.

Key words: Black tea, green tea, omega n-3 polyunsaturated fatty acids, liver, plasma.

PO2101**ANTI-INFLAMMATORY EFFECTS OF FARNESOL, A SESQUITERPENE, ON OVALBUMIN-SENSITIZED AND -CHALLENGED ASTHMATIC MICE***J.Y. Lin¹, C.M. Ku¹*¹Department of Food Science and Biotechnology, National Chung Hsing University, Taichung, Taiwan, ROC

Background and objectives: Farnesol, that is a sesquiterpene (C₁₅H₂₆O) widely exists in fruits, vegetables, herbs and essential oils was found to have a relative Th1-inclination property on immune cells in vitro, suggesting that it may be applied to improve Th2-skewed allergic asthma. To investigate the protective effect of farnesol on asthmatic inflammation, farnesol was administered to ovalbumin (OVA)-sensitized and -challenged mice.

Methods: Three farnesol doses, including low dose (0.003%), medium dose (0.017%) and high dose (0.067%), were extra-added into the AIN76 feed consumed by the OVA-challenged mice continuously for 5 weeks. The experimental mice sacrificed and their body weights, feed intakes and weights of visceral organs were analyzed. Cytokine and inflammatory mediator levels in bronchoalveolar lavage fluid (BALF) and the supernatant of peritoneal macrophage cultures from the experimental mice were determined.

Results: The results showed that there were no significant differences in body weights, feed intakes and visceral organ weights between farnesol supplementation groups and dietary control group, suggesting that farnesol supplementation at the indicated doses shows no apparent toxicity to the experimental mice. However, farnesol supplementation decreased interleukin (IL)-6/IL-10 ratios in BALF, suggesting an anti-inflammatory effect of farnesol on the lung and the airways. Furthermore, OVA sensitization and challenge significantly ($P < 0.05$) inhibited IL-1 β , IL-6, tumor necrosis factor (TNF)- α and IL-10 productions by peritoneal macrophages. Importantly, farnesol supplementation significantly increased the suppressed cytokines levels, but slightly decreased TNF- α , IL-10 (pro-/anti-inflammatory) cytokine secretion ratios, indicating that farnesol may enhance immunity but inhibit inflammation in asthmatic mice.

Conclusions: In conclusion, farnesol supplementation at appropriate doses showed no toxic side effects on asthmatic mice, but might improve immunity and allergic inflammation.

Key words: allergic asthma; anti-inflammatory effects; cytokines; farnesol; sesquiterpene.

PO2102**GLUCOSE DISPOSITION INDEX BASED ON THE ORAL GLUCOSE TOLERANCE TEST IN CHILEAN ADULTS**

M. Morales¹, J L. Santos¹, C. Arancibia¹, O. Barrera¹, J. Galgani¹, J P. Valderas¹, F. Pollak¹

¹Department of Nutrition, Diabetes and Metabolism, School of Medicine, Pontificia Universidad Catolica de Chile, Santiago, Chile

Background and objectives: Insulin secretion and insulin sensitivity indexes derived from intravenous glucose tolerance tests are mathematically related by hyperbolic functions. This type of relation allows the calculation of the glucose Disposition Index (DI) as the product of the acute insulin response and the insulin sensitivity index. Our objectives are to evaluate the hyperbolic relation between insulin secretion and insulin sensitivity indexes calculated from Oral Glucose Tolerance Test (OGTT) and to assess the discriminatory capacity of an Oral Disposition Index (ODI) in Chilean adults with different range of glucose tolerance.

Methods: A sample of 744 adults (age: 48±14 years; 83% women) completed an OGTT with glucose and insulin measurements. Subjects were classified into 5 groups: Normal Glucose Tolerance (NGT; n = 369), Impaired Fasting Glucose (IFG; n = 114), Impaired Glucose Tolerance (IGT; n = 167), IFG+IGT (n = 46) and Diabetes Mellitus (DM; n = 48). The Insulino-genic Index, the First-Phase Stumvoll Index and the Insulin-to-Glucose Area-Under-Curve ratio (AUCIns/Glu) were used as insulin secretion indexes, while ISI-Comp index was used as a measure of insulin resistance. Adjustment to hyperbolic function was assessed after logarithmic transformation and statistical evaluation of the negative slope ($m = -1$) by Deming regression.

Results: An satisfactory statistical adjustment for an hyperbola was found between AUCIns/Glu and ISI-Comp Index in all groups (NGT, $m = -1.04$; 95%CI: -1.2,-0.8; IFG, $m = -2.3$; 95%CI:-3.8,-0.9; IGT, $m = -0.98$; 95%CI: -1.2,-0.7; IFG+IGT, $m = -1.03$; 95%CI: -1.5,-0.5; and DM, $m = -0.94$; 95%CI: -1.5,-0.5). ODI showed differences across study groups ($p < 0.01$): NGT, 472±176; IFG, 476±1130; IGT, 233±68; IFG+IGT: 166±49; DM: 136±65. Receiver Operating Characteristic (ROC) analysis showed adequate discriminatory capacity of ODI (AU-CROC=0.98; 95%CI: 0.97-0.99; NGT versus diabetes).

Conclusions: ODI constitutes a simple surrogate of insulin secretion relative to insulin sensitivity that replicate mathematical properties of DI showing discriminatory capacity in Chilean adults with varying degree of glucose tolerance.

Key words: insulin, glucose, disposition index, diabetes.

PO2103**TYPE OF VEGETARIAN DIET AND PREVALENCE OF DIABETES IN ADULT MEN AND WOMEN IN INDIA**

S. Agrawal¹, C. Millett², SV. Subramanian³, S. Ebrahim⁴

¹South Asia Network For Chronic Disease, New Delhi, India

²Imperial College, London, UK

³Harvard School of Public Health, Boston, USA

⁴LSHTM, London, UK

Background and objectives: Vegetarian diets may play a beneficial role in promoting health and preventing diabetes epidemic in developing countries. We examined the prevalence of diabetes among adult men and women in India following different types of vegetarian diet compared with that in non-vegetarians.

Methods: Analysis is based on a population based cross sectional data of 99,574 women and 56,742 men aged 20-49 years included in India's third National Family Health Survey, conducted during 2005-06. Information on socioeconomic, demographic, anthropometric, lifestyle and self-reported medical conditions were collected by face to face interview. Associations between type of vegetarian diet (vegan, lacto-vegetarian, lacto-ovo vegetarian, pesco-vegetarian, semi-vegetarian and non vegetarian), categorization based on frequency of consumption (daily, weekly, occasionally and never), and self-reported diabetes were estimated using multivariate logistic regression.

Results: Prevalence of diabetes varied from 0.9% each in lacto-vegetarian, lacto-ovo vegetarian and semi-vegetarian to 1.2% in nonvegetarians and highest in pesco-vegetarian diets (1.4%). After adjustment for age, education, household wealth, rural/urban residence, religion, caste, smoking, alcohol use, television watching and BMI, lacto-vegetarian (OR:0.67; 95%CI:0.58-0.76; $p < 0.0001$), lacto-ovo vegetarians (OR:0.69; 95%CI:0.50-0.95; $p = 0.023$) and semi-vegetarians (OR:0.76; 95%CI:0.60-0.98; $p < 0.033$) had a lower risk of diabetes than non-vegetarians.

Conclusions: In a large sample of adult men and women in India, variants of vegetarian diets such as lacto-vegetarian and lacto-ovo vegetarian were associated with 30% or more reduction in risk of diabetes. Semi-vegetarian diets were associated with intermediate risk reduction, about one-quarter than non-vegetarian diets. The protection afforded by lacto-vegetarian was strongest. These findings are important for public health interventions in diabetes care in India but warrants replication in studies with different methods of measuring dietary intake and objective assessments of diabetes.

Key words: type of vegetarian diets; diabetes; men; women; NFHS-3; India

PO2104**EFFECT OF CONSUMPTION OF DARK CHOCOLATE ON THE EXPRESSION OF PROINFLAMMATORY CYTOKINES IN OLDER ADULTS WITH DIABETES MELLITUS II**

M. Pita-López¹, P. Acosta-Aguilar^{1,3}, P. Ortiz-Lazareno², A. Cárdena-Villalvazo³, P. López-Urriarte⁴, F. Santoyo-Telles⁵, M. Padilla-Galindo^{1,3}

¹Molecular Biology and Immunology Unit, South University Center, University of Guadalajara, , Guzmán City, Jalisco, México

²División de Inmunología, Centro de Investigaciones Biomédicas de Occidente (CIBO), Instituto Mexicano del Seguro Social (IMSS), Guadalajara, Jalisco, México

³Behavioral feeding and nutrition research center. South University Center, University of Guadalajara, Guzmán City, Jalisco, México

⁴Laboratorio de Evaluación del Estado Nutricio. Departamento de Reproducción Humana, Crecimiento y Desarrollo Infantil. Centro Universitario de Ciencias de la Salud (CUCS), Universidad de Guadalajara. Guadalajara, Jalisco, Mexico

⁵Departamento de Ciencias Exactas Tecnologías y Metodologías, Centro Universitario del Sur, Universidad de Guadalajara, Guzman city , Jalisco, México

Background and objectives: The feeding behavior of the elderly and immune senescence are risk factors for Inflammation. Healthy elderly show chronic inflammation, which can be modulated by the use of anti-inflammatory foods that modulate the secretion of pro-inflammatory cytokines. Consuming foods such as dark chocolate (polyphenols) modulates the transcription and secretion of pro-inflammatory cytokines. The aim of this study was to determine the effect of chocolate consumption for 4 weeks on the plasma concentrations of IL-2, IL-5, IL-12, IL-13 and TNF- α in older adults with diabetes mellitus II.

Methods: We performed a clinical intervention study, involving 11 older adults with type II diabetes self-reported; 3 controls (average: 65 years old, glucose 112 mg/dL) and 8 experimental (average: 69 years old, 143 mg glucose/dL). Older adults were instructed to consume 20 g of dark chocolate (Rey Amargo)/day (200 mg polyphenols) for 4 weeks. Cytokine expression was evaluated using the Human Flow Cytomix Kit eBiosciences 13 plex by flow cytometry.

Results: We compared the average plasmatic cytokines of two groups after to treatment: control and experimental via a statistical analysis of T-test for independent samples, there was not statistically significant to IL-2 ($p = 0.604$), IL-5 ($p = 0.526$), IL-12 ($p = 0.706$), IL-13 ($p = 0.567$) and TNF-alpha ($p = 0.755$). It may be that there was no difference because the

BMI for controls was 30 and 29 for experimental, which indicates overweight. Perhaps to observe the effects of anti-inflammatory polyphenols in dark chocolate, in older adults with diabetes II, must increase the g of chocolate consumed per day, the number of participants and intervention days.

Conclusions: The consumption of 20 g of dark chocolate for 4 weeks does not decrease the concentration of proinflammatory cytokines in plasma of older adults with diabetes II compared to the control group.

Key words: dark chocolate, proinflammatory cytokines, Inflammation, diabetes mellitus II.

PO2105**DIETARY PATTERNS AND BMI AND SERUM LIPIDS IN A POLISH WOMEN**

K. Przybylowicz¹, J. Hamuka², A. Wawrzyniak², K. Janiszewska¹

¹Department of Human Nutrition, University of Warmia and Mazury, Olsztyn, Poland

²Department of Human Nutrition, Warsaw university of Life Sciences, Warszawa, Poland

Background and objectives: BMI, biochemical parameters have been recognized as an emerging risk factor for cardiovascular disease. Associations between dietary patterns and cardiovascular disease risk factors remain unclear. The objective of this study was to evaluate the association between dietary patterns and BMI and the levels of serum lipids in a Polish women.

Methods: A total of 453 women aged between 39 and 59 years were included in this study. The evaluation of the eating manner was made using the individual 24-hour recall method, repeated 7 times, and made in irregular terms of time. To establish dietary patterns, factor analysis was performed, which led to characterization of the Varied and Fatty dietary patterns.

Results: Individuals in the top quintile of the Varied dietary pattern had lower BMI [odds ratio (OR), 0.62; 95% CI, 0.48–0.81] than those in the lowest quintile. In contrast, the Fatty dietary pattern was associated with higher BMI (OR, 1.54; 95% CI, 1.03–2.29). The major dietary patterns and the levels of lipid profiles were not associated. The lack of a significant association between the major dietary patterns and the level of serum lipids in our study is surprising, but it must be taken into account that dietary patterns are not the single determinant of serum lipid profiles. Other factors such as physical activity, and smoking should also be considered.

Conclusions: Dietary patterns were associated with being overweight or obese but not associated with the level of lipids in a Polish women.

Key words: dietary patterns, women, lipids, cardiovascular disease.

PO2106**PREVALENCE OF ANEMIA IN CHILDREN AND ADOLESCENTS AFTER NUTRITIONAL INTERVENTION***L. Ribeiro¹, L. Rodrigues¹*¹Unirio, Rio de Janeiro, Brazil

Background and objectives: Anemia and overweight are considered the major public health problems in children and adolescents who may have a negative impact in their current and future life. According to the WHO, anemia affects 30% of the world population, and 50% can be attributed to iron deficiency. The objective of this study was to describe the prevalence of anemia in children and adolescents with weight excess before and after nutritional intervention.

Methods: A descriptive observational study was conducted with a sample of children and adolescents that were recruited to take part in a clinical trial in pediatric nutrition clinic of a university hospital. Were selected children above 2 years of age with an IMC \geq p85 coupled with the presence of alterations in lipid profile and/or blood pressure. After the first visit, before and after intervention, a complete blood count was performed for diagnosis of anemia with the following criteria: hemoglobin (Hgb $<$ 11g/dL), MCV $<$ 80fL, MCH $<$ 27pg and RDW $<$ 13%. The study was conducted for 6 weeks (PO and P6). Descriptive statistics and paired t sample test and the significance level were 0.05. The sample consisted in 135 aged 10.2 ± 2.8 years, 50% male and weight 57.3 ± 21.8 kg at PO and 55.1 ± 21.5 kg at P6 both indicating obesity, but with a significant reduction. The values of Hgb, MCV, MCH and RDW at PO and P6 were, respectively: 13.2 ± 1.1 g/dL/ 13.2 ± 0.9 g/dL, 27.0 ± 1.8 fL/ 27.3 ± 2.0 fL, 81.4 ± 5.2 / 81.2 ± 4.7 and 14.1 ± 1.0 pg/ 14.2 ± 1.4 pg. No significant changes occurred between the two periods ($p < 0.05$) except for HGM that had a small improvement. There was reduction of BMI and weight and increase in HGM, but no statistical change of the other indices related to iron status, despite the use of oat flakes. This success can be attributed to the guidance provided at baseline regarding factors activators and inhibitors of iron absorption.

Key words: anemia; obesity; children; intervention

PO2107**INTERNET-BASED WEIGHT LOSS PROGRAMS: A REVIEW***C. Torreglosa^{1,2}, A. Galante², C. Colli¹*¹Department of Food Sciences and Experimental Nutrition/ Faculty of Pharmacy/ University of São Paulo, São Paulo, Brazil²Department of Nutrition/ Centro Universitário São Camilo, São Paulo, Brazil

Background and objectives: The high prevalence of overweight and obesity among adults is a concern in public health because of their strong relation with heart disease, stroke, diabetes and cancer. Programs for weight reduction via web are viable, affordable and complementary to the consensual pharmacological and surgical therapies. In addition, many studies have been showed that internet-based program designed for third generation computers could promote tailoring nutrition education. The scope of this review was to evaluate the potential impact of internet-based programs on weight reduction.

Methods: A search of articles published between 2002 and 2012 at MEDLINE and EMBASE was conducted using the key words internet, overweight, obesity, body weight changes, food habits, web-based, computer tailoring, nutrition education and adults and only randomized controlled trials were included.

Results: 201 articles were found, of these 15 trials were selected for analysis. 78% of studies recruited obesity patients (BMI 30-34.9 kg/m²), from both genders and between 36 to 50 y. 33% of these studies presented 6 months follow-ups and 60% had more than 20% losses at the end. The weight reduction achieved by web groups ranged considerably from 0.9 to 8.8 Kg. Despite this, studies with web programs designed for third generation computers seemed to be able to promote more than 5% of weight loss than the others web interventions.

Conclusions: This review highlights the need of new studies that focus on improving the treatment adherence and on giving assistance during weight loss maintenance period. However, the internet-programs appear to be a new and viable tool on nutritional clinical practice.

Key words: weight loss, web-based, computer-tailoring.

PO2108**OBESITY HAS LEVELED OFF IN FINLAND: FORTY-YEAR TRENDS OF OBESITY FROM THE NATIONAL FINRISK STUDY**

S. Männistö^{1,2}, T. Laatikainen¹, K. Harald¹, K. Borodulin¹, P. Jousilahti¹, M. Peltonen¹, E. Vartiainen¹

¹Department of Chronic Disease Prevention, National Institute For Health and Welfare, Helsinki, Finland

Background and objectives: The proportion of obese adults has reached an epidemic scale worldwide, moving steadily away from the Healthy People 2010 goal of 15 % prevalence of obesity (BMI>30kg/m²). Obesity is one of the leading risk factors for the global disease burden, and its importance has increased over the last decades.

Methods: This study is part of the National FINRISK Studies, which have been carried out regularly every five years to monitor the cardiovascular risk factors in Finland. The cross-sectional representative samples included 8000-10000 working-age adults from 2-5 geographical areas (participation rates 60-90%). We investigated the long-term trends (1972-2012) and recent changes (2007-2012) in BMI by age groups and area. Weight and height were measured by a standardized international protocol.

Results: The BMI trend increased among Finnish men from the 1970's and among women from the 1980's. Although the newest results from 2012 showed that the prevalence of obesity has leveled off over the last ten years, 66% of men and 46% of women had BMI at least 25 kg/m², and of those one in five were obese (BMI≥30kg/m²). The mean BMI was 27.1 kg/m² for men and 26.0 kg/m² for women. In general, overweight subjects carry an average of 10 kg and obese subjects of 30 kg excess fat load compared with normal weight subjects. The participants who lived in the metropolitan area were thinner than the others. The BMI differences between age groups were higher in women than in men.

Conclusions: Finland is among those few countries where obesity trends have appeared to be leveling off over the last years. However, the prevalence of obesity has consistently remained high. The National Obesity Prevention Program 2012-2015 is established in order to lower the prevalence of obesity and obesity-related diseases.

Key words: BMI, obesity, survey, trends.

PO2109**NUTRITIONAL ASSESSMENT, SUPPORT AND DIET INDICATED IN ONCOLOGY INPATIENTS.**

L. Arribas¹, E. Fort¹, L. Hurtós¹, I. Peiró¹

¹Clinical Nutrition Unit, Institut Català D'Oncologia, L'Hospitalet de Llobregat, Barcelona, Spain

Background and objectives: The aim of the study was to assess the nutritional status, nutritional support and the prescriptive diet of oncology inpatients.

Methods: A cross-sectional study was performed at the oncology and hematology wards. A patient generated subjective global assessment (PG-SGA) was carried out including the type of nutritional support given. In parallel the hospitalized diet system was analyzed of those patients evaluated, i.e. the indicated diet was the most appropriated for the clinical situation and if there was any mistranscription until the diet is served on the ward.

Results: 46 patients were evaluated (21 men and 25 women). After the PG-SGA, 67.4% of patients were malnourished or at risk of malnutrition, 21.7% of which were severe malnourished. Between the oncology and hematology wards there were no statistically differences on malnutrition. Malnutrition was present in 62% of the patients hospitalized for less than 10 days versus 76.4% in patients with longer length of stay. Despite high percentage of malnutrition only 21.7% has been assessed by the clinical nutrition unit. Regarding the prescription of the diets, 28.3% had mistakes in the indicated diet and 3 mistranscriptions from the ward to the catering were found.

Conclusions: Patients admitted to a cancer hospital have a high degree of malnutrition. This figure rises with prolonged hospital stay. We need awareness of health professionals of our center for screening and subsequent nutritional consulting the nutrition unit to patients during hospitalization. It is important to conduct training sessions on the wards for proper indication of the diets.

Key words: nutritional assessment, diet, cancer.

PO2110**INTERMITTENT FASTING MODULATION OF THE DIABETIC NEPHROPATHY SYNDROME IN STREPTOZOTOCIN-INJECTED RATS**

L. Belkacemi^{1,2}, G. selselet-Attou¹, M H. Antoine², J. Nor-tier², E. Hupkens², A. Sener², W. Malaisse²

¹Laboratory of Food Technology and Nutrition, Mostaganem University, Mostaganem, Algeria

²Laboratory of Experimental Hormonology, Free University of Brussels, Brussels, Belgium

Background and objectives: Intermittent fasting miming Ramadan fasting was previously reported to exert a beneficial effect on hyperglycemia and pancreatic parameters on streptozotocin-induced diabetic rats. Our aim was to afford several new pieces of information concerning intermittent fasting effect on diabetic nephropathy.

Methods: Wistar rats were injected intraperitoneally with streptozotocine (STZ) (65 mg/kg body wt.) freshly dissolved in a citrate buffer (50 mM, pH 4.5). Control rats were injected with the citrate buffer. Only rats displaying a glycemia in excess of 16.7 mM were kept for further investigations. Control and STZ rats were either given free access to food throughout the experimental period (NF: non-fasting), deprived of food from 5 p.m. to 8 a.m. (IF: intermittently fasting) or given access onwards to an amount of food comparable to that ingested by the IF rats (CR: calorie-restricted). Relative to the food intake in NF rats, such a caloric restriction represented a 20% and 40% decrease in food intake respectively in the control animals and STZ rats. Plasma creatinine and urea concentration was measured. Renal sections were stained with Schiff periodic acid and immunostaining for PCNA detection.

Results: Kidney histology revealed that, in the streptozotocin rats, intermittent fasting prevented such anomalies as the presence of Armani-Ebstein cells in proximal tubules. The kidney PCNA index was lower ($p < 0.04$) in the IF and CR STZ rats (150.3 ± 12.5 10⁻⁴; $n = 80$) than in the NF STZ rats (209.3 ± 30.5 10⁻⁴; $n = 40$). A comparable situation prevailed in the case of the plasma concentration of urea and creatinine in IF and CR STZ rats.

Conclusions: Improvement of hyperglycemia and beta cell mass by intermittent fasting may exert a favorable effect on diabetic nephropathy.

Key words: streptozotocin-induced diabetic rats, diabetic nephropathy, PCNA, intermittent fasting.

PO2111**IDENTIFICATION OF NUTRITION TRANSITION IN PATIENTS TREATED BY DIALYSIS IN A BRAZILIAN HOSPITAL**

F P. Maniglia¹, J A C da Costa¹

¹Faculty of Medicine of Ribeirão Preto (University of São Paulo), Ribeirão Preto, São Paulo, Brazil

Background and objectives: It is known that the nutritional state is a strong determinant of the prognosis of individuals with chronic kidney disease, treated by dialysis. The nutritional transition which took place over the past years also reached the dialysis population, creating a common paradox "overweight and nutritional deficiencies". This study had as aim verify the nutritional state of patients treated by hemodialysis in a Brazilian hospital.

Methods: the study included 42 patients with average 51.31 ± 15.5 years old (from 23 to 79), of which 57% is represented by the male gender, and with an average of dialysis therapy of 41.14 ± 38.56 months (from 5 to 185 months). Were used anthropometric parameters [after-dialysis weight, stature and Body Mass Index (BMI)] and laboratorial (serum albumin and total proteins).

Results: the results pointed a BMI average of 24.94 ± 6.06 kg/m² on adults, classifying them at the upper limit of eutrophia. Among the individuals, two were defined as malnourished, with one of them classified as critical. Eleven adult participants presented overweight and one was classified as obese level II. The individuals beyond 60 years old shown an average BMI of 25.21 ± 4.06 kg/m², revealing themselves eutrophics in the majority according to the Pan American Health Organization (PAHO). Still considering the PAHO, four elderly individuals were classified underweight and five were overweight. The average of serum protein of all participants (5.21 ± 0.59 g/dL) did not show impairment of the nutritional state, as well as the average of the total proteins (9.64 ± 1.3 g/dL). There was no correlation between the BMI and serum albumin ($p = 0.45$).

Conclusions: the patients treated by dialysis reflects not just the current epidemiological transition, but also the nutritional transition, being necessary follow the serum concentration of vitamins and minerals in order to analyze if they also follow the verified trend.

Key words: chronic kidney disease, nutritional state, albumin.

PO2112**NUTRITIONAL KNOWLEDGE AND ASSOCIATION WITH DIETARY PRACTICES AMONG CANCER PATIENTS: A CASE STUDY OF KENYATTA NATIONAL HOSPITAL CANCER TREATMENT CENTER.***C. Muthike¹, J. Imungi, G. Muchemi*¹University of Nairobi, Nairobi, Nigeria

Background and objectives: The main objective of the study is to assess the nutritional knowledge and determine its association with dietary practices of cancer patients. Also to determine the socio-economic and socio-demographic characteristics of cancer patients attending the cancer treatment center at KNH. To determine nutritional knowledge among cancer patients attending cancer treatment center at KNH. To determine dietary practices among cancer patients attending cancer treatment center at KNH. The hypothesis is that there is no association between nutritional knowledge and the dietary practices of the cancer patients.

Methods: This study was cross-sectional design. The study involved patients attending the cancer treatment center for a period of 3 weeks where patients were interviewed through questionnaires related to nutritional knowledge, food frequency and dietary diversity.

Results: Pearson's correlation coefficient showed a positive correlation between nutrition knowledge and dietary diversity score $r = 0.392$, $n = 130$, $p = 0.000$. The odds ratio between nutritional knowledge and fruit frequency, 10 using binary logistic regression, $P = 0.018$.

Conclusions: There is association between nutritional knowledge and the dietary practices of the cancer patients.

Key words: cancer, nutritional knowledge and dietary practice.

PO2113**ASSOCIATION BETWEEN IRON NUTRITION AND INFLAMMATION WITH TYPE 2 DIABETES DEVELOPMENT***M. Arredondo-Olguín^{1,2}, M. Andrews¹, N. Soto², I. Acevedo¹, V. Candia¹*¹INTA, University of Chile, Santiago, Chile²Arriaran Hospital, SSMC, Santiago, Chile

Background and objectives: Type-2 diabetes mellitus (T2DM) patients present increased iron storage and high levels of oxidative stress parameters. Also, T2DM share with obesi-

ty a pro-inflammatory profile. The aim was to evaluate mRNA expression of genes related to iron nutrition and inflammation in patients obese with or without T2DM and to evaluate its association with type-2 diabetes development.

Methods: We studied 48 obese men (OB); 40 diabetic patients (DM), 44 obese diabetics subjects (OBDM) and 43 healthy subjects (Cn). Glucose, insulin, lipid profile, oxidative stress parameters, and iron nutrition were evaluated. In peripheral mononuclear cells (PMCs) we isolated RNA and we studied the expression of TNF α , hepcidin, TLR4, TLR2, NF κ B, and mTOR by qPCR.

Results: Ferritin levels were higher in OB; DM and OBDM than Cn groups (in g/L: 89.7; 76.2; 92.8 and 71.1, respectively. One way ANOVA $p < 0.005$). Total body iron (TBI) and hs-CRP showed the same behavior (One way ANOVA $p < 0.01$ and < 0.0001 , respectively). Oxidative stress parameters were high in OB; DM and OBDM (One way ANOVA: heme oxygenase $p < 0.0001$ and TBARS $p < 0.003$). The expressions of genes related to inflammation (TNF α , TLR2, NF κ B, and IL6) were higher than Cn group (One way ANOVA $p < 0.001$). The main differences were between controls with obese subjects and obese with DM and OBDM patients. Hepcidin mRNA expression was increased in all the groups compared to controls (One way ANOVA $p < 0.001$). mTOR was different between OBDM and controls (One way ANOVA $p < 0.04$). Higher levels of ferritin (quartile 4) were associated as a risk factor for diabetes mellitus.

Conclusions: High iron levels (ferritin and TBI) and inflammation (TNF α , IL6 and TLR2) induce the expression of hepcidin. High levels of ferritin are a risk factor for T2DM development.

Key words: ferritin, oxidative stress, inflammation, diabetes mellitus, obesity. Funded by Grant Fondecyt 1110080.

PO2114**METABOLIC SYNDROME AND ITS COMPONENTS, AND ADHERENCE TO THE MEDITERRANEAN DIET AMONG THE BALEARIC ISLANDS' ADULT POPULATION***M. González¹, M M. Bibiloni¹, A. Pons¹, I. Llupart¹, J A. Tur¹*

¹Research Group on Community Nutrition and Oxidative Stress, University of Balearic Islands, E-07122 Palma de Mallorca, Spain, and CIBER: CB12/03/30038 Fisiopatología de la Obesidad y la Nutrición, CIBERobn, Instituto de Salud Carlos III (ISCIII), Spain.

Background and objectives: Lately, the Metabolic Syndrome (MetS) has been subject to a great deal of interest and at-

tention. The aim of this study was to determine the prevalence of MetS and its components among the Balearic Islands' adult population, and to assess its association with the Mediterranean diet (MD).

Methods: A cross-sectional nutritional survey was carried out in the Balearic Islands adult population (16-65 years) in 2009-2010. A random sample (n = 232, 68.5% women) provided a fasting blood sample and anthropometric measurements. The MetS prevalence was defined by the NCEP/ATP-III criteria. Diet was assessed using a validated semi-quantitative food frequency questionnaire and two non-consecutive 24h diet recalls. Adherence to the MD was obtained by the modified-Mediterranean Diet Score.

Results: The overall MetS prevalence was 13% (men 16.4%, women 11.4%). The MetS criteria were met in 60.0% of obese and 12.9% of overweight subjects. No normal-weight subject met the MetS criteria. Overall, at least one MetS component was found in 60.9% of adults, and the five components were found in 1.4% of them. Abdominal obesity (92.6%), hypertension (88.9%), low HDL cholesterol level (77.8%), high triglyceride level (44.4%) and high fasting glycaemia (40.7%) were common among adults with MetS. Higher adherence to the MD was associated with significant lower risk for high triglyceride level (OR=0.31, 95%CI: 0.15-0.63, p = 0.001).

Conclusions: MetS prevalence was 13%, higher in men than in women. High triglyceride level, which was found in 44% of adults with MetS, could be reduced by high adherence to the MD. The other MetS components were not associated with adherence to the MD.

Key words: metabolic syndrome, mediterranean diet, adult population, balearic islands

Methods: Two independent cross-sectional nutritional surveys were carried out in the Balearic Islands adult population (16-65 years) in 1999-2000 (n = 1200) and 2009-2010 (n = 1388). Body mass index (BMI) and waist-to-height ratio (WHtR) were measured. BMI was classified as normal-weight (<25 kg/m²), overweight (25-29.9 kg/m²) and obesity (>30 kg/m²). WHtR was classified as normal (<0.5), elevated (0.5-0.59) or abdominal obesity (AO) (>0.6).

Results: The prevalence of overweight and obesity remained constant across all age groups in both sexes over the 10-year period. Contrarily, the prevalence of elevated abdominal fat decreased in <45 years men, and the prevalence of AO decreased in >46 years women. Logistic regression model adjusted for age showed that obesity prevalence increased in men (OR=1.71, 95%CI: 1.09-2.68, p < 0.05) while the prevalence of elevated abdominal fat decreased in them over the 10-year period (OR=0.55, 95%CI: 0.38-0.79, p < 0.01). In women, decreased the prevalence of AO (OR= 0.50, 95%CI: 0.33-0.78, p < 0.01). After adjusting for age and sociodemographic variables, only the increase of obesity prevalence observed in men remained significant (OR=2.33, 95%CI: 1.25-4.34, p < 0.01).

Conclusions: An increase of obesity prevalence in men has been observed over the 10-year period. Contrarily, the prevalence of excess abdominal fat, a major factor for the clustering of cardiovascular risk factors, decreased in both sexes over the 10-year period. These results also reflect the limitations of BMI as abdominal fatness marker.

Key words: overweight, obesity, balearic islands, adult population

PO2115

TEN-YEAR TRENDS IN THE PREVALENCE OF OVERWEIGHT AND OBESITY, AND EXCESS ABDOMINAL FAT AMONG THE BALEARIC ISLANDS' ADULT POPULATION (1999-2010)

J.L. Coll¹, M.M. Bibiloni¹, R. Salas¹, A. Pons¹, J.A. Tur¹

¹Research Group on Community Nutrition and Oxidative Stress, University of Balearic Islands, E-07122 Palma de Mallorca, Spain, and CIBER: CB12/03/30038 Fisiopatología de la Obesidad y la Nutrición, CIBERobn, Instituto de Salud Carlos III (ISCIII), Spain

Background and objectives: Overweight and obesity constitute an important public health problem. The aim of this study was to assess trends in overweight and obesity, and excess abdominal fat prevalence (1999-2010) in Balearic Islands adult population.

PO2116

ACID ACETYLSALICYLIC AND DECREASE OF HIGH-SENSITIVITY C-REACTIVE PROTEIN IN INDIVIDUALS TREATED BY DIALYSIS IN A BRAZILIAN HOSPITAL

F. P. Maniglia^{1,2}, J. A. C. da Costa¹

¹Faculty of Medicine of Ribeirão Preto (University of São Paulo), Ribeirão Preto, São Paulo, Brazil

Background and objectives: Studies point the C-reactive protein (CRP) as an important inflammatory indicator in individuals treated by dialysis. The aim was to evaluate the effect of acid acetylsalicylic (ASA) usage in serum concentrations of high-sensitivity CRP in individuals treated by dialysis.

Methods: the population of the study was composed by 42 patients with average age of 51.31±15.5 years old, of which 57% is represented by the male gender, and with an average of renal substitution therapy of 41.14±38.56 months. The patients made usage of 300 mg of ASA for two months. In the meanwhile, blood samples were collected in three moments:

before the medicine intervention, at the 30th and at 60th day after medication start.

Results: the results did not indicate differences between the CRP serum concentrations before the medicine intervention (8.3 ± 9.09 mg/dL) and at the 30th day of ASA usage (7.88 ± 8.95 mg/dL), as well as between the serum concentration at the 30th and at the 60th days of the medicine ministrations (6.37 ± 8.90 mg/dL). However, occurred a difference ($p = 0.01$) between the serum concentration before the medicine intervention and the one at the 60th day of study, indicating that even using a lower dosage than those pre-established as anti-inflammatory, the ASA seems to reduce inflammatory markers. There was positive association between the dialytic therapy and the high-sensitivity CRP serum concentrations, reinforcing that the dialytic procedure provide the increase of the inflammatory state.

Conclusions: can affirm the need to investigate the ASA effects in others inflammatory markers in patients under dialyses treatment, once they are exposed to the usage effects of a variety of others medicines which can have an indirect repercussions towards the prognosis. Beyond that, it is recommended the development of specific medicines for the chronic kidney patients, as long as its inflammatory situation is complex and requires comprehensive care.

Key words: kidney disease, inflammation, medicines.

PO2117

NUTRITIONAL ASSESMENT IN PATIENTS WITH CHRONIC MALNUTRITION AND ANXIETY

D. V. Popova^{1,2}, D. Vundeva¹, B. Strahilova¹, F. Curakova¹, R. Michaylov², E. Dimitrova¹

¹Clinic of Metabolic and Endocrine Diseases and Dietetics, University Hospital Queen Giovanna-ISUL, Medical University of Sofia, Bulgaria

²Department of Clinical Laboratory, University Hospital Queen Giovanna-ISUL

Background and Objectives: Anxiety can affect many aspects of human life as the food choice and the food intake which in turn could impair the nutritional status. The aim of our study was to conduct nutritional assessment and to evaluate the frequency of food intake and metabolic changes in female patients with chronic malnutrition and anxiety.

Methods: A group of 47 females with malnutrition and anxiety hospitalized, aged from 18 to 55 years, 22 underweight, 25 overweight and 20 healthy controls, were examined. Anthropometric measurements, clinical examination, hematological and biochemical tests, food frequency questionnaire and Hamilton anxiety scale were conducted.

Results: The patients' nutritional assessment showed important deviations compared to controls. The mean BMI was

16,7 kg/m² in underweight and 31.8 kg/m² in overweight and the mean Fat mass /BIA/ - 6.5 kg in underweight and 37.9 kg in overweight. Mild severity anxiety in 77% of the underweight and 76% of overweight was found. Examination of food frequency discovered that 50% of overweight and only 35.3% of underweight consume white bread more than once a day. Overweight consume more frequently vegetables but less fruits. Underweight consume more chicken meat, nuts, sausages, but less pork, milk and cheese than overweight. More people of the both groups use sunflower oil. Some hematological abnormalities were found in 18.2 % of underweight and in 28 % overweight. There were also metabolic abnormalities - low values of urea but still in reference in 27,3% underweight and 20% overweight, dyselectrolytemia in 9% and hypoalbuminemia in one underweight. The dysglycemia, dyslipidemia and hyperuricemia predominate in the overweight.

Conclusions: Chronic malnutrition as overweight and underweight, some slight variations in hematological and metabolic parameters and disturbed food frequency was found in females with mild anxiety compared to healthy controls.

Key words: malnutrition, food frequency, anxiety, nutritional assessment

PO2118

SENSITIVITY ANALYSES ON HEALTH IMPACT ASSESSMENT OF SALT REDUCTION: EFFECTS OF MODIFYING SALT INTAKE, BLOOD PRESSURE OR RELATIVE RISKS

M. Hendriksen^{1,2}, J. van Raaij^{1,2}, J. Breda³, M. Geleijnse², H. Boshuizen^{1,2}

¹National Institute For Public Health and The Environment (RIVM), Bilthoven, the Netherlands

²Division of Human Nutrition, Wageningen University, Wageningen, the Netherlands

³Noncommunicable Diseases and Health Promotion, World Health Organization Regional Office for Europe, Copenhagen, Denmark

Background and objectives: Excessive salt intake is associated with hypertension and subsequently with cardiovascular diseases. In the European region, salt intake is substantially above the WHO population goal of 5 grams per day. We assessed the health impact of salt intake reduction towards the population goal in four European countries, and studied whether the health impact assessment could be simplified.

Methods: Through literature research we obtained current age-specific salt intake and systolic blood pressure levels of Italy, Netherlands, Spain and UK. The DYNAMO-HIA model

was used to predict the prevalence of stroke for each country, estimating the effect of salt reduction through its effect on blood pressure levels. The country-specific relative risks between salt intake and stroke depended on country-specific blood pressure data. In additional sensitivity analyses, the three input parameters (salt intake, blood pressure and relative risks) were modified (specific vs average) to identify the consequences on the outcomes.

Results: The prevalence of stroke reduced by 8.9% in Spain (current mean salt intake 10.0 g/d), using age-specific salt intake and blood pressure. When average salt intake but age-specific blood pressure was used the prevalence of stroke reduced by 9.6%. Average salt intake and average blood pressure lead to a substantial lower health impact estimate for stroke (5.4%). Average relative risk hardly modified the estimates compared with country-specific relative risks and age-specific blood pressure levels. In this analysis, the prevalence of stroke reduced by 9.0% using age-specific salt intake estimates and by 9.6% using average salt intake estimates. Similar patterns were observed among the other countries.

Conclusions: Average data on salt intake and relative risks is sufficient to perform health impact assessment compared with age-specific salt intake or country-specific relative risks. This will simplify the health impact assessment when expanding to more countries.

Key words: health impact, salt, sensitivity analyses

PO2119

DIETARY INDICES, CARDIOVASCULAR RISK FACTORS AND MORTALITY IN MIDDLE-AGED ADULTS: FINDINGS FROM THE AEROBICS CENTER LONGITUDINAL STUDY

M. Cuenca-García^{1,2}, E.G. Artero^{2,3}, X. Sui², D.C. Lee⁴, J.R. Heber⁵, S.N. Blair^{2,5}

¹Department of Physiology, University of Granada, Spain

²Department of Exercise Science, University of South Carolina, Columbia, SC

³Area of Physical Education and Sport, University of Almería, Almería, Spain

⁴Department of Kinesiology, Iowa State University, Ames, IA

⁵Department of Epidemiology and Biostatistics, University of South Carolina, Columbia, SC

Background and objectives: Recent reports indicate that cardiorespiratory fitness may confound diet-mortality relationship. However, none of the studies using a predefined dietary index to predict mortality have explored the influence of

fitness. We examined the association between three predefined dietary indices and cardiovascular disease (CVD) risk factors; and their ability to predict long-term mortality in adults from the Aerobics Center Longitudinal Study.

Methods: Between 1987-1999, a total of 12 449 (9 544 male) participants aged 20-84 years completed a clinical examination in which dietary intake was measured by 3-day diet records. After 11.6 years of follow-up, 358 deaths occurred: 102 (28.5%) from CVD and 134 (37.4%) from cancer. The dietary indices used were: the Ideal Diet Index (IDI), the Diet Quality Index (DQI) and the Mediterranean Diet Score (MDS). CVD risk factors measurements included body mass index (BMI), total cholesterol, fasting glucose, blood pressure and cardiorespiratory fitness. We calculated hazard ratios from Cox regression analyses, adjusting for potential confounders including physical fitness.

Results: Higher IDI, DQI and MDS scores were consistently associated with lower BMI, cholesterol and glucose levels, and diastolic blood pressure, and higher cardiorespiratory fitness (all $p < 0.05$). However, after adjusting for age, sex, energy intake, and baseline examination year, the indices were not significantly related to all-cause, CVD or cancer mortality. No association was found in fully-adjusted models, after additional adjustment for fitness.

Conclusions: In middle-aged adults, these dietary indices are cross-sectionally associated with CVD risk factors; however, they may not be useful predictors of mortality in long-term follow up.

Key words: dietary patterns, all-cause mortality, cardiovascular disease, cancer, physical fitness.

PO2120

INFLAMMATORY AND OXIDATIVE EVALUATION OF INDIVIDUALS TREATED BY DIALYSIS IN A BRAZILIAN HOSPITAL

F.P. Maniglia¹, J.A.C. da Costa¹

¹Faculty of Medicine of Ribeirão Preto (University of São Paulo), Ribeirão Preto, São Paulo, Brazil

Background and objectives: The inflammatory state and the oxidative stress are described as a constant condition in patients with Chronic Kidney Diseases (CKD) in dialysis, based on several manifestations presents in those individuals, what may lead to a hyper production of inflammatory makers and free radicals. The aim of the study was to verify the inflammatory and oxidative state of individuals under dialysis treatment in a Brazilian hospital.

Methods: the studied population was composed by 42 patients with average 51.31 ± 15.5 years old (from 23 to 79), of which 57% is represented by the male gender, and with an

average of dialysis therapy of 41.14±38.56 months (from 5 to 185 months). The main causes of the renal function loss was hypertensive nephrosclerosis and diabetic nephropathy. The involved patients had a regular usage of C-Vitamin and folic acid, in agreement to the dialysis service standardization. Analysis of serum concentrations of the inflammatory biochemistry markers [high-sensitivity C-reactive protein (hs-CRP)] and the oxidative stress [malondialdehyde (MDA) e hydrogen peroxide (H₂O₂)] were carried out.

Results: the results indicated a high inflammatory level throughout an average of 8.3±0.09g/dL of hs-CRP (0.36 a 46.2g/dL) and a high production of free radicals according to the average of hydrogen peroxide (18.23±6.7umol/gP) and MDA (0.04±0.02umol/gP).

Conclusions: in conclusion, despite of the action taken to attenuate the oxidative effects of CKD, it is still necessary to evaluate others alternatives that decrease the inflammatory state and the oxidative stress, as long as these conditions interfere negatively in the patients clinic state.

Key words: inflammation, chronic kidney diseases, oxidative stress.

PO2121

ASSOCIATION BETWEEN FOOD PATTERNS AND BIOMARKERS OF ENDOTHELIAL FUNCTION: A SYSTEMATIC REVIEW

M. Defagó¹, N. Elorriaga¹, V. Irazola¹, A. Rubinstein¹

¹Southern Cone American Center For Cardiovascular Health (CESCAS/SACECH), Institute For Clinical Effectiveness and Health Policy (IECS), Buenos Aires, Argentina

Background and objectives: It has been suggested that dietary factors can be involved in endothelial dysfunction, increasing risk of cardiovascular diseases (CVD). We aimed to summarize the findings on the associations of food patterns (FPs) and endothelial biomarkers.

Methods: An electronic literature search from 1990-2012 in Medline, Embase, Lilacs, Google Scholar, and reference lists and consulting experts was conducted. We combined search terms related to the exposure (i.e., food pattern, diet) and outcomes of interest (endothelial markers, CVD, endothelium). Studies without dietary intervention such as cohort studies, case-control studies, case series, surveillance, and cross-sectional studies without language restrictions were also considered. PRISMA guidelines were employed. Methodological quality, i.e. study design, sample size, bias, and statistical analysis, was assessed by STROBE.

Results: 532 references were identified, of which 10 were finally included. Four articles were cross-sectional cohort stu-

dies, two cohort studies, one nested case-control, and three cross-sectional studies. FPs was defined as usual consumption of food combinations in individuals and groups. In 90% of the articles, usual dietary intake was determined by food frequency questionnaire, and FPs were identified by factor analysis. Several FPs were identified. All articles presented some degree of association between several markers and FPs. Healthy FPs (such as olive oil and vegetables, whole grains and fruits, and Prudent) had a beneficial impact on endothelial function as estimated by circulating levels of biomarkers such as CRP, sICAM-1, sVCAM-1 and sE-selectin, molecules related to endothelial dysfunction. Westernized patterns (e.g. High-fat and processed meat, Western) were positively associated to inflammation molecules and atherogenic promoters.

Conclusions: Major FPs are associated with markers of endothelial dysfunction and inflammation. The study of FPs in relation to endothelial function contributes to the development of dietary recommendations and lifestyle in general, to promote improved cardiovascular health.

Key words: food patterns, endothelium, biomarkers.

PO2122

DOES VITAMIN D STATUS PREDICT ERECTILE DYSFUNCTION AND CARDIOVASCULAR RISK IN AGEING MEN? A NEW ZEALAND PILOT STUDY

M. Quilter^{1,2}, L. Hodges², J. Coad¹

¹Institute of Food Nutrition and Human Health, Massey University, Palmerston North, Manawatu, New Zealand

²School of Sport and Exercise, Massey University, Palmerston North, Manawatu, New Zealand

Background and objectives: Suboptimal vitamin D status is associated with increased risk of cardiovascular disease (CVD) and poor cardiovascular outcomes in epidemiological studies. Erectile dysfunction (ED) is increasingly accepted as an early marker of occult CVD; vasculogenic ED is synonymous with endothelial dysfunction. This study investigated whether vitamin D status is associated with ED and other CVD markers.

Methods: We conducted a pilot study in 35 healthy men aged 40-70 years in the Manawatu region, New Zealand. Self-selected participants volunteered with written consent. Participants attended the Nutrition Research Unit for assessment of medical history, height, weight, waist circumference, waist:hip (WHR), waist:height, percentage body fat (%BF) and android:gynoid fat using Dual-energy X-ray absorptiometry, blood pressure, pulse wave velocity using SphygmoCor CPV, fasting lipid profile, vitamin D status (serum 25-hydroxyvitamin D) and ED severity (International Index of Erectile Function 5-item (IIEF-5)). Framingham scores were calculated.

Results: Vitamin D status correlated with HDL-c ($r_2 = 0.414$ $p = 0.013$), T:HDL-c ($r_2 = -0.342$ $p = 0.045$) and pulse ($r_2 = -0.373$ $p = 0.027$). A positive trend was observed with IIEF-5 score ($r_2 = 0.328$ $p = 0.055$), and negative trends with %BF ($r_2 = -0.320$ $p = 0.065$) and android:gynoid fat ($r_2 = -0.308$ $p = 0.072$). IIEF-5 score correlated with age ($r_2 = -0.429$ $p = 0.01$), WHR ($r_2 = -0.417$ $p = 0.013$), android:gynoid fat ($r_2 = -0.368$ $p = 0.03$) and pulse ($r_2 = -0.427$ $p = 0.011$).

Conclusions: The sample size limited power to detect a statistically significant relationship between vitamin D status and ED. A strong trend was observed and further sampling is underway. Vitamin D status negatively correlated with T:HDL-c, a biomarker of CVD risk. ED negatively correlated with abdominal adiposity, an anthropometrical marker of CVD risk. Identification of vasculogenic ED could support early intervention in ageing men. A randomized controlled human intervention trial is warranted to investigate whether improving vitamin D status in men with vasculogenic ED ameliorates ED and reduces the risk of CVD.

Key words: erectile dysfunction, IIEF-5, vitamin D status, CVD risk.

PO2123

ASSOCIATION BETWEEN RS1137100 SNP IN LEPR GENE AND WAIST-TO-HEIGHT RATIO IN BRAZILIAN OVERWEIGHT CHILDREN AND ADOLESCENTS

C T H. Fujiwara^{1,2}, A E. Fernades^{1,2}, M E. Melo^{1,2,3}, A. Santos², C. Cercato³, A. Halpern³, M C. Mancini^{1,2,3}

¹League of Childhood Obesity, Discipline of Endocrinology & Metabolism Hospital Das Clinicas, Faculty of Medicine, Sao Paulo, Sao Paulo, Brazil

²Laboratory of Carbohydrates and Radioimmunoassay/LIM-18, Faculty of Medicine, Sao Paulo, Sao Paulo, Brazil

³Obesity & Metabolic Syndrome Group, Discipline of Endocrinology & Metabolism, Hospital Das Clinicas, Faculty of Medicine, Sao Paulo, Sao Paulo, Brazil

Background and objectives: Genetic factors participate in the complex ethiopathogenesis of obesity and increase the risk of developing eating disorders such as binge eating (BE), which are influenced by neural and hormonal defects in appetite and satiety control. Nevertheless, the relationship between single nucleotide polymorphisms (SNPs) in the leptin receptor gene (LEPR), binge eating and the risk of obesity remains controversial. Our aim was to verify the influence of the rs1137100 (A>G, K109R) in LEPR over BE symptoms, adiposity and cardiometabolic risk factors in overweight children and adolescents.

Methods: The study included 333 subjects aged 7 to 18 years. The rs1137100 was determined by TaqMan genotyping assay. The BE Scale was used to assess BE symptoms, anthropometric measures comprehended ZBMI, percentage of fat mass (%FM), waist-to-height ratio (WHtR) and cardiometabolic risk factors comprised levels of fasting glucose, HOMA-IR, HDL-cholesterol, triglycerides, leptin and blood pressure percentiles. Statistics were performed using Qui-square test, ANOVA and Kruskal-Wallis Test with level of significance set at $p < 0.05$.

Results: Population was in Hardy-Weinberg equilibrium (AA: 64.9%, AG: 29.6%, GG: 5.5%, $p = 0.12$). The A/A homozygous group presented a lower WHtR mean value when compared to A/G heterozygous individuals (0.67 ± 0.07 vs. 0.65 ± 0.07 , $p = 0.029$), though no statistical difference was found with the G/G homozygous group ($p = 0.44$). Furthermore, mean values of anthropometric measures and cardiometabolic risk factors were not statistically different between groups.

Conclusions: Our study showed that A/A homozygous for the rs1137100 SNP in LEPR present a lower WHtR than the A/G heterozygous group, although it seems not to be involved with other anthropometric and cardiometabolic risk factors in our sample of Brazilian overweight children and adolescents.

Key words: LEPR, rs1137100, inge eating, waist-to-height ratio.

PO2124

RS1137101 SNP IN LEPR GENE IS NOT ASSOCIATED WITH BINGE EATING AND CARDIOMETABOLIC RISK IN BRAZILIAN OVERWEIGHT CHILDREN AND ADOLESCENTS

C T H. Fujiwara^{1,2}, A E. Fernandes^{1,2}, M E. Melo^{1,2,3}, A. Santos², C. Cercato³, A. Halpern³, M C. Mancini^{1,2,3}

¹League of Childhood Obesity, Discipline of Endocrinology & Metabolism Hospital das Clinicas, Faculty of Medicine, University of Sao Paulo, Sao Paulo, Sao Paulo, Brazil

²Laboratory of Carbohydrates and Radioimmunoassay/LIM-18, Faculty of Medicine, University of Sao Paulo, Sao Paulo, Sao Paulo, Brazil

³Obesity & Metabolic Syndrome Group, Discipline of Endocrinology & Metabolism, Hospital Das Clinicas, Faculty of Medicine, University of Sao Paulo, Sao Paulo, Sao Paulo, Brazil

Background and objectives: Leptin plays a crucial role in body weight regulation and satiety signaling, exerting its effects through the interaction with leptin receptor. Common single nucleotide polymorphisms (SNPs) in the leptin receptor gene

(LEPR) such as the rs1137101 (A>G), a non-synonymous mutation, has been associated with increased risk for binge eating, obesity and related metabolic disturbances, though this association is not well established in children and adolescents. Our aim was to determine whether the rs1137101 SNP in LEPR is associated with binge eating, anthropometric measures and cardiometabolic risk factors and in overweight children and adolescents.

Methods: The study population comprehended 333 overweight youngsters aged 7 to 18 years old (46.8% boys; 12.4±2.7 years old, ZBMI 3.23±0.65). TaqMan assay was used for rs1137101 genotyping. Binge eating (BE) was assessed through the BE Scale score. Anthropometric measures were ZBMI, percentage of fat mass (%FM), waist-to-height ratio (WHtR), whereas cardiometabolic risk factors included levels of fasting glucose, HOMA-IR, HDL-cholesterol, triglycerides (TG), leptin and blood pressure percentiles (BPP). Statistics were performed using Qui-square test, ANOVA and Kruskal-Wallis Test with level of significance set at $p < 0.05$.

Results: Population was in Hardy-Weinberg equilibrium (AA: 26.7%, AG: 50.5%, GG: 19.5%, $p = 0.38$). No statistical significant differences were found between the different genotype groups with BES score ($p = 0.09$) and anthropometric measures: ZBMI ($p = 0.81$), %FM (0.54), WHtR ($p = 0.46$). Furthermore, cardiometabolic risk factors also did not differ among groups: glucose ($p = 0.83$), HOMA-IR ($p = 0.50$), HDL-cholesterol ($p = 0.62$), TG ($p = 0.41$), leptin ($p = 0.31$), systolic BPP ($p = 0.68$) and diastolic BPP ($p = 0.85$).

Conclusions: Our results suggest the lack of association of the rs1137101 SNP in LEPR with binge eating, anthropometric measures and cardiometabolic risk factors in Brazilian overweight children and adolescents.

Key words: LEPR; rs1137101; Binge eating; Overweight

PO2125

THE DIETS' NUTRITIONAL VALUE OF WOMEN WITH NORMAL WEIGHT BUT OBESE

J.W. Szczepanska¹, L. Wadolowska¹

¹Department of Human Nutrition, University of Warmia and Mazury, Olsztyn, Poland

Background and objectives: The aim of the study was to compare the diets' nutritional value of women with different body fat content and different weights.

Methods: The study included 450 women aged 20-45 with BMI>18.5 kg/m². Body weight, height and thickness of skin-folds were measured. The women were classified into three groups: normal body weight (NW: BMI=18.5-24.9 kg/m² and FM<32%), normal weight but obese (NWO: BMI=18.5-24.9 kg/m² and FM>32%) and overweight (OW: BMI=25.0-29.9

kg/m²). A three-day dietary record was used. Two of those days were working days and the third a day off. The under-estimation of the energy intake was verified by the Goldberg method (1991) and corrected by neural networks according to body fat and age of women. Finally, 303 women had a correct estimation of the energy intake.

Results: Women with NWO, NW, and OW were 32%, 57%, 11% of the sample, respectively. Women with NWO had higher mean only of vegetable protein (relative difference: 4.6%), carbohydrates (5.8%) and fiber (6.6%) intake compared to women with OW. There was no statistical difference in the eating habits between women with NWO and OW. Women with NWO compared to women with NW had a higher average of intake of animal protein (13.5%), fat (10.4%), SFA (9.4%), MUFA (13.7%), cholesterol (13.5%), sugar (18.2%), sodium (10.6%), potassium (10%), iron (9.5%), but also vitamins: B1 (8.5%), B2 (12.1%), B12 (31.8%), A (30.9%) and D (23.8%). More women with NWO than NW were not eating the dinner (16.7% vs. 1.4%).

Conclusions: Women with normal weight but obese consumed more nutrients of plant origin compared to obese women and more nutrients of animal origin compared to women with normal weight.

Key words: body fat, diets, women. J.W. Szczepanska was supported by the European Union within The European Social Fund

PO2126

ASSOCIATIONS BETWEEN ADIPOSITY AND MICRONUTRIENT DEFICIENCIES IN MEXICAN WOMEN

K. Long^{1,2}, A. Tunkar¹, M. Flores²

¹School of Population Health, University of Queensland, Australia

²National Institute of Public Health, Herston, Australia

Background and objectives: Micronutrient status may play a role in adipogenesis and fat deposition in the body. We addressed whether obesity as characterized by BMI, waist circumference and waist to hip ratio is associated with micronutrient deficiencies among Mexican women.

Methods: Body mass index (BMI), waist circumference (WC), and waist to hip ratios (WHR) were determined for 1056 women aged 12-49 years who were included in the 1999 National Nutrition Survey of Mexico (ENN-99). Determinations of serum zinc, serum retinol, serum ascorbic acid and C-reactive protein (CRP) were made from a single blood sample collected from these women. Linear and logistic regression were carried out to determine linear associations between micronutrient

serum concentrations and BMI, WC, and WHR and between and micronutrient deficiencies and categories of these indices, respectively.

Results: Serum concentrations of all three micronutrients were associated with obesity and abdominal fat though the direction of these associations differed for each. Vitamin C serum concentrations were inversely associated with greater BMI, greater WC and greater WHR ratio while serum zinc was inversely associated with greater WHR in women. In contrast, vitamin A concentrations were positively and strongly associated with greater BMI and greater WC but not WHR. There was also a strong association between vitamin C deficiency and obesity and abdominal fat.

Conclusions: These findings suggest that increased obesity and abdominal fat have significant influences on the serum concentration of micronutrients but that these effects are micronutrient specific in terms of direction and obesity measure. The supplementation of obese women should be an important public health priority.

Key words: obesity; zinc; vitamin A; vitamin C.

PO2127

LOW VITAMIN B12 AND FOLATE SERUM CONCENTRATIONS, AND B-VITAMIN INTAKE ARE ASSOCIATED WITH GREATER ADIPOSITY IN MEXICAN AMERICAN CHILDREN

K. Long, I. Gunanti¹, G. Marks¹, A. Al Mamun¹

¹School of Population Health, University of Queensland, Australia

Background and objectives: Studies investigating associations between vitamin B serum concentrations and B-vitamin intake with adiposity have reported inconsistent findings. We examined associations between serum concentrations of vitamin B12 and folate, and intakes of B-vitamins with body fat among Mexican American children.

Methods: We used data on 1,131 Mexican American children 8-15 years of age included in the 2001-2004 National Health and Nutrition Examination Surveys (NHANES). Children's body mass index (BMI), truncal fat mass (TrFat) and total body fat mass (TBF) were used as body adiposity measures (BA). Intake of B-vitamins was collected based on 24-hour dietary-recall. Associations of BA with vitamin B12 and folate serum concentrations and B-vitamin intake were determined using linear and multinomial regression models.

Results: B12 and folate serum concentrations were inversely associated with BMI ($r=-2.58$; 95% CI= -3.54 -1.62 ; $r=-1.27$; 95% CI= -2.19 -0.36), with TrFat ($r=-1.58$; 95% CI= -2.11 -1.06 ; $r=-0.85$; 95% CI= -1.46 -0.26) and with TBF ($r=-3.05$; 95% CI= -4.55 -1.56 ; $r=-2.05$; 95% CI= -3.29 -0.81).

Thiamine and riboflavin intake was inversely associated with BMI ($r=-1.25$, 95% CI= -2.33 -0.17 ; $r=-1.32$; 95% CI= -2.39 -0.30 ; $r=-1.11$; 95% CI= -2.12 -0.11) and TrFat ($r=-0.84$; 95% CI= -1.63 -0.05 ; $r=-1.26$; 95% CI= -2.36 -0.15 ; $r=-1.37$; 95% CI= -2.40 -0.35). Folate intake showed similar but less significant associations.

Conclusions: Vitamin B12 and folate status may be important in determining body adiposity. Similarly, inverse associations between thiamine and riboflavin intake and adiposity may reflect the role of these micronutrients on energy balance.

Key words: obesity, body fat, B-vitamins, children.

PO2128

EFFECT OF OBESITY ON SELF-ESTEEM IN SECONDARY SCHOOL-AGE STUDENTS OF NORTHERN REGION OF THAILAND

S. Satoh¹, P. Leelahagul¹, S. Khamvang², N. Chaiwut²

¹Graduate Program In Nutrition, Ramathibodi Hospital

²Srinagarindra The Princess Mother School, Phayao, Thailand

Background and objectives: Self-esteem is important to the success, especially in adolescence, because physical, mentality, social and thinking process are developed in this age group. Many studies in adolescents found obesity leads to risk of chronic diseases and psychosocial problem, i.e., low self-esteem and lack of confidence. This research aimed to study about self-esteem in Northern Thai adolescents according to their body weight. Method: A prospective study carried in 60 secondary school-age students of Srinagarindra The Princess Mother School, Phayao, aged 12-18 years. These subjects classified by body weight, i.e., under, normal, and over body weight, consisted of 20 subjects/group. Body composition analysis were measured by Tanita BC-420, and dietary intake were assessed by 24 hour-dietary record 3 days/week at weeks 0, 8, 16 and 24. The Five-Scale-Test of Self-Esteem for children questionnaires were used for self-esteem test.

Results: Mean self-esteem score of 60 students was 56.8 (range 38.0-75.0). No significant differences of mean self-esteem score among 3 groups: underweight (55.7), normal weight (59.5) and overweight (55.3). When high self-esteem score was defined as >57.0 , 60% of normal weight group had high self-esteem score which were higher than overweight group (50%) and underweight group (35%). According to their body weight groups and sex, we found that most of females and males of underweight groups had low self-esteem score. The most of females and males in normal weight groups had high self-esteem score.

Conclusions: Our study show that body weight status had effects on self-esteem, thus this evidence should be concerned in nutritional therapy for weight reduction and improving self-esteem.

Key words: body weight, self-esteem, adolescent.

PO2129

MICRONUTRIENT STATUS AND IMMUNITY: A CASE STUDY AMONG INDONESIAN ACTIVE PULMONARY TUBERCULOSIS PATIENTS

D. Dillon^{1,2}, M. Anastasia², D. Sutoyo³

¹SEAMEO RECFON, Jakarta, Indonesia

²Department of Nutrition, Faculty of Medicine, University of Indonesia, Jakarta, Indonesia

³Departement of Pulmonology and Respiratory Medicine, Faculty of Medicine, University of Indonesia, Jakarta, Indonesia

Background and objectives: Poor nutritional status is highly prevalent among tuberculosis patients. Vitamin A, vitamin D, and zinc play an important role in the production of cathelicidin, an antibacterial peptide to fight against tuberculosis bacillus. The objective was to investigate the role of micronutrients in the immune system of active pulmonary tuberculosis patients.

Methods: A cross sectional study, involving 27 Indonesian healthy adults and 44 newly diagnosed tuberculosis patients with normal liver and kidney functions, was conducted in Indonesia. Body Mass Index (BMI), polymorphism of vitamin D receptor (VDR) gene Fok I, serum retinol, calcidiol, zinc and cathelicidin concentrations were assessed.

Results: Tuberculosis patients were more prone to low BMI ($p < 0.0001$), low serum concentrations of retinol ($p < 0.0001$), calcidiol ($p < 0.0001$) and cathelicidin ($p < 0.0001$) compared to healthy subjects. Sex ($p = 0.019$; 95% CI: -16.5 to -1.5) and serum retinol concentration ($p = 0.003$; 95% CI: -38.7 to -8.2) play a significant role in serum cathelicidin concentration.

Conclusions: Micronutrients status of tuberculosis patients was lower compared to healthy subjects. Sex and serum retinol concentration play an important role in the immune function of tuberculosis patients.

Key words: vitamin A, vitamin D, zinc, tuberculosis

PO2130

VITAMIN D STATUS OF HEMODIALYSIS PATIENTS IN KOREA

S.S. Lee^{1,2}, Y.J. Lee¹, Y. Lee¹, H.J. Woo¹, I.W. Owe², C.H. Lee²

¹Department of Food and Nutrition, College of Human Ecology, Hanyang University

²Department of Internal Medicine, Hanyang University Seoul Hospital

Background and objectives: Vitamin D deficiency is highly prevalent among hemodialysis patients and contributes to secondary hyperparathyroidism. The objective of this study is to investigate the status of 25(OH)D₃, 1,25(OH)₂D₃ and intact parathyroid hormone(iPTH) in hemodialysis patients, and its relation with vitamin D intake and exposure to sun light.

Methods: This study included 46 patients (19 male and 27 female) with renal disease on hemodialysis, and their blood was obtained for 25(OH)D₃ and 1,25(OH)₂D₃ analysis in October and November (fall season), 2012. The prevalence of vitamin D deficiency defined as serum 25(OH)D₃ levels of less than 15 ng/ml. The biological parameters, iPTH, hs CRP, albumin, creatinine and eGFR (ml/min), were analyzed according to level of 25(OH)D₃, sex and age. Vitamin D and calcium intakes of these subjects were estimated by using 3-day dietary records and FFQ.

Results: The percentage of vitamin D deficiency (<15ng/ml) in the study subjects was 71.7% (n = 33), 63.2% of male and 77.8% of female. The average concentrations of serum 25(OH)D₃, 1,25(OH)₂D₃ and iPTH were 13.6 ng/ml, 20.8 pg/dl and 301.3 pg/ml, respectively. There was no association between serum 25(OH)D₃ status and age, sex, time spent outdoors, the use of sunscreen and the duration of hemodialysis. The intakes of vitamin D were not significantly different between the vitamin D deficient subjects and the others. However, the calcium intake was significantly higher in vitamin D deficient subjects than the others ($p = 0.043$). Serum albumin and creatinine levels were significantly lower in female subjects than male ($p = 0.035$, $p = 0.010$), and eGFR (ml/min) and hsCRP levels were significantly higher in elderly over 65 years old ($p = 0.016$, $p = 0.006$).

Conclusions: A high prevalence of vitamin D deficiency was observed in Korean hemodialysis patients, consequently iPTH levels were severely elevated in these subjects.

Key words: Hemodialysis, 25(OH)D₃, 1,25(OH)₂D₃, iPTH, deficiency.

PO2131**METABOLIC AND BONE DISORDERS IN VERTICALLY HIV-INFECTED CHILDREN**

³Instituto de Nutrición y Tecnología de los alimentos (INTA), Universidad de Chile, Santiago, Chile

⁴Unidad de Inmunología, Hospital Roberto del Río, Santiago, Chile

⁵Unidad de Infectología, Hospital San Borja Arriarán, Santiago, Chile

⁶Departamento de Pediatría, Universidad de los Andes, Santiago, Chile

⁷Departamento de Pediatría Norte, Hospital Roberto del Río, Universidad de Chile, Santiago, Chile

Background and objectives: Life expectancy of children infected with human immunodeficiency virus (HIV) has increased due to Highly Active Antiretroviral Therapy. Studies have reported that metabolic disorders and changes in bone mineral density (BMD) are common in adult patients with HIV. There are few studies exploring metabolic and bone involvement in children infected. The aim of this study was to evaluate metabolic disorders and BMD in vertically HIV-infected children in two Chilean medical centers.

Methods: A total of 34 children (19 females), 11.8 years (3.8 to 18.5), with HIV infection were evaluated. We determined weight, height, BMI, zBMI, zheight/age and BMD. Intake of energy, protein and calcium was calculated using a 24 hours dietary recall. The percentage of dietary adequacy was estimated according RDI.

Results: 2 patients were at stage A1, 8 in B1, 2 in B2, 6 in B3, 3 in C1, 2 in C2 and 5 in stage C3. The highest percentage of patients (68%) was eutrophic (23/34), 2 were at risk of malnourished, 6 overweight and 3 obese. Despite the above 44% had body fat > 30% and 49% elevated triglycerides. 36% had a height/age < -2 SD. 15% (5/34) patients had a BMD < -1.5 SD and 12% (4/34) < -2 SD in column. 30% (10/34) had BMD < -1.5 SD and 6% (2/34) < -2 SD in hip. All patients consumed about 2.5 times their protein requirements, however, 42% and 72% of patients consume less than 75% of its energy and calcium requirements respectively. We found a significant correlation between stage of disease and increased triglycerides, decreased CD4% and lower hip BMD (P < 0.05).

Conclusions: Our data indicate that pediatric patients with perinatal HIV infection have a high percentage of body fat mass, triglycerides and early engagement of BMD. This is higher in more advanced stages of the disease.

Key words: HIV children, metabolic disorders, bone mineral density.

PO2132**EFFECT OF SWEETENERS ON THE PEYER'S PATCHES OF THE SMALL INTESTINE OF BALB/C MICE**

B.E. Martínez-Carrillo¹, R. Valdes-Ramos¹, M.C. Rojas de la Cruz¹, R. Oros-Pantoja¹

¹Center For Research and Graduate Studies In Health Sciences, Faculty of Medicine, UAEM, Mexico

Background and Objectives: In recent years the trend towards health, body image and physical fitness have increased, so there is the need to find a sugar substitute with a similar flavor, but providing less energy intake. The incorporation of sweeteners in the diet and their relationship with the immune system, particularly the gastrointestinal tract associated lymphoid tissue (GALT), has been rarely studied. The objective of this study was to determine the effect of sweeteners on Peyer's patches of small intestine from Balb/c mice.

Methods: Thirty-two 60-day old Balb/c mice, weighing 20-25 g, were divided into 4 groups of 8 animals each: control (without sweetener), sucrose, stevioside or sucralose, were administered in drinking water for 6 weeks; weight was measured weekly. Lymphocytes were obtained from the Peyer's patches of the small intestine by enzymatic chemical method and then quantified by flow cytometry: T-lymphocytes (CD3+, CD4+ and CD8+), B-lymphocytes (CD19+) and IgA+ cells.

Results: No significant differences were found in T-cells; B CD19+ cells were significantly different between groups (49.27% +- 4.8 sucrose, 41.13% +- stevia, 36.25% +- 5.6 sucralose) compared with the control group (51.09% +- 6.24), with an F = 14.77, p < 0.003; IgA+ cells were higher in the control group (5.26% +- 0.483), 5.34% +- 0.168 sucrose, 5.80% +- 0.411 sucralose and 6.49% +- 0.269 stevia, with F = 20.22, p < 0.001.

Conclusions: humoral immunity was modified by increasing IgA+ cells, natural and artificial sweeteners alter the percentage of CD19+ lymphocytes which has been associated with inflammatory bowel disease. Acknowledgements: This project was financed by UAEM.

Key words: Sweeteners, immunity, GALT

PO2133**NUTRITIONAL AND DIETARY FACTORS AND RISK OF HIP FRACTURES IN ELDERLY CHINESE: A MATCHED CASE-CONTROL STUDY**

Y. Chen^{1,2}, W. Xue¹, F. Fan¹, F. Zeng¹, B. Wu¹, W. Ouyang¹, S. Tu¹

¹Department of Medical Statistics and Epidemiology, Sun Yat-Sen University, Guangzhou, China

Background and objectives: The effects of nutritional factors and risk of osteoporotic fractures remains unclear. We examined the association of nutritional and dietary factors with risk of hip fractures in elderly Chinese men and women.

Methods: 581 (M/F: 148/433) incident cases of hip fractures were enrolled from four hospitals, with 581 sex- and age-matched (± 3 years) controls from hospitals or communities in Guangdong, China during 2008.1- 2012.6. Face-to-face interviews were conducted to collect general information, habitual dietary intake (by FFQ) and various covariates.

Results: Multivariate conditional logistic regression analyses showed: A dose-dependent decreased risk of hip fractures was associated with greater intakes of fruit & vegetables, seafood, skin-free poultry, β -carotene and other antioxidative nutrients, K and Mg, but lower consumption of red meat, pickled vegetables, oils and fat, and net endogenous acid production (NEAP). The adjusted odds ratios (95%CI) of hip fractures for various foods and nutrients comparing their consumption levels of extreme quartiles were: total fish & shell fish: 0.47(0.28-0.79), seafood: 0.31(0.18-0.52), fresh-water fish: 0.80(0.48-1.31), total fruit & vegetables: 0.22(0.13-0.39), vegetable: 0.29(0.17-0.52), fruit: 0.62(0.36-1.08), skin-free poultry: 0.52(0.34, 0.82), β -carotene: 0.15(0.06-0.34), vitamin C: 0.28(0.13-0.61), K: 0.27(0.13-0.53), Mg: 0.30(0.14-0.65), tea drinker (Y/N): 0.72(0.54-0.95), red meat: 2.74(1.61, 4.67), organ meat: 1.54(1.07, 2.23), pickled vegetable: 3.49(1.72-7.10), oil & fat: 4.48(2.15-9.34), and NEAP: 4.94(3.16-7.73), respectively. Dietary pattern analyses suggested that "healthy dietary pattern" was associated with lower hip fracture risk, whereas "high-fat dietary pattern" might increase the risk.

Conclusions: Greater intakes of fruit & vegetables, seafood, skin-free poultry, antioxidative nutrients, K and Mg, but lower consumption of red meat, pickled vegetables, fat, and NEAP may be protective against hip fractures in elderly Chinese.

Key words: nutrition; dietary factor; hip fracture; case-control study; chinese.

PO2134**ASSOCIATION OF DIETARY FACTORS AND DIETARY QUALITY WITH RISK OF NASOPHARYNGEAL CARCINOMA IN CHINESE ADULTS: A CASE-CONTROL STUDY**

Y. Chen^{1,2}, Y. Liu¹, J. Dai², C. Xu¹, Y. Lu³, Y. Fan², X. Zhang²

¹Department of Medical Statistics and Epidemiology, Sun Yat-Sen University, Guangzhou, China

²Sun Yat-sen University Cancer Center, Sun Yat-Sen University, Guangzhou, China

³Sun Yat-sen University Ophthalmic Center, Sun Yat-Sen University, Guangzhou, China

Background and objectives: To examine the association of dietary factors and dietary quality with risk of nasopharyngeal carcinoma (NPC) Chinese men and women.

Methods: 600 (M/F: 448/152) incident nasopharyngeal carcinoma (NPC) cases (47+/-9y) were enrolled from hospitals, with 600 sex- and age-matched (± 3 years) controls from hospitals or the community in Guangzhou, China during 2009.7-2011.3. Face-to-face interviews were conducted to collect general information, habitual intake of foods and nutrients (by a 79-item FFQ) and various covariates. Dietary quality was evaluated according to the Diet Quality Index-International (DQI-I), Alternate Healthy Eating Index (AHEI) and alternate Mediterranean Diet Score (aMED). Subjects were classified into quartiles (Q1~Q4) by the consumption of each food/food group item or the quality scores.

Results: Multivariate conditional logistic regression analyses showed: a dose-dependently decreased risk of hip fractures was associated with greater intakes of fruit & vegetables (particular those with dark color), low-fat dairy products, lower consumption of seafood and shell-fishes, pickled vegetables, processed fish and meat, or higher quality diet. The multivariate adjusted odds ratios (95%CI) of NPC for various foods comparing their consumption levels of extreme quartiles were: total fruit & vegetables: : 0.37(0.25-0.55), vegetable: 0.33(0.22-0.50), dark-color vegetable: 0.30(0.20-0.45), light-color vegetable: 0.77(0.53-1.13), fruit: 0.70(0.47-1.04), dark-color fruit: 0.50(0.32-0.76), low-fat dairy (Yes vs. No): 0.52(0.28-0.95), sea fish: 1.87(1.29-2.70), shellfish: 1.61(1.07-2.41), pickled vegetables: 2.31(1.54-3.46), and processed fish and meat: 1.80(1.21-2.66). ORs (95%CI) of NPC for dietary quality scores (Q4 vs. Q1) were: DQI-I: 0.64(0.45-0.93), AHEI: 0.49(0.33-0.72), and aMED: 0.58(0.37-0.92).

Conclusions: Greater intakes of fruit & vegetables, low-fat dairy products, lower consumption of sea fish and shell-fishes, pickled vegetables, processed fish and meat, or increased total dietary quality may be helpful for the prevention of NPC Chinese adults.

Key words: nutritional and dietary factors; nasopharyngeal carcinoma; case-control study; chinese.

PO2135**BINGE EATING DISORDER IN OBESE WOMEN: A QUALITATIVE STUDY IN BRAZIL***M J. Teixeira¹, M L M. Bosi¹*¹Faculty of Medicine, Federal University of Ceará, Brazil

Background and objectives: The Binge Eating Disorder (BED) is characterized by the ingestion of large amounts of food in a short period of time with a sensation of lack of control. It is a new nosological entity that has a narrow relation with obesity and therefore, with chronic diseases. The prevalence and etiology of BED is not sufficiently known but the literature recognizes that specific and differentiated assistance is needed. This study aims to analyze perceptions and experiences of obese women who suffer from BED, focusing on body related aspects, and also to analyze the public assistance model offered to this group in the municipality of Rio de Janeiro (Brazil).

Methods: This study was based on the qualitative health research approach. A total of 15 non-directive interviews were conducted with obese women who suffer from BED, aged 18-55 years, assisted by a specialized program in a public hospital. The qualitative material was analyzed and categorized in thematic axes.

Results: Social prejudice directed towards the obese body is a possible aggravating factor for BED and obesity. The biography of the interviewed women confirmed literature data and went beyond showing evidences such as: chemical dependency of first degree relatives; difficulties in the individuation process; social stigmatization; conflictive family dynamic; and lack of personal autonomy. Negative experiences with diet formulas were reported to be associated with susceptibility to the beauty standards appeal promoted by media, leading to social isolation and low self-esteem.

Conclusions: Obesity is an important public health challenge, especially when associated to BED. The BED multidimensional etiology indicates that psycho-affective and social components are involved in its complex genesis. The assistance offered, by an interdisciplinary team, should include those aspects in order to facilitate adhesion to treatment and refrain the problem to become chronic.

Key words: obesity, binge eating, nutrition.

PO2136**THE EFFECT OF FRUIT INTAKE ON BLOOD LIPID PROFILE IN HEMODIALYSIS PATIENTS***P Y. Wu^{1,2}, S H. Yang^{1,2}, J. Yang³, H Y. Chang⁴, H H. Chen⁵*¹School of Nutrition and Health Sciences, Taipei Medical University, Taipei, Taiwan, R.O.C²Nutrition Research Center, Taipei Medical University Hospital, Taipei, Taiwan, R.O.C³Department of Internal Medicine, Keelung Hospital, Department of Health Executive Yuan⁴Department of Dietitians, Keelung Hospital, Department of Health Executive Yuan⁵Department of Internal Medicine, Taipei medical University Hospital, Taipei, Taiwan, R.O.C

Background and objectives: To evaluate the association between fruit intake and blood lipid profile in hemodialysis (HD) patients.

Methods: This is a cross-sectional study. All subjects were outpatients from two dialysis centers in Taipei and Keelung in Taiwan. Thirty-eight HD patients were completed this study. The dietary intake was calculated from the average of 3-day dietary record. Fasting predialysis blood samples were drawn from all subjects and measured by Department of Laboratory Medicine of Taipei Medical University Hospital. The lipid profile (serum total cholesterol, low-density lipoprotein cholesterol, high-density lipoprotein cholesterol, non-high-density lipoprotein cholesterol, triglyceride), nutritional markers (dry body weight and serum albumin), and concentration of hemoglobin and potassium were measured.

Results: twenty-two of HD patients usually ate fruits, and the mean intake of fruits was 0.8 servings (95% confidence interval 0.5-1.1 servings). Comparing with patients without fruits intake, patients ate fruits with significantly higher dietary fiber intake, and lower level of serum low-density lipoprotein cholesterol, non-high-density lipoprotein cholesterol and triglyceride, but the lipid profile did not achieve statistical significance. Eating fruits did not significantly affect the level of blood potassium, hemoglobin and albumin.

Conclusions: HD patients in this study eating fruits had significantly increased dietary fiber intake without elevated the concentration of serum potassium. However, we need more and bigger future studies to document the benefit of fruits intake of HD patients.

Key words: hemodialysis, lipid profile, fruit intake.

PO2137**GENDER DIFFERENCE IN DIETARY PATTERN BETWEEN NON-DIALYSIS DAY IN WEEKDAY AND WEEKEND OF HEMODIALYSIS PATIENTS IN NORTH TAIWAN.**

⁴Department of Internal Medicine, Taipei Medical University Hospital, Taipei, Taiwan, R.O.C

⁵Department of Internal Medicine, Keelung Hospital, Department of Health Executive Yuan

⁶Department of Dietitians, Keelung Hospital, Department of Health Executive Yuan

Background and objectives: To find out the effect of gender on dietary intake of hemodialysis patients between non-dialysis day in weekday (NDWD) and weekend (NDWE).

Methods: One hundred and ten adult hemodialysis patients from 3 hemodialysis centers in North Taiwan were recruited in this study, and 51 were male (46%). All subjects were under in-center hemodialysis treatment for at least 2 months, and without any parenteral nutrition therapy. Three days dietary record was collected for dietary information, including one hemodialysis day, one non-dialysis day in NDWD and NDWE.

Results: Age, hemodialysis vintage and severity of comorbidity were no significant different between male and female patients. Comparing with male subjects, female had significantly lower cereal, meat, fish, eggs and soy protein, and dietary protein, fat, cholesterol, iron, zinc, polyunsaturated fatty acid, niacin, and vitamin B6 and B12 intake ($p < 0.05$). Both genders had higher phosphorus and iron intake in Sunday than NDW, but did not attend significantly difference. Only female subjects had significant higher vitamin A intake in Sunday than NDWD ($p = 0.04$). The evaluated variables of dietary pattern and nutrients intake in male patients were no significantly different between NDWD and NDWE

Conclusions: In this study, dietary intake in patients with hemodialysis treatment was not significantly different between NDWD and NDWE, except vitamin A intake in female patients.

Key words: hemodialysis, Taiwan, dietary pattern .

PO2138**INCREASE OF SERUM CHOLESTEROL LEVEL INDUCED BY DIETARY CHOLESTEROL INVOLVES SECRETION OF TRIACYLGLYCEROL FROM LIVER IN EXHC RATS.**

Y. Tanaka¹, K. Nagao¹, H. Nakagiri¹, T. Nagaso¹, Y. Iwasa¹, H. Mori¹, M. Asahina¹, K. Imaizumi¹, M. Sato¹

¹Department of Bioresource and Bioenvironmental Sciences, Faculty of Agriculture, Graduate School of Kyushu University, Fukuoka, Japan

Background and objectives: Clinically, high serum total cholesterol levels have been identified as risk factors for atherosclerosis and cardiovascular disease for decades. Cholesterol in serum derived from de novo synthesis in the liver and diets. Exogenously hypercholesterolemic (ExHC) rats, the model animal of diet-induced hypercholesterolemia, develop hypercholesterolemia only when dietary cholesterol is loaded. We previously showed that ExHC rats develop symptoms of hepatic low triacylglycerol (TAG) levels compared with Sprague-Dawley (SD) rats, the original strain, concurrently with hypercholesterolemia when dietary cholesterol is loaded. In this study, we compared ExHC and SD rats to explore a relationship between hypercholesterolemia and lower hepatic TAG levels in ExHC rats. This study provides new insight into regulation of cholesterol metabolism.

Methods: ExHC and SD rats were fed a 1% cholesterol diet for 1 week. Hepatic and serum lipid parameters, gene expressions and enzymatic activities related to lipid metabolism in the liver were measured.

Results: We reproducibly observed higher serum cholesterol and lower hepatic TAG levels in ExHC rats. The livers in ExHC rats developed Golgi apparatus to secrete beta-very low density lipoprotein (beta-VLDL) that contained higher cholesterol ester (CE) and lower TAG contents than those secreted by SD rats. Gene expressions related to fatty acid and TAG synthesis in ExHC rats were lower than that in SD rats. Enzymatic activities for fatty acid synthesis were also lower in ExHC rats. Moreover, according to fatty acid compositions of hepatic and serum CE in ExHC rats, these CEs were not modified after secretion from the liver.

Conclusions: Low production of liver TAG and secretion of CE-rich and TAG-poor lipoprotein of beta-VLDL without modification in the circulation caused hypercholesterolemia induced by dietary cholesterol in ExHC rats.

Key words: ExHC, triacylglycerol, beta-VLDL

PO2139**DNA MICROARRAY STUDY REVEALING THE GENE ALTERATIONS UNDER ANTI-DIABETIC EFFECT OF DECAFFEINATED COFFEE ON DIABETIC KKAY MICE**

S. Takahashi^{1,2}, Y. Mizutani^{1,2}, H. Kato²

¹Department of Applied Biological Chemistry, Graduate School of Agricultural and Life Sciences, The University of Tokyo

²Food for Life, Organization for Interdisciplinary Research Projects, The University of Tokyo

Background and objectives: Many epidemiological studies have suggested the risk-reducing effects of coffee consumption on diabetes, while the detailed mechanisms are poorly understood. Our previous experiments using C57BL/6J mice fed a high-fat diet showed that coffee intake suppressed hepatic fat accumulation, which is one of the important upstream events of type 2 diabetes. The present study was conducted to obtain information on the alterations in gene-expression to clarify molecular mechanisms underlying the effects of coffee on genetically-diabetic mice.

Methods: Male KK-Ay mice at 5 weeks of age were fed a high-fat diet (HF) or HF containing 2% powders of decaffeinated coffee (DC) for 3 weeks. Global gene expression profile of liver and adipose tissue were analyzed by DNA microarray.

Results: The results showed that DC prevented body weight gain and fat accumulation of mice. DC group showed a tendency of alleviated insulin resistance evaluated with an insulin tolerance test. The amount of plasma glucose, plasma free fatty acids and hepatic fat accumulation were lower in mice of DC group. DNA microarray analysis on adipose tissue revealed that the expression of genes involved in inflammation (MCP-1, CCR2 and LCN2) and extracellular matrix (Col8a1) were down-regulated by the intake of DC. Furthermore, the hepatic gene expression profile showed that the expression of Gclc gene, the deletion of which leads to hepatic steatosis with mitochondrial injury, was up-regulated by the intake of DC. These alterations were further validated by quantitative RT-PCR.

Conclusions: The present study suggests that the intake of DC may suppress inflammation of adipose tissue and dysfunction of its extracellular matrix, and suppress steatosis with mitochondrial injury in liver. These alterations may lead to the suppression of insulin resistance, and these findings provide significant insights into the association of the coffee intake and prevention of diabetes.

Key words: Coffee, diabetes, transcriptomics.

PO2140**EFFECT OF CHIA (SALVIA HISPANICA L) CONSUMPTION ON TNF- α LEVELS AND NUTRITIONAL STATUS IN BREAST CANCER PATIENTS**

L. Solano^{1,2}, A. Cardenas¹, C. Beltrán¹

¹Behavioral Feeding and Nutrition Research Center, Universidad de Guadalajara-CUSUR, Ciudad Guzman, Jalisco, México

Background and objectives: Breast cancer is the second cause of death in women in Mexico. Factors involved in cancer progression are increased levels of pro-inflammatory cytokines such as TNF- α and nutritional status. Chia is a seed rich which provides nutrients like antioxidants, proteins, vitamins, minerals and omega-3, it is a good nutritional alternative in cancer patients due to levels reduction of inflammation. Our objective was to associate the chia effect consumption on the levels of TNF- α and nutritional status in patients with breast cancer.

Methods: In 60 patients with breast cancer who were diagnosed in the period September to December 2012. In this period we divided the study in two phases; first, nutritional status was measured by body weight, body mass index, waist hip index, 24 hour recall and questionnaire nutrition. In serum samples, TNF- α were evaluated by ELISA. Then, subjects received 25 g of chia to consume three times a day for a month. After 1 month we did repetitions of previous experiments to evaluate chia effects on nutritional status and levels of TNF- α .

Results: We found decreased levels of TNF- α levels after consumption of chia and improving the nutritional status of patients with breast cancer.

Conclusions: Chia is a food endemic in Mexico used since pre-Hispanic times as medicine and has nutritional potential because it is rich in omega-3, has some properties to reduce levels of pro-inflammatory cytokines in patients with breast cancer, enhance the appetite and reduce weight loss. This food could be an alternative to breast cancer treatment.

Key words: Chia, breast cancer, nutritional status, TNF- α .

PO2141**PROTEOMIC ANALYSIS OF GLUCOSE AND LIPID METABOLISM IN LIVER OF DIABETIC MICE FED WITH TOONA SINENSIS LEAF ETHANOL EXTRACT***B. C. Yu¹, Y. T. Tsai¹, N. L. Ta¹, W. J. Yu², S. J. Chang¹*¹Department of Life Sciences, National Cheng Kung University, Tainan, Taiwan²Department of Biotechnology, Hung Kung University, Taichung, Taiwan

Background and objectives: Hepatic insulin resistance has been implicated in the hyperglycemia and dyslipidemia in the diabetic patients. *Toona Sinensis* leaf ethanol extract (TSL-E) has been reported to improve the hyperglycemia and dyslipidemia in *in vivo* and *in vitro* models. However, the mechanism of TSL-E on the glucose and lipid metabolism in liver remains unclear. Therefore, the aim of the present study is to investigate the mechanism of TSL-E on the liver metabolism.

Methods: The liver of diabetic mice and FLB3 hepatocytes were used to investigate the effects of TSL-E on liver metabolism. Proteomic analysis, Western blot and real-time PCR were used to analyze the changes of hepatic protein and RNA expression. The oil red O stain was used to examine the lipid accumulation in hepatocytes.

Results: Proteomic analysis results showed that TSL-E inhibited the sorbitol dehydrogenase (SDH), UDP-6 glucose dehydrogenase (UDH), and glutamate dehydrogenase (GDH) protein expression, leading to the reduction of gluconeogenesis in the liver of diabetic mice. Results of Western blot and real-time PCR demonstrated that TSL-E (100 µg/mL) increased the level of PPAR γ , uncoupled protein-3 (UCP), carnitine palmitoyl transferase 1 (CPT) and acyl-CoA oxidase (ACO) protein/RNA expressions, indicating that TSL-E increased the fatty acid β oxidation in hepatocytes. The results of oil red O stain showed that TSL-E inhibited the lipid accumulation in hepatocytes.

Conclusions: TSL-E decreased SDH, UDH, and GDH protein expression and increased PPAR γ , UCP, CPT and ACO expressions, leading to the reduction of gluconeogenesis and the induction of fatty acid oxidation in hepatocytes. These results suggest that TSL-E can be developed into a supplement for diabetic patients to improve the glucose and lipid metabolism of liver.

Key words: *Toona Sinensis*, liver, gluconeogenesis, fatty acid oxidation, diabetes.

PO2142**INDEPENDENT CONTRIBUTION OF NECK CIRCUMFERENCE TO THE RISKS OF CARDIO-METABOLIC SYNDROME IN PEOPLE OF SOUTHERN CHINA***H. Zhu¹, J. Zhou¹, H. Ge², M. Zhu², L. Wang¹, L. Chen¹, Y. Tan¹, Y. Chen*¹Department of Nutrition, Sun Yat-Sen University, Guangzhou, Guangdong, China²Health check-up Department, First Affiliated Hospital of Sun Yat-sen University, Guangzhou, Guangdong, China

Background and objectives: The aim of this study was to investigate and compare neck circumference as screening tool of cardio-metabolic risks with existing classical anthropometric indices as Body Mass Index (BMI), Waist Circumference (WC) and Waist to Hip Ratio (WHpR) in a large population of southern China.

Methods: A total of 4201 participants (2508 men and 1693 women) age 20-85 years were recruited from the routine health check-up department. Anthropometric indices, bio-chemical and clinical parameters were measured. Receiver-operating characteristic curves were performed and area under the curve (AUC) of anthropometric indices were calculated to evaluate the prediction of cardio-metabolic risks. Partial correlation and logistic regression analysis were employed to determine the association and likelihood of anthropometric indices and cardio-metabolic risks.

Results: NC positively correlated with SBP and DBP ($r=0.250$ and 0.261), fasting blood glucose ($r=0.177$), TG ($r=0.240$), TC ($r=0.143$) and LDL-C ($r=0.088$) and negatively correlated with HDL-C ($r=-0.202$) in male (all $p < 0.01$). Similar results were found in female with the exception of TC. Compared with the classical anthropometric indices, The AUCs of NC for all risk factors of cardio-metabolic syndrome were the lowest. However, the adjusted ORs (95% CIs) in men and women of NC for MS-rf were 1.39 (1.14-1.68) and 1.84 (1.39-2.43); for high BP were 1.32 (1.09-1.59) and 1.48 (1.12-1.93); for increased TG were 1.23 (1.02-1.48) and 1.72 (1.29-2.28); for increased FBP were 1.33 (1.03-1.70) and 1.44 (1.01-2.04); for decreased HDL-C only in women (OR; 1.47).

Conclusions: Neck circumference was significantly associated with cardio-metabolic risk factors and independently contributed to predict cardio-metabolic risks beyond the classical anthropometric indices in adults of southern China.

Key words: Cardio-metabolic risk factors, neck circumference, central obesity. [This study was supported by grants from National Natural Science Foundation of China (81072302 and 81273050) and Natural Science Foundation of Guangdong Province of China (10151008901000207)]

PO2143**COMPARATIVE ASSESSMENT OF NUTRITIONAL STATUS OF PATIENTS WITH END STAGE RENAL DISEASE ON HAEMODIALYSIS AND CONSERVATIVE THERAPY IN IBADAN, NIGERIA***O. Fabusoro¹, G. Fadupin¹*¹Department of Human Nutrition, University of Ibadan, Ibadan, Nigeria

Background and Objectives: Many experimental and clinical studies have shown that end stage renal disease patients are wasted or malnourished. This study was carried out to determine and compare the nutritional status of patients with end stage renal disease (ESRD) on hemodialysis and conservative therapy.

Methods: The study was an analytical study and it involved thirty (30) patients with ESRD (experimental group) and age and sex-matched apparently healthy subjects (control). Socio-demographic characteristics, medical history, lifestyle, anthropometric indices, dietary intake using 24-hr dietary recall and biochemical indices such as urea, creatinine, electrolyte (sodium and potassium) and packed cell volume (PCV) were obtained.

Results: The mean±SD age of the patients on conservative therapy, hemodialysis and controls were 49.7±14.4 years, 46.5±14.9 years and 44.4±12.3 years respectively. Majority (63.3%) of the patients had ESRD within one year, low proportion (15.6%) and (31.1%) of the patients had ever smoked cigarette and drank alcohol respectively. The mean±SD BMI of the patients on conservative therapy, hemodialysis and controls were 24.18±3.44 kg/m², 22.28±4.03 kg/m² and 24.86±5.03 kg/m² respectively while the mean±SD waist-hip ratio were 0.89±0.07, 0.90±0.05 and 0.86±0.06 respectively. The energy, protein, fat, retinol, ascorbic acid, zinc and iron intakes of the experimental groups were lower than the recommended daily allowance ($p < 0.05$). The serum urea (138.00±63.09 mg/dl, 104.80±41.57 mg/dl) and creatinine (5.93±2.62 mg/dl, 4.75±1.53 mg/dl) levels of the patients on conservative therapy and hemodialysis were high but better in hemodialysis group while their PCVs were low when compared with reference values. Potassium levels of the patients on conservative therapy were also high but normal for patients on hemodialysis.

Conclusions: For improvement of nutritional status of these patients there should be periodical assessment of nutritional status and appropriate measures taken to improving the quality of life and disease outcome.

Key words: End stage renal disease, biochemical indices, anthropometric indices.

PO2144**ASSOCIATIONS BETWEEN DIETARY FAT AND SERUM LIPID PROFILE DEPEND ON BODY FAT AND GENDER IN EUROPEAN ADOLESCENTS: THE HELENA STUDY***S. Bel-Serrat¹, T. Mouratidou¹, I. Huybrechts^{2,3}, M. García-Cuenca⁴, G. Palacios⁵, C. Breidenassel^{6,7}, D. Molnár⁸, R. Roccaldo⁹, K. Widhalm¹⁰, F. Gottrand¹¹, A. Kafatos¹², O. Androutsos¹³, K. Vyncke², M. Sjostrom¹⁴, L. Libuda¹⁵, A. Marcos¹⁶, L A. Background and objectives: Dietary and body fat are associated with adverse serum lipid profile and higher cardiovascular diseases (CVD) risk in adults. The aim of this study was to investigate the relationship between fat intake and body fat and serum lipid profile in European adolescents from eight European cities participating in the cross-sectional (2006-2007) HELENA study.

Methods: Weight, height, waist and hip circumferences, skinfolds thicknesses, total cholesterol (TC), high density lipoprotein-cholesterol (HDL-c), low density lipoprotein-cholesterol (LDL-c), triglycerides, apolipoprotein B and A1 were measured in 454 adolescents (44% boys) aged 12.5-17.5 years. TC/HDL-c, apolipoprotein B/apolipoprotein A1, waist-to-hip and waist-to-height ratios were calculated. Fat intake was assessed by two 24-hour dietary recalls. Associations were evaluated by multilevel analysis stratified by gender.

Results: After adjustments for potential confounders, a negative association was observed between dietary fat (g/day) and triglycerides, TC, TC/HDL-c ratio, LDL-c, apolipoprotein B and apolipoprotein B/apolipoprotein A1 ratio among female adolescents. Moreover, the ratios waist-to-hip and waist-to-height were positively related to triglycerides and TC/HDL-c ratio and negatively with HDL-c. A positive association was also found between waist-to-height ratio and apolipoprotein B and apolipoprotein B/apolipoprotein A1 ratio. No significant associations were observed in boys. An interaction was found between fat intake and body fat-related variables. Indeed, considerable adverse serum lipid profile was observed across tertiles of fat intake for those adolescents with higher sum of skinfolds and waist-to-hip and waist-to-height ratios compared to those with lower values for body fat measures.

Conclusions: Our results suggest that fat intake and body fat are associated with serum lipid profile and that this association differs according to gender and initial body fat status. These findings should be considered when developing strategies to prevent CVD risk among adolescents since serum lipids are major markers of CVD risk.

Key words: fat intake, body fat, gender, adolescents

PO2145

PINE BARK EXTRACT ATTENUATES COX-2 EXPRESSION IN INFLAMED CACO-2 CELLS

C. Frontela-Saseta¹, R. López-Nicolás¹, R. Canali², C. A. González-Bermúdez¹, P. Peso-Echarri¹, L. Fernández-Palacios¹, G. Ros-Berruazo¹, F. Virgili²

¹University of Murcia, Spain

²National Research Institute for Food and Nutrition (INRAN), Italy

Background and objectives: There is evidence that French maritime pine bark extract (PBE), used as ingredient of po-

lyphenol-enriched fruit juices improves inflammatory symptoms in vivo and in vitro. Cyclooxygenase-2 (COX-2) catalyzes the enzymatic conversion of arachidonic acid to prostaglandins and is induced in response to inflammatory stimuli, being demonstrated as a major molecular target for the prevention of cancer. In this study, we determine the effect of pine bark extract on the relative COX-2 mRNA expression in colon cancer cells.

Methods: Caco-2 cells and LPS stimulated Caco-2/RAW 264.7 cells, as model of intestinal inflammation, were exposed 2 h daily (4 days) to 4% of 0.5 g.L-1 PBE aqueous solution. Total RNA was isolated using RNeasy Mini kit (QIAGEN). The relative quantification of COX-2 expression was determined by qPCR with ABI PRISM[®] 7900 HT Instrument (Applied Biosystem) using SYBR Green and JumpStart[™] Taq Ready Mix kit (SIGMA). α -actin gene was used as reference. Data were collected and processed with SDS2.2 software. Results were expressed as fold induction compared with the relative COX-2 expression in untreated cells (DMEM) considered as control. Data were expressed as mean \pm SEM. Statistical analysis was performed by using paired t-test ($p < 0.05$).

Results: The in vitro inflammatory model determines an increase in COX-2 expression (about 3 times of untreated control cells). Following 4 days of PBE exposure, an inhibition of COX-2 gene expression in inflamed Caco-2 cells was observed. In fact PBE supplementation seems to be associated with a lack of induction of COX-2.

Conclusions: Future studies should elucidate the molecular effects of PBE on the translation of COX-2 enzyme in colonic cell lines in response to pro-inflammatory stimuli. This would help to better understand the kinetics of prostaglandin synthesis involved in the anti-inflammatory activity of PBE.

Key words: pine bark extract, Caco-2/RAW 264.7, COX-2

PO2146

LONG TERM INTAKE OF CARBOXYMETHYL-LYSINE GIVE RISE TO LOW-GRADE GUT INFLAMMATION

S. Pastoriza¹, C. Delgado-Andrade¹, J. A. Rufián-Henares²

¹Institute of Animal Nutrition, EEZ-CSIC, Granada, Spain

²Universidad de Granada, Granada, Spain

Background and objectives: The purpose of this study was to unravel the effect of a high long-term intake of carboxymethyl-lysine (CML), an advanced glycation compound produced in the Maillard reaction during the heat processing of foods, over the development of low-grade inflammation at the gut level.

Methods: Bovine serum albumin (BSA) was glycosylated with glyoxylic acid to produce a glycosylated BSA (G-BSA) enriched in CML. It was added to the AIN-93G diet to reach a final concentration of 3%. Wild type. BALB/c mice were fed for three months, monitoring the evolution of permeability, anti-proinflammatory cytokines and chemokines (IL1 β , IL6, IL10, IL18, TNF- α , CCL5), occludin, NLRP6 inflammasome, RAGE and GPR43 expression, mBD-3 defensin as well as gut microbiota composition were assayed.

Results: CML intake increased production of proinflammatory cytokines and RAGE expression, whereas a decrease on GPR43 and NLRP6 expression was observed. At longer times, a two-times increase on mBD-3 defensin and CCL5 produced changes in gut microbiota, decreasing commensal bacteria such as *Faecalibacterium prausnitzii* and increasing more detrimental ones like *Prevotella* spp. Then, a higher production of mucus degrading sulphatases gave rise to an increase of intestinal permeability and inflammation.

Conclusions: Dietary CML influences gut metabolism and immunity, producing a low-grade inflammation. Then, a high intake of severely heat-treated foods could increase the risk of inflammatory bowel disease development in those people with genetic susceptibility due to an immune system deregulation.

Key words: Carboxymethyl-lysine; gut; RAGE; GPR43; inflammation.

increased the release of proinflammatory IL1 β upon activation with LPS and ATP of the NLRP3 inflammasome. Taken together, these results indicate that propionic acid and CML competes in the inflammasome axis with opposite activities over NLRP3 and NLRP6.

Conclusions: Short chain fatty acids, produced after fermentation of dietary fiber, maintains gut homeostasis at the epithelium level through the activation of the NLRP6 axis, with an increase of IL18 release after danger stimuli such as ATP. However, CML coming from heat-treated foods produce an inverse effect, giving rise to release of inflammatory mediators (IL1 β) upon NLRP3 activation. Then, an imbalance on the dietary fiber and Maillard reaction products intake could trigger gut inflammation.

Key words: Inflammasome; carboxymethyl-lysine; short chain fatty acids; gut; inflammation.

PO2147

PROPIONIC ACID AND CARBOXYMETHYL-LYSINE REGULATES THE INFLAMMASOME AXIS IN GUT CELLS

S. Pastoriza¹, C. Delgado-Andrade¹, J A. Rufián Henares²

¹*Institute of Animal Nutrition, EEZ-CSIC, Granada, Spain*

²*Universidad de Granada, Granada, Spain*

Background and objectives: This study aims to study the effect of carboxymethyl-lysine (CML), an advanced Maillard reaction product found in the heat-processed foods, over the inflammasome axis in gut epithelial cells and neutrophils.

Methods: Neutrophils and gut epithelial cells obtained from BALB/c mice were cultured in RPMI 1640 medium supplemented with heat-inactivated 10% fetal bovine serum. Crystalline CML, propionic acid, LPS or ATP were added to the culture medium to assess their activity. IL1 β , IL18, proIL1 β , proIL18, NLRP3 and NLRP6 content were assessed with ELISA kits after cellular lysis.

Results: Epithelial cells produced a larger amount of IL18 than neutrophils because of IL18 sustains gut epithelium regeneration. Propionic acid stimulated NLRP6 inflammasome production whereas CML blocked this effect. However, CML

PO2148

A RAT MODEL OF GENETIC OBESITY SHOWS CHANGES IN SECRETION OF CYTOKINES (BASAL AND CON A STIMULATED) BY SPLEEN LEUCOCYTES

N.M. de Castro¹, J. Cruces¹, M. de la Fuente¹

¹*Department of Physiology, Faculty of Biology, Complutense University of Madrid, Spain*

Background and objectives: Obesity is characterized by a low and chronic inflammatory state due to the increased secretion of pro-inflammatory cytokines (PI) by the adipose tissue. Zucker rats (fa/fa), which carry the homozygotic mutation in the leptin receptor gene, are a model of genetic obesity. Previous studies have shown that these animals at adult age show a premature immunosenescence. It is well known that with ageing there is an imbalance in the secretion of cytokines, with higher levels of PI (such as TNF- α and IL-1 β) and lower levels of the anti-inflammatory (AI) (for example, IL-10) and IL-2 cytokines. For this reason, we have investigated the secretion of these cytokines by spleen leucocytes in these obese rats.

Methods: Male genetically obese rats (fa/fa), lean heterozygotic (fa/+) and Wistar rats fed with a standard diet were used. The spleen leucocytes of these animals at six months of age were obtained and maintained in a basal and stimulate culture with the T lymphocyte mitogen, concanavaline A (Con A). After 48 hours the culture medium was collected and the secretions of IL-2, IL-10, IL-1 β , and TNF- α were measured by luminometry.

Results: The results showed that the basal secretions of IL-10 and TNF- α were higher, and those of IL-2 lower, in obese animals compared to lean and Wistar rats. In response to Con A the levels of IL-10 and IL-2 in fa/fa rats were lower, and those of TNF- α higher, in comparison with the lean and Wistar rats.

Conclusions: The secretion of cytokines in obese rats, in response to the mitogen, seems to corroborate the premature immunosenescence in these animals, especially in the T cell response against infections, and their inflammatory state (high and low levels of PI and AI, respectively).

Key words: Obesity, Cytokines, Rats, Immunosenescence, Inflammation. Support: MCINN (BFU2011-30336); UCM Research Group (910379); RETICEF (RD12/0043/0018) ISCIII-FEDER (European Union).

PO2149

WEIGHT LOSS METHODS IN RELATION TO WEIGHT MAINTENANCE STATUS: FOCUS GROUPS RESULTS

E. Karfopoulou¹, K. Mouliou¹, Y. Koutras¹, M. Yannakouli¹

¹Department of Nutrition and Dietetics, Harokopio University, Athens, Greece

Background and objectives: Weight loss experiences may affect weight loss maintenance. We qualitatively explored experiences during weight loss and potential differences between weight loss maintainers and weight regainers.

Methods: 44 volunteers (41% males) formed 8 Focus Groups, 4 of maintainers and 4 of regainers. Participants had intentionally lost at least 10% of their starting weight and kept it off for at least 1 year (maintainers), or had regained most of the weight initially lost (regainers).

Results: Maintainers compared to regainers were younger (27±7 vs. 42±16 yrs, $p = 0.002$) and had a lower BMI (24.1±2.8 vs. 31.2±4.3 kg/m², $p < 0.001$). Reports on weight loss methods differed between the groups, with maintainers stating losing weight mostly on their own and regainers reporting seeking professional help. Maintainers applied modest diet changes, e.g. limiting intake of sweets and junk food, increasing eating frequency, increasing fruit/vegetable consumption, reducing portion sizes, and relied on self-monitoring techniques, e.g. keeping a diet diary, calorie counting, and regular weighing. In contrast, regainers had tried more extreme approaches, namely diet pills, detox/fasting diets, and meal substitutes. It is also of interest that the “experts” to whom regainers referred in order to lose weight, were not always accredited health professionals. Another prominent difference between the groups was physical activity experiences. Maintainers stressed the importance of exercising during weight loss, while regainers gave mixed remarks.

Conclusions: Maintainers and regainers reported differences in weight loss experiences. Maintainers made modest changes, on their own, while regainers tried more extreme approaches. Modest changes may be sustainable in the long-term,

hence leading to weight loss maintenance. Moreover, the ability to self-regulate diet and physical activity behaviors, contrary to having to seek external help, could be a feature positively influencing maintenance.

Key words: focus groups, weight loss maintenance, maintainers, regainers.

PO2150

CONSUMPTION OF PHENOL-RICH VIRGIN OLIVE OIL IMPROVES HIGH FAT DIET-INDUCED TYPE 2 DIABETES MELLITUS

E. Jurado^{1,2}, A. Cardenas^{1,2}, G. Berná^{1,2}, B. Soria^{1,2}, F. Martín^{1,2}

¹Andalusian Center of Molecular Biology and Regenerative Medicine (CABIMER), Seville, Spain

²CIBER de Diabetes y Enfermedades Metabólicas Asociadas (CIBERDEM), Seville, Spain

Background and objectives: Mediterranean dietary pattern appears to decrease the risk of type 2 diabetes (DM2). However, it is unclear whether the consumption of extra virgin olive oil (EVOO), alone, is able to improve DM2. Thus, we evaluated the differential effects of saturated, monounsaturated and phenol-rich monounsaturated (5-times higher levels of phenolic compounds) high fat diets (HFD) on endocrine function and glucose homeostasis.

Methods: 5-week-old male C57BL/6 mice were fed (3 months) with a HFD (48% energy from saturated fat; $n = 90$) and 9 months with standard diet (11% fat; control group; $n = 30$). Then, HFD mice were divided into 3 groups and fed 6 months more with: i) saturated HFD (HFD/SAT; $n = 30$); ii) EVOO HFD (HFD/EVOO; $n = 30$) and iii) phenol-rich EVOO HFD (HFD/EVOOP; $n = 30$). We measured body weight (BW), fasting blood glucose, serum insulin, intraperitoneal glucose tolerance test, insulin tolerance test, insulin resistance and insulin sensitivity, at different times. Moreover, we tested pancreatic islets insulin content, glucose stimulated insulin release (GSIR) and β -cell mass, at the end of the study.

Results: After 3 months, HFD mice developed obesity and DM2 with significantly ($p < 0.01$; $n = 90$) hyperglycemia, hyperinsulinemia, glucose intolerance, lower insulin response and insulin resistance, lower islet insulin content and GSIR and lower β -cell mass. Six months later, HFD/EVOO and HFD/EVOOP mice significantly ($p < 0.05$; $n = 20$) reduced their BW, glycemia and insulinemia, improved their insulin response and insulin resistance. Moreover, their islet insulin content, GSIR and β -cell mass significantly ($p < 0.05$; $n = 20$) increased.

Conclusions: These data support that monounsaturated and phenol-rich monounsaturated HFD improved BW, β -cell function and glucose homeostasis in a model of diet-induced

DM2. No special effects were observed with the presence of significantly higher ($p < 0,01$; $n = 3$) levels of phenolic compounds.

Key words: Olive oil, diabetes, insulin, obesity, pancreatic islet

PO2151

S- ADENOSYLMETHIONINE AS A MODULATOR OF HEPATOCYTE SURVIVAL IN NON- ALCOHOLIC FATTY LIVER DISEASE IN RATS

K. Bratoeva¹, I. Shterev², M. Tsaneva³, G. Bekyarova¹

¹Department of Pathophysiology, Medical University, Varna, Bulgaria

²Department of Medical Oncology, Medical University, Varna, Bulgaria

³Department of General and Clinical Pathology, Medical University, Varna, Bulgaria

Background and objectives: Chronic excessive fructose intake causes obesity, intrahepatic lipid accumulation, liver oxidative injury and Non-alcoholic fatty liver disease (NAFLD). Therapeutic approach to increase hepatic autophagy can prevent the progression of NAFLD from steatosis to steatohepatitis and liver diseases. Recent data suggest that pathologically activated apoptosis suppresses autophagy, which in an environment of oxidative stress and overfeeding should serve as a mechanism for hepatocyte survival. The aim of this study was to investigate the role of S- adenosylmethionine (SAM-e) (nutrient with antioxidant and antiapoptotic effects) in the mechanism of hepatocyte injury leading to cell death or survival.

Methods: Male Wistar rats ($n = 21$) were used in the experiment. They were divided into 3 groups: control, fructose fed (35 %, 16 weeks), fructose fed and treated with SAM-e (20 mg/kg b.w., 16 weeks). The expression of hepatic Bax (proapoptotic protein) and Beclin 1 (initiating autophagy protein) using light immunohistochemistry and malondialdehyde (MDA) as markers of oxidative stress were investigated. Liver histopathology was observed on light microscopy.

Results: The results showed microvesicular steatosis, increase liver MDA levels ($p < 0.05$), activation of Bax protein and diminished Beclin 1 expression in fructose fed rats compared with control group. In the group treated with SAM-e the expression of Beclin 1 was significantly higher while steatosis, MDA levels ($p < 0.001$) and Bax expression were reduced compared with fructose fed rats.

Conclusions: Our data showed that high fructose diet induces oxidative injury, apoptosis and steatosis in the liver. The administration of SAM-e inhibited oxidative damage and apoptosis suppressed autophagy in hepatocytes and it may be critical in the elimination of lipid accumulation in hepatocytes and the prevention of high fructose-induced steatosis.

Key words: apoptosis, autophagy, NAFLD, fructose.

PO2152

PREDICTIVE POWER OF DIFFERENT ANTHROPOMORPHIC MEASUREMENTS OF CENTRAL FAT DISTRIBUTION IN HAEMODIALYZED PATIENTS

M. Ruperto¹, S. Bastida¹, G. Barril², F.J. Sánchez-Muniz¹

¹Universidad Complutense de Madrid, Madrid, Spain

²Hospital Universitario de la Princesa, Madrid, Spain

Background and objectives: Increased central fat deposition is associated with inflammation, insulin resistance, hyperadipokinemia, dyslipidemia and oxidative stress, and a cardiovascular risk factor in general population as well as in hemodialysis (HD) patients. The study aimed to assess the predictive power of anthropomorphic measurements of central fat distribution [BMI, waist circumference (WC), Conicity index (Ci) and Waist-to-height ratio (WHR)] in HD patients.

Methods: Cross-sectional study in 80 HD patients (52 males, 65%) aged of 68 ± 14.4 y. Primary etiology of chronic kidney disease was diabetes mellitus (15.8%). Mean time on HD: 42.2 ± 39.6 months. Each participant underwent clinical assessment including anthropomorphic central fat distribution measurements (BMI, WC, Ci and WHR). Patients were classified by gender (men vs women). We also studied additional nutritional and inflammatory markers and were compared the interaction between them. Statistical analysis was performed by SPSS.

Results: By comparing variables adjusted by gender significant differences were found in standard body weight, WC, fat mass index, Ci (all, $p < 0,001$); and total cholesterol, C-HDL, CRP (all, $p < 0.05$). Multivariate analysis model showed significance association with WC and Ci ($p < 0.01$). The best anthropomorphic predictors of central fat distribution by analyzing ROC curves (95% CI) were both for men and women WC and Ci ($p < 0.01$). BMI and WHR took over areas under curves with no statistical differences between these indicators in both sexes (BMI, $p = 0.68$; WHR, $p = 0.77$).

Conclusions: Anthropomorphic measurements that include measure of central fat deposition are more reliable factors in HD than BMI alone. WC and Ci were the only predictors found to be related to central fat deposition in both sexes.

Key words: central fat deposition, inflammation, conicity index, hemodialysis.

PO2153**LEUCINE AND GLUTAMINE AS KEY AMINO ACIDS IN THE PREVENTION OF CANCER, RHEUMATISM, HIGH BLOOD PRESSURE AND DIABETES**

P. Ximenes¹, F. Jimenez Sanchez¹

¹Área de Dietética Y Nutrición Aplicada, Colegio Oficial Técnicos Superiores Sanitarios Comunidad de Valencia, España, Spain

Background and objectives: After decades of neglect of metabolites and nutrients in clinical and epidemiological research, we are witnessing a renewed interest in the application of these nutrients metabolites. Especially leucine and glutamine in clinical nutrition and sports are admitted as anabolics. Consumption of leucine and glutamine or its precursors (glutamine) provided by statistical and epidemiological data, if the assumption is consistent with the facts, should be found in both observational studies and intervention.

Methods: Search the PubMed database using keywords leucine, glutamine, oncology, epidemiology, rheumatology, diabetes, hypertension. The restriction on the last 6 years. Includes systematic reviews, clinical trials, meta-analysis.

Results: The selected bibliography suggest a central role for these two amino acids in these pathologies and exercise. Even certain nutritional interventions are questioning that glutamine and leucine might act negatively on expectations of healing.

Conclusions: It begins a discussion of nutrition policy in the community and in the clinic to undertake a more effective prevention of diseases such as cancer, metabolic (diabetes, dyslipidemia), rheumatic and hypertension. A new design of foods with leucine and glutamine (or their precursors) with the correct content should start studying.

Key words: leucine, glutamine, oncology, rheumatology, metabolism

PO2154**FREE INTAKE OF SOME VEGETABLES AND FRUITS IN TREATMENT OF PHENYLKETONURIA (PKU).**

V. Hamilton¹, G. Benedetti¹, G. Castro¹, C. Arias¹, E. Raimann¹, J. Cabello¹, A. Valiente¹, K. Betta¹, M. Colombo¹, V. Cornejo¹

¹Laboratorio de Genética y Enfermedades Metabólicas, INTA, Universidad de Chile, Santiago, Chile

Background and objectives: Phenylketonuria (PKU) treatment consist in a restricted phenylalanine (Phe) intake, mainly based on special formula, vegetables, fruits and few amounts of cereals. The Phe levels must be maintained below 8

mg/dl. The aim was to evaluate if free intake of some vegetables and fruits alters Phe level.

Methods: 8 PKU patients 3–15 years old, were included in a longitudinal study. Phe intake was maintained and children could consume as free food all the fruits and vegetables with less than 75 mg Phe/100g. Phe intake record was done daily and Phe levels were measured once a week (mass spectrometry method).

Results: 4 patients were males (6.5±2.4 years) and 4 females (7.6±4.6 years). Before the study Phe intake was 453.6±104.6 mg/d, post intervention increased to 555.7±134.8 mg/d ($p < 0.05$). They ate 30% additional Phe intake from cereal, vegetables and fruits with more than 75 mg Phe/100 g ($p < 0.05$). Had 102 mg extra Phe intake from vegetables and fruits with less 75 mg Phe. Phe levels before study were 4.1±0.8 mg/dl, and increased to 5.3±0.9 mg/dl during the study ($p < 0.05$), (normal range: 2–8 mg/dl).

Conclusions: Study suggests that the liberation of vegetables and fruits containing less than 75 mg Phe does not increase Phe level above the normal range.

Key words: PKU, phenylalanine, PKU treatment.

PO2155**EFFECT OF SUPPLEMENTATION WITH OMEGA-3 ON DYSLIPIDEMIA IN CHILDREN AND ADOLESCENTS INFECTED WITH HIV ON ANTIRETROVIRAL TREATMENT**

M. Araujo¹, M. Goehnix¹, N. Escobal¹, A. Agostinho¹, R. Uicich¹

¹Hospital Nacional de Pediatría J P Garrahan, Buenos Aires, Argentina

Background and objectives: The extended life expectancy in HIV patients favored the development of metabolic abnormalities that contribute to the accelerated progression of cardiovascular disease (CVD), dyslipidemia being the most frequent abnormality in the pediatric population. Effective dyslipidemia treatment could help reduce the risk of premature CVD. The aim of the study was to investigate the effect of supplementation with n-3 polyunsaturated fatty acid on dyslipidemia and atherosclerosis in HIV patients on antiretroviral therapy highly effective.

Methods: Prospective, interventional. We analyzed variables related to illness, anthropometric, laboratory and intima-media thickness (IMT) assessing the effect of daily administration of 2 g of polyunsaturated fatty acids n-3 for 6 months in a group of 25 patients between 8 and 18 years with dyslipidemia and HIV infection controlled, monitoring at the Hospital Garrahan.

Results: Adherence was measured by dosage of DHA and EPA in erythrocyte membrane, with a statistically significant increase for both 2.6% and 5.1% DHA and 0.18% to 0.42% EPA ($p < 0.001$). Triglycerides, total cholesterol, LDL-cholesterol and HDL-cholesterol showed no significant differences after 6 months of supplementation. The IMT of the carotid arteries (0.50 mm basal - 0.51 mm 6 months $p = 0.36$) did not show a significant decrease, either. A significant decrease in fatty acid precursors of the inflammatory mediators AA (20:4 w6) and dihomo-gamma-linolenic acid (20:3 w 6), in the erythrocytes membrane, was showed as a secondary outcome.

Conclusions: There was no evidence a favorable change in dyslipidemia and / or subclinical atherosclerosis in this group of patients with good adherence. This study showed a statistically significant decrease in the precursors of some inflammatory markers involved in CVD.

Key words: HIV, cardiovascular disease, dyslipidemia, omega 3

PO2156

NUTRITIONAL PROFILE OF PATIENTS TREATED IN AN ENDOCRINOLOGY OUTPATIENT CLINIC IN SOUTHERN BRAZIL

E. I. Rabito^{1,2}, F. M. Busnello¹, P. Vargas¹, T. Medeiros¹

¹Department of Nutrition, Universidade Federal de Ciências da Saúde de Porto Alegre, Porto Alegre, Brazil

Background and objectives: Considering that non-communicable chronic diseases (NCDs), such as diabetes mellitus (DM), cardiovascular diseases (CVDs), systemic arterial hypertension (SAH) and obesity have become the main priority of Brazilian public health system and that the most afflicted have low purchasing power¹ and sedentary habits, like inadequate food intake, this study intended to characterize the nutritional profile of patients treated in endocrinology an outpatient clinic in southern Brazil.

Methods: The follow-up of patients occurred once a week in a reference hospital. The referral for nutritionists was made by endocrinologists. In the first appointment, information about gender, age, abdominal circumference and occurrence of DM and SAH (subject to prior medic diagnosis) were collected. This data was utilized for characterization of the nutritional profile presented in this work, and is related to the period from March 2012 to February 2013.

Results: 55 first appointments were made, being 64% ($n = 35$) women and 36% ($n = 20$) men, all with average age of 52.7 years. According to the abdominal circumference data, 91.4% ($n = 32$) of women and 65% ($n = 13$) of men presented very increased risk for CVDs. In total, 74.5% ($n = 41$) of the patients

were diagnosed with DM, being 60.97% ($n = 25$) women and 39.02% men. 69% ($n = 38$) of the patients were diagnosed with SAH, being 63.15% ($n = 24$) women and 36.84% ($n = 14$) men.

Conclusions: Although the results refer to a segment of risk of the population, the high prevalence of DM, SAH and risk for CVDs found shall serve as alert for the public health system. Besides, the bigger portion of women with pathologies, even if the analysis is only focused on individuals of the same gender and doesn't refer to the total number of individuals, might instigate association studies between gender, income and NCDs prevalence.

Key words: chronic disease, obesity, outpatient clinic.

PO2157

DIETARY INTAKE IN ADULTS WITH CHRONIC HEPATITIS C

E. I. Rabito¹, T. G. Pereira¹, G. C. B. A¹

¹Department of Nutrition, Universidade Federal de Ciências Da Saúde de Porto Ale

Background and objectives: Liver disease patients may have low food intake, it may result in nutritional deficiencies and malnutrition, influencing their prognosis. The aim of the study was to describe the prevalence of inadequacy dietary intake in of patients infected with hepatitis C virus (HCV).

Methods: The is a cross-sectional study conducted among 94 outpatients, aged 30 to 76 years, both sexes, infected with hepatitis C virus non-cirrhotic and non-transplanted. We measured weight, height and calculated body mass index (BMI). The 24 hours recall has been applied to evaluate the food intake.

Results: Mean age among was 52.6 years and 46 were males.. Mean weight was 70.2 kg and BMI=26.3 kg/m² The energy intake below the recommended levels was detected in 49 (52.1%) individuals and low protein intake in 44 (46.8%). We found inadequate intake of Calcium, Potassium, Zinc and Vitamin C in 92.6%, 97.9%, 63.8% and 60.6% of the sample, respectively, and excessive consumption of sodium occurred in 53.2%.

Conclusions: Most patients with HCV has low energy and protein intake and high intake of sodium.

Key words: nutritional status, dietary intake, liver disease.

PO2158**CARDIOVASCULAR OUTCOMES OF REFINED CARBOHYDRATES ARE INFLUENCED BY THE TYPE OF DIETARY FAT**

M. Abeywardena^{1,2}, J. Dallimore¹, M. Adams¹, S. Burnard¹

¹CSIRO - Animal, Food & Health Sciences, Adelaide, S A, Australia

Background and objectives: Recent reviews of evidence show that a reduction in saturated fat intake leads to a modest reduction in cholesterol, but not in incidence of cardiovascular disease. Conversely, the advice to replace of dietary fat with carbohydrates, notably those with a high glycemic index, has inadvertently exacerbated weight gain, obesity, insulin resistance and metabolic syndrome in humans, and is associated increased cardiovascular risk. It is also possible that the type of dietary fat may influence the metabolic outcomes of refined carbohydrates. The aim was to evaluate the effects of potential dietary matrix interactions between refined carbohydrates and different dietary fatty acids (monounsaturated and saturated) on the development of cardio-metabolic abnormalities including body composition (e.g. fat and lean mass), tissue fatty acid composition, blood pressure (BP), vascular function and vulnerability to cardiac arrhythmia and sudden cardiac death.

Methods: Rats were fed standard diets consisting of either high oleic sunflower oil (HOSO) or anhydrous milk fat (MF) as the source of fat (7% w/w) and further supplemented with fructose (60% w/w). Diets were matched for linoleic acid content. After 8 week of feeding body composition determined by DEXA scanning, BP monitored by tail-cuff and the animals were subjected to in vivo coronary artery ligation to induce myocardial ischemia and arrhythmia outcomes quantified.

Results: High fructose diet increased BP in the HOSO group (BP 14mmHg, $P < 0.001$ vs control) but not in the MF-fed rats. Compared to the diet rich in MF, HOSO feeding was associated with a lower vulnerability to cardiac arrhythmia that was increased by the presence of fructose. The higher incidence of arrhythmia outcomes associated with MF was not further influenced by fructose. Considerable differences in tissue fatty acids were noted between dietary groups.

Conclusions: Cardiovascular outcomes of refined carbohydrates are modulated by type of fatty acid in the diet.

Key words: diet, carbohydrates, fat, cardiovascular disease.

PO2159**RESVERATROL PROTECTS VASCULAR ENDOTHELIAL CELLS FROM HIGH GLUCOSE-INDUCED APOPTOSIS THROUGH INHIBITION OF NADPH OXIDASE ACTIVATION DRIVEN OXIDATIVE STRESS**

F. Chen^{1,2}, L. Qian¹, B. Deng¹, Y. Zhao², Z. Liu³, Y. Le¹

¹Key Laboratory of Nutrition and Metabolism, Institute for Nutritional Sciences, SIBS, Chinese Academy of Sciences, Shanghai, China

²Department of Neurology, Changzheng Hospital, Second Military Medical University, Shanghai, China

³Department of Endocrinology, Changzheng Hospital, Second Military Medical University, Shanghai, China

Background and objectives: Hyperglycemia induced oxidative stress has been implicated in diabetic vascular complications in which NADPH oxidase is a major source of reactive oxygen species (ROS) generation. Resveratrol is a naturally occurring polyphenol which has vasoprotective effects in diabetic animal models and inhibits high glucose-induced oxidative stress in endothelial cells. We aimed to examine whether high glucose (HG)-induced NADPH oxidase activation and ROS production contribute to glucotoxicity to vascular endothelial cells and the effect of resveratrol on glucotoxicity.

Methods: Murine microvascular endothelial cell line bEnd3 was used in all experiments. Cell viability was examined by MTT or Hoechst 33258 staining. NADPH oxidase activity was measured by the lucigenin chemiluminescence method. ROS production was measured with H2DCF-DA. The expression of NADPH oxidase subunits was examined by RT-PCR and Western blot. Inhibitors for NADPH oxidase, MAP kinases, or PKC; siRNA against Nox1; and dominant-negative I κ B α expressing plasmid were used in the mechanistic study.

Results: We found that NADPH oxidase inhibitor (apocynin) and resveratrol both inhibited HG-induced endothelial cell apoptosis. HG-induced elevation of NADPH oxidase activity and production of ROS in endothelial cells was inhibited by apocynin, suggesting that HG induce endothelial cell apoptosis through NADPH oxidase-mediated ROS production. Mechanistic studies revealed that HG upregulated NADPH oxidase subunits Nox1 but not Nox2 and p22phox expression through ERK/JNK/PKC-NF- κ B pathway, which resulted in elevation of NADPH oxidase activity and consequent ROS production. Resveratrol prevented HG-induced endothelial cell apoptosis through inhibiting HG-induced NF- κ B activation, NADPH oxidase activity elevation and ROS production.

Conclusions: Our results demonstrate that HG induces endothelial cell apoptosis through ERK/JNK/PKC-NF- κ B-NADPH oxidase-ROS pathway, which was inhibited by resveratrol. Our findings provide new therapeutic targets against vascular complications of diabetes.

Key Words: resveratrol, hyperglycemia, vascular endothelial cells, NADPH oxidase, apoptosis.

PO2160**DIETETIC PRACTICES IN THE MANAGEMENT OF CHILDHOOD OBESITY IN MALAYSIA**

N B. Md. Yusop¹, Z. Mohd Shariff¹, T. Tzer Hwu¹, R. Abd. Talib², N. Spurrier³

¹Department of Nutrition and Dietetics, Faculty of Medicine and Health Sciences, Universiti Putra Malaysia, Serdang, Selangor, Malaysia

²Department of Nutrition and Dietetics, Faculty of Allied Health Sciences, The National University of Malaysia, Kuala Lumpur, Malaysia

³Department of Paediatrics and Child Health, Flinders University and Flinders Medical Centre, Flinders University, South Australia, Australia

Background and objectives: Dietitians play an essential role in the management of childhood obesity and consistency in dietetic practices is required to ensure the effectiveness of the treatment. This study aimed to assess dietitians' current practices in the management of childhood obesity, compare the practices with practice guidelines used by dietitians in other countries and identify practice components for the development of nutrition clinical practice for the management of childhood obesity in Malaysia.

Methods: A cross-sectional study was conducted among 40 dietitians in 16 Ministry of Health hospitals and three teaching hospitals. Information on current dietetic practices in the management of childhood obesity was obtained through mailed survey questionnaire. The practices included nutritional assessment, energy requirement determination, dietary prescription and physical activity modification. Emails were sent to 31 dietetic associations in other countries to obtain information on practice guidelines used by dietitians. Practice guidelines from the United States, Canada and New Zealand were used for comparison.

Results: About 45% and 55% of dietitians used CDC growth reference (2000) and WHO growth standard (2007) to determine child obesity, respectively. Frequently used dietary intervention and physical activity modification approaches were high fiber diet (65%), low fat diet (40%), reduction of sedentary pursuits and screen times (67.5%) and increase in duration of current activities (60%). In comparison to other dietetic practice guidelines, the current dietetic practices in Malaysia did not include waist circumference, biochemical data and blood pressure. Similar to other guidelines, the current dietetic practices included a low dietary fat, high fiber diet, decrease sedentary activity and increase physical activity.

Conclusions: The management of childhood obesity in our clinical setting is diverse and a comprehensive nutritional clinical practice guideline that includes nutritional status assessment, energy requirement determination, dietary prescription and physical activity modification is urgently needed.

Key words: childhood, obesity and dietitians

PO2161**DIETARY HABIT AND PREVALENCE OF GUM DISEASE IN OBESE CHILDREN**

T A. Ndanu¹, A. Lartey², R. Ayeetey³, J. Sackeyfio¹, G. Otoo²

¹University of Ghana Dental School, Korle Bu

²Nutrition and Food science Department, University of Ghana, Legon, Ghana

³School of Public Health, University of Ghana, Legon, Ghana

Background and objectives: Poor dietary habits and oral hygiene practices are major factors for gum disease in adults and children. Obesity in adults has been associated with increased risk in gum diseases but this association is not yet clear in obese children. To assess the relationship between dietary habits and gum disease among obese and non-obese school children.

Material and methods: 510 (219 obese and 291 non-obese) School children (9-15 yrs) were recruited from 8 selected private schools in Accra, Ghana. Oral examination was done for all the children, breakfast intake, frequency of consumption of various foods, snacking habit and soft drink intake were assessed. Frequency of tooth cleaning, tooth cleaning material, mouth wash and toothpick use, were determined. Oral plaque, calculus, and gingival indices were used to estimate oral hygiene status and Community periodontal index of treatment needs (CPITN) score was used to assess gum disease. Logistic regression was used to assess the influence of the dietary factors on the gum disease.

Results: Mean age was 11.5yrs, Weekly frequency of consumption of fruit juices, evaporated milk, milk drinks and pizzas were significantly higher among the obese but corned beef, and watermelon were higher for non-obese, ($p < 0.050$), but were not significantly associated gum disease. Breakfast, and soft drink intake did not significantly affect gum disease. Weekly intake of snacks showed a significant association with gum disease (OR 0.782, CI; 0.626-0.976, $p = 0.030$). Overall prevalence of gum disease was 4.7%; (obese 3.7% and non-obese 5.5%, $p = 0.330$).

Conclusions: Only snack consumption was associated with gum disease in the two groups. Most oral health indices between obese and non-obese were similar but lower Plaque index for obese suggest better oral hygiene in the obese than the non-obese. Gum disease did not differ for the two groups.

Key words: dietary habit, gum disease, plaque index, snacks.

PO2162**SYSTEMATIZATION OF NUTRITIONAL ASSISTANCE TO PATIENTS OF THE ONCOLOGY AND HEMATOLOGY UNIT, UNIVERSITY HOSPITAL VIRGEN DE LAS NIEVES IN GRANADA**

K. Borges Mustafa¹, A M. Trigo Fonta¹, G. Lobo Támer¹, A. Pérez de la Cruz¹, A. Navarro Medina¹

¹Hospital Universitario Virgen de Las Nieves, Granada, Spain

Background and objectives: Cancer patients at high risk of malnutrition due, first, to the characteristics of the underlying disease, and secondly, to the treatments. The assessment of nutritional status provides preventive and therapeutic tools where necessary. Establish routine nutritional care of patients admitted to the units of Oncology and Hematology of a hospital.

Methods: The techniques used were: classification of patients based on attendance levels, previously determined by observing these, nutritional interview, anthropometry and dietary record. Attendance levels of the patients were classified as 1-3 Clinical and nutritional profile: Level 1 (N1) well-nourished patients without nutritional risk without specific diet or overweight without comorbidities, Level (N2) Nutritional risk, overweight, obesity and comorbidities good diet acceptance, Level 3 (N3) with low nutritional risk acceptance of diet, nutrition therapy. From the list of patients admitted was performed nutritional assessment (dietary recall and medical history) of new revenue and their relative rankings by level of care, determining the total weekly visits for follow up. During follow-up the patient was carried food delivery record for those who had low dietary acceptance, besides doing anthropometry and nutritional assessment.

Results: We evaluated 35 patients (18 of Hematology and 17 of Oncology). Of which were classified as 34.28% N1, 40% N2 and 25.71% N3. The sickest patients in relation to their nutritional status and that required a larger number of weekly visits were in Hematology (N3 - 66.9%). From observation and nutritional monitoring of patients, was discussed with the medical team the need to supplement or an alternative supply.

Conclusions: The Nutritional assessment must be performed to diagnose the disease and continuously at different stages of evolution of the disease. It should therefore be included in the daily routine management of patients with these characteristics.

Key words: cancer. nutritional assessment.

PO2163**PERCEPTION OF PAIN IN CHILDREN, ITS IMPACT ON LIFESTYLE AND DIETARY HABITS**

M I. Aguirre Gallego¹, G. Lobo Támer¹, M A. López Casado¹, A. Perez Aragon¹, J. Romero Gonzalez¹, C. Caro Morente¹

¹Hospital Universitario Virgen de Las Nieves, Granada, Spain

Background and objectives: It has been well established Helicobacter pylori as a cause of peptic ulcer (PU) in adults, but in children the evidence is not as strong, although highly suggestive. The most common symptom in PU is epigastric burning pain that typically occurs when the stomach is empty. The aim of the study was to determine the prevalence of HP infection in children, assess the impact of pain on their daily activities. Assess willingness to change eating habits.

Methods: Children with pain and evaluated in the child outpatient Gastroenterology Unit, are referred to the Functional Tests Unit for diagnosis, and the presence of HP is determined by the "urease test". The survey "EVA" was administered to all patients in addition to the scales "ECR" and "EAF".

Results: A sample of 181 children on ages from 3 to 15 years old (average age 8.9±2.8 years). The 46.4% of the sample were male. In regard to weight, 17.3% had low weight according to the age (T 10 percentile), and the body mass index (BMI) was 18.8±4.3 kg/m². The perception of pain assessed with the scale "VAS" reflects that children are suffering severe pain, which leads them to interrupt the hours of play (66.4%), sleep hours (44.2%), and truancy (66.3 %). In 12% of the cases are both parents who are absent from their work, however, the parents' concern about pain is low in 47% of cases. An attitude change referring to these habits is proposed, 64.6% of families willingly accepted a nutrition change, and it was proved in subsequent interviews that 70.2% of those who accepted actually accomplished with the habits change.

Conclusions: It's necessary to develop preventive and therapeutic strategies targeting children at risk and it should be our challenge for the coming years in pediatrics, in order to predict future complications.

Key words: pain, children, helicobacter pylori, peptic ulcer.

PO2164**PREVALENC OF METABOLIC AND BEHAVIOR CARDIOVASCULAR RISK FACTORS IN INDONESIAN POPULATION 2007***R. Sukirna*¹¹Department of Epidemiology, School of Public Health University of Indonesia

Background and objectives: Cardiovascular disease is becoming more prevalent in Indonesia. Risk factors are a condition that might increase the risk of developing cardiovascular disease. The objective of this study is to determine the prevalence of metabolic and behavior cardiovascular risk factors among Indonesian population.

Methods: Data for this study derived from sub sample of the National Basic Health Survey 2007. The studied population consisted of 5851 adults aged 40 years and older. Hypertension, abnormal blood lipids, hyperglycemia, obesity were identified as metabolic cardiovascular risk factor while current smoking, physical inactivity, stress and consumed less fiber food were identified as behavioral risk factors.

Results: Prevalence of hypercholesterolemia was 53.0 %. Prevalence of low level of HDL (high density lipoprotein) cholesterol was 59.3 %, hypertension 44.2 %, hyperglycemia 25.5 %, obesity abdominal 34.9 % and prevalence of individual clustering metabolic risk factors were 37.2 %. Prevalence of hypercholesterolemia, low level of HDL and obesity abdominal as well as clustering of metabolic risk factors were significant higher among those who lived in urban area compared to rural. Prevalence of smoking was 31.7%, of low intake of fiber was 57.5%, of physical inactivity was 19.8% and of stress was 12.7%. Prevalence of individual clustering of behavioral risk factors was 36.0 %. Prevalence of smoking and low intake of fiber and clustering of behavioral risk factors were significant lower among those who lived in urban compared to rural area.

Conclusions: Difference prevention strategy should be taken into consideration to reduce metabolic cardiovascular risk factors among urban population and to reduce behavior cardiovascular risk factors among those rural population.

Key words: cardiovascular disease, risk factors, urban, rural

PO2165**DIETARY INTAKE OF VITAMIN A, E, C, MAGNESIUM, ZINC AND SELENIUM IN ASTHMATIC PATIENTS***L. Maghsumi Noroozabad*¹, *A.R. Ostadrahimi*², *M.E. Hejazi*³, *R. Abed Viarsagh*¹, *A.R. Safaiyan*⁴¹MSc Students' Research Committee, Faculty of Health & Nutrition, Tabriz University of Medical Sciences, Tabriz, Iran²PhD, Department of Nutrition, Nutrition Research Center, Faculty of Health & Nutrition, Tabriz University of Medical Sciences, Tabriz, Iran³PhD, Department of Respiratory Medicine, Tabriz University of Medical Sciences, Tabriz, Iran⁴MSc, Department of Statistics and Epidemiology, Faculty of Health and Nutrition Tabriz University of Medical Sciences, Tabriz, Iran

Background and objectives: The aim of this study was to compare dietary intake of vitamins A, E, C and minerals (magnesium, zinc, and selenium), energy and anthropometric measurements (height, weight, BMI) among people with and without asthma.

Methods: This cross-sectional study included 148 adults aged 20 to 60 years old. Seventy-four were recruited from one of the centers of Tabriz medical clinics as patient group. The control group consisting of 74 subjects was from various places. A general questionnaire and three food questionnaires were filled for each person. The nutrient intake was determined using nutritionist IV software. Consent letter was obtained. Statistical analysis of X² and student t-test were used.

Results: Difference in the average intake of zinc from supplements was significant ($p = 0.009$). Intake of zinc from supplement in the patient group was (0.68 ± 0.68) and control group was (6.08 ± 1.91). The Average intake of vitamin E ($p = 0.033$) from food between two groups was significant. Intake of vitamin E in the case group was (5.4 ± 1.13) and the control group (14.32 ± 3.94). There was a significant difference in the average total intake of vitamin A ($p = 0.027$) from different sources between two groups. The average total intake of vitamin A in cases was (2444.15 ± 799.43) and controls was (5892.01 ± 1313.9). The difference in total average intake of zinc ($p = 0.023$) from various sources was significantly different between two groups. There were significant differences in average height between two groups ($p = 0.000$); average height of the patients was (168.50 ± 1) and control group was (170.31 ± 0.96). Use of supplement in control group was higher ($p = 0.017$).

Conclusions: Intakes of total vitamin A and total zinc from various sources, vitamin E from food, zinc from supplements, average height and Frequency distribution for qualitative variable minerals used from supplements in the case group were significantly lower than controls.

Key words: asthma, vitamins A, E and C, selenium, magnesium, zinc.

PO2166**INFLAMMATORY RESPONSE AFTER PARENTERAL NUTRITION LIPID EMULSIONS IN CHILDREN WITH BONE MARROW TRANSPLANTATION**

M A. Baena-Gomez¹, M J. de la Torre¹, J. Olza², F J. Llorente-Cantarero¹, J L. Perez-Navero¹, M. Gil-Campos¹

¹Reina Sofia University Hospital, IMIBIC, Córdoba, Spain

²University of Granada, Granada, Spain

Background and objectives: Parenteral nutrition (PN) side effects are associated with metabolic and inflammatory changes. There is evidence that emulsions enriched with omega-3 fatty acids can modify the inflammatory response. The objective of this study was to compare changes in levels of plasma cytokines in children undergoing bone marrow transplantation (BMT) after a fish oil or soybean PN.

Methods: 14 children with BMT and requiring PN for at least 10 days were selected. They were randomized in a clinical trial to use a lipid emulsion with fish oil or soybean oil. Blood samples at baseline, at 10 days and at the end of the PN were taken to analyze plasma cytokines: interleukin 1 beta (IL-1 β), 2 (IL-2), 6 (IL-6), 8 (IL-8) and 10 (IL-10) and tumor necrosis factor alpha (TNF- α).

Results: After 10 days of PN, there were no significant changes in the levels of interleukins when comparing the two groups or by time. However, in patients requiring PN more than 21 days (4 in each group), those receiving the emulsion enriched with soybean showed higher levels of IL-10 and TNF- α ($p < 0.05$) at the end of PN, than omega-3 emulsion group. Similarly, levels of IL-1 β showed a tendency to be higher in soybean group ($p = 0.07$).

Conclusions: PN administered in children for a short period of time up to 10 days, and even with different fat formulas, does not cause significant inflammatory changes. However, when PN is prolonged in time (over 21 days), fish oil formulas appear to modulate the inflammatory response. So, more studies are still required in childhood to provide information on the effects of lipid emulsions.

Key words: parenteral nutrition, cytokines, inflammation, childhood, bone marrow transplant.

PO2167**IMPACT OF NUTRITION EDUCATION ON PATIENTS UNDERGOING CHRONIC HEMODIALYSIS AT GENERAL HOSPITAL OF DOUALA**

P N. Zebaze¹, C M. Mbofung¹, M P. Halle², H G. Mbiat³

¹National Advanced School of Agro Industrial Sciences, Ngaoundéré, Cameroon

²Nephrology/ Hemodialysis unit, General Hospital of Douala, Douala, Cameroon

³Dietetic unit, General Hospital of Douala, Douala, Cameroon

Background and objectives: Protein-energy malnutrition is common in chronic hemodialysis. Furthermore there is accumulation of substances normally excreted by the kidneys between dialysis sessions. All significantly increase morbidity and mortality risk. The objective of this study was to evaluate the nutritional status of patients undergoing chronic hemodialysis at general hospital of Douala and find out the impact of nutrition education on their nutritional features.

Methods: A randomized trial was conducted on 113 chronic dialysis patients at general hospital of Douala between March 2012 and September 2012. The intervention group received in addition to usual treatment 3 sessions of weekly nutrition education based on the nutrition guideline of national kidney foundation from 1st to 21st June 2012 whereas the control group received regular treatment. Both groups were observed for a further 2 months to assess the impact. Information on socioeconomic status, anthropometric and biochemical features, dietary intake assessed by the 24 hours recall was collected.

Results: The study population consisted of 67.3% men, mean age 49 \pm 14 years. According to the Body Mass Index, only 3.5% of patients were malnourished. 27.7% had interdialytic weight gain > 5.7% of dry weight. 39.8% presented a muscle wasting. Biochemical features were done in only 50.4%. Among this 31.6% had hypoalbuminemia, and 35.10% had hypocholesterolemia. 44.1% of patients consume less than 3 principal meals per day and only 9.30% had diversified diet. Two months after intervention, interdialytic weight gain and ultrafiltration of the intervention group significantly dropped. In the same way, the percentage of patients having diversified diet increased significantly. No significant change was observed in control group.

Conclusions: This study shows that malnutrition is largely present among hemodialysis patients of general hospital of Douala and that Nutrition education can help to ameliorate their nutritional status.

Key words: Chronic hemodialysis, nutritional status, food habit, nutritional education.

PO2168

ASSOCIATION BETWEEN ABO BLOOD GROUPS AND BODY MASS INDEX AMONG ADULT PARTICIPANTS IN EAST AZERBAIJAN, IRAN

N. Mesri¹, N. Roshan Ravan¹, M. Asghari Jafarabadi², B. Mohammadi³, F. Anari⁴

¹Department of Biochemistry and diet therapy, Student Research Center, Faculty of Nutrition, Tabriz University of Medical Sciences, Tabriz, Iran

²Medical Education Research Center, Department of Statistics and Epidemiology, Faculty of Health, Tabriz University of Medical Sciences, Tabriz, Iran

³Faculty of Management and Medical Information, Kerman University of Medical Sciences, Kerman, Iran

⁴Roh zende health and Therapeutic center 2, Sha-bestar, Iran

Background and objectives: Overweight and obesity are among the most common health problems. Obesity as a potential risk factor for chronic diseases, rapidly increasing in Iran and other developing countries. ABO blood groups are associated with the risk of certain chronic disease. The purpose of this study was to investigate possible association between ABO blood type and overweight and obesity among adult population.

Methods: Total population of 381 men and women based on the inclusion and exclusion criteria were selected. Anthropometric measurements and type of blood were determined. To define the obesity and overweight in population study, body mass index (BMI) were used. To determine the correlation between body mass index and blood type chi-square statistical tests and One-way ANOVA was applied using SPSS ver.16 Software.

Results: 15.2% of participants were male and 84.8% were female. 5.8% of them were underweight, 41.5% normal weight, 27.8% overweight and 24.9% were obese. Blood group O was the most common one in the study population (35.95%). Although the correlation between blood groups and different BMI categories were poor and non-significant ($p = 0.42$) but the highest frequency of overweight and obesity were observed in blood group AB (36.4%) and blood group A (29.6%) respectively. The Average BMI and body weight in A blood group was higher compared to other blood types.

Conclusions: Results indicate no possible association between ABO blood group and overweight and obesity in adult population. However further studies to accept or reject this hypothesis seems necessary.

Key words: ABO blood group, body mass index (BMI), obesity, overweight.

PO2169

ZINC, COPPER AND MAGNESIUM CONCENTRATIONS IN IMPAIRED GLUCOSE TOLERANCE: THEIR RELATION

N. Roshan Ravan¹, M. Asghari Jafarabadi², N. Mesri Alamdari¹

¹Department of Biochemistry and diet therapy, Student Research Center, Faculty of Nutrition, Tabriz University of Medical Sciences, Tabriz, Iran

²Medical Education Research Center, Department of Statistics and Epidemiology, Faculty of Health, Tabriz University of Medical Sciences, Tabriz, Iran

Background and objectives: Diabetes mellitus is a chronic metabolic disorder which affects carbohydrate, lipid and protein metabolism. There is strong evidences that homeostasis of trace elements can be disrupted by impaired glucose tolerance. On the other hand, disturbance in trace element status in impaired glucose tolerance may contribute to the insulin resistance and development of diabetic complication. The aim of present study was to compare the concentration of essential trace elements, zinc, copper and magnesium in serum of pregnant women with impaired glucose tolerance ($n = 44$) with those of healthy pregnant subjects ($n = 44$).

Methods: The serum concentrations of zinc, copper and magnesium were measured by means of an atomic absorption spectrophotometer (AAS) after acid digestion. To compare the mean serum levels of variables in 2 groups Independent Samples T-Test analysis was applied using SPSS ver.16 Software. $p < 0.05$ was considered as significant.

Results: There were no differences in plasma magnesium levels between groups ($p = 0.998$). Plasma copper ($p = 0.000$) and zinc ($p = 0.028$) was lower in women with impaired glucose tolerance than in control subjects.

Conclusions: The results of this study showed that deficiency of some essential trace elements may play a role in the development of impaired glucose tolerance and gestational diabetes mellitus. However, it is not known whether differences in trace element status are a consequence of impaired glucose tolerance, or alternatively, whether they contribute to the expression of the disease.

Key words: impaired glucose tolerance, zinc, copper, magnesium, trace element

PO2171**REDUCED ACID LOAD OF THE MACROBIOTIC MA-PI DIET IMPROVES GLYCEMIC CONTROL AND CARDIOVASCULAR RISK FACTOR IN TYPE 2 DIABETES.**

C. Porrata-Maury¹, F. Fallucca², A. Bufacchi³, M. Hernández-Triana⁴, V. Ruíz-Álvarez⁴, M. Pianesi⁵

¹Macrobiotic Diet Service, Finlay Institute, La Havana, Cuba

²University La Sapienza, Rome, Italy

³Centre for Preventive Medicine IPA, Italy

⁴Department of Biochemistry and Physiology, Institute of Nutrition, La Havana, Cuba

⁵UPM Un Punto Macrobiotico, Italy

Background and objectives: The diet acid load has been associated to inflammation, insulin resistance, and cardiovascular risk. Main purpose of this study was to evaluate the impact of the lower acid load of the macrobiotic vegetarian Ma-Pi diet (70% carbohydrate as whole cereals, 12% vegetable protein, 18% fat) on this association.

Methods: A prospective 21 days dietary intervention was carried out in 24 adults with type 2 diabetes (15 men, 9 women; 60.3±6.4 y of age). Cases were selected from diabetic patients afferent to the Preventive Medicine Centre of IPA, Rome. Subjects were submitted to anthropometric, body composition, biochemical, and blood pressure records. Data at onset and termination were compared.

Results: The lower diet acid load was evidenced by the 7% increase in urinary pH ($p = 0.0027$) and 10% in blood bicarbonate ($p = 0.0014$), together with a 27% reduction of the serum anion Gap ($p = 0.0006$). Significant decreases were present in: leucocytes, 18% ($p = 0.0000$); glycaemia, 35% ($p = 0.0000$); insulinemia, 68% ($p = 0.0000$); HOMA-IR, 69% ($p = 0.0000$); total cholesterol, 23% ($p=0.0000$); LDLc, 24% ($p = 0.0000$); LDLc/HDLc, 17% ($p=0.0013$); triglycerides, 53% ($p = 0.0000$); urea, 45% ($p=0.0000$); homocysteine, 17% ($p=0.0002$); microalbuminuria, 81% ($p=0.0000$); systolic blood pressure, 8.3% ($p=0.0000$); and diastolic blood pressure, 7.5% ($p = 0.0000$).

Conclusions: The macrobiotic Ma-Pi diet improved, at short term, insulin resistance and decreased the cardiovascular risk in type 2 diabetic patients. The reduced lower acid load was evidenced.

Key words: macrobiotic diet, diet acid load, insulin resistance, cardiovascular risk, diabetes.

PO2172**EFFECT OF AMARANTH GRAIN CONSUMPTION ON HEALTH AND NUTRITION STATUS OF ADULTS LIVING WITH HIV IN MWEIGA, NYERI -KENYA**

Z. Ndungu¹, E. Kuria¹, N. Gikonyo², D. Mbithe¹

¹Department of Foods, Nutrition and Dietetics, Kenyatta University, Nairobi, Kenya

²Department of Pharmacy and Complementary/ Alternative Medicine, Kenyatta University, Nairobi, Kenya

Background and objectives: People living with HIV (PLHIV) are at greater risk of under nutrition, infections and death. Use of nutrient dense foods is one of the interventions to deal with these challenges. Minimal information exists on effect of consumption of amaranth grain on health and nutrition status. The objective of this study was to assess the effect of amaranth grain consumption on health and nutrition status of PLHIV.

Methodology: One group pre-test post-test experimental design was adopted. A comprehensive sample of 66 PLHIV not on antiretroviral therapy was purposively selected. The intervention involved daily consumption of porridge made from 100 grams of amaranth grain flour for six months. Dietary practices, nutrition status and CD4 cell count were monitored during the intervention period. Data were analyzed using SPSS computer software.

Results: mean energy consumption increased by 13.1% from 3139±365 SD to 3549±386 SD for males and by 16.7% from 2479±312 SD to 2892±330 SD for females. There was a significant increase ($p = 0.041$) in CD4 cell count by 22.0% (105±16.3SD). The proportion of the respondents who met the RDAs for zinc, iron, magnesium, calcium and vitamin E increased from below 40% to over 77% after addition of amaranth grain to the diet. The mean weight gain was 3.35±0.5 kg which led to a reduction on proportion that was underweight from 71.2% at baseline to 7.6% at month six.

Conclusions: Consumption of amaranth grain porridge supplemented the diet of PLHIV and enabled them to meet the RDAs for energy and selected micronutrients. It also led to increased CD4 count. This study recommends adoption of amaranth grain by PLHIV both at community and health facility level for improved health and nutrition status.

Key words: amaranth grain, HIV, CD4 count, weight gain, micronutrient status.

PO2173

URBANIZATION AND RISK FACTORS FOR NON-COMMUNICABLE DISEASES IN THE WESTERN CAPE PROVINCE, SOUTH AFRICA

i. Lombard¹, A. Belonje², S. Ho²

¹NICUS, Division of Human Nutrition, Stellenbosch University, Stellenbosch, South Africa

²Athena Institute, VU, Amsterdam, The Netherlands

Background and objectives: There are correlations between urbanization and prevalence of risk factors for non-communicable diseases (NCDs), but little is known about elements of urban environments contributing to the development of these factors. In developing countries with overburdened health systems, allocating limited resources effectively are essential. The aim was to identify environmental factors contributing to the development of risk factors for NCDs in resource-poor urban contexts.

Methods: Two communities in the Western Cape, South Africa were included. A community-based survey (n = 230 female adults), using the WHO STEPwise approach to Chronic Disease Risk Factor Surveillance, was conducted. Risk factors included overweight (BMI \geq 25), alcohol use, tobacco smoking, low fruit and vegetable consumption, and physical inactivity. A socioeconomic score was calculated based on education, occupation, and wealth. Urban elements identified were population composition, physical environment, social environment and access to health and social services.

Results: Overweight/obesity was found in 149 participants (64.8%); 43 participants (18.7%) reported daily smoking; 50 participants (21.7%) reported binge drinking, fruit and vegetable consumption was extremely low with 94.8% (n = 218) of respondents consuming less than the recommended 5 servings per day. 50% (n = 115) had insufficient weekly physical activity. In total, 115 (50%) participants were at high risk (3 or more risk factors) for developing NCDs. Being at high risk for NCDs was independently associated with working (OR 0.31; 95%CI:0.12-0.74; p = 0.008), being married (OR 2.22; 95%CI:1.08-4.54; p = 0.030), having a larger house (OR 1.44; 95%CI:1.06-1.95; p = 0.019), and never having visited a health center (OR 0.19; 95%CI:0.04-0.92; p = 0.040).

Conclusions: The study shed light on the relationship between urban living environment and risk factors for NCDs. Future studies should include quantitative and qualitative research to strengthen the knowledge base from which sustainable interventions can be derived.

Key words: non-communicable diseases, urbanization, risk factors, physical environment, lifestyle.

PO2174

FACTORS INFLUENCING NUTRITION EDUCATION OF FARM WORKERS IN THE WESTERN CAPE PROVINCE, SOUTH AFRICA

M. Lombard¹, A. Belonje², A. Vermond²

¹NICUS, Division of Human Nutrition, Stellenbosch University, Stellenbosch, South Africa

²Athena Institute, VU, Amsterdam, The Netherlands

Background and objectives: Nutrition education, focusing on the stages of change is the foundation to prevent the increased prevalence of obesity. The aim of this study was to identify factors that influence nutrition education in farming communities.

Methods: The study comprised semi structured in-depth interviews with male and female farm workers (n = 16) and managers (n = 4) from randomly selected wine farms (n = 4) in the Western Cape, South Africa.

Results: Workers were aware of the importance of healthy eating via repeated messages from the media and health workers, but had difficulties defining healthy food, and evaluating their own food habits. They were motivated to change because they value their family's health and fear diseases. Factors influencing nutrition education programs in this farming community included: i) social norm (awareness should be raised amongst all workers, regardless of job description, gender or age, to increase motivation, create a sense of ownership and obtain sustainability); ii) social structure (men should support change and women should obtain social support and empowerment to implement change) iii) limited education and learning experience in general (programs should be basic, especially because participants have limited experience in nutrition education), iv) lack of financial management skills (workers have sufficient financial resources to buy and prepare healthy food, but lack budgeting and planning skills), v) lack of ownership (a sense of ownership regarding health should be created) and vi) familiarity (program should focus on familiar food products and dishes to increase the likelihood of change).

Conclusions: Long term, practical, repetitive, short and small classes rather than theoretical courses were supported. The consultation of farm workers to develop a suitable nutrition education program is valued and can be recommended for development of nutrition education in other communities.

Key words: nutrition education, farm workers, overweight and obesity, behavior change.

PO2175**NUTRITIONAL MANAGEMENT OF CHILDREN WITH CANCER: CASE OF KENYATTA NATIONAL HOSPITAL - KENYA***R. Shikuri¹, J. Waudu², E. Kuria²*¹Masinde Muliro University of Science and Technology, Kakamega, Kenya²Kenyatta University, Nairobi, Kenya

Background and objectives: Observations at the Kenyatta National Hospital wards prior to the research period indicated a marked increase in cases of child cancer patients being admitted with various complications. These complications interfered with the children's food consumption patterns as there was increased morbidity and infections since the immunity of these children was compromised. The purpose of this study was to investigate the nutritional management of children with cancer at Kenyatta National Hospital by investigating the food consumption patterns of children with cancer and finding out their nutritional status.

Methods: A descriptive survey design was used. The study sample was made up of 60 children aged 6 months' to 14 years and 15 service providers. Purposive sampling was used. Data collection instruments included a self-administered questionnaire, an interview schedule, anthropometry, 24 hour dietary recall and an observation checklist. Data was analyzed using the Statistical Package for Social Sciences Programme. **Results:** 32% of the children were stunted, 26% were underweight while 12% were wasted. The findings confirmed that all the 18.3% children in the advanced stage of the disease were malnourished. A majority (88.5%) of the children's food intake was affected by the type of treatment received while the disease process affected 71.8% of the patient's food intake. Most of these interferences occurred in the middle (55%) and advanced stages (18.3%) of the disease.

Conclusions: Food consumption patterns of children with cancer at Kenyatta National Hospital were influenced by the following factors: type of cancer a child suffered from, stage of the disease, duration of cancer disease and therapy used to manage their conditions. In view of these findings, the study recommends that nutritionists should emphasize the importance of adherence to the amounts of nutrients recommended for individual child cancer patients.

Key words: nutritional status, food consumption patterns, stunting, wasting, underweight.

PO2176**RESISTANT STARCH AND DIETARY FIBRE CONTENT OF COMMON INDIAN COOKED FOODS AND ITS EFFECT ON GLYCEMIC INDEX***K. Krishnaswamy¹, R. Vaidya¹, K. Balasubramaniam¹, D. Asha¹, V. Sudha¹, R M. Anjana¹, V. Mohan¹*¹Madras Diabetes Research Foundation, Gopalapuram, Chennai, Tamil Nadu, India

Background and objectives: The prevalence of Type 2 diabetes and NCDs had risen to 8.3% in 2011 and is expected to be 9.9% by 2020 globally. Attempts are being made to reduce the risk of NCDs by modifying dietary carbohydrates to impact glycemic index (GI) and glycemic load (GL) of the diet. In view of this, the present study was undertaken to determine the resistant starch (RS) and dietary fiber (DF) content of cooked Indian foods and its impact on GI.

Methods: A total of 8 Indian food items prepared by moist heat cooking method and 13 Indian foods prepared by dry heat method were selected. They were prepared using standard recipes in the test kitchen facility. All the samples were freeze dried and analyzed for DF and RS content using Megazyme Enzymatic Kit at the Foods Analytical Lab of our center. The GI of foods were estimated using internationally recognized GI protocol in-house and for some foods GI values have been imputed from the international GI table.

Results: The RS content of traditionally cooked Indian foods ranged from 0.33 g (fermented rice cake) to 2.83 g (legume and rice based pancake). The Indian cooked foods with dry heat method showed significantly higher RS content than the moist heat method based food items ($p < 0.027$). DF and RS content of the foods were inversely correlated with GI ($r = -0.671$ and $r = -0.587$ respectively).

Conclusions: Cooking methods could influence RS content of the foods. Both DF and RS impact the GI of the Indian foods. Future research to study the impact of RS on glycemic response by continuous glucose monitoring test is required. **Acknowledgement:** This study was sponsored by Department of Science and Technology (DST), New Delhi, India

Key words: Resistant starch, dietary fiber, glycemic index, moist heat, dry heat

PO2177

THE RELATION BETWEEN SOCIOECONOMIC SITUATION, ECONOMIC ENVIRONMENT AND OBESITY IN TURKISH ADULTS

E. Sezer¹, M. Bas¹, H. Avsar¹

¹Baskent University, Faculty of Health Science, Department of Nutrition and Dietetics, Ankara, Turkey

Background and objectives: This research was done in order to investigate the relation between socioeconomic situation, economic environment and obesity. The number of total participants is 487.

Methods: A survey, which includes general demographics information and nutritional behavior was filled by the researcher. Socio economic status determination scale, developed by Kuppuswamy from India, was used for socio economic classification of the participants. Each participant was assigned a score related to his/her education status, occupation and income status and then classified according to the summation of these scores. 5 socio economic status are determined according to the survey results and they are; upper, upper middle, middle, lower middle and lower classes.

Results: In the research, it was determined that, participants who are classified in lower socio economic status have higher BMI averages. It was extracted from the study that, the upper socio economic status participants have an average BMI of 23 ± 4.6 kg/m² and the lower socio economic status participants have an average BMI of 28.7 ± 7.7 kg/m². It was noticed that, there is an important statistical relation between the socio economic status and BMI of the participants ($p < 0.05$). The average waist circumference of male participants in upper socio economic status was found as 98.8 ± 15.5 cm, and the average waist circumference of female participants were found as 72.5 ± 11.8 cm.

Conclusions: In this research, it was determined that there is a relationship between socioeconomic status and obesity. Participants are in lower socioeconomic class have greater BMI and waist circumference values than the other participants.

Key words: BMI, obesity, socioeconomic status.

PO2178

PREVALENCE AND DETERMINANTS OF OBESITY AMONG SCHOOL CHILDREN 13-17 YEARS OF BHILAI CITY

A. Joglekar^{1,2}, G. Jain², S. Bhardwaj³

¹Department of Nutrition/ Govt. G.N.A. College, Bhatapara, Pt.R.S. University, Raipur, Chhattisgarh, India

²Department of Nutrition / Guest Lecturer Govt. K.D.M College, Pt.R.S. University, Raipur, Chhattisgarh, India

³Department of Home-Science / Govt. Dr WW P Girls PG college, Pt.R.S. University, Raipur, Chhattisgarh, India

Background and objectives: The WHO refers obesity as a global epidemic because of rapid increase in the number of overweight and obese individuals in last 20 years. The onset of obesity may occur at any age and it may be triggered by factors such as early weaning, inadequate food intake, eating disorders and problems related to disturbed family relationships.

Methods: We measured the weight, height, body mass index, Waist Hip ratio of children. The children were classified as normal, underweight, overweight or obese, according to body mass index per age. 500 children were assessed at a school of Bhilai Nagar.

Results: The overall prevalence of overweight among children was 23.8% and obesity was 8.4%. The prevalence of overweight was 23.44% among boys and 24.22% among girls; 8.02 and 8.81% were obese, respectively. WHR provides index of relative accumulation of abdominal fat. According to WHR among 500 subjects 9.1% boys are overweight and nil obese, where as in girls 41.40% are overweight and 21.14% obese. The prevalence rate of central obesity is higher in girls in comparison to boys.

Conclusions: We observed an association between excess weight and obesity and inactivity in children. The time spent in watching TV was a positive factor for maintaining a balance between weight and height. The study also suggested that under nutrition rates remain high in children. Therefore Special attention has to be given for their overall nutrition.

Key words: abdominal obesity, adolescent, physical activity.

PO2179

L-ARGININE SUPPLEMENTATION PREVENTS ALLODYNIA AND HYPERALGESIA IN A RAT MODEL OF DIABETIC NEUROPATHIC PAIN BY NORMALIZING PLASMA NITRIC OXIDE CONCENTRATIONS.

L. Rondón^{1,2}, A M. Privat², N. Davin², J. Fialip², A. Eschallier³, C. Courteix²

¹Laboratorio de Fisiología Molecular, Centro de Bioquímica y Biofísica, IVIC, Altos de Pipe, Estado Miranda, Venezuela

²INSERM U766, Clermont Université, Université d'Auvergne, UFR Pharmacie, UFR Medicine, Clermont-Ferrand, France

³CHU, Clermont-Ferrand, France

Background and objectives: Neuropathic pain is a common feature of diabetic patients. It is characterized by symptoms of spontaneous and stimulus-evoked pain including hyperalgesia and allodynia. Arginine-deficiency has been observed in diabetes. Arginine has been implicated in numerous physiologic and pharmacological effects. Its metabolites are considered important neurotransmitters, related to exert regulation on cationic channels responsible for pain processing at the N-methyl-D-aspartate (NMDA) receptor channel complex. Thus, if arginine deficiency and changes in its metabolites might contribute to the development of neuropathic pain we propose to evaluate the effects of arginine supplementation on its metabolites, and on biological and clinical parameters in the development of neuropathic pain in diabetic rats.

Methods: Male Sprague-Dawley rats were rendered diabetic by an intraperitoneal (i.p.) injection of STZ (72mg kg⁻¹). Controls received an i.p.-injection with distilled water. One week after, animals were assigned to three experimental groups: Control non-diabetic, Non-supplemented STZ-D, and L-Arg-supplemented STZ-D rats receiving L-arginine (2.5 g.l⁻¹ of L-Arginine in drinking water for 3 weeks). Measurement of clinical (body weight, food and water intake); biological (blood glucose, plasma insulin, and urine nitrogen) parameters; arginine and its metabolites (ornithine, glutamate, glutamine, citruline and nitric oxide (NO)); and pain sensitivity (mechanical hyperalgesia, tactile and thermal allodynia) were performed.

Results: STZ-administration induced typical symptoms of type-1 diabetes. Diabetic-rats also displayed mechanical hypersensitivity, tactile and thermal allodynia, and increased NO plasma concentrations. Arginine supplementation increased insulinemia and reduced polydipsia, polyuria and urine nitrogen excretion. Moreover, it abolished thermal and tactile allodynia, mechanical hypersensitivity in 80% of the rats, and normalized NO plasma concentration.

Conclusions: Neuropathic pain symptoms can be attenuated by arginine supplementation, targeting the NO production and probably agmatine-mediated blockade of NMDA receptors, offering new therapeutic opportunities for the management of chronic neuropathic pain.

Key words: arginine, nitric oxide, NMDA receptors, STZ-D rats, pain.

PO2180

EFFICACY OF GLUTAMINE IN THE PREVENTION OF OXIDATIVE STRESS IN CANCER PATIENTS UNDERGOING RADIOTHERAPY IN THE ABDOMINAL OR PELVIC REGION.

B. San-Miguel^{1,2}, J. Ortiz de Urbina², I. Crespo¹, A. Laliena¹, D. Vallejo¹, A. Vidal-Casariago², J. Culebras², M J. Tuñón¹

¹Institute of Biomedicine (IBIOMED) and CIBERehd, University of León, León, Spain

²Complejo Asistencial Universitario de León, Hospital of León, León, Spain

Background and objectives: Among the antineoplastic therapies, radiotherapy plays an important role, either as first choice or adjuvant to surgery. Radiotherapy, can produce acute and chronic toxicity of non-tumor tissues due to its cytotoxic effects, resulting from direct DNA damage and production of free radicals. Reactive oxygen and nitrogen species initiate a series of chain changes that ultimately cause tissue damage. In the case of patients with pelvic tumors radiotherapy leads to gastrointestinal damage. Glutamine, the most abundant amino acid in the bloodstream, plays a protective role in intestinal cells during physiologic stress; however, the protective mechanisms are not fully understood. Objective. The aim of this study is to determine if glutamine prevents oxidative stress during radiotherapy in cancer patients undergoing radiotherapy of the abdomino-pelvic cavity.

Methods: Double-blind, randomized, controlled trial including 69 patients that received glutamine (Gln, 30 g/day) or placebo (Pla). Oxidant/antioxidant blood markers were determined by ELISA.

Results: Most patients (65.2%) were male, 66.6 (9.9) years of age, with urologic (44.9%), rectal (24.6%) and gynecological cancer (23.1%). Markers of inflammation and oxidative and nitrosative stress do not differ between the two groups at endpoint: IL-1beta [Gln 4.56±0.38 pg/ml vs Pla 4.64.89±0.29 pg/ml], MPO [Gln 29.65±2.3 ng/ml vs Pla 28.99±0.7 pg/ml], protein carbonyl [Gln 0.58±0.06 nmol/mg vs Pla 0.55±0.042 pg/ml] and nitric oxide [Gln 3.0±0.1µM vs Pla 2.9±0.1 µM]. Moreover, glutamine administration produced no significant changes in glutathione concentration [Gln 0.382±0.04 µM

vs Pla $0.363 \pm 0.03 \mu\text{M}$], antioxidant capacity [Gln $14.49 \pm 1.3 \text{ mM}$ trolox vs Pla $13.89 \pm 1.5 \text{ mM}$ trolox] and catalase activities [Gln $261.8 \pm 29 \text{ UL-1min-1mgp-1}$ vs Pla $227.8 \pm 55 \text{ UL-1min-1mgp-1}$].

Conclusions: Glutamine does not prevent the development of oxidative stress during radiotherapy.

Key words: glutamine, oxidative stress, cancer.

PO2181

STUDY ON RELATIONSHIP BETWEEN DIETARY SODIUM INTAKE AND HYPERTENSION IN HEILONGJIANG RESIDENTS

G. Jiang¹, A. Qin¹, S. Liu¹, Y. Zhang¹

¹Department of Nutrition and Food Safety, Heilongjiang Center For Disease Control and Prevention, Beijing, China

Background and objectives: To explore the relationship between dietary sodium intake and hypertension and provide scientific evidence on hypertension intervention.

Methods: We used a subpopulation of 1,254 subjects aged 18-65 years old in Heilongjiang province from an ongoing longitudinal study, China Health and Nutrition Survey. We used a stratified multistage cluster sampling scheme to randomly select two cities and four counties in Heilongjiang province. Experienced physicians collected detailed diet data and measured blood pressures.

Results: The prevalence of hypertension increased from 25.0% in 2004 to 28.0% in 2009. Added salt intake decreased slightly from 7.6 g/day to 7.4 g/day; however this was offset by an increased sodium intake from 3.6 d/day to 3.8 g/day. One key change was the significant increase in processed food consumption from 60.5 g/day to 70.4 g/day.

Conclusions: The increased prevalence of hypertension is much more rapid and has attained a much higher level in Heilongjiang than in other areas in China. Excessive intakes of sodium and processed foods, particularly pickled vegetables, may attribute to the high prevalence of hypertension.

Key words: sodium intake, hypertension, processed food.

PO2182

DYNAMICS OF NUTRITION TRANSITION AND RISK OF DIABETES IN HUBEI, 1991-2009

S. Liu¹, J. Lie, C. Gong¹, M. Cheng¹, Y. Song¹

¹Institute of Health Surveillance, Analysis and Protection, Hubei Center For Disease Control and Prevention, Hubei, China

Background and Objectives: To examine the effects of dynamics of nutrition transition on risk of diabetes in Hubei, China.

Methods: A subsample of adults aged 18-75 years ($n = 1,169$ at baseline) from the China Health and Nutrition Survey was used. Dietary data were collected by using 3 consecutive 24-hour recalls in combination with weighing methods. Exploratory factor analysis method was used to analyze dietary patterns and scores. Multivariate logistic regression models were used to estimate the association between dietary patterns and risk of diabetes.

Results: During 1991 and 2009, Hubei witnessed a significant increase in intakes of vegetables, fruits, meat, eggs, fish, milk and oil, and a significant decrease in intakes of cereals, legumes and salt (p -trends < 0.01). Accordingly, energy intake decreased but energy from fat increased over time. Seven dietary patterns among male and six patterns among female were observed and determined. Multivariable logistic regression demonstrated that meat-fruit pattern and meat-fast food pattern were positively related with risk of diabetes risk among both male and female. Compared to the 1st quartile of meat-fruit pattern, the risk of the 4th quartile increased by 8 times (OR=8.29, 95% CI: 1.69-40.63) among male. Compared to the 1st quartile of meat-fast food pattern, the risk increased by 7.5 times in the 3rd quartile (OR=7.50, 95% CI: 1.96-58.61) and the 4th quartile (OR=7.55, 95% CI: 1.67-45.23) among female.

Conclusions: Dietary patterns among residents in Hubei province are shifting toward meat-fruit pattern and meat-fast food patter that significantly increase the risk of diabetes among male and female.

Key words: dietary pattern, nutritional status, factor analysis, diabetes, risk factors.

PO2183**SMOKING MAY INCREASE THE RISK OF DIABETES AMONG ADULTS**

¹Department of Nutrition and Food Safety, Huairou District Centre For Disease Prevention and Control, Beijing, China

Background and objectives: The prevalence of diabetes is increasing in Beijing, China, while the risk factors remain unknown.

Methods: a subsample of 1,085 adults aged 18 years old and older from the China Health and Nutrition Survey was used. Hemoglobin A1c was used to determine diabetes status. Blood pressure and anthropometric data were measured with standard protocols. Binary logistic regression models were used to examine the association between smoking and diabetes.

Results: The prevalence of diabetes was 8.4% in this study population, with higher prevalence among men than among women (9.6% vs. 7.3%), and higher prevalence in elder people than in younger people. Adjusted for age, gender, and body mass index (BMI), smoking significantly increased the risk of diabetes (OR=1.432, 95% CI: 1.00-2.05).

Conclusions: smoking cessation may decrease the risk of diabetes among adults in Beijing.

Key words: diabetes, smoking, BMI.

PO2184**RELATIONSHIP BETWEEN BODY MASS INDEX, WAIST CIRCUMFERENCE AND HYPERTENSION**

Z. Tang¹, Z. Fang¹, H. Yang¹, Q. Wang¹, X. Liu¹, Y. Chen¹

¹Guangxi Zhuang Autonomous Region Center For Disease Control and Prevention, Beijing, China

Background and Objectives: To explore the relationship between body mass index (BMI), waist circumference (WC) and the prevalence of hypertension among residents in Guangxi, China.

Methods: A multistage random cluster sampling method was used to draw the sample for the China Health and Nutrition Survey in Guangxi. A subsample of 1,131 adults aged 18 years old and older was used in this study. Blood pressure and anthropometric data were measured with standard protocols. Multivariate logistic regression models were used to examine the association between BMI and WC and hypertension.

Results: The overall prevalence of hypertension was 21.4% in Guangxi. It was 17.3% among normal weight group (BMI 18.5 to 23.9), 33.0% among overweight group (BMI 24.0 to 27.9), and 39.0% among obesity group (BMI > 28). The linear trend was significant ($p < 0.01$). The prevalence of hyperten-

sion was 15.7% among normal WC group (WC < 85 cm in men or <80 in women and 34.1% among central obesity group (WC > 85 cm in men or > 80 cm in women). Central obesity significantly increased the risk of hypertension (OR = 2.769, $p < 0.01$).

Conclusions: Overweight and obesity significantly increases the risk of hypertension. Central obesity or waist circumference may be a better indicator to predict hypertension than BMI.

Key words: Body mass index, waist circumference, hypertension.

PO2185**STUDIES ON PHYSICOCHEMICAL AND BIOLOGICAL ACTIVITIES OF OPHICEPHALUS STRIATUS BLOCH COLLECTED FROM THE FRESH WATER IN THE BANGLADESH**

E. Mollik¹

¹Department of Biological Sciences, Peoples Integrated Alliance, Dhaka, Bangladesh

Background and objectives: Bangladesh is a land of rivers. She well and woe depends on rivers. There are many big and small rivers. The studies depict the content of moisture, protein, fat, minerals, and antimicrobial activities in the fresh water fish of Bangladesh. Fish selected for the studies is *Ophicephalus striatus* Bloch.

Methods: Oil was extracted from the *Ophicephalus striatus* Bloch. Fatty acids analysis of the oil by G.L.C indicated relatively high proportions of oleic acid (33.08%), stearic acid (28.97%), palmitic acid (17.66%), linoleic acid (03.75%), and lauric acid (02.73%). Chloroform and methanol mixture was used for lipid extraction. The physical and chemical properties of the lipid were determined by the standard methods.

Results: The lipid showed saponification value (205.92), saponification equivalent (272.43), iodine value (87.34), peroxide value (40), acid value (01.76), and free fatty acids (0.88%); ester value (204.16), unsaponifiable matter (0.5535), specific gravity (0.9297) at 300C, refractive index (1.4643) at 300C, coefficient of viscosity (418.5836 millipoise) at 300C, energy of activation (6.1017 Kcal/mol), Reichert-Miessel value (0.898), Polenske value (0.5958), acetyl value (13.436), and cholesterol (12%). *Ophicephalus striatus* Bloch contained highest percentage of moisture (70%), dry matter (30%), ash content (1.97%), carbohydrate (6.93%), calcium (5.297 mg/kg), magnesium (276 mg/kg), iron (4.93 mg/kg), zinc (8.30 mg/kg), lead (0.06 mg/kg), chromium (less than 0.01 mg/kg), and mercury (less than 0.01 mg/kg). The lipid and protein in *Ophicephalus striatus* Bloch were found to be 2.86% and 18.24%. Only studies on

the antimicrobial activities against organisms *Escherichia coli*, *Staphylococcus aureus*, *Salmonella* spp., and *Shigella sonnei*.

Conclusions: The indigenously available medicines and technologies can prove an asset in the tropical and developing countries of the world. At the same time developed countries also can be benefited because of safety profile of the extracts and microbial activities.

Key words: Bangladesh, Fatty acids, *Ophicephalus striatus* Bloch.

PO2186

OVERWEIGHT AND OBESITY: A COMPARATIVE STUDY BETWEEN PREDOMINANTLY STATIONARY MARKET WOMEN AND THEIR MOBILE COUNTERPARTS IN TAMALE METROPOLIS OF GHANA

P. Aryee¹, G. Helegbe², A. Ahmed¹, A. Kasim¹

¹Community Nutrition Department, University For Development Studies, Tamale, Ghana

²Biochemistry Department, University For Development Studies, Tamale, Ghana

Background and objectives: The sedentary lifestyle of most market women in the developing world is likely to increase their risk for becoming overweight and/or obese. The purpose of this study was to compare overweight and obese tendencies between predominantly sedentary market women/traders (PST) and their mobile counterparts (PMT).

Methods: This was a cross sectional survey undertaken in 3 markets within the Tamale Metropolis of Ghana. Socio-demographic characteristics as well as anthropometric measurements of weight, height and waist and hip circumferences were assessed. Physical activity levels were also estimated using MET scores.

Results: In all 180 market women (90 PST and 90 PMT) aged 15 to 65 years were surveyed. Sedentary women were significantly more likely to be older than their mobile counterparts ($p = 0.043$). Overall, 32.8% and 15.6% were overweight and obese respectively. PST were significantly more likely to be overweight (20.0% cf. 12.8%, $p = 0.002$) and obese (10.6% cf. 5.0%, $p = 0.008$), to have higher Waist (94.5cm cf. 76.2, $p = 0.012$) and Hip (104.6cm cf. 97.5cm, $p = 0.034$) circumferences and lower PAL (459-MET-min/week cf. 587 MET-min/week, $p = 0.051$) than PMT.

Conclusions: The increasing tendencies for overweight and obesity in PST has implications for emerging non-communicable diseases of diabetes, hypertension and arteriosclerosis in a rapidly urbanizing population.

Key words: overweight, obesity, prevalence, market women, Ghana.

PO2187

CARDIOMETABOLIC RISK MARKERS IN ADULT ARGENTINE WOMEN WITH INSULIN RESISTANCE

M E. Torresani¹, L. Maffei², C. Squillace¹, B. Alorda¹, M L. Rossi¹, M L. Oliva¹, L R. Belén¹

¹School of Nutrition, Faculty of Medicine, University of Buenos Aires, UBACYT Proje¹t 2010-2012, Buenos Aires, Argentina

²Foundation for Research on Endocrine Metabolic Diseases and Applied Clinical Research (FIEEM-ICA), Buenos Aires, Argentina

Introduction: Waist-to-height ratio (WHtR) and triglyceride HDL-cholesterol ratio (TG/HDL-C) are relevant cardiometabolic risk markers (CMR) which as can be linked to insulin resistance (IR). Objective: To evaluate the prevalence of IR and compare to CMR: WHtR and TG/HDL-C in adult women attending the Foundation for Research on Endocrine Metabolic Disease and Applied Clinical Research (FIEEM-ICA).

Methodology: A cross case-control study in non-pregnant women over 30 years old without previously diagnosed diabetes which attended the Nutrition and Endocrinology center of Buenos Aires City, Argentina. Dependent Variable: HOMA-IR homeostasis model > 2.5 (cases) without IR (controls). Independent variables: WHtR (height in cm considering $CMR \geq 0.50$), TG/HDL-C (high value considering ≥ 3.0), body mass index (BMI), considering overweight ≥ 25 kg/m²). Analysis: SPSS 19.0, Fisher exact test for categorical variables, OR with confidence intervals of 95% and logistic regression by establishing Spearman test p value < 0.05 .

Results: $n = 213$ women (50.9 ± 9.7 years). 87.8% were overweight or obese and 64.8% increased WC. CMR 90.6% by WHtR and 22.1% by TG/HDL-C. 46.9% had IR and 53.1% had a HOMA-IR less than or equal to 2.5 (not considered controls IR). Significant association between IR and overweight or obesity (OR=3.36, 95% CI= 1.29-8.76, $p=0.007$), WHtR increased (OR= 9.28, 95% CI= 2.09-41.1, $p= 0,000$) and TG/HDL-C elevated (OR = 2.72, 95% CI = 1.38-5.36, $p= 0.003$) compared to controls. In the multivariate analysis revealed a direct correlation between HOMA-IR and BMI ($r = 0.35$, $p < 0.001$), WHtR ($r = 0.37$, $p < 0.001$) and the ratio TG / HDL-C ($r = 0.26$, $p < 0.001$).

Conclusions: Higher WHtR and TG/HDL-C were associated with the possibility of finding IR diagnosis. Slight direct correlation was found between HOMA-IR and BMI.

Key words: insulin resistance, TG/HDL-C ratio, Waist-to-height ratio, nutritional assessment

PO2188

THE EFFECT OF MILK AND MILK PRODUCTS ON THE CHILD'S OSTEOPOROSIS

G. Enkhtaivan¹, D. Bayarsaikhan²

¹Nutrition and Food Services Department, School of Food Engineering and Biotechnology, Mongolian University of Science and Technology, Ulaanbaatar, Mongolia

²Clinical Diet Department, Shastin Central Hospital, Bayangol District, Ulaanbaatar, Mongolia

Background and Objectives: The greatest increase in bone mineral content occurs during adolescence. This study aimed to evaluate the effects of usual childhood dairy intake on adolescent bone health.

Methods: Some types of yogurt, dried curds, milk products, bio sorbent were selected for the purpose of investigating the effect of milk and milk product on the children's osteoporosis. The survey covered 194 children aging between 2 to 6 from kindergartens % were 57.3 males, 42.7 % were females, and 120 children aging 10-12 from middle schools 40.9% were males, 59.1% were females. The questionnaire method was used to determine the life style, food consumption, and the adequacy of food consumption with direct intention. The mineral content of foods was determined using PFA method. The random selection covered 40 children under age of 2-5 and 20 children under age of 10-12 and the dynamic comparison using osteodensitometry method was made to determine the level of osteoporosis comparing the status before and 30-45 days after the consumption of milk products as supplements. Survey data were developed using Excel and SPSS 16 software based on survey data collected and child nutrition facts.

Results: The study showed that osteoporosis decreases by 6.5%-23%, and density, and bone mineral density improves significantly when the person uses for 30-45 days the milk products including 200-250 ml consumption of milk and yogurt as well as 50 g of curds on daily basis. The result showed that bone mineral density improved up to 23% for children consumed the curd and dried curd as combined.

Conclusions: These prospective data provide evidence for a beneficial effect of childhood dairy consumption on adolescent bone health.

Key words: dairy product, osteoporosis, bone density, child.

PO2189

DOCOSAHEXAENOIC ACID REBALANCES STAT3/PPAR γ EQUILIBRIUM IN ADIPOCYTES OF OBESE PATIENTS AFFECTED BY COLON CANCER EXERTING ANTI-INFLAMMATORY ACTIVITY

M. D'Archivio¹, B. Scazzocchio¹, R. Vari¹, S. Giammarionli¹, M. del Cornò¹, A. Iacovelli², A. Veneziani³, S. Gessani¹, R. Masella¹

¹Department Veterinary Public Health and Food Safety, Nutrition Unit, Italian National Institute of Health, Rome, Italy

²Fabia Mater Hospital, Rome, Italy

³Catholic University "Sacro Cuore", Rome, Italy

Background and objectives: Obesity is associated with high incidence of colorectal cancer (CC). White adipose tissue (WAT), an active endocrine organ secreting many products, plays a crucial role in obesity-associated inflammation. Obesity, by altering adipocyte homeostasis, leads to a chronic inflammatory status that might play a role in cancer development. The activity of inflammatory mediators can affect the balance between pro/anti-tumorigenic pathways involving a number of transcription factors, e.g. STAT3 and PPAR γ . STAT3 promotes inflammatory/carcinogenic processes. PPAR γ shows anti-inflammatory properties, inhibits growth, and induces apoptosis. Notably, PPAR γ inhibits STAT3 through a transcriptional mechanism. Therefore STAT3 and PPAR γ form a signaling loop potentially crucial for CC development. Dietary fatty acids (FAs) are major determinants in inflammation given their precursor status to signaling mediators. The ω -3 and ω -6 polyunsaturated FAs (PUFA) show opposite behaviors in modulating adipocyte functions. In particular, docosahexanoic acid (DHA) has been shown to exert a strong anti-inflammatory activity. We hypothesized that STAT3/PPAR γ imbalance occur in WAT of CC patients, creating a pro-inflammatory environment that might influence cancer development. DHA, by rebalancing STAT3 and PPAR γ , may elicit anti-inflammatory responses in adipocytes. To test this hypothesis, adipocytes isolated from visceral WAT of normal-weight (BMI 22-24.9 kg/m²), and overweight/obese subjects (BMI 25-40 kg/m²), affected or not by CC, were treated with DHA.

Results: Visceral fat isolated from CC patients showed an increase of STAT3 and a concomitant decrease of PPAR γ activation, with respect to control subjects. The up-regulation of STAT3 was independent from BMI, whereas was associated with a lower n-3/ n-6 ratio than controls. DHA treatment, likely by increasing the adipocyte n-3-PUFA content, counteracted the over-expression of STAT3 as well as stimulated PPAR γ activation, particularly in obese/CC subjects.

Conclusions: These findings suggest that DHA might represent a useful tool for preventive and therapeutic strategies aimed at reducing CC risk.

Key words: obesity, colon cancer, DHA, STAT3.

PO2190**ASSOCIATION BETWEEN OBESITY AND COMMON MENTAL DISORDERS AMONG NUTRITIONISTS, RIO DE JANEIRO, BRASIL**

T. Muzy¹, O B. Aguiar², M J M. Fonseca³

¹Josue de Castro Nutrition Institute, Rio de Janeiro Federal University, Rio de Janeiro, Brazil

²Nutrition Institute, State University of Rio de Janeiro, Rio de Janeiro, Brazil

³Department of Epidemiology, National School of Public Health, Brazil

Background and objectives: Demographic changes, in food consumption patterns, in lifestyles and rapid urbanization are among the main factors for the increase in chronic diseases conditions. Obesity, for its multifactorial characterization, has been shown to be associated with several factors and among them the minor psychiatric morbidity. The main aim of this study was to analyze the association between obesity and common mental disorders among nutritionists working in the municipal public area of Rio de Janeiro.

Methods: Sectional study conducted in 23 hospitals in the municipal health system of Rio de Janeiro, in the form of census, with 289 nutritionists, (15) 4.9% refused to participate. Analyses were performed using the multinomial regression model adjusted for covariates morbidity, age, years of work, other employment link, type of main link, tertile of income per capita and color.

Results: Most nutritionists were women (97.2%), mean age 41 years (Dp = 10.0) and 48.4% were post graduated. The prevalence of overweight, obesity and common mental disorders were 32.3%, 15.3% and 37.5%, respectively. The association between obesity and TMC, although not statistically significant, showed a significant magnitude. We observed a crude OR of 1.26 (IC 95% 0.63 2.51), even after adjusting multiple covariates the OR was 1.14 (IC 95% 0.52 2.49).

Conclusions: The high prevalence of overweight, obesity and common mental disorders in this population are consistent with population surveys conducted in Brazil and worldwide, and emphasize the need for further studies with these professionals (nutritionists) for being placed in the group of health professionals who are dedicated to being caretakers of population health. The magnitude of association may be a starting point to support improved strategies for prevention and promotion of health of these workers.

Key words: obesity, common mental disorders, nutritionist.

PO2191**THE DIETARY POLYPHENOL PROTOCATECHUIC ACID EXERTS INSULIN-LIKE ACTIVITIES BY IRS-1 ACTIVATION IN HUMAN PRIMARY ADIPOCYTES**

B. Scazzocchio¹, R. Vari¹, C. Giovannini¹, C. Santangelo¹, C. Filesi¹, A. Iacovelli², M. D'Archivio¹, R. Masella¹

¹Department Veterinary Public Health and Food Safety, Nutrition Unit, Italian National Institute of Health, Rome, Italy

²Fabia Mater Hospital, Rome, Italy

Background and objectives: Anthocyanins, naturally occurring in vegetables, fruit, and beverages, appear to exert beneficial effects in preventing atherosclerosis and other chronic-degenerative diseases, such as type 2 diabetes and insulin resistance. In particular, they have been demonstrated to ameliorate hyperglycemia and insulin sensitivity. We have recently shown that the main anthocyanin metabolite, the protocatechuic acid (PCA), enhances glucose uptake and GLUT4 translocation in human visceral adipocytes. Aim of the study was to investigate the molecular events elicited by PCA in human visceral adipocytes responsible for the insulin-like activity.

Methods: Human adipocytes were collected from anesthetized individuals undergoing abdominal surgery for benign conditions. Glucose uptake, and the activation of IRS-1 and the main upstream kinases involved, namely Akt and PI3K, were evaluated in cells after treatment with 25µM PCA. Untreated adipocytes were used as controls.

Results: PCA-treated cells showed higher levels of glucose uptake and IRS-1 tyrosine-phosphorylation than control cells. We also found a strong increase in Akt serine-phosphorylation after PCA treatment. Furthermore, in a set of experiments the cells were pre-treated with specific PI3K kinase inhibitors, LY294002 and wortmannin. The treatment with the inhibitors significantly reduced Akt and IRS1 phosphorylation and glucose uptake. Our data clearly show a direct involvement of PI3K and Akt in PCA-induced IRS1 up-regulation.

Conclusions: These results provide evidence that PCA might exert insulin-like effect by activating insulin signaling pathway. Dietary polyphenols, thus, could be included in the preventive/therapeutic armory against pathological conditions associated with obesity and insulin resistance.

Key words: dietary polyphenols, anthocyanins, insulin resistance, obesity.

PO2192**CONSUMPTION FREQUENCY OF SELECTED GROUPS OF FOOD PRODUCTS AND THE PREVALENCE OF COLORECTAL POLYPS***M. Jarosz¹, I. Sajór¹*

¹Department of Dietetic and Nutrition in Hospitals with Clinic of Metabolic Diseases and Gastroenterology, National Food and Nutrition Institute, Warsaw, Poland

Background and objectives: The results of many studies suggest that regular consumption of foods rich in dietary fiber and calcium-rich dairy products can be associated with reduced risk of colorectal cancer. Moreover, individuals who frequently consume red meat and alcohol have increased risk of this malignancy. The aim of study was to analyze a relationship between the consumption frequency of certain groups of foods and the prevalence of colorectal polyps.

Methods: The study included 460 individuals subjected to lower gastrointestinal endoscopy. On the basis of histopathological findings, they were classified to the group with colorectal polyps (n = 237) and the polyp-free control group (n = 223). Consumption frequencies of cereals, vegetables, fruits, meat, fish, dairy products, eggs, and alcohol amongst participants of both groups were determined with a questionnaire survey. The results were subjected to statistical analysis.

Results: The fraction of the controls who declared the everyday consumption of cheese (both cottage and ripening cheese) and fruits were significantly higher than in the polyp group (36.5% vs. 28.3%, p = 0.019; and 69% vs. 60.3%, p = 0.050, respectively). No significant intergroup differences were documented with regards to the consumption frequency of the remaining food products and alcohol.

Conclusions: Higher consumption of cheese and fruits may represent a protective factor against colorectal polyps.

Key words: consumption frequency, food, colorectal polyps.

PO2193**DXA MEASURES OF BONE MASS IN MORBIDLY OBESE YOUNG ADULT WOMEN***M. Crivelli^{1,2}, G. Chagas¹, I T F. da Silva³, A M. Waked³, F F. Bezerra¹*

¹Instituto de Nutrição, Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil

²International Society for Clinical Densitometry

³Unidade de Cirurgia Bariátrica e Metabólica, Hospital Naval Marcílio Dias, Rio de Janeiro, Brazil

Background and objectives: Studies suggest that fat mass does not exert a protective effect on bone mass, being even sometimes harmful. It is possible that morbidly obese patients constitute a group particularly susceptible to loss of bone mass as a result of hormonal and metabolic changes. The aim of the present study was to assess bone health and vitamin D status of morbidly obese young adult women.

Methods: Twenty women (18-49 y) bariatric surgery candidates with BMI higher than 40 kg/m² participated in the study. Body composition and bone mass of the whole body and specific sites (lumbar spine-LS, total proximal femur and forearm) were assessed by dual energy X-ray absorptiometry (LUNAR - DXA). Concentrations of parathyroid hormone (PTH), 25-hydroxyvitamin D (25OHD), C-telopeptide (CTX) and osteocalcin were determined in serum samples.

Results: Total body mass (TBM) ranged from 93 to 180 Kg and total fat was on average 53±3%. Mean Z-scores at total femur and forearm were 0.57±0.96 and 0.68±0.79, respectively, and all women studied were within the expected values for their age at these sites. Mean LS Z-score was -0.76±1.36. LS Z-score was lower than the expected for age in four women (Z-score < -2.0) and between -1.0 and -1.9 in six women. TBM, BMI and fat mass were not significantly associated with Z-scores at any site. Serum concentrations of 25OHD (28.4±10.7 ng/mL), PTH (47.4±28.3 pg/mL), osteocalcin (15.8±8.8 ng/mL) and CTX (0.32±0.20 ng/mL) were on average adequate.

Conclusions: Although it is necessary to consider possible misreading of DXA measures due to the excess of fat mass in abdominal region, our results of lumbar spine Z-scores suggest some impairment of bone mass at this specific site in the morbidly obese women studied.

Key words: morbid obesity, DXA, bone health, vitamin D. Financial support: FAPERJ and CNPq (Brazil).

PO2194**VITAMIN D AND DIABETIC RETINOPATHY**

Z. Aslani¹, S. Edalati¹, F. bagherzadeh¹

¹Students' Research Committee, Faculty of Health & Nutrition, Tabriz University of Medical Sciences, Tabriz, Iran

Background and objectives: Diabetic retinopathy (DR) is one of the serious microvascular complications in diabetes. Micronutrients may potentially alter the risk of DR by interfering with pathologic mechanism. Recent studies have been focused on Vitamin D and its effect on pathogenesis of DR. vitamin D may protect diabetic retina through its effects on normal insulin secretion, glycemic control and hypertension. It may also play a role in the pathogenesis of diabetic retinopathy through its anti-inflammatory, anti-proliferative, and anti-angiogenic mechanisms. Objective: The aim of this review is to explore the current data on how vitamin D may contribute to diabetic retinopathy.

Results: Plasma concentration of vitamin D has been inversely correlated with the severity of DR. diabetic patients especially those with proliferative diabetic retinopathy have lower Vitamin D levels than those without diabetes or PDR.

Key words: Diabetes; diabetes complication; diabetic retinopathy; vitamin D .

PO2195**ASSESSMENT OF RISK FACTORS OF LIPID IN CARDIOVASCULAR COMPLICATIONS FOR 121 DIABETIC WOMEN TYPE II**

B. Loubna¹, A. Merazka¹

¹Institut of Nutrition, Food and Food Technology-INATAA, Depok, West Java Province, Indonesia

Background and objectives: Diabetes is the kind of chronic disease that severely exacerbates health budgets, Algeria, food culture is still lacking even in the healthy population. To facilitate the patient's ability to achieve and especially long-term plan of cardiovascular prevention, the prevention of lipid score or SLP was developed. Our goal is to evaluate the risk factors of lipid cardiovascular complications in a population of non-insulin dependent diabetic women to better understand issues related to their diet.

Methods: A dietary survey was carried out for a population of 121 non-insulin dependent diabetic women (NIDD) aged 34-78 years at two diabetes centers in Constantine compared to a population consisting of 121 non-diabetic women (healthy) aged from 39 to 45 years. (Reminder food 24 hours). Entry and data processing is done by the software Microsoft Excel 2007, comparisons between means were performed by the student and the test-score thresholds 1%, 5% and 99%.

Results: Our results show that there is an increase in triglycerides, a decrease in HDL-C, and a decrease of daily lipid score and the daily intake of lipid and a decrease in SLP (compared to recommended).

Conclusions: The power followed by our diabetic women is low in saturated fatty acids (SFA) and MUFA but rich in PUFA which could exclude the occurrence of cardiovascular complications as a result of the diet.

Key words: women NIDD- SLP, lipids, cardiovascular complications, anthropometric parameters.

PO2196**EVOLUTION OF NUTRITIONAL STATUS IN CHILDREN WITH CYSTIC FIBROSIS IN EASTERN ROMANIA**

L. Trandafir¹, G. Diaconu¹, D. Anton-Paduraru¹

¹Department of Pediatrics, University of Medicine and Pharmacy Grigore T. Popalasi, Romania

Background and objectives: The importance of nutritional intervention for children with cystic fibrosis (CF) is well recognized. Improved nutritional status early in life is associated with better long term evolution in patients with CF. The authors evaluated the nutritional status of children with CF in a Regional Center in Eastern Romania.

Methods: We performed a retrospective study included 37 children with CF followed between January 2010 - January 2012. Mean age was 87.27 months \pm 59.3SD(min.: 4 months; max.: 216 months). Nutritional status was assessed based on weight, height, weight and height Z score. Pulmonary function was evaluated by determining FEV1 in children older than 6 years and frequency of respiratory infections. We followed the nutritional status correlate with age at diagnosis, age at disease onset, impaired lung function, frequency of lung infections and number of hospitalizations.

Results: The mean Z score for weight and age were: $-0.91 \pm 2.07SD$ (min: -3.7, max: 3.8) and mean Z score for height and age were: $-0.802 \pm 1.74SD$ (min:-3.6; max: 3.5). Lower age at onset was significantly correlated with disease severity ($r = -0.696$). The result of multiple logistic regression analysis on nutritional status assessed Z score was significantly influenced by late age of diagnosis ($R = 0.453862$, $p = 0.007539$, 95% CI) and repeated respiratory infections ($R = 0.279127$, $p = 0.042693$, 95% CI).

Conclusions: The worse nutrition is associated with late aged of diagnosis and early respiratory infections of children with CF. In order to improve nutritional status and a better clinical evolution is necessary to introduce newborn screening program for CF in Romania.

Key words: cystic fibrosis, nutritional status, Z score, children.

PO2197**RELATIONSHIP AMONG TG/HDL-C RATIO, NUTRITIONAL STATUS AND INTAKE OF OMEGA-6 AND OMEGA-3 FATTY ACIDS IN PRE AND POSTMENOPAUSAL WOMEN**

E. Torresani¹, M V. Caamaño¹, A. Carrera¹, M P M. Doyle¹, M J. Llorente¹

¹School of Nutrition, Faculty of Medicine - University of Buenos Aires, UBACYT Project 2010-2012, Buenos Aires, Argentina

Background and objectives: The triglyceride/HDL cholesterol (TG/HDL-C) ratio has been significantly associated with insulin resistance and cardiometabolic disease. Fatty acids diet intake may influence this ratio. The main objective was to investigate the relationship among TG/HDL-C ratio, nutritional status and essential fatty acids intake in pre and postmenopausal women.

Methods: Observational Analytic Transversal study. Convenience sample of women over 40 years-old, from the city of Buenos Aires. Dependent variable: TG/HDL-C ratio (expected: <3 and high: >3). Independent variables: nutritional status by BMI and waist circumference (WC); omega-6 (W6) and omega-3 (W3) essential fatty acids intake by amount, type and adequate ratio between them (Adequate < 10:1 and inadequate: > 10:1). Control variables: biological stage (pre and post-menopause) and lifestyle (smoking, alcohol intake and physical activity). Anthropometric assessment was carried out by direct measurement and fatty acids intake was estimated by 24-hour recall. We used Table Chemical Composition of German origin Fachmann-Kraut-Souci and data provided by the food industry. Statistical analysis with SPSS 15.0 calculating Odds ratio with 95% confidence intervals, chi-square or Fisher test, considering $p < 0.05$.

Results: 96 women were included, 45.8% of them premenopausal and 54.2% of them postmenopausal. 34.4% had a BMI > 25 kg/m² and 16.7% WC > 88 cm. 21.9% had a TG/HDL-C ratio > 3 and 61.5% W6/W3 ratio > 10:1. 61.5% consumed below the W6 DRI and 87.5% below the W3 DRI. A significant association between TG/HDL-C and overweight by BMI > 25 kg/m² ($p = 0.000$) and with increased CC ($p = 0.000$) but not with the intake of W6 and W3. Regarding biological stage and lifestyle only significant association was found with smoking ($p = 0.002$)

Conclusions: TG/HDL-C ratio was significantly associated with nutritional status and smoking but not with consumption of W6 and W3.

Key words: TG/HDL-C ratio, nutritional status, W6 – W3, menopause.

PO2198**EFFECT OF THE TEMPORAL PATTERNS OF FOOD INTAKE ON GLYCEMIC CONTROL IN JAPANESE MALE TYPE 2 DIABETIC PATIENTS**

S. Wada¹, M. Sugiyama¹, Y. Kobayashi¹, M Kadono², H. Iwase², W. Aoi¹, M. Fukui², G. Hasegawa², N. Nakamura², A. Higashie¹

¹Kyoto Prefectural University, Kyoto, Japan

²Kyoto Prefectural University of Medicine, Kyoto, Japan

Background and objectives: Type 2 diabetes mellitus is strongly influenced by life style, especially dietary habits. Food intake entrains physiological and genetic circadian rhythms, which regulate the glucose metabolism. However, the correlation between meal timing and glycemic control has not yet been fully elucidated. Therefore, we investigated the role of temporal patterns of caloric intake in daily blood sugar control.

Methods: This was a cross-sectional study with 71 Japanese men under treatment for type 2 diabetic mellitus in an outpatient department. Meal times and dietary intake were assessed using a one-day 24-hour dietary recall. Blood biochemical data and medication status were obtained from the medical records. We hypothesized that any hypoglycemic episode might influence the dietary habit, and divided the patients into two groups according to the medication prescribed, a group treated with insulin and/or sulfonylurea hypoglycemic agent (INS•SU) ($n = 46$), and another group with other or no medication (Non-INS•SU) ($n = 25$). Then, we conducted multivariate regression analyses with controls for age, BMI, and medication status in order to determine the independent association of meal times and the blood biochemical data.

Results: The average age, BMI and HbA1c of the subjects were 66.3 ± 8.9 , 24.0 ± 3.6 kg/m² and $7.0 \pm 0.8\%$, respectively. The INS•SU group showed a significantly higher caloric intake after 9 p.m. (163.8 ± 354.6 kcal) than the non-INS•SU group (32.9 ± 138.6 kcal). The evening/ (morning + lunch) caloric intake ratio was significantly correlated with HbA1c in the non-INS•SU group ($r=0.393$, $p = 0.040$), but not in the INS•SU group.

Conclusions: When considering dietary intervention for type 2 diabetes, it is necessary to take into account not only total caloric intake, but also the temporal patterns of food intake, in particular, the evening ratio of daily calorie intake.

Key words: type 2 diabetes mellitus, meal times, glycemic control.

PO2199**A GENE VARIANT IN THE TRANSCRIPTION FACTOR 7-LIKE 2 (TCF7L2) IS ASSOCIATED WITH AN INCREASED RISK OF GESTATIONAL DIABETES MELLITUS**

A. Pagán¹, M. Sabater², J. Olza³, M T. Prieto-Sánchez², J E. Blanco-Carnero², J J. Parrilla², A. Gil³, L. Larque¹

²Gynecology Service, Virgen de la Arrixaca Hospital, Murcia, Murcia, Spain

³Department of Biochemistry and Molecular Biology II, University of Granada, Granada, Spain

Background and Objectives: Adipokines play an important role in the pathogenesis of insulin resistance during pregnancy. Variations in transcription factor 7-like 2 (TCF7L2) and fat mass and obesity associated (FTO) genes have been associated with type 2 diabetes and FTO also with obesity. We aimed to study the association of genetic variants previously linked with type 2 diabetes in subjects with gestational diabetes mellitus (GDM) and its influence on maternal adipokines during pregnancy.

Methods: We recruited 25 healthy pregnant women (Controls) and 45 women with GDM between weeks 24 and 28 of gestation. Maternal blood samples were collected at recruitment and at delivery. Adipokines were determined at both sampling times using LINCoplex kits of human monoclonal antibodies. Genomic DNA was extracted from blood recruitment samples and FTO rs9939609, TCF7L2 rs4506565, rs7901695, rs12243326, rs12255372 and rs7903146, INSIG2 rs7566605, SREBF1 P197L, P576P and IVS20+151T>C and FATP4 IVS12+147G>A were genotyped.

Results: Plasma adiponectin was significantly lower in GDM than Controls at the time of recruitment and a trend was observed at the time of delivery (GDM 7.43±0.53 mg/L vs. Controls 9.2±0.8 mg/L, $p = 0.060$). In contrast, serum resistin showed a trend to higher levels in the GDM group only at the time of recruitment. TCF7L2 rs4506565 (OR=2.31, 95% CI: 1.97-5.01; $p = 0.031$) and FTO rs9939609 (OR=2.17, 95% CI: 1.07-4.41; $p = 0.039$) were associated with the risk of GDM. TCF7L2 rs4506565 was associated with resistin at delivery; women carrying the T allele had increases in plasma resistin of 9.38 µg/L (95% CI 1.39-17.37; $p = 0.022$) per allele; this association remained significant after adjusting for pre-gestational body weight.

Conclusions: TCF7L2 rs4506565 variant (T/T) is associated with an increased risk of GDM and it is associated with plasma resistin concentrations in woman with GDM at delivery.

Key words: Gestational diabetes mellitus, adipokines, TCF7L2.

PO2200**VITAMIN D STATUS AND MORTALITY IN PATIENTS WITH STABLE ANGINA**

E M. Degerud¹, K H. Løland¹, R. Seifert², O. Nygård^{1,2}, Ø. Midtun³, P M. Ueland³, J. Dierkes¹

¹Department of Clinical Medicine, University of Bergen, Bergen, Norway

²Department of Heart Disease, Haukeland University Hospital, Bergen, Norway

³Bevital AS, c/o Section for Pharmacology, University of Bergen, Bergen, Norway

Background and objectives: Vitamin D is a candidate nutrient which status may be relevant to survival and cardiovascular risk. The vitamin is associated with cardiovascular risk factors, including body mass, inflammation and hypertension, which may confound this relationship. We assessed the association between vitamin D status and all-cause and cardiovascular mortality in patients with stable angina.

Methods: From the Western Norway Coronary Angiography Cohort (WECAC, 2000–2004) we measured serum 25-hydroxyvitamin D (25OHD) by LC-MS/MS at baseline in 4118 participants with stable angina pectoris. 68% were males and the mean age was 60.1 (SD 11.1) years. Cox proportional hazards models were used to compare survival across quartiles of 25OHD concentrations adjusted for month of blood draw.

Results: A total of 302 deaths occurred during a mean follow-up of 4.7 years, upon which 163 were due to cardiovascular causes. In Cox models adjusted for age and gender, the risk of death (Hazard ratio [95% confidence interval]) differed across 25OHD quartiles for all-cause mortality (p for trend < 0.001) when comparing the 1st quartile to the 2nd 0.60 [0.45-0.82], 3rd 0.54 [0.40-0.74] and 4th 0.46 [0.33-0.63] quartiles and for cardiovascular mortality (p for trend = 0.001) when comparing the 1st quartile to the 2nd 0.79 [0.53-1.18], 3rd 0.61 [0.40-0.94] and 4th 0.49 [0.32-0.78] quartiles. The associations remained similar after adjustment for smoking, diabetes, low-density lipoprotein, ejection fraction and above mentioned cardiovascular risk factors.

Conclusions: Normal and high vitamin D status were associated with reduced all-cause and cardiovascular mortality in patients with stable angina.

Key words: Vitamin D, 25OHD, mortality, cardiovascular mortality.

PO2201**PREVALENCE OF OBESITY IN THE "INMA: ENVIRONMENT AND CHILDHOOD" SPANISH COHORT, ACCORDING TO DIFFERENT CRITERIA**

I. Calvente¹, C. Dávila-Arias¹, A. Fernández-Somoano^{2,5}, R. García-Esteban^{3,5}, O. Ocón-Hernández¹, R. Pérez Lobato¹, R. Ramos^{1,5}, L. Santa Marina^{4,5}, D. Valvi^{3,5}, M. Fernandez^{1,5}

³Centre for Research in Environmental Epidemiology (CREAL), Hospital del Mar Research Institute (IMIM), Barcelona, Spain

⁴Biodonostia. Instituto de Investigación Biomédica; Departamento de Sanidad Gobierno Vasco, Subdirección de Salud Pública de Gipuzkoa, Donostia-San Sebastián, Spain

⁵CIBER de Epidemiología y Salud Pública (CIBERESP), Spain

Background and objectives: The INMA -Environment and Childhood- Project is a network of Spanish birth cohorts that aims to study the role of environmental pollutants in air, water and diet during pregnancy and early childhood in relation to child growth and development. The most appropriate parameters and reference populations for assessing childhood obesity are still controversial. We estimated the prevalence of child obesity in the INMA cohort according to different international and national criteria.

Methods: The height and weight of 1552 children from the INMA cohort were directly measured at the age of 4 and 10 years (4.4±0.2 and 10.6±1.2 yrs). We calculated the prevalence of overweight and obesity according to: the International Obesity Task Force (IOTF), enKid study, Obergozo Foundation (Hernandez 1988 and Sobradillo, 2004), and Carrascosa tables (2008).

Results: We observed a wide variability in the prevalence of obesity according to the criteria used. At 4 years, the highest prevalence of excess weight was obtained by applying Carrascosa tables (23.6%) and the lowest with the enKind study (8.3%). Considering children by gender, the same results were only obtained among boys. The prevalence of obesity was comparable using different national or international standards, but there were major discrepancies in overweight prevalence. The prevalence of excess weight in INMA children increased throughout the follow up. At 10 years, the highest frequency of excess weight was obtained with the IOTF criteria (33.5%) and the lowest with the enKind (23.8%) and Carrascosa (23.7%)

criteria. Analyzing by gender, IOTF obtained the highest prevalence for excess weight in both genders. The prevalence of overweight and obesity was also dependent on the criteria used, but the differences among criteria decreased.

Conclusions: The variability in results demonstrates the importance of the criteria selected to assess overweight and obesity for the comparison and follow-up of childhood obesity.

Key words: Obesity, childhood, overweight

PO2202**EFFECTS OF FRUCTOOLIGOSACCHARIDES IN THE CD4+CD62L+ T CELL TRANSFER MODEL OF COLITIS**

F. Capitán-Cañadas¹, B. Ocon², C J. Aranda¹, M D. Suárez³, A. Zarzuelo⁴, O. Martínez-Augustin³, F. Sánchez de Medina⁴

³Department of Biochemistry and Molecular Biology II, CIBERehd, School of Pharmacy, University of Granada, Granada, Spain

⁴Department of Pharmacology, CIBERehd, School of Pharmacy, University of Granada, Granada, Spain

Background and objectives: Fructooligosaccharides (FOS) are used as functional foods due to their prebiotic effects. Previous studies demonstrated that FOS may improve intestinal inflammation. Our aim is to study the antiinflammatory effect of FOS in the CD4+CD62L+ T cell transfer model of colitis.

Methods: CD4+CD62L+ T cell transfer model of colitis. CD4+CD62L+ T cells were purified from spleen mononuclear cells of C57 healthy mice by CD4+CD62L+ T Cell Isolation Kit with immunomagnetic microbeads (Miltenyi Biotec). CD4+CD62L+ T cells (1x10⁶) were resuspended in 100 µl of sterile phosphate-buffered saline (PBS) and injected intraperitoneally in recipient RAG1 deficient mice. Colitic activity was monitored by weight changes. After 8 weeks mice were used for experiments. T-cell free PBS injected RAG1 mice were used as control. Experimental design. Three groups were established: control, CD4+CD62L+ and FOS. Saline or FOS (75 mg/mouse/day) were administered by gavage daily. Mice were sacrificed after 12 days. Assessment of colonic damage and inflammation. Large intestine status was evaluated by macroscopic scoring, myeloperoxidase (MPO) and alkaline phosphatase (AP) colonic activity.

Results: Treatment of mice with 75 mg of FOS daily partially improved colitis, as evidenced by a significantly increased body weight gain (+3.0±1.6%) compared with colitic mice (-6.5±1.5%). Macroscopic score of the large intestine was lower in FOS-treated mice (1.6) vs. colitic mice (2.5). Neutrophil recruitment to the inflammatory site was significantly lower ($p < 0.05$) in treated animals than in colitic controls, as measured by MPO activity (23.1±6.9 vs. 51.6±8.6 mU•mg protein⁻¹). AP was also diminished by FOS (131.7±7.3 vs. 200.9±24.5 mU•mg protein⁻¹), and its sensitivity to levamisole was lower.

Conclusions: FOS exerts intestinal antiinflammatory activity in T lymphocyte dependent colitis.

Key words: fructooligosaccharides, colitis, CD4+CD62L+ T cell, inflammatory bowel disease

PO2203

EFFECT OF PRE/POST RICE CONSUMPTION OF MILK AND FERMENTED SOYBEAN ON POSTMEAL GLYCEMIA AND INSULIN RESPONSES IN HEALTHY STUDENTS

K. Sueda¹, E. Sakai¹, T. Uno¹, Y. Sato²

¹Department of Health and Nutrition, Aichi Gakuin University, Nisshin, Japan

²Department of Health Science, Aichi Gakuin University, Nisshin, Japan

Background and objectives: The objective was to describe the effect of milk or fermented soybean when consumed before/after a rice on postprandial blood glucose and insulin in healthy students.

Methods: 1) Thirty five students were divided into two groups. One group (milk group; female 21) has consumed 200ml milk, the other group (soybean group; male 3, female 11) fermented soybean (90g). 2) Two studies were conducted. In experiment 1 (reference meal), white rice (carbohydrate 50g) only was provided. In experiment 2 (test meal), 200 ml milk / 90g fermented soybean with white rice (total carbohydrate 50g) were provided. At 15min before/after a white rice consumption, the subjects were provided milk or soybeans. 3) Blood glucose and insulin were measured at baseline and at intervals both experiments. The area under the curves for glucose (GAUC) and insulin (IAUC) were calculated. Comparisons between meals were analyzed based on paired t-test.

Results: 1) The milk before a rice had significantly lowered blood glucose at 30, 45 and 60 min after a rice eating ($p < 0.05$), and significantly lowered the GAUC values ($p < 0.05$), compared with the white rice only. The milk after a rice had no effects on reducing postprandial blood glucose. 2) The fermented soybeans before/after a rice had significantly lowered the GAUC values ($p < 0.05$), compared with the white rice only.

There is no difference between rice IAUC and corresponding fermented soybean IAUC.

Conclusions: Milk consumption before a rice, not after a rice, reduced postprandial blood glucose and insulin. Fermented soybean before/after a rice reduces postprandial blood glucose, but had no effects on insulin secretion.

Key words: postprandial blood glucose, insulin, rice, milk, soybean products.

PO2204

FOOD PATTERN, BMI, BODY COMPOSITION AND CD4 CELL COUNT OF ADULT LIVING WITH HIV/AIDS IN EAST JAVA (INDONESIA)

S.R. Nadhiroh¹, S. Adiningsih¹

¹Nutrition Department, Public Health Faculty, Universitas Airlangga, Surabaya, East Java, Indonesia

Background and objectives: Cumulative HIV and AIDS cases from 1 April 1987 through 30 September 2012 are 92251 for 39434 for AIDS. This epidemic has caused a real challenge to overcome. Massive efforts required to minimize the impact of the epidemic, which of course must be integrated with the support and care in nutritional aspects. The purpose of this study was to analyze the relationship between food pattern, BMI and body composition with the CD4 cell count in HIV infected adult.

Methods: This study was an analytical observational research with cross sectional design. The samples were 69 people living with HIV/AIDS from outpatient clinic at Dr. Soetomo Hospital (East Java Province, Indonesia) that was taken by purposive sampling. Food pattern (semi quantitative food frequency), Body Mass Index, Body Composition (bioelectrical impedance), and CD4 cell count were assessed. Data collection was done from August–December 2012. The data were analyzed by Pearson Correlation Test.

Results: There was 40.6% responden with CD4 cell count under 200 cells/mm³. Average BMI, fat mass and fat free mass were 20.6; 10.9 kg and 41.1 kg. Significant correlations were found for BMI and CD4 cell count ($p = 0.00$), fat mass and CD4 cell count ($p = 0.01$), fat free mass and CD4 cell count ($p = 0.028$). The study group had a poor energy intake with average intake 1833 Calories per day.

Conclusions: Significant relationships existed between BMI and the CD4 cell count, and also between body composition and the CD4 cell count. Strategies for increasing food pattern, BMI, body composition and CD4 cell count ought to be identified and implemented in communities.

Key words: BMI, body composition, food pattern, CD4.

PO2205**RETINOL, TOCOPHEROL AND β -CAROTENE STATUS AND OXIDATIVE STRESS IN CHINESE PATIENTS WITH PULMONARY TUBERCULOSIS**

A. Ma¹, H. Liang¹, Y. Dou¹, E. Wang¹, X. Han¹, Y. Sun¹

¹The Institution of Human Nutrition, Medical College, Qingdao University, Shandong, China

Background and Objectives: In pulmonary tuberculosis (PTB), oxidative stress is a result of tissue inflammation, poor dietary intake of micronutrients due to illness. The objective was to investigate retinol (VA), tocopherol (VE) and β -carotene (α -C) status and oxidative stress among PTB patients.

Methods: Totally 70 tuberculosis patients were randomly selected as the case group, and 70 health persons matched on age, gender, etc. as the control group. The information of the body mass index (BMI), and serum lipid levels such as triglyceride (TG), total cholesterol (TCHO) and high-density lipoprotein (HDL) was collected. The activities of superoxide dismutase (SOD) and catalase (CAT), and VA, VE and α -C were detected.

Results: BMI values was 19.13 kg/m² in the case group, lower than 21.95 kg/m² in the control group (both $p < 0.05$). The values of serum TG, TCHO, HDL were 1.54 mmol/L, 4.47 mmol/L and 1.21 mmol/L, respectively, in the case group, significantly lower than those of the control group (all p values < 0.05); The activities of serum SOD and CAT were 78.20 U/ml and 5.24 U/ml respectively, in the case group, also lower than the control group (83.27 U/ml and 9.99 U/ml respectively) ($p < 0.05$). Compared with the control group, the levels of VA and VE were 25.6 μ g/100ml and 38.5 μ g/100ml, respectively, lower than the control group ($p < 0.05$). However, levels of serum β -carotene were 4.8 μ g/100ml and 5.1 μ g/100ml, respectively, in the case group and control group, which did not showed significant differences ($p > 0.05$).

Conclusions: The status of retinol, tocopherol and β -carotene is poor, and activities of SOD and CAT were lower in PTB patients. The implication of the study was that oxidative stress increased and the supplementation with micronutrients, such as VA, VE and β -carotene should be considered.

Key words: retinol; tocopherol; β -carotene; oxidative stress; pulmonary tuberculosis. Granted by The National Natural Science Fund (81172662).

PO2206**EFFECT OF RETINOL AND VITAMIN D TREATMENT ON THE GROWTH OF MYCOBACTERIUM TUBERCULOSIS FROM TUBERCULOSIS PATIENTS**

A. Ma¹, X. Liu¹, Q. Wang¹, W. Zhou², J. Wang², Y. Liu²

¹The Institute of Human Nutrition, Medical College of Qingdao University, Shandong, China
²Qingdao Chest Hospital, Shandong, China

Background and Objectives: The objective was to assess the effect of retinol (VA) and vitamin D (VD) on the growth of Mycobacterium tuberculosis (MTB).

Methods: Totally 118 tuberculosis patients with positive sputum culture were selected. Strains isolated from sputum were cultured and used for drug sensitivity test by the absolute concentration method. In addition, strains was treated with three dosages of retinol, i.e. VA1 with 500 IU/mL, VA2 1000 IU/mL and VA3 2000 IU/mL; and vitamin D treatments included VD1 (25 IU/mL), VD2 (50 IU/mL), VD3 (75 IU/mL) and VD4 (100IU/mL), added to the Lowenstein-Jensen medium, and no treatment of VA and VD as control medium. All strains were inoculated simultaneously in the medium, cultured for 3 to 4 weeks and observed colony growth conditions.

Results: The study showed that the positive percentages of MTB colony growth were 92.37%, 81.36% and 86.44% in the groups VA1, VA2 and VA3, respectively, which were all less than the control group (100%) (all p values < 0.05); while the positive percentages of VD1, VD2, VD3 and VD4 groups were 94.1%, 93.2%, 94.9% and 91.5% respectively, less than those in the control group (all p values < 0.05). Moreover, administration of higher dosage of retinol in A2 group was better than the low dose in inhibiting MTB growth ($p < 0.017$). The inhibitory effect of 4 groups VD had no statistically significant differences ($p > 0.05$); Comparing the inhibitory effect of VA and VD, the effect of VA2 and VA3 group was better than the VD group ($P < 0.05$).

Conclusions: The appropriate dosages of VA (1000 IU/ml) and VD (25 IU/ml) could inhibit the growth of MTB, and the further study of retinol and/or vitamin D supplementation in the population of TB patients in China will be expected.

Key words: retinol; vitamin D; mycobacterium tuberculosis; strain.

PO2207

EFFECT OF AMMONIA AND GLUTAMINE ON BRANCHED-CHAIN AMINO ACID OXIDATION AND PROTEIN METABOLISM IN HEALTHY AND ENDOTOXEMIC RATS

M. Holecek¹, M. Kovarik¹, L. Sispera¹

¹Charles University Prague Medical Faculty In Hradec Kralove Hradec Kralove, Prague

Background and objectives: Enhanced oxidation of branched-chain amino acids (BCAA; valine, leucine and isoleucine) in skeletal muscle, that is a typical metabolic alteration in sepsis, is coupled with activated synthesis of glutamine and development of muscle wasting. It can be hypothesized that modulation of glutamine synthesis by reactant availability may affect BCAA oxidation and protein metabolism in skeletal muscle.

Methods: Two separate experiments were performed using male Wistar rats in which the effects of inhibition and stimulation of glutamine synthesis on BCAA and protein metabolism was evaluated. In the first study, glutamine synthesis was inhibited by alanyl-glutamine infusion in healthy and endotoxin treated rats. In the second study, glutamine synthesis was stimulated by infusion of ammonium acetate/bicarbonate mixture. The parameters of protein metabolism and leucine oxidation were measured under steady state conditions using L-[1-¹⁴C] leucine infusion. Statistical comparisons were performed using ANOVA and Bonferroni test.

Results: Infusion of alanyl-glutamine induced a decrease in plasma BCAA levels, a decrease in leucine oxidation, and an improvement of protein balance due to the decrease in proteolysis both in intact and endotoxemic rats. Ammonium infusion induced an increase in ammonia and glutamine, an increase in BCAA oxidation, a decrease in BCAA and alanine levels in blood plasma, and a decrease in whole-body protein turnover and protein synthesis in skeletal muscle.

Conclusions: It is concluded that changes in glutamine synthesis induced by alanyl-glutamine and by ammonia infusion are associated with significant alterations in BCAA and protein metabolism. The results also demonstrate that the cause of decreased plasma BCAA levels observed frequently in liver cirrhosis is hyperammonemia.

Key words: glutamine, ammonia, branched-chain amino acids, leucine oxidation. Supported by PRVOUK P37/02.

PO2208

CLEAR KEFIR PROBIOTICS REDUCED POTENTIALY ON GLYCEMIC STATUS, LIPID PEROXIDATION OF THE DIABETES MELLITUS PATIENTS IN WEST JAVA, INDONESIA

J. Judiono^{1,2}, S. Hadisaputro², R R J. Djokomoeljanto², I. KS³

¹The Bandung Health Polytechnic, MOH RI. Nutrition Faculty, Java, Indonesia

²Professor in Medicine Medical Faculty, Diponegoro University, Semarang, Java, Indonesia

³Senior Lecture in Clinical Pathology Specialized of Medicine Faculty, Diponegoro University, Semarang, Java, Indonesia

Background and objectives: Hyperglycemia causes excessive free radicals, may increase reactive oxygen species, lipid peroxidation, as well as dysfunction of the pancreatic β cells. Kefir consists of bioactives, exopolysaccharides, antioxidants, immunomodulator. This study was validating the effect of clear kefir probiotic on glycemic status, lipid peroxidation of the Diabetes Mellitus Patients in West Java, Indonesia.

Methods: The randomized pretest-posttest control group study design was conducted in 108 diabetes mellitus (DMT2) patients in public hospitals. Sample were randomized into three groups: (1) DMT2 with HbA1c < 7, received diet and 200 ml clear kefir as intervention group 1, (2) DMT2 with HbA1c > 7, received diet and 200 ml clear kefir as intervention group 2. (3) DMT2 received diet as control group. Blood exopolysaccharide glucose was measured by enzymatic. Peroxidation was measured by MDA-TBARs. Probiotics characterization was done by microbiology. Data were analyzed by One Way Anova, Duncan test with significance level $p < 0.05$. Research was approved by Ethical Clearance Medicine Faculty of Diponegoro University.

Results: Clear kefir supplementation 200 ml/day for 30 days administration, affected on reduction of the blood glucose and MDA level. Statistical analysis showed there were respectively decreased of glucose ($p < 0.001$), MDA ($p < 0.001$) except in control. Probiotics were found as many as 106-109 cfu/mL and declined to 105 cfu/ml during storage. It was five species of probiotics; Lactobacillus Sp, Sp Lactococcus and Acetobacter and Saccharomyces Sp.

Conclusions: Kefir was significantly decreased of the blood glucose, level of MDA. Exploring potentially in a pathogenesis of the pancreatic β cells repairs and antioxidants is challenge for future research.

Key word: Probiotic, kefir, diabetes mellitus, hyperglycemia, lipid peroxidation.

PO2209

MICRONUTRIENTS DIETS MODIFICATION REDUCED ON BLOOD GLUCOSE OF THE TYPE 2 DIABETES MELLITUS (T2DM) IN WEST JAVA, INDONESIA (STUDY ON ENRICHMENT DIET OF ZINC, SELENIUM AND ZINC AND SELENIUM SELENIUM COMBINED)

J. Judiono¹, R. Titisundari¹

¹The Bandung Health Polytechnic, MOH RI. Nutrition Faculty, Java, Indonesia

Background and objectives: Micronutrients Zinc (Zn) plays glucose tolerance, immune and healing wounds of diabetes mellitus in patients. Selenium is an essential part of the enzyme glutathione peroxidase related to the body's immune system and works synergistically with the vitamin E. Supplementation vitamins and trace elements are still controversial used and no strong evidence approved for diabetes therapy. This study aimed to validate the effect of enrichment modification intake of zinc, selenium and combination in the diet on blood sugar levels.

Methods: Quasi-experimental design was using 28 T2DM patients selected by the purposive sampling. Samples were divided into three intervention groups; (1) sample received a diet enriched by Zinc, (2) sample Selenium enriched diet, (3) diet enriched in Zinc and Selenium, and (4) received diet as the control group. Socioeconomic was measured by questionnaire. Body composition measured by anthropometry. Blood glucose were measured by enzymatic. Nutritional intake was measured by FFQ. Data were analyzed by statistical program with significance level $p < 0.05$. Ethical was approved this research.

Results: Micronutrient dietary modification reduced delta fasting glucose 14.50 mg/dL in the group Zinc+Selenium diet enrichment, the selenium enrichment diet obtained about 7.88 mg/dL, and Zinc diet groups achieved at 6.38 mg/dL and the control group at 5, 25 mg/dL ($p = 0.027$). Delta postprandial glucose levels achieved at 12.50 mg/dL in the group Zinc + Selenium diet group, the enrichment of Zinc at 12.25 mg/dL, and Selenium diet group about 6.75 mg/dL, and a control group of 2.50 mg/dL ($p = 0.007$).

Conclusions: Modification of diet enrichment of Zinc+Selenium reduced significantly of blood glucose. Further research is challenge with a larger sample.

Key words: Diet modification, Zinc, Zinc, blood glucose, antioxidant.

PO2210

RELATIONSHIP BETWEEN SLEEP, HUNGER, CRAVINGS FOR FOOD, SEDENTARY LIFESTYLE AND WEIGHT IN ADOLESCENTS

V.M. Cardenas-Villarreal¹, Y. Flores-Peña¹, R.G. Hernández-Carranco¹, R.M. Cerda-Flores¹

¹Universidad Autónoma de Nuevo León, Monterrey, Mexico

Background and objectives: The recent epidemic of obesity in adolescents has been accompanied by a parallel decrease in hours of sleep. Physiological studies suggest that a reduction in sleeping time can have an effect on weight through the effects on appetite, physical activity and/or thermo-regulation. The purpose of this study was to determine the relationship between quality of sleep (QS), hunger, sense of satiety, cravings for food, sedentary lifestyle and weight in adolescents.

Methods: 323 adolescents, 12 to 18 years old who were registered in public schools participated in the study. The Pittsburgh Index of Sleep Quality was used. The data obtained included demographic, hunger level and satiety, cravings for food, sedentary lifestyle, and height and weight data. Descriptive and non-parametric procedures were used for the analysis of the data ($\alpha = 0.05$).

Results: The adolescents' age mean was 14.6 ± 1.7 years, and BMI mean was 22.55 ± 4.72 kg/m². The night sleeping time mean during the week was 6.15 ± 1.7 hours, and 8.55 ± 2.0 hours on weekends. 72.8% reported a global score of bad QS during the week. A relationship between sleeping time and BMI ($r_s = -0.131$ $p < 0.05$), hunger level ($r_s = -0.178$ $p < 0.05$) and cravings for food ($r_s = -0.168$ $p < 0.05$) was identified. The greater the sleeping disorders, the higher the level of cravings ($r_s = 0.186$ $p < 0.001$). The greater the daily dysfunction, the greater the sedentary lifestyle ($r_s = 0.164$ $p < 0.001$), the greater the level of hunger ($r_s = 0.149$ $p < 0.05$) and cravings for food ($r_s = 0.230$ $p < 0.001$).

Conclusions: These results point to a relationship between QS and behaviors during the day that can lead to obesity. Longitudinal studies using objective measurements of sleep, appetite regulation, and caloric intake are needed.

Key words: Sleep, obesity, food cravings.

PO2211**RELATIONSHIP BETWEEN SLEEP AND OBESITY IN ADOLESCENTS IN NORTHEASTERN MEXICO**

V M. Cardenas-Villarreal¹, Y. Flores-Peña¹, R. Ortiz-Feliz¹, R M. Cerda-Flores¹

¹Universidad Autónoma de Nuevo León, Monterrey, Mexico

Background and objectives: Adequate sleep has been considered important for the health and wellbeing of adolescents. Several studies have indicated that a decrease in night sleeping time in adults and children would be a risk factor for weight gain and the development of obesity (OB); the relationship is not clear for adolescents. The objective of this study was to evaluate the prevalence of short sleeping time and its relationship to OB in Mexican adolescents.

Methods: A transversal study was carried out; the sample consisted of 250 participants, 10 to 18 years old, both male and female, who were registered in three public education institutions. The participants were randomly selected using stratified sampling. Self-reporting questionnaires were used to assess sleeping time. Weight, size, waist circumference, and body mass index were determined.

Results: The sleeping time mean (SD) was 7.3 (1.5) hours/day during the week and 8.5 (2.0) hours on weekends. Around 30% sleep less than 7 hours per day and 20% more than 9 hours per day. It was identified that adolescents with long sleeping times (more than 9 hours per night) have a higher BMI score $\chi^2= 7.14$ $p = 0.02$, waist circumference $\chi^2= 4.70$ $p = 0.02$ and percentage of body fat $\chi^2= 5.16$ $p = 0.05$.

Conclusions: The results obtained in this study show high prevalence of short sleeping times among Mexican adolescents and that longer sleeping times are significantly associated with a higher risk for overweight and obesity. Longitudinal studies are essential to address the magnitude of causality and, concurrently, to identify the biological mechanisms involved in the development of obesity.

Key words: Adolescents, obesity, sleeping time, waist circumference.

PO2212**OATS AS HIGH-VALUE CEREAL ADDITIVE FOR COELIAC SUBJECTS: DEVELOPMENT OF NEW VARIETIES NON-TOXIC FOR THE COELIAC POPULATION**

C. Sousa¹, I. Comino¹, A. Real¹, L. Isabel¹, M.J. Giménez², M. del Mar. Rodríguez³, A. Arnaud³, F. Montes⁴, A. Rodríguez⁴, A. Cebolla⁵, I. Solis⁶, F. Barro

¹Departamento Microbiología y Parasitología, Facultad de Farmacia, Universidad de Sevilla, Sevilla, Spain

²IAS-CSIC Av. Menéndez Pidal s/n. Campus Alameda del Obispo, Córdoba, Spain

³SANAVÍ, S.A., Granada, Spain

⁴CITAGRO, Sevilla, Spain

⁵BIOMEDAL, S.L., Sevilla, Spain

⁶AGROVEGETAL, Sevilla, Spain

Background and objectives: Contrary to the case of other diseases, the treatment of coeliac patients is based not on drugs but on the maintenance of a gluten-free diet, which means the exclusion of wheat, barley, rye, and oats from the daily diet. The introduction of oats into the gluten-free diet has been a topic of debate in recent years. Earlier works of Comino et al. (2011. Gut 60:915-922), with monoclonal antibodies (G12 and A1) and T lymphocytes of coeliac patients, demonstrated that the immunogenicity of oats depended on the cultivar used. The results established a basis for the selection and development of new varieties safe for the coeliac population. With this background, the main aim of this work is the development of new oat varieties non-toxic for coeliac patients, offering the grower a greater diversification of traditional crops.

Methods: The oat varieties previously reported as non-toxic for coeliac subjects have been used as parentals and crossed with new varieties that present good adaptation and yields under Mediterranean crop conditions.

Results: Analysis of the toxicity, using the G12 and A1 antibodies, of a collection of 100 cultivated oat varieties from Mediterranean countries and subsequent crossing of the selected lines with the oat varieties previously reported as non-toxic.

Conclusions: The demonstration that the new oat lines generated are non-toxic, and should be suitable for consumption by the coeliac population, could allow their incorporation, via various types of prepared foods, into the daily diet of these patients, which would be of great importance for the patients both nutritionally and therapeutically.

Key words: oat varieties, coeliac disease, monoclonal antibodies.

PO2213**ROLE OF NUTRITIONAL INTERVENTION, AS ONE OF THE PACKAGE OF SERVICES PROVIDED TO HIV INFECTED PATIENTS**

G. Saleh¹, C. Mireille², M. Ahmed¹, E G. Hany¹

¹National Nutrition Institute, Cairo, Egypt

²Center of ambulatory treatment, Libreville, Gabon

Background and objectives: The Centre of Ambulatory Treatment (CAT) at Libreville, the capital of Gabon, provides a package of services to HIV infected patients composed of medical examination and providing antiviral treatment. Nutritional assessment with management of malnutrition and related symptoms, was added to the provided services, to improve the immunity level of the patients, their general condition, and the prognosis of the disease.

Methods: The study was conducted at the CTA, during one year, with follow-up of cases through a monthly visit. The sample of the study was formed of 117 patients. Nutritional education, nutritional assessment (medical, anthropometry and hemoglobin and CD4& CD8 levels) were achieved. Nutritional demonstration for healthy food and sanitary precautions during food preparation and supplement supplies were distributed when needed.

Results: Males formed 40.3% of cases, while women (59.7%). The mean age of men and women were: 40.5 and 34.3 years respectively. After the fifth visits the following figures were changed: The mean hemoglobin is increasing from 9.9 to 11.9 g/lit. The mean number of CD4 from 279.2 to 489. The mean weight for men from 55 to 67 kg.

Conclusions: Nutrition intervention is an important pivot in the package of services provided to HIV patients, to improve their immunity, their general health, and for the management of the complications of the disease and the retroviral treatment.

Key words: Nutrition, HIV, Gabon

PO2214**CLINICAL-NUTRITIONAL STATUS OF OBESE POST-MENOPAUSAL WOMEN ON A WEIGHT LOSS PROGRAM BASED ON PREPARED DISHES**

J. Molina-López¹, G. Rodríguez Navarrete¹, B. López González¹, J. Jiménez Rodríguez², E. Planells del Pozo¹

¹Department of Physiology, Institute of Nutrition and Food Technology, University of Granada, Granada, Spain

²Department of Evolutive Psychology, University of Granada, Granada, Spain

Background and objectives: Few studies have evaluated the efficacy and reliability of weight loss-focused prepared food dishes in obese post-menopausal women. To compare the efficacy of a weight loss program based on a balanced hypocaloric diet using prepared dishes* with that of a similar program based on standard commercially available foods and with a non-intervened control group. A further aim was to evaluate the subjectivity of participants in the preparation of the diet-adjusted dishes based on usually consumed products.

Methodology: Controlled longitudinal interventional study with obese post-menopausal women aged between 55 and 65 years. 75 female volunteers divided in three groups of 25 women: control, who consume their usual non-dietary adjusted meals (CG); treated with a diet adjusted to their individual requirements based on standard commercially available food (SG); and similar but based on prepared dishes (PG). Data were gathered on anthropometric variables, consumption habits and physical activity levels, and clinical-nutritional levels were conducted at the start and every two weeks to the end of the 8-week study in order to evaluate biochemical changes.

Results: The weight loss was significantly higher in SG y PG than CG (losses of 7.60 kg in PG and 7.01 kg in SG versus 2.10 kg in CG ($p < 0.01$). PG showed a significantly higher ($p < 0.01$) loss of fatty mass and abdominal circumference versus the SG women.

Conclusions: Two groups treated lost more weight than those untreated. The diet based on prepared dishes obtained more reliable and higher quality outcomes, achieving a positive change at fatty compartment level and in the abdominal circumference.

Key words: Obesity. Prepared dishes, weight loss, hypocaloric diet, post-menopausal women.

PO2215**DOCOSAHEXAENOIC ACID SUPPLEMENTATION AND INSULIN RESISTANCE IN OBESE CHILDREN IN A DOUBLE-BLIND RANDOMISED CONTROLLED CLINICAL TRIAL: A PILOT STUDY**

E. Verduci¹, M. Salvioni¹, C. Arrizza¹, G. Banderali¹, E. Riva¹, M. Giovannini¹

¹Department of Pediatrics, San Paolo Hospital, University of Milan, Milan, Italy

Background and objectives: Insulin resistance is highly prevalent among children with severe obesity. Long chain polyunsaturated fatty acids (LCPUFAs) are major components of cell membranes. Low levels of LCPUFAs, especially docosahexaenoic acid (C22:6 n-3, [DHA]) and a high n-6/n-3 LCPUFA ratio in skeletal muscle membrane phospholipids have been associated with insulin resistance in adults. The aim of the present study was to investigate whether dietary supplementation with DHA would be more effective than nutritional-behavior intervention alone in reducing insulin resistance in obese children.

Methods: We performed a randomized controlled trial of DHA supplementation (500 mg/day) versus placebo in 30 children (8-13 years) obese children. Both the intervention product and placebo were prepared as gelatin-soft gel pills (AFR Advanced Food Research, Limbiate, Milan, Italy). The main outcome was the change in insulin resistance as detected by homeostatic model assessment method (HOMA-IR) after 6 months of treatment. Secondary outcomes were the changes in body mass index z-score, alanine transaminase, triglycerides after 6 months of treatment.

Results: All children completed the study. At recruitment (baseline), the two groups were comparable with respect to nutritional, anthropometric and metabolic variables (minimum $p = 0.372$). At the end of the study reduction of plasma insulin and HOMA index was higher ($p = 0.046$ and $p = 0.045$, respectively) in DHA (mean 34.6%; 33.4%) than placebo (20.7%; 20.3%) group. Triglycerides decreased in DHA group as compared to placebo but there was no effect on alanine transaminase and body mass index. At the end of the intervention children showed a reduction in BMI z-score from 2.25 (0.49) a 1.90 (0.95) in DHA group and from 2.27 (0.47) to 1.95 (0.96) in placebo group.

Conclusions: Daily dietary supplementation of DHA at adequate dose may contribute to improve the insulin sensitivity of obese children undergoing a nutritional-behavior intervention.

Key words: DHA, obesity, insulin resistance, nutritional intervention, LCPUFA.

PO2216**POLYMORPHISM RS17782313 IN MC4R GENE IS NOT ASSOCIATED WITH BINGE EATING BEHAVIOR IN A BRAZILIAN COHORT OF OVERWEIGHT CHILDREN**

A E. Fernandes¹, M E. Melo¹, C T H. Fujiwara¹, A. Santos¹, C. Cercato², A. Halpern², M. Mancini^{1,2}

¹Laboratory of Carbohydrates and Radioimmunoassay/LIM-18, Faculty of Medicine, University of Sao Paulo, Sao Paulo, SP, Brazil

²Obesity and Metabolic Syndrome Unit, Endocrinology and Metabolism Department, Hospital das Clínicas, Faculty of Medicine, University of Sao Paulo, Sao Paulo, SP, Brazil

Background and objectives: Melanocortin-4 receptor (MC4R) mutations are the most common known cause of monogenic obesity. The rs17782313 is a common allelic variant, located near MC4R, and associated with an increased risk for obesity. MC4R is involved in the melanocortinergic system, and is deeply involved in energy homeostasis and body weight regulation. Thus, variations in this receptor might disturb the control over eating behavior. Binge eating (BE) may be originated in neural and hormonal defects in appetite and satiety control. Although the prevalence of BE disorder as defined in DSM-IV in the normal adult population ranges from 2% to 5%, rates in cohorts of obese adults seeking treatment for obesity rise up to 30%. The association of rs17782313 with BE behavior has been controversial. The main goal of this study was to investigate the association between rs17782313 with adiposity, BE and metabolic profile in overweight children.

Methods: 333 obese children (53.2% girl; 12.4±2.7 years-old, ZBMI 3.23±0.65) were genotyped for rs17782313 by TaqMan assay. Different genotypes were analyzed according to BE behavior (as measured by the BE Scale), percentage of fat mass (%FM) and cardiometabolic risk factors. The statistical analysis was performed with chi-square and one-way ANOVA tests by SPSS software, with level of significance set at $p < 0.05$.

Results: The population was in Hardy-Weinberg equilibrium (CC: 4.66%, CT: 33.8%, TT: 61.5%, $p = 0.74$). We found 142 (42.6%) binge eaters without association with rs17782313 ($p = 0.40$). The presence of variant allele rs17782313 (T>C) was not associated with %FM ($p = 0.33$), triglyceride levels ($p = 0.50$), fasting glucose levels ($p = 0.97$), insulin resistance-HOMA ($p = 0.79$), HDL-cholesterol levels ($p = 0.67$).

Conclusions: The prevalence of binge eaters in our cohort of Brazilian overweight children seeking treatment for obesity is extremely high, but the polymorphism rs17782313 in MC4R is not involved in BE behavior, increased adiposity and metabolic parameters in our sample.

Key words: MC4R, variant rs17782313, binge eating.

PO2217

RS12970134 IN MC4R GENE IS NOT RELATED TO WORST METABOLIC PROFILE IN OVERWEIGHT CHILDREN

A.E. Fernandes¹, C.T.H. Fujiwara¹, M.E. Melo¹, A. Santos¹, C. Cercato², A. Halpern², M. Mancini^{1,2}

¹Laboratory of Carbohydrates and Radioimmunoassay/LIM-18, Faculty of Medicine, University of Sao Paulo, Sao Paulo, SP, Brazil

²Obesity and Metabolic Syndrome Unit, Endocrinology and Metabolism Department, Hospital das Clínicas, Faculty of Medicine, University of Sao Paulo, Sao Paulo, SP, Brazil

Background and objectives: Genome-wide association studies have shown that variants near the melanocortin-4 receptor gene (MC4R) are associated with higher risk of obesity. The variant rs12970134, located 154 kb downstream from the MC4R was associated with increased adiposity, insulin resistance (estimated by HOMA-IR) and prevalence of type 2 diabetes. However, the results are still controversial. The main goal was to verify the influence of the rs12970134 in MC4R on adiposity and cardiometabolic risk factors in a cohort of overweight children and adolescents.

Methods: 333 obese subjects aged 7 to 18 years-old (53.2% girl; 12.4±2.7 years-old, ZBMI 3.23±0.65) were genotyped for rs12970134 by TaqMan assay. The variables analyzed were ZBMI, percentage of fat mass (%FM), fasting glucose, HDL-cholesterol (HDL-c), triglyceride (TG) levels, HOMA-IR and blood pressure percentiles (BPP). Statistics were performed using Qui-square test, ANOVA and Kruskal-Wallis Test and the level of significance was set at $p < 0.05$.

Results: The population was in Hardy-Weinberg equilibrium (AA: 4.39%, AG: 33.1%, GG 62.5%, $p = 0.16$). The presence of the variant allele rs12970134 (G>A) was not associated with any parameters: ZBMI ($p = 0.15$), %FM ($p = 0.57$), TG levels ($p = 0.23$), glucose levels ($p = 0.20$), HOMA-IR (0.42), HDL-c levels ($p = 0.94$), systolic BPP ($p = 0.94$) and diastolic BPP ($p = 0.68$).

Conclusions: We conclude that the variant allele rs12970134 in MC4R is not associated with increased adiposity and cardiometabolic risk factors in our sample of Brazilian overweight children and adolescents.

Key words: MC4R, variant rs12970134, childhood obesity.

PO2218

ASTHMA E EXCESS BODY WEIGHT

F. Benedetti^{1,2}, G. Fischer², V. Bosa²

¹Centro Universitário Franciscano – Unifra, Rio Grande do Sul, Brazil

²Universidade Federal do Rio Grande do Sul – UFRGS, Rio Grande do Sul, Brazil

Background and objectives: Central obesity was more associated with the presence of asthma in children compared with body mass index (BMI). The main goal was to assess the association between measures of adiposity and asthma in adolescents.

Methodology: This cross-sectional study. The study consisted of adolescents aged 10-18 and enrolled in public schools in the city of Santa Maria/RS/Brazil. The characteristics of asthma questionnaire were evaluated by the ISAAC, 1998. Anthropometric measurements using standardized techniques. High BMI indicates children with 85th percentile (WHO, 1997). The waist circumference (WC) cutoff point was defined as the 80th percentile (Taylor et al., 2000). The significance level adopted was 5%, and the analyses were carried out with the SPSS 11.5. The research was approved by the ethics in research committee.

Results: 867 adolescents with a mean age of 15.53±1.27 years, and 365 (42.1%) were male. Considering the 233 (26.8%) adolescents who are overweight observed that 48 (32%) had asthma sometime in their lives and 184 (26.3%) had no ($p = 0.157$), 49 (27.7%) had wheezing ever in life and 71 (32.4%) did not ($p = 0.308$) in the last 12 months 66 (32%) had wheezing and 165 (25.7%) did not ($p = 0.075$), 72 (32%) had no crisis, 41 (25.2%) of 1-3, 6 (46.2%) of 4-12 and 5 (71.4%) > 12 crisis ($p = 0.002$). Among the 140 (16.1%) adolescents with WC > 80th observed that 28 (18.7%) had asthma sometime in their lives and 111 (15.9%) had no ($p = 0.399$), 27 (15.3%) had wheezing ever in life and 45 (20.5%) did not ($p = 0.810$) in the last 12 months 38 (18.4%) had wheezing and 99 (15.4%) had no ($p = 0.300$), 44 (19.8%) had no crisis, 26 (16%) of 1-3, the second (15.4%) of 4-12 and 1 (14.3%) > 12 crisis ($p = 0.780$).

Conclusions: a higher percentage of adolescents with BMI > 85th have asthma and wheezing ever in life and in the last 12 months and had more than 12 crises.

Key words: asthma, adolescents, obesity.

PO2219**ASSOCIATION BETWEEN INTAKE OF FRUITS AND BETA-CAROTENE AND AMYOTROPHIC LATERAL SCLEROSIS RISK IN KOREANS: A CASE-CONTROL STUDY**

Y. Park¹, Y. Jin¹, K. Oh², S.I. Oh², H. Baek³, S.H. Kim²

¹Department of Food and Nutrition, Hanyang University, Seoul, Korea

²Department of Neurology, Hanyang University Hospital, Seoul, Korea

³Department of Food and Nutrition Services, Hanyang University Hospital, Seoul, Korea

Background and objectives: Amyotrophic Lateral Sclerosis (ALS), a rare progressive neurodegenerative disease, has been suggested to be associated with oxidative stress, and thus antioxidant dietary factors or dietary habits may influence pathophysiological mechanisms or the risk of ALS. The purpose of the present study was to investigate the hypothesis that intakes of fruits, rich in antioxidant nutrients are negatively associated with the risk of ALS.

Methods: Seventy seven Koreans diagnosed ALS by the EI Escorial criteria-revised and same numbers of age- and sex-matched healthy controls were participated in this study. Dietary intake was estimated by the standardized food frequency questionnaire.

Results: Multivariate logistic regression analysis showed that fruits consumption was negatively associated with the risk of ALS, but intake of beef, fish, and fast food were positively associated with the risk of ALS. Consumption of ≥ 20 servings of fruits per week reduced the risk of ALS by 66% as compared with consumption of ≥ 9 servings of fruits per week. In addition, the risk of ALS was negatively associated with an intake of plant calcium and beta-carotene, while positively associated with an intake of total calcium and animal calcium. Intake of vegetables and other antioxidant nutrients had no effect on the risk of ALS in the present study.

Conclusions: In conclusion, this present study suggests that intake of fruits and beta-carotene may be related with decreased risk of ALS in the aspect of diet habits. However, large prospective and intervention studies are needed to support the effect of fruits and beta-carotene intake on reducing the risk of ALS.

Key words: Amyotrophic lateral sclerosis, Beta-carotene, Case-control study, Fruit, Korean. (This study was supported by the Korea Research Foundation Grant 2012R1A1A2040553, funded by the Korean Government)

PO2220**ROLE OF TYPE OF DIETARY FAT IN THE ETIO-
PATHOGENESIS OF CARCINOGEN-INDUCED
BREAST NEOPLASM IN FEMALE FISCHER RATS**

U. Putcha¹, V. Ayyalasomayajula², S. Mullapudi¹, S S Y H. Qadri¹, S. Krishnakumar¹, K. Subramanyam³, S. Boindala¹

¹Pathology Division, National Institute of Nutrition, Hyderabad, Andhra Pradesh, India

²Lipid Chemistry Division, National Institute of Nutrition, Hyderabad, Andhra Pradesh, India

³National Center for Lab Animal Sciences, National Institute of Nutrition, Hyderabad, Andhra Pradesh, India

Background and objectives: Cancers most frequently seen in India are being associated with lifestyle changes and the type of diet consumed is also emerging as one of the important risk factors in carcinogenesis. Among the various dietary components, the role of fat as a risk factor has been extensively studied. High fat diets are known to promote cancer cell proliferation. The aspect of fat quality (saturated/unsaturated/trans-fat) in cancer causation is complex and not clearly elucidated. Evidence is accumulating that consumption of specific types of fat may be an important determinant of breast cancer risk. The present study looked into the role of saturated vs unsaturated vs PHVO (partially hydrogenated vegetable oil) in experimental DMBA [DiMethylBenzAnthracene]-induced mammary carcinogenesis in female Fisher 344 rats.

Methods: Forty weanling female rats were divided into five groups and maintained on synthetic diets with fat content at 10% level comprising saturated fat [palmolein oil], PHVO [vanaspati], n-6 PUFA [sunflower oil], ALA [soybean oil] alone and ALA + long chain (LC) n3 PUFA [soybean+fish oil] respectively for 4 months, after which DMBA was administered orally once a week (for 4 weeks) and continued on same diets for 8 more months, till termination of the experiment.

Results: Tumors (malignant, benign & metastatic) developed least in PHVO group followed by (LC) n3 PUFA and ALA-fed animals as compared to other groups and this could be attributed to low level of PUFA in the PHVO group, and ALA in the n3-PUFA containing groups.

Conclusions: Regardless of the dietary fat consumed, the predominant tumor type was adenocarcinoma followed by squamous carcinomas.

Key words: Diet, saturated, unsaturated, PHVO, cancer.

PO2222

ADEQUACY OF SHROB RATS AS A MODEL FOR THE METABOLIC SYNDROME IN NUTRITIONAL STUDIES

E. Molinar-Toribio¹, J. Pérez-Jiménez¹, L. Lluís², V. Sánchez-Martos², M. Giralt², M. Pazos³, L. Méndez³, I. Medina³, J. Torres¹

¹Institute of Advanced Chemistry of Catalonia (IQAC-CSIC), Barcelona, Spain

²Faculty of Medicine and Health Sciences, Universidad Rovira i Virgili, Reus, Spain

³Instituto de Investigaciones Marinas (IIM-CSIC), Vigo, Spain

Background and objectives: SHROB (spontaneously hypertensive obese) rats have been proposed as a model for Metabolic Syndrome (MS), an increasing public health problem. They have a mutation in DNA loci coding for the extracellular domain of the leptin receptor, which has been properly described, as well as some derived phenotypic aspects, i.e., hyperinsulinemia or hyperlipidemia always in comparison with the already mutated SHR rats. Other parameters related with cardiovascular disease (CVD) and oxidative stress have not been explored in this rat. This work aimed to provide an adequate phenotypic characterization of SHROB rats, as compared with Wistar rats, in order to evaluate its validity as a model for MS in nutritional interventions.

Methods: Female SHROB rats (n = 7) were followed up from an age of 7 up to 28 weeks together with a control group of female Wistar rats (n = 7). Body weight was recorded weekly. At the end of the study, parameters related with CVD, glycaemia and oxidative stress were evaluated in plasma, urine and in different organs by validated methodologies.

Results: SHROB rats presented statistically significant differences with Wistar rats in CVD risk factors, e.g., LDL-cholesterol (nine-fold increase), abdominal fat as percentage of body weight (+50%) or C-reactive protein (+66%). Lipid oxidation (as urinary F2-isprostanes) was significantly higher in SHROB rats than in Wistar rats, while the inverse tendency was observed for protein oxidation (carbonyl groups in plasma and liver). SHROB rats also exhibited hepatic steatosis and renal atrophy.

Conclusions: SHROB rats present, in comparison with Wistar rats, extreme phenotypic alterations in parameters related with CVD, not previously measured in this animal model, and in oxidative status. These alterations are too severe to be reversed merely by nutritional interventions; therefore, this model may not be adequate for nutritional studies on MS.

Key words: SHROB rats, metabolic syndrome, animal models, oxidative stress.

PO2223

THE FLAVONOID RUTIN ATTENUATES RAT ILEITIS INDUCED BY TRINITROBENZENE SULFONIC ACID

C. Mascaraque Molina², M. González², A. Anzola Santander², A. Zarzuelo¹, M.D. Suárez¹, O. Martínez-Augustín¹, F. Sánchez de Medina¹

¹University of Granada/ CIBERehd, Granada, Spain

²University of Granada, Granada, Spain

Background and objectives: The pathogenesis of inflammatory bowel disease (IBD) remains undefined to date, and there is a need for new treatments for this condition. The flavonoid rutin has colonic anti-inflammatory effects which have been ascribed to the intracolonic release of the aglycone quercetin as active moiety. Our objective is to assess whether rutin may exert similar protective effects in ileal inflammation.

Methods: rat ileitis was induced by the intraluminal injection of a TNBS solution dissolved in 50% ethanol (30 mg/kg) at a site 10 cm proximal to the ileocecal valve, under isoflurane anesthesia. Control rats were injected with saline. Treatment with rutin 20 mg/Kg (or 1% methylcellulose) administered by gavage was started 2 days before ileitis induction. Six days after the TNBS injection the animals were sacrificed and the ileum examined for macroscopic and microscopic, damage score, weight/length ratio, myeloperoxidase (MPO) and phosphatase alkaline (AP) activity. Experimental groups: control, TNBS, TNBS+rutin.

Results: TNBS ileitis was characterized by diarrhea and anorexia. In the TNBS group, the body weight gain was significantly decreased and the damage score visibly elevated above the levels observed in control group. The administration of the flavonoid rutin resulted in an increased body weight gain, a lowered ileal weight/length ratio (23.3% relative to TNBS) and a decreased macroscopic damage score (37.5% relative to TNBS) and indicating protection against TNBS induced inflammation. Rutin treatment also significantly decreased tissue MPO (35% relative to TNBS) and AP activity (27% relative to TNBS).

Conclusions: oral administration of rutin is effective for attenuating rat TNBS-induced ileitis, even though it is not considered to release quercetin at this level.

Key words: rutin, ileitis, flavonoid, quercetin.

PO2224**APIGENIN K HAS INTESTINAL ANTI-INFLAMMATORY EFFECT IN TWO EXPERIMENTAL MODELS COLITIS IN THE RAT.**

R. González¹, C. Mascaraque², A. Anzola Santander², M D. Suárez¹, A. Zarzuelo¹, O. Martínez-Augustin¹, F. Sánchez de Medina¹

¹University of Granada/ CIBERehd, Granada, Spain

²University of Granada, Granada, Spain

Background and objectives: Flavonoids are polyphenolic compounds which are widespread in nature and are consumed as part of the human diet in significant amounts. Many flavonoids have been studied for their intestinal anti-inflammatory activity. The aim of this study was to test the intestinal anti-inflammatory activity of apigenin K, a soluble form of apigenin, in two models of rat colitis, the trinitrobenzene sulfonic acid (TNBS) model and the dextran sulfate (DSS) model.

Methods: Apigenin K (3 mg/kg, p.o.) was administered as a pretreatment to rats with TNBS and DSS colitis and colonic status was checked 7 and 9 days after colitis induction, respectively, by macroscopic and biochemical examination.

Results: Apigenin K pretreatment resulted in amelioration of the morphological signs and biochemical markers in the TNBS model. The results demonstrate a reduction in inflamed area of 2.4 cm compared with TNBS group, lower values of macroscopic damage (5.8 ± 1.1 vs 8.6 ± 1.4 , $p < 0.05$) and a slight decrease in the colonic weight/length ratio. Myeloperoxidase and alkaline phosphatase colonic activities were reduced by 34% ($p < 0.05$) and 18%, respectively. Moreover, apigenin K also ameliorated morphological signs and biochemical markers in the DSS model, the comparable results. Thus macroscopic damage was significantly reduced (0.5 ± 0.5 vs 2.1 ± 0.6 , $p < 0.05$) and the colonic weight/length ratio was lowered by approximately 10%. Colonic myeloperoxidase and alkaline phosphatase activities decreased 30% and 20%, respectively ($p < 0.05$). Apigenin K treatment additionally reduced the colonic expression of IL1 β , IL6, Foxp3, TLR2 and TGF- β compared with the TNBS group ($p > 0.05$ for the latter two).

Conclusions: Apigenin K has anti-inflammatory effects in two preclinical models of inflammatory bowel disease.

Key words: apigenin K, trinitrobenzene sulfonic acid, dextran sulfate, colitis, rat.

PO2225**EFFECTS OF REDUCED FAT FRANKFURTERS AND PÂTÉS ON METABOLIC SYNDROME COMPONENTS OF VOLUNTEERS AT INCREASED CARDIOVASCULAR RISK. A PLACEBO-CONTROLLED STUDY**

P. Celada¹, G. Delgado-Pando², F. Jiménez-Colmenero², B. Olmedilla-Alonso², FJ. Sánchez-Muniz¹

¹Departamento de Nutrición y Bromatología I (Nutrición). Facultad de Farmacia, Universidad Complutense, Madrid

²Instituto de Ciencia y Tecnología de los Alimentos y Nutrición (ICTAN), CSIC, Madrid, Spain

Background and objectives: Meat and meat products consumption is very high in Spain and developed countries. Meat appears as suitable matrix for incorporating functional ingredients. The aim was to analyze the effect of consuming 200 g and 250 g per week of reduced-fat frankfurters and pâté (RF), respectively on metabolic syndrome components (waist perimeter, glycaemia, triglyceridemia, blood pressure and high density lipoproteinemia) of volunteers at high CVD risk classified according to low-normal and increased blood pressure.

Methods: Twenty-two volunteers consumed RF (frankfurters, 15.3% fat; pâté, 15.2% fat) during 4-wk in the frame of each own diet. Cutoff points selected for high systolic and diastolic blood pressures were 130/85 mmHg.

Results: The intervention did not globally modify any component of metabolic syndrome. However, significant different diet response was observed for normo vs hypertense volunteers with respect to glycaemia ($p < 0.001$) and blood pressure ($p < 0.02$) changes. Thus, in normotensives the intervention increased the glycaemia ($P < 0.05$) but in hypertensives decreased the glycaemia ($p < 0.02$) and the systolic pressure ($p < 0.05$).

Conclusions: Hypertense volunteers appear as the target population for consuming RF meat products as improved two components of metabolic syndrome

Key words: Reduced-fat, frankfurters, pâtés, glucose, waist perimeter, HDL-cholesterol, triglycerides. . Granted by Consolider-Ingenio-2010, CARNISENUSA-CSD2007-00016. Ministerio de Ciencia y Tecnología (Spain).

PO2226**POSITIVE INTERACTION BETWEEN PREBIOTIC NUTRIENTS AND THIAZOLIDINEDIONE IN THE CONTROL OF ADIPOSITY**

M. Alligier¹, E. Dewulf¹, N. Salazar¹, L. Bindels¹, A. Neyrinck¹, P. Cani¹, N. Delzenne¹

¹Metabolism and Nutrition Research Group, Louvain Drug Research Institute, Université Catholique de Louvain, Louvain-La-Neuve, Belgium

Background and objectives: In a model of diet-induced obesity, fat mass accumulation was associated with activation of the peroxisome proliferator-activated receptor gamma (PPARgamma), a master regulator of adipocyte differentiation. Inulin-type fructans (ITF) are non-digestible, fermentable carbohydrates that counteract the high-fat (HF) diet-induced metabolic disorders such as increased adiposity. Thiazolidinediones are PPARgamma agonists currently used as anti-diabetic agents in humans but they induce one important side effect, namely an increased adiposity. The aim of this study was to investigate the impact of ITF prebiotics on adiposity in a model of pharmacological activation of PPARgamma in HF diet fed mice.

Methods: Male C57bl6/j mice were fed a HF diet alone or a HF diet supplemented with ITF (0.2 g/day*mouse) or pioglitazone (30 mg/kg body weight*day) or both during 4 weeks.

Results: As expected, pioglitazone improved glucose response to insulin but also importantly increased plasma adiponectin levels and brown adipose tissue (BAT) weight. Furthermore, it induced an over-expression of several PPARgamma target genes in white adipose tissues. ITF prebiotics modulated the pioglitazone-induced PPARgamma activation in a tissue-dependent manner. The co-treatment with ITF prebiotics and pioglitazone maintained the beneficial impact of the PPARgamma agonist on glucose homeostasis and adiponectinemia. Moreover, the combination of both treatments induced a reduction in fat mass accumulation, in circulating lipids and hepatic triglycerides content, thus suggesting an overall improvement of metabolism linked to ITF co-treatment.

Conclusions: ITF prebiotics improve the metabolic response in HF fed mice treated with an anti-diabetic agent and could be considered as an interesting nutritional approach in the management of diabetes in obese patients.

Key words: thiazolidinedione, inulin-type fructan prebiotics, adipose tissue.

PO2227**NUTRITIONAL KNOWLEDGE AND ASSOCIATION WITH DIETARY PRACTICES AMONG CANCER PATIENTS: A CASE STUDY OF KENYATTA NATIONAL HOSPITAL CANCER TREATMENT CENTER.**

C. Muthike¹, J. Imungi¹, Gerald. Muchemi¹

¹University of Nairobi, Nairobi, Kenya

Background and Objectives: It has been indicated that Malnutrition can affect up to 85% of patients with cancer depending on the type (Argilés, 2005). The hypothesis of this study was that there was no association between the nutritional knowledge of cancer patients and their dietary practices. The objectives of this study were the social demographic status, the nutritional knowledge and the dietary practice of patients attending the cancer treatment center at the hospital.

Methods: This study intends to use the cross-sectional design to establish the level of nutritional knowledge and their usual food habits (dietary practice). The tools mainly used will be a nutrition knowledge questionnaire to determine the level of knowledge and food frequency and dietary diversity to determine the dietary practice.

Results: From the analysis of this study using the Pearson's correlation showed that there was a significant positive correlation between the nutrition knowledge cancer patients and their dietary diversity score which was $p = 0.000$ at $p < 0.01$ and $r = 0.392$. Further a logistic regression was done $r^2 = 0.147$ indicating that 15% of the Dietary Diversity Score (DDS) could be explained by the nutrition knowledge. The linear equation was $DDS = 4.084 \pm 0.030(\text{Knowledge score})$. Using logistic regression the frequency in which patients was eating fruits is predicted to increase 10 times by increasing their nutrition knowledge, this relationship was statistically significant $p = 0.018$ at $P < 0.05$.

Conclusions: There is an association between nutrition knowledge and dietary practice among cancer patients attending the CTC (Cancer Treatment Center).

Key words: nutritional knowledge, dietary practice and cancer.

PO2228

HEALTH IMPLICATIONS OF RICE CULTIVAR DIVERSITY AND CARBOHYDRATE DIGESTIBILITY IN CAMBODIA

S. Sar^{1,2}, R.G. Gilbert¹, G.C. Marks²

¹Centre for Nutrition and Food Sciences, Queensland Alliance for Agriculture and Food Innovation, The University of Queensland, Brisbane, QLD 4072, Australia

²School of Population Health, The University of Queensland, Herston, QLD 4006, Australia

Background and objectives: The association of rice consumption with risk of type 2 diabetes was recently reported. The current prevalence of diabetes in Cambodia is 3.1% and projected to increase to 6.5% by 2030. Rice is a staple food for Cambodians. Foods containing slowly digestible starch and resistant starch can both mitigate, and prolong the onset of, obesity and diabetes. The objectives of this study are: to investigate rice choice and consumption behavior, to understand the digestibility of cooked Cambodian rice, and to suggest suitable rice varieties with less adverse impact on human health.

Methods: A quantitative survey of a representative sample of 250 rural and urban households in five different agro-climatic zones of Cambodia was done to investigate the rice consumption patterns. An in-vitro method was used to study the starch digestibility of cooked rice.

Results: The survey results showed that rice varieties commonly grown and consumed by Cambodian people differ across agro-climatic zones. Rural people, men, and rice growers consumed a significantly larger proportion of rice than urban people, women, and non-rice growers, respectively. The most important attributes in purchasing rice for consumption were price, taste, and texture. The in-vitro study suggested that the digestibility of cooked rice was significantly different among the ten most popularly consumed varieties. There were at least 39% of respondents consumed very high and high digestibility rice varieties, which may cause significant future health implications. Low digestibility rice varieties, IR66 and Bei Katam, are hypothesized to lower risk of diabetes and other related metabolic diseases.

Conclusions: Cambodian people tend to grow and consume different rice varieties across agro-climatic zones. Individual households may have a restricted selection of rice that they routinely consume, which might have a pronounced effect on their health due to their particular digestibility properties.

Key words: rice, starch digestibility, diabetes.

PO2229

FISH OIL INTAKE ENHANCES ENERGY UTILIZATION BY INDUCTION OF UCP1 EXPRESSION IN ADIPOSE TISSUE

M.J. Kim^{1, 2}, T. Goto^{1,2}, N. Takahashi^{1,2}, Y. Kano³, T. Kawada^{1,2}

¹Laboratory of Molecular Function of Food, Division of Food Science and Biotechnology, Graduate School of Agriculture, Kyoto University, Uji, Japan

²Research Unit for Physiological Chemistry, Kyoto University, Kyoto, Japan

³Laboratory of Nutrition Chemistry, Faculty of Home Economics, Kobe Women's University, Kobe, Japan

Background and objectives: Mammals have two types of adipose tissue. White adipose tissue (WAT) accumulates excess dietary fat. On the other hand, brown adipose tissue (BAT) dissipates excess energy through adaptive thermogenesis. The key of this process is uncoupling protein 1 (UCP1), a specific mitochondrial protein. Several studies indicate that treatment of obese animals with b3-adrenergic agonist induce UCP1 expression in BAT and WAT, resulted in increasing of lipid mobilization and finally reduce body fat. Our previous study showed that intake of fish oil reduced the body fat accumulation and induced UCP1 expression in BAT (J. Agric. Food Chem. 1998). In this study we investigated the anti-obesity effect of fish oil intake was linked to UCP1-mediated thermogenic activity in adipose tissue.

Methods: Male C57BL/6J mice were fed a high fat diet (on a calorie basis, contained 14% protein, 41% carbohydrate, 45% fat) or supplemented with two types of fish oil (contained 5% or 10% in 45% fat) for 10 weeks. Results and

Conclusions: Fish oil intake reduced body weight gain and lipid accumulation, while increasing of oxygen consumption and rectal temperature compared with high-fat diet-fed mice. Fish oil intake induced UCP1 mRNA and protein expression in both of BAT and WAT, and also induced b3-adrenergic receptor mRNA expression. In addition, fish oil intake increased the amount of catecholamines in the urine. Elevation of urinary catecholamine levels suggested that fish oil intake stimulates the sympathetic nervous system. Thus, the fish oil intake enhanced energy utilization by induction of UCP1 in response to up-regulation of b3-adrenergic receptor in both adipose tissues.

Conclusions: Our study indicated that fish oil intake could be useful to prevent obesity and related metabolic disorders.

Key words: Fish oil, brown adipose tissue, uncoupling protein 1, sympathetic nervous system

PO2230**TOBACCO SMOKE AND SIDE-STREAM CIGARETTE SMOKE INDUCE THE RISK OF CARDIOVASCULAR DISEASE**

D. Viroonudomphol^{1,2}, *S. Tribanyatku*², *U. Pinyosirikul*³, *T. Harnroongroj*⁴

¹Department of Chemical Metrology and Biometry, National Institute of Metrology (Thailand), Pathumthani, Thailand

²Pramongklaw Hospital and College of Medicine, Bangkok, Thailand

³Department of Clinical Chemistry, Faculty of Medical technology, Mahidol University, Bangkok, Thailand

⁴Department of Tropical Nutrition and Food Science, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand

Background and objectives: Disease risk due to smoking is not limited to smokers only. Passive smoking exposure to environmental tobacco smoke is associated with adverse health effect. Side-stream cigarette smoke, a major component of secondhand smoke induces reactive oxygen species with promote oxidative stress. This paper summarizes the cardiovascular effects of tobacco smoke.

Methods: Studies were carried out on 150 smokers (50 industrial cigarette smokers, 50 passive smokers and 50 local tobacco smokers compared with 50 nonsmoking controls. Blood samples were collected and determined for level of biochemistry substances, Cholesterol (C), HDL- Cholesterol (HDL-C), LDL-Cholesterol (LDL-C), Triglyceride (TG), Malondialdehyde (MDA), Conjugate diene (CD) and Homocysteine (Hcy).

Results: Levels of C, LDL-C, TG and MDA were significantly lower in smokers than in controls. Whereas Hcy levels were significantly higher among smokers than controls. No significant differences of HDL- C and CD were found between both groups. For dietary intake assessment, smokers consumed significantly less energy from carbohydrate, fat compared to controls, while energy derived from protein did not differ between groups. Moreover, smokers consumed less dietary fiber and vitamins compared with controls.

Conclusions: Increasing whole blood toxic trace elements in healthy smokers may be explained by low antioxidant trace elements and vitamins that lead to develop oxidative stress and cardiovascular disease. Therefore public health should not only aim for smoking cessation, but also concern about diet in terms of vitamin and mineral content to protect the risk of cardiovascular disease.

Key words: tobacco smoke; side-stream smoke; cardiovascular disease.

PO2231**CEREAL FOODS AND COMPONENTS IN OUR DAILY DIETS AND THEIR IMPORTANCE FOR HEALTH**

*G. Riccardi*¹

¹Federico II University, Napoli, Italy

Background and objectives: Cereal foods are the most important component of the human diet; they are major contributors of dietary carbohydrates and, therefore, play an important role in energy and substrate metabolism. The relevant literature has been reviewed to better understand the relationship between cereal food intake and major chronic non communicable diseases (NCD), trying to elucidate potential mechanisms linked to food constituents.

Methods: A PubMed search has been undertaken utilizing as key-words cereals (refined and wholegrain) plus other terms identifying NCD and associated relevant body functions; both epidemiological and human intervention studies have been included.

Results: Relationships between cereal food consumption and health outcomes have heterogeneous patterns, depending on the type of cereal, on whether cereals are consumed as wholegrain or in refined form, on the amount of fiber, food structure, glycemic index, polyphenol content, micronutrients, etc. Recent research indicates as relevant for health not only the rate of starch accessibility and digestion in the small intestine, but also carbohydrate fermentation in the gut. Prebiotic compounds present in cereal products may influence the composition of intestinal microbiota and promote production of short chain fatty acids in the colon; this may represent one of the relevant mechanisms of the beneficial impact of many cereal foods on energy, glucose and lipid metabolism and intestinal cell proliferation (linked to the risk of cancer).

Conclusions: Epidemiological surveys consistently show an association between cereal consumption (mostly wholegrain) and prevention of several NCD; however, there is a gap between the health benefits shown in observational studies and the elucidation of the mechanisms involved. More research (particularly human intervention studies) is needed to fill this gap and provide solid grounds for more specific guidelines for cereal food consumption at the population level.

Key words: cereal foods, health benefits, blood glucose regulation, energy metabolism, plasma lipids.

PO2232

ACTIVATION MECHANISM OF DRUG-METABOLIZING PHASE II ENZYMES BY 3-O-[2-O-(α -D-XYLOPYRANOSYL)- β -D-GALACTOPYRANOSYL]-KAEMPFEROL

S. Iwami¹, T. Hashimoto¹, T. Shimoaki¹, K. Kanazawa¹

¹Graduate School of Agricultural Science, Kobe University, Japan

Background and objectives: The consumption of 3-O-[2-O-(α -D-xylopyranosyl)- β -D-galactopyranosyl]-kaempferol (kaempferol-GX), one of the major polyphenols in horseradish leaves, for 1 week activated drug-metabolizing phase II enzymes, glutathione S-transferase (GST) and quinone reductase (QR), in the liver of mice. However, there is no information on the activation mechanism. The present study investigated the metabolites of kaempferol-GX in the plasma of mice and the involvement of intestinal flora in the activation.

Methods: To investigate the metabolites, ICR mice were given ad libitum access to a diet or water including kaempferol-GX (KFR-GX group), kaempferol (KFR group), or sucrose (control group) for 1 week. The metabolites of kaempferol-GX or kaempferol in the plasma were determined by HPLC-colorimetric ECD and LC/MS/MS analysis. To investigate the involvement of intestinal flora, germ-free IQI/Jic mice were given ad libitum access to plain water or kaempferol-GX-supplemented water for 1 week. The hepatic GST and QR activity and the metabolites of kaempferol-GX in the plasma were then examined.

Results: In ICR mice, kaempferol conjugates in the plasma of the KFR-GX group were significantly lower than those of the KFR group, although the hepatic enzyme activities of the KFR-GX group were higher than those of the KFR group. On the other hand, p-cresol conjugates, which were considered as one of the metabolites, in the plasma of the KFR-GX group were higher than those of the KFR group. Furthermore, 4-hydroxyphenylacetic acid (4-HPAA) in both non-conjugated and conjugated forms significantly increased in the plasma of the KFR-GX group compared with control group. In germ-free mice, the administration of kaempferol-GX did not increase the plasma concentrations of 4-HPAA and p-cresol conjugations or hepatic QST and QR activities.

Conclusions: These results suggest that kaempferol-GX was catabolized by the intestinal flora, and that its catabolites might activate hepatic GST and QR activity.

Key words: 3-O-[2-O-(α -D-xylopyranosyl)- β -D-galactopyranosyl]-kaempferol, 4-hydroxyphenylacetic acid, drug-metabolizing phase II enzymes, germ-free IQI/Jic mice.

PO2233

6-METHYLSULFINYL HEXYLISOTHIOCYANATE INHIBITS CELL CYCLE PROGRESSION ACCOMPANIED BY INTERACTION WITH GLYCERALDEHYDE-3-PHOSPHATE DEHYDROGENASE

M. Ishimura¹, T. Hashimoto¹, M. Tanaka¹, Y. Aihara¹, K. Kanazawa¹

¹Graduate School of Agriculture, Kobe University, Japan

Background and objectives: 6-Methylsulfinyl hexylisothiocyanate (6-MSITC), one of the major isothiocyanates in wasabi (*Wasabia japonica*), exhibits anti-carcinogenic activity. We have previously reported the inhibitory effects of 6-MSITC on cell cycle progression from the G0/G1 to S phase in quiescent JB6 cells after treatment with growth stimulators. The present study investigated the structure-activity relationship and target proteins for 6-MSITC to cause cell cycle arrest.

Methods: To examine the structure-activity relationship, quiescent JB6 cells, which were serum-starved for 36 h, were treated with 6-MSITC or its analogues, followed by stimulation with epidermal growth factor. The cell cycle was analyzed by flow cytometry. To identify the target proteins, ethynyl 6-MSITC and ethynyl 6-methylthiohexyl isothiocyanate (6-MTITC) were synthesized, and the cellular proteins interacting with isothiocyanates were isolated using magnetic beads, in which the linker terminal was modified with the azide group to bind to ethynyl isothiocyanates. These proteins were separated by SDS-PAGE, and identified by nano-LC/MS/MS analysis and a Mascot search using the Swiss-Prot database.

Results: The 6-MSITC significantly inhibited cell cycle progression, as shown in our previous report, but 6-MTITC hardly inhibited it. The results suggest that the sulfinyl group of 6-MSITC plays an important role in cell cycle arrest. The magnetic beads isolated several proteins bound to isothiocyanates, and the nano-LC/MS/MS analysis and Mascot search indicated that one protein bound to 6-MSITC but not to 6-MTITC was glyceraldehyde-3-phosphate dehydrogenase (GAPDH).

Conclusions: Immunoprecipitation analysis demonstrated that GAPDH interacted with retinoblastoma protein and the transcription factor E2F in quiescent JB6 cells. Our previous study demonstrated that 6-MSITC inhibited gene expression of cyclin A2, which is known to be expressed by E2F, and to be one of the S phase-regulating proteins. These suggested that 6-MSITC might inhibit the transcriptional activity of E2F through interaction with GAPDH, and then cause cell cycle arrest.

Key words: 6-methylsulfinyl hexylisothiocyanate, glyceraldehyde-3-phosphate dehydrogenase, cell cycle, JB6 cells.

PO2234**OSTEOPOROSIS RISK FACTORS CONNECTED WITH NUTRITION AMONG ADULTS WITH CARDIOVASCULAR DISEASES**

A. Ostachowska-Gasior¹, A. Skop-Lewandowska¹, W. Szot¹

¹Jagiellonian University Medical College Hygiene and Dietetics Dpt, Poznan, Poland

Background and objectives: Proper nutrition constitute an important factor improving pharmacological treatment of cardiovascular diseases, simultaneously can prevent or inhibit development of other illnesses, including osteoporosis. The aim was assessment of nutrition patterns among adults above 39 years old with recognized cardiovascular disease in aspect of dietetic recommendations in osteoporosis prophylaxis.

Methods: 173 individuals were examined (81 women, 92 men) divided into two age groups: I- 39-59, II- >60. All participants were under control of I Clinic of Cardiology and Hypertension in Krakow. Nutrition was assessed on basis of 24-hour recall, three per each participant. The recall focused on home nutrition. The correctness of results was assessed using updated norms prepared by National Food and Nutrition Institute.

Results: Energetic value of recalls was lower than recommendations: group I - 50% of norm (N) for both sexes; group II - 66%N for women, 60%N for men. Fat intake in group I was 74%N for women, 78%N for men; in group II 80%N for both sexes. Low intake was observed for: calcium (group I 26.2%N for women, 7.6%N for men; group II: 26.2%N for women, 25.8%N for men) and magnesium (group I 72%N for women, 60%N for men; group II 71%N for women, 58%N for men) but uptake of phosphorus exceeded norms (group I 149%N for women, 166%N for men; group II 147%N for women, 162%N for men). Ratio of calcium to phosphorus in group I was 1:2.5 for women, 1:1.27 for men; in group II was 1:1.25 for women, 1:1.3 for men.

Conclusions: Observed nutritional mistakes can influence on development and enhancement of already present osteoporotic changes and can constitute diagnostic premises for dietetic interventions like practical dietetic advices that could modify current eating habits, adjusted to individual needs.

Key words: adults, nutrition, osteoporosis prophylaxis.

PO2235**DAIRY PRODUCTS IN A DIET OF OBESE MEN WITH CARDIAC DISORDERS AND HYPERCHOLESTEROLEMIA**

A. Ostachowska-Gasior¹, S. Wisniowska-Smialek²

¹Department of Hygiene and Dietetics, Medical College, Jagiellonian University, Krakow, Poland
²Department of Cardiac and Vascular Disorders, John Paul II Hospital, Krakow, Poland

Background and objectives: Calcium, in particular calcium from dairy products, is considered as a factor inhibiting lipogenesis and stimulating lipolysis. The aim of this study was to examine the impact of calcium from food on anthropometric and biochemical markers of nutritional status. 42 hospitalized and obese men (39-65 years old) with cardiac and vascular disorders were qualified to dietary intervention focused on diet rich in calcium from dairy products. By January 2013 six month lasting dietary intervention was completed for 12 of them.

Methods: The full examination included 5 sessions with dietitian (in every 6th week) and three laboratory examination of physiological fluids: blood cholesterol, thyroid-stimulating hormone (TSH), parathormone (PTH), calcium in the urine. Body composition and body mass were being monitored. Bioimpedance method was used for monitoring changes in fat mass, fat free mass, body water. Individual dietary recommendations focused on low-fat dairy products (3-4 servings/day) and 500 kcal energy deficit were prepared for the participants. To control the way of nutrition 24-hour dietary recall and Food Frequency Questionnaire (FFQ) were applied.

Results: Anthropometric parameters before and after dietary intervention: BMI (39.7±4.66; 31.9±2.32), %Fat Mass (44.7±3.5; 29.9±4.6), %Fat Free Mass (53.3±4.4; 70.1.9±2.5), % of body water (43.9±1.5; 49.2±1.9). Before dietary intervention total cholesterol, LDL, HDL, TG exceeded norms and after 6 month cholesterol was in normal range: 4.56±0.7mmol/L total cholesterol, 2.53mmol/L LDL, 1.11±0.5 HDL, 1.7±0.16 TG. Average PTH, TSH in blood and calcium in the urine were within the range before and after dietary intervention. Daily average calcium intake from food of all was 423±96mg/day.

Conclusions: Calcium from dairy products affects weight loss that is especially important for people with hypercholesterolemia. All patients should be encouraged to consume 3 to 4 servings of low-fat dairy products every day.

Key words: hypercholesterolemia, dairy products, dietary intervention, obesity

PO2236**EVOLUTION OF LYMPHOCYTE SUBSETS IN FIRST-EPIISODE ANOREXIA NERVOSA PATIENTS DURING THE FIRST YEAR OF TREATMENT**

A. Gheorghie^{1,2}, A. Elegido¹, S. Gómez-Martinez¹, P. Andrés², M. Graell², A. Marcos¹, E. Nova¹

¹Department of Metabolism and Nutrition, Institute of Food Science and Technology and Nutrition (ICTAN)-CSIC, Madrid, Spain

²Psychiatry and Psychology Unit, Children University Hospital Niño Jesus, Spain

Background and objectives: The undernourished state of Anorexia nervosa patients (AN) is associated with relative lymphocytosis and decreased numbers of T lymphocytes. However, little is known about its reversibility with treatment. The aim of this study was to evaluate lymphocyte subsets' changes in AN patients during the first year of multidisciplinary treatment.

Methods: Sixty-six adolescents diagnosed with AN or an Eating Disorder Not Otherwise Specified (EDNOS) were recruited at an Eating Disorders Unit on their first episode (40 AN-restricting type, 9 AN-binge/purging type, 17 EDNOS. Age: 12-17 y). All patients received multidisciplinary treatment including nutritional rehabilitation and psychotherapy. The lymphocyte subset profile was studied upon admission (T0) and after one month (T1), six months (T6) and one year of treatment (T12). The following lymphocyte subsets were assessed by flow cytometry: CD3+ (T cells), CD4+ (helper T cells), CD8+ (cytotoxic T cells), naive [CD45Ra+] and memory [CD45RO+] T cells, CD3-CD16+CD56+ (NK) and CD19+ (B lymphocytes). Differences between time points were assessed through paired T tests.

Results: BMI increased significantly from 16.0±1.8 in T0 to 19.2±2.2 in T12. T and B cells (cel/μL) showed a significant decrease in T1, T6 and T12 compared to T0. B cell percentage showed significantly lower values in T1, T6 and T12 compared to T0 (p < 0.01), and %CD4+ significantly higher values. Memory T cells decreased with nutritional recovery (T1, T6 and T12 compared to T0, p < 0.001 all) to a higher extent than naive T cells (T1, T6 and T12 compared to T0, p < 0.05 all). The percentage of CD4+CD45Ra+ did not change during weight recovery while the percentage of CD3+CD4+CD45RO+ decreased. The CD4+/CD8+ ratio did not change.

Conclusions: Nutritional recovery is associated with a decrease in T and B lymphocyte numbers; however, adaptation mechanisms are probably triggered in order to increase T lymphocyte production.

Key words: anorexia nervosa, lymphocyte subsets, follow-up.

PO2237**EFFECT OF WHOLE GRAIN WHEAT VERSUS REFINED WHEAT DIET ON METABOLIC HEALTH IN ZUCKER FA/FA RATS**

J P. Godin^{1,2}, A. Ross^{1,2}, M. Scherer¹, B. Berger¹, S. Kochhar¹

¹Nestlé Research Center, Lausanne, Switzerland

²Chalmers University of Technology, Gothenburg, Sweden

Background and objectives: Greater intake of whole grain (WG) cereals has been consistently associated with a lower risk of many diet related diseases. However, results from in vivo studies on metabolic health are mixed. The objective of the work was to compare the effect of a whole grain wheat versus refined wheat diet in a model mimicking the development of obesity by overeating.

Methods: Male Zucker (fa/fa) rats (n = 11/group) were fed diets based on AIN-93G, with part of the carbohydrate component based on either WG or refined flour wheat (RF), for 8 weeks. A control group of normal weight Zucker (fa/-) rats were fed RF diet. Classical clinical chemistry parameters, lipid levels from 18 lipid classes in plasma and liver samples and caecal microbiota concentrations were analyzed.

Results:WG wheat significantly decreased glycated hemoglobin, and altered the metabolism of several lipid classes in both plasma and liver (ceramides, sphingomyelins and phosphatidylcholines). Rats fed WG diet had concentrations of these lipids closer to that of the lean control group than the Zucker (fa/fa) littermates fed on RF. WG wheat also increased populations of bifidobacteria and lactobacilli compared to the RF fed rats.

Conclusions:The WG diet led to some changes in metabolism and gut microbiota in Zucker fa/fa) rats, including hitherto unobserved changes to hepatic lipid metabolism, suggesting new avenues for research into how whole grains may impact on health.

Key words: Whole grain, Zucker fa/fa, lipidomics, microbiota.

PO2238**DAILY INCLUSION OF ALMONDS (1.5 OUNCES) IN A CHOLESTEROL-LOWERING DIET MAINTAINS HDL-CHOLESTEROL AND HDL SUBCLASSES IN MILDLY HYPERCHOLESTEROLEMIC ADULTS**

C.E. Berryman^{1,2}, S.G. West², P.L. Bordi^{3,4}, J.A. Fleming¹, P.M. Kris-Etherton¹

¹Department of Nutritional Sciences, The Pennsylvania State University, University Park, Pennsylvania, United States

²Department of Biobehavioral Health, The Pennsylvania State University, University Park, Pennsylvania, United States

³Department of Hospitality Management, The Pennsylvania State University, University Park, Pennsylvania, United States

⁴Center for Food Innovation, The Pennsylvania State University, University Park, Pennsylvania, United States

Background and objectives: Reducing dietary saturated fat and cholesterol is recommended to decrease total and LDL-cholesterol levels; however, this strategy also decreases HDL-cholesterol (HDL-C). Almonds previously have been shown to improve HDL-C in hypercholesterolemic individuals. Therefore, we hypothesized that incorporating almonds into a cholesterol-lowering diet would maintain HDL-C and HDL subclasses in mildly hypercholesterolemic adults.

Methods: A randomized, 2-period (6 wk/period), crossover, controlled-feeding study was designed to examine the effects of 1.5 oz. almonds vs an isocaloric muffin substitution on cardiovascular disease risk factors. Differences in nutrient profiles of the control (CON: 59% CHO, 15% PRO, 26% FAT, no almonds/d) and almond (ALD: 51% CHO, 16% PRO, 33% FAT, 1.5 oz. of almonds/d) diets were due to nutrients inherent to each snack and did not differ in saturated fat or cholesterol. Participants were healthy adults (n = 53) with elevated LDL-cholesterol (148.0±2.6 mg/dl) and normal HDL-C (54.4±2.1 mg/dl).

Results: HDL-C and α -1 HDL decreased on both diets vs. baseline (ALD: -3.7±0.8 and -1.6±0.7, CON: -5.6±0.8 and -4.2±0.7 mg/dl, respectively; P < 0.02); however, ALD maintained HDL-C and α -1 HDL compared to CON (P < 0.01). CON decreased α -2 HDL vs. baseline (-2.6±0.8 mg/dl; P < 0.01). The diets had different effects on α -3 HDL (ALD: -0.9±0.5 vs. CON: 0.2±0.5 mg/dl; P = 0.05). Both diets decreased α -4 HDL vs. baseline (ALD: -1.0±0.3 and CON: -1.2±0.4 mg/dl; P < 0.01). CON decreased the α -1: pre α -1 HDL ratio vs. baseline (-0.5±0.2; P = 0.01) and ALD (-0.4±0.2; P = 0.04).

Conclusions: Almonds (1.5 oz./d) have beneficial effects on HDL-C and HDL subclasses, thus demonstrating an approach to maintain HDL-C in a cholesterol-lowering diet.

Key words: HDL-cholesterol, HDL subclasses, cardiovascular disease, almonds.

PO2239**DIETARY PATTERNS AND NUTRITIONAL STATUS IN METABOLIC SYNDROME PATIENTS**

J. Mulero¹, J. Bernabé¹, P. Zafrilla¹, M.D. Barnuevo¹, J.A. Abellán¹

¹Universidad Católica San Antonio, Guadalupe, Murcia, Spain

Background and objectives: The aim of this study was to assess the differences in the nutritional status of patients with Metabolic Syndrome (MetS) and a group of healthy volunteers.

Methods: A cross-sectional comparative study was carried out, with a representative sample of population with and without MetS. The study included 74 subjects (34 men and 40 women) 32 healthy subjects and 42 patients who fulfilled the Adult Treatment Panel III criteria for the MetS Dietary data, anthropometric measurements and Biochemical parameters were determined in both groups.

Results: Mean of weight, waist circumference and Body Mass Index, were higher in MetS patients than in Control Group (CG). No significant differences were observed in protein intake between the two study groups, although the average of protein intake in the MetS group was higher (1.3 g/kg/day) than in CG (1 g/kg/day). The lipid profile of fat intake in the CG was slightly better than the MetS group. The CG covers the recommendations on the consumption of monounsaturated fatty acids, saturated fat intake was at the limit of recommendations (< 10%) and polyunsaturated fatty acid intake was low, although satisfying the recommendations of < 10%. Although we found no significant differences in the nutrient intake between the two groups of study, the lipid profile of the diet and fiber was poor in MetS patients if compared to the control group. Respect biochemical parameters we founded significant differences between the CG and patients with MetS in glucose levels and TG values (p < 0.05).

Conclusions: In summary, dietary intake in MetS patients was inadequate and of less nutritive quality than in the control group

Key words: Metabolic syndrome, diet, nutrient intake, macronutrient, lipidic profile.

PO2240**FLAXSEED LIGNAN METABOLITES ELICIT ANTI-HYPERTENSIVE EFFECTS IN PAD PATIENTS IN THE FLAX-PAD TRIAL**

A. Edel^{1,2}, D. Rodriguez-Leyva², W. Weighell³, R. La Vallee¹, M. Aliani⁴, R. Guzman³, G. Pierce¹

¹Department of Physiology, Institute of Cardiovascular Sciences, University of Manitoba and St. Boniface Research Centre, Winnipeg, Manitoba, Canada

²Cardiovascular Research Division, VI Lenin University Hospital, Holguin, Cuba

³Department of Surgery, Asper Clinical Research Institute, University of Manitoba, St. Boniface Hospital, Manitoba, Canada

⁴Department of Human Nutritional Sciences, Faculty of Human Ecology, University of Manitoba and Canadian Centre for Agri-food Research in Health and Medicine, Winnipeg, Manitoba, Canada

Background and objectives: Flaxseed is highly prevalent in cardioprotective lignans, alpha-linolenic acid (ALA) and fiber. Secoisolariciresinol diglucoside is the major lignan found in flaxseed whose metabolites demonstrate antioxidant action. Peripheral arterial disease (PAD) is highly associated with hypertension. The aim of this study was two-fold: (i) to determine the effects of milled flaxseed on plasma bioavailability of enterolignans (enterodiol and enterolactone) and ALA and (ii) to examine their correlation with systolic (SBP) and diastolic (DBP) blood pressure. It was hypothesized that PAD patients would exhibit elevated plasma enterolignan and ALA concentrations upon consuming flaxseed with an associated attenuation of blood pressure.

Methods: A clinical population with PAD consumed food varieties containing either 30 g of ground flaxseed or 30 g of whole wheat placebo daily for one-year. This study, known as the Flax-PAD Trial, was a single center, prospective, double-blinded, randomized controlled clinical trial (NCT00781950 at clinicaltrials.gov) involving 110 patients > 40 years of age with PAD [ankle-brachial index (ABI)<0.9]. Plasma enterolignans and fatty acids were measured at baseline, 1-, 6- and 12-months using gas chromatographic techniques. BP was measured using a sphygmomanometer.

Results: Within the flaxseed group, plasma enterolignan and ALA levels increased significantly compared to baseline and placebo ($p < 0.003$). SBP was reduced by ~10 mmHg ($p < 0.04$) and DBP by ~7 mmHg ($p < 0.004$) in the flaxseed group relative to control following 6 months of intervention. Inverse correlations with DBP were observed with both plasma enterolactone ($r = -0.35$; $p = 0.02$) and total enterolignans ($r = -0.4$; $p = 0.01$). ALA levels did not correlate with changes in BP.

Conclusions: Consuming milled flaxseed offers potential advantages in lowering BP levels in hypertensive populations

where drug interventions may not be possible or more naturopathic routes are desired. Plasma enterolactone derived from dietary lignans found in flaxseed can decrease DBP selectively.

Key words: Flaxseed, lignans, hypertension. Supported by CIHR, Flax2015, St. Boniface Hospital Foundation, MMSF and ARDI.

PO2241**NUTRITIONAL MANAGEMENT OF BLOOD GLUCOSE LEVELS**

W. Russell^{1,2}, A. Baka², I. Björck³, N. Delzenne⁴, D. Gao⁵, H. Griffiths⁶, E. Hadjilucas⁷, K. Juvonen⁸, S. Lahtinen⁹, M. Lansink¹⁰, L. van Loon¹¹, H. Mykkänen⁸, E. Östman³, G. Riccardi¹², S. Vinoy¹³, M. Weickert¹⁴

⁹Danisco A/S Health and Nutrition, Kantvik, Finland

¹⁰Danone Research, Centre for Specialised Nutrition, Wageningen, The Netherlands

Background and Objectives: Nutritional management of blood glucose levels is a strategic target in the prevention and management of type 2 diabetes mellitus (T2DM), applicable across the population. To implement a successful strategy it is essential to understand the impact of dietary modulation on the postprandial rise in blood glucose concentrations.

Methods: Using the highest quality data, a systematic and comprehensive literature review was undertaken. Included in this review were the major macronutrients (carbohydrate, protein, fat), micronutrient vitamins and minerals, non-nutrient phytochemicals and additional foods such as low-calorie sweeteners, vinegar and alcohol.

Results: The strongest corroboration of efficacy for improving glucose homeostasis was for insoluble and moderately fermentable cereal-based fiber and mono-unsaturated fatty acids as replacement of saturated fat. Postprandial glycaemia was decreased by intake of viscous soluble fiber and the predo-

minant mechanism of action was considered to be by delaying absorption of co-ingested carbohydrates. There was weaker but substantial evidence that certain phytochemical-rich foods were likely to be effective. This may be associated with the suggestion that the gut microbiota plays an important role in metabolic regulation, which includes provision of phytochemical and other metabolites.

Conclusions: Based on the evidence, it is clear that dietary components have significant and clinically relevant effects on blood glucose modulation. This suggests that employing a dietary regimen to attenuate the postprandial rise in blood glucose levels along with previously identified targets (reducing excess body weight and an increase in physical activity) will benefit the health of the population and limit the increasing worldwide incidence of T2DM.

Key words: diabetes, postprandial glycaemia, blood glucose.

PO2242

DIETARY AND URINARY PHYTOESTROGENS AND PLASMA LIPIDS IN MEXICAN WOMEN

G. Caire-Juvera^{1,2}, M. Orduño-Flores¹, M. Chávez-Suárez¹, M. Campa-Siqueiros¹, S. Saucedo-Tamayo¹, L. Luna-Parra¹, N. Ballesteros-Vásquez¹, E. Artalejo-Ochoa¹, A I. Valenzuela-Quintanar², M I. Ortega-Vélez¹, S A. Palma-Durán², M R. Robles-Burgueño², P. Grajeda-Cota², L. Gutiérrez-Coronado²

¹Direction of Nutrition, Centro de Investigación en Alimentación y Desarrollo, Hermosillo, Mexico

²Food Sciences Department, Centro de Investigación en Alimentación y Desarrollo, Hermosillo, Mexico

Background and objectives: Phytoestrogens are plant-derived phenolic compounds, structurally and functionally similar to 17 β -estradiol; they also have weak estrogenic and antiestrogenic effects. Phytoestrogens may prevent some chronic diseases, such as cardiovascular disease, by improving the levels of triglycerides, total cholesterol, HDL and LDL in humans. The objective of this cross-sectional study was to evaluate the association of dietary and urinary phytoestrogens with the lipid profile of 135 healthy women older than 25 years, from Northwest México.

Methods: A sociodemographic and health questionnaire was administered to the participants, and anthropometric measures were taken. A 24-h Recall (24-H R) and a Food Frequency Questionnaire (FFQ) were applied to evaluate the phytoestrogen consumption. The lipid profile was analyzed by enzymatic methods using commercial kits. Urinary phytoestrogens were analyzed using HPLC-MS in a subsample of 84 women.

Results: The mean age of the participants was 44.6 years and 65% of them were of low socioeconomic level. According to BMI, 85% of women were classified as overweight (40.3%) or obese (44.7%). By using the FFQ, naringenin (flavonoid) was associated to total cholesterol (R=-24.1, p = 0.00) and LDL (R=-19.4, p = 0.00). Associations were found between lariciresinol and LDL cholesterol (R=-20.8, p = 0.00), glicitein and VLDL cholesterol (R=-9.9, p = 0.00), and glicitein and triglycerides (R=-49.9, p = 0.00) when the 24-H R was used. Coumestans (found in beans, a highly consumed food in Northwest México), were associated to VLDL cholesterol (R=-9.3, p = 0.02) and triglycerides (R=-46.6, p = 0.02). Urinary lignans were associated to VLDL cholesterol (R=-8.7, p = 0.04) and triglycerides (R=-43.5, p = 0.04), while resveratrol was related to total (R=-24.5, p = 0.01) and LDL cholesterol (R=-17.3, p = 0.04).

Conclusions: A high intake of total phytoestrogens as well as dietary coumestrol, naringenin and lignans, may contribute to the prevention of a high risk lipid profile in women from Northwest México.

Key words: phytoestrogens, plasma lipids, diet, associations.

PO2243

ANTHROPOMETRIC INDICATORS IN A REPRESENTATIVE SAMPLE OF SPANISH ADULTS: DIFFERENCES BY HYDRATION STATUS

L. Gonzalez-Rodriguez¹, M. Mascaraque¹, C. Peñas¹, E. Aguilar¹, R. Ortega-Anta¹

¹Department of Nutrition, Faculty of Pharmacy, Complutense University of Madrid, Madrid, Spain

Background and objectives: Studies suggest that energy expenditure, energy, macronutrient and food intakes may be conditioned by hydration status, so it would be expected that also might influence the anthropometric parameters. The aim of the study was to analyze several anthropometric indicators according to the hydration status in a representative sample of Spanish adults.

Methods: A representative sample of 418 individuals of 18-60 years (196 men and 222 women) was studied. Weight, height, waist (WC) and hip circumferences (HC) were measured, and Body mass index (BMI), waist-to-height ratio (WHtR) and waist-to-hip ratio (WHR) were calculated. Urine specific gravity (USG) was used as indicator of hydration status, considering as hydrated subjects (USG <1.020) and subjects in risk of dehydration (USG >1.020). All calculations were made using SPSS (v19.0). Statistical significance was set at p < 0.05.

Results: 45.5% of the participants were in risk of dehydration (54.6% men and 37.4% women, p = 0.04). After adjusting for age, it was observed a positive and significant association between the USG and weight (r=0.135, p = 0.040), WC

($r=0.184$, $p = 0.002$), HC ($r=0.158$, $p = 0.015$), BMI ($r=0.172$, $p = 0.006$) and WHtR ($r=0.195$, $p < 0.001$) in women, while in men with WC ($r=0.129$, $p = 0.046$) and WHR ($r=0.141$, $p = 0.022$). In addition, after adjusting for age, it was observed that women with risk of dehydration had a higher risk of having values of WC \geq P50 (78 cm) (OR=2.275 (1.243-4.164, $p = 0.008$), in comparison with the hydrated women.

Conclusions: The results of the study highlight the existence of differences in the anthropometric parameters according the hydration status. This might suggest that an adequate intake of water or high water content foods may help control body weight.

Key words: hydration status, anthropometric indicators, Spanish adults
Acknowledgements: The study was supported by the AESAN (Spanish Agency for Food and Nutritional Safety, Spanish Ministry of Health and Consumer Affairs, Spain) (Project:337/2008).

PO2244

ASSOCIATION OF SUBCLINICAL ATHEROSCLEROSIS WITH DIFFERENT STANDARDS OF THE METABOLIC SYNDROME AND INSULIN RESISTANCE

P. Arnai¹, A. Dominguez¹, S. Barja¹, I. Godoy¹, L. Villarroel¹, O. Castillo¹, M. Farias¹, F. Mardones¹

¹Pontificia Universidad Catolica de Chile, Santiago de Chile, Chile

Background and objectives: we have previously selected two metabolic syndrome (MS) components blood pressure (BP) and high density lipoprotein cholesterol (HDL) as associated with carotid intima media thickness (CIMT) a surrogate marker of subclinical atherosclerosis in children (Rev Med Chile 2012; 140: 1268-75). We aimed to ascertain with a higher sample size the influence of the above mentioned variables and three standards defining the MS plus three standards defining insulin resistance (IR).

Methods: A cross-sectional study of 447 children 10-14 years old of low socio-economic strata from an urban area of Chile was performed during years 2009-2011. This sample was selected considering the presence of one or more MS component and IR. Anthropometry and BP were assessed. A blood sample for determination of glycaemia, insulinemia (quimioluminescence) and blood lipids were taken; HOMA was calculated and three standards were applied to select HOMA-IR cases. Three standards to define MS were also used. Medium CIMT was assessed using ultrasonography with automated software. Chi-squared test and stepwise regression were used.

Results: Mean age was 11.5 \pm 1.0 years old; 59% girls; 92.6% pubertal; 72% excess weight. Three standards for MS had prevalence of 24.4% (Cook, 2004), 14.1% (IDF, 2007), 42.9% (De Ferranti, 2004). Three standards for HOMA-IR had the following

prevalence: 15.2% (Barja, 2011), 37.4% (Burrows, 2006), 23.0% (De Onis, 2012). Elevated blood pressure and reduced CHDL had significant associations with CIMT \geq percentile 75. The logistic regression for CIMT \geq percentile 75 only selected BP \geq percentile 90 (OR = 2.963) and CHDL < 40 mg/dL (OR = 1.789)

Conclusions: None of the various classifications for the MS and the HOMA-IR were selected in the multivariate analysis confirming the previously found influence of increased BP and reduced CHDL on medium CIMT.

Key words: metabolic syndrome, insulin resistance, carotid intima-media thickness, child.

PO2245

EFFECT OF HASS AVOCADO INTAKE ON POST-INGESTIVE SATIETY AND SUBSEQUENT ENERGY INTAKE IN HEALTHY OVERWEIGHT ADULTS

M. Wien¹, E. Haddad¹, J. Sabate¹

¹Department of Nutrition, Loma Linda University, Loma Linda, California, USA

Background and Objectives: Avocados are nutrient dense whole foods with properties that have the potential to favorably impact energy balance. Since 72% of their weight is water, they increase the volume when added to a meal, which may enhance satiety. Further, avocados are also a source of fiber, which is an additional factor linked to enhanced satiety. This study sought to evaluate if incorporating \sim 1/2 of a fresh Hass avocado by inclusion or addition into a meal will influence post-ingestive satiety and subsequent energy intake in overweight adults.

Methods: We performed a randomized 3x3 single blind cross-over study (three 1-day study periods scheduled 1 week apart) in 26 healthy overweight adults (16 women, 10 men; mean \pm SD age 40.8 \pm 11.0 years; BMI 28.1 \pm 2.4 kg/m²). Subjects consumed a standardized breakfast meal on each of the 3 days, followed by 1 of 3 lunch test meals [Control (C), avocado-free; Avocado Inclusive (AI); and, Avocado Added (AA)]. Visual analog scales (VAS) were administered prior to the lunch meal and at specific intervals over 5 hours following the start of the test meal to assess 5 measures of appetite sensation. Mixed model analysis was used to compare differences among the 3 lunch test meals. The area under the curve (AUC_{0-xh}) was computed for the VAS using the linear trapezoidal rule.

Results: The AA meal increased satisfaction ($p = 0.02$) and decreased the desire to eat ($p = 0.01$) as compared to the C meal for the AUC (0-3h). Energy intake at the subsequent ad libitum dinner meal and evening snack and dietary compensation did not differ between the 3 lunch test meals.

Conclusions: The inclusion or addition of avocado to a meal is an effective approach to reduce hunger and the desire to eat in overweight adults.

Key words: avocado; satiety; VAS; overweight adults.

PO2246**EFFECT OF HASS AVOCADO INTAKE ON POST-INGESTIVE GLUCOSE AND INSULIN LEVELS IN HEALTHY OVERWEIGHT ADULTS***E. Haddad¹, M. Wien¹, J. Sabate¹*¹Department of Nutrition, Loma Linda University, Loma Linda, California, USA

Background and Objectives: Avocados are rich in antioxidants (e.g. polyphenolic compounds) which may be effective in improving insulin sensitivity in an overweight cohort. This study sought to evaluate if incorporating ~½ of a fresh Hass avocado by inclusion or addition into a meal will influence measures of post-ingestive glucose homeostasis in overweight individuals.

Methods: A randomized 3 x 3 single blind cross-over study (three 1-day study periods scheduled 1 week apart) was performed in a controlled setting in 26 healthy overweight adults (16 women, 10 men; mean±SD age 40.8±11.0 years; BMI 28.1±2.4 kg/m²). Subjects consumed a standardized breakfast meal on each of the 3 days, followed by 1 of 3 lunch test meals [Control (C), avocado-free; Avocado Inclusive (AI); and, Avocado Added (AA)]. Blood glucose and insulin levels were measured before lunch and at specific intervals over 3 hours following the start of the test meal. Mixed model analysis was used to compare differences among the 3 lunch test meals adjusting for study periods as fixed effects and treating subjects as random effects. The area under the curve (AUC_{0-xh}) was computed for glucose and insulin using the linear trapezoidal rule.

Results: Compared to the AI meal, the AUC (0-3h) for blood insulin was higher in the C and AA meals ($p = 0.04$ and $p = 0.05$, respectively). Both the AI and AA meals attenuated the rise in postprandial blood insulin levels 30 minutes after the start of the lunch meal as compared to the C meal.

Conclusions: The inclusion or addition of avocado to a meal is an effective approach to favorably influence measures of glucose homeostasis in overweight adults. The attenuation in the rise of insulin in the AI intervention is worthy of future exploration in persons with insulin resistance and type 2 diabetes mellitus.

Key words: avocado; glucose; insulin; overweight adults.

PO2247**METHIONINE ADENOSYLTRANSFERASE EXPRESSION DEPENDS ON METHIONINE CONCENTRATIONS IN THE CULTURE MEDIA***M.P. González¹, G. Varela-Moreiras¹, J. Selhub², L. Paul², M.A. Pajares^{3,4}*¹Department of Pharmaceutical and Food Sciences, Universidad CEU San Pablo, Madrid, Spain²Department of Vitamin Metabolism and Aging, Tufts University, Boston (MA), USA³Department of Metabolism and Cell Signalling, Instituto de Investigaciones Biomedicas Alberto Sols (CSIC-UAM), Madrid, Spain⁴Molecular Hepatology Group, IdiPAZ, Madrid, Spain

Background and objectives: Methionine and ATP are joined by methionine adenosyltransferases (MATs) to produce S-adenosylmethionine in the first step of the methionine/homocysteine cycle. MAT1A and MAT2A are the genes encoding mammalian MAT catalytic subunits (á1 and á2, respectively), whereas MAT2B codifies for the regulatory subunit (â). High methionine levels increase the flux through this pathway, leading to enhanced homocysteine levels that may be secreted to the plasma. Such mechanism could contribute to explain the potential atherogenic properties of dietary methionine excess and the epidemiological relationship between elevated homocysteine levels and cardiovascular disease. In order to analyze this possibility, the effect of a range of methionine concentrations was assessed using several cell lines.

Methods: H35 and Cos7 cell lines were grown in DMEM culture medium supplemented with 10% FBS and including 0.01, 0.05, 0.2 (control), 2 or 15 mM methionine for 4 days. Total mRNA was obtained and the expression levels of MAT genes analyzed by real-time RT-PCR (7300 RT PCR System, Applied Biosystems).

Results: Methionine concentrations below control levels induced expression of the three MAT genes in H35 cells, whereas only MAT2A and MAT2B were induced in Cos7 cells. In contrast, methionine concentrations above control levels induced no significant expression changes in Cos-7 cells and only MAT2B was modified in H35 cells. ($p < 0.05$ Unpaired t test).

Conclusions: Our results show that methionine deficient medium affects expression of MAT genes in several cell lines, the specific effect depending on the cell origin. High methionine, however, seems no effect regardless of the concentration.

Key words: Methionine metabolism, methionine adenosyltransferase, homocysteine, cardiovascular disease, cell line.

PO2248**HYPERTENSION AND LIPID TRIAD ARE THE MOST IMPORTANT ATTRIBUTABLE RISKS FOR MYOCARDIAL INFARCTION IN A MIDDLE CLASS URBAN MEXICAN POPULATION**

T. Estrada-García¹, A. Meaney^{1,2}, D. López-Hernández¹, E. Meaney², O. Sánchez-Hernández¹, E. Rodríguez-Arellano¹, G. Solache-Ortiz²

¹Cinvestav-IPN, Mexico

²Hospital Regional 1º de Octubre del ISSSTE, Mexico

Background and objectives: Although myocardial infarction (MI) is the main cause of death in Latin-America there are few studies describing the populations prevalence of classic cardiovascular risk factors (CCVRF) in this region. Determination of potential modifiable risk factors is necessary to focus prevention strategies. The study objectives were to establish both the distribution of CCVRF and the population attributable risk (PAR %) for MI in a middle class urban Mexican population.

Methods: A case-control observational study was conducted, 11 CCVRF were examined among 210 patients, with a first acute non-fatal MI, and 607 matched controls from a middle class urban population (MCUP). Continue variables were analyzed by Mann-Whitney U and Student t tests, Odds Ratios (OR) were established by logistic regression and PAR % for MI were calculated.

Results: Eight of the 11 CCVRF analyzed were significantly different ($P < 0.05$) between MI patients and controls. By logistic regression analysis hypertension (OR 3.0 95% CI 1.7-5.3, OR 5.5 95% CI 3.5-8.8) hypertriglyceridemia (OR 2.3 95% CI 1.2-4.5, OR 3.5 95% CI 2.3-5.5) and lipid triad (OR 2.2 95% CI 1.1-4.3, OR 3.2 95% CI 2.0-5.1) were a risk for MI in both female and male groups respectively, in the latter group hypoalphalipoproteinemia (OR 2.8 95% CI 1.4-5.6), hypercholesterolemia low density lipoprotein (OR 2.0 95% CI 1.1-3.9) and atherogenic index (OR 2.5 95% CI 1.6-3.8) were also a risk for MI. The main PAR % for both genders (female, male) were hypertension (51, 45), lipid triad (36, 40) and atherogenic index (37, 28), respectively and also for the male group hypertriglyceridemia (41) and smoking (26). CCVRF prevalence and PAR% were higher among men than women in this population.

Conclusions: Strategies as healthy diet, exercising and quitting smoking will prevent MI in this MCUP.

Key words: myocardial infarction, population attributable risk.

PO2249**INSULIN RESISTANCE AND METABOLIC SYNDROME ASSOCIATED TO BANKING EMPLOYEES IN SOUTHEASTERN BRAZIL.**

L. Salaroli¹, E. Zandonade², M. Molina³, N. Bissoli⁴

¹Physiological Sciences, Postgraduate Program, Federal University of Espírito Santo, Vitoria, Brazil

²Public Health, Postgraduate Program; Federal University of Espírito Santo, Vitoria, Brazil

³Public Health, Postgraduate Program, Federal University of Espírito Santo, Vitoria, Brazil

⁴Physiological Sciences, Postgraduate Program, Federal University of Espírito Santo, Vitoria, Brazil

Background and objectives: Metabolic syndrome (MS) has been the subject of growing concern worldwide, since it is related to increased risk of cardiovascular disease. Insulin resistance (IR) seems to be the link between alterations present in the SM, which may be linked to increase the visceral fat deposition. Thus, we evaluated determine the prevalence of IR, MS and associated factors among banking workers in southeastern Brazil.

Methods: Out of 501 males and females banking employees, 20 years old were evaluated by cross-sectional study including demographic, biochemical, anthropometric and hemodynamic. The SM was determinate by NCEP and IDF. The IR was determined by HOMA-IR, with the cut off > 2.71 .

Results: 86 (17.2% 95% CI 13.8 to 20.6) and 113 (22.6% 95% CI 18.8 to 26.3) of banking employees with MS according to the NCEP and IDF, respectively and 52 (10.4%) workers with RI. The likelihood of developing the syndrome is greater in individuals with high level of education (OR 2.16 (95% CI 1,11-6-13) and among those with overweight and obesity, the possibility of having MS is 12, 6 (95% CI 4.80 to 33.26, $P = 0.000$) and 43.6 (95% CI 16.05 to 118.88, $P = 0.000$) times over, respectively, compared with normal weight. Persons who are overweight are at risk of 4.97 (95% CI 1.31 to 18.83) times more likely to have elevated HOMA, and among those who are obese, the risk rises to 17.87 (95% CI 4 0.36 to 73, 21).

Conclusions: High number of employees that have similar characteristics to a large portion of the working population, which despite high education have MS and IR, and the consequent risk of developing cardiovascular disease.

Key words: Insulin resistance, metabolic syndrome, banking employees, obesity.

PO2250**ASSOCIATION OF AREA, INCOME, OCCUPATION AND EDUCATION LEVELS WITH OBESITY IN JILIN PROVINCE IN CHINA**

Q. Wei¹, J. Sun¹, Y.L. Liu¹, X.X. Liu¹, X.D. Shi², J.Q. Niu³

¹Department of Cardiology, The First Hospital of Jilin University, Changchun, Jilin Province, China

²Department of Rheumatism, The First Hospital of Jilin University, Changchun, Jilin Province, China

³Department of Hepatology, The First Hospital of Jilin University, Changchun, Jilin Province, China

Background and objectives: Nowadays the economy has been obviously improved in both rural area and urban area in China. To explore the association to obesity is necessary among area, monthly income occupation type and education level in Jilin province.

Methods: A cross-sectional study (n = 7556) has been conducted in Jilin Province of China. Each participant underwent a standard questionnaire and physical examinations. The associations of demographic and clinical factors with body mass index (BMI) were tested using binary logistic regression.

Results: The prevalence of obesity is 16.2% and 11.2%, respectively, among general population in city area and rural (p < 0.001). High monthly income, high education level and brain work had a high prevalence compared to low monthly income, low education level and physical work, respectively (p < 0.001). Binary logistic analysis shows that, gender (male vs. female) and education levels (low level vs. high level) is positive with obesity, and the Odd Ratio (OR) of male is 1.181 (p = 0.018), the OR of low education level is 1.215 (p = 0.033). However, rural area (OR: 0.718, p < 0.001), adolescent (OR: 0.556, p < 0.001) and low monthly income (OR: 0.588, p < 0.001) is negative with obesity, no related with type of occupations.

Conclusions: Occupations were not associated with obesity in this survey. The prevalence of obesity in urban is higher than rural area. The association between areas and obesity may be explained by gender, monthly income, education levels and areas, but no occupations.

Key words: Obesity, Prevalence, areas, monthly income.

PO2251**INFLUENCE OF BODY COMPOSITION IN BONE MASS**

P. Freitas¹, E. Yokoo¹, L. Canto¹, V. Wahrlich², M.L. Rosa¹

¹Institute of Community Health of Fluminense Federal University, Niterói, Rio de Janeiro, Brazil

²Nutrition Faculty, Fluminense Federal University, Niterói, Rio de Janeiro, Brazil

Background and objectives: Body composition has proved related to bone through mechanisms such as mechanical overload, osteogenesis and increased interaction of body weight. But the studies are controversial on which component has the most influence on bone mineral content.

Objective: To evaluate the influence of body composition on bone mineral content in adults.

Design: Cross-sectional study with 630 adults of both sexes over 45 years, 392 women and 238 men that attended at the Family Doctor Program in the metropolitan area of Rio de Janeiro, Brazil. The total bone mineral content (BMC), lean mass (LMA) and fat mass (FMA) were measured by dual energy x-ray absorptiometry (DEXA). The Body Mass Index (BMI) was calculated using the formula: weight/height².

Results: The Pearson correlation showed that the BMC was significantly associated with LMA, FMA and BMI (p < 0.000, p < 0.015, p < 0.000, respectively) in both genders analyzed together. However, the association was much greater with the LMA (r = 0.793) than with FMA (r = 0.119). When analyzed separately, for men and women, all body components were positively correlated (statistically significant, p < 0.000), being the largest association with LMA.

Conclusions: The results showed that BMI, LMA and FMA are positively associated with BMC and suggest that the body lean mass component rather than fat mass is more beneficial to bone mass in the population.

Key words: body composition, bone mass, BMI.

PO2252**NUTRITIONAL CARE OF A HEMODIALYTIC PATIENT WITH LIVER CIRRHOSIS: A CASE REPORT**

M.L. Lu¹, H.M.L. Chin²

¹Department of Dietetics & Nutrition, Taipei City Hospital Zhongxiao Branch, Taipei, Taiwan

²Department of Dietetics & Nutrition, Taipei City Hospital, Taipei, Taiwan

Background and objectives: Sepsis is a common clinical syndrome with high mortality rates. Acute lung injury is the

most frequent complication of sepsis. Previous study reported that $\gamma\delta$ T cells play a major role in linking innate and adaptive immune systems and are instrumental in reducing lung damage associated with inflammation. Glutamine (GLN) has been considered as an essential amino acid during catabolic conditions due to its immunomodulating properties. This study investigated the effects of GLN administration on regulating lung $\gamma\delta$ T cells in polymicrobial sepsis.

Methods: Mice were randomly assigned to normal group (NC), septic saline group (SS), and septic GLN group (SG). All mice were fed with chow diet. Sepsis was induced by cecal ligation and puncture (CLP). The SS and SG groups were respectively injected with saline and 0.75 g GLN/kg body weight once via tail vein 1 h after CLP. Mice were sacrificed 6, 12, and 24 h after CLP. Their lungs were collected for further analysis.

Results: Compared to normal mice, sepsis resulted in higher lung $\gamma\delta$ T cell and neutrophil percentages and higher cytokine expressed by $\gamma\delta$ T cells. The SG group had higher lung $\gamma\delta$ T cell percentage and lower neutrophil numbers. Apoptotic rates of lung $\gamma\delta$ T cells were lower, whereas neutrophils were higher than those of the SS group. Moreover, interleukin (IL)-17A, interferon- γ , and IL-10 expressed by $\gamma\delta$ T cells, and CXCR2 expressed by neutrophils decreased in the SG group. Also, GLN reduced IL-17A, IL-1 β , and IL-23 concentrations and myeloperoxidase activity in lung tissues.

Conclusions: Our results suggest that GLN administration after initiation of sepsis affects lung $\gamma\delta$ T cell percentage and cytokine secretion, and prevented apoptosis of $\gamma\delta$ T cells and neutrophil infiltration to the lungs.

Key words: sepsis; acute lung injury; $\gamma\delta$ T cell; glutamine; Interleukin 17

PO2253

THE BRIGHT AND HEALTHY THAI KID PROJECT, A THREE-YEAR STUDY TO COMBAT CHILDHOOD OBESITY

C. Sirikulchayanonta¹, P. Temcharoen¹, S. Tansaku²

¹Department of Nutrition, Faculty of Public Health, Mahidol University, Nakhon Pathom, Thailand

²Department of Health Education and Behavioral Sciences, Faculty of Public Health, Mahidol University, Nakhon Pathom, Thailand

Background and objectives: Obesity has reached epidemic proportions globally, and is a major contributor to the global burden of chronic disease and disability. The project aimed to improve nutrition and activity among primary school children in Bangkok via targeted activities.

Methods: This was a longitudinal study. A preliminary nutritional survey was carried out involving 5,126 children in 4

public schools in Bangkok. Participatory action research involving students, teachers, and parents was conducted. After a 2-day training course, teachers integrated project concepts into their course curriculum. Seminars on weight management were given separately to parents and students. Multimedia materials prepared included a DVD for children (songs, cartoon animation for healthy eating and exercise) and computer assisted instruction for self-learning. The ongoing and post program evaluation at 2 and 3 years of obese and normal groups were carried out.

Results: The prevalence of obesity in boys (25.4%) was about two times higher than in girls (12.2%) and was more prevalent in the 11-12 years group than the 6-10 years group for both sexes. It was reported that high caloric dietary intake significantly decreased for the obese group ($p < 0.001$), aerobic exercise activity increased in both groups ($p < 0.001$), and overall prevalence of obesity declined from 19.3% to 16.8 and 18.0% respectively. The high blood cholesterol reduced from 78% to 34%. Parents provided their children with healthier foods and intake of unhealthy foods significantly decreased ($p < 0.001$). However, fruits and vegetables remained the least desirable foods.

Conclusions: A long-term, participatory effort to promote healthy diets and physical exercise could be effective with primary school students, and public policy for a healthy school lunch and environment with public relations, positive mass media and parental role models can be effective in combating childhood obesity and future cardiovascular diseases.

Key words: childhood obesity, primary school, hypercholesterolemia, Bangkok.

PO2255

DIETARY EGG YOLK PROTEINS SUPPRESS INFLAMMATION OF DEXTRAN SULFATE SODIUM-INDUCED COLITIS IN MICE

S.I. Ishikawa¹, S. Tanaka¹, M. Sasaki¹

¹School of Food, Agricultural and Environmental Sciences, Miyagi University, Miyagi, Japan

Background and objectives: Ulcerative colitis (UC) is a chronic inflammatory disease of the colonic mucosa that can dramatically increase the risk of colon cancers. Dietary egg yolk proteins have been reported to suppress expression of colon tumors and improve experimentally induced constipation in rats. The aim of this study was to determine whether egg yolk proteins alleviate the inflammatory responses of dextran sulfate sodium (DSS)-induced colitis in mice.

Methods: Female C57BL/6J mice were fed a purified AIN-93G diet containing either 20% casein or 20% egg yolk proteins for 14 days. Seven days after starting diets, animals were exposed to 3% DSS in drinking water developed chronic colitis for 7

days, which was evaluated by disease activity index (DAI) and histology. We investigated clinical and biochemical markers at the end of the experimental period. The contents of the cecum were analyzed for the presence of short-chain fatty acids.

Results: Dietary egg yolk proteins significantly attenuated DSS-induced DAI scores and colonic myeloperoxidase activity, which implied that it suppressed weight loss, diarrhea, gross bleeding, and the infiltrations of immune cells. Histological examinations indicated that egg yolk proteins suppressed edema, mucosal damage, and the loss of crypts induced by DSS. Egg yolk proteins diet inhibited the mRNA expressions of inflammatory mediators such as tumor necrosis factor- α , interleukin-6, and inducible nitric oxide synthase in colonic tissues. Furthermore, a significant increase in cecal n-butyrate concentration was observed in the mice that were fed egg yolk proteins.

Conclusions: These results suggest that egg yolk proteins have an anti-inflammatory effect at colorectal sites that is due to the down-regulations of the expressions of inflammatory mediators and the production of n-butyrate in colon. We concluded that egg yolk proteins-enriched diet could be a beneficial functional food on UC.

Key words: egg yolk proteins, ulcerative colitis, anti-inflammation.

Methods: Mice were transplanted with Bcr-Abl-transfected proB lymphocytes (BaF3) cells mimicking leukemia and received either inulin-type fructans (ITF) as prebiotic control or POS in their diet (5%) for 2 weeks.

Results: POS administration increased total bacteria, bifidobacteria, roseburia and bacteroides numbers in the caecal content, in more extent than ITF. DGGE 16S rDNA analysis revealed qualitative changes in bacteroides for the POS group. ITF and POS reduced BaF3 cell infiltration in liver and adipose tissue, respectively. Only ITF lessened the induction of MCP1 (inflammatory marker) in the liver tissue. Interestingly, POS (and to a lesser extent ITF) delayed the fall of the caloric intake (anorexia) linked to cancer progression. In contrast to ITF, POS treatment reduced the loss of fat mass and the induction of atrophy markers in muscle.

Conclusions: Selected prebiotic approaches appear as innovative tools to modulate cancer progression and associated muscle atrophy and fat mass loss. POS derived from beet may constitute a new nutritional strategy to modulate gut microbiota with positive consequences during cachectic episode. This study confirms the importance of research focusing on gut microbes-host interactions for managing systemic and severe diseases, such as cancer.

Key words: cancer, cachexia, pectic oligosaccharides, muscle atrophy, prebiotics.

PO2256

DIETARY PECTIC-OLIGOSACCHARIDES FROM BEET PULP MODULATE THE GUT MICROBIOTA AND CONTROL CANCER ASSOCIATED CACHEXIA IN MICE.

L. B. Bindels^{1,2}, A. M. Neyrinck¹, N. Salazar¹, J. Mahillon², P. D. Cani¹, N. M. Delzenne¹

¹Metabolism and Nutrition Research Group, Louvain Drug Research Institute, Université catholique de Louvain, Brussels, Belgium

²Applied Microbiology, Earth and Life Institute, Université catholique de Louvain, Brussels, Belgium

Background and objectives: The gut microbiota has recently been proposed as a novel component in the regulation of energy homeostasis. Our latest studies suggest that changing gut microbiota can reduce leukemia progression and associated metabolic disorders (cachexia, characterized by a loss of fat mass and muscle atrophy). In this study, we tested the hypothesis that pectic oligosaccharides (POS) prepared from beet pulp are original colonic nutrients able to influence the progression of cancer cachexia.

PO2257

HIGHER DIETARY QUALITY IS ASSOCIATED WITH LOWER RISK FOR TYPE 2 DIABETES IN A MIDDLE-AGED AND OLDER CHINESE POPULATION

X. Ye¹, H. Li¹, L. Sun¹, L. Lu¹, X. Lin¹

¹Institute For Nutritional Sciences, Shanghai Institute For Biological Sciences, Chinese Academy of Sciences, Shanghai, China

Background and objectives: Prevalence of type 2 diabetes (T2DM) increased dramatically in China during the past two decades. Diet plays a key role in the prevention of this disease. However, data about dietary quality and risk for T2DM were scarce in China.

Methods: A population-based study with participants aged 50 to 70 years in 2005 was conducted in local communities from both urban and rural areas in Beijing and Shanghai, China. Dietary intake was assessed with a validated food frequency questionnaire. Dietary quality was measured with Healthy Eating Index score 2005. The follow-up survey was performed in 2011. T2DM was defined as meeting at least one of following criteria: fasting plasma glucose ≥ 7.0 mmol/L, HbA1c $\geq 6.5\%$, or self-reported use of diabetic medications.

Results: A total of 1912 participants without T2DM at baseline were successfully followed after 6 years. Approximately 48.3% met one or more criteria for T2DM during follow-up. Compared with those with lowest quartile of dietary quality score, those with highest quartile had 15% lower risk for T2DM (relative risk: 0.85, 95% confidence interval: 0.74-0.97, P value = 0.016). This association was independent of age, sex, body mass index, smoking, alcohol drinking, physical activity and total energy intake.

Conclusions: High dietary quality is associated with lower risk for T2DM. Adherence to healthy eating may protect people from T2DM in China.

Key words: type 2 diabetes, dietary quality, Chinese.

PO2258

MODERATE MISO SOUP CONSUMPTION MAY REDUCE THE RISK OF CARDIOVASCULAR RISK FACTORS IN JAPANESE PROSPECTIVE COHORT STUDY: THE SUITA STUDY

Y. Kokubo^{1,2}, M. Watanabe¹, Y. Furukawa², Y. Miyamoto¹

¹National Cerebral and Cardiovascular Center, Osaka, Japan

²Kyoto Kouka Women's University, Kyoto, Japan

Background and Objectives: Miso soup has gradually come into the limelight due to its association with reduced risk of lifestyle-related disease. However, there have been few prospective studies on the association between miso soup and lifestyle-related disease. We assessed the hypothesis that miso soup would be inversely related with hypertension and dyslipidemia in a general urban population in Japan.

Methods: A total of 2,215 participants (40-64 years old) in the Suita Study underwent a medical examination as a baseline survey between 1994 and 1996. Each subject completed a food frequency questionnaire. The frequencies of miso soup were 'rarely', '1-2 days/week', '3-4 days/week', and 'almost daily' (and the average number of times per day). Hypertension was defined blood pressures $\geq 140/90$ mmHg or antihypertensive medication. Diabetes was defined as fasting/occasional blood glucose $\geq 126/200$ mg/dL, respectively, or anti-diabetic medication. Dyslipidemia was defined as non-HDL cholesterol ≥ 170 mg/dL or antihyperlipidemic medication. Of the baseline participants, 720, 1,206, and 291 subjects were excluded due to hypertension, dyslipidemia, and diabetes at the baseline survey, respectively. All study participants were invited every 2 years to undergo a medical examination for 10.5 years on average. The risks of incident hypertension, diabetes and dyslipidemia were analyzed by the adjusted Cox proportional hazards model according to the miso soup categories, adjusting for age, sex, body mass index, smoking, drinking, exercise, and medications of (hypertension, diabetes, and dyslipidemia).

Results: The adjusted hazard ratios (95% confidence intervals) of hypertension and dyslipidemia were 0.72 (0.55-0.95) and 0.69 (0.51-0.94) in subjects with 1 cup/day of miso soup, respectively, compared with rarely consumed miso soup. However, for the higher frequencies of miso soup, the associations were attenuated.

Conclusions: Moderate miso soup consumption may prevent hypertension and dyslipidemia in the general urban population.

Key words: miso soup, hypertension, dyslipidemia, prospective cohort study.

PO2259

EFFECTS OF PERILLA OIL ON BONE LOSS IN OVARIECTOMIZED RATS

Y.S. Chiu^{1,2}, W.C. Chiu¹, C.C. Huang³, C.C. Li¹, Y.H. Chen¹

¹School of Nutrition and Health Sciences, Taipei Medical University, Taipei, Taiwan

²Department of Orthopedics, Shuang Ho Hospital, Taipei Medical University, Taipei, Taiwan

³Graduate Institute of Sports Science, National Taiwan Sport University, Taoyuan, Taiwan

Background and objectives: Estrogen deficiency contributes bone loss in postmenopausal women. Several studies have shown that increasing diet content of n-3 fatty acids will inhibit osteoclast production and reduce bone loss. Perilla oil, rich in n-3 polyunsaturated fatty acids, is able to be a good plant oil source for vegetarian. Ovariectomized (OVX) rat was used to be an estrogen-deficiency osteoporotic model. Thus, this study was aimed at studying the effects of perilla oil on bone mass density in OVX rats.

Methods: Forty female Sprague Dawley rats were divided in to four groups: normal control (NC), OVX control (OC), OVX-perilla oil with n-3/n-6 ratio 1/2(OP2) and OVX perilla oil with n-3/n-6 ratio 1/4(OP4) groups. C and OC groups fed with a semi-purified diet with 10% corn oil; perilla oil groups adjusted diet n-3/n-6 ratio to 1/2 or 1/4. After 16 weeks of treatment, the animals were sacrificed. The blood and femur were collected for analysis.

Results: Compare with the NC group, OVX rats had a lower estradiol level in plasma as well as percent of bone volume, trabecular number and higher trabecular separation. The plasma osteocalcin (OCN) concentration was higher in the OVX rats than NC group for bone formation. It has been observed that higher plasma OCN levels are relatively well correlated with increases in bone mineral density. However, perilla oil groups had a lower OCN level than those in the OC group, maybe can regulate the bone remodeling.

Conclusions: These results indicated that compare with OVX fed with corn oil, dietary perilla oil administration may

regulate bone formation. But the bone loss is not obviously affected by the perilla oil supplementation in this study.

Key words: perilla oil, bone loss, ovariecromized rats, n-3 fatty acids.

PO2260

FACILITATORS AND BARRIERS TO ADOPTING RECOMMENDATIONS OF THE HEBAT! PROGRAMME (A FAMILY-BASED CHILDHOOD OBESITY INTERVENTION): FINDINGS FROM FOCUS GROUP DISCUSSION

B S Sabariah^{1,2}, T. Ruzita², B K. Poh², J. Reilly³

¹Department of Nutrition & Dietetics, Centre For Study of Disease Prevention & Healthcare Services, Faculty of Health Sciences, MARA University of Technology, Selangor, Malaysia

²Nutritional Sciences Programme, School of Healthcare Sciences, Faculty of Health Sciences, Universiti Kebangsaan, Selangor, Malaysia

³School of Humanities and Social Sciences, University of Strathclyde, Glasgow, Scotland, UK

Background and Objectives: The HEBAT! Programme is a comprehensive intervention for treating childhood obesity by reducing weight, increasing physical activity and improving eating habits of overweight children. The programme involves overweight and obese children and their parents. This presentation aims to identify the facilitators and barriers faced by the parents in adopting recommendations of the intervention program.

Methods: A total of three focus groups were conducted among 24 sets of parents. The main discussion focused on recommendations of HEBAT! Programme, such as increasing healthy snacking, more fruits and vegetables, balanced diet, low fat food preparation, shopping behavior, reducing fast foods and screen time, and increasing physical activity. Parents were asked to discuss factors that made each recommendation easy (facilitator) or difficult (barriers) to follow.

Results: Far less facilitators than barriers were identified. The facilitators were changes in parental shopping behavior in relation to reading food labels, reducing frequency of eating fast foods, preferences of children on eating balanced meals and ability of children to reduce screen time. The barriers identified were difficulty to overcome child preferences when practicing balanced diet, eating low fat meals, and healthy snacking. Parents identified time-cost barriers in preparing healthy foods, buying fresh fruits, and participation in physical activities with their children. Economic barriers includes higher price of healthy foods and fruits. Neighborhood safety was another

factor that limits physical activity and walking to school.

Conclusions: Parents identified more barriers particularly in relation to child preferences, time and economic costs and neighborhood safety when adopting recommendations to reduce childhood obesity. Hence, development of intervention programs should consider both facilitators and barriers when obesity related recommendations are offered to enhance parental compliance.

Key words: Childhood obesity, obesity treatment, childhood obesity intervention.

PO2261

DO VEGETARIANS HAVE A LOWER RISK OF OBESITY THAN NON-VEGETARIANS IN HIGH AND LOW OBESITY ENVIRONMENTS?

N. Rizzo^{1,2}, S. Soret², J. Sabate¹

¹Department of Nutrition, School of Public Health, Loma Linda University, Loma Linda, USA

²Department of Environmental Health and Geoinformatics Sciences, School of Public Health, Loma Linda University, Loma Linda, California, USA

Background and objectives: Obesity has become an epidemic in the U.S. and other countries with detrimental effects to the quality of life and health perspectives. Lifestyle factors such as dietary patterns may contribute in the prevention of obesity. The purpose of the study was to investigate associations between dietary patterns based on the inclusion or absence of meat and obesity in high and low obesity environments.

Methods: Cross-sectional study of 55676 U.S. subjects (age range 30 to 110 years) from the Adventist Health Study-2 with a complete set of data. Dietary pattern was classified as vegetarian and non-vegetarian based on meat intake derived from a validated food frequency questionnaire. County-level estimates of obesity provided by the CDC were stratified in quintile levels and cohort based individual level BMI values were calculated. Logistic regression analysis was employed to assess the association between dietary pattern and obesity stratified by quintiles of county-level obesity prevalence. Adjustments were made for cohort based information on race, sex, age, physical activity, caloric intake and sedentary behavior.

Results: After multiple adjustments the odds ratios of being obese were substantially lower for vegetarians than non-vegetarians in all quintiles of county level obesity with odds ratios (OR) between 0.460 and 0.522. The odds ratios for vegetarians were lowest in counties with the two highest obesity quintiles (4th quintile OR=0.460, CI=0.406-0.521 and 5th quintile OR=0.469, CI=0.400-0.549).

Conclusions: A vegetarian diet is associated with a lower

risk of being obese in high and low obesity environments and may show the greatest benefit in higher obesity environments.

Key Words: Obesity, Dietary Pattern, Environment, Prevention

PO2262

DIETARY PATTERNS AND THEIR ASSOCIATION WITH THE METABOLIC SYNDROME AND ITS COMPONENT RISK FACTORS

N. Rizzo¹, J. Sabate¹

¹Nutrition Department, School of Public Health, Loma Linda University, California, Loma Linda, USA

Background and Objectives: In the US 27% of the population have the Metabolic Syndrome (MetS). The identification of amendable dietary factors that may help in the prevention of the MetS thus becomes an important goal. The purpose of the study was to investigate associations between dietary patterns specified by degree of meat and dairy intake with the MetS and its component factors.

Methods: Cross-sectional analysis of 1278 subjects (mean age 63 years) with a complete set of clinical and dietary data from the Adventist Health Study II. Subjects were classified as non-vegetarian, semi vegetarian, pesco vegetarian, lacto-ovo vegetarian and strict vegetarian. ANCOVA was used to determine associations between dietary pattern and metabolic risk factors while controlling for possible confounding factors such as sex, age, ethnicity, physical activity and other relevant factors. Odds ratios for being over the risk threshold as defined by the Adult Treatment Panel III for each metabolic risk factor and the MetS were calculated with non-vegetarians being set as the group of reference.

Results: After multiple adjustments the odds ratio of having a waist circumference that was over the risk threshold was halved for pesco vegetarians (OR=0.49, CI=0.32-0.73) and semi vegetarians (OR=0.49, CI=0.36-0.67) and reduced by two thirds for strict vegetarians (OR=0.32, CI=0.19-0.55). The OR for high blood pressure was reduced by half for lacto-ovo vegetarians (OR=0.53, CI=0.39-0.72) and the OR of high glucose levels was significantly reduced in lacto-ovo vegetarians (OR=0.64, CI=0.45-0.92) and strict vegetarians (OR=0.42, CI=0.22-0.78). Strict vegetarian had the lowest risk for MetS (OR=0.33, CI=0.17-0.61) followed by lacto-ovo vegetarians (adjusted OR=0.65, CI=0.47-0.90).

Conclusions: Dietary patterns characterized by lower intakes of animal products are associated with a lower metabolic risk profile and may thus contribute in the prevention of metabolic disease.

Key Words: Obesity, Dietary Pattern, Environment, Epidemiology, Prevention.

PO2263

ANTIHYPOGLYCEMIC ACTIVITY OF MYRTUS COMMUNIS IN ALLOXAN-INDUCED DIABETIC RATS

H. Berredjem¹, S. Besnaci¹, M. Benlaifa¹, N. Bouzerna¹

¹University of Badji Mokhtar, Annaba, Algeria

Background and objectives: the actual treatment of diabetes is efficacious to decrease glycaemia; however, the good control of the glycaemia is, sometimes, difficult to reach and leads to the emergence of serious complications. Phytotherapy offers an opportunity to use natural substances with beneficial effect on glucose homeostasis and without side effects observed with drug therapy. The aim of this study was to evaluate the use of *Myrtus communis*, a hypoglycemic plant, for treating diabetes mellitus in alloxan-induced diabetic rats.

Methods: two extracts (powder and infusion) were administered orally and daily, during 12 days to experimental alloxenic Wistar rats at the respective doses of 250 and 500 mg/kg b.w. and 25 and 50 g/l. Body weight, liver index, blood glucose, serum level of creatinine, transaminase, phosphatase alkaline activity (PAL), cholesterol and hepatic glutathione were evaluated.

Results: the effect of the extracts was advantageous in reducing blood glycaemia (121,80g±22.50) ($p \leq 0.001$) comparing to the control one (357.00g ± 145.40), and regulating biochemical parameters except the cholesterol one. Indeed, the powder extract (250 mg/kg) showed better results than the infusion one. The two extracts have not a hepatocytotoxicity and did not showed any sign of toxicity in rats.

Conclusions: the presented data suggest that the two extracts of *Myrtus communis* have beneficial effect on the hyperglycemia in diabetic Wistar rats; however, the powder extract results are better than the infusion one. Further studies are needed to study the active constituents responsible for this properties.

Key words: alloxane, diabetes, myrtus communis, wistar rats.

PO2264**FORMULATION AND OPTIMIZATION BY EXPERIMENTAL DESIGN OF LOW-FAT MAYONNAISE BASED ON SOY LECITHIN AND WHEY**

N. Zaouadi^{1,2}, A. Hadj ziane²

¹Department of Agronomy, Faculty of Veterinary and Agro Biology, SAAD DAHLAB University, BP 270, soumâa, Blida, Algeria

²Department of Chemistry, Faculty of Science, SAAD DAHLAB University, BP 270, soumâa, Blida, Algeria

Background and objectives: Traditional mayonnaise is a relatively microbiologically stable product containing high oil content and among its ingredients, egg yolk is most critical for the stability of the product (Hasenhuettl, 2008; Narsimhan and Wang, 2008). Nevertheless, one main problem with egg yolk is its high cholesterol content. In this way, extensive investigations are being carried out actually to develop low cholesterol sauces with similar characteristic to real mayonnaise.

Methods: For this purpose, we focused on the following investigated steps: Characterization of commercial mayonnaise on low-fat (10%), as reference product, Experimental formulation tests, finally a design study that consists to make tests using the method of design of experiments and to determine the optimal formula which has characteristics approximating those of the reference product.

Results: Emulsifying power is provided by the use of soy lecithin and the total fat content in our formulations was limited to 16%. Droplet size measurement of employed mayonnaise samples at different times, show that the largest diameter of fat made of 16 tests does not exceed 18.5 µm. Results of stability to centrifugation reveals that the absence of the supernatant oily layer ensures the stability of the emulsion. However, the rheological of used of mayonnaises gives a yield stress of 56.1 Pa. Using the experimental design method, the number of trials can be limited to a number of design experiments of 16, and best formulation of the mayonnaise (without cholesterol) was obtained.

Conclusions: Therefore, we can conclude that we have formulated a product without cholesterol, reduced fat and can provide the body full of essential nutrient, namely whey protein (essential amino acids), fatty acids essential minerals (calcium, phosphorus, sodium, potassium) and polysaccharides.

Key words: low-fat mayonnaise, soy lecithin, whey, guar gum, design of experiments.

PO2265**PREVALENCE AND PREDICTING CLINICAL OUTCOME OF CARDIAC PATIENTS BY NUTRITION RISK SCREENING (NRS).**

R. Jayawardena^{1,2}, A. Pathirana³, N. Lokunarangoda^{3,4}, I. Ranathunga³, W. Santharaj³, S. Premaratne³

¹Diabetes Research Unit, Department of Clinical Medicine, Faculty of Medicine, University of Colombo, Colombo, Sri Lanka

²Institute of Health and Biomedical Innovation, Queensland University of Technology, Brisbane, Queensland, Australia

³Institute of Cardiology, National Hospital of Sri Lanka, Colombo, Sri Lanka

⁴Department of Medicine, Faculty of Medicine and Allied Sciences, Rajarata University of Sri Lanka, Mihintale, Sri Lanka.

Background and objectives: Malnutrition is highly prevalent among hospital admissions and is associated with, poor response to medical treatment as well as increased mortality, increased length of hospital stay and increased cost to the state. Cardiac patients are especially prone for nutritional risk due to apparent factors. The aim of this study is to assess the nutritional status and the ability of the Nutrition Risk Screening (NRS) to predict the clinical outcome when applied to cardiac patients.

Methods: Five hundred twenty six patients underwent nutritional screening NRS on admission and each subject was followed up until discharge and after one month to identify the clinical course and outcome.

Results: Three hundred twenty three males (61.22%) and 204 females (38.78%) were participated in the study. NRS divided patients in to malnutrition categories of normal (230; 43.7%), mild (33; 6.3%), moderate (132; 25.1%) and severe (131; 24.9%) respectively. The mean hospital stay is increasing with the NRS, patients with 'normal' nutrition category discharged mean days of 4.5, whereas patients with severe malnutrition stayed average 5.9 days. Compared to patients with severe malnutrition, other patients had two folds higher mortality and three folds higher morbidity during hospital stay. During one month follow up severe malnourish patients had increased risk for death (two times) and hospital readmission compared to the rest of the patients.

Conclusions: Among cardiac patients nearly a quarter suffers from severe malnutrition according to NRS. Prolonged hospital stay, higher mortality and morbidity were predicted by NRS among this patient population. Therefore, the nutritional screening should be applied to all cardiac patients to predict the unfavorable clinical outcome.

Key words: cardiac patients, NRS, nutrition risk screening, malnutrition.

PO2266**DIFFERENCES BETWEEN FEMALE AND MALE DIABETIC PATIENTS IN FACTORS ASSOCIATED WITH HYPERTRIGLYCERIDEMIA***B. Muktabhant¹, N. Jeenkao¹*

¹Research Group on Prevention and Control of Diabetes in the Northeast, Faculty of Public Health, Khon Kaen University, Khon Kaen, Thailand

Background and objectives: Diabetic patients with hypertriglyceridemia frequently develop atherosclerosis. The aim of this study was to analyze factors associated with hypertriglyceridemia in male and female diabetic patients.

Methods: Subjects were 196 female and 61 male diabetic patients living in Krasung District, Burirum Province, Thailand. Fasting blood samples were taken for the determination of triglyceride (TG) levels. Body mass index (BMI) was calculated, and waist circumference (WC) measured. Data were collected during the period January to April, 2011. Multiple logistic regression was used to identify factors associated with hypertriglyceridemia in female and male diabetic patients.

Results: The mean (SD) age of the diabetes subjects was 59.8 (10.5) years in females, and 57.4 (12.7) in males. The average (SD) duration since the diagnosis of diabetes mellitus was 6.1 (4.0) and 5.7 (4.6) years for female and male subjects, respectively. The prevalence of abnormal TG levels (> 150mg/dl) was 31% in females and 23% in males. The female and male subjects categorized as obese (BMI > 25.0 kg/m²) were 33% and 39%, respectively. Abdominal obesity was found in 64% of females (WC > 80 cm) and only 23% of males (WC > 90 cm). The results of the multiple logistic regression showed that abdominal obesity was the only factor associated with hypertriglyceridemia in the female subjects (OR adj = 2.50, 95% CI: 1.21 – 5.19), whereas diabetic duration more than five years was the only factor associated in the male subjects (OR adj = 0.17, 95% CI: 0.03 – 0.87).

Conclusions: Greater emphasis needs to be placed on decreasing abdominal obesity to reduce triglyceride levels in female diabetic patients. The issue in male patients should be further investigated due to the small sample size in the present study.

Key words: diabetes, hypertriglyceridemia, obesity.

PO2267**BIRTH WEIGHT AND BREASTFEEDING: PROTECTIVE FACTORS AGAINST OBESITY***F. Tebbani¹, H. Oulamara¹, A. Agli¹*

¹Institute of Nutrition, Food and Food Technologies, Constantine, Algeria

Background and Objectives: Overweight at birth is correlated with the occurrence of childhood obesity. Many epidemiological studies are in favor of a protective effect of breastfeeding against the development of childhood obesity. The objective was to study the prevalence of overweight and obesity in the child population of Constantine (Algeria) in terms of birth weight, type and duration of breastfeeding and the impact of socio-economic status.

Methodology: A study was conducted on a sample of 340 children (153 girls and 187 boys) aged 6 to 12 years old, enrolled in the commune of Constantine in 2011. The questionnaire includes questions on the practice of breastfeeding, birth weight, socio-economic and anthropometric measurements (weight and height) of children. The IOTF criteria were used to assess overweight and obesity.

Results: The overall prevalence of overweight is 21.76%. That of obesity is 5%. A significant association was observed between obesity and female gender ($p = 0.007$). The percentage of overweight children seems to be higher for the group with birth weight greater than or equal to 4 kg (26.47%, $p = 0.6$). A proportion of 85% of mothers reported having breastfed their children. The percentage of overweight appears to be the highest among children who were not breastfed (31.37%) against 20.17% among children exclusively breastfed. The percentage of non-breastfed children is higher when the level of education of mothers is higher compared to the low level (27.63% vs 13.25%, $p = 0.005$). The prevalence of overweight appears to decrease with increasing of the total duration of breastfeeding.

Conclusions: The prevalence of breastfeeding is quite high in our population. The determining factors are the socio-economic status and maternal education. A protective effect of breastfeeding against overweight seems to be highlighted.

Key words: Birthweight, breastfeeding, children, overweight, prevention.

PO2268**STRAIN-DEPENDENT ANTIBODY AND ANAPHYLACTIC RESPONSES TO WHEAT GLIADIN IN A/J MICE: AN ANIMAL MODEL FOR WHEAT-INDUCED FOOD ALLERGY**

K. Hirano^{1,2}, S. Hino², K. Oshima¹, T. Okajima³, D. Nada-no¹, T. Matsuda¹

¹Department of Applied Molecular Biosciences, Graduate School of Bioagricultural Sciences, Nagoya University, Chikusa-ku, Nagoya, Japan

²Department of Applied Biological Chemistry, Faculty of Agriculture, Shizuoka University, 836 Ohya Suruga-ku Shizuoka, Japan

³Department of Biochemistry II, Graduate School of Medicine, Nagoya University, 65 Tsurumai, Showa-ku, Nagoya, Japan

Background and objectives: Wheat gliadins are major causative allergens of wheat-induced food allergy, including anaphylaxis, despite of their insolubility to water/salt-solutions. Detailed mechanisms on allergic sensitization and elicitation with gliadins remain unclear, though individual genetic predisposition must in part be involved. In this study, we establish an animal model to better understand the allergenicity of gliadins and the immunological and pathophysiological mechanisms of wheat allergy.

Methods: Four strains of mice with different H-2 haplotype (A/J, AKR/N, BALB/c, C3H/HeJ) were injected intraperitoneally with fractionated gliadin. Specific antibodies to gliadin in mouse serum were evaluated using the ELISA and immunoblotting. The mice were orally administered with gliadin and systemic allergic and anaphylactic responses were studied.

Results: Among four mouse strains, A/J mice showed the highest IgE response to i.p.-injected gliadins as analyzed by ELISA and immunoblotting, and provoked severe anaphylactic reactions as estimated by measuring rectal temperature decrease and capillary permeability increase after administration of gliadin. Despite that serum IgE anti-gliadins levels as measured by ELISA were not significantly different between the two strains, A/J mice experienced maximum drop after the gliadin challenge and severely decreased temperature in contrast with BALB/c mice. Causative allergenic components reactive with the IgE of A/J mice were estimated to be several components in α -gliadins and in α -gliadins as well as minor components in α -gliadins using ELISA and immunoblotting in combination with aluminum lactate-PAGE and SDS-PAGE.

Conclusions: We report here a high-responder mouse strain, A/J, to gliadins on not only specific IgE response but also anaphylactic reaction to oral gliadins. It was suggested that component- and/or epitope-specific IgE rather than the IgE to total gliadins affected provocation of severe anaphylactic responses to oral challenge with gliadins in A/J mice.

Key words: wheat gliadin, allergy, anaphylaxis, mouse model.

PO2269**EVALUATION OF THE HYPOCHOLESTEROLEMIC EFFECT OF ANTIOXIDANT EXTRACTS FROM SOME ALGERIAN DATE VARIETIES (PHOENIX DACTYLIFERA) IN RATS**

S. Ouardia^{1,2}, S. Selma¹, B. Lynda¹

¹Departement of food sciences, faculty of sciences, Blida University, Blida, Algeria

Background and objectives: Because of the many virtues attributed to natural antioxidants, the aim of this study is to evaluate cholesterol lowering effect of dates phenols extracts.

Methods: The first step of this work is the extraction and purification of the phenolic fraction from three Algerian date varieties (Mech Degla, Deglet Nour and Ghars) using two solvents (methanol and ethanol) to assess their anti-radical potential and hypocholesterolemic activity in vivo.

Results: The results show that the three ethanolic extracts are the most biologically active after purification. Also, it exists a correlation between the rate of total polyphenols that the ethanolic purified extracts contain, their anti-radical potential and their hypocholesterolemic activity, through the proportionality of the found results, because more the extract is rich in total polyphenols more its antioxidant activity is raised and its hypolipemiant effect is effective. Mech Degla illustrates very well this relativity with a content total polyphenols of 311.65 mg EAG / 100g, an antioxidant activity of 74,07% and a reduction of more than half rate of LDL in the blood at the second week of the treatment.

Key words: Dates, phenolic extracts, purification, anti-radical potential, hypocholesterolemic effect.

PO2270**EFFECT OF HIGH OLIVE OIL DIETS ON PLASMA GLP1 LEVEL AND ADIPOCYTE DPP4 ACTIVITY**

A B. Segarra^{1,2}, M. Martínez-Cañamero¹, A B. Villarejo¹, L. Gajdošechová², M. Ramírez¹, I. Prieto¹

¹Department of Health Sciences, University of Jaen, 23071 Jaen, Spain

²Institute of Experimental Endocrinology, Slovak Academy of Sciences, Bratislava, Slovakia

Background and objectives: Olive-oil enriched diets have demonstrated that increase GLP-1 release and improve glucose tolerance. GLP-1 is cleaved by the proteolytic-activity dipeptidyl-peptidase-IV (DPPIV), and several DPPIV-inhibitors have been developed for type-2-diabetes treatment. DPPIV is present on the surface of different cells, and there is a soluble

form in plasma. DPPIV also has been localized in epididymal adipose tissue, where it seems play an important role in the impaired glucose tolerance induced by high fat diets. In the present study, we analyzed the effect of different diet on plasma GLP-1 and DPPIV activity in adipose tissue.

Methods: We analyzed the effect of two diets, enriched with olive oil (OO) and virgin olive oil (VOO), on plasma GLP-1 and DPPIV-activity in epididymal adipose tissue, compared with a standard (S) and a high saturated fat diet (butter, B).

Results: Only B group had high body weight gain ($p < 0.05$). The weight of adipose tissue also was higher in B mice compared with S diet ($p < 0.01$). No changes were observed in fasting plasma glucose. However, insulin levels in OO and VOO groups were lower compared with B ($p < 0.05$), improving the index of insulin resistance (HOMA) in VOO compared with B ($p < 0.01$). It was accompanied by an increased levels of GLP-1 in VOO, although not significantly compared with S ($p > 0.05$). DPP4-activity was significantly increases in epididymal adipose tissue of VOO compared with B ($p < 0.05$). A significant inverse correlation was demonstrated between adipose tissue DPP4-activity and several components of the metabolic syndrome cluster: body weight ($r = -0.52$, $p < 0.01$), and HOMA index ($r = -0.47$, $p < 0.05$).

Conclusions: These results indicate that the intake of a rich diet in VOO may be an effective prevention strategy for obesity and metabolic disorders.

Key words: olive-oil, DPPIV, GLP-1. Acknowledgements: Plan Propio UJA (PP2009/13/03) / PI Excelencia, Junta de Andalucía (AGR-6340).

PO2271

HIGH FAT DIETS AND PLASMA LEVELS OF ADIPOKINES: EFFECT OF DIETARY FATTY ACIDS

A B. Segarra¹, M. Martínez-Cañamero¹, A B. Villarejo¹, M. Ramírez¹, I. Prieto¹

¹Department of Health Sciences, University of Jaen, Jaen, Spain

Background and objectives: High fat diets are normally associated with the development of obesity, insulin resistance and abnormalities in the regulation of food intake. The long term administration of these diets plays an important role in the development of obesity and insulin resistant, and obesity is usually characterized by a 'low grade of inflammatory status'. However, it seems that the type of fat is critical for these effects. The main objective of this work was analyzed the effect of high fat diets, with different fatty acid profile and polyphenols contents, on postprandial levels of leptin, resistin and IL-6.

Methods: Four groups of male Swiss Webster mice ($n = 9$) were fed for 12 weeks with different diets: standard (S, 3% fat),

and supplemented (20%) with olive oil (OO), virgin olive oil (VOO) or butter (B). After experimental period, only B group reached significantly higher body weight and visceral (epididymal) adipose tissue amount, compared with standard diet. Plasmatic postprandial levels (30 min after feeding) of leptin, resistin and IL-6 were determined by Luminex Assay.

Results: Data indicate significantly higher levels of leptin in B versus S and OO diets ($p < 0.01$). Similarly, the high level of plasmatic IL-6 corresponded to B compared with the others three diets ($p < 0.001$). B diet also increased significantly ($p < 0.001$) plasmatic levels of resistin.

Conclusions: These results indicate a specific effect of the fat type on plasma levels of adipokines involved in control of food intake, insulin resistant and inflammatory markers, and could support the beneficial effects of high monounsaturated fatty acids diets.

Key words: Leptin, resistin, IL-6, olive oil. Acknowledgements: Plan Propio UJA (PP2009/13/03) / PI Excelencia, Junta de Andalucía (AGR-6340).

PO2272

PREVALENCE OF FOOD INTOLERANCE AND DUMPING SYNDROME IN BARIATRIC SURGERY PATIENTS

R F. Simony¹, L. Garcia¹

¹Mackenzie University, São Paulo, Brazil

Background and Objectives: Obesity is considered a chronic disease whose prevalence has grown substantially. One of the treatments proposed for obesity is bariatric surgery, however, brings with it some important complications for healthy. This study is aimed at assessing the prevalence of food intolerance and dumping syndrome in bariatric surgery patients.

Methods: In a cross sectional study, subjects were asked to answer a questionnaire provided on a web-based platform linked to a blog specifically addressing bariatric surgery and nutrition themes and advertised on discussion groups and social networks.

Results: We evaluated 71 patients, both sexes, aged between 18 and 50 years who underwent bariatric surgery. The prevalence of food intolerance was 60.6% and of dumping syndrome was 66.1%. The main foods that triggered food intolerance were meat (28.1%), rice (11.2%) and vegetables (4.2%). The main foods that triggered dumping syndrome were ice cream (49.2%), condensed milk (49.2%) and fried foods in general (49.2%). The most common symptoms related to food intolerance were pinching (38%), abdominal discomfort (38%) and vomit (27%) and the main symptoms related to dumping syndrome were nausea (60.5%), 'wishing to lie down' (56.3%) and sleepiness (52.1%).

Conclusions: Although most subjects affirmed being familiar with the concepts of dumping syndrome and food intolerance, clinical and nutritional monitoring is fundamental before and after bariatric surgery in order to prevent the development of such complications.

Key words: dumping syndrome, bariatric surgery, food intolerance.

PO2273

MULTIPLE MICRONUTRIENT SUPPLEMENTATION IMPROVES SMALL BOWEL HISTOLOGICAL ARCHITECTURE AND ABSORPTIVE AREA IN ZAMBIAN ADULTS.

J. Louis-Auguste^{1,2}, S. Greenwald², R. Banda³, P. Kelly^{1,3}

¹Centre for Digestive Diseases, Queen Mary University of London, London, UK

²Pathology Group, Queen Mary University of London, London, UK

³Tropical Gastroenterology & Nutrition Group, University of Zambia School of Medicine, Lusaka, Zambia

Background and objectives: Disadvantaged populations in tropical and subtropical zones have a high incidence of environmental enteropathy (EE), characterized by abnormalities of small bowel architecture, intestinal permeability and absorptive capacity. This hitherto untreatable disorder may explain why oral vaccine efficacy in tropical populations is markedly reduced compared to Western populations. We investigated the effect of multiple micronutrient supplementation (MM) on small bowel architecture in EE.

Methods: As part of a randomised double blind placebo controlled trial (ISRCTN68751738) of MM on oral vaccine efficacy, consenting adults from Misisi, Lusaka, Zambia, were randomized to receive six weeks of 15 micronutrients as a daily capsule or placebo, followed by oral Typhoid vaccine (Ty21a). Small bowel biopsies were collected after the supplementation period, and 2-14 days after vaccination. For this study, correctly orientated biopsy sections were digitized and analyzed using a semi-automated image analysis program. Villous height (VH), crypt depth (CD), villous width (VW), villous perimeter (VP as a measure of epithelial surface area), villous cross sectional area (VA as a measure of villous compartment volume) and muscularis mucosae length were measured.

Results: 23 patients received MM and 23 received placebo. Baseline characteristics in the two groups were comparable. Mean VH was 12.9% greater and VP per 100µm of mucosa was 31.0% greater in the MM group (mean values MM vs placebo: VH 276.5µm v. 244.9µm, $p = 0.02$; VP 411.4µm/100µm v.

314.0µm/100µm, $p = 0.01$; Kruskal-Wallis). No significant differences were observed in VW, CD or VA per unit ML. There was no effect of HIV status. Well orientated biopsies before and after the vaccination phase were available for 14 patients; no changes were observed attributable to vaccination.

Conclusions: Multiple micronutrient supplementation improves small bowel villous height and absorptive area in adults with EE. This effect is independent of HIV status.

Key words: Environmental enteropathy; morphometry; micronutrients; malnutrition.

PO2274

PARAOXONASE 1 ACTIVITY AND ITS RELATIONSHIP WITH OBESITY AND CARDIOVASCULAR RISK IN ADOLESCENTS

A. Mello¹, C. Sanibal¹, I. Silva¹, N. Damasceno¹

¹School of Public Health, University of Sao Paulo, USP, Brazil

Background and objectives: Obesity adolescence as a metabolic disorder considered an important factor for cardiovascular diseases in adults. Lipid profile, electronegative LDL [LDL (-)], non-esterified fatty acids (NEFAs), adipokines and paraoxonase 1 (PON1) are potential new risk factors for cardiovascular disease, however this biomarkers are sparkly monitored in adolescents. Our goal was to assess the PON1 activity and investigate its possible relationship with obesity and cardiometabolic risk factors of adolescents.

Methods: 237 adolescents, aged 10-19 years, both sexes from public school (Sao Paulo, Brazil) were included in this study. Anthropometric and body composition parameters were monitored. Lipid profile, LDL(-), anti-LDL(-) antibodies, NEFAs, α -tocopherol, leptin, resistin, adiponectin levels were analyzed in plasma. Statistical analysis was performed by linear tendency and Spearman test ($p < 0.05$).

Results: Adolescents were distributed in tertiles of PON1. It was not observed differences in total cholesterol, LDL-C and ApoB in function of tertiles of PON1. However, body mass index (BMI) ($p < 0.001$), waist circumference (WC) ($p < 0.001$), body fat mass (BFM) ($p < 0.001$), HOMA ($p < 0.001$), triglycerides ($p = 0.025$), NEFAs ($p = 0.020$), LDL (-) ($p = 0.029$), leptin ($p < 0.001$) and resistin ($p = 0.022$) were significantly higher in adolescents in the lowest tertile of PON1. In opposite, HDL-C ($p = 0.014$), ApoA1 ($p = 0.004$), anti-LDL (-) antibodies ($p = 0.003$), α -tocopherol ($p = 0.002$) and adiponectin ($p = 0.014$) showed higher values in adolescents in the highest tertile of PON1. The impact of PON1 on cardiovascular risk factors was confirmed by negative correlation with BMI ($r = -0.62$, $p < 0.001$), WC ($r = -0.60$, $p < 0.001$), BFM ($r = 0.40$, $p < 0.001$), HOMA ($r = -0.28$, $p < 0.001$), NEFAs ($r = -0.14$, $p = 0.037$), leptin

($r = -0.49$, $p < 0.001$) and resistin ($r = -0.22$, $p = 0.007$). Positive correlation were found between PON1 and HDL-C ($r = 0.16$, $p = 0.013$), ApoA1 ($r = 0.23$, $p < 0.001$), α -tocopherol ($r = 0.15$, $p = 0.024$), anti-LDL (-) antibodies ($r = 0.20$, $p = 0.002$) and adiponectin ($r = 0.26$, $p = 0.001$).

Conclusions: Elevated PON1 activity is associated as protector factor for obesity and cardiovascular risk of adolescents.

Key words: Adolescents, obesity, cardiovascular disease, PON1. Financial Support: FAPESP (07/57601-5, 07/57602-1).

PO2275

ELETRONEGATIVE LDL AND ITS AUTOANTIBODIES IN ADOLESCENTS WITH RISK FOR CORONARY ARTERY DISEASE

A. Mello¹, I. Silva¹, T. Sampaio¹, N. Damasceno¹

¹ School of Public Health, University of Sao Paulo, USP, Brazil

Background and objectives: Recent studies indicate that the atherosclerotic process starts in the childhood. Early detection of high blood cholesterol in asymptomatic persons allows the identification of an important modifiable risk factor for coronary artery disease (CAD). Electronegative LDL [LDL(-)] and its autoantibodies could elucidate predictive information to evaluate atherosclerosis progression and it can represent a biomarker for CAD. Our goal was to determine LDL (-) and its autoantibodies in adolescents with risk for CAD.

Methods: 237 adolescents, aged 10-19 years, both sexes from public school (Sao Paulo, Brazil) were included in this study. Anthropometric and body composition parameters were monitored. Lipid profile, LDL(-), anti-LDL(-) antibodies, NEFAs, α -tocopherol, leptin, resistin and adiponectin concentration were analyzed in plasma. Statistical analysis was performed by t-student and Mann-Whitney ($p < 0.05$).

Results: The body mass index (BMI) was calculated, and adolescents were classified in Eutrophic and Overweight group, according WHO (2007). It was not observed differences in relation LDL(-), total cholesterol (TC), LDL-C, triglycerides (TG), ApoB and α -tocopherol concentration. Anti-LDL(-) antibodies ($p = 0.001$), HDL-C ($p = 0.001$), PON1 ($p < 0.001$), ApoA1 ($p < 0.001$) and adiponectin ($p < 0.001$) were significantly lower in Overweight group. Opposite results were found in TC/HDL-C ($p = 0.008$), ApoB/ApoA1 ($p = 0.001$), NEFAs ($p = 0.012$), leptin ($p < 0.001$) and resistin ($p = 0.001$). The waist circumference was measured, and adolescents were classified in Normal and CAD group, according Fernández (2004). It was not observed differences in relation TC, LDL-C, TG, ApoB and NEFAs. Anti-LDL(-) antibodies ($p = 0.002$), HDL-C ($p = 0.002$), PON1 ($p < 0.001$), ApoA1 ($p = 0.047$), HDL-C/ApoA1 ($p = 0.004$), adiponectin ($p = 0.001$) and α -tocopherol ($p =$

0.011) concentration were significantly lower in CAD group. Inverse results were observed for LDL(-) ($p = 0.023$), CT/HDL-C ($p = 0.001$), non-HDL ($p = 0.025$), ApoB/ApoA1 ($p = 0.010$), resistin ($p = ep < 0.001$).

Conclusions: High LDL(-) and low anti-LDL(-) antibodies concentration can be associated as risk factor for overweight and CAD in adolescents.

Key words: adolescents, overweight, CAD, LDL(-), anti-LDL(-) antibodies. Financial Support: FAPESP (07/57601-5, 07/57602-1).

PO2276

ASSOCIATION OF TRANS-FATTY ACIDS IN ABDOMINAL SUBCUTANEOUS AND VISCERAL FAT WITH DIABETES MELLITUS AND CARDIOVASCULAR RISK FACTORS IN MEXICAN WOMEN

M. Ballesteros-Vásquez^{1,2}, E. Guillot¹, A. Robles¹, I. Grijalva¹, R. Nieblas¹, E. Artalejo¹, C. Ramirez¹, R. Cisneros², G. Caire¹, M. Ortega¹

¹Departamento de Nutrición y Metabolismo, Centro de Investigación en Alimentación Y Desarrollo A.C (CIAD AC), Hermosillo, Sonora, México

²Clínica de Obesidad. Hospital Ignacio Chávez, Ave Juárez Sn, Hermosillo, Sonora, Mexico

Background and objectives: Trans fatty acids (TFA) are produced as a result of the partial hydrogenation of cooking oils, so they are found in a variety of foods. Clinical and epidemiological studies indicate that these fatty acids may be deposited in abdominal subcutaneous tissue and be a risk factor for myocardial infarction. Objective: To determine if dietary TFA are deposited in the abdominal subcutaneous and visceral adipose tissues, and evaluate their potential associations with diabetes mellitus and cardiovascular disease.

Methods: The study was cross-sectional and included 18 adult women aged 22-54 years undergoing abdominal surgery. Body composition, diet (food frequency questionnaire), glucose, insulin, lipid profile, blood pressure, and the content of TFA of abdominal subcutaneous and visceral adipose tissues were measured.

Results: Results indicate that TFA are deposited in higher quantities in visceral compared to subcutaneous adipose tissue (1.8 vs 1.3%; < 0.05). The main trans isomers in both tissues were the elaidic (18:1n9t) and linoelaidic (18:2n6t) acids. Positive correlations between TFA in visceral fat and body weight, waist circumference and % of fat were found ($r = 0.62$; $r = 0.61$; $r = 0.54$ respectively; $p < 0.05$). After adjustment for age, BMI, caloric intake from monounsaturated and saturated fat, the variability of HDL-C levels was explained by age and the 18:1

isomer in subcutaneous fat ($R^2 = 0.87$; $p < 0.01$). Insulin was related to the intake of saturated fatty acids and the 18:2 isomer of TFA in visceral fat ($R^2 = 0.87$; $p < 0.01$).

Conclusions: The dietary TFA are deposited in abdominal fat and affect HDL-C and insulin levels.

Key words: Trans fatty acids, adipose tissue, cardiovascular disease, diabetes mellitus.

PO2277

THE RELATIONSHIP BETWEEN DIETARY CALCIUM INTAKE, PHYSICAL ACTIVITY AND BONE LOSS RATE AMONG CHINESE PERIMENOPAUSAL WOMEN

J. Deng^{1,2}, Q. Lin², Y.M. Huang², G.L. Yang³, J.J. Liu³

¹Department of Epidemiology and Health Statistics, School of Public Health, Central South University, Changsha, Hunan, China

²Department of Nutrition and Food Hygiene, School of Public Health, Central South University, Changsha, Hunan, China

³Department of Women Healthcare, Women's Healthcare Centre, Changsha Hunan, China

Background and objectives: Although a number of treatments have been taken in the therapy of postmenopausal osteoporosis, prevention of this disease is still considered more profound and mainly focused on increase dietary calcium intake and physical activity level, especially for Asian women. The aim of this study is to determine the relationship between dietary calcium, physical activity and their interaction with bone loss in Chinese perimenopausal women.

Methods: 189 perimenopausal women who go to women's health care center of Hunan province, China for routine physical examination were selected. The bone mineral density at Femoral Neck, Ward's triangle, trochanter, total hip and lumbar 2~4 were measured, daily dietary calcium intake and physical activity were estimated by validated calcium FFQ and WHO recommended physical activity questionnaire. The BMD were retest 10~13 months later. Main effects of calcium intake, physical activity and their interaction on bone loss were analyzed.

Results: Among women dietary calcium intake low than 505.6 mg/d, insufficient activity lead to an additional 0.64% and 0.84% bone loss of the Wards triangle and total hip compared to the high active physical activity group. Among women whose dietary calcium intake ranged 505.6 mg/d~ 652.2 mg/d, insufficient activity lead to an additional 0.79% bone loss of the Wards triangle compared to the high active physical activity group. Among women dietary calcium intake between 652.2 mg/d~ 851.7mg/d, full sit-active group leading to an additional 1.67% and 1.88% bone loss of the torchanter and the total hip.

Conclusions: The interaction between dietary calcium intake and physical activity level impacted the bone loss of Ward triangle, trochanter and total hip of Chinese perimenopausal women; dietary calcium intake low than 505.6 mg/d and full sit-active were of the greatest impact.

Key words: Postmenopausal Osteoporosis (PMOP), bone loss, dietary calcium intake, physical activity, mixed linear model.

PO2278

NUTRITION SUPPORT IN OLDER INPATIENTS AND ITS ASSOCIATION WITH NUTRITIONAL STATUS AND CLINICAL OUTCOME

H. P¹, B. Dong¹

¹West China Hospital, Sichuan University, Sichuan, China

Background and objectives: Malnutrition is a medical condition caused by an improper or insufficient diet and associated with negative clinical outcomes. Older inpatients are easy to develop to malnutrition. Methods to improve or maintain nutritional intake are known as nutrition support (NS). Nutritional status and NS of Chinese older inpatient is unclear. This study intends to know the current situation of NS in China.

Methods: This study was taken at West China Hospital of Sichuan University in March and April of 2012. Two doctors take a questionnaire in 24 hours after patients' admission. Patients were followed up to discharge day or the 30th days after hospitalization. Mini Nutritional Assessment-Short Form (MNA-SF) and Nutritional Risk Screening 2002 (NRS) of nutritional status were used to assess nutritional status. SPSS Statistics version 19 was used for analysis.

Results: 933 older inpatients were included, 49 inpatients were excluded, and 407 patients were followed up (19 patients died). 14.5% patients assessed by MNA-SF and 41.2% patients assessed by NRS were malnourished. 532 patients received NS, comprised 36.8% ($n = 196$) patients with parenteral nutrition (PN), 54.4% ($n = 279$) patients with enteral nutrition (EN). NS was not associated with nutritional status assessed by MNA-SF (OR: 1.3, 95% CI 0.9-1.9) and NRS (OR: 1.29, 95% CI 0.97-1.68). LOS of patients with NS was 17.5 ± 9.7 days, and patients without NS was 11.3 ± 7.1 days ($p = 0.000$). Four dead patients received NS, and 15 dead patients did not receive NS (OR: 15.9, 95% CI: 5.13-49.3).

Conclusions: Nutritional support was not guided by nutritional status in this study. Patients who were older, poor nutritional status were easy to receive PN. Though patients received NS had a longer LOS and a higher mortality than patients did not received in this study. More multicenter and larger researches about older patients' NS are needed.

Key words: malnutrition, nutritional support, aged, MNA-SF, NRS.

PO2279

RESVERATROL UPTAKE BY VASCULAR ENDOTHELIAL CELLS IS THROUGH PASSIVE DIFFUSION AND AN SGLT1-MEDIATED PROCESS

Y. Long¹, C. Ming-liang¹, J. Xin¹, X. Qi¹, Z. Ting¹, C. Hui¹, F. Yu-jie¹, Z. Jun-dong¹, Z. Qian-yong¹, M. Man-tian¹

¹Research Center For Nutrition and Food Safety, Institute of Military Preventive Medicine, Third Military Medical University, Chongqing, P.R. China

Background and objectives: Resveratrol is a natural polyphenol that exerts potent effects on suppress atherosclerosis (AS). However, its low concentration in plasma has placed this role in doubt. Thus, resveratrol effects might be dependent on its transport into vascular endothelium; a question not previously addressed, in spite of its obvious and fundamental importance.

Methods: Human umbilical vein endothelial cells (HU-VECs) were cultured and exposed to different doses (0.1, 1, 10 and 20 μ M) of resveratrol. The uptake of resveratrol by HU-VECs were detected by fluorescence microscopy and HPLC assays. and the role of sodium-dependent glucose transporter 1 (SGLT1) in resveratrol uptake were measured. Additionally, Sprague-Dawley rats were administrated intragastrically with resveratrol of 100mg/kg and the concentration of resveratrol in the blood and blood vessels were measured.

Results: Via HPLC, we found that resveratrol was absorbed by human umbilical vein endothelial cells in a temperature-, concentration-, and time-dependent manner suggesting the involvement of passive diffusion and active transport. As determined by confocal laser scanning microscopy, resveratrol primarily distributed throughout the cytoplasm. Furthermore, resveratrol absorption was modulated by serum proteins and sodium-dependent glucose transporter 1 (SGLT1), yet inhibited by glucose (an SGLT1 substrate) and phlorizin (an SGLT1 selective inhibitor) as well as SGLT1 siRNA transfection. Additionally, the concentration of resveratrol in blood vessels of rats administrated with resveratrol declined more slowly up to 24 h compared to that in the blood.

Conclusions: Our results suggested that the intracellular resveratrol pool was more important than the serum level in vivo and SGLT1 was a key factor in transmembrane polyphenol transport.

Key words: resveratrol, vascular endothelial cells, atherosclerosis, sodium-dependent glucose transporter, transmembrane transport. Acknowledgements This work was supported by the National Natural Science Foundation of China (grant number 81172670) and the Youth Innovation Foundation of the Third Military Medical University (2012XJQ06).

PO2280

SUPPRESSION OF DIABETES-ASSOCIATED GLOMERULAR ANGIOGENESIS BY ANTHOCYANIN-RICH PURPLE CORN EXTRACT

M K. Kang¹, S H. Park¹, Y H. Kang¹

¹Department of Food Science and Nutrition, Hallym University, Chuncheon, Republic of Korea

Background and objectives: Diabetic nephropathy (DN) is one of the major diabetic complications and the leading cause of end-stage renal disease of which prevalence continues to increase. Abnormal angiogenesis results in new vessels that are often immature and play a pathological role in DN, contributing to renal fibrosis and disrupting glomerular failure. Purple corn utilized as a daily food exerts various disease-preventive activities. This study focused on the implication of HIF (hypoxia inducible factor)-1 α -vascular endothelial growth factor (VEGF)-angiopoietin (Ang) in the development of diabetic kidney and on the therapeutic role of purple corn extract (PCE) in delaying diabetic glomerular angiogenesis.

Methods: Human endothelial cells were cultured in conditioned media of renal mesangial cells exposed to 33 mM high glucose (HG-HRMC) in the presence of 1-20 μ g/ml PCE. Cellular expression levels of the angiogenesis biomarkers, endothelial HIF-1 α , VEGF, Ang-1 and Ang-2, were determined by Western blot analysis. In the in vivo study db/db mice received 10 mg/kg PCE for 8 weeks. Plasma level of VEGF was determined by ELISA, and renal tissue levels of HIF-1 α , VEGF, Ang-1, Ang-2 and Tie2 were measured by Western blot analysis.

Results: PCE inhibited endothelial expression of HIF-1 α , VEGF, Ang-1 and Ang-2 induced by HG-HRMC conditioned media. Additionally, oral administration of PCE diminished plasma level of soluble VEGF. PCE alleviated glomerular angiogenesis of diabetic kidney by attenuating the induction of HIF-1 α , VEGF, Ang-1, Ang-2 and Tie2 in kidney tissue of db/db mice. Accordingly, PCE appeared to antagonize glomerular angiogenesis due to chronic hyperglycemia.

Conclusions: PCE may be a potent therapeutic agent targeting abnormal angiogenesis in DN leading to kidney failure.

Key Words: Purple corn, diabetic nephropathy, glomerular angiogenesis, vascular endothelial growth factor, angiopoietin.

Acknowledgement: This work was supported by the National Research Foundation of Korea grant funded by the Korea government (2012H1B8A2026122).

PO2281**ANTIOXIDANT SUPPLEMENT HAD A LOWER EFFECT OF ATOPIC DERMATITIS IN YOUNG CHILDREN: A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED, CLINICAL TRIAL**

S Y. Oh^{1,2}, S O. Kwon¹, H S. Park², J W. Seo³, H Y. Choi⁴, J Y. Chung¹

¹Department of Food and Nutrition, Kyung Hee University, Seoul, Korea

³Department of Pediatrics, School of Medicine, Ewha Womans University, Seoul, Korea

⁴Department of Dermatology, School of Medicine, Ewha Womans University, Seoul, Korea

Background and objectives: Antioxidant intakes such as vitamin A, C and E have been reported to have an inverse association with the prevalence of atopic dermatitis (AD) in epidemiological studies. In order to confirm these findings, we conducted a randomized, double blind, and placebo controlled clinical trial in 109 young children with atopic dermatitis (n = 55 for the control group and n = 54 for the placebo group).

Methods: We developed an antioxidant supplement including vitamin E, vitamin C and β -carotene as a chewable tablet and provided the supplement to SG for 3 months. Placebo tablets were given to the control group children. Nutrient levels of the antioxidant supplement were approximately 30% of the upper levels for Korean young children. Besides the SCORing Atopic Dermatitis (SCORAD) index evaluation, we measured levels of blood antioxidant nutrients (α -tocopherol, β -carotene, and vitamin C), oxidative stress (blood malondialdehyde [MDA] and 8-isoprostane) and immune marker (serum IgE) before and after supplementation.

Results: Antioxidant supplementation had significant effects on increased serum α -tocopherol and β -carotene levels and decreased SCORAD scores ($p < 0.05$). No such effect existed in blood MDA.

Conclusions: These findings suggest that adequate doses of multiple antioxidant supplements may be beneficial for AD in young children.

Key words: atopic dermatitis, antioxidants, SCORAD, supplement, children.

PO2282**MARKERS OF INFLAMMATION ASSOCIATED WITH NAFLD**

R Leis¹, A Gonzalez¹, C Aguilera², Y Olza², M Gil-Campos³, N Martín¹, A Gil², R Tojo¹

¹Department of Pediatrics, University Clinic Hospital of Santiago-Santiago de Compostela University, Santiago de Compostela, Spain

²Department of Biochemistry and Molecular Biology II, School of Pharmacy, Institute of Nutrition and Food Technology, Centre of Biomedical Research, University of Granada, Granada, Spain

³Department of Pediatrics, Hospital Reina Sofía, Córdoba, Spain

Background and objectives: Non alcoholic fatty liver disease (NAFLD) is closely associated with obesity, being this a proinflammatory state. Pro-inflammatory cytokines such as tumor necrosis factor-alpha (TNF-alpha), interleukin-6 (IL-6) and C-reactive protein (CRP) or the antiinflammatory adiponectin, could be critically involved in the pathophysiology of NAFLD. The objective of this work is to study the relation between NAFLD and inflammatory markers.

Methods: We studied 593 children and adolescents, age range 2 to 18 years. NAFLD presence was determined by ultrasound by a single observer. Analytical data were collected assessing CRP by Inmulite 2000 Siemens autoanalyzer, TNF alpha by Inmulite one Siemens autoanalyzer, and adiponectin and IL-6 by radioimmunoassay.

Results: The prevalence of NAFLD in this sample (78.9% present overweight) is 17.8%. Most of children develop the grade I NAFLD (88.5%), 9.5% grade II, and only 1.9% grade III. Children with CRP serum levels above 3mg/l present higher percentage of NAFLD (22.8% vs 15.8%, $p = 0.002$). In relation to IL-6, 78.3% children and adolescents with levels below 7ng/l do not present NAFLD, 19.1% present grade I and only 2.6% of them develop grade II-III. Instead children with IL-6 levels above 7ng/l do not develop NAFLD in a lower percentage (68.7%), being more frequent mild and moderate-severe NAFLD in this group (26.7% and 5% respectively). Other markers such as TNF alpha and adiponectin no statistically significant differences observed regarding NAFLD.

Conclusions: In view of the results could be of interest performing liver ultrasound in children and adolescents with high BMI and high CRP and/or IL-6 levels, in order to diagnose the presence of NAFLD.

Key words: Obesity, cytokines, inflammation, non alcoholic fatty liver disease.

PO2283**KAEMPFEROL ATTENUATES AIRWAY FIBROSIS BY DISTURBING TGF- β 1-PAR-1 SIGNALING IN HUMAN BRONCHIAL EPITHELIAL CELLS AND OVALBUMIN-CHALLENGED MICE***J.H. Gong¹, S.Y. Han¹, Y.H. Kang¹*¹Department of Food Science and Nutrition, Hallym University, Chuncheon, Republic of Korea

Background and objectives: Asthma is characteristic of the structural remodeling of airway epithelium accompanying epithelial damage, mucosal fibrosis, smooth muscle thickening and increased deposition of extracellular matrix components. Airway fibrosis entails epithelial cell modulation and matrix expansion increased submucosal cells expressing the profibrotic cytokine, transforming growth factor (TGF)- β . However, little is known about the localization of lung airway protease activated receptor-1 (PAR-1) and relationship between PAR-1 and epithelial to mesenchymal transition (EMT) in airway fibrosis. This study investigated that kaempferol attenuated airway allergic responses by blocking epithelial PAR-1 signaling activated by lipopolysaccharide (LPS)-associated TGF- β .

Methods: Epithelial BEAS-2B cells were pretreated with 1-20 μ M kaempferol and stimulated with 2 μ g/ml LPS or 10 ng/ml TGF- β 1. BALB/c mice were sensitized with ovalbumin (OVA) and received a single dose of OVA with oral treatment of 10-20 mg/kg kaempferol. Cellular expression of several target gene proteins and matrix proteinase (MMP) activity were determined by Western blot analysis and gelatin zymography, respectively.

Results: Kaempferol nontoxic at 1-20 μ M suppressed the LPS induction of epithelial PAR-1 and TGF- β 1. This compound attenuated TGF- β 1-enhanced MMP-9 secretion and cellular PAR-1 expression. Additionally, the TGF- β 1 induction of mesenchymal marker proteins such as collagen I and smooth muscle α -actin through was attenuated by kaempferol through disturbing PAR1 activation. The epithelial adherence junction protein E-cadherin was substantially induced by treating kaempferol. Oral administration of kaempferol suppressed PAR-1 expression and encumbered smooth muscle cell excrescence in OVA-challenged mice. Therefore, kaempferol inhibited airway wall thickening and EMT via disrupting TGF- β 1-PAR-1 signaling.

Conclusions: The dietary compound kaempferol may be a potent therapeutic agent for preventing airway fibrosis and remodeling due to endotoxin-associated profibrotic cytokine.

Key Words: Kaempferol, asthma, protease activated receptor-1, epithelial cells, ovalbumin.

Acknowledgement: This work was supported by the National Research Foundation of Korea grant funded by the Korea government (2012H1B8A2026122).

PO2284**A BETTER WAY TO REDUCE CARDIOVASCULAR RISK AMONG PATIENTS WITH METABOLIC SYNDROME? STUDY PROTOCOL FOR A HOSPITAL-BASED RANDOMIZED CONTROLLED TRIAL***P. Amarasekara^{1,2}, P. Katulanda², P.A. de Silva³*¹National Hospital of Sri Lanka, Colombo, Sri Lanka²Department of Clinical Medicine, Faculty of Medicine, University of Colombo, Sri Lanka³Department of Physiology, Faculty of Medicine, University of Colombo, Sri Lanka

Background and objectives: Non communicable diseases (NCD's) are the commonest cause of disease burden in Sri Lanka (SL), accounting for 85% of ill- health, disability and early death, contributed by behavioral risk factors leading to metabolic syndrome (MS) and increasing risk of cardiovascular diseases (CVD). Presently, management of NCDs in SL lacks an evidence based, culturally sensitive lifestyle intervention program for patients attending medical clinics. This randomized controlled trial aims to develop and assess effectiveness of a culturally relevant lifestyle intervention program for reduction of cardiovascular risk in urban adults with MS.

Methods: A culturally relevant lifestyle program, including an activity booklet will be designed after a participatory process involving patients, health staff and other stakeholders. N =423 participants with MS will be randomized into 3 groups: Group1 will follow routine care, group2, individually counseled for nutrition and lifestyle modification along with routine care while group3 in addition, will have peer support. The 6 month intervention will consist of individual counseling, peer support groups will complete the activity booklet in the peer group sessions (14- 15 members/group). At baseline and post intervention, participants will undergo an assessment regarding anthropometric measurements (weight, height, waist and hip circumference), medication, and blood pressure. Biochemical parameters; Fasting Blood sugar, HbA1c, lipid profile, liver function and inflammatory status will be assessed and knowledge, attitudes and practices regarding CVD risk, and dietary practices will be recorded.

Results: Outcomes of the study will indicate effectiveness of routine practice, individual dietary counseling with or without peer support in reducing chronic disease and CVD risk.

Conclusions: If culturally appropriate individual counseling and clinic based peer support is proved to be effective, it will be an invaluable tool in controlling and reducing MS and CVD risk.

Key words: randomized controlled trial, peer support, metabolic syndrome, cardiovascular risk, protocol.

PO2285**SOY FIBER IMPROVES WEIGHT LOSS AND LIPID PROFILE IN OVERWEIGHT AND OBESE ADULTS: A RANDOMIZED CONTROLLED TRIAL**

X. Hu¹, J. Gao¹, Q. Zhang¹, Y. Fu¹, K. Li¹, S. Zhu¹, D. Li¹

¹Zhejiang University, Zhejiang, China

Background and objectives: Studies have suggested that food rich in dietary fiber may facilitate body weight loss, lower total and low-density lipoprotein cholesterol levels, and reduce body fat. However, few clinical trials have explored whether soy fiber contributes to weight loss and improves lipid profile of overweight and obese participants. The aim of this study was to examine the effects of soy fiber on body weight, body composition and blood lipids in overweight and obese participants.

Methods: Thirty nine overweight and obese college adults (19-39 y) were randomly assigned to consume control biscuits or biscuits supplemented with soy fiber for 12 weeks (approximately 100g/d).

Results: Body weight, body mass index, waist circumference, diastolic blood pressure, serum levels of total cholesterol, low density lipoprotein cholesterol and glucose of participants in soy fiber group were decreased significantly over the study period compared with the baseline. Body fat ($P < 0.05$) and trunk fat ($P < 0.01$) of participants in soy fiber group were also lowered significantly at week 12 than that of baseline.

Conclusions: Soy fiber had favorable effects on body weight, blood pressure, fasting lipid levels and body fat in overweight and obese adults. These effects may be beneficial in anti-obesity and the improvement of hyperlipidemia and hypertension.

Key words: soy fiber; weight loss; body fat; overweight; obesity.

PO2286**CALCIUM INTAKE IN SPANISH ADOLESCENTS IS RELATED WITH THEIR LEVEL OF BONE MINERAL DENSITY**

B. Rueda^{1,2}, M. Correa-Rodriguez², E. Delgado-Rico³, C. Flores-Navarro², R. Montoya-Juarez^{R1}, J. SchmidtRio-Valle¹

¹Department of Nursing, Granada Health Sciences Faculty, University of Granada, Granada, Spain

²University of Granada, Granada, Spain

³Department of Personality, Evaluation and Psychological Treatment, University of Granada, Granada, Spain

Background and objectives: Osteoporosis is considered one of the most prevalent chronic diseases caused by a misba-

lanced equilibrium between bone formation and bone resorption mechanisms. It is essential to optimize calcium intake during growth in childhood and adolescence since in this period around a 40% of total bone mass is gathered. The aims of this study were evaluate bone mineral density (BMD) in adolescents and the influence of daily calcium intake in their BMD levels.

Methods: A total of 170 Spanish healthy adolescent (11-18 years) at secondary school were included in the study. Calcium daily intake was assessed using a 72h-recall. BMD was evaluated through a dual-energy X-ray absorptiometry (DEXA) measurement at both calcanei. Data analysis was performed using the SPSS software.

Results: Calcium daily intake was insufficient according to RDA recommendations for adolescent population (medium intake in study population 913.58 mg). After analyze the levels of BMD we found that a 27.4% of adolescents included in the study showed low levels of BMD in both legs (T-score less than -2.5 SD). Interestingly we observed a statistically significant relation between BMD levels and daily Ca intake ($p < 0.0001$).

Conclusions: Our results reveal that the percentage of healthy adolescents at risk of osteoporosis is worrying. In addition, we observe that low daily Ca intake is related with low levels of BMD.

Key words: calcium intake, bone mineral density, adolescent.

Acknowledgements: This work was supported by grant of the "Campus de Excelencia Internacional Proyecto GREIB", subprogramme START-UP PROJECTS FOR YOUNG RESEARCHERS (GREIB.PYR_2011_27)

PO2287**BONE MINERAL DENSITY AND PHYSICAL ACTIVITY ARE RELATED IN SPANISH ADOLESCENTS**

J. SchmidtRio-Valle^{1,2}, C. Flores-Navarro², E. González-Jimenez³, M. Correa-Rodriguez², E. Delgado-Rico⁴, B. Rueda¹

¹Department of Nursing, Granada Health Sciences Faculty, University of Granada, Granada, Spain

²University of Granada, Granada, Spain

³Department of Nursing, Melilla Nursing Faculty, University of Granada, Granada, Spain

⁴Department of Personality, Evaluation and Psychological Treatment, University of Granada, Spain

Background and objectives: Levels of bone mineral density (BMD) in adolescence is of great relevance to prevent osteoporosis in adult age. However, only a few studies have been performed to evaluate the bone mineral density in healthy ado-

lescents and none of them has assessed the relation between BMD and physical activity level. The aims of this study were to evaluate BMD in a group of healthy adolescents and investigate the influence of physical activity in BMD levels.

Methods: Study population was composed of a total of 227 healthy adolescents (12-17 years) recruited in three secondary schools from Granada (Spain). Physical activity levels were assessed with the validated questionnaire "Kreca-Plus". BMD was evaluated through a dual-energy X-ray absorptiometry (DEXA) measurement at both calcanei. Data analysis was performed using the SPSS software.

Results: Statistically significant differences were found when analyzing physical activity levels by gender (good physical activity levels in boys 33% compared to 23% in girls; $p = 0.001$). Most of adolescents included in the study showed good levels of BMD, however we observed that the number of girls with BMD levels at osteopenia was double than in boys ($p = 0.009$).

Conclusions: Our results suggest that physical activity level could influence BMD acquisition, since the worse level of physical activity in girls seems to correlate with worse levels of BMD (osteopenia).

Key words: physical activity, bone mineral density, adolescence.

Acknowledgements: This work was supported by grant of the "Campus de Excelencia Internacional Proyecto GREIB", subprogramme START-UP PROJECTS FOR YOUNG RESEARCHERS (GREIB.PYR_2011_27)

PO2288

IMPACT OF OBESITY AND PHYSICAL INACTIVITY ON FASTING BLOOD GLUCOSE, LIPID PROFILE AND HOMEOSTATIC MODEL ASSESSMENT (HOMA) AMONG CHILDREN

N. Aboul Ella¹, D. Shehab¹

¹National Nutrition Institute, Cairo, Egypt

Background and objectives: Obesity in children seem to be on the rise to become a significant public health problem. Excess adiposity is more than just a cosmetic problem, having substantial metabolic consequences. Insulin resistance, hyperinsulinemia, impaired fasting glucose, and frank diabetes are often seen in obese children. Aim of the study is to illustrate the impact of overweight and obesity on fasting blood glucose level and lipid profile among children, to test for the presence of insulin resistance among those with glucose and lipid disorders and to clarify the association between overweight, obesity in one hand and physical inactivity and bad dietary habits on the other hand.

Methodology: A cross sectional study included 200 child aged 2 -12 years was done to screen for plasma glucose, lipid profile and insulin abnormalities. They were assessed by interview questionnaires, anthropometric measures and by measuring their fasting blood glucose and plasma lipid levels.

Results: The risk for having high triglycerides and low HDL levels is more than double among obese children compared to non-obese. Physically inactive children have 7.8 times the risk for obesity compared to active children. Significant high percentages among obese as regards prediabetes state and insulin resistance. The consumption of unhealthy snacks was higher than vegetables and fruits regardless of BMI.

Conclusions: High BMI predisposes children to many of the medical complications of obesity found in adults, in particular components of insulin resistance syndrome: High HOMA-IR, dyslipidemia, and impaired glucose metabolism. Health care providers of overweight children need to pursue efficient screening procedures earlier in the progression of overweight in order to prevent children from developing type 2 DM and cardiovascular diseases.

Key words: screening, risk factors, fasting blood glucose, lipid profile, insulin resistance, HOMA, children

PO2289

HYPOVITAMINOSIS D AND OBESITY

R. Leis¹, C. Mota¹, C. Aguilera², Y. Olza², M. Gil-Campos³, A. Gil², R. Tojo¹,

¹Department of Pediatrics, University Clinic Hospital of Santiago-Santiago de Compostela University, Santiago de Compostela, Spain

²Department of Biochemistry and Molecular Biology II, School of Pharmacy, Institute of Nutrition and Food Technology, Centre of Biomedical Research, University of Granada, Granada, Spain

³Department of Pediatrics, Hospital Reina Sofía, Córdoba, Spain

Background and objectives: Obesity is a first order sanitary problem and the most frequent nutritional disorder in developed countries during the infancy and the adolescence.

The aim of the present study is to analyze the relation between the levels of vitamin D and the degree of obesity in a sample of children and teenagers from the northwest of Spain.

Methods: This is an observational, descriptive and cross sectional study performed in 466 children and adolescents evaluated in the Pediatric Nutrition Unit of a tertiary hospital, aged between 1.1 and 18.5 years. Those with vitamin D metabolism altered were excluded. The variables studied were weight, height, body mass index (BMI) and vitamin D (25(OH)

D) levels. Patients were stratified according to their BMI, following Cole's international standards. Serum calcidiol levels were determined by immunoassay, defined as suitable for cellular health (>30 ng/mL), suitable for bony health (>20 ng/mL), insufficiency (15-20 ng/mL) and deficiency (<15 ng/mL).

Results: 25 (OH) D levels are negatively correlated with BMI ($p = 0.005$), so that the risk of hypovitaminosis D is increased in case of obesity. Serum calcidiol levels are significantly lower in obese subjects than in not obese ones (26.51 ± 14.65 ng / mL vs 32.30 ± 18.91 ng / mL, $p = 0.023$). 20.4% of children and teenagers with obesity present 25(OH)D levels <15 ng/mL, opposite to 14 % of those with suitable weight. By contrast, the percentage of children with 25(OH)D >30ng/mL is lower in obese children (30.1 % vs 43.9 %).

Conclusions: Obesity seems to be a risk factor of hypovitaminosis D, and for not reaching the recommended levels that ensure cellular health. Therefore, we believe it would be interesting to determine vitamin D levels in obese children and adolescents, in order to establish appropriate intervention strategies.

Key words: Obesity, hypovitaminosis D, cellular health.

PO2291

PREDICTORS OF WEIGHT LOSS AND/OR WEIGHT LOSS MAINTENANCE: AN INTERNET BASED SURVEY

K. Myrissa^{1,2}, L. Dye¹, A. Gusnanto², R. Danks¹, C. Lawton¹

¹Institute of Psychological Sciences, University of Leeds, Leeds, UK

²School of Mathematics, University of Leeds, Leeds, UK

Background and objectives: Overweight and obesity are amongst the major public health problems in our society affecting 30-80% of people in Europe with health care costs rising to £50 billion per year by 2050 in the UK alone. Current interventions are ineffective in the long term with most people regaining their weight loss within 5 years. Relapse is often due to poor behavioral adherence but predicting those susceptible to relapse is difficult. This study aimed to identify predictors of weight loss and/or weight loss maintenance in free-living individuals (male and female) who have previously attempted to lose weight using dietary, exercise, behavioral or other methods.

Methods: Over 500 participants completed an online survey which recorded demographic characteristics, details of weight loss strategies and body weight trajectory over the previous 6 months following dieting attempts. Validated psychological questionnaires to assess psychological and behavioral traits and eating behavior and diet satisfaction were completed.

Results: The relative contributions of individual, behavioral and psychological characteristics, which predict weight loss and/or weight loss maintenance were examined using multiple regression and structural equation modelling techniques. Body shape perception, eating behavior traits, diet satisfaction, depression, anxiety, stress and dichotomous thinking style were predictors of weight loss and /or weight loss maintenance with complex interactions depending on the weight loss methods, age and gender.

Conclusions: Obesity is a heterogeneous condition and different physiological, environmental and psychological factors interact to predict post intervention weight trajectory. Improving a person's ability to lose weight and prevent weight gain in the long term remains a major challenge. Identifying the predictors of weight loss and/or weight loss maintenance will enable prescription of tailored interventions with greater likelihood of long term success.

Key words: weight loss, predictors, psychological characteristics, internet survey.

PO2292

ANTHROPOMETRIC EVOLUTION IN PEDIATRIC PATIENTS TREATED WITH HOME ENTERAL NUTRITION

P. Malillos^{1,2}, C. Pedrón-Giner¹, C. Calderón², M A. Salmerón³, V. Almazán⁴, A.I. Jiménez¹, A.B. Martínez-Zazo¹

¹Division of Pediatric Gastroenterology and Nutrition, Hospital Infantil Universitario Niño Jesús, Madrid, Spain

²Department of Personality, Assessment and Psychological Treatment, Faculty of Psychology, University of Barcelona, Barcelona, Spain

³Department of pediatrics, Hospital Universitario La Paz, Madrid, Spain

⁴Department of pediatrics, Centro de Salud de Maracena, Granada. Spain

Background and objectives: Home enteral nutrition (HEN) is an important treatment for children with chronic diseases or feeding problems. It is a safe and effective therapy that may improve weight and growth. Our objectives were to describe the characteristics of pediatric patients requiring HEN and analyze the improvement in weight gain, by body mass index (BMI)-forage Z-score, and improvement in growth, by height-for-age Z-score after treatment.

Methods: All patients under 18 years old requiring treatment with HEN between January 1995 and December 2004 were analyzed retrospectively.

Results: Two hundred seventy-six patients were studied. The mean age at the start of treatment was 4.04±4.07 years, median of 2.5 years. 104 patients (37.7%) were younger than 18 months. The most common indications were oncological disease in 87 patients (31.5%), followed by digestive disease in 82 (29.7%) and neurological disorders in 53 (19.2%). The mean duration of support was 293±530 days. Nutrients were delivered mainly by nasogastric tube in 202 patients (74%). All patients improved their BMI with a statistically significant increase ($F = 20,847$, $p = 0.0001$). The mean BMI for-age Z-score at baseline was -1.26 (SD = 1.94), and at the end of treatment was -0.50 (SD = 1.67). Height for age Z-score at baseline was -1.33 (SD = 1.74), and at the end was -1.10 (SD = 1.84), height improved in all patients ($F = 13,406$, $p = 0.0001$). Both, Z-BMI and Z-height increases were associated with the duration of the support. Z-BMI changes were similar in all diagnostic groups but in Z-height we observed variations depending on the diagnosis.

Conclusions: The longitudinal anthropometric assessment conducted after the implementation of HEN shows a statistically significant increase in the height and BMI Z-scores for age.

Key words: home enteral nutrition, children, body mass index, height.

PO2293

DOWNREGULATION OF EPIDERMAL GROWTH FACTOR RECEPTOR BY CURCUMIN-INDUCED UBE1L IN LUNG CARCINOGENESIS

Q. Feng¹, A. Jiang¹, D. Zhou¹, X. Meng¹, A. Zhang², C. Zhang²

¹Department of Nutrition and Food Safety, School of Public Health, Nanjing Medical University, Nanjing, China

²Department of cardiothoracic surgery, Nanjing first hospital, Nanjing Medical University affiliated hospital, Nanjing, China

Background and objectives: UBE1L, ubiquitin activating enzyme E1-like, is the activating enzyme of ISG15ylation. Loss of UBE1L and activation of epidermal growth factor receptor (EGFR) signaling are common events in lung carcinogenesis. Curcumin, known as a chemopreventive agent, was able to down-regulate EGFR. In the present study, a novel chemopreventive mechanism of curcumin was explored as curcumin could UBE1L which down-regulated EGFR and its downstream signaling in lung carcinogenesis.

Methods: Human bronchial epithelial (HBE) Beas-2B cells and lung cancer A549 cells were used as the cell models. Immunoblot analysis and reverse transcription-polymerase chain reaction was used to measure the EGFR and other protein and

mRNA expression respectively. Immunoprecipitation and pull down analysis were used to detect the ISGylation. Transient transfection of UBE1L and siRNA targeting UBE1L were for overexpression and knockdown of UBE1L. EGFR internalization analysis was performed. Lung cancer tissues and adjacent tissues were collected from patients. The relative proteins expressions in the tissues were analyzed.

Results: Curcumin decreased EGFR expression in HBE Beas-2B cells and A549 cells. For the first time, UBE1L was found to be induced by curcumin in HBE cells. Interestingly, overexpression of UBE1L reduced EGFR at post-translational level in HBE cells. UBE1L triggered EGFR membrane internalization and promoted a complex between ISG15 and EGFR. Curcumin decreased EGFR downstream signaling pAKT and NF-κB. Overexpression or knockdown of UBE1L also resulted in down-regulation or up-regulation of PI3K/AKT/NF-κB correspondently. There was a reverse relationship between UBE1L and EGFR-AKT-NF-κB in non-small cell lung cancer tissues and adjacent tissues.

Conclusions: These results uncover a novel chemopreventive mechanism of curcumin which induce UBE1L and downregulate EGFR signaling in HBE and lung cancer cells.

Key Words: Curcumin; UBE1L; EGFR.

PO2294

PREVALENCE AND FACTORS ASSOCIATED WITH OVERWEIGHT AND OBESITY AMONG HIV-INFECTED PATIENTS IN DAR ES SALAAM, TANZANIA

H. Semu^{1,6}, E. Liu², J. Ye³, E. Hertzmark³, K. Sztam⁵, R. Zack⁴, A. Muya⁶, G. Chalamila⁶, H. Siril⁶, C. Hawkins⁷, R. Mwiru⁶, D. Spiegelman³, D. Mtasiwa¹, W. Fawzi^{2,4}

²Department of Nutrition, Harvard School of Public Health, Boston, Massachusetts, USA

³Department of Biostatistics, Harvard School of Public Health, Boston, Massachusetts, USA

⁴Department of Epidemiology, Harvard School of Public Health, Boston, Massachusetts, USA

⁵Clinical Nutritional Service, Division of GI/Nutrition, Childrens Hospital, Boston, Massachusetts, USA

⁶Management and Development for Health (MDH), Dar es Salaam, Tanzania

⁷Northwestern University, Feinberg School of Medicine, Chicago, IL, USA

Background and objectives: Overweight and obesity are increasingly prevalent among HIV-infected populations in Sub-Saharan Africa. We describe the prevalence of overweight

and obesity, and associated risk factors, among HIV-infected adults in Dar es Salaam, Tanzania.

Methods: A cross-sectional study of HIV-infected adults was conducted at enrollment into the Harvard PEPFAR-supported Management and Development for Health (MDH) HIV care and treatment program from 2004-2011 to determine the proportion of patients who were overweight or obese. Multi-variable relative risk regression models were fit to identify risk factors.

Results: 53,825 patients were included in the analysis. Median age was 35 years, median BMI was 22, and 69% were female. The proportion of women and men who were overweight was 21% and 12% and obese was 9% and 3%, respectively. 47% of the overweight and obese patients had CD4+ cell counts < 200 cells/mm³ and 58% had WHO HIV stage III or IV. In multivariable analyses, compared to patients aged <30, the prevalence ratios for obesity among patients aged 30-<40, 40-<50, and >50 were 2.0 (95%CI: 1.8-2.2), 3.0(95%CI: 2.7-3.3) and 3.2(95%CI: 2.8-3.7), respectively (P for trend < 0.0001). Compared to men, women had an almost 5-fold increased risk of obesity. CD4+ cell count and hemoglobin were positively associated with obesity and overweight and WHO HIV disease stage was negatively associated with obesity and overweight.

Conclusions: Overweight and obesity were highly prevalent among HIV-infected patients. Given the adverse health consequences associated with obesity, screening for overweight and obesity and focused interventions should be integrated into routine HIV care.

Key words: obesity, overweight, HIV.

PO2295

LIQUIRITIGENIN INHIBITS SERUM-INDUCED HIF-1 α AND VEGF EXPRESSION VIA THE AKT/MTOR-P70S6K SIGNALLING PATHWAY IN HELA CELLS

X. Si-Rou¹, W. Yu¹, L. Chang-Wei¹, L. Kang¹, C. Yun-Qing¹

¹Department of Nutrition and Food Hygiene, School of Public Health, Nanjing Medical University, Nanjing, China

Background and objectives: Tumor angiogenesis plays an important role in the tumor growth, invasion and metastasis. Abundance studies have demonstrated that many flavonoids have antiangiogenesis effects. Liquiritigenin(LQ) is a flavanone existed in Radix glycyrrhizae glycyrrhizae, with the polyphenolic structure. The objective was to investigate the anti-angiogenesis effects of LQ on angiogenic growth factors VEGF and HIF-1 α in human cervical carcinoma (HeLa) cells and study the mechanism of the effects on the gene expression and PI3K/AKT/mTOR-p70S6K and ERK1/2 pathways.

Methods: RT-PCR was used to detect mRNA levels of VEGF and HIF-1 α . The protein levels of VEGF, HIF-1 α , PI3K/

AKT/mTOR-p70S6K and ERK1/2 pathways were detected by western blot, and the degradation and synthesis of HIF-1 α protein were detected.

Results: (1) HeLa cells were treated with LQ (25, 50, 75 and 100 μ M) for 12h, the expression of VEGF at the protein and mRNA levels were both decreased, and the HIF-1 α protein accumulation was inhibited, but no obvious effects on HIF-1 α mRNA were observed. (2) HeLa cells were treated with cycloheximide (CHX) or proteasome inhibitor MG132, LQ reduced HIF-1 α protein accumulation by reducing its stability and decreasing its synthesis. (3) LQ inhibited the PI3K/AKT/mTOR-p70S6K pathway in HeLa cells. To further confirm the result, HeLa cells pretreated with PI3K inhibitor LY294002 and p70S6K inhibitor Rapamycin, respectively, the expression of VEGF and HIF-1 α which mediated by PI3K/AKT/mTOR-p70S6K pathway were also decreased. The results were consistent with the previous study, but there was no obvious inhibitory effect on ERK1/2.

Conclusions: LQ inhibited angiogenic growth factors VEGF and HIF-1 α expression in HeLa cells and the molecular mechanism was related to PI3K/AKT/mTOR-p70S6K signaling pathway.

Key words: Liquiritigenin (LQ), VEGF, HIF-1 α , PI3K/AKT/mTOR-p70S6K.

PO2296

FEEDING PROBLEMS OF THE DIABETICS AND ITS IMPLICATIONS IN THE TREATMENT OF DIABETES IN IDEMILI NORTH L.G.A OF ANAMBRA STATE, NIGERIA.

N. Anene^{1,2}, O. Ifebi²

¹Nutrition Society of Nigeria, Nigeria

²Federation of African Nutrition Societies, Ibadan, Nigeria

Background and objectives: Obtaining information on the knowledge and practices of a target group is essential for the development of effective health education programs. This study was conducted to investigate the feeding problems of the diabetic patients and its implications in control and management of diabetes in Idemili North Local Government Area of Anambra State, Nigeria.

Methods: Selected towns and hospitals were visited and questionnaires were administered personally to the respondents and collected back after completion. Data on feeding pattern of diabetics, types of food eaten and problems encountered with their feeding practices were captured. Interpretation of data was done using percentage, mean for score percentage. Monte Carlo proportion was used to compare right answers.

Results: The result shows that the major problems the respondents encounter with their feeding is the high cost of their food items (100%), 90% indicate that the foods are seasonal, 50% indicate that the foods are scarce in the market, 83.3% indicated that the foods needed are highly perishable and 40% indicate that some foods are not easily prepared. Seventy-seven percent (77%) admitted that the guide or advice was given them by a medical doctors, 4% by pharmacist; 14% by dietitian while 5% by nutritionist. Nineteen percent (19%) of the respondents reported that they had been seen by dietitians or nutritionist while 81% had never been seen since their diagnosis. 100% of the foods listed in the questionnaire were taken without restriction, because they were not properly guided they eat whatever they believed was good for them.

Conclusions: Findings of the study suggest the need for health education programs by Nutritionist, taking care to reach the grassroots disseminating information on the importance of meeting the Nutritionist and Dietitians for proper diet guides on how to make the food items readily available.

Key words: Diabetes, Nigeria, health education.

PO2297

NUTRITIONAL STATUS ASSESSMENT OF CELIAC CHILDREN FROM THE BASQUE COUNTRY

A. Lasa¹, M A. Bustamante¹, J. Miranda¹, E. Simón¹, I. Churruga¹

¹Gluten Analysis Laboratory, Dpt. Nutrition & Food Sciences, Faculty of Pharmacy, University of the Basque Country (UPV/EHU), Vitoria, Spain

Background and objectives: Celiac disease is a common digestive disorder that appears at any age from childhood onward. The only effective treatment consists on a lifelong strict gluten-free diet, which can affect the nutritional status and growth of celiac children. Thus, we aimed to assess the nutritional status of celiac children by analyzing their body and diet composition.

Methods: 32 celiac children, up to 14 years (8.2±2.7 years), from Basque Autonomous Community were recruited. Height, weight and body composition (by electrical impedance) were measured. Children completed three pass 24-hour dietary recalls and energy consumption and macronutrient distribution of their diet were analyzed.

Results: Celiac infants presented a BMI=17.3±2.5 kg/m². Nobody was obese, most of the children were under P50 and 91% within normality ranges (P15-P85). Although only 9% of them had a high value of BMI, when fat mass was measured more than 20% (n = 7) of the infants had an excess of fat mass (> 25%). With regard to diet composition, the majority of participants met the recommendations of energy intake (2029±465

kcal). Macronutrient distribution was as follows: protein intakes slightly exceed distribution ranges (16.2±2.1%), carbohydrate intake was insufficient (43.0±4.9%) and high fat intakes (40.7±4.3%) were observed. Dietary cholesterol was very high (284±93 mg) in the vast majority of children.

Conclusions: Body weight and fat mass were slightly lower than those observed for general population. Overall, children from this study did not meet recommendations of the balanced diet, mainly due to insufficient carbohydrate intake. Thus, specific tools for nutritional education need to be developed in order to improve eating habits and nutritional status among celiac children.

Key words: celiac, body composition, macronutrient distribution.

PO2298

EVALUATION OF BODY COMPOSITION AND DIETARY BEHAVIOUR IN ADULT CELIAC WOMEN FROM THE BASQUE COUNTRY

J. Miranda¹, M A. Bustamante¹, A. Lasa¹, I. Churruga¹, E. Simón¹

¹Gluten Analysis Laboratory, Dpt. Nutrition & Food Sciences, Faculty of Pharmacy, University of the Basque Country (UPV/EHU), Vitoria, Spain

Background and objectives: Celiac disease is one of the most common digestive disorders in Western countries. The only current treatment for this disease consists on a lifelong strict gluten-free diet (GFD), which can often represent an unbalanced diet. Thus, we aimed to evaluate the nutritional status of a group of adult celiac women following a GFD, by anthropometric and food consumption analyses.

Methods: 47 adult celiac women from the Basque Country took part in the study (age=37±12 years). Weight and height were measured. Bioelectrical impedance was used for body composition analysis. Food Frequency Consumption Questionnaires were collected from each patient.

Results: Celiac women showed a BMI=21.6±2.4kg/m² and none of the analyzed patients were obese. Body weight and body fat mass were inside the normality ranges for most of them (87% and 73% respectively). With regard to food consumption, dairy products and fruit intakes met the recommendations of an equilibrated diet. 79% of the women consumed an excessive amount of meat portions/week and only half of the patients ate enough fish. Gluten free cereals or gluten-free rendered foods consumption was very low (47% consumed less than 2 portions/day). Whereas vegetables consumption was not enough, legume consumption was higher than that observed in the Spanish population (2 portions/week) in 2/3 of the patients. Nevertheless, dietary fiber consumption was very low (16.4±5.7g/day).

Conclusions: Celiac women showed a lower body weight and fat mass, and thus lower obesity incidence, when compared to the general population. Although a wide diversity of gluten free cereals exists in the market, the consumption of these foods, and thus that of complex carbohydrates, was very low in the studied patients. Thus, strategies for nutritional education need to be developed in order to improve eating habits among adult celiac women.

Key words: Body composition, Celiac, Food Consumption.

PO2299

EFFECT OF ALMOND SUPPLEMENTATION ON THE CARDIO-VASCULAR RISK FACTORS IN TYPE 2 DIABETES

S. Gulati^{1,2,3}, A. Misra^{1,2,3,4,5}

¹Diabetes Foundation (India), New Delhi, India

²National Diabetes, Obesity and Cholesterol Diseases Foundation (N-DOC), New Delhi, India

³Center of Nutrition & Metabolic Research (C-NET), New Delhi, India

⁴Ortis C-DOC Center for Excellence for Diabetes, Metabolic Disease and Endocrinology, New Delhi, India

⁵Fortis Ft. Lt. Rajan Dhall Hospital, Center for Internal Medicine, New Delhi, India

Background and objectives: Asian Indians are at a high risk for development of the metabolic syndrome and type 2 diabetes mellitus (T2DM). Cost effective strategies focusing on correct nutrition can help in lowering the cardio-vascular risk factors. Some studies indicate beneficial effect of almond supplementation on human health. However, no data is available on use of almonds in dyslipidemia and T2DM among Asian Indians. Hence, the present study was planned to investigate the effect of almond supplementation along with lifestyle management (including energy controlled diet) on cardio-vascular risk factors of Asian Indians with T2DM.

Methods: This prospective twenty four-week observational cohort study was conducted in 50 T2DM patients (LDL-C levels > 100 mg/dL) in New Delhi, India. The intervention was preceded by a diet and exercise run-in period of 3 weeks. All the patients were followed up for 6 months to study the long term effects of almond supplementation. Raw almonds (20% of energy intake) were provided to the patients for consumption along with diet and physical activity counseling. Patients were assessed for anthropometry, blood pressure, measures of glycaemia (fasting blood glucose (FBG), glycosylated hemoglobin (HbA1C), lipids [total cholesterol (TC), triglycerides (TG), high density lipoprotein cholesterol (HDL-c), low density li-

poprotein cholesterol (LDL-c), lipoprotein (a) (Lp (a))], fatty liver, surrogate marker of atherosclerosis (Pulse Wave Velocity), and marker of inflammation (hs-CRP) at baseline and after intervention period.

Results: Statistically significant difference in mean values for various parameters and percent improvement post intervention were as follows: WC (p < 0.03, 1.6%), waist-to-height ratio (p < 0.005, 1.6%), TC (p < 0.002, 6.9%), TG (p < 0.004, 12.3%), glycosylated hemoglobin (p < 0.4, 5.2%) and hs-CRP (p < 0.01, 20%). Remarkable improvement was observed for pulse wave velocity (p < 0.06, 3.7%) post intervention.

Conclusions: Intervention with almonds led to reduction in cardio-vascular risk factors in Asian Indians with T2DM.

Key words: CVD, almonds, Indians, T2DM.

PO2300

DETECTION OF S-(2-SUCCINYL) CYSTEINE (2SC) IN ADIPOCYTES AND IN SERUM BY LC-MS/MS AS A MARKER FOR ADIPOSE TISSUE METABOLISM

i. Nagai¹, J.I. Shirakawa¹, M. Nagai¹

¹Tokai University, Kanagawa, Japan

Background and objectives: S-(2-Succinyl) cysteine (2SC) is formed by reaction between thiol group of proteins and fumarate of the Krebs cycle intermediate, a process termed succination of protein. We previously demonstrated that 2SC significantly increased during maturation of 3T3-L1 fibroblasts to adipocytes. Fumarate concentration increased > 5-fold during adipogenesis in medium containing 30 mM glucose, producing a > 10-fold increase in 2SC-proteins in adipocytes compared with undifferentiated fibroblasts grown in the same high glucose medium. Furthermore, several of the prominent and well resolved proteins such as adiponectin, cytoskeletal proteins, enzymes, heat shock and chaperone proteins were identified by matrix-assisted laser desorption ionization time-of-flight/time-of-flight mass spectrometry. However, little is known about the presence of 2SC in serum. In the present study, we have measured 2SC level by liquid chromatography tandem mass spectrometry (LC-MS/MS) in serum.

Methods: Murine fibroblasts (3T3-L1) were cultured on 10-mm plates in basal Dulbecco's modified Eagle's medium containing 5 mM D-glucose supplemented with 10% fetal bovine serum. Differentiation of confluent fibroblasts into adipocytes was induced by the addition of dexamethasone, 3-isobutyl-1-methylxanthine, insulin, and glucose in complete culture medium for 2 days. This mixture was then replaced with basal medium containing a 25 mM glucose and insulin for a further 2-8 days. Human serum was hydrolyzed in 6 M hydrochloric acid at 100 °C for 24 h. The samples were dried in vacuo, and brown materials were removed by application to a

C-18 Sep Pak column, followed by elution of polar amino acids with H₂O and then analyzed by LC-MS/MS on a TSQ Vantage (ThermoFisher Scientific).

Results: 2SC was detected in human serum as well as matured adipocytes by LC-MS/MS.

Conclusions: This result demonstrates that the metabolic condition of adipocyte could be estimated by measuring 2SC in serum sample.

Key words: Adipocyte, obesity, diabetes, succination, post-translational modification.

PO2301

THE EFFECT OF COMBINATION OF LAURIC AND OLEIC ACIDS ON LIPOTOXICITY

Y. Kitaura¹, K. Inoue¹, N. Kato¹, N. Matsushita¹, Y. Shimomura¹

¹Graduate School of Bioagricultural Sciences, Nagoya University, Nagoya, Japan

Background and objectives: Long-chain saturated fatty acids such as palmitic acid (PA) have been reported to induce cell death (lipotoxicity), which is attenuated by supplementation of unsaturated fatty acids such as oleic acid (OA). Medium-chain saturated fatty acids such as lauric acid (LA) have little effect on lipotoxicity which is promoted by OA, however it is unclear how the combination of LA with OA induces cell death.

Methods: Fatty acids (LA with OA, or PA alone)-induced cell death of human fibrosarcoma-derived HT1080, lymphoma-derived Jurkat and hepatoma-derived HepG2 cells were analyzed by MTT assay. The reactive oxygen species (ROS) production, mitochondrial depolarization, caspase-3 activation and lipid droplet formation of these cells were detected by using fluorescent probe or substrate, and the fluorescent intensities in each cells were analyzed by flow cytometry. Fatty acid uptake was analyzed by counting intracellular ¹⁴C-fatty acid.

Results: The treatment of LA with OA dramatically decreased the cell viabilities of several cell lines (Jurkat, HepG2, HT1080). While the cell death accompanies ROS production, mitochondrial depolarization, caspase-3 activation in Jurkat cells, they were not seen in HepG2 and HT1080 cells. The lipid droplet formation was increased in all these cells by LA with OA but not PA alone. LA also markedly promoted uptake of OA.

Conclusions: These results suggest that LA increase the uptake of OA and the excess amount of intracellular OA induce cell death by lipotoxic stress response which vary by cell type.

Key words: Fatty acid, lipotoxicity, combination.

PO2302

INSULIN RESISTANCE IN GLUCOSE TOLERANT OBESE ADOLESCENTS ARE ASSOCIATED WITH INCREASED LEVEL OF PLASMA HSCRP AND URIC ACID

A. Bukhari^{1,2}, I. Patellongi², I. Idris², N. Astuti¹, H. Hasanuddin³, M. Limbong⁴, R. Mahmud⁵, S. Hamsinah⁶, S. Saminah⁷, T. Damayanti⁸

⁴STIKES YAPMA Makassar, Indonesia

⁵AKPER Muhammadiyah, Makassar, Indonesia

⁶STIKES FAMIKA, Makassar, Indonesia

⁷Syekh Yusuf Hospital, Sungguminasa, Indonesia

⁸Bhayangkara Nursery School, Makassar, Indonesia

Background and Objectives: The increasing prevalence of insulin resistance and obesity has also affected adolescent. This study aimed to compare the level of insulin resistance and metabolic disorder indicators between obese and non-obese male adolescent.

Methods: Thirty nine male Indonesian adolescent students with no family history of type 2 diabetes were enrolled in this study. They were classified as obese, overweight, and normal weight according to International criteria. After a 12-h overnight fast, blood vein was taken for measurement of fasting blood glucose, insulin, hsCRP, uric acid, and antioxidant status (AOS) and OGTT was performed.

Results: Of 39 subjects 9 were obese, 16 were overweight and 14 were normal weight. Obese subjects were clearly insulin resistant compare to overweight and normal weight subjects evidenced by higher insulin level with value of 14.177 ± 6.921 , 6.55 ± 4.72 , and 4.48 ± 4.51 respectively ($p < 0.001$) and higher HOMA-IR i.e., 2.66 ± 1.464 , 1.193 ± 0.891 , and 0.607 ± 0.347 respectively ($p < 0.001$). Interestingly, these were associated with significant higher level of hsCRP and uric acid in obese subjects. Level of hsCRP in obese, overweight, and normoweight subjects were 2.32 ± 2.23 , 1.10 ± 0.43 , and 0.56 ± 0.40 respectively ($p < 0.003$). Whereas uric acid level for obese, overweight, and normal weight subjects were 7.406 ± 1.3025 , 6.878 ± 1.1959 , and 5.704 ± 1.0406 respectively ($p < 0.001$). The values of 2 h-pp blood glucose level during OGTT in obese, overweight, and normal weight subjects were 96.90 ± 17.38 , 98.92 ± 17.49 , and 90.65 ± 14.46 respectively ($p < 0.433$). Similarly, insignificant difference of AOS was observed between obese, overweight, and normal weight subjects with value of 1.98 ± 0.34 , 1.96 ± 0.33 , and 1.99 ± 0.35 respectively ($p = 1.232$).

Conclusions: There was a clear association between high IMT with insulin resistance markers and increased plasma uric acid level and are moreover associated with increased level of

plasma hsCRP in male adolescents with normal glucose tolerance.

Key words: adolescents, obesity, insulin resistance, hsCRP, Uric acid.

PO2303

OBESITY AND MASTICATORY EFFICIENCY

C H. Malek-Zadeh¹, C N. Ferreira¹, M. Palinkas², P B. Vasconcelos², W. Mestriner-Junior³, S C H. Regalo², J S. Marchini¹, C B. Nonino¹

¹Department of Internal Medicine, Faculty of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, SP, Brazil

²Department of Morphology, Stomatology and Physiology, Faculty of Dentistry of Ribeirão Preto, University of São Paulo, Ribeirão Preto, SP, Brazil

³Department of Pediatric Clinics, Preventive and Social Dentistry, Faculty of Dentistry of Ribeirão Preto, University of São Paulo, Ribeirão Preto, SP, Brazil

Background and objectives: Obesity is a heterogeneous disorder that involves genetic and phenotypic components, which affect endocrine metabolism and regulatory events of the organism. Actually, it is considered by the World Health Organization as a major and increasing public health problem. The stomatognathic system is responsible for vital functions, such as chewing and swallowing and there is evidence to be less effective in obese people, compared to normal weight individuals. This can be considered another factor that impairs chewing and therefore, the adequate dietary intake of obese individuals. The objective of the present study was verifying the influence of the obesity on the eletromiographic activity, bite strength and masticatory efficiency.

Methods: Were included in this study 28 subjects, all female, aged between 24 and 63 years. They were divided into two groups: G1 – obese (14 subjects); G2 – healthy (14 subjects, matched each subject with G1). The masticatory efficiency was evaluated by eletromiographic activity of masseter and temporal muscles, registered in different clinical posture conditions of the mandible, using the EMG Myosystem BR-1 and the bite force, with a dinamometer adapted for oral condition.

Results: The eletromiographic averages showed statistically significant differences (test t of Student, $p < 0,05$) for the rest, right and left laterality and protrusion conditions and the higher values were from the obese group. In the evaluation of maximal molar bite force and the mastication, the obese subjects showed lower values in both activities, with results statistically significant.

Conclusions: The eletromiographic results showed that for the obese individuals maintain the positions of the jaw postu-

ral, they requested more muscle fiber trigger, compared with healthy subjects. Furthermore, lower values in bite force, lead to the conclusion that obesity directly affects the function of the masticatory system, reducing the mastication efficiency.

Key words: Obesity, stomatognathic system, masticatory efficiency.

PO2304

"KIDS IN MOTION" PROGRAM FOR OBESE MEXICAN POPULATION: A CASE REPORT

E. Escalante-Izeta¹, A. Vergara², A. Parra¹, S. Gutierrez³, T. Ochoa¹

¹Health department, Universidad Iberoamericana, Mexico DF, Mexico

²Universidad La Salle, Madrid, Spain

³Communication department, Universidad Iberoamericana, Mexico DF, Mexico

Background and objectives: Currently, Mexico has the highest prevalence of childhood obesity worldwide. It is necessary to address effective interventions, proven and culturally adapted to the Mexican population. This case study documents the effect of the Spanish program 'Kids in Motion', that aims to cause changes in the child and their family, in lifestyle, eating habits and emotional factors that contribute the weight gain.

Methods: Group of ten Mexican children, diagnosed as overweight or obese according to WHO standards. The three-month intervention consisted of 11 group sessions where children worked through fairy tale as symbolic framework, included activities such as drawing, music, dancing and games. The main topics were: nutrition, food false advertising, body image, communication, conflict resolution, assertiveness, self-esteem, relaxation and physical activity. The evaluation compared the variables: BMI, waist circumference, food intake, physical activity, anxiety, depression, body image and self-esteem. After the intervention the participants were interviewed and joined a focus group.

Results: Discrete changes (10%) in abdominal circumference of children and their mothers. The main changes were reported in daily habits such as increased consumption of vegetables (15%), skim milk (30%) and slowly absorbed carbohydrates (32%). Decreased the consumption of foods and beverage high in sugar (soft drinks 23%). Participants learned to work by goals, being the easiest: try new vegetables for a week, and the most difficult: to do 30 minutes of physical activity every day. The interviews highlighted that the intervention was successful in children's self-esteem and improved communication skills of parents.

Conclusions: The program had a positive effect. Need to be modified for Mexican population: language, exercises of as-

sertiveness in parents and to include available Mexican food. The symbolic framework caused enthusiasm and impact in children, who immediately identified with the story and its characters.

Key words: child obesity, psychology intervention, Mexico.

PO2305

APPLICATION OF NUTRITION CARE PROCESS FOR HIV POSITIVE PATIENTS IN INDONESIA: AN EXPLORATORY STUDY

M T P L. Kusuma¹, A. Titisari¹, N. Suni¹, Y. Subronto²

¹School of Health Nutrition, Faculty of Medicine, Universitas Gadjah Mada, Yogyakarta, Indonesia

²Department of Internal Medicine, Dr. Sardjito General Hospital, Yogyakarta, Indonesia

Background and objectives: Nutrition care process is a standardized process utilized by professional dietitians and serves as a framework for decision making and problem solving in nutrition. The activity includes four critical tasks; nutrition assessment, diagnosis, intervention as well as monitoring and evaluation. It is a guideline to provide proper nutrition care for patients. Nutrition plays a significant role on treating patients with HIV and AIDS. It should be an integral element of hospital care to ensure that HIV positive patients get the benefit of treatment. The main objective was to evaluate the implementation of nutrition care process for HIV positive patients in HIV referral hospitals in Yogyakarta, Indonesia.

Methods: This study was a qualitative research using an exploratory study design done in five HIV referral hospitals in Yogyakarta, Indonesia between September and October 2012. There were 34 dietitians participated in the study comprising of dietitians who work in the decision-making process (structural level) as well as in the operational level. Information was obtained from an in depth interview with respondents and recorded at verbatim.

Results: This study found that four out of five HIV referral hospitals in Yogyakarta have set a guideline for nutrition care that complies with the NCP principles. However, there were only 85.3% of dietitians working in those hospitals aware of the guideline. In terms of nutrition care for HIV cases, some hospitals have set instruction for HIV general treatment and protection to staffs, though; most dietitians in the operational level were unaware of the guideline. Yet, no HIV referral hospitals in Yogyakarta have clear protocols for HIV-nutrition treatment.

Conclusions: NCP has been implemented in HIV referral hospitals in Yogyakarta, Indonesia; nonetheless, an individualized nutrition protocol for HIV cases is still unavailable.

Key words: nutrition care process, HIV, patients, exploratory study

PO2306

THE MAGNITUDE OF OVERWEIGHT AND OBESITY AMONG UNDER-FIVE CHILDREN IN IDO AND IBADAN NORTH LOCAL GOVERNMENT AREAS NIGERIA

B. Bamisaye¹, I. Akinyele¹

¹Department of Human Nutrition, College of Medicine, Faculty of Public Health, University of Ibadan, Nigeria

Background and Objectives: Childhood obesity is one of the most serious public health challenges of the 21st century. The problem is global and is steadily affecting many low and middle-income countries, particularly in urban settings. It is associated with an increased risk of adult obesity, which is a major risk factor for chronic diseases. However there is dearth of information on childhood obesity in Nigeria. It is against this background that this study was conducted to determine the prevalence of obesity among under-five children in Ido and Ibadan North Local Government Areas (LGA), Nigeria.

Methods: A four stage random sampling technique was used to select 450 under-five children from Ibadan North (Urban settlement) and Ido LGAs (Rural settlement) of Oyo State, Nigeria. A pre-tested, interviewer administered semi-structured questionnaire was used and anthropometric indices of weight and height measured according to the international standards were used to calculate the body mass index for age. The classification of overweight and obesity was based on World Health Organization growth standard.

Results: The total mean age of the children in the Study was 29.8±17.0 months (Ibadan North=29.1±16.8, Ido=31.9±17.4 months) with 52.6% being Female. The magnitude of overweight and obesity in the LGAs were 14.4% and 20.2% respectively (Ibadan North= 17.2% and 22.1%, Ido= 5.0% and 13.9%) while underweight, wasting and stunting were 4.9% and 16.8%, 2.9% and 11.9% and 28.9% and 38.6% in Ibadan North and Ido respectively.

Conclusions: The study shows a significant difference ($p < 0.05$) between the urban (Ibadan North) and rural setting (Ido LGA) as the prevalence for overweight and obesity were almost 3.5 times for overweight and two times for obesity higher in the Urban than rural LGA, emphasizing the need for timely nutritional and educational interventions to prevent associated morbidity and mortality.

Key words: obesity, overweight, magnitude, under-five, children

PO2307**LIFESTYLE INTERVENTIONS IN OBESITY TREATMENT**

M. Andjelkovic¹, N. Dikic¹, M. V. Vesic¹, N. Mikovic¹, I. Baralic¹, T. Antic¹

¹Sports Medicine Association of Serbia, Belgrade, Serbia

Background and objectives: Weight reduction can be achieved in several ways but dietary regime, moderate physical activity and behavior modifications remain the current fundament of obesity treatment. Weight-loss maintenance is more successful if diet and exercise are accomplished in groups formed by similar body weight (BW), health status and nutritional habits with constant medical support.

Methods: This ongoing intervention study includes participants with BMI > 30. Next measurements and tests were conducted at the beginning and end of three months program: body composition, anthropometry, waist circumference, blood pressure (TA), ergospirometry, blood analyses, diet record, Beck Depression Inventory (BDI), Pittsburgh Sleep Quality Index (PSQI) and International Physical Activity Questionnaire (IPAQ). Lifestyle changes include diet regime with meal replacement, nutrition education with group workshops and moderate physical activity. Regular controls are conducted by physician.

Results: First group of 13 participants aged 46.2±12.0 y had average BMI 36.6±5.8 kg/m², mean BW 109.0±24.9 kg and body fat percentage (F%) 38.2±6.6 at the start of program. 80% had metabolic syndrome and 50% hypertension. Mean VO₂ max (21.6±4.7 ml/kg/min) indicated a low body shape that is confirmed with IPAQ low level of physical activity. Half of participants was rated as 'poor sleepers'. At the start depression was observed in three patients. Significant difference at the end of program existed for: BW (106.5±24.3kg), BMI (35.6±5.5), body fat mass (2.5±21.1kg), F% and fat mass in both arms. Systolic TA were significantly lowered for 21.8±11.9 mmHg and diastolic for 20.7±12.0 mmHg. Fat free mass did not change.

Conclusions: Lifestyle interventions in this program lead to reduction in BW without health consequence. Program caused a significant change in the body composition, morphological and nutritional status but still requires further evaluation of additional participants.

Key words: obesity, life style, meal replacement.

PO2308**PROTEIN AND CALCIUM INTAKE AND ITS RELATIONSHIP WITH BONE REMODELING MARKERS DURING THE REPRODUCTIVE AGING OF WOMEN**

A L. Carvalho¹, F J A. Paula¹, A M. Navarro¹

¹Department of Internal Medicine, School of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, São Paulo, Brazil

Background and objectives: Calcium and protein are components of bone tissue, and are related to bone mass peak and formation of bone matrix, respectively. The study evaluated dietary protein and calcium intake and its relationship with bone remodeling markers in different stages of the reproductive aging of women.

Methods: Food record method was used to assess food intake and body mass index (BMI) was also calculated. Serum osteocalcin (OC) and urinary deoxypyridinoline (DPD) were determined. Women were divided into four groups according to information about their menstrual cycle or amenorrhea, and hormonal profile (serum follicle stimulating hormone and estradiol). The serum concentrations of parathormone, 25-hydroxyvitamin D and serum calcium demonstrated that the bone metabolism of the participants appeared to be in homeostasis. It was performed linear regression and ANOVA with the aid of the SAS 9.2 software (p value < 0.05).

Results: The study was conducted on 42 healthy women aged 42 to 64 years. According to BMI, 52% of the women were overweight. Dietary intake above recommended values was observed for protein (median = 0.86 g/kg current weight/day; range = 0.52-2.05 g/kg current weight/day) and phosphorus (median = 827.93 mg/day; range = 343.6-1282.07 mg/day), while intake below recommended values was observed for calcium (median = 632.44 mg/day; range = 82.17-1185.28 mg/day) and magnesium (median = 170.62 mg/day; range = 94.93-293.64 mg/day), according to the Dietary Reference Intake (DRI) recommendations. Models of linear regression analysis showed that after adjustment for the factors inherent to the groups, protein and calcium intake was found to be negatively associated with OC concentrations.

Conclusions: Despite the associations detected between nutrients and bone formation marker, the present results suggest that the hormonal variations occurring during reproductive aging in women have a greater impact on their indicators of bone health.

Key words: protein, calcium, menopause, bone markers.

PO2309**INCREASING WHOLE GRAIN FOOD CONSUMPTION SEEMS TO BE A PROMISING STRATEGY IN PROMOTING WEIGHT LOSS IN OVERWEIGHT OR OBESE ADULTS.**

E. Fappa^{1,2}, T. Georgiadi², S. Mestana², B. Vasiliki¹

¹Department of Nutrition and Dietetics, Harokopio University, Athens, Greece

²Department of Dietetics, IST College - University of Hertfordshire, Athens, Greece

Background and objectives: Epidemiological data indicate that a diet rich in whole grains is associated with lower BMI, waist circumference and risk of being overweight. On the other hand, few intervention studies have examined the effect of whole grain intake on body weight regulation of overweight or obese individuals. The majority of these trials have examined that as part of a hypocaloric diet. Aim of the present study was to explore the effect of increasing the consumption of whole grain foods, on body weight of overweight or obese adults, in the absence of calorie restriction.

Methods: Thirty apparently healthy overweight or obese adults (53% men, BMI range 25.2-30.7kg/m²) participated in a two-month dietary intervention. Anthropometric and dietary characteristics were assessed at the beginning and at the end of the study. After baseline evaluation, all participants were informed about the recommended consumption of whole grain foods and were randomized into two groups: 1) Control group (CG) (n = 15), 2) Whole grain group (WG) (n=n = 15). Participants of the CG received no other contact until the end of the study. Participants in the WG received nutritional counseling, aiming at the increase of consumption of whole grain products, provided in 7 weekly small-group sessions, until the end of the study.

Results: At the end of the study, the two groups differed in the changes of consumption of all whole grain foods evaluated ($p < 0.002$), as well as in body weight changes ($p = 0.030$). In specific, patients in the WG decreased their body weight (85.4 ± 13.1 vs. 84.8 ± 12.3 kg, $p = 0.016$) whereas patients in the CG maintained it (80.1 ± 10.2 vs 80.3 ± 9.4 kg, $p = 0.55$).

Conclusions: Increasing whole grain food consumption seems to be an effective strategy in promoting body weight loss in overweight or obese people in the absence of calorie restriction.

Key words: whole grains, obesity, group counseling, weight loss.

PO2310**EFFECT OF NUTRITIONAL COUNSELING BASED ON QUALITY AND QUANTITY OF CARBS ON METABOLIC PARAMETERS IN INSULIN-RESISTANT ADOLESCENTS (IR)**

P. Ortiz^{1,2}, M. del Castillo¹, C. Vega²

¹Carrera Nutricion y Dietética, Facultad de Farmacia, Universidad de Valparaíso, Valparaíso, Chile

²Departamento Nutrición y Alimentos, Facultad de Farmacia, Universidad de Valparaíso, Valparaíso, Chile

Background and objectives: currently, nutritional counseling to treat Insulin Resistance (IR) is based on counting carbohydrates (CHO). Objective: To compare the effect of nutritional counseling based on carbs quantity v/s nutritional counseling based on both quality and quantity of carbs.

Methods: Seven female individuals were studied, from 14 to 18 years old suffering from IR, treated exclusively with diet and/or Metformin. The adolescents were subjected to two nutritional interventions: the first based on counseling on carbs quantity and exchange portions (conventional treatment) and the second based on counseling regarding quality of carbs, using glycemic index (GI) as the backbone of the intervention. Besides, a third session was included to evaluate outcomes. Variables studied were: glycaemia, insulinemia and weight. Through a 24 hour reminder GI and g of carbs of the diet were obtained in the two periods of intervention. Results were tabulated and processed by SPSS software version 18.0. To determine significant differences between both interventions ANOVA of repeated samples and DMS Test were used. It was considered significant $p < 0.05$.

Results: insulinemia ($p = 0.049$) as well as GI ($p = 0.005$) had a significant decrease in time considering both interventions. By comparing the effect of quality and quantity based counseling with the one only based on quantity of carbs, showed a BMI ($p = 0.032$), insulinemia (0.027) and GI (0.008) all of them had a significant decrease.

Conclusions: the current research shows that carbs quality counseling should be included in IR treatments.

Key words: Insulin resistance, glycemic index, carbohydrates, insulinemia, glycaemia.

PO2311**RELATIONSHIP BETWEEN ENERGY INTAKE, BODY COMPOSITION AND RISK OF HYPERTENSION IN AN ADULT MALE PUNJABI MIGRANT POPULATION IN KENT, UK**

S. Sarkar^{1,2}, P. Amuna¹, F.B. Zotor², T. Ndanu³, J. Tetteh¹, L.S. Harbige¹

¹School of Science, University of Greenwich, Greenwich, UK

²Faculty of Medicine, University of Alberta, Edmonton, Canada

³College of Health Sciences, University of Ghana Dental School Accra, Ghana

Background and objectives: Chronic non-communicable disease (NCD) trends in England show disproportionately higher prevalence of diabetes and hypertension among migrant populations including South Asians and current guidance on primary and secondary prevention appear not to be well tailored and culturally specific. In this study, our objective was to examine relationships between energy intake, body composition and risk of hypertension in a homogeneous migrant adult male population of Punjabi origin in Kent, UK.

Methods: A random sample of 137 free-living apparently (undiagnosed) males aged 21 - 55 years meeting the selection criteria were recruited for the study. Dietary energy intake was satiated from the mean of three repeat 24-hour recalls; physical and physiological parameters were measured. Systolic and diastolic blood pressure (SBP, DBL) were also measured. Body mass index (BMI), Waist and Hip circumference (WC; HC) were used as proxy measures of overweight and obesity (OW+OB). Spearman's coefficient of determination was used to test relationships and single factor ANOVA applied to test their significance.

Results: Mean (\pm SD) of age, weight, height and BMI, were 37 (7.35) yrs; 86.34 (9.21) kg, 1.74 m(0.07) and 28.22 (2.34) respectively. Mean (\pm SD) WC, HC and WHR were 88 (5.49) cm, 101 (9.55) cm and 0.87 (0.07). Mean energy intake (EI) was 3201kcal/day (1218.48). An excess intake of 646 kcal/d compared to recommended values for a sedentary population. Mean (SD) SBP and DBP were 135.78 (9.95) and 86.25(5.17) mmHg respectively. Over 91% of subjects were OW+OB with 31.3% with BMI > 30. Despite positive coefficients of determination, ANOVA did not show significance. Significant relationships were established between BMI v. SBP (r_2 , 0.291; $p < 0.001$); BMI v. DBP (r_2 , 0.285; $p < 0.001$); BMI v. WC (r_2 , 0.465; $p < 0.001$); and WC v. DBP (r_2 , 0.224; $p = 0.008$).

Conclusions: This population is largely sedentary, is overweight and obese and has evidence of pre-hypertension requiring appropriate and culturally tailored intervention.

Key words: Risk of Hypertension, Non communicable diseases, south asian, body mass Index, overweight and obesity.

PO2312**EXERCISE IS A LEPTIN SIGNALLING MIMETIC, AND WHEY PROTEIN INGESTION FACILITATES LEPTIN SIGNALLING IN HUMAN SKELETAL MUSCLE**

J.G. Ponce-González^{1,2}, J. Calle-Herrero¹, I. Pérez-Suárez¹, J. Losa-Reyna¹, A. Santana^{1,2}, H.C. Holmberg³, J.A.L. Calbet¹

¹Department of Physical Education, University of Las Palmas de Gran Canaria, Campus Universitario de Tafira s/n, Las Palmas de Gran Canaria, Spain

²Research Unit, Hospital de Gran Canaria Dr. Negrín, Las Palmas de Gran Canaria, Spain

³Department of Health Sciences, Swedish Winter Sports Research Centre, Mid Sweden University, Östersund, Sweden

Background and objectives: Leptin and leptin receptor (LEPR) polymorphisms have been associated with obesity and muscle hypertrophy. LEPRs are increased in the dominant arm of tennis players. The aim of this study was to determine whether exercise up-regulates the expression of LEPRs and the leptin signaling cascade in arm and leg muscles. **Methods:** Fifteen overweight men first performed 4 days of prolonged exercise (45min of one-arm cranking followed by 8h walking each day) with caloric restriction (0.8 g whey protein (PRO) ($n = 8$) or sucrose (SU)($n = 7$) per kg body weight each day) (designated PE+CR period). Thereafter followed 3 days of reduced exercise and balanced diet (isoenergetic with their usual diet) (designated CD). Muscle biopsies from both deltoid and vastus lateralis (135 biopsies in all) were used to determine: LEPR mRNA, the protein levels of SOCS3 (inhibitor of leptin signalling), and the total and phosphorylated levels of LEPR (Tyr1141 and Tyr985), JAK2, and STAT3.

Results: LEPR were more abundant in arm than leg muscles. Serum leptin was reduced by 64 and 50% following PE+CR and CD, respectively ($P < 0.05$). After PE+CR, LEPR mRNA was increased in exercised muscles, but the protein expression of LEPR was increased only in the arms, more in the PRO than in the SU ($P < 0.05$). After CD, LEPR mRNA returned to basal levels whilst LEPR expression was increased in all muscles ($P < 0.05$). The fraction of LEPR activated (Tyr1141 and Tyr985 phosphorylated) was reduced in arms but not in leg muscles. LEPR phosphorylation was correlated with JAK2 (upstream kinase) and STAT3 (downstream kinase) phosphorylation ($r=0.67-89$, $P < 0.05$). SOCS3 remains unaltered in exercised muscles.

Conclusions: The leptin signaling system is very active in human skeletal muscles. Exercise can be considered as a leptin mimetic because it increases the expression of LEPR and facilitates leptin signaling. Whey protein ingestion facilitates these effects.

Key words: Leptin, obesity, exercise.

PO2313**WEIGHT LOSS BEFORE BARIATRIC SURGERY: HOW LONG PATIENTS REACH THE GOAL?**

L. Galdino Dos Santos¹, M. Melendez-Araújo¹

¹Hospital Regional Da Asa Norte SES-DF, Brasilia, Brazil

Background and objectives: To determine how much time patients take to reach the weight loss goal in the preoperative bariatric surgery. To determine how long patients pre-surgery stage of bariatric surgery.

Methods: This is a retrospective observational study. The sample was composed by 44 patients who were undergone gastric bypass in 2011, and assessed in two moments: first and last nutritional pre-surgery evaluation. Three groups were divided for time analyses (T1: 1-6 Months, T2: 7-12 months, T3: 13-18 months).

Results: There was meaningful difference in weight loss, BMI and alimentary consumption on preoperative stage ($p < 0.001$) with an average time of nutritional evaluation of patients of 9 ± 4.46 months. Comparing the in-group variables, the results showed weight loss in the T1 group was more favorable to the number of evaluation than in the other groups ($p = 0.028$). On group T3, it was meaningful related to %EWL with a variation of energetic consumption.

Conclusions: The average time to reach the weight loss goal was set to 9 months. Thus might improve life quality of patients on the post-surgery stage.

Key words: Bariatric surgery, gastric bypass, preoperative weight loss, morbid obesity.

PO2314**VARIABLES ASSOCIATED WITH ABDOMINAL OBESITY IN ADULTS: POPULATION-BASED STUDY IN CAMPINAS/SP.**

D F. Mendes Camargo¹, A M. Segall-Corrêa¹, L. Marín-Leon¹

¹Department of Public Health, State University of Campinas – UNICAMP, Campinas, Brazil

Background and objectives: Obesity is the major and increasing nutritional problem among adult Brazilian population. The main goal was to analyze factors associated with abdominal obesity.

Methods: Cross-sectional study with a population-based random sample of residents in Campinas/SP city. In 2011-2012 were interviewed 546 people, 18 years or older. Abdominal obesity was defined as waist circumference (WC) in women >80 cm and >94 cm in men. Association analysis was performed

by calculating crude odds ratio (OR) for each independent variable. A multiple logistic regression model was built with the variables that were associated with WC at a significance level of less than 0.20, in the final model remained those with $p < 0.05$.

Results: The prevalence of abdominal obesity was 77.2%. There was no association with: paid work, being head of household, social class and depression. The chance of having abdominal obesity was four times higher among women (OR 4.66, 95% CI 3.03 to 7.16) ($p < 0.001$); twice: among those older than 35 years (OR 2.32, 95% CI 1.52 to 3.54) ($p < 0.001$) and who reported hypercholesterolemia (OR 2.56, 95% CI 1.50 to 4.36) ($p = 0.001$), seven times more among those who reported having diabetes mellitus (OR 7.24, 95% CI 2.23 to 23.4) ($p = 0.001$). Having hypertension showed nearly four times more likely to have abdominal obesity and arthritis three times more likely. In the final regression model with a higher chance of having abdominal obesity remained: lower education (OR 1.96, 95% CI 1.14 to 3.36) ($p = 0.014$); socioeconomic class A or B (OR 2.33 95% CI 1.33 to 4.09) ($p = 0.003$); diabetes (OR 5.35, 95% CI 1.18 to 24.2) ($p = 0.029$) and hypertension (OR 3.52, 95% CI 1.84 to 6.7%) ($p < 0.001$).

Conclusions: Obesity was more common among women and lower educational level. Individuals with excessive abdominal fat were more likely to have chronic diseases.

Key words: abdominal obesity, chronic diseases, population survey.

PO2315**OPPORTUNITIES AND CHALLENGES IN OBESITY PREVENTION AND CONTROL: STUDY DESIGN AND BASELINE FINDINGS FROM A PILOT STUDY IN CHINA**

M. Yang¹, L. Wang¹, J.J. Li¹, L.B. Li¹

¹Institute of Child & Adolescent Health, School of Public Health, Peking University Health Science Center, Beijing, China

Background and Objectives: Obesity prevention and control is one of the work priorities in Non-communicable chronic diseases (NCD). Although developments in theory and technology improved interventional practices in obesity control greatly, there are still many challenges in study design and program implementation. The aim of this study is to indicate some important issues in study design and program implementation in some settings with limited resources and funding.

Methods: In 2012, we designed an obesity control intervention study for Chinese children and adolescents. Based on the three approaches for setting priority areas for action in obesity prevention (The stepwise framework, the modified problem/solution tree, and the Analysis Grid for Elements Linked to

Obesity (ANGELO process) and literature reviews, we designed a cross-sectional study for identifying energy balance related behaviors (eg., unhealthy eating, physical activity and sedentary lifestyles) and for needs analysis in 7200 children (6-18 years) in three provinces. Then, we designed a set of interventional components based on some behavior change theories and the corresponding intervention techniques. The school teachers/doctors were designated for organizing intervention activities for the obese students (1.0 hour per week for six consecutive weeks) and parents (1.0 hour per month for) in school. A manual with pictures is provided to each student for learning and behavior monitoring.

Results: The intervention components were welcomed. Most obese children expected to lose weight and be ready for behavior change, but some children were absent in intervention activities due to time pressure and worrying about obesity bias. Few parents with obese children participated in the lectures. Inadequate health education curricula and parents' unawareness about child obesity hampered the program implementation.

Conclusions: Web-based intervention and other new technologies maybe promising for child obesity intervention.

Key Words: Obesity prevention, behavior change, study design, Chinese children.

PO2316

ASSESSMENT OF DIETARY KNOWLEDGE AND INTAKE AMONG PEOPLE LIVING WITH HIV/AIDS IN NEPAL

D. Upreti^{1,2}, J. Kyle¹, P. Simkhada², J. Thoulass¹, G. McNeill¹

¹Institute of Applied Health Sciences, University of Aberdeen, Aberdeen, UK

²School of Health and Related Research (SchARR), University of Sheffield, Sheffield, UK

Background and objectives: In Nepal there are approximately 63,500 people living with HIV/AIDS (PLHA); or 0.4% of the adult population. As nutrition is important for immunity and general health in HIV/AIDS, this study aimed to measure dietary intake and nutritional knowledge among PLHA in Nepal.

Methods: 601 PLHA (M: 314 and F: 287) were recruited from the Kathmandu valley and Terai highway, nutrient intake was measured using a food frequency questionnaire which also contained questions on nutritional knowledge, socio-economic and demographic information. Height and weight were measured for calculation of BMI.

Results: The median age of the participants was 34 (IQR 29 - 38) years and 29% were classified as undernourished (BMI

<18.5kg/m²). The mean energy intake of men and woman was 1960 (SD±195) and 1880 (SD±261) kcal/d respectively, which is lower than WHO recommendations, particularly for men. Fat, protein and carbohydrate contributed 12%, 10% and 79% to total energy intake respectively. Iron, vitamin C and vitamin A intakes tended to be lower than WHO recommendations. 82% of participants believed that PLHA need a special diet but less than half of these reported changing their diet after diagnosis. A major reason for not being able to follow a healthy diet was insufficient income: 46% of participants reported not being able to afford sufficient food for the whole year, with 57% of those borrowing food for more than 4 months a year.

Conclusions: PLHA in Nepal are aware of the importance of a good diet but have insufficient intake of energy and essential micronutrients. Poverty is the main reason for the poor diet and low nutrient intake.

Key words: diet, Nepal, HIV/AIDS.

PO2317

EVALUATION OF PLASMA ANTIOXIDANT STATUS AND ANTIOXIDANT ENZYME ACTIVITY IN TYPE 2 DIABETES MELLITUS PATIENTS AND NON-DIABETIC CONTROLS

K D R R. Silva^{1,2}, H P. Gunawardana², R. Sivakanesan³

¹Department of Applied Nutrition, Faculty of Livestock, Fisheries & Nutrition, Wayamba University of Sri Lanka, Kuliapitiya, Sri Lanka

²Postgraduate Institute of Science, University of Peradeniya, Peradeniya, Sri Lanka

³Department of Biochemistry, Faculty of Medicine, University of Peradeniya, Peradeniya, Sri Lanka

Background and objectives: Oxidative stress is implicated in the pathogenesis of diabetes and its complications. Chronic exposure to elevated levels of glucose generates oxidative stress. The aim of the study was to evaluate plasma antioxidant status in patients with uncomplicated type 2 diabetes mellitus (T2DM) in order to understand interactions between its components with glycemic control.

Methods: Male and female T2DM patients (n61) and non-diabetic controls (n43) were compared for adiposity (BMI), waist circumference (WC), waist:hip ratio (WHR), fasting glucose (FG), insulin, glycosylated hemoglobin (HbA1c), lipid profile, total protein (TP), uric acid (UA), superoxide dismutase (SOD) and glutathione peroxidase activity (GPx). Homeostatic Model Assessment of Insulin Resistance (HOMA-IR) was derived. Total antioxidant capacity of plasma (TAC) was determined using Ferric Reducing Antioxidant Capacity of Plasma (FRAP).

Results: T2DM patients had significantly higher age and BMI-adjusted WHR, FBG, HbA1c and triacylglycerol (TAG)

and significantly lower LDL, total: HDL cholesterol, insulin, UA, TP, GPx and SOD compared to controls. There was no significant difference in FRAP, HOMA-IR and other lipid variables between T2DM and controls. Among the T2DM, FRAP showed significant positive correlation with UA ($r = 0.52$); SOD had significant inverse correlation with HbA1c ($r = -0.64$); GPx had significant inverse correlation with BMI ($r = -0.42$), WC ($r = -0.29$) and TAG ($r = -0.28$). HOMA-IR was positively correlated with WC ($r = 0.32$) and WHR ($r = 0.29$) and inversely correlated with HDL ($r = -0.29$) and TP ($r = -0.28$). Among the controls, SOD had significant positive correlation with FRAP ($r = 0.40$) and negative correlation with GPx ($r = -0.35$). UA ($R=1.35$) was an independent predictor of FRAP among T2DM ($R^2 = 0.27$).

Conclusions: T2DM had lower levels of antioxidant enzyme activity and unfavorable glycemic and lipid milieu despite similar levels of TAC as determined by FRAP compared to controls. Adiposity and HbA1c have inverse relation with antioxidant enzymes. Uric acid is an independent predictor of TAC of T2DM.

Key words: type 2 diabetes mellitus, total antioxidant capacity.

PO2318

BODY COMPOSITION AND CARDIOVASCULAR RISK FACTORS IN PATIENTS WITH SCHIZOPHRENIA

B. Vidovic^{1,2}, S. Milovanovic^{2,3}, B. Djordjevic¹, S. Sobajic¹, I. Stankovic¹

¹Department of Bromatology, Faculty of Pharmacy, University of Belgrade, Belgrade, Serbia

²Clinic of Psychiatry, Clinical Centre of Serbia, Belgrade, Serbia

³Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Background and objectives: Patients with schizophrenia treated with antipsychotics are at increased risk for weight gain, metabolic syndrome and cardiovascular disease. The purpose of this study was to assess body composition and the prevalence of some cardiovascular risk factors in schizophrenic patients compared with healthy controls in Serbia.

Methods: We studied 60 patients with schizophrenia (22 men and 38 women, mean age $40,1 \pm 10,7$ treated with antipsychotics and 60 control subjects (16 men and 44 women, average age $38,7 \pm 11,1$). For all participants anthropometric measurements including weight, height, waist circumference, body fat as well as lipids profile, glycaemia and blood pressure were determined.

Results: Patients with schizophrenia when compared to the control group had significantly higher body mass index

(27.9 ± 4.9 kg/m² to 24.5 ± 3.3), higher waist circumference (96.4 ± 13.9 , to 84.0 ± 11.3) and higher percentage of body fat ($33.4 \pm 9.3\%$ to $29.5 \pm 7.7\%$). Based on classification of nutritional status by body mass index, the group of schizophrenic patients was the most overweight (36.7%) and obese (33.3%), while the control group was normal (53.3%) or overweight (36.7%). A total of 51.7% of patients met the criteria for the metabolic syndrome of the International Diabetes Federation (IDF). The most common risk factors linked to metabolic syndrome were abdominal obesity (81.7%) and dyslipidemia (81.7%), followed by hyperglycemia (61.7%) and hypertension (23.7%).

Conclusions: Antipsychotic therapy increases the risk of obesity and developing metabolic and cardiovascular disease. It is necessary to continually monitor parameters of nutritional and metabolic status. The implementation of appropriate measures will reduce the cardiovascular risk of patients on antipsychotic therapy.

Key words: body composition, schizophrenia, antipsychotics, metabolic syndrome, cardiovascular disease. This work was supported by the Ministry of Education, Science and Technological Development, Republic of Serbia, Project No III-46001.

PO2319

COMORBIDITIES ASSOCIATED WITH OBESITY BEFORE AND ONE YEAR AFTER BARIATRIC SURGERY IN A PUBLIC HOSPITAL IN BRASÍLIA, BRAZIL.

L. Jorge¹, M. Melendez-Araújo¹

¹Hospital Regional Da Asa Norte SES-DF, Brasilia, Brazil

Background and objectives: To determine the prevalence and possible remission of comorbidities associated with morbid obesity before surgery, at six and twelve months after surgery in a public hospital in Brasília-DF, Brazil.

Methods: This is an observational retrospective analytical study. Patients were studied from April to July 2011. Patients were analyzed in four stages: first and last preoperative nutritional visits, at 6 months and 1 year after surgery.

Results: Analyzing the sample, it is observed that 89.5% were women, mean age was 41.3 ± 9.88 years. Mean the BMI, preoperative were: 42.7 ± 7.24 kg / m². The main comorbidities preoperatively and their prevalence: hypertension, 71%; DM2, 39.4%, dyslipidemia, 36.8%; syndrome of obstructive sleep apnea (OSA) 39.4%. On the sixth postoperative, 100% showed remission of DM2 and OSA, and one year after, only 13.5% still had hypertension. Eighty-seven percent were using at least one medication in preoperative phase. After 6 and 12 months, the use of medicines is summarized antihypertensive 18% and 10.5%, respectively.

Conclusions: In this way, weight loss influences preoperative weight loss of greater postoperative and helps lower incidence of hypertension after surgery. The GRDIYR, then, is an effective tool in weight loss and helps in improving expressively and remission of comorbidities in severely obese.

Key words: Bariatric Surgery, Diabetes Mellitus 2, hypertension, sleep apnea.

PO2320

HYPERTRIGLYCERIDEMIC WAIST PHENOTYPE AND LIPID MARKERS OF CARDIOMETABOLIC RISK IN ADOLESCENTS

M.E. Conceição-Machado^{1,2}, L. Silva², M. Leila. Santana¹, E. Pinto¹, R. de C. Silva², L.T. Moraes¹, A. Marlúcia. Assis²

¹Department of Nutritional Science, Nutrition School, Universidade Federal Da Bahia (ENUFBA), Salvador de Bahia, Brazil

²Department of Paediatrics and Program of Post-graduate of Medicine and Health, Faculty of Medicine of Bahia, Federal University of Bahia, Salvador de Bahia, Brazil

Background and objectives: The atherogenic risk markers have great clinical and epidemiological importance because they can provide early identification of cardiometabolic risk. This research aims to investigate the relationship between the hypertriglyceridemic waist phenotype (HW) and lipid markers of cardiometabolic risk.

Methods: Cross-sectional study with a random sample of 1,076 adolescents aged 11 to 17 years, both sexes, students from public schools in a large urban center. We conducted anthropometric assessment, self-assessment of pubertal stage of development and determination of serum total cholesterol (TC), cholesterol of low density lipoprotein (LDL-C), lipoprotein cholesterol (HDL-C), cholesterol of high density lipoproteins did not (non-HDL) and triglyceride (TG). We calculated the ratios TC / HDL-C, LDL-C/HDL-C, TG / HDL-C and phenotype HW (simultaneous presence of increased waist circumference and high triglycerides). We used the correlation coefficient tetracoric and Kappa to evaluate the relationship between the phenotype HW and the lipid markers.

Results: The phenotype HW was identified in 7.2% of adolescents and high non-HDL cholesterol in 41.3%. It was found that 41.4% of adolescents had reasons TC / HDL-C high, 38.1% and 32.7% of them had, respectively, LDL-C/HDL-C reasons and TG / HDL-C high. The correlation between the phenotype HW, non-HDL cholesterol ratios and TC / HDL-C, LDL-C/HDL-C and TG / HDL-C was moderate and agreement between them poor.

Conclusions: The results of this study showed that the correlations between the phenotype HW, non-HDL cholesterol and ratios TC / HDL-C, LDL-C/HDL-C and TG / HDL-C were moderate and poor agreement.

Key words: hypertriglyceridemic waist, fat, non-HDL cholesterol, lipid ratios, cardiometabolic risk.

PO2321

PREVALENCE OF UNDETECTED COELIAC DISEASE IN CHILDREN BETWEEN 2 AND 4 YEARS OLD, STUDIED BY A RAPID IMMUNOCROMATOGRAPHIC TEST

V. Almazán Fernández de Bobadilla^{1,2}, R. Moreno Torres², J. Caballero Villarraso³, E. Ortega Pérez¹, M. Tovar López¹, J. Romero González⁴, M. A. López Casado¹, J. Maldonado Lozano^{2,4}

¹Maracena Primary Care Center (Pediatrician), Granada, Spain

²Department of Pediatrics, University of Granada, Granada, Spain

³IMIBIC/Reina Sofia Hospital/University of Córdoba, Córdoba, Spain

⁴Virgen de las Nieves University Hospital, Granada, Spain

Background and objectives: screening of coeliac disease (CD) is cost-effective as its prevalence is usually underestimated and there is a useful treatment. Our aim is to study the prevalence of hidden CD and to analyze the diagnostic yield for undetected CD with a new rapid test in children between 2 and 4 years old.

Methods: we designed a transversal study, taking as reference population children from 2 to 4 years old from the same metropolitan area (Maracena, Granada-Spain). We included apparently healthy subjects, and collected clinical, anthropometric, analytical and serological variables (IgA and IgA antiendomysium and antitranglutaminase, that were the "gold-standard" for the screening test study). We also measures antigliadin and antitranglutaminase IgG and IgA with a rapid immunocromatographic test (CD1WB y CD2WB, from Operón®). Statistical analysis was performed with SPSS 17.0 program (Chicago, USA®).

Results: we included 198 children to whom the complete protocol was applied and who signed the informed consent document. Mean age 32.2±8.8 months, 52% males. CD prevalence basing on the serological test was 3% (CI 95% 1.4-64.4%). The diagnosis was histologically confirmed in all of them. Sensitivity and negative predictive value in our population of the immunocromatographic system CD2WB was 100% and 1 respectively. Sensitivity of CD1WB was 16.6% with a high specificity (89.1%).

Conclusions: Hidden prevalence of CD in our population of children between 2 and 4 years old was higher than the one found by other authors. Immunocromatographic system CD-2WB showed as an excellent diagnostic screening test with a high sensitivity and negative predictive value.

Key words: celiac disease, serum biomarkers, screening, biochemical test.

PO2322

VITAMIN C DEFICIENCY DURING CHEMOTHERAPY FOR COLORECTAL CANCER

S. Ribeiro^{1,2}, C. Braga¹, F. Peria², J. Ribeiro³, O. Feres³, S. Cunha¹

¹Nutrology Division, Department of Internal Medicine, Ribeirão Preto School of Medicine, University of São Paulo, Brazil

²Oncology Division, Department of Internal Medicine, Ribeirão Preto School of Medicine, University of São Paulo, Brazil

³Division of Coloproctology, Department of Surgery and Anatomy, Ribeirão Preto School of Medicine, University of São Paulo, Brazil

Background and objectives: Some studies evidenced that blood vitamin C concentration falls after surgery. There is no information available on further decreases on vitamin C serum levels during chemotherapy for colorectal cancer. The objective was to compare vitamin C serum levels on patients undergoing chemotherapy cycles for colorectal cancer.

Methods: We conducted this longitudinal study with 16 colorectal cancer patients from a university hospital (Chemotherapy Group). The data was obtained in four occasions: before the first, second, third and fourth chemotherapy cycles. Nutrient intake, BMI and vitamin C serum levels were determined during all of the study phases. The experiment included 19 healthy subjects (Control Group), paired by age (64±16 vs. 63±9) and gender. We used Statistica 8.0 with significance set at $p < 0.05$.

Results: The Chemotherapy Group presented the lowest BMI (23.5±5.2 vs 28.4±4.7 kg/m²), vitamin C intake [90 (27-409) vs 213 (32-562) mg] and serum levels (0.12±0.05 vs 0.34±0.18 mg/dL), even before the treatment. Vitamin C intake varied among the subjects, without statistical significance. When compared to the initial values, we noticed a decrease on serum vitamin C levels prior to the second cycle (0.09±0.02 mg/dL). Levels remained low before the third (0.09±0.03 mg/dL) and fourth (0.08±0.03 mg/dL) chemotherapy cycles.

Conclusions: Patients undergoing chemotherapy presented vitamin C deficiency, which demands supplementation and/or orientation towards ingesting food rich in vitamin C.

Key words: nutritional status; chemotherapy; vitamin C.

ABETALIPOPROTEINEMIA: VENEZUELA CASE REPORT

N. Colina^{1,2}, M. Mariño², V. Bosch³, M. Rodriguez¹, L. Villarreal⁴, G. Daoud¹, Y. Rojas²

¹Unit of Pediatric Gastroenterology and Nutrition, Dr. Carlos Arvelo Military Hospital, Caracas, Venezuela

²Care Center Child Nutrition Antímamo (CANIA), Caracas, Venezuela

³Unit lipidology Central University of Venezuela, Caracas Venezuela

⁴Department of Pathology Dr. Carlos Arvelo Military Hospital Dr. Carlos Arvelo, Caracas, Venezuela

Background and objectives: Abetalipoproteinemia (ABL) is a rare autosomal recessive disorder with a frequency <1 in 100,000, approximately 100 cases described worldwide. ABL can result from mutation in the gene encoding the large subunit of microsomal triglyceride transfer protein (MTP). Phenotypically ABL is characterized by hypocholesterolemia, low apolipoprotein B, chronic malabsorptive diarrhea, malnutrition, polyneuritis, ataxia, retinitis pigmentosa and acanthocytes in blood smears.

Methods: We present a thirteen month-old infant, with steatorrhea, failure to thrive, hepatic steatosis, iron deficiency anemia, Vitamin E deficiency, low serum cholesterol (31 mg/dl) and low apolipoprotein B (< 11 mg/dl) were detected since second month of life. Duodenal biopsy revealed normal villi and lipid deposition in cytoplasm of affected cells. Genetic analysis revealed that our case was homozygous for a p.Ala835Pro mutation in MTP gene. This mutation, to the best of our knowledge, has not been described before and is the first case of ABL clearly documented in Venezuela. The nutritional treatment consisted in dietetic controlled fat plan <25g total fat/day (42 to 50% medium-chain triglycerides (MTC)), which was provided by breast milk, semi-elemental formula with MTC and MTC oil. To complete caloric and protein requirements, protein and carbohydrate modules were used, also high doses of fat soluble vitamins and IV lipid emulsion to avoid essential fatty acid deficiency were administered three times per week.

Results: After 5 follow-ups over a year period, a substantial nutritional improvement was accomplished; with favorable changes in body composition parameters: mid-upper arm circumference and triceps skinfold increment of the order of 3.5 and 2.8 z-score each. Weight-age increased 2.7 z-score and height-age, deeply affected (-5.8 z-score) before our treatment, increased 1.7 z-score, but still remains below normal, although steadily improving.

Key words: Abetalipoproteinemia, MTP, p.Ala835Pro.

PO2324**EFFECT OF SUPPLEMENTATION WITH BETA-GLUCAN FROM PLEUROTUS OSTREATUS IN CHILDREN WITH RECURRENT RESPIRATORY TRACT INFECTIONS**

L. Pico^{1,2}, J. Sapena², M. Morera³, M. Rivero³

¹Hospital Casa Salud, Valencia, Spain

²Centro Médico Teknon, Barcelona, Spain

³Scientific Unit, Laboratorios Ordesa, Sant Boi Llobregat, Barcelona, Spain

Background and objectives: Recurrent respiratory tract infections (RRTIs) are among the most frequent consultations in pediatric practice especially in children of preschool age. A variety of nutritional supplements have shown clinical efficacy in the prevention of RRTIs, but only few of them are supported by scientific evidence. Our objective was to evaluate the preventive effect of a syrup containing beta-glucan from *Pleurotus ostreatus* and vitamin C on the frequency of RRTIs in children.

Methods: 166 children from 1 to 10 years old (3.0 ± 1.7) from 20 pediatric consultations with a history of at least 6 RRTIs during the previous year were enrolled in a prospective observational multicenter study. Children received supplementation with beta-glucan from *Pleurotus ostreatus* and vitamin C (1ml syrup/5kg) for 3-months and followed-up until 6 months. Number of respiratory infections, emergency visits and hospitalizations were registered during four visits and compared with the same 6 months period from previous year. Product acceptability was also measured.

Results: Total respiratory infections were significantly reduced compared to the previous year (4.08 ± 2.25 vs 8.80 ± 3.41 , $p < 0.001$) either in children under 3.5 years old (4.67 ± 2.17 vs 9.51 ± 3.12 , $p < 0.001$) or above (3.37 ± 2.05 vs 7.41 ± 3.44 , $p < 0.001$). There was a statistically significant reduction of each of the infections except for pneumonia: 50.53% otitis (OR[IC95%]:3.85 [2.34-6.36]); 27.03% common cold (OR[IC95%]:5.29 [2-66-10.65]), 44.14% pharyngitis (OR[IC95%]:4.16 [2.5-6.94]); 72.78% laryngitis (OR[IC95%]:4.98 [2.48-10.15]) and 45.73% bronchitis (OR[IC95%]: 3.61 [2.2-5.93]). Pneumonias were reduced 46.7% (OR [IC95%]:2.04 [0-93-4.5] $p = 0.55$). Significant reduction of number of emergency visits was observed. Product acceptability was either good or very good in 90.6% of children.

Conclusions: Results from this study demonstrate that supplementation with beta-glucan from *Pleurotus ostreatus* and vitamin C syrup is effective in the prevention of RRTIs in children.

Key words: *Pleurotus ostreatus*, Nutritional supplement, recurrent respiratory tract infections, Children.

PO2325**GLYCEMIC INDEX DIET AND RELATION WITH WEIGHT LOSS IN WOMEN WITH SEVERE AND MORBID OBESITY UNDERGOING BARIATRIC SURGERY.**

C. Vega^{1,2}, K. Basfi-fer², P. Rojas², J. Codoceo², J. Inostroza², F. Carrasco², M. Ruz²

¹Departamento Nutrición Y Alimentos, Facultad de Farmacia, Universidad de Valparaíso, Valparaíso, Chile

²Departamento Nutrición, Facultad de Medicina, Universidad de Chile, Chile

Background and objectives: At present, studies show an association between the glycemic index (GI) diet and weight loss in individuals undergoing bariatric surgery, however the evidence is not enough. The main objective to determine the correlation between GI diet and weight loss in women undergoing gastric bypass and sleeve gastrectomy. Method: in 40 (Sleeve gastrectomy, 20. Gastric bypass, 20) women with severe and morbid obesity it was assessed their GI diet at 6 and 12 months after bariatric surgery through three-day food records. In addition, body weight was measured during follow up. Quantitative variables were analyzed with Pearson correlation test, considering significant a $p < 0.05$.

Results: the average of GI at 6 and 12 month was 47.6 ± 6.4 and 52.7 ± 6.7 respectively. Percentage of weight loss at 6 and 12 months was $67.1 \pm 14.6\%$ and $78 \pm 20.1\%$ respectively. A negative relation between GI of the diet and percentage of weight loss ($r = -0.4$ $p = 0,004$) was obtained at 6 months after surgery. Furthermore, a negative correlation ($r = -0.34$, $p = 0,048$) was found between GI of the diet and percentage of weight loss at 12 months after surgery. **Conclusions:** according to the current research the GI diet shows a negative association with the percentage of weight loss at 6 and 12 months after bariatric surgery.

Key words: Glycemic index, weight loss, diet, bariatric surgery. FONDECYT 1080576.

PO2326**EFFECTS β -GLUCAN IN GENE EXPRESSION OF MCF-7 CELL ON NUTRITIONAL ASSESSMENT, HEMATOLOGICAL, BIOCHEMICAL AND OXIDATIVE STRESS, WOMEN WITH BREAST CANCER.**

C. Carreira¹, D. Moraes¹, D. Sartori¹, S. Lepri¹, J. Couto¹, I. Dichi¹, M. Mantovani¹

¹Universidade Estadual de Londrina, Londrina, Brazil

Background and objectives: β -glucan (β G) with *S.cerevisiae* is polysaccharide binding (beta 1-3, 1-6 beta), considered as a biological response modifier and contribute repair the DNA damage. The purpose of this study was evaluated the Effects of β G in vitro on the expression of genes CCNA1, CASP9, SOD1 in cell MCF-7 and in vivo the profile of the dietary, status nutritional, hematological, and biochemical indicators of oxidative stress (OS) in women with breast cancer undergoing chemotherapy. In this in vitro tests were used the concentration 50 μ g/mL of G and 0.1 g/mL to doxorubicin (DOX). Results demonstrated that MCF-7 cells exposed to G increased gene expression CASP9, inducing apoptosis, but was not able to stop cell cycle. The simultaneous exposure of these cells the β G and DOX increased the expression CCNA1 and SOD1, indicating that this association may be responsible for the increase intracellular antioxidant defenses and thus contribute to inhibition of proliferation of MCF-7 cells and contribute to repair the DNA damage caused by chemotherapy. We investigated 52 patients with breast cancer before and after supplementation with 1 gram of β G or gelatin during 84 days of anticancer treatment. The nutritional assessment carried out identified the prevalence of overweight and obesity. A significant increase in blood levels after supplementation with β G: hemoglobin ($p = 0.031$), hematocrit ($p = 0.021$), basophils ($p < 0.001$) and eosinophils ($p = 0.005$) and a significant reduction in plasma levels of LDL cholesterol ($p = 0.021$) and triglycerides ($p = 0.005$), whereas in the control group, significant reductions hemoglobin ($p = 0.013$), leukocytes ($p = 0.001$), lymphocytes ($p < 0.001$) and eosinophils ($p = 0.046$), the analysis of OS markers showed significant reduction in plasma concentrations of NO ($p < 0.001$) after supplementation with β G. Therefore, it is suggested that the β G can be important nutrient for patients with of anticancer treatment.

Key words: β -glucans, cancer.

PO2327**THERMAL IMAGINE OF BROWN ADIPOSE TISSUE ACTIVITY IN CHILDREN BORN TO OVERWEIGHT, OBESE AND DIABETIC PREGNANT WOMEN**

D. Campos^{1, 2}, R. Moreno-Torres¹, V. Macías¹, F J. Torres-Espinola¹, P. Brandi¹, C. Martínez-Zaldivar¹, S. Altmaumle^{1,2}, A. Agil³, T. Anjos¹, C. Campoy^{1,2}

¹EURISTIKOS Excellence Centre for Paediatric Research, University of Granada, Granada, Spain

²Department of Paediatrics, University of Granada, Granada, Spain

³Department of Pharmacology, University of Granada, Granada, Spain

Background and objectives: Brown adipose tissue (BAT) persists beyond the neonatal period and is primarily located within the supraclavicular regions in adults of all ages. Its growth during gestation is largely dependent on glucose supply from the mother to the fetus. Normal fat development profiles in the offspring are modified by changes in maternal diet at defined stages of pregnancy, ultimately leading to adverse long-term outcomes. The aim of the present study is to analyze BAT activity in overweight, obese, gestational diabetic women 2 years after delivery, and in their offspring at 3.5 years.

Methods: 51 'mother-children pairs' participants in the PREOBE study* were invited to evaluate their BAT using thermal imagine at supraclavicular regions in the mothers, 2 years after delivery and in their children at 3.5 years; the methods followed is extensively published in The Journal of Paediatrics by Symonds, et al., 2012. 22 healthy and normoweight mothers ($n = 22$), women with overweight (pre-pregnancy $25 < \text{BMI} < 30$) ($n=9$), obese women (pre-pregnancy $\text{BMI} \geq 30$) ($n = 8$) and mothers which developed gestational diabetes ($n = 10$) were included in this study.

Results: No differences in BAT activation were shown between the mothers and between children of the different groups. Close correlations were established between lifestyle indicators in the mothers during pregnancy and BAT activity in their offspring at 3.5 years: sleeping hours at 24 weeks of pregnancy ($r = 0.39$, $p = 0.012$); smoking before pregnancy ($r = -0.36$, $p = 0.046$), the perception of wellness in the mother 6 months after delivery ($r = 0.56$, $p = 0.001$).

Conclusions: Lifestyle during pregnancy and body composition are factors influencing the BAT activity in their offspring at 3.5 years. A programming effect is suggested.

Key words: Brown adipose tissue, thermal imagine, obesity.

PO2328**NUTRITIONAL PROFILE OF PATIENTS IN PREOPERATIVE CARDIAC SURGERY.**

L. Brito¹, B. Santos¹, J. Silva¹, F. Lima¹, O. Raposo¹

¹Federal University Aracaju, Sergipe, Brazil

Background and objectives: The obesity increased in Brazil has been observed together with the economic and epidemiologic changes, and as consequence some comorbidities, like cardiovascular diseases. Changes in Brazilian population's eating habit, with the higher consumption of high-caloric food, with saturated fat, sodium and sugar, shows an important association with the increase in cardiac complications. Therefore, it becomes necessary to evaluate the nutritional state and the food consumption in patients of cardiac surgeries in preoperative status at a Sergipe's public hospital.

Methods: The study was characterized as descriptive and cross-sectional, composed by 110 patients which were submitted to a nutritional evaluation status by weight, height, body mass index, waist and arm circumference, triceps skinfold thickness and a food consumption analyses with the application of a quantitative questionnaire of food frequency.

Results: From the total of the patients, 58.2% were male and 41.8% were female, the most prevalent comorbidity was the systemic arterial hypertension and the most accomplished surgical procedure was the Myocardial revascularization. The anthropometric evaluation revealed that the population is in nutritional risk, due to the overweight/obesity prevalence (56%), body mass index, and raised risk of metabolic complications in agreement with the waist circumference.

Conclusions: Patients scheduled for cardiac surgery presented high prevalence of hypertension and a risk nutritional profile due the inadequate nutritional status with predominance of overweight/obesity, a low potassium, calcium, vitamin E and fiber consumption and a high saturated fat, sodium and cholesterol consumption.

Key words: Nutritional status. food consumption. cardiac surgeries.

PO2329**SELENATE PREVENTS DIET-INDUCED OBESITY WITH IMPROVED INSULIN SENSITIVITY IN VIVO**

K.H. Kim¹, C.Y. Kim¹, Y. Zhu¹

¹Department of Food Science, Purdue University, West Lafayette, Indiana, USA

Background and Objectives: Selenium is an essential micronutrient required for optimum human health. Although various forms of selenium are known to be beneficial in preven-

ting some chronic diseases such as cancer and cardiovascular disease, the role of selenium in obesity remains elusive. We recently found that selenate, an inorganic form of selenium, exhibits an anti-adipogenic function through induction of transforming growth factor-beta1 signaling pathway in preadipocytes with no effect on cell viability in vitro. The objective of this study is to test a hypothesis that selenate is a novel anti-obese micromineral that prevents the development of diet-induced obesity in vivo.

Methods: 3-week old mice were placed on a high fat-diet (HFD) with control water or water supplemented with selenate (20% of LD50) for 8 weeks.

Results: Selenate administration resulted in little effect on overall food intake, water intake and fecal calories in mice groups in control HFD and HFD with selenate (HFD-Se). While HFD group developed adiposity with increased adipose tissue weight, mice in HFD-Se showed decreased body weight and body fat mass with smaller adipocyte size. In addition, HFD induced hyperglycemia and insulin resistance. However, mice in HFD-Se displayed lower blood glucose, insulin, and free fatty acid and glycerol levels with improved glucose tolerance. Real-time PCR analysis revealed that adipose tissue isolated from mice in HFD-Se exhibited reduced levels of genes involved in adipogenesis, lipid metabolism and altered transforming growth factor-beta1 signaling pathway compared with those in HFD mice.

Conclusions: Collectively, our results demonstrate that chronic administration of low dose of selenate at a safe concentration abrogates adiposity and its associated insulin resistance in a mouse model of diet-induced obesity. This suggests that selenate is a novel anti-obese dietary micromineral.

Key words: selenate, selenium, obesity, insulin resistance.

PO2330**CORRELATION OF NUTRITIONAL FACTORS WITH THE QUALITY OF LIFE AND FATIGUE INTENSITY AMONG PATIENTS UNDERGOING CHEMOTHERAPY CYCLES**

S. Ribeiro^{1,2}, C. Braga¹, F. Peria², S. Cunha¹

¹Medical Nutrition Division, Department of Internal Medicine, Ribeirão Preto, Medical School, University of São Paulo, Ribeirão Preto, São Paulo, Brazil

²Oncology Division, Department of Internal Medicine, Ribeirão Preto Medical School, University of São Paulo, Ribeirão Preto, São Paulo, Brazil

Background and objectives: Fatigue is a prevalent symptom among individuals under chemotherapy and it may result in reduced overall quality of life (QoL). The aim of this study was to correlate the fatigue intensity and the QoL with the nu-

tritional status on patients undergoing chemotherapy cycles for colorectal cancer.

Methods: We conducted this longitudinal study with 24 colorectal cancer patients (63.2 ±14.9 years, 62.5% female) from a tertiary university hospital. The data was obtained in four occasions: before the first, second, third and fourth chemotherapy cycles. The FACIT Fatigue Scale and the QoL questionnaire were determined during all of the study phases. The energetic and protein intake, body mass index (BMI), serum levels of hemoglobin and albumin were also obtained.

Results: There was no statistical difference in QoL and fatigue intensity among chemotherapy cycles. The energy and protein intakes did not show correlation with QoL and fatigue intensity. However, before the first chemotherapy cycle, there was a correlation of QoL with serum levels of hemoglobin ($r = 0.57$, $p = 0.01$) and albumin ($r = 0.73$, $p = 0.004$). Similarly, there was a correlation of fatigue intensity with serum hemoglobin ($r = 0.48$, $p = 0.04$) and albumin ($r = 0.63$, $p = 0.02$).

Conclusions: The QoL and the fatigue intensity before the first chemotherapy cycle showed correlation with the serum levels of hemoglobin and albumin, probably due to colorectal surgery. The BMI showed correlation with QoL and fatigue at a later stage, before the 4^o chemotherapy cycle.

Key words: nutritional status; chemotherapy; quality of life; fatigue.

resistance. Blood BCAA concentrations were not increased. The activity of hepatic BCKDC that was present in the active form in the liver was higher in DIO rats compared to controls, although the total activity and the enzyme amount were not different between two diet groups. The activity of hepatic BDK and the abundance of BDK bound to the BCKDC were decreased in DIO rats. The total amount of hepatic BDK was also significantly decreased in DIO rats. In rats made obese through HFD feeding, in contrast to prior studies in rat models of type 2 diabetes, hepatic BDK was down-regulated and thereby hepatic BCKDC was activated, suggesting that DIO promotes liver BCKA catabolism.

Conclusions: In this model there was no evidence that increased blood BCAAs drive DIO-associated insulin resistance, since concentrations of BCAAs were not altered by DIO.

Key words: BCKA, high-fat diet, BCAA.

PO2331

REGULATION OF HEPATIC BRANCHED-CHAIN ALPHA-KETOACID DEHYDROGENASE COMPLEX IN RATS FED A HIGH-FAT DIET.

Y. Kadota¹, Y. Kitaura¹, A. Inukai¹, Y. Shimomura¹

¹Department of Applied Molecular Biosciences, Graduate School of Bioagricultural Sciences, Nagoya University, Nagoya, Japan

Background and objectives: Branched-chain alpha-ketoacid (BCKA) dehydrogenase complex (BCKDC) regulates branched-chain amino acid (BCAA) metabolism at the level of BCKA catabolism. It has been demonstrated that the activity of hepatic BCKDC is markedly decreased in type 2 diabetic animal models and increased in type 1 diabetic animal models.

Methods: In this study, we examined the regulation of hepatic BCKDC in rats with diet-induced obesity (DIO). Rats were fed a control or a 60% of energy high-fat diet (HFD) for twelve weeks. Concentrations of blood components and the activities and protein amounts of hepatic BCKDC and its specific kinase (BDK) were measured.

Results: The concentrations of plasma glucose, insulin, and corticosterone were significantly elevated in DIO rats compared to those fed the control diet, suggestive of insulin

PO2332

EARLY INDICATORS OF CHRONIC DISEASE IN OVERWEIGHT MEXICAN CHILDREN

R. Arellano^{1,2}, L. Ricavar², A. Anaya¹

¹Maestría de Nutricion , Facultad de Ciencias Naturales, Universidad Autónoma de Querétaro

²Secretaría de Salud, San Luis Potosí, México

Background and objectives: A question arising from the childhood obesity epidemic is when chronic diseases start. The study objective was to evaluate insulin resistance (IR) and Reactive C Protein (RCP) as indicators of early chronic disease in children aged 5 to 9, from a Health State Unit in San Luis Potosi, Mexico.

Methods: Transversal study of 124 children attending routine medical screening excluding those with recent infection, inflammatory disease or using anti-inflammatory medication. Anthropometric measurements, clinical history, physical activity (PA) questionnaire (Serra, 2006), and biochemical analysis were performed.

Results: 2% had low body weight, 67% normal, 13% overweight and 18% obesity. Average values for waist circumference (WC) were 50, 55, 64 and 72 cm for each Body Mass Index (BMI) category respectively. PA was not different among groups. Biochemical analysis of 96 children reported 7.4% abnormal fasting glucose (AFG), 1% hyperinsulinemia (HI), 25% IR and 4.2 % positive RCP. According to BMI categories 4.5% normal and 18.7 obese had AFG ($p < 0.06$). Average insulin levels were 3.7, 6.2 and 8.9 for the normal, overweight and obese children. HI was present in only one child (8.3% of overweight children) . IR was found in 14.1%,16.7% and 68.8% of normal, overweight ($p < 0.03$) and obese ($p < 0.0001$) children respectively , (OR 12.5) and positive RCP in 4.5% normal and 6.3%

obese (PO.06) (OR 1.4) There was a positive correlation among increasing levels of BMI, WC, IR and Insulin. Abdominal adiposity measured by WC was greater >p85 BMI. ($p < 0.0001$) and a value >65cms was positively related to IR ($p < 0.0001$).

Conclusions: Risk of early chronic disease only demonstrated by IR was 12.5 greater for BMI>p85. A WC value>65 cm was related to IR and it is an easy anthropometric measurement to be considered in populations studies.

Key words: BMI, Waist circumference, Insulin resistance, c reactive protein.

PO2333

ASSOCIATION OF MACRONUTRIENT INTAKE WITH OVERWEIGHT AND OBESITY AMONG BANGLADESHI POPULATION: A HOSPITAL BASED STUDY

S. Hossain^{1,2}, U.S. Munni², T. Khan¹, K. Fatema³, L. Ali⁴

¹Department of Health Promotion and Health Education, Bangladesh Institute of Health Sciences, Dhaka, Bangladesh

²Institute of Nutrition and Foods Science, University of Dhaka, Dhaka, Bangladesh

³Dept of Epidemiology & Biostatistics, Bangladesh Institute of Health Sciences, Dhaka, Bangladesh

⁴Dept of Biochemistry & Cell Biology, Bangladesh Institute of Health Sciences, Dhaka, Bangladesh

Background and objectives: Obesity is one of the most important risk factors for diabetes and other disorders of metabolic syndrome. Nutritional intake is a major determinant of obesity and it needs to be studied in various population groups. In the present study we have investigated the nutritional intake of a group of Bangladeshi non-diabetic and diabetic subjects in relation to their demographic and anthropometric status.

Methods: It was an observational exploratory study with 4063 subjects (1571 male and 2492 female; 1552 non-diabetic and 2511 diabetic) attending 20 healthcare centers and hospitals run by the Diabetic Association of Bangladesh. Anthropometric measurements (height, weight, waist and hip) were done by standard techniques. Dietary data were collected by 3days food frequency method. A BMI of 23 was taken as the cut-off point for overweight as defined by WHO for this population.

Results: The mean (\pm SD, years) age of the subjects was 46 ± 14 . The proportion of subjects with lower, middle and upper socioeconomic classes were 20.6%, 51% and 28.4% respectively. BMI was 24.71 ± 5.24 and Waist-Hip ratio was 0.91 ± 0.57 . The proportion of calorie contributed by the three principal macronutrients was as follows: carbohydrate 58%, fat 25%, and

protein 17%. On group comparison between overweight plus obese (BMI>23) and normal weight individuals the intake of carbohydrate and protein did not vary between the groups, but fat intake was paradoxically lower in the overweight group. Logistic regression with normal weight and over weight (plus obesity) as dependent variables carbohydrate and protein intake was found to be associated with overweight when other confounders were adjusted.

Conclusions: Weight gain in Bangladeshi subjects (both non-diabetic and diabetic) is associated with higher carbohydrate intake and a targeted approach to modify this nutritional behavior need to be taken in non-diabetic as well as diabetic population.

Key words: macronutrient, overweight, obesity, Bangladesh, diabetes.

PO2334

EFFECTS OF A DIET RICH IN OLIVE OIL AND AN EPA + DHA PHARMACEUTICAL COMPOUND IN THE RHEUMATOID ARTHRITIS

J. Caballero-Villarraso^{1,2}, L. Louhibi Rubio², M D. Cañete Vázquez¹, P. Benito Lopez², M A. Galvez Moreno², E L. van Donkelaar³, F. Rodriguez Cantalejo¹, R. Cañete Estrada¹

¹IMIBIC/Reina Sofia Hospital/University of Cordoba, Cordoba, Spain

²Endocrinology Service/Reina Sofia Hospital, Cordoba, Spain

³Faculty of Health, Medicine and Life, Maastricht University, Maastricht, The Netherlands

Introduction and Objectives: For years many scientific evidences provide benefits to certain nutrients and diets with positive effects on biological variables and inflammatory activity in rheumatoid arthritis (RA). This is the case of polyunsaturated fatty acids omega 3 and olive oil. It is known that especially eicosapentanoic acids (EPA) and docosahexaenoic acid (DHA) have anti-inflammatory, immunomodulatory and cardioprotective. Our goal is to compare the effect of a diet rich in omega 3 versus another enriched olive oil on biochemical markers of inflammation in patients with rheumatoid arthritis.

Methods: We included 106 patients previously diagnosed with RA and pretreatment. Were assigned to three groups with different treatments were added to standard treatment of RA itself. Group A: 35 subjects with diet supplemented with 30 ml of olive oil, group B: 35 subjects, with a capsule every twelve hours consisting of 465 mg EPA and 375 mg DHA, C: control group (standard treatment only AR). Were determined serum biochemical markers proinflammatory proinflammatory

markers (TNF- α , IL-1, IL-6, ferritin, CRP) at baseline and at 6 and 12 months. To compare differences of values in each group, we conducted a repeated measures ANOVA. For differences between groups ANOVA test was performed.

Results: The groups A and B showed a significant decrease in TNF- α decreased between 0 and 6 months ($p = 0.043$, $p = 0.039$). Also reduced IL-1 between 0 and 6 months ($p = 0.037$, $p = 0.046$). No significant differences were observed between groups A and B.

Conclusions: Fatty acids enhance proinflammatory profile in patients with RA. No significant differences were detected between providing a supplement of olive oil and a pharmaceutical EPA + DHA.

Key words: fatty acids, rheumatoid arthritis, proinflammatory biomarkers.

PO2335

FUNCTIONAL COMPOUNDS IN COMBINATION WITH NANO-GOLD PARTICLES MODULATE APOPTOSIS AND MIGRATION POTENTIAL IN HUMAN COLORECTAL CARCINOMA CELLS

R F. Shu Huang^{1,2}, B H. Chen², H S. Chiang³, Y J. Wei⁴, S H. Hsu⁵

¹Department of Ph.D. Program In Nutrition and Food Science, Fu Jen Catholic University, Xinzhuang, Taiwan, Republic of China

²Department of Food Science, Fu-Jen Catholic University, Taipei, Taiwan

³Department of Graduate Institute of Basic Medicine, Fu-Jen Catholic University, Taipei, Taiwan

⁴Department of Nutritional Science, Fu-Jen Catholic University, Taipei, Taiwan

⁵Department of Nutritional Science, Fu-Jen Catholic University, Taipei, Taiwan

Background and objectives: Colorectal cancer (CRC) is the third leading cause of cancer deaths in Taiwan. High mortality rate of CRC is caused by malignancy metastasis. Recent researches demonstrated that nanogold particles (AuNPs) are high biocompatibility, which can be used as pharmaceutical carriers to promote drug efficacy. Functional compounds of lycopene and DHA were effective for CRC treatment. The aims of this study were to examine whether AuNPs in combination with functional compounds enhanced cytotoxicity of CRC cells and its molecular mechanisms.

Methods: Human colorectal carcinoma HT-29 cells was treated with 1~3 nm, 3~5 nm and 10~15 nm AuNPs after 24 h exposure by MTT assay. Apoptotic death and migration potentials are evaluated by flow cytomics analysis and wound healing assays.

Results: AuNPs at 3~5 nm size significantly induced cellular death by decreased viability of 64% and 71% for the concentrations of 25 and 30 ppm respectively ($p < 0.05$). The half lethal dosage (IC₅₀) of 3~5 nm AuNPs in HT-29 cells was determined at 20.7 ppm. A time course study has investigated the AuNPs induced death. Significant growth inhibition as well as necrotic and apoptotic phenotypes were observed in the 24 h AuNPs treated HT-29 cells. An apparent cell death, 3~5 nm AuNPs significantly increased 34% of apoptosis in HT-29 cells stained with Annexin V, but there was no effect on necrosis by staining with the PI. In addition, HT-29 cells treated 3~5 nm AuNPs 24 h significantly increased the migration. Lycopene or DHA in combination with AuNPs at lower dose enhanced apoptosis and migration of HT-29 cells, possibly through modulation of intracellular molecular signaling.

Conclusions: Our data demonstrated that AuNPs alone or in combination with functional compounds enhanced apoptosis and migration that it may affect potential metastasis of human colorectal carcinoma cells metastasis.

Key words: Colorectal cancer, nanogold particles, apoptosis, Migration.

RECOMMENDATIONS FOR CANCER PREVENTION WORLD CANCER RESEARCH FUND (WCRF): ANALYSIS FOR CHILE

M. Crovetto^{1,2}, R. Uauy²

¹Facultad de Ciencias de La Salud, Centro de Estudios Avanzados. Universidad de Playa Ancha, Valparaíso, Chile

²Instituto de Nutrición Y Tecnología de Los Alimentos. Universidad de Chile, Santiago, Chile

Background and objectives: Cancer is the second leading cause of death in the Americas and in Chile, representing 25.6% of all deaths in 2009. The main diet-related cancer sites include colorectal, lung, breast in postmenopausal women, stomach, esophagus, prostate, and pancreas. After tobacco; obesity is the leading cause of cancer, accounting for one third of all cancers. Obesity related exposure that define cancer risks include total body fat, abdominal fat and weight gain in adulthood. These are potentially modifiable risk factors; consuming a healthy diet and living an active life can significantly reduce body fat and thus cancer risk. The aim of this study was to analyze recommendations published by the International Fund for Cancer Research (WCRF) and American Institute for Cancer Research (AICR) for the prevention of cancer in 2007.

Methods: We compared these recommendations with the situational analysis of risk factors described, based on national studies that report prevalence of these factors in Chile. We

propose National recommendations in accordance with the WCRF 2007 document.

Results: The pattern of food consumption in Chile is characterized by over consumption of products that increase risk of cancer (alcoholic drinks, sugary juices and ultra-processed foods high in sodium and total fat) and low consumption of protective foods (legumes, vegetables, fruits high in antioxidants and fiber).

Conclusions: The analysis reveals that Chile has an increase cancer risk associated with poor quality diets, high Body Mass Index (BMI), and sedentary behavior. We recommend the promotion of healthy diets and active lifestyles conducive to lower cancer risks and good health across all stages of the life-course.

Key words: Diet, cancer, risk factor, chronic non communicable disease, health promotion.

⁶Department of Cardiology, Hospital Txagorritxu, Vitoria, Spain

⁷Redes Temáticas de Investigación Cooperativa RD06/0045, ISCIII, Spain

Background and objectives: Because it has been suggested that osteocalcin, an osteoblast-derived hormone, is a new link between bone and glucose metabolism, we tested whether serum carboxylated (cOC) and undercarboxylated osteocalcin (ucOC) levels are independently associated with the development of type-2 diabetes in subjects at high cardiovascular risk.

Methods: A prospective, nested case-control study was conducted using data from the PREDIMED study. We included

153 cases of newly diagnosed diabetes and 306 individually matched-controls free of diabetes identified during a mean 5-year follow-up. Conditional logistic regression models were used to estimate matched ORs for incident diabetes according to categories of both forms of osteocalcin measured by ELISA.

Results: Baseline serum concentrations of both forms of osteocalcin were significantly lower in cases than in controls. In incident cases, concentrations of cOC, but not ucOC, were inversely and significantly associated with insulin and HOMA-IR levels ($r = -0.334$ and $r = -0.323$, respectively), and with fasting glucose concentrations ($r = -0.058$) in controls, independently of the intervention group, sex, age and BMI. In the conditional logistic model that took into account the matching factors, the ORs for diabetes incidence in the highest vs the lowest tertile of cOC and ucOC were 0.49 (95% CI: 0.32-0.75) and 0.53 (0.35-0.80), respectively. Further adjustment for family history of diabetes, lifestyle and other confounding factors did not appreciably change the magnitude of these associations.

Conclusions: In a population at high cardiovascular risk, elevated concentrations of serum cOC and ucOC were strongly associated with a decreased risk of incident diabetes.

Key words: Carboxylated osteocalcin, undercarboxylated osteocalcin, PREDIMED study, biomarkers, type 2 diabetes mellitus.

PO3146

INCIDENCE OF INSTITUTIONAL FOOD SERVICE PRACTICE MANAGEMENT ERRORS IN THE KITCHEN OF A GENERAL HOSPITAL, CHUBU REGION, JAPAN

S. Maruyama¹, M. Ichie², T. Tsuruta²

¹College of Human Life and Environment, Kinjo Gakuin University, Nagoya, Aichi, Japan

²Nagoya Ekisaikai Hospital, Nagoya, Aichi, Japan

Background and objectives: Institutional food service practice is an important medium for therapeutic patient education in hospitals in Japan. Thus, institutional food service practice management errors are major issues. Such errors in the kitchen are caused by some professionals who are the members of the nutrition section, i.e. registered dietitians, dietitians, chefs, cooks and others. Objective: To assess the incidence of institutional food service practice management errors in the kitchen of a general hospital, Chubu region, Japan.

Methods: A cross-sectional study was conducted on incident reports based on institutional food service practice management errors from January 1 to December 31, 2011. Data was collected from incident reports of the kitchen using a structured format. Data was edited and coded. Descriptive statistics were computed to determine specific errors. Prior to the

start of data collection, permission was obtained from hospital management to use it. Health professionals were replaced with codes to avoid individual identifiers. We assessed times, day of the week, work complex and practitioner condition.

Results: The prevalence of institutional food service practice management errors in the kitchen of this general hospital was 42 times in 365 days. Many errors occurred on Thursday and Friday. Commonly prescribed errors included serving a different menu or mixing contents of the menu. When practitioners were busy and got tired, many errors occurred.

Conclusions: Institutional food service practice management errors in the kitchen were common in this general hospital. An error-free system is required through continued therapeutic patient education.

Key words: Institutional food service, practice management errors.

DEVICE INVENTION FOR ASSESSMENT AND TRAINING BETWEEN HOSPITALS BASED ON PRACTICE PROBLEMS

V. Schejter¹, L. Selvatici¹, J. Cegatti², P. de Raco², F. Ugo², M. Jesiotr², M. Bovisio², N. Elli², S. Blasi¹, P. Elmeaudy¹

¹Hospital de Pediatría 'Prof. Dr.J.P.Garrahan', Buenos Aires, Argentina

²Cátedra de Psicología Institucional, Facultad de Psicología, Universidad de Buenos Aires, Buenos Aires, Argentina

Background and objectives: This article presents a field work experience analysis related to an UBACyT 2010-2012 research plan. Its main goal was to characterize collaborative interchange patterns, training and knowledge production in work situation between different levels of complexity hospitals from diverse provinces and their incidence in institutional changes.

Methods: An assessment experience and training between Garrahan Hospital's Food and Dietetic area and pediatric hospitals of several provinces is analyzed. It develops different stages in which the project was implemented and how interventions were defined from "field" problems. Empirical workers in health institutions, usually not taken into account, are considered a priority in these training programs. This consideration and conditions created to facilitate the implementation are explained.

Results: Interinstitutional net building is analyzed as well as its incidence among different provinces, government instances, hospitals and universities. Importance of academic accreditation for field training, effects due to developed devices in every day work and in the participants' subjectivity are

considered. Documentary information, field observations and interviews were systematized for this study.

Key words: Ground training, permanent education, institutional psychology, institutional assessment.

PO3345

THE KETOGENIC DIET FOR THE TREATMENT OF DRUG-RESISTANT EPILEPSY AND OTHER SYNDROMES: STRATEGIES TO IMPROVE COMPLIANCE AND THERAPEUTIC EFFECT

G. Mestre¹, A. Rojano¹, S. Blasi¹

¹Hospital de Pediatría 'Prof. Dr.J.P.Garrahan' Buenos Aires, Argentina

Background and objectives: The classic ketogenic diet (CKD) has been used by our department as an effective, for children with seizures of different etiologies since 1988, in a multidisciplinary team using a treatment protocol. Of 66 patients treated from 2008 to 2012, 40 children stayed on the KD between 3 years and 6 months and 26 discontinued the diet. In 20% discontinuation was due to non-medical causes. The objective was to search for tools to improve compliance in patients treated with the KD.

Methods: From June 2012 to May 2013 a literature review was conducted to identify strategies to improve compliance with the CKD. Information for the patients and their families, health awareness, the professional-patient relationship, availability of recipes and meal plans, and forms of preparation were looked for to increase adherence to the KD in 40 patients who have been on the oral CKD successfully.

Results: Forty-two recipes were selected, adapted, and prepared (27 main courses, 7 desserts, 10 bread preparations, 3 snacks) of which 26 were approved and added to recipe books or meal plans and were divided into three categories (training, problem solving, motivation). Additionally, our 40 patients who are successfully following the oral CKD received at least one of the tools. To evaluate the impact of the strategy, a questionnaire was designed and administered personally or by phone to 19 families (47%). Of these families, 100% had tried at least one of the possibilities, agreed that they were useful, and were willing to try additional tools.

Conclusion: The tools assessed were well accepted by the families. Nevertheless, further studies should be conducted to measure the true impact of the strategies for the improvement of adherence to the CKD.

Key words: Ketogenic diet, adherence, epilepsy.

PO3346**THE KETOGENIC DIET: A RETROSPECTIVE STUDY OF THE EXPERIENCE OF NUTRITION SUPPORT SERVICES***G. Mestre¹, A. Cresta¹, S. Blasi¹*

¹Hospital de Pediatria 'Prof. Dr.J.P.Garrahan' Buenos Aires, Argentina

Background and objectives: The ketogenic diet (KD) is a non-pharmacologic treatment proven effective for the management of epilepsy of different etiologies in centers throughout the world, using different protocols and forms of administration. We have worked in a multidisciplinary fashion together with the departments of neurology and clinical nutrition since 1988, using a treatment protocol. The objective was to evaluate different diet types and administration modalities of the KD used at our center.

Methods: Between 1988 and 2012, 203 children were put on the MCT ketogenic diet, the classical ketogenic diet (CKD) or the modified ketogenic diet (MKD) Data of 66 patients with different etiologies who received the diet between January 2008 to December 2012 were retrospectively assessed.

Results: Forty-eight of 66 children received the CKD in a 4:1 or 3:1 ratio orally, 12 through a nasogastric (NG) tube or gastrostomy (GT), and six received the MKD orally. Of all 66 children treated with the KD, 60% responded well to the treatment and stayed on the diet. Three children adhered to the oral CKD and one to the CKD through a NG tube for more than 3 years. Four children kept on the oral CKD, three on the CKD through a NG tube or GT, and one on the oral MKD for more than 2 years. Nine children adhered to the oral CKD and four to the CKD through a NG tube or GT for more than 1 year. Fifteen patients have been on the CKD (13 orally and two who started on the NG tube and switched to the oral CKD) and three have been on the MKD for more than 6 months. Twenty-six children discontinued the KD for different reasons.

Conclusion: The KD is successfully managed at the hospital, using different types of diets and forms of administration.

Key words: Ketogenic diet, epilepsy.

PO3347**EFFICACY OF A LOW-FAT YOGURT SUPPLEMENTED WITH A ROOSTER COMB EXTRACT ON JOINT FUNCTION IN MILD KNEE PAIN PATIENTS: A SUBJECT-LEVEL META-ANALYSIS***D. Moriña¹, R. Solà², R M. Valls², V. López de Frutos³, M. Montero³, M. Giralt², I. Papell¹, G. Bernal³, J. Faba³, M C. Casajuana³, A. Rodríguez¹, C. Chetrit⁴, D. Martínez-Puig⁴*

¹CTNS-TECNIO-Technology Center of Nutrition and Health, Reus, Spain

²Facultat de Medicina i Ciències de la Salut - Universitat Rovira i Virgili, Reus, Spain

³Hospital Universitari Sant Joan de Reus, Reus, Spain

⁴Bioiberica S.A., Palafolls, Barcelona, Spain

Background and objectives: The aim of this meta-analysis was to determine the effects of daily consumption of a low-fat dairy product supplemented with Mobicel™, a rooster comb extract rich in HA and other glycosaminoglycans (80 mg/d), on muscle function, echographic evolution and knee discomfort using a Visual-Analogue-Scale (VAS) compared with a low-fat dairy product consumed by 3 months on affected knee.

Methods: The individualized results from 148 volunteers of Intention-To-Treat population (ITT) (51 men; aged from 20 to 75y) of two randomized, controlled, double-blind, parallel trials (68 volunteers; Martínez-Puig D, 2012) and 80 volunteers; ClinicalTrials.gov Identifier: NCT01303432) performed on patients with mild knee pain (VAS between 30 and 50 mm) developed in Barcelona and Reus (Spain) by implementing the same protocol. The muscle function determined by peak torque, total work, and power mean in flexion and extension at speeds of 180°/s and 240°/s using an isokinetic dynamometer Biodex 4. The outcomes evaluation was performed by an ANCOVA model with the baseline value as covariables without missing data imputation on the ITT.

Results: After 3 months, compared to control, improved total work in flexion at 180°/s (P=0.039); reduced synovial effusion (P =0.037); 3) and perception of pain diminished (P=0.003) on affected knee, particularly in men older than 50.

Conclusions: Long-term low-fat dairy product supplemented with HA consumption improves muscle strength, synovial effusion and pain providing clinical benefit on patients with mild knee pain, specially in men 50 years and older.

Key words: Glycosaminoglycans, knee pain.

PO3348**DIETARY INTAKE OF FOLATE, VITAMIN B6 AND RIBOFLAVIN AND RISK OF DEVELOPMENT OF DIFFERENT MOLECULAR SUBTYPES OF BREAST CANCER IN THE ORDET COHORT**

S. Sieri¹, Pala. V¹, C. Agnoli¹, S. Grioni¹, C. Riva², V. Krogh

¹Epidemiology and Prevention Unit, Fondazione IRCCS Istituto Nazionale Dei Tumori, Milan, Italy

²Department of Pathology, Ospedale di Circolo and University of Insubria, Varese, Italy

Background and objectives: Vitamins involved in one-carbon metabolism have been hypothesized to influence the risk of breast cancer (BC). Epidemiologic studies that examined associations between folate or vitamin B intake and BC risk have provided inconsistent results. Recent studies suggest that molecular subtypes of BC defined by expression of HER2, estrogen receptors (ER), progesterone receptors (PR), differ in terms of the risk factors influencing their occurrence. We prospectively also examined whether the consumption of folic acid and vitamin B was associated with the incidence of breast cancer and breast cancer tumor characteristics.

Methods: Participants were 10,766 women enrolled in the ORDET study, who completed a dietary questionnaire 1987-1992. Cox proportional hazard models adjusted for energy intake and confounders, estimated Relative Risk (RR) and 95% CIs for breast cancer.

Results: After a mean of 16 years of follow-up, 388 incident cases of BC were ascertained. The multivariate RR of total BC for riboflavin intake was 0.49 (95% CI, 0.33-0.72 highest vs. lowest quartiles; P trend=0.001) and 0.57 (95% CI, 0.38-0.87 highest vs. lowest quartiles; P trend=0.009) for vitamin B6. Folic Acid intake was inversely associated with BC (RR of 0.66, 95% CI, 0.45-0.96). When relations between folic acid and vitamins B and risk of BC expressing various receptor combinations were assessed, riboflavin and folic acid were significantly associated with decreased risk of estrogen and progesterone receptor-positive cancers. High riboflavin intake was also associated with decreased risk of both HER2-negative and HER2-positive cancers whereas folic acid intake was inversely associated with HER2-negative cancer.

Conclusions: These findings support an overall association between folic acid, riboflavin and vitamin B6 intake and decreased risk of overall BC, and suggest that folic acid and riboflavin intake may be inversely associated with ER+/PR+ and Her2-tumors.

Key words: Vitamin B, folate, breast cancer, receptor status.

PO3349**DRINKING RAW MILK: DOES THIS AFFECT ALLERGY RESPONSES?**

A. Hodgkinson¹, N. McDonald¹, L. Kivits¹, D. Hurford¹, O. Wallace¹, B. Hine¹

¹Food and Bio-based Products, AgResearch Ruakura, Hamilton, New Zealand

Background and objectives: Epidemiological studies have shown an association between consumption of raw farm milk and reduced incidence of allergy. We fed untreated raw, gamma-sterilized, heat-treated milks or water to groups of mice then compared their responses to allergen exposure and challenge, in a model of gastrointestinal allergy.

Methods: Raw farm milk was collected and not treated, gamma-sterilized or heated to 85°C, cooled and strained. Levels of bacteria and milk proteins were assessed in milk samples. From weaning (3 weeks), groups of Balb/c mice (n=8/group) received milks via drink bottles. Control groups received water and all mice were fed standard (dairy-protein free) rodent diet. At 6 and 8 weeks, mice were given intra-peritoneal injections of ovalbumin/alum, to sensitize them to antigen. At week 10, mice were challenged four times on alternate days by intra-gastric gavage with 50 mg ovalbumin or saline. Following the final gavage, serum levels of total and specific IgE, IgG1 and IgG2a antibody and Mouse Mast Cell Protease-I (MMCP-I) were determined. Interleukin-4, interleukin-10 and interferon-gamma responses following activation with antigen were measured in cultured splenocytes.

Results: Sterilized and heated milks contained no viable bacteria, in contrast to raw milk. Heating and sterilizing milks reduced the detectable level of many milk proteins. Mice drinking raw milk had the highest levels of MMCP-I of all groups and higher levels of specific IgE compared with mice drinking heated milk. Cultured splenocytes from ovalbumin-primed mice produced similar levels of interleukin-4 when incubated with ovalbumin; however, interleukin-10 levels were highest from mice drinking raw milk.

Conclusions: The data suggested that consumption of raw (untreated) milk enhanced allergy responses compared with treated milks. The change in response may be due to milk components and/or bacteria in raw milk that are modified or removed during treatment processes.

Key words: Milk, allergy, raw milk.

PO3350**INADEQUATE MICRONUTRIENT INTAKE FOR FOOD SECURITY SITUATION OF BENEFITING PRESCHOOL CHILDREN OF BOLSA FAMÍLIA PROGRAM, VIÇOSA, MINAS GERAIS, BRAZIL**

S. Priore¹, Sperandio. N¹, D. Morais¹, L. Dutra¹, S. Franceschini¹

¹Federal University of Viçosa, Viçosa, Minas Gerais, Brazil

Background and objectives: The investigation of individual food intake is able to detect, with fidelity, food insecurity situation in the investigated period. The objective is to evaluate the inadequate micronutrient intake for food security situation.

Methods: Sectional study with 243 children 2-6 years of age, beneficiaries of Bolsa Família of the Federal Government, living in the city of Viçosa, Minas Gerais, Brazil. The sampling was random, based on the registration of beneficiaries of Bolsa Família of the Department of Social Welfare of the city, using 80.3% prevalence of food insecurity in the Southeast Brazil. Food consumption has been assessed by the 24-Hours Dietary Recall on two separate days, the average being used for analysis. The adequacy of intake of micronutrients (vitamins A, C and D, calcium, iron, selenium and zinc) was based on the Estimated Average Requirement (EAR). The analyzes were separated for children 2-3 years and 4-6 years, depending the values of EAR and food insecurity: mild and moderate/severe. The study was approved by the Ethics Committee.

Results: The mild food insecurity was present in 37.7% (n = 29) and 51.8% (n = 86) of children 2-3 years and 4-6 years, respectively, while the moderate or severe 27.3% (n = 21) and 24.1% (n = 40), respectively. The median intake of vitamin D and calcium was below the recommendations (p>0,05), independent of the child's age and situation (in) security. The intake of vitamin A, calcium and iron of children 2-3 years there was difference (p <0.001) between the groups, as well as of children 4-6 years to calcium and selenium (p <0.05).

Conclusions: Inadequate intake of micronutrients is present in children receiving the Program, and differs according to the situation (in) food security for some micronutrients.

Key words: Food security, food consumption, preschool.

PO3351**POST-PRANDIAL GUT HORMONE RELEASE AFTER A HIGH-FAT MEAL CHALLENGE DIFFERS BETWEEN HEALTHY NORMAL WEIGHT AND OBESE VOLUNTEERS**

T. Yeh¹, C. Childs¹, C. Paras Chavez¹, P. Noakes¹, J. Olza Meneses¹, P. Calder¹

¹Human Development & Health Academic Unit, Faculty of Medicine, University of Southampton

²This research was supported by the European Commission under Framework 7: BIOMarkers of Robustness of Metabolic Homeostasis for Nutri-genomics-derived Health CLAIMS Made on Food (KBBE-244995)

Background and objectives: Obesity is associated with chronic low-grade inflammation[1]. In response to a meal there is a transient increase in the blood concentrations of inflammatory markers[2]; this is referred to a post-prandial inflammation. We are investigating the anti-inflammatory action of n-3 fatty acids in normal weight and obese subjects.

Methods: Normal weight (18.5–25 kg/m²) and obese (30–40 kg/m²) volunteers were randomised to receive either fish oil (3g fish oil, containing 1.8g/day EPA + DHA) or placebo (3 g corn oil) daily for three months prior to a high-fat meal challenge. The gut hormone content of protease-treated plasma was assessed in post-prandial samples collected from 25 subjects (n=11 normal weight and n=14 obese) for analytes including amylin, ghrelin, GIP, GLP-1, insulin, leptin, PP and PYY. Area under the curve data was analysed by two-way ANOVA to assess the effect of obesity status and fish oil treatment.

Results: A significant effect of obesity status was observed upon post-prandial ghrelin (p=0.001) and leptin (p=0.002) concentrations with a trend upon GLP-1 (p=0.063) and insulin (p=0.072) concentrations. Obese subjects had lower post-prandial ghrelin and GLP-1 and higher insulin and leptin compared to normal weight subjects. No significant treatment effects or obesity x treatment interactions were identified.

Conclusions: These data indicate that healthy obese subjects have an altered gut hormone response to a high-fat meal in comparison to normal weight individuals. Our data are consistent with data suggesting leptin resistance and increased ghrelin-sensitivity as a feature of obesity[3]. Further work will identify whether post-prandial gut hormone responses relate to measures of post-prandial inflammation.

PO3352**ANTIOXIDANT EFFECT EXERTED BY MEAT EXTRACTS IN A CELL MODEL OF ANGIOTENSIN II INDUCED DAMAGE**

M C. Asensio-López¹, A. Lax¹, J. Sánchez-Más¹, S. Abenza¹, F J. Pastor¹, J. Planes², A. Avellaneda², D. Pascual-Figal¹

¹Cardiology Department, University Hospital Virgen de la Arrixaca, Murcia, Spain

²I+D+i Department, ElPozo Alimentación, S.A., Alhama de Murcia, Spain

Background and objectives: Oxidative stress is directly related to the development of hypertension and hypertensive heart disease. One of the ways to slow the processes related with chronic hypertension has focused on the search of natural antioxidants from the diet. This study evaluated the antioxidant capacity of hydrophilic (HFL) and hydrophobic (HFB) fractions of pork meat products in a cellular model of damage induced by angiotensin II (Ang-II), one of the main factors involved in the development and complications of hypertension.

Methods: Mouse adult cardiomyocytes (HL-1) were subjected to damage induced by Ang-II (48 h, 1 μ M). Oxidative stress was evaluated by measuring the levels of reactive oxygen species (ROS) and activity of the antioxidant enzymes catalase (CAT) and glutathione peroxidase (Gpx-3). 50 g of each product (dry-cured pork sausage and cooked pork ham) was processed following standard protocols to obtain their respective HFL and HFB fractions. Results are expressed as percentage of control \pm standard deviation.

Results: The exposition of HL-1 cells to Ang-II was associated with an increase on ROS levels (210 \pm 30%) and a decrease of CAT (30 \pm 9%) and Gpx-3 activity (43 \pm 8%). The pre-exposition for 24h with the HFL fraction of either product was able to prevent the increase in ROS (109 \pm 10%, cooked; 120 \pm 20%, cured) and the loss of CAT (62 \pm 8%, cooked; 98 \pm 10%, cured) and Gpx-3 activity (73 \pm 15%, cooked; 89 \pm 17%, cured) induced by Ang-II. The pre-exposition for 24h with HFB fraction of either product showed preventive effects similar to those observed for HFL fractions. The administration of different fractions in the absence of Ang II did not affect levels of ROS or antioxidant activity.

Conclusions: Extracts from selected elaborated pork products exert a cardioprotective effect against oxidative stress induced by Ang-II, which may suggest a potential beneficial effect associated with anti-hypertensive activity.

Key words: Meat extracts, hypertension, cardioprotection.

PO3353**ASSOCIATION BETWEEN CENTRAL BODY ANTHROPOMETRIC MEASURES AND CARDIOVASCULAR RISK FACTORS IN ADOLESCENTS**

S. Priore¹, F. Faria¹, P. Pereira¹, E. Faria², S. Franceschini¹, M C. Peluzio¹, A. Queiroz¹

¹Federal University of Viçosa, Viçosa, Minas Gerais, Brazil

²Federal University of the Espirito Santo, Alegre, Espirito Santo, Brazil

Background and objectives: The use of central body anthropometric measures is important in the evaluation of cardiovascular risk due to the rise of obesity prevalence in adolescents. The objective was to evaluate the association between several anthropometric measurements in the diagnosis of cardiovascular risk factors in adolescents, according to sex regardless body mass index (BMI) and percentage body fat (%BF).

Methods: it was a cross-sectional study involving 336 adolescents of both sexes aged 10-13 years old from Viçosa, MG, Brazil. The nutritional status was evaluated according to the World Health Organization and the %BF by bioelectrical impedance. We measured the waist circumference (WC), hip circumference (HC), neck circumference (NC), waist-height ratio (WHtR), waist-to-hip ratio (WHR), serum total cholesterol (TC), HDL, LDL, triglycerides (TG), uric acid (UA), insulin, fasting glucose, Homeostasis Model Assessment-Insulin Resistance (HOMA-IR) and the blood pressure (BP). We used the Kolmogorov-Smirnov test, Student's t test and Mann-Whitney test and multiple logistic regression, adjusted for BMI and %BF. We adopted a significance level of $p < 0.05$. The study was approved by the Ethics Committee of the institution.

Results: mean age was 11.6 \pm 1.1 years old, 53.3% male, 39.3% had excess body fat and 25.0% were overweight by BMI/age. Multiple regression analysis in females presented positive associations between TG, TC/HDL with WHtR and WHR, regardless of BMI, and insulin, HOMA-IR with WC and NC, regardless of %BF. In males, positive associations between TC, LDL, insulin, HOMA-IR, AU and measures WHtR, WC, HC, and NC remained significant, independently of %BF. When adjusted for BMI, the positive association between TC/HDL and WHR persisted.

Conclusions: all central body anthropometric measures associated with at least one cardiovascular risk factor independently of nutritional status and body composition, especially in males, and could be used to assess the nutritional status of adolescents. Support: FAPEMIG/ CNPq.

Key words: Adolescent; cardiovascular diseases; anthropometry; body fat.

PO3354**COMPARISON OF TREATMENT EFFECTS BETWEEN STERIOD THERAPY AND STEROID-TCM THERAPY IN IGA NEPHROPATHY USING QUANTITATIVE PROTEOMICS***R X. Li¹, X F. Cai², R. Zeng¹, Y Y. Deng²*

¹Key Laboratory of Systems Biology, Institute of Biochemistry and Cell Biology, Shanghai Institutes for Biological Science, Chinese Academy of Sciences, Shanghai, China

²Department of Nephrology, Longhua Hospital, Shanghai University of Traditional Chinese Medicine, Shanghai, China

Background and objectives: Primary IgAN is characterized by deposition of the IgA antibody in the glomerulus, while diverse efficacies would be resulted from different treatments and individual specification.

Methods: In the present study, we used a strategy combining chemical-labeling and peptide fractionation coupled with mass spectrometry to quantify the protein changes in IgAN urine treated by steroid and steroid combined Traditional Chinese Medicine (TCM).

Results: More than 1000 proteins were quantified in the urine of IgAN before and after treatment by steroid and steroid-TCM therapy. Both PCA analysis and HCA analysis can clearly distinguish the treatment by steroid and steroid-TCM. Additionally, quantified proteins were clustered into different group according to the change trend by fuzzy c-means cluster and proteins shown significant change were also submitted to David GO analysis. We found some proteins were consistently changed by both therapies, such as pro-epidermal growth factor, collagen alpha-1(I) chain and Ras-related C2 botulinum toxin substrated 1, etc.. However, the change curves of certain proteins are different between the two therapies.

Conclusions: Our data provided potential disease-related biomarkers for evaluation of treatment by steroid and steroid-TCM therapy, and the TCM may play a role in protection of renal function.

Key words: IgA nephropathy, steroid combined Traditional Chinese Medicine, chemical-labeling, protection of renal function.

PO3355**EFFECTS OF DIETARY INDUCED WEIGHT LOSS ON PLASMA AMINO ACID PROFILES***R. Zeng¹, Liu. X², X. Gao¹, L. Sun², X. Lin²*

¹Key Laboratory of Systems Biology, Institute of Biochemistry and Cell Biology, Shanghai Institutes for Biological Sciences, Chinese Academy of Sciences, Shanghai, China

²Key Laboratory of Nutrition and Metabolism, Institute for Nutritional Sciences, Shanghai Institutes for Biological Sciences, Chinese Academy of Sciences, Shanghai, China

Background and objectives: Both low-carbohydrate (LC) and calorie-restricted (CR) diets could effectively reduce body weight. However, little is known about the changes of plasma amino acid (AA) profiles during the dietary induced weight loss. Thus, this study aimed to investigate the changes of plasma AA profiles and their relationships with cardiometabolic risk factors in a randomized controlled feeding trial.

Methods: A total of 50 overweight or obese Chinese women (age: 47.9 ± 6.6 years; BMI: 26.7 ± 2.3 kg/m²) were randomly assigned to either a low-carbohydrate non-calorie-restricted diet (initial carbohydrate intake 20 g/d, with 10 g increase weekly) or a calorie-restricted diet (carbohydrate 156-205 g/d, 35% average energy reduction) for 12 weeks. Plasma AAs before and after the intervention were measured by gas-chromatograph/mass-spectrometer.

Results: Mean weight losses were similar in two groups (LC: -5.27 [95%CI -6.08, -4.46] kg; CR: -5.09 [95%CI -5.50, -4.67] kg, P=0.67). Twenty-two AAs were detected from plasma samples. Three AAs in the LC group (alanine, -18.9%, P=6.3e-4; glycine, -23.0%, P=2.5e-4; serine, 22.8%, P=5.5e-4), and six AAs in the CR group (alanine, -18.3%, P=1.1e-4; glycine, -25.0%, P=6.5e-6; serine, 26.7%, P=3.8e-5; asparagine, 22.1%, P=1.9e-3; glutamine, 22.0%, P=6.2e-4; and lysine, 15.4%, P=1.1e-3) changed significantly. The ratio of triglycerides to HDL cholesterol (P=0.01) reduced more in the LC group than those in the CR group. However, no between-group difference was observed for any plasma AA. Meanwhile, none of the AA changes were correlated with changes in body mass index, weight, waist circumference, or plasma concentrations of glucose, triglycerides, total cholesterol, and HDL or LDL cholesterol.

Conclusions: Although certain plasma AAs fluctuated during dietary induced weight loss, reduced body weight and improved lipid profiles could not be explained by changes of plasma AA profiles.

Key words: Plasma amino acids, weight loss, Chinese women.

PO3356**EFFECTS OF INDIVIDUAL BRANCHED-CHAIN AMINO ACIDS DEPRIVATION ON INSULIN SENSITIVITY AND GLUCOSE METABOLISM IN MICE***F. Xiao¹, W. Chunxia¹, Q. Zhang¹*¹Institute For Nutritional Sciences, SIBS, CAS, China

Background and objectives: We have previously shown that serum insulin levels decrease threefold and fed blood glucose levels remain normal in mice fed a leucine-deficient diet, suggesting increased insulin sensitivity. The goal of the present study was to investigate the effect of branched chain amino acids (BCAAs) deficiency on insulin sensitivity and underlying mechanisms.

Methods: Changes in metabolic parameters and expression of genes and proteins involved in regulation of insulin sensitivity and glucose metabolism were analyzed in mice, human HepG2 cells, primary hepatocytes and C2C12, a mouse myoblast cell line under different BCAAs deprivation.

Results: We showed that all three BCAAs deprivation for 7 days improves hepatic insulin sensitivity via General Control Nondepressible 2/mammalian Target of Rapamycin and AMP-activated protein kinase pathways. Different from leucine, valine or isoleucine deprivation for 7 days significantly decreased fed blood glucose levels, possibly by decreasing expression of a key gluconeogenesis gene glucose-6-phosphatase. Finally, we showed that insulin sensitivity is rapidly improved in mice 1 day following maintenance on a diet deficient for any individual BCAAs.

Conclusions: Our results showed that the effect of leucine deprivation represents a general effect of BCAAs on regulation of insulin sensitivity, but not glucose levels, suggesting that each individual BCAA has unique feature in metabolism regulation. These observations are also important for understanding the molecular mechanisms underlying regulation of insulin sensitivity during different BCAAs deprivation and provide a rationale for short-term dietary deprivation or restriction of BCAAs for the treatment of insulin resistance and associated metabolic diseases. The effect of other individual amino acids will be investigated in the future.

Key words: Leucine deprivation, valine deprivation, isoleucine deprivation, insulin sensitivity, glucose metabolism.

PO3357**HEALTH BENEFITS OF VITAMIN E IN HUMAN STUDIES: EPIDEMIOLOGY VERSUS RANDOMIZED CLINICAL TRIALS***S. Peter¹, P. Weber¹, M. Eggersdorfer¹*¹DSM Nutritional Products Ltd., Kaiseraugst, Switzerland

Background and objectives: Evidence from various observational studies indicates that vitamin E has beneficial effects on the cardiovascular system. However, results from RCTs did not consistently confirm these findings. Based on the available data, our aim is to propose a more holistic approach in defining daily intake recommendations for vitamin E.

Methods: Existing evidence from epidemiological studies and randomized clinical trials was reviewed, summarized, evaluated and the respective conclusions were drawn.

Results: Outcomes of the main epidemiological studies show a 24% risk reduction for cardiovascular events at vitamin E plasma concentration above 30 µmol/l. Data from the WHS and ATBC studies suggest that vitamin E supplementation may reduce the risk of venous thromboembolism and can increase the life expectancy of some population groups. In contrast, discrepant results have been obtained by the CHAOS study with a vitamin E supplementation of 400-800 IU/d and results of the GISSI-Prevenzione (300 mg/d) and HOPE (400 IU/d) trials suggest the absence of relevant clinical effects. However, data also show that the genotype appears to be important in this regard. In the ICARE study the primary composite outcome was myocardial infarction, stroke, and cardiovascular death, which was significantly reduced in diabetics receiving 400 IU/d vitamin E (2.2%) compared with placebo (4.7%; p=0.01). These findings were confirmed in a post-hoc analysis of the HOPE study: Risk for cardiovascular events was significantly reduced only in the diabetics carrying the Hp 2-2 gene. **Conclusions:** Observational studies might be useful for identifying target plasma concentrations associated with health benefit(s), which then can be translated into respective intake recommendations to achieve these plasma concentrations. However, there still exists a great need for well-designed RCTs to address potential health benefits of vitamin E on relevant clinical health outcomes.

Key words: Vitamin E, health benefits, epidemiology, randomized clinical trials.

PO3358**INTERACTION BETWEEN BMI AND PERSONALITY SUBTYPES IS ASSOCIATED WITH CHANGES IN HPA-AXIS REACTIVITY**

D. Hoogeboom¹, A. Anneke², K. Bocker¹, H. Koppeschaar³, S. Scholte⁴, I. Itimu³, A. Tuiten³

¹Alan Turing Institute Almere, Amere, The Netherlands

²Academisch Medisch Center, The Netherlands

³Emotional Brain, The Netherlands

⁴University of Amsterdam, Amsterdam, The Netherlands

Background and objectives: Interaction between BMI and Personality subtypes is associated with changes in HPA-axis reactivity. The reinforcement sensitivity theory (RST) of Gray explains individual differences in emotional and motivational behaviour and is funded on two brain systems that control behaviour. The behavioural approach system (BAS) controls appetitive approach, motivation and dominance and depends on dopamine levels. High BAS is associated with strong impulsivity, proneness to addiction and sensitivity to food-related cues. Low BAS individuals seek substances that activate the dopamine-mesolimbic system (DA-ML). The behavioural inhibition system (BIS) is associated with activation of the hypothalamus-pituitary-adrenal (HPA)-axis that controls cortisol dependent anxiety-based avoidance. Both DA-ML and HPA-axis have been reported to play a role in addiction. We examined DA-ML and HPA-axis activity in the BIS/BAS groups by measuring the cortisol awakening response. We hypothesise that individual variance in CAR contributes to differences in susceptibility to food addiction.

Methods: 95 participants aged 20-25 years were included and divided into BIS/BAS group based on the relevant questionnaire. BMI (body mass/square of height) was classified as healthy, overweight or obese. Interaction between BIS/BAS and BMI was analysed by Two-way ANOVA and posthoc analysis.

Results: We find a significant effect of obesity on CAR-response in the low BAS group who increase food intake to augment DA levels. DA activates the HPA axis thereby stimulating cortisol production. Through a negative feedback mechanism cortisol shuts down the HPA axis. On continuous activation by stress or DA, as we see in the obese low BAS group, cortisol is unable to shut down the HPA-axis resulting in a rise in cortisol levels and responsiveness.

Conclusion: These data support our hypothesis that, at least for the low BAS group, individual variance in cortisol responsiveness accounts for differences in susceptibility to food addiction.

Key words: Obesity, Dopamine Mesolimbic-system, hypothalamus-pituitary-adrenal, BIS/BAS.

PO3359**MEAT PORK EXTRACTS PROTECT CARDIOMYOCYTE AGAINST DAMAGE INDUCED BY ISCHEMIA**

M C. Asensio-López¹, A. Lax¹, J. Sánchez-Más¹, S. Abenza¹, I. Garrido¹, J. Planes², A. Avellaneda², D. Pascual-Figal¹

¹Cardiology Department, University Hospital Virgen de la Arrixaca, Murcia, Spain

²I+D+i Department, El Pozo Alimentación, S.A., Alhama de Murcia, Spain

Background and objectives: Oxidative stress is a main process in ischemic heart disease. Processed meat pork products represent a potential source of antioxidants that may protect against the deleterious effects of ischemia. This study evaluated the antioxidant activity of the hydrophilic (HFL) and hydrophobic (HFB) fractions from two meat products on a cardiac model of ischemic damage.

Methods: Each meat pork product (cooked ham and dry-cured sausage) was processed to obtain their respective HFL and HFB fractions. Adult mouse cardiomyocytes HL-1 cell line were subjected to oxidative stress induced by ischemia (15 h under <2% oxygen in absence of glucose). Cell damage was characterized analyzing percentage of cell viability, generation of reactive oxygen species (ROS) and activity of the antioxidant enzymes catalase (CAT) and glutathione peroxidase (Gpx-3). Results are expressed as percentage of control (%) ± standard deviation.

Results: After ischemia, HL-1 cells showed a decrease in cell viability, as showed by decreasing in survival index (35%±9) compared with control. Ischemia also increased ROS levels (190±20%) and reduced CAT (22±8%) and Gpx-3 activity (45±6%). The pre-treatment for 24h with HFL fraction of either product was able to partially prevent the lost of cell viability induced by ischemia (59±6%, cooked; 45±8%, cured), to block the increase of ROS levels (110±15%, cooked; 99±10%, cured) and to prevent the lost of antioxidant activity: CAT (81±15%, cooked; 82±20%, cured) y Gpx-3 (68±10%, cooked; 85%±12, cured). The pre-treatment for 24h with HFB fraction of either product did not restore survival index (21±5%, cooked; 30±8%, cured), but it blocked ROS generation (115±20% cooked; 98±10%, cured) and attenuated the lost of CAT (80±8%, cooked; 90±10%, cured) and Gpx-3 activity (92±15%, cooked; 79±6%, cured).

Conclusions: Extracts from processed meat pork products exert a cardioprotective effect against oxidative stress induced by ischemia.

Key words: Pork meat, ischemia, cardioprotection.

PO3360**RAPID INCREASES IN PLASMA ANTI-INFLAMMATORY AND PRO-RESOLVING LIPID MEDIATOR SPECIES WITH OMEGA-3 EPA AND DPA SUPPLEMENTATION**

D. Cameron-Smith¹, M. James¹, G. Kuar², K.R. Maddipati³, A. Sinclair⁴

¹Liggins Institute, Auckland, New Zealand

²Victoria University, Melbourne, Victoria, Australia

³Wayne State University, Detroit, USA

⁴Deakin University, Geelong, Victoria, Australia

Background and objectives: EPA and DHA are the predominant dietary omega-3 species in the diet, capable of generating bioactive metabolites with anti-inflammatory activity including resolvins, protectins and maresins. Additionally, there is an appreciable contribution of dietary DPA, although the metabolic fate of DPA is poorly understood. Using a target lipidomics approach, the human plasma profile of lipid mediator species derived from cyclooxygenase (COX-1 and 2), lipoxygenase (5-, 12, 15-LOX), and epoxygenase (CYP) pathways was determined.

Methods: In a randomized cross-over study, female subjects (n=8) ingested 2 grams daily of pure EPA, DPA, or placebo control (olive oil; OO) for 7 days. Fasting plasma was drawn before (day 1) and following (day 8) dietary fatty acid supplementation.

Results: In total 126 lipid mediator species resolved by LC-MS. 29 lipid mediator species were influenced by OO supplementation, whilst EPA and DPA supplementation uniquely regulated a further 37 and 27 lipid mediators, respectively. In response to OO supplementation, eicosanoids derived from linoleic acid (LA) (HODEs, HOTrEs & EpOMEs) and dihomo γ -linolenic acid (DGLA) (HETrEs) were suppressed. The arachidonic acid (AA)-derived prostaglandins (PGE2 & TXB2) were also increased almost 2 fold in response in OO. EPA supplementation, circulating EPA metabolites, most notably LOX-derived hydroxyl-eicosapentaenoic acids (HEPEs), 8-HEPE and 18-HEPE increased >10 fold. Additionally, EPA derived prostaglandins (PGE3), leukotrienes (LTB5), and remaining HEPEs (5-, 9-, 11-, 12, 15-HEPE) were elevated (~2 fold). DPA supplementation resulted in marked (≥ 20 -fold) increase in plasma concentration of the putative bioactive DHA metabolites 7,17-DiHDoPE and 19,20-DiHDoPE. Additionally, the DHA metabolites resolvin D1 (RvD1) and 7(S)-Maresin1 were increased (30-60%) by DPA. All EPA metabolites remained unaltered following DPA supplementation.

Conclusions: There is a complex inter-relationship between lipid mediators derived from the omega-3 and -6 FA families. Lipidomic analysis was able to resolve the unique metabolites derived from differing dietary omega-3 species.

Key words: Inflammation, lipidomics, omega-3 fatty acids, protectins, resolvins.

PO3361**ROLE OF EDUCATION IN THE MANAGEMENT OF TYPE 2 DIABETES DURING RAMADAN FASTING**

M.B. Khaled¹

¹Djillali Liabes University, Sidi Bel Abbes, Algeria

Background and objectives: Undertaking fasting during Ramadan constitutes a real challenge for people with diabetes, for their health care providers and even for their families. The therapeutic strategy should be individualized and patients who want to fast Ramadan safely should be previously educated in order to avoid diabetes complications during this period.

Methods: 125 patients with diabetes type 2 aged of 51 \pm 7 years were selected before Ramadan 2011 in Sidi-Bel-Abbes city (West of Algeria). Before Ramadan, 70 individuals, among the studied population (group 1), have been given advices and training on how to manage their diet, medication and monitoring their serum glucose. The rest (group 2) did not. The food consumption was assessed using the three days food record. FSG (fasting serum glucose), PPG (postprandial serum glucose), HbA1c, total cholesterol, HDL-c, LDL-c and Lp (a) lipoprotein a, were measured before during and after fasting month.

Results: Results showed that 96% of group 1 were able to fast more than 21 days with a frequency of hypoglycemic episodes of 9 fold lower than group 2. 16 patients from group 2 were hospitalized because of severe hypoglycemic events (<3.3 mmol L⁻¹) and therefore interrupted fasting. Significant differences (p<0.05) have been noticed between the two studied groups for FSG, HbA1c, total cholesterol and Lp (a).

Conclusion: Education people with diabetes type 2, who want to fast safely Ramadan, will help greatly to prevent metabolic complications such as hypoglycemia and hyperglycemia during this period.

Key words: Ramadan fasting, type 2 Diabetes, education.

PO3362**SELECTED DIETARY NUTRIENTS AND THE PREVALENCE OF METABOLIC SYNDROME IN ADULT MALES AND FEMALES IN SAUDI ARABIA**

⁶College of Applied Medical Sciences, King Saud University, Riyadh, Kingdom of Saudi Arabia

⁷Department of Pharmacology and Pharmacy, Li KaShing Faculty of Medicine, 21 Sassoon Road, Hong Kong, China

Background and objectives: In recent decades, Saudi Arabia has developed very fast economically and socially. This pace of change has affected the general dietary intake pattern of the Saudi Arabian population diverging from traditional foods towards increased consumption of energy dense and processed foods that are high in fat, sugar and salt. We aimed to examine the relationship between selected dietary nutrient intakes and prevalence of metabolic syndrome in the general population of Riyadh, Saudi Arabia, including adult males and females.

Methods: In this cross-sectional study, 185 Saudi adults aged 19 to 60 years (87 males and 98 females with a mean age of 35.6 ± 13.2 , 37.6 ± 11.7 respectively) were included. The criteria for metabolic syndrome were based on those of the International Diabetes Foundation (IDF) and the dietary food intake was assessed by the two 24 hour dietary recall method.

Results: The odd ratios (ORs) of metabolic syndrome across quartiles of selected dietary nutrients had significantly lower inverse relationships for carbohydrate and protein, as well as for vitamin A, C, E, K, calcium, zinc and magnesium ($p < 0.05$ for all) in the female group with metabolic syndrome as compared to those without metabolic syndrome.

Conclusions: The pattern of daily dietary intake of selected nutrients among the general population of Riyadh raises

concern and this dietary imbalance could increase the risk of high prevalence of metabolic syndrome in particular in adult females compared to males.

Acknowledgements: We thank the Prince Mutaib Chair for Biomarkers of Osteoporosis for technical and financial support. Special thanks to Mr. Benjamin Vinodson for the statistical analysis

Key words: Dietary micronutrients, metabolic syndrome, vitamins, Saudi Arabia.

PO3363**S-EQUOL ENHANCES THE PROLIFERATION OF PANCREATIC BETA-CELLS**

N. Harada¹, H. Hiroko¹, Y. Nakano², R. Yamaji¹, H. Inui¹

¹Osaka Prefecture University, Japan

²Osaka Women's Junior College, Japan

Background and objectives: Type 2 diabetes mellitus is one of the major health problems worldwide. Decrease of pancreatic β -cell mass, which is the result of impaired cell proliferation and increased β -cell death, is observed in type 2 diabetes mellitus patients and has been directly linked to defects in insulin secretion. The aim of this study is to identify food factors that enhance the proliferation and reduce the cell death of β -cells.

Methods: We examined the effects of food factors on the proliferation and alloxan-induced cell death of INS-1 rat β -cells.

Results: S-Equol, a metabolite of the soy isoflavone daidzein, enhanced the proliferation of INS-1 cells. Although the transcriptional activation of estrogen receptor by S-equol (10 μ M) were comparable to that by R-equol (10 μ M) or 17 β -estradiol (10 nM), growth stimulation were only observed in the presence of S-equol. The estrogen receptor antagonist ICI182,780 did not affect the S-equol-enhanced INS-1 cell growth. H89 (an inhibitor of protein kinase A signaling), but not LY294002 (an inhibitor of PI3K/Akt signaling), abolished S-equol-enhanced proliferation of INS-1 cells. S-Equol elevated intracellular cAMP levels and induced cAMP-response element-mediated transcription measured by luciferase reporter assay. S-Equol suppressed alloxan-induced cell death. H89 diminished the cytoprotective effects of S-equol against alloxan. The cytoprotective activity of S-equol was not observed in the presence of cycloheximide.

Conclusions: These results indicate that S-equol increases proliferation and survival through activation of protein kinase A signaling. Our data suggest that S-equol is effective for prevention of type 2 diabetes mellitus.

Key words: S-equol; pancreatic β -cell; type 2 diabetes mellitus; protein kinase A signaling; soy isoflavone.

PO3364**VITAMIN D IN BARIATRIC SURGERY PATIENTS**

M R. Alhambra Expósito¹, A. Herrera Martínez¹, C. Muñoz Jiménez¹, M J. Molina Puerta¹, P. Benito López¹

¹Reina Sofía University Hospital, Murcia, Spain

Background and objectives: Bariatric surgery is the only demonstrated method that causes enough weight loss to control long term comorbidities in morbid obesity. This surgery could increase Vitamin D deficit, observational studies have demonstrated an association between obesity and lower 25-hydroxyvitamin D serum levels (25(OH)D). The objective was to analyze the relation between weight loss, surgical techniques and serum 25(OH)D concentration in bariatric surgery patients.

Methods: We reviewed the medical records of morbidly obese patients referred to our clinic prior to bariatric surgery between January 2001 and December 2011. All patients had a complete medical history including physical examination, surgical technique, vitamin D levels and weight loss percentage.

Results: 435 patients, 76.6% women. Mean age 46,57±10,96 years. Following mean time 39,01±23,56 months, 56,52±22,83% of loss weight. Vertical banded gastroplasty and gastric bypass were practiced in 92,4% of patients, tubular gastrectomy in 1,8% and adjustable gastric band in 5,5%. After surgery, insufficient vitamin D serum levels were found in 11,1% patients (25(OH)D <20 ng/dl), low levels in 51% (25(OH)D 20 -30 ng/dl), normal levels in 37,2% (25(OH)D >30 ng/dl). Mean Vitamin D levels of 31,50+/- 15,57 after Vertical banded gastroplasty and gastric bypass; 33,45 +/- 12,74 after tubular gastrectomy and 39,91 +/- 16,14 ng/dl after adjustable gastric band without statistical differences (p 0,528). Obese patients after surgery (IMC ≥ 30 kg/m²) have significant lower serum Vitamin D (30,87 ±14,17 ng/dl) than patients with normal weight (IMC < 30 kg/m²; 35,99 +/- 20,12 ng/dl) (p = 0,021). No statistical differences between serum vitamin D levels and weight loss percentage were founded (p=0,695).

Conclusions: Vitamin D deficiency was similar to general population even with 880 UI calcidiol supplementation. No statistical differences were founded in serum vitamin D levels, surgical technique and weight loss percentage. Obese patients after surgery have significant lower serum Vitamin D levels than patients that normalize weight.

Key words: Bariatric surgery, calcidiol, obesity, 25-hydroxyvitamin D, vitamin D.

PO3365**REPRODUCTIVE FACTORS AND THE RISK OF BREAST CANCER: STUDY OF A POPULATION OF WOMEN IN GRANADA (SPAIN)**

E González-Jiménez¹, J Schmidt-Río-Valle¹, Ma Montero-Alonso¹, S Navarro-Prado¹, M López-Bueno¹

¹Universidad de Granada, Granada, Spain

Background and objectives: Breast cancer is the second cause of cancer deaths in women, and accounts for 19% of all malignant tumors. Thus, the objective of this study was to discover whether there was a possible link between factors such as duration of maternal breast-feeding and its correlation with the subject's age at breast cancer diagnosis.

Methods: In this study, the sample population consisted of 199 women 30-85 years of age, with no family history of breast cancer, who had been diagnosed and treated for the disease at the Virgen de las Nieves University Hospital in Granada (Spain). Data from the clinical histories of each patient in the study were collected and statistically analyzed.

Results: This study found that those subjects who had not breastfed their children had been diagnosed with breast cancer at a younger age. In contrast, when the lactation period was from three to six months, the subject's age at diagnosis was more advanced (54 years of age). However, those women who had breastfed their children for over six months had been diagnosed with breast cancer significantly (p<0.005) later in life.

Discussion: These results coincide with those of other studies, which found that a lactation period of over six months reduced the risk of breast cancer.

Conclusions: The results obtained showed that maternal breast-feeding for more than six months favors a later development of breast cancer.

Key words: Breast cancer, Breastfeeding duration, Age of Menarche, Prevention.

T5. Nutrients and Nutritional Assessment**PO2338****MACRONUTRIENTS AND ENERGY INTAKE OF ADULTS WITH SICKLE CELL DISEASE***J. Anglin¹, J. Adkins², A. Johnson²*¹College of Health and Human Services, California State University, Long Beach, USA²Department of Nutritional Sciences, Howard University, Washington DC, USA

Background and objectives: Nutritional factors play crucial roles in the expression of a variety of chronic diseases; their roles in sickle cell disease pathophysiology and treatment have not been fully examined. Sickle cell disease (SCD) is a debilitating disease resulting in chronic hemolytic anemia and vaso-occlusion in almost all organs leads to significant morbidity and early death. The objective was to assess the dietary intake of adults with sickle cell disease and healthy controls.

Methods: Twenty-two (22) adults participated in the study – fourteen controls and eight homozygous sickle cell disease (SCD) individuals. A weighed food intake was conducted. Independent sample t-test was used to assess differences between groups.

Results: Based on the calculated estimated energy requirement (EER) values, the participants' energy intakes were exceeded by 27.64% and 64.59% by the control and the sickle cell groups respectively. The SCD group had a significantly higher intake of energy, fats, and carbohydrates ($p < 0.01$). Calories from fats and sugars accounted for 66% of the total energy intake in the SCD group compared to 57% in the control group.

Conclusions: Further studies are required to examine the impact of diet in the management of SCD and decreasing the dietary risk factors for developing other chronic diseases.

Key words: Sickle cell disease (SCD), Energy, Carbohydrates, Fats

PO2339**COMPARISON BETWEEN BIOELECTRICAL IMPEDANCE ANALYSIS AND BODY MASS INDEX METHODS IN DETERMINATION OF OBESITY PREVALENCE AMONG IRANIAN WOMEN***M. Shaneshin¹*¹Community Nutrition Department, Faculty of Nutrition Sciences and Food Technology, National Nutrition and Food Technology Research Institute, Shahid Beheshti University of Medical Sciences and Health Services, Tehran, Iran

Background and objectives: Obesity has an increasing trend worldwide. application of body mass index (BMI) cutoff points of obesity classification for all population studies has been questioned. On the other hand, bioelectrical impedance analysis (BIA) is a safe, accurate, reliable and inexpensive method for screening the overweight and obesity in such studies. Objective was identifying the prevalence of obesity and overweight using BMI and BIA methods among Tehrani women.

Methods: In this cross-sectional study, one hundred and eighty-seven healthy women 18–45 years aged were recruited. Demographic and anthropometric data were collected by the trained students. Body fat percent (%BF) and body fat mass (BFM) were measured using BIA method. $BMI \geq 25$ and ≥ 30 kg/m² were used as criteria for determining the overweight and obese women, respectively. $\%BF \geq 30\%$ and $\%BF \geq 35\%$ was regarded as cutoff for defining over fat and obesity. results Mean age \pm SD. of the women was 34.9 ± 8.1 years.

Results: the BMI, %BF and waist-to-hip ratio were: $27.7(5.8)$ kg/m², $35.5(6.9)\%$ and $0.77(0.08)$, respectively. Central obesity was prevalent in 32.6% of the subjects. Prevalence of obesity determined by BMI and BIA methods was 35.8 and 57.8% and women within normal ranges were detected in 28.9 and 23% of the subjects by these methods, respectively. About one half of the women were overweight or obese. Women with higher age levels had higher BMI than the other subjects but this difference are not significant for body fat percentage ($p = 0.134$).

Conclusions: Obesity and overweight is prevalent in about one-half of the Tehrani women and more than one-third of the subjects have central obesity. BIA and BMI methods are different in determining the thin, normal and obese women.

Key words: Overweight, obesity, bioelectrical impedance analysis, body mass index, women

PO2341**VALIDITY OF ENERGY INTAKE REPORTS IN RELATION TO DIETARY PATTERNS***M. Shaneshin*¹

¹Community Nutrition Department, Faculty of Nutrition Sciences and Food Technology, National Nutrition and Food Technology Research Institute, Shahid Beheshti University of Medical Sciences and Health Services, Tehran, Iran

Background and objectives: The role of under- and over-reporting of energy intake in determining the dietary patterns is yet unclear, especially in Middle Eastern countries. This study identifies the prevalence of misreporting among Tehranian women and to compare the dietary intake patterns of plausible and all energy reporters

Methods: In this cross-sectional study, dietary intakes of 187 women aged 18-45 years were assessed using food frequency questionnaire. Demographic, medical and anthropometric data were collected using pre-tested questionnaires. FitMate™ metabolic analyzer and Goldberg equation were used to determine the under/over-reporting of energy intake among participants. Cluster analysis was performed for extraction of dietary patterns.

Results: Under-reporters (35.3% of subjects) were more likely to be overweight and older compared to plausible reporters. Three dietary patterns emerged for all reporters (healthy, unhealthy and mixture patterns) and two were identified for plausible reporters (healthy and unhealthy patterns). The mean intakes of fish, poultry, low-fat dairy products, fruits, other vegetables, green vegetables, tomato, dry fruits, grain, potato, nuts, sauce and yogurt drinks were significantly higher in “healthy food cluster” compared to “unhealthy food cluster” ($p < 0.01$). Plausible reporters in “healthy food cluster” consumed more other vegetables, potato, yellow vegetables and tea compared to “unhealthy food cluster”. Using only plausible reporters to determine dietary patterns was not similar to using all reporters. The proportion of under-reporters was 59.3 % in the mixture cluster; 30.4 % in the unhealthy cluster and 35.3 % in the healthy cluster ($p < 0.05$).

Conclusions: Among Tehranian women, under-reporting of energy intake is not uniformly distributed among dietary pattern clusters and tends to be less severe among subjects in the unhealthy cluster. Our data suggested that misreporting of energy intake might affect the dietary pattern analysis.

Key words: Validity, energy under-reporting, dietary patterns, women

PO2342**DIETARY DIVERSITY AND NUTRITIONAL STATUS OF URBAN PRIMARY SCHOOL CHILDREN FROM IRAN AND INDIA***S. Hooshmand*¹, *M.R. Bagherzadeh Ansari*²

¹Department of Food Science and Nutrition, SNTD Women's University, Mumbai, Maharashtra, India
²Department of Accounting, Islamic Azad University, Shooshtar, Khoozestan, Iran

Background and objectives: Nutritional status of children is influenced by diet. Better dietary diversity helps ensure adequate intake of essential nutrients especially for growing school going children.

Methods: The present study examined dietary diversity, weight-for-age (WA) and height-for-age (HA) and weight-for-height weight-for-age z-scores and nutritional status of 4570 children aged 6-9 years, including 2234 Iranian (1016 boys, 1218 girls) and 2336 Indian (1240 boys, 1096 girls) attending primary schools residing in Mumbai and Ahwaz, Iran, from low and middle income categories. Dietary diversity scores were assessed based on frequency of consumption of individual food items categorized into 11 individual food groups.

Results: Total dietary diversity scores were significantly higher for Indian children who had normal weight or who were overweight ($F = 32.197$, $p = 0.000$) and lowest for underweight children. Similar trends were observed for the children from Iran ($F = 9.345$, $p = 0.000$). Total food group scores increased with better height status of the children. In both countries, severely and moderately stunted children had lower total mean scores than those who had normal and above average height. Wasting was also associated with lower total mean scores. Analysis of data for individual food groups showed that increasing weight was associated with higher scores for almost all food groups in India. In Iran, mean scores for vegetables, beverages, sweets and fats increased with increasing weight. Height for age z-scores were positively associated with mean score for pulses in both countries and dairy products, beverages and fats. Higher BMI was associated with higher scores for cereals, fruits, vegetables, dairy products, mixed dishes, beverages, sweets and fats.

Conclusions: Higher consumption of energy dense foods may contribute to overweight and obesity whereas low dietary diversity may be associated with undernutrition.

Key words: Nutritional status, dietary diversity, school children

PO2343**ANTHROPOMETRIC MEASUREMENTS AND NUTRITIONAL STATUS OF URBAN PRIMARY SCHOOL CHILDREN IN SELECTED AREAS OF IRAN AND INDIA: A COMPARATIVE STUDY**

S. Hooshmand¹, M.R. Bagherzadeh Ansari²

¹Department of Food Science and Nutrition SNTD Women's University, Mumbai, Maharashtra, India

²Department of Commerce, Azad University, Shooshtar, Khoozestan, Iran

Background and objectives: Malnutrition is a widespread problem in developing countries. Information on nutritional status of school children are not enough in Iran and India. The present study, made to assess prevalence of undernutrition, stunting and wasting among children in India and in Iran.

Methods: Height and weight of 4570 including 2234 Iranian (1016 boys, 1218 girls) and 2336 Indian (1240 boys, 1096 girls), aged 6-9 years, attending primary schools residing in Mumbai (India) and Ahwaz (Iran) were measured and the body mass index (BMI) calculated. The World Health Organization's (WHO) anthropometric indices of weight-for-age (WA) and height-for-age (HA) and weight-for-height were used to assess the children's nutritional status.

Results: Underweight, stunting and wasting occurred in 3.2%, 1.5% and 4.1% of Indian and 0.2%, 5.4% and 1.7% of Iranian children. WAZ mean scores were -0.071 ± 1.195 for boys and -0.287 ± 3.241 for girls in Iran and -0.238 ± 0.823 for boys and 0.108 ± 1.080 for girls in India. HAZ mean scores were -0.163 ± 1.219 for boys and -0.515 ± 3.141 for girls in Iran and -0.028 ± 0.770 and -0.017 ± 0.993 for girls in India. Iranian children 0.2% ($X^2=30.428$, $p=0.000$) and 3.2% Indian had weight for age z-scores -2 SD ($X^2=55.361$, $p=0.000$). Only 1.5% Indian children and 5.4% Iranian had height for age z-scores below -2 SD ($X^2=11.553$, $p=0.000$ and $X^2=24.034$, $p=0.000$). In Iran 1.7% and 4.1% of Indian children were wasted ($X^2=11.176$, $p=0.004$ and $X^2=40.088$, $p=0.000$). Indian children, 1.3% had weight for height z-scores $> +2$ SD compared to 3.6% Iranian.

Conclusions: Most of children in both countries were well nourished. Stunting was more prevalent in Iran than India. In India children were more wasted than Iran. The percentage of stunted children was more in Iran than in India, and a slightly higher percentage of Iranian children tended to be overweight / obese compared to Indian children.

Key words: Anthropometry, nutritional status, school children

PO2344**ZINC, RETINOL AND CD4 STATUS OF HIV/AIDS PATIENTS IN ABEOKUTA, NIGERIA.**

T. Bello¹, I. Olayiwola², M. Bello³

¹Department of Human Nutrition, University of Pretoria, Pretoria, South Africa

²Department of Human Nutrition, Federal University of Agriculture, Abeokuta, Nigeria

³Department of Microbiology, Moshood Abiola Polytechnic, Abeokuta, Nigeria

Background and objectives: This study was both qualitative and quantitative which investigated the zinc, retinol and Cluster of Differentiation 4 (CD4) status of the People living with HIV/AIDS (PLWHA) in Abeokuta, Nigeria.

Methods: Purposive sampling technique was used to select two hundred PLWHA respondents at the Federal Medical Center (FMC) Idiaba, Abeokuta. Blood samples were carefully collected from subsamples of hundred subjects for serum zinc, retinol and CD4 counts analysis.

Results: The values obtained were compared with Centers for Disease Control (CDC), reference values. 62% of the respondents had mean CD4 cell count moderately low (200-499 μ l), 38% had a mean CD4 cell count below 200 cell/ μ l. Using 1993 CDC guidelines, majority of the patients had moderate HIV disease i.e stage B, while the remaining respondents had advance HIV disease i.e. stage C. The correlation coefficient of zinc and CD4 ($r= -0.080$ $p<0.05$) showed very weak negative relationship, unlike retinol and zinc ($r= 0.11$ $p<0.05$) so also retinol and CD4 ($r= 0.036$ $p<0.05$), they both showed weak positive linear relationship.

Conclusions: The government of Nigeria should provide adequate diets for PLWHA as part of component for positive living and not just provision of free drugs in order to boost the CD4 counts and immunity of PLWHA.

Key words: HIV/AIDS, serum zinc, serum retinol, CD4 counts.

PO2346**COMPARISON OF HEIGHT FOR AGE BY STANDING AND ESTIMATED HEIGHT BY SHOULDER-ELBOW, KNEE-HEEL AND TIBIA-MALLEOLUS, IN COLOMBIAN SCHOOL CHILDREN**

N. Sepúlveda¹, L. Ladino^{1,2}, C. Velasco²

¹Pontificia Universidad Javeriana, Bogotá Colombia

²GASTROHNUP Universidad del Valle, Cali, Colombia

Background and objectives: The measure of size is essential for the nutrition assessment of pediatric patients, but in some circumstances it is difficult to take height by standing, due to pathological complications that may occur in hospitalized patients. The segments can be measured by estimating the size in those patients who can not be measured by standing. The objective is to identify in school children in a public school in Bogotá, Colombia, the best approach to height by standing (H/A) when compared with the estimated size by shoulder-elbow (H/SE), knee-heel (H/KH) and tibia-malleolus (H/TM) according to Stevenson and Chumlea techniques.

Methods: The study included 432 children from a public school in Bogotá, Colombia, between 5 and 9 years of age who are taking the height in centimeters by standing and estimated size was calculated as H/SE, H/KH and H/TM.

Results: We included 432 children aged 7 years 7 meses \pm 1 year 3 months (range 5 to 9 years 11 months), 242 were female (56.0%), the mean \pm standard deviation measures: H/A = 122.6 \pm 9.2 cm, H/SE = 132.3 \pm 10.0 cm, H/KH = 124.3 \pm 16.6 cm and H/TM = 112.1 \pm 63.8 cm, significant differences between H/A versus H/SE and H/A versus H/TM ($p=0.000$) but not between H/A versus H/KH ($p>0.05$).

Conclusions: In school children of a public school in Bogotá, Colombia, the estimated size by H/SE and H/TM are approximate and alternatives, when you can not take a H/A by standing, especially in patients who can not ambulate, regardless of classification indicator H/A.

Key words: Nutrition assessment, height, children

PO2347**INCREASING DIETARY CALCIUM IN THE FACE OF CALORIC RESTRICTIONS IN HUMANS**

J N D. Sasraku¹

¹Pantang Nursing Training College, Accra, Ghana

Background and objectives: Increasing 1,25-hydroxide vitamin D in response to low-calcium diets stimulates adipocyte Ca²⁺ influx and, as a consequence, stimulates lipogenesis, suppresses lipolysis, and increases lipid accumulation, whereas

increasing dietary calcium inhibits these effects and markedly accelerates fat loss in mice subjected to caloric restriction. Our objective was to determine the effects of increasing dietary calcium in the face of caloric restriction in humans.

Methods: We performed a randomized controlled trial in 32 obese adults. Patients were maintained for 24 weeks on balanced deficit diets (500 kcal/d deficit) and randomized to a standard diet (400 to 500 mg of dietary calcium/d supplemented with placebo), a high-calcium diet (standard diet supplemented with 800 mg of calcium/d), or high-dairy diet (1200 to 1300 mg of dietary calcium/d supplemented with placebo).

Results: Patients assigned to the standard diet lost 6.4 \pm 2.5% of their body weight, which was increased by 26% (to 8.6 \pm 1.1%) on the high-calcium diet and 70% (to 10.9 \pm 1.6% of body weight) on the high-dairy diet ($p<0.01$). Fat loss was similarly augmented by the high-calcium and high-dairy diets, by 38% and 64%, respectively ($p<0.01$). Moreover, fat loss from the trunk region represented 19.0 \pm 7.9% of total fat loss on the low-calcium diet, and this fraction was increased to 50.1 \pm 6.4% and 66.2 \pm 3.0% on the high-calcium and high-dairy diets, respectively ($p<0.001$).

Conclusions: Increasing dietary calcium significantly augmented weight and fat loss secondary to caloric restriction and increased the percentage of fat lost from the trunk region, whereas dairy products exerted a substantially greater effect.

Key words: Lipogenesis, suppresses lipolysis, augmented weight, substantially, randomized

PO2348**NEED FOR TRACE ELEMENTS IN THE PARENTERAL NUTRITION AFTER ABDOMINAL SURGERY IN CHILDREN**

K. Masumoto¹

¹Department of Pediatric Surgery, Faculty of Medicine, University of Tsukuba, Tsukuba, Ibaraki, Japan

Background and objectives: The need to administer trace elements (TE) during the short period after surgery has not yet been fully studied in children receiving parenteral nutrition (PN). Therefore, we tried to clarify whether pediatric patients require the administration of TE, including zinc (Zn) and copper (Cu), while receiving PN during the short period after abdominal surgery.

Methods: Sixteen children were prospectively studied and divided into two groups; one group received PN without TE after surgery (n=8), while the other group received PN with TE after surgery (n=9). In both groups, both Zn and Cu concentrations in the blood were measured on the preoperative day and the changes of the Zn and Cu concentrations over time were measured during the starvation period from the first to the 5th postoperative day.

Results: The preoperative Zn and Cu concentrations in the blood were within normal range in both groups. In the group receiving PN without TE, the Zn concentration continued to be below the normal range during the starvation period after the operation, while the Zn concentration decreased to be below the normal range on the 1st postoperative day and thereafter increased to be the normal range during the period in the group receiving PN with TE. Regarding the Cu concentration in the blood, the concentration continued to be within the normal range in both groups after the operation.

Conclusions: During the short starvation period after abdominal surgery, the Zn concentration in the blood decreased, if the pediatric patients received PN without TE. Therefore, clinicians treating pediatric patients should add TE to the PN solution during the short starvation period after abdominal surgery.

Key words: Abdominal surgery, children, parenteral nutrition, zinc, copper

PO2349

ROLE OF SUB-CLINICAL INFLAMMATION ON IRON SUPPLEMENTATION

M K. Htet^{1,2,3}, U. Fahmida¹, D. Dillon⁴, A. Akib⁴, B. Uto-mo⁵, D. Thurnham⁶

¹South East Asian Ministers of Education Organization, Regional Center For Food and Nutrition, University of Indonesia, Indonesia

²Department of Health, Ministry of Health, Myanmar, Indonesia

³Research Institute Trisakti University, Indonesia

⁴Faculty of Medicine, University of Indonesia, Indonesia

⁵Faculty of Public Health, University of Indonesia, Indonesia

⁶Northern Ireland Centre for Food and Health, School of Biomedical Science, University of Ulster, Coleraine, UK

Background and objectives: Anaemia is one of major nutritional problems in Myanmar and poor vitamin A status is common in SE Asia. Nutritional status of iron and vitamin A is influenced by sub-clinical inflammation (SCI). There is lack of information on the influence of SCI on the effectiveness of iron supplementation to reduce anaemia. The study was conducted to determine whether SCI influenced the impact of iron supplementation on anaemia.

Methods: A randomized, double-blinded, placebo-controlled experimental study (ClinicalTrials.gov: NCT01198574) was conducted in the Ayeyarwady region of Myanmar among post-menarcheal, anaemic adolescent schoolgirls (Hb<120

g/L). A total of 402 schoolgirls were recruited from 6 schools after screening among 1269 subjects. Subjects were assigned into one of four groups: control (FA, 2.5 mg of folate), vitamin A (VA, 15,000 IU), iron-folic-acid (IFA, 60 mg elemental iron and folate) and IFA+vitamin A (IFA+VA, iron, vitamin A and folate). Supplementation was done once a week for 12 weeks. Iron, vitamin A and inflammation status were measured at baseline, middle and endline.

Results: Iron status of the subjects was improved by the intervention. Odds ratios of iron deficiency reduced significantly in IFA and IFA+VA (by 71% and 64% respectively) as compared to FA group. The prevalence of SCI was low but had an influence on iron supplementation. Among those with SCI, there was VA*SCI interaction in which the groups receiving VA showed higher mean Hb (112.5 vs 105.7 g/L) and lower sTfR (5.8 vs 9.6 mg/L) as compared to the other groups.

Conclusions: Weekly iron supplementation combined with vitamin A for 12-week significantly reduced the prevalence of anemia and iron deficiency. SCI has negative impact on iron supplementation. Vitamin A positively contributes to iron supplementation when there is SCI.

Key words: Anemia, iron deficiency, sub-clinical inflammation

³Laboratorios de Investigación Médica (LABIMED), Universidad Mayor de San Simón, Cochabamba, Bolivia

⁴Department of Clinical Nutrition, Skåne University Hospital, Lund, Sweden

Background and objectives: The tuberculosis infection triggers in the host a complex immune response and the involvement of CD4 and interferon-gamma (INF-gamma) of lymphocytes in these processes has been reported. Since nutritional status e.g. regarding zinc may have potent effects on the immune response, we hypothesized that an increased supply of zinc can affect the immune function in pulmonary tuberculosis.

Methods: We conducted a zinc supplementation study in twenty-one patients randomized to be given zinc or placebo

for 3 months during concomitant drug therapy. The plasma concentration of immunoglobulins, the in vitro proliferation of peripheral blood mononuclear cells (PBMC), the production of INF-gamma and the magnitude of the CD4/CD8/CD3 lymphocyte subpopulations after stimulation with Concanavalin A were measured.

Results: The results showed that the immune system of the patients was activated compared to matched healthy control subjects as reflected in the increased concentration of immunoglobulins and in the ability of the PBMC to proliferate and produce INF-gamma in response to stimuli and also by the increased proportion of PBMC expressing the CD4 marker. There was no difference in these variables between the zinc-supplemented and placebo groups and the magnitude of the findings were not related to the clinical recovery. The addition of zinc sulphate in vitro to PBMC inhibited the expression of CD4, but the reasons for this inhibition are not clear.

Conclusions: It is concluded that the immune system of the Bolivian tuberculosis patients was activated and in response to therapy the immune response seemed to take a Th1-orientation to a higher degree. It was not possible to establish a clear role of zinc supplementation on the immune response using this study design.

Key words: Zinc addition, immune response, Th1 orientation

FOOD DIVERSITY IN RELATION TO SCHOOLCHILDREN'S GROWTH IN MOROCCO

Y. Aboussaleh¹, R. Sbaibi¹, H. El bilal²

¹Nutrition and Health Laboratory, Ibn Tofail University, Kenitra, Kenia, Morocco

²Sustainable Agriculture Department, Mediterranean Agronomic Institute of Bari, Bari, Italy

Background and objectives: About 20% Moroccan children under the age of 15 years are stunted or delayed in growth. Dietary quality is much associated with dietary diversity. The purpose of the study was to assess dietary diversity by comparing a dietary diversity score (DDS) and a weekly food frequency score (WFFS) and study their relationship to stunting in school-age children in the province of Kenitra (Morocco).

Methods: A stratified random sample of 263 pupils including one-third from rural schools were administered a weekly food frequency questionnaire. A health team assessed the anthropometric status. Dietary diversity was appraised with two types of indices: a dietary diversity score (DDS) based on the number of food categories consumed over a week, and a weekly food frequency score (WFFS) which also takes into account the frequency of food intake.

Results: the average age was 12.9 ± 0.9 years. The DDS was significantly higher in rural than in urban children, whereas the WFFS was lower, in rural children owing primarily to less frequent intake of fruits and vegetables than in the urban children. Maternal level of instruction was also positively associated with a higher consumption of fruits and vegetables and milk, and with a higher WFFS. Both indices were significantly associated with stunting.

Conclusions: The study suggested that diet quality is associated with height status and food diversity indices that take food frequency into account which may provide a better reflection of diet quality.

Key words: Diet, schoolchildren, Morocco

PO2352

NUTRITIONAL STATUS IN COLOMBIAN CHILDREN WITH LIVER ABSCESS

C. Velasco¹, A. Guzman¹, L. Valencia¹

¹Universidad del Valle, Cali, Colombia

Background and objectives: The detection of in-hospital malnutrition in children with liver abscess (LA) is required to initiate a prompt and proper nutritional recovery plan. The objective was to determine the nutritional status (NE) of 14 children with LA from Hospital Universitario del Valle "Evaristo Garcia" in Cali, Colombia.

Methods: A descriptive, observational, cross sectional study in 14 children with 8.7 ± 3.8 years of age, 50% female, with first diagnosed by clinical and ultrasound for LA. It was evaluated NE by anthropometric, and other variables.

Results: The mean \pm standard deviation ($X \pm SD$) for body mass index, weight, height, and height/age, was 29.2 ± 11.6 kg, 128.3 ± 23.0 cm, -0.1 ± 0.9 SD and -0.3 ± 1.1 SD, respectively, with malnutrition in 42.9% and failure to thrive in 7.1%. The $X \pm SD$ for hemoglobin and albumin was 9.9 ± 1.2 g/dl and 3.0 ± 0.3 g/dl, respectively, with anemia and hypoalbuminemia in 92.3% and 83.3%, respectively. Most came from Cali and Valle, Colombia. The $X \pm SD$ for evolution time and hospital stay was 12.0 ± 9.4 days and 22.3 ± 20.9 days, respectively. Besides the triad fever, hepatomegaly and right upper quadrant pain occurred vomiting in 57.1%, anorexia and diarrhea in 21.4%, respectively, and cough in 14.2%. Predominated the LA in right location and unique. The positive cultures was 64.2% and amoebae in stool in 14.2%. All received antibiotics and 35.7% surgical drainage.

Conclusion: Nearly one third of children with LA presented risk of undernutrition with anemia and hypoalbuminemia in 92.3% and 83.3%, respectively.

Key words: Nutritional status, liver abscess, children

PO2353**NUTRITIONAL STATUS OF COLOMBIAN GIRLS CHILDREN WITH HELICOBACTER PYLORI GASTRITIS***C. Velasco¹, C. Ochoa¹, N. Muñoz¹*¹Universidad del Valle, Cali, Colombia

Background and objectives: Helicobacter pylori gastritis (Hp) in children can compromise their nutritional status (NS). The objective was to determine the NS in children from Rozo, Colombia with Hp gastritis and possible associations.

Methods: Case (n = 11) and controls (n = 19) study in a group of children from Rozo, Colombia with Hp gastritis diagnosed by IgG in who was considered the age, weight and height. Statistical analysis included estimation of the prevalence of malnutrition (MNT) and failure to thrive (FT), confidence interval corresponding to 95%, the estimate of other descriptive measures of interest and association analysis by multiple logistic regression.

Results: In this group of girls children with a mean age of 10.2 ± 3.0 years (range 6 to 18) found a prevalence of 26.7% for MNT and (FT) of 23.3%. The mean \pm standard deviation (X \pm SD) for weight, height, body mass index and height/age was 31.6 ± 8.5 kg, 136.8 ± 13.6 cm, -0.3 ± 0.8 and -0.3 ± 1.2 . Association analysis found > FT opportunity to > age (OR 1.2 95%CI 2.4-6.2, p=0.000), and was eventually associated factor (OR 2.7 95%CI 1.2-5.8, p=0.011).

Conclusions: Nearly one third of the girls children had malnutrition and > FT, and it was found with age.

Key words: Nutritional status, Helicobacter pylori gastritis, malnutrition, failure to thrive, children

PO2354**THE EFFECT OF AGE AND SEX DIFFERENCES ON MAGNESIUM ABSORPTION IN RATS***M. Hanai¹, T. Esashi²*¹Department of Nutrition and Life Science, Kanagawa Institute of Technology, Atsugi, Kanagawa, Japan²Department of Nutrition and Life Science, Kanagawa Institute of Technology, Atsugi, Kanagawa, Japan

Background and objectives: Decrease in magnesium (Mg) absorption in aged male rats is well documented in the literature. However, few studies have reported the effect of age and sex on Mg absorption. This study was designed to simultaneously evaluate the effect of age and sex on Mg absorption and balance in rats.

Methods: Thirty-six male and female Fischer 344 rats at three different ages (1, 6, and 18 months) were fed the AIN-76 diet (0.05% Mg) for 2 weeks. The animals were fed fresh food and ion-exchanged water ad libitum. The Mg balance test was performed for the last 5 consecutive days.

Results: The results clearly demonstrated that apparent Mg absorption (per-cent) was significantly lower in aged rats (6 and 18 months) than that in young (1 month) rats. High Mg absorption was seen in 1-month-old male rats and in 6- and 18-month-old, female rats. Apparent Mg retention (per-cent) was significantly lower in aged rats (6 and 18 months) than that in young (1 month) rats. However, it was not significantly altered with sex. Between 6 and 18 months, no significant difference was observed in apparent Mg absorption and retention in rats. Apparent urinary Mg excretion (per-cent) was significantly altered with age in female rats (18 > 6 > 1 month) but not in male rats. Apparent urinary Mg excretion (per-cent) was significantly altered with sex and was higher in 6- and 18-month-old female rats.

Conclusions: Age and sex differences affect apparent intestinal magnesium absorption in rats.

Key words: Magnesium, absorption, sex difference, aging

PO2355**THE DOUBLE BURDEN OF MALNUTRITION AMONG UNDERGRADUATE STUDENTS IN SOUTH WESTERN NIGERIA***C. Badejo¹, R. Akano¹*¹Home Economics Unit, Department of Vocational and Technical Education, Tai Solarin University of Education, Ijebu-Ode, Ogun State, Nigeria

Background and objectives: The co-existence of under-nutrition and over-nutrition in the same population has its implications and has been associated with the incidence of various diseases. There are few data to support the prevalence of both conditions among the entire populations in Nigeria. Therefore the aim of this study is to assess the double burden of malnutrition among undergraduate students in south Western Nigeria.

Methods: A cross-sectional study of 2950 apparently healthy and non-pregnant undergraduate students of Tai Solarin University of Education Ijebu-ode Ogun State Nigeria was conducted. Anthropometric assessment was done. Body mass index (BMI) was calculated and the students were grouped under the various categories. Excess abdominal fat was determined measuring the Waist Circumference (WC). Statistical Package for Social Science (SPSS) version 15 was used for data analysis.

Results: Female respondents were 1835 (62.2%) and 1115 (37.8%) were males. Mean age, height, weight and BMI were 23

± 2.98 years, 1.63 ± 0.09 m, 60.99 ± 12.22 kg and 22.80 ± 4.59 kg/m² respectively. Mean WC was 80.55 ± 20.80 cm among the females and 82.21 ± 10.56 cm among the males. The prevalence of underweight was 13.4%; 16.9% were overweight, 7.5% were obese out of which 0.6% were morbidly obese. Age and sex of the respondent did not significantly affect BMI (p=0.464 and 0.115, respectively). About half (50.64%) of the overweight and obese respondents also had excess abdominal fat among the female students. A similar trend was observed among the male respondents. There was a significant relationship between BMI and WC (p<0.05) with both sexes.

Conclusions: Both under-nutrition and over-nutrition are existing among the respondents from this study. Obesity seems to be more common among the female students. Nutrition education is suggested as a means of intervention to curb the increasing trend of overweight and obesity.

Key words: Malnutrition, undergraduates, burden, disease, double

PO2356

FACTORS AFFECTING THE NUTRITIONAL STATUS OF UNDER-FIVE CHILDREN IN IJEBU-ODE, OGUN STATE, NIGERIA

R. Akano¹, A. Badejo¹, R. Sanusi²

¹Home Economics Unit, Department of Vocational and Technical Education, Tai Solarin University of Education, Ijebu-Ode, Ogun State, Nigeria

²Department of Human Nutrition, University of Ibadan, Ibadan, Oyo State, Nigeria

Background and objectives: Under-five (U5) children are vulnerable to malnutrition especially in the developing countries. In Nigeria, more than 50% of all childhood deaths have under-nutrition as an underlying factor. At the dawn of the 21st century, it is tragic that one in seven Nigerian children die before his or her fifth birthday. The underlying causes of malnutrition have been identified by the UNICEF conceptual framework. This study therefore aims at assessing the factors that contribute to malnutrition among U5. Cross-sectional study of 400 U5 was conducted.

Methods: Validated semi-structured questionnaire were administered to obtain information on socio-economic characteristics of household. Anthropometric assessment of height and weight were done and analyzed using the WHO Anthro Software. A 24-hr recall was done to assess nutrient intakes and analyzed using the adapted Total Dietary Assessment (TDA) software. Statistical Package for Social Science (SPSS) version 15 was used for data analysis. One hundred and eighty-four (46.0%) male and 216 (54.0%) female children participated in the study.

Results: The total prevalence of stunting (HAZ) was 18.5%. Wasting (WHZ) was 6% and underweight (WAZ) was 4.5%. The nutritional status of male and female children were not significantly different (p>0.05). Children from larger household size had a higher risk of becoming malnourished. Educational level of the household-head and of the mother significantly affected all the malnutrition indices (p=0.002). Income of the household-head also had a significant relationship (p<0.05) with all the malnutrition indices. Occupation of the household-head and religion of parents had no significant relationship (p>0.05) with the indices of malnutrition among the children.

Conclusions: Family planning and education of the female child should be encouraged. The problem of poverty also needs to be addressed as interventions to reduce the level of malnutrition among U5 children.

Key words: Assessment, education, poverty, malnutrition

PO2357

NATIONAL NUTRITION SURVEY IN THE STATE OF KUWAIT

J. Al-Ghanim¹, S. Al-Hooti¹

¹Biotechnology Department, Kuwait Institute for Scientific Research, Safat, Kuwait

Background and objectives: The National Nutrition Survey of the State of Kuwait (NNSSK) used a stratified probability cluster sampling to obtain a representative national sample of Kuwaiti households, based on 82 clusters from the six governorates of Kuwait.

Methods: 545 households (1830 individuals representing six age groups; <5, 6-9, 10-19, 20-49 and >50 years, participated in the survey (July 2008 to November 2009). The survey collected anthropometric, health, dietary and socio-economic data and biological samples.

Results: The prevalence of overweight or obesity among children and young adults (≤19 year) was 35% for males and 28% for females. For adults, the prevalence was 70% for males and 75% for females. Approximately 15% fasting blood glucose values were indicative of diabetes and another 33% at increased risk of diabetes. The prevalence increased with age to more than 50% of men and women age ≥ 50 years. The prevalence of hypertension was 26% with more than 60% of men and women ≥50 years of age being hypertensive.

Conclusions: Overweight and obesity, and related non communicable diseases, are major public health problems in Kuwait. Urgent action is needed to address these problems, in particular to combat overweight and obesity during childhood.

Key words: Nutrition survey, anthropometric, biological.

PO2358**UNDERREPORTING OF ENERGY INTAKE FROM 24-HOUR DIETARY RECALL IN KOREAN NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEY**

S. Kye¹, S. Kwon², J. Lee³, S. Lee¹, B. Kim⁴, H. Suh⁵, H. Moon⁶

¹Department of Preventive Medicine and Public Health, School of Medicine, Ajou University, Suwon, Gyeonggi, Korea

²Department of Food and Nutrition, Kyung Hee University, Seoul, Korea

³Division of Media Study, Ewha Womans University, Seoul, Korea

⁴Department of Food and Nutrition, Chosun University, Gwangju, Korea

⁵Department of Food Science, Sun Moon University, Asan, Chungnam, Korea

⁶Department of Food and Nutrition, Dankook University, Yongin, Gyeonggi, Korea

Background and objectives: Chronic degenerative diseases are closely associated with dietary habits, nutritional status and particularly energy balance. To study the relationship, it is very important for the dietary surveys to report energy intake accurately. This study attempted to identify the frequency of underreporting and its related characteristics based on the Korean National Health and Nutrition Examination Surveys conducted in the years 2007-2009.

Methods: This study analyzed dietary intake data from 15,133 men and women aged 19 and older using 24-hour dietary recalls. The basal metabolic rate(BMR) was calculated from the age- and gender-specific equations of Schofield, and underreporting was defined by computing a ratio of energy intake(EI) to estimated basal metabolic rate(BMRest).

Results: Under reporters(URs) included 14.4 % of the men and 23.0 % of the women. Underreporting of energy intake was low in men and women who had high school or higher education, or lower income. Older respondents in the group of URs were found to comprise a large portion of single-person households. The health-related characteristics of URs showed that low self-rated health was reported at a higher frequency in all age groups of 30 years than from non-URs(non-Under reporters). The proportion of respondents who reported severe physical activity was relatively high in the group of women aged 19-29 being URs, whereas small portions of respondents reported in the group of URs (both men and women) aged 65 and over compared to non-URs. The proportion of overweight people among URs, compared to non-URs, was higher in all age groups of women and in the groups of men aged 19-29 and 30-49.

Conclusions: In conclusion, underreporting was correlated to age, gender, education level, income level, household status, self-rated health, physical activity and overweight.

Key words: Underreporting, 24-hour recall, Korean National Health and Nutrition Examination Survey

PO2359**ASSESSMENT OF THE DIETARY INTAKE OF WOMEN OF REPRODUCTIVE AGE IN THE GA EAST DISTRICT, ACCRA-GHANA**

M. Anim-Fofie¹, M. Steiner-Asiedu¹, J. Setorglo², F. Saalia¹, D. Nakimbugwe³, J. Chen⁴, R. Philips⁴

¹Department of Nutrition and Food Science, University of Ghana, Accra, Ghana

²School of Medical Sciences, University of Cape-Coast, Cape-Coast, Ghana

³Department of Food Technology and Nutrition, University of Makerere, Kampala, Uganda

⁴Department of Food Science, University of Georgia, Griffin, USA

Background and objectives: Strategies to improve maternal nutrition and health remains an important component of the national agenda. One way to improve maternal nutrition before and during pregnancy is to provide Ready to Use Supplementary Food (RUSF). The objective of this study was to assess nutrient and energy intake and compare with Recommended Dietary Allowances (RDA) among women of reproductive age who enrolled in an efficacy study on a peanut base RUSF.

Methods: This was a cross sectional study conducted in 5 peri-urban communities involving 134 women. Data on socio-demographics and usual dietary intake were collected. Socio-demographic data were analysed using SPSS version 16.00 and ESHA FPRO (version 10.0.1.) was used to convert dietary data into nutrients. The RDA cut-offs were used to assess the prevalence of inadequate dietary intakes of energy, protein, fat, iron, vitamin A, vitamin B12, folate and iodine. Statistical significance was set at $p < 0.05$.

Results: Participants' age range was 18-45 years and majority (61.2%) was in formal employment. All women met the RDA for total energy (2314.95 ± 915.07), protein (66.72 ± 27.19), fat (68.00 ± 29.76) and iron (23.68 ± 11.91). However, none of the participants met the RDAs for folate, vitamin B12 and iodine. More than a half did not meet their RDAs for calcium (54.5%) and vitamin A (74.6%). A weak correlation was found between total energy intake and all micronutrients except for iron ($p < 0.001$).

Conclusions: Micronutrient under-nutrition still remains an issue of public health concern in Ghana and predisposes women to high risk of adverse pregnancy outcome, reduced quality of health and contribution to labour force and productivity. Interventions to improve dietary intakes of women are imperative.

Key words: RUSF, women, dietary assessment, micronutrients.

PO2360**NEW TRENDS IN NUTRITIONAL STATUS ASSESSMENT IN A GROUP OF CHILDREN WITH CANCER FROM ROMANIA**

M. Chincesan^{1,2}, O. Marginean^{1, 2}, A. Grama^{1, 2}, D. Baghiu¹

¹University of Medicine and Pharmacy Tg-Mures, Targu Mures, Romania

²Emergency County Hospital, Pediatric Department, Targu-Mures, Romania

Background and objectives: Nutritional status is an important consideration in the treatment of pediatric cancer patients because it is linked to poor outcomes. There are still controversies regarding the criteria used to assess nutritional status in children with cancer. We proposed to define the best modalities to assess nutritional status in children with cancer using anthropometric and biochemical parameters.

Methods: A prospective study was performed on 64 children hospitalized and diagnosed with cancer in the Pediatric Clinic Targu-Mures, Romania, between 2009- 2012. We evaluated anthropometric and biochemical parameters: weight, height, body mass index (BMI), middle-upper arm circumference (MUAC), triceps skin fold thickness (TSF), total protein, albumin and Insulin-like growth factor-1 (IGF-1). The values of anthropometric parameters were converted in Standard Deviation (SD) for age and sex using Switzerland Growth Chart 1989.

Results: Of the 64 children with cancer, 40,6% were diagnosed with leukemias, 28,1% with lymphomas and 31,2% with solid tumors. Medium values of weight, height and BMI were -0.26 SD, -0.19 SD, respectively -0.36 SD. Assessing arms anthropometry, we found lower values of MUAC (-0.56 SD) and TSF (-0.77 SD) than weight and height indicators. At the onset of malignant disease, 28.1% of patients had low serum protein values and 25% had low levels of serum albumin. IGF-1 was decreased in 65,6% of patients. We found a good correlation, statistically significant between MUAC and serum proteins ($r=0.30$; $p=0.01$), MUAC and albumins ($r=0.27$; $p=0.02$) and MUAC and IGF-1 ($r=0.40$; $p=0.001$) and between TSF and albumins ($r=0.28$; $p=0.02$), TSF and IGF-1 ($r=0.38$; $p=0.002$).

Conclusions: The arms anthropometry better identify malnutrition in children with cancer than simply assessing weight or height measurements. MUAC and TSF in conjunction with serum protein, albumin and IGF-1 most accurately characterizing the nutritional status.

Key words: Child, cancer, nutritional status

PO2361**ANEMIA, IRON DEFICIENCY AND RELATIONSHIP WITH NUTRITIONAL STATUS IN CHILDREN AGED 2-5 YEARS OLD**

N. Dung¹, P. Thuy², L. Hop³

¹Department of Nutritional Biochemistry and Metabolism, National Institute of Nutrition, Hanoi, Vietnam

²Counseling center for nutrition rehabilitation & obesity control, National Institute of Nutrition, Hanoi, Vietnam

³Food and Nutrition Training Center, National Institute of Nutrition, Hanoi, Vietnam

Background and objectives: Anemia is a significant public health problem in many countries in the world including Vietnam. The aim of the study was to determine the prevalence of anemia, iron deficiency and the relationship between anemia and nutritional status in preschool children.

Methods: In 2009, 78 preschool children aged 2-5 years old from Tien Phuong commune, Chuong My district, Hanoi participated in the study. Body weight, height of the subjects were measured, blood samples were taken for analyzing the Hemoglobin level and serum ferritin concentration. The nutritional status was classified according to the WHO 2007 child growth standards.

Results: The prevalence of anemia was 17.9%, iron deficiency was 26.9%. There was no correlation between Hb concentration and weight, height, age, serum Ferritin concentration: $r=0.091$, 0.143 , 0.141 , 0.142 , respectively ($p>0.05$). Hb and serum Ferritin concentration of the stunted or underweight children tended to be slightly lower but were not different compared to those of children with normal nutritional status ($p>0.05$).

Conclusions: In preschool children in a suburban district of Hanoi, anemia is still a mild public health problem, prevalence of iron deficiency is relatively high, no correlation is found between anemia and nutritional status. Anemia can be found in malnourished and normal preschool children.

Key words: Anemia, iron deficiency anemia, stunting, underweight, nutritional status.

PO2362**DIETARY INTAKE AND MAJOR FOOD SOURCES OF FOLATE OF ADULTS LIVING IN REPUBLIC OF KOREA***Y.N. Kim¹, Y.O. Cho¹*

¹Department of Food and Nutrition, Duksung Women's University, Seoul, Republic of Korea

Background and objectives: Folate deficiency may be a risk factor for several pathologies, such as neural tube birth defects, dementia, and cardiovascular disease. The objective of this study was to estimate folate intakes and major food sources of Korean adults.

Methods: Three consecutive 24-hour recalls were collected from 167 healthy adults, aged 20-64y, living in Seoul and metropolitan area, Gumi, and Kwangju, Republic of Korea, during November, 2011 - March, 2012. A computer-aided nutritional analysis program developed by the Korean Nutrition Society was used in determining the dietary intakes and major food sources of folate.

Results: The mean folate intake was 527.29/177.09 ug DFE/day (mean/SD). Foods from animal and plant sources provided 19% and 81%, respectively, of the total folate intake. There was no significant difference in folate intakes by gender. The top 10 major dietary sources of folate in these Korean adults were Korean Chinese cabbage kimchi, rice, spinach, eggs, laver, mandarin, soybean sprout, beer, sweet potato, and radish. The number one major source, Korean Chinese cabbage kimchi, contributed 23% of total folate intake. As for major dietary sources of folate, the top 30 foods provided 76% of folate intake. Approximately 11% of the subjects consumed less than Korean Estimated Average Requirements and 23% had folate intakes less than Recommended Nutrient Intakes for folate.

Conclusions: Folate intakes of the Korean adults in the current study were generally adequate. (Supported by 2012 research fund of National Research Foundation of Korea: 2012R1A1A2A04669745).

Key words: Folate, dietary intake, food source, Korean adults

PO2363**A SYSTEMATIC REVIEW ON THE EFFECTS OF MULTI-MICRONUTRIENT FORTIFIED BEVERAGES ON NUTRITIONAL STATUS OF CHILDREN IN LOWER-INCOME COUNTRIES***G.J. Aaron^{1,2}, D.K. Dror², Z. Yang³*

¹Global Alliance For Improved Nutrition (GAIN), PO Box 55, 1211 Geneva, Switzerland

²Western Human Nutrition Research Center, 430 W. Health Sciences Dr., Davis, CA 95616, USA

³National Institute of Nutrition and Food Safety, Chinese Center For Disease Control and Prevention, No 29, Nanwei Road, Xicheng District, Beijing 100050

Background and objectives: Fortification is a widely adopted intervention strategy globally to increase micronutrient intakes in the diet. In the context of lower-income countries, fortification has mostly focused on centrally processed foods and condiments. Other vehicles such as beverages may be viable; however, less information is available about the overall impacts of this approach.

Methods: A systematic review and meta-analysis was undertaken on the nutritional impacts of multi-micronutrient fortified beverages on children in lower-income countries. Multiple PubMed searches were conducted and subject matter experts were contacted to identify relevant studies for inclusion. All co-authors independently reviewed studies to determine those for inclusion in the review.

Results: A total of 911 citations were screened, of which 9 randomized controlled trials were included in the meta-analysis (n = 2759 children at end line). Preliminary findings show that compared with controls who received non-fortified beverages children who received multi-micronutrient fortified beverages for a duration of 8 weeks to 6 months demonstrated significantly greater improvements in serum ferritin (+20.2 pmol/L, 95% CI [16.0,24.5]; 8 studies), hemoglobin (+2.07 g/L [1.53,2.63], 8 studies), retinol (+0.35 mol/L [0.26,0.43]; 5 studies), zinc (+4.76 mol/L [3.62,5.88]; 3 studies), and vitamin B12 (+91.3 pmol/L [78.8,103.8]; 3 studies); p<0.0001 for all. Weight and height gains were modestly but significantly greater in the intervention compared with the control groups (+0.39 kg [0.29,0.50]; 6 studies and +0.19 cm [0.09,0.28]; 5 studies, p ? 0.0001 for both) while change in weight-for-age Z-score did not differ significantly between groups. Consumption of fortified beverages significantly reduced the risk of iron deficiency (RR 0.38 [0.25,0.57]) and iron deficiency anemia (RR 0.17 [0.06,0.53]) but did not significantly alter the risk of vitamin A or zinc deficiency.

Conclusion: Multi-micronutrient fortified beverage interventions are effective in improving the nutritional status of children in lower-income countries.

Key words: Fortification, Micronutrients, Beverages, Lower-income countries, Children

PO2364**CHINESE CHILD DIET QUALITY INDEX**

X. Zhou¹, R.N. Duan¹, H.M. Xue¹, Y. Liu¹, G. Cheng¹

¹Department of Nutrition and Food Hygiene, West China School of Public Health, Sichuan University, Chengdu, Sichuan, P.R.China

Background and objectives: To overview the current diet quality indexes published and used in Europe, USA and China, and to create a diet quality index for Chinese Children.

Methods: Papers published from 1976 to 2012 were collected. According to all diet quality indexes in the world and Chinese Dietary Guidelines issued by Chinese Nutrition Society, Chinese Child Diet Quality Index (CCDQI) was created.

Results: To date, the indexes using for adults included: Diet Quality Index-International, Diet Quality Index Revised and Healthy Eating Index. Revised Children's Diet Quality Index, Youth Healthy Eating Index and Nutritional Quality Index were used among children. Diet Balance Index and Desirable dietary Pattern were created for Chinese adults. Refer to Chinese Children's recommend foods and nutrient intakes, four parts of factors were took into account by proper weigh coefficient. These components were: 10 food groups (cereals, meat and meat products, vegetables, fruits, dairy and its products, beans and its products, fried foods, soft drinks, water and foods diversification), 10 nutrients (intakes of protein, fat, saturated fatty acid, dietary fiber, Ca, Fe, Zn, VA, VD and VC), the information of physical activities (inactive pursuits) and eating behaviors. This Index contained 23 items, each scored 0~5 or 0~10. The total scores ranged from 0 to 200, a higher score indicated better diet quality.

Conclusions: To date, the diet quality indexes were available for both adults and children, however, there was few for Chinese children. Therefore, CCDQI created in this study could be used in the further study investigating potential association between diet quality in childhood and overweight/obesity and other related diseases.

Key words: Chinese, diet quality index, children.

PO2365**VERY YOUNG NIGERIAN INFANTS FIT INTO THE WHO CHILD GROWTH STANDARDS WELL, AS LONG AS THEY ARE HEALTHY**

I. Ezeofor¹, S. Ibeziako², A. Garcia¹, C. Wright¹

¹Paediatric Epidemiology and Community Health (PEACH) Unit, University of Glasgow/Royal Hospital for Sick Children, Yorkhill, Glasgow, UK

²Department of Paediatrics, College of Medicine, University of Nigeria, Nsukka/University of Nigeria Teaching Hospital, Enugu, Nigeria

Background and objectives: The WHO child growth standards are already widely adopted but it is important to establish how well individual population fit to them. We aimed to assess the growth of very young infants compared to the WHO standards at the University of Nigeria Teaching Hospital, Enugu, Nigeria from February to July 2012.

Methods: Weight, length, mid-upper-arm-circumference (MUAC) and skinfolds (Triceps and subscapular) of infants 0 – 6 months old admitted to hospital were compared to the retrospective weights of their healthy peers seen at the well baby clinic. These were expressed as z-scores compared to the WHO standards.

Results: Well baby clinic weights were recorded for 382 infants at birth, 400 at 6 weeks, 391 at 3 months and 307 at 6 months. Their mean (SD) weight z-scores were close to the expected values of 0 (1) at all ages (Birth -0.0 (1.1); 6 weeks -0.3 (1.1); 3 months -0.3 (1.2); 6 months -0.4 (1.2)). Of the 210 hospitalized infants, 87 (41.4%) were under 2 weeks old and 68 (32.4%) were aged 3-6 months. Sepsis (28.6%) and respiratory tract disorders (27.1%) were the commonest diagnoses. For these infants, weight z-scores tended to be low (-1.1 < 1m; -1.2 1 – 3m; -1.2 3 – 6m) but length z-scores were less so as age increased (-1.2 for < 1m; -0.8 for 1 - 3m; -0.4 for 3 - 6m). The mean skinfold z-scores (mean of triceps and subscapular SDS) also tended to be low (-1.6 for > 3 month-olds) as were MUAC SDS (-1.0 for > 3 month-olds).

Conclusions: The weight and length z-scores of healthy young Nigerian infants fit the WHO standards well. The poor weight gain observed in the hospitalized group is likely to be the effect of their medical conditions.

Key words: Malnutrition, skinfolds, growth standards

PO2366

SCHOLASTIC ACHIEVEMENT LEVEL OF THE EDUCATIONAL ESTABLISHMENT AND ITS ASSOCIATION WITH POSTNATAL GROWTH AND DEVELOPMENT OF SCHOOL-AGE CHILDREN

D. Ivanovic¹, C. Ibaceta¹, Y. Orellana¹, P. Calderón¹, G. Morales², B. Leyton¹, A. Almagià³, P. Lizana³, R. Burrows¹

¹Institute of Nutrition and Food Technology (INTA), University of Chile, Santiago, Chile

²Public Health Department, University of La Frontera, Temuco, Chile

³Institute of Biology, Pontificia Universidad Católica de Valparaíso, Valparaíso, Chile

Background and objectives: Scholastic achievement (SA) is a multifactorial process conditioned by multiple variables dependent on the child, his/her family and the influence of the educational system. This is the first study carried out in Chile, using the results of the educational establishment in the SIMCE tests, administered by the Ministry of Education, and its association with nutritional status of school-age children. The objective of this study was to describe the postnatal growth and development by SA levels of the educational establishments. The purpose was to confirm the hypothesis that school-age children attending to educational establishments with similar SA have similar postnatal growth and development parameters by socioeconomic status (SES).

Methods: A representative sample of 33 schools was randomly chosen in 2010 in the Metropolitan Region of Chile. The sample consisted of 1,353 school-age children of both sexes, from the fifth grade of elementary school and first grade of high school who at the end of 2009 took the SIMCE tests. Postnatal growth and development was assessed through anthropometric parameters as head circumference-for-age Z score (Z-HC), height-for-age Z score (Z-T) and body mass index-for-age Z score (Z-BMI).

Results: Schools with high SIMCE results grouped children with significantly higher values of Z-HC >2SD and lower values of growth failure compared with schools with low SA ($p < 0.0001$). In schools with similar SIMCE results, postnatal nutritional parameters did not differ by SES.

Conclusions: We confirm the hypotheses that school-age children attending to educational establishments with similar SA have similar postnatal growth and development parameters by socioeconomic status.

Key words: Nutritional assessment; head circumference; growth failure; socioeconomic status; learning

PO2367

THE ANALYSIS OF IMBALANCES WITHIN LIPID COMPONENT OF STUDENTS' DIET

A. Korolev¹, E. Nikitenko¹, N. Pernik¹, E. Denisova¹

¹Department of Human Ecology and Environmental Hygiene, I.M. Sechenov First Moscow State Medical University, Moscow, Russia

Background and objectives: This study aimed to assess and analyze the fat content of students' diet at weekend. The participants were students of Moscow medical university.

Methods: In investigation the diets of representative group of students were studied: 9 men and 26 women aged 20-22. The method of 24-hour recall was used and the nutrient content was further estimated using standard data base.

Results: The average energy value was estimated as 2559.7±463,5 kcal in men and 1711.7±80,1 kcal in women. The percentage of energy from total fat was higher than RDA: 42.9% (122.1±22.1 g) and 38.3% (72.8±5.6 g) in men and women respectively. Particular attention was paid to the absolute amount and ratio of fatty acids. While the linoleic acid/ α -linolenic acid ratio was equal (12.9/1) both in men and women, there has been shown significant difference in their quantity: linoleic acid/ α -linolenic acid in men was estimated as 22.1 g/1.69 g and 11.95 g/0.93 g in women. The sum of essential fatty acids composed 8.4% and 6.8% of total energy. The consumption of n-3 longer chain polyunsaturated fatty acids was extremely low: 49.1±32.7 mg and 200.4±122.4 mg of EPA and DHA respectively for males; 29.1±11.2 mg and 85.3±24.7 mg for females. Cholesterol and plant sterols intake as well as their ratio have been found as fairly optimal in women 1.1/1 (223.2±17.6 mg/209.9±27.2 mg) and rather negative in men 1.85/1 (540.9±155.6 mg/291.7±74.6 mg).

Conclusions: The results have shown that there is significant imbalance within fat component of students' diet. It is essential to decrease the proportion of total fat as well as to optimize the ratio of different food sources of fatty acids by taking some measures including functional products use.

Key words: linoleic acid, α -linolenic acid, EPA, DHA.

PO2368**CACO-2 CELL AND ANIMAL MODEL (GALLUS-GALLUS) STUDIES ARE EFFECTIVE AT SCREENING AND DEVELOPING STAPLE FOOD CROPS WITH IMPROVED FE-BIOAVAILABILITY***E. Tako¹, R.P. Glahn¹*¹USDA-ARS, Robert Holley Center For Agriculture and Health, Cornell University, New York, USA

Background and objectives: Iron (Fe) biofortification is a strategy that alleviates Fe deficiency by improving Fe bioavailability and/ or concentrations in staple crops. In order to develop improved lines of staple food crops, breeders need a high throughput screening approach that accurately ranks bioavailability relative to standard reference controls. Molar ratios of known food factors such as phytic acid, polyphenols, and ascorbic acid are often highly linked to environmental and processing effects and thus not reflective of the genetics of Fe bioavailability.

Methods: A bioassay such as the *in vitro* digestion/Caco-2 cell model is therefore necessary for measurement of Fe bioavailability during the crop development stage. This should follow by a subsequent animal studies that are useful and cost-effective to confirm the *in vitro* observations and advance select lines for human efficacy studies.

Results: Our research team has conducted several studies aimed to screen Fe bioavailability in different crops using our *in vitro* (Caco-2) and *in vivo* (Gallus gallus) models. In these studies, we implement physiological, cellular and molecular parameters in order to accurately measure the dietary Fe bioavailability in the tested crops. This approach has been particularly effective when coupled with QTL (quantitative trait loci) mapping at developing high bioavailable Fe maize. Furthermore, this strategy has identified possible Fe bioavailability QTL in bean cotyledons, and has found seed coat polyphenols to be major inhibitors of bean Fe absorption.

Conclusions: Differences identified by this model in crops such as maize, lentils and beans indicate that plant breeding can significantly improve Fe bioavailability in these crops.

Key words: Biofortification, iron bioavailability, *in vitro* digestion/Caco-2 cell model

PO2369**MELATONIN TREATMENT ENHANCES PLASMA VANADIUM LEVELS IN YOUNG MALE ZUCKER DIABETIC FATTY (ZDF) RATS***M. Navarro-Alarcón¹, J.F. Ruiz-Ojeda¹, R.M. Blanca-Herrera¹, A. Agil²*¹Department of Nutrition and Food Science, University of Granada, Granada, Spain²Department of Pharmacology and Neurosciences Institute, University of Granada, Granada, Spain

Background and objectives: Vanadium (V) and its complexes mimic the action of insulin by increasing glucose uptake and augmenting insulin-receptor tyrosine kinase activity. Our group previously reported that melatonin administration ameliorates glucose homeostasis in young Zucker Diabetic Fatty (ZDF) rats by enhancing insulin action and β -cell function. The purpose of the present study was to study the activity of melatonin in diabetes in relation to the levels and regulation of plasma V in ZDF and Zucker lean (ZL) rats.

Methods: At 6 weeks of age, ZDF (n= 30) and ZL (n= 30) groups were each subdivided into three subgroups (n= 10 each one): control (C-ZDF, C-ZL), vehicle-treated (V-ZDF, V-ZL) and melatonin-treated (M-ZDF, M-ZL; 10 mg/kg/day) groups for a 6-weeks period. At the end of the treatment, plasma V levels were measured by an electrothermal atomic absorption spectrometry technique by using a previously optimised time-temperature program.

Results: No significant differences were found between C-ZDF and V-ZDF groups ($p>0.05$). Plasma V levels were significantly higher in M-ZDF versus C-ZDF rats.

Conclusions: Melatonin administration ameliorates the diabetic status of ZDF rats by enhancing plasma V levels. This finding supports the potential therapeutic value of melatonin against insulin resistance by enhancing plasma levels of V, which is directly involved in regulating glucose-insulin homeostasis in obese and/or diabetic individuals.

Key words: Melatonin, plasma vanadium, Zucker diabetic fatty rats

PO2370**PLASMA SELENIUM, ZINC AND COPPER LEVELS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE: RELATIONSHIP WITH DISEASE SEVERITY AND BIOCHEMICAL BIOMARKERS**

M. Navarro-Alarcón¹, T. Castro-Aguilar², R. Blanca-Herrera¹, F. Nogueras-López², A. Agil³

¹Department of Nutrition and Food Science, University of Granada, Granada, Spain

²Service of Hepatology, Ruiz de Alda Hospital, Granada, Spain

³Department of Pharmacology and Neurosciences Institute, University of Granada, Granada, Spain

Background and objectives: Inflammatory bowel diseases (IBD) such as ulcerative colitis (UC) and Crohn's disease (CD) are associated to enhanced biochemical inflammatory and oxidative stress biomarkers. The purpose of the present study was to study if enhanced oxidative stress characteristic of these diseases is also associated to an alteration in the regulation and plasma levels of antioxidant minerals (Se, Zn and Cu). The influence that on these plasma mineral levels exerts the clinical activity (disease severity) of the UC and CD diseases has also been performed.

Methods: IBD patients included in this study were 115 (57 with UC and 58 with CD). A healthy control group (n= 30) was also studied. Plasma samples were analyzed by hydride generation atomic absorption spectrometry (HG-AAS) for Se and by flame-AAS for Zn and Cu. Biochemical indexes (n= 18) were determined with an automated analyzer.

Results: Mean serum Se levels were significantly lower in both groups of IBD patients (UC and CD) than in the controls (p<0.001). Contrarily mean plasma Cu levels measured in controls were significantly lower than those for UC and CD group (p<0.01). For Zn, mean plasma level in UC patients was significantly higher than those for CD patients and controls (p< 0.05). Plasma Se and Zn levels decreased significantly with the disease severity. Contrarily, biochemical biomarkers of inflammation such as alpha-1-antitrypsin, alpha-1-globulin, alpha-2-globulin, orosomucoid and C-reactive protein (CRP) significantly enhanced with the disease severity.

Conclusions: The IBD influences plasma levels of antioxidant minerals diminishing those for Se and enhancing those for Cu. Plasma Se and Zn levels in both groups of IBD patients decreased with the enhancement of the disease severity.

Key words: Inflammatory bowel disease, plasma Se, Zn and Cu levels

PO2371**OPTIMAL CUTOFFS OF BMI, PERCENTAGE BODY FAT, AND WAIST CIRCUMFERENCE FOR PREDICTING METABOLIC SYNDROME AMONG LEBANESE ADULTS**

N. Bachir¹

¹American University of Beirut, Beirut, Israel

Background and objectives: Obesity is a main predictor for metabolic abnormalities. Body mass index (BMI), percentage body fat (%BF) and waist circumference (WC) have been proposed as indices to assess obesity. Various cut-off values were developed, however, ethnic differences have been shown to affect the sensitivity and specificity of these indices. The objective of the study was to determine population specific cut-off points for BMI, %BF and WC associated with an increased risk of metabolic syndrome (MetS) among Lebanese adults.

Methods: This is a secondary analysis of data drawn from the National Nutrition and Non-Communicable Disease Risk Factor Survey conducted in Lebanon between 2008 and 2009. Survey participants older than 18 years and with no chronic diseases were included in this analysis (n=314; 146 males and 168 females). MetS was diagnosed using the 'Harmonizing criteria of A Joint Interim Statement of IDF/NHLBI/AHA/WHF/IAS/IASO 2009'. Receiver Operating Characteristic curves analysis was employed to derive cut-off points for BMI, %BF and WC associated with increased risk of MetS.

Results: Prevalence of MetS in the study sample was 23.9% (33.6% males, 15.5% females). The cut-off points for BMIs for males and females respectively were 27.26 and 28.35 kg m⁻² with AUC of 0.743 and 0.830. As for %BF, cut-off values were 25.2 and 35.9% with AUC of 0.713 and 0.820. Regarding WC, cut-offs were 94.7 and 90.1 cm with AUC of 0.74 and 0.85.

Conclusions: The optimal cut-off values to predict MetS of BMI, %BF and WC were derived. Our findings indicated that Lebanese adults are obese at lower BMI values as compared to the internationally recommended (WHO) standards. To prevent development of metabolic syndrome among Lebanese, it might be useful to lower the cut-off for obesity as defined by BMI.

Key words: BMI, body fat, waist circumference, metabolic syndrome

PO2372**BODY COMPOSITION AND FAT DISTRIBUTION IN RELATION TO BALANCED CALORIC DIET AND PHYSICAL ACTIVITY AMONG OBESE EGYPTIAN ADOLESCENT GIRLS**

N.E. Hassan¹, S. El-Masry¹, S. Zaki²

¹Biological Anthropology Department, National Research Centre, Cairo, Egypt

²Child Health (Clinical Nutrition) Department, National Research Centre, Cairo, Egypt

Objectives and background: Obese adolescents are at risk for developing many co-morbidities, so, the need for evidence-based treatment recommendations is a critical health care issue. Objective: to evaluate effect of 6 months of balanced caloric moderately deficit diet program combined with individualized moderate Physical exercise on body weight, composition and fat distribution of adolescent girls.

Methods: It was a longitudinal study; comprised 111 obese girls (BMI > 95th percentile for age and gender, with mean age 15.82 ± 0.75 years. They were undergoing nutritional intervention (specific dietary program, nutritional education and exercise) for 6 months. At the start of this program, they were assessed for their anthropometric measures: body weight, height, waist and hip circumferences, skin folds thickness at 5 sites (triceps, biceps, sub scapular, suprailiac and abdominal) and, according to BIA, their body composition. Then, BMI and waist/hip ratio were calculated. This assessment was repeated after 6 months. Only thirty eight girls completely finished the program till the end.

Results: The current study showed that after following the dietary program and physical activity, there were highly significant reduction in waist circumference, the skin fold thickness at the 5 sites, peripheral and central adiposity, and fat mass, and significant reduction in body weight, hip circumference and fat%. The change in BMI was insignificant. On the other hand, there was a highly significant increase of the total body water and Basal metabolic rate after following the dietary program and physical activity.

Conclusions: Nutritional intervention program was succeeded in 38 obese adolescent girls. These girls show highly significant reduction in body composition and body fat distribution. This revealed that combined program of diet restriction and exercise is necessary.

Acknowledgements: All obese girls; without their help, this study couldn't be completed and National Research Centre for funding.

Key words: Obese, adolescents, nutritional program, anthropometry.

PO2373**VALIDATION OF FOOD FREQUENCY QUESTIONNAIRE FOR LOCAL SOY BASED PRODUCTS AND ISOFLAVONES INTAKES WITH THREE-DAY FOOD RECORD**

H. Haron¹, S.N. Syed Mu'azam Shah¹, F. Mohd Azmi¹

¹Nutrition Science Programme, School of Health Care, Faculty of Health Sciences, Universiti Kebangsaan Malaysia, Kuala Lumpur, Malaysia

Background and objectives: Food Frequency Questionnaire (FFQ) is a suitable tool to be used in order to determine the common intake of food or nutrient among the population. FFQ for local soy products and isoflavones intakes has not been developed in Malaysia. Thus, the validation for this type of FFQ containing 24 food items is important in order to determine the accuracy of soy products and isoflavone intakes among the Malaysian. The objective of this study was to validate the FFQ of the local soy products and isoflavones with three-day food record (3DR) which were administered among the Malay subjects at Kuala Lumpur campus of Universiti Kebangsaan Malaysia (UKM).

Methods: It was a cross sectional study involving 100 Malay subjects aged 20 to 59 years. The FFQ was administered after interviewing the subjects by using 3DR. The data obtained from 3DR was analysed using Nutritionist Pro software while the isoflavone content in foods was derived from the isoflavone database.

Results: The mean intakes of soy products (206.64 g) and isoflavones (64.47 g) measured using FFQ were significantly higher ($p < 0.05$) than the ones measured using 3DR (134.71 g soy products and 60.69 g isoflavones). However, there was a relatively good correlation between these two methods for both total intakes of soy products ($r = 0.46$) and isoflavones ($r = 0.29$). Analysis of Bland Altman plot also showed an agreement between the FFQ and 3DR by the distribution of the data between ± 2 standard deviation lines.

Conclusions: This FFQ was acceptable in determining the local soy products and isoflavones intakes among the Malaysian adults. Further modifications should be made on this FFQ in order to make it more precise and accurate.

Key words: Three-day food record, FFQ, isoflavones, soy products, validation.

PO2374

COMPARISON OF THE IDEAL DIET IN JAPAN AND IN THE KINGDOM OF SAUDI ARABIA BASED UPON THE DRAWING METHOD

M. Hasegawa¹, I. Armad²

¹Kyorin University, Tokyo, Japan

²Effat University, Jeddah, Saudi Arabia

Background and objectives: Saudi Arabia has enjoyed good bilateral relations with Japan since 1955 and is also regarded as the most friendly country in the Middle East region. Economically, the two countries are of great significance to each other with Saudi Arabia being the principal country which exports to Japan (crude oil and petroleum products), and Japan is Saudi Arabia's main partner in trade and investment. Socially, from the viewpoint of dietary culture, an average Saudi Arabian meal is quite different from a standard Japanese meal. For the understanding, maintaining and promoting of good relations with Saudi Arabia, it is very important to compare the Japanese dietary habits with Saudi Arabian dietary habits. Based upon the aspects above, the objective of this research is to compare the dietary habits of a select sample of participants in the two countries of Japan and the Kingdom of Saudi Arabia.

Methods: The subjects of this research are female students at University A in Japan and University B in Saudi Arabia. The research was conducted by using the Drawing Method and the statistical analysis was performed using IBM SPSS Ver. 16.0.

Results: The results show that there are significant differences in dietary knowledge, dietary behavior, dietary habits and the dietary environment between Japan and Saudi Arabia. Japanese students participating in this study preferred Japanese traditional cuisine much more than foreign cuisine, while the Saudi Arabian student participants favored foreign foods over their traditional foods.

Conclusions: The differences between dietary knowledge, behavior and habits, and the dietary environment between Japan and Saudi Arabia. Japanese students were due to factors such as culture, religion and climate.

Key words: Drawing method, ideal diet, Saudi Arabia, Japan

PO2375

ROTATION CRITERIA FOR EXPLORATORY FACTOR ANALYSIS: IMPLICATIONS FOR INTERPRETABILITY AND VALIDITY OF EMPIRICALLY DERIVED DIETARY PATTERNS

M. Castro¹, V. Baltar¹, S. Selem¹, D. Marchioni¹, R. Fisberg¹

¹Department of Nutrition, School of Public Health, University of São Paulo, São Paulo, Brazil

Background and objectives: Exploratory factor analysis has been used in nutritional epidemiology to empirically derive dietary patterns. However, remain unclear the effects of rotation criteria on interpretability and validity of the dietary patterns. The present study aims to investigate the effects of rotation criteria on composition, interpretability and validity of empirically derived dietary patterns.

Methods: A total of 1102 adults participating in a population-based survey "Health Survey of São Paulo (HS-SP)", Brazil, between 2008-2011, with complete food consumption data (24-hour recalls) were evaluated. Two dietary patterns were derived from exploratory factor analysis after adjustment for the within-person variation of the food group intakes. The rotation criteria evaluated were Varimax (orthogonal) and Promax and Direct Oblimin (both oblique). Confirmatory factor analysis was performed to assess the validity of dietary patterns. Two factor loading cut-offs were used to select food groups for confirmatory analysis: $\geq|0.20|$ and $\geq |0.25|$. Goodness-of-fit indexes were used to assess model fit.

Results: Differences in composition and interpretability of the first dietary pattern were observed between Varimax and Promax/Oblimin at low factor loading cut-off ($\geq|0.20|$). At high cut-off ($\geq|0.25|$), these differences were no longer observed. None of the dietary patterns derived at factor loading cut-off $\geq|0.20|$ showed acceptable model fit. The Promax rotation, however, showed better model fit than either Varimax or Oblimin at factor loading cut-off $\geq|0.25|$.

Conclusions: The effects of rotation criteria on composition, interpretability and validity of dietary patterns differed according to factor loading cut-off. Researchers should perform at least one orthogonal and one oblique rotation criteria, apply the factor loading cut-off and then compare the factor solutions. The confirmatory factor analysis should also be conducted to test the validity of dietary patterns and the adequacy of the factor loading cut-off chosen during exploratory factor analysis.

Key words: Nutritional assessment, dietary patterns, factor analysis; rotation criteria

PO2376**EVALUATION OF THE IMPACT OF VITAMIN A AND ZINC SUPPLEMENTATION ON MALARIAL MORBIDITY IN GHANA.**

S. Newton¹, S. Owusu-Agyei¹, L. Gyabaa-Febir¹, M. Ali¹, K. Adjei¹, E. Mahama¹, K. Tchum¹, L. Alhassan¹, S. Tanumihardjo²

¹Kintampo Health Research Centre, Kintampo, Ghana

²University of Madison, Wisconsin, USA

Background and objectives: Malaria is a leading cause of morbidity and mortality among young children and is estimated to cause at least 1 million deaths each year especially among pregnant women and young children under the age of five. Vitamin A supplementation is known to reduce morbidity and mortality in young children. Zinc is also required for growth and immunity. The study sought to replicate the study by Zeba et al which showed 30% lower cases of malaria in infants on a combination of zinc and a large dose of vitamin compared to infants on vitamin A alone. The primary objective was to determine the effect of vitamin A alone vs. vitamin A and zinc supplements on the incidence of clinical malaria. It also sought to assess the effects on the incidence of anaemia, diarrhoea and pneumonia.

Methods: The study was community-based and 200 infants between the ages of 6-24 months were randomised to receive either vitamin A and 10 mg daily zinc or Vitamin A and zinc placebo for 6 months.

Results: The number of children who were diagnosed with uncomplicated malaria in the intervention group were 27% significantly lower compared to the children in the control group ($p=0.03$). There were however no effects on severe malaria, pneumonia, anaemia and diarrhea.

Conclusions: Our study confirms a significant role of vitamin A and zinc in reducing malaria morbidity.

Key words: Vitamin A, zinc, malaria

PO2377**ASSESSMENT OF FOLATE STATUS USING BIOMARKERS AND NUTRIENT INTAKE DATA AMONG AUSTRIAN SCHOOL CHILDREN AGED 7–14 YEARS**

N. Weidl¹, K. Wagner¹, I. Elmadfa¹

¹Institute of Nutritional Sciences, University of Vienna, Vienna, Austria

Background and objectives: Biomarkers deserve special attention in nutritional epidemiology and give an objective

measurement when assessing the nutritional status. Analysis of plasma folate and homocystein concentrations are important tools to determine early functional and metabolic changes of a folate deficiency.

Methods: 387 Austrian school children aged 7 to 14 years have been recruited through quota sampling stratified for gender, age and geographical region. Blood and urine samples in addition to two 24h-recalls (via interview) have been collected from October 2010 through February 2012. Plasma concentrations were analysed for folate (using RIA) and homocystein (using HPLC). All results are presented as median values (IQR).

Results: Plasma concentrations for folate were 14.7 (9.9-19.5) nmol/l and for homocystein 8.8 (7.8-10.1) μ mol/l with an average folate intake of 153 (117-194) μ g/d. Folate concentrations correlated negatively with age ($r=-.352$, $p<0.01$), homocystein concentrations however positively ($r=0.198$, $p<0.001$). Plasma homocystein was higher among boys (8.9 (8.0-10.4) μ mol/l) when compared to girls [8.5 (7.5-9.7) μ mol/l ($p<0.05$)]. No significant difference was observed for plasma folate [boys: 14.2 (10.0-18.8) nmol/l, girls: 14.7 (10.0-14.7) nmol/l]. Folate intake was a little higher in boys [160 (129-200) μ g/d] compared to girls (146 (111-190) μ g/d ($p<0.05$)), but both were below the recommended reference values of 180-300 μ g/d.

Conclusions: The determination of plasma folate and homocystein seems to be adequate to describe the folate status. The folate status among Austrian school children (7-14 years) is in 75 % of the population optimal, however the average folate intake of approximately 150 μ g/d should be improved to meet the recommendations.

Key words: Folate, homocystein, status, biomarker

PO2378**ASSOCIATION BETWEEN CONSUMPTION OF FORTIFIED FIRST GRADE FLOUR AND IRON AND FOLATE STATUS OF WOMEN OF REPRODUCTIVE AGE IN UZBEKISTAN**

C. Northrop-Clewes¹, L. Hund², R. Nazario³, D. Suleymanova⁴, L. Mirzoyan⁵, M. Irosova⁵, M. Pagano², J. Valadez⁶

¹Global Alliance for Improved Nutrition, Geneva, Switzerland

²Harvard School of Public Health, Boston, MA, USA

³Instituto de Investigación Nutricional, La Molina, Lima, Perú

⁴Ministry of Health, Research Institute of Hematology and Blood Transfusion, Tashkent, Uzbekistan

⁵Joint Projects Implementation Bureau, Health-2, and "Woman and Child Health Development", Tashkent, Uzbekistan

⁶Liverpool School of Tropical Medicine, Liverpool, UK

Background and objectives: The Uzbekistan Demographic Health Survey (1996) reported 60.4% of women of reproductive age (WRA) had low concentrations of hemoglobin (<120 g/L), hence anemia was an important public health problem. Bread is consumed with most meals, so to address the anemia a National Flour Fortification Program (NFFP) was implemented. The objective of the study was to assess the coverage of fortified first grade UzDonMakhsulot (UDM) flour/grey loaf, its association with the iron and folate status of WRA, and the knowledge of women of dietary and health concepts after 5 years of the NFFP.

Methods: A national survey using large country-lot quality assurance sampling.

Results: Confidence intervals (CIs) were set at 95%. UDM first grade flour was reported in 58.2% (CI: 55.2, 61.2) and the grey loaf in 11.5% (CI: 9.7, 13.3) of households. The qualitative iron spot test identified 41.6% (CI: 39.2, 43.9) of flour tested was fortified. Consumption of heme iron-containing food (91%), iron absorption enhancers (97%) and iron inhibitors (95%) were high. Anemia prevalence was 34.4% (CI: 32.0, 36.7), iron depletion (ferritin <15µg/L) 47.5% (CI: 45.1, 49.9) and low folate (<10nmol/L) 28.8% (CI: 26.8, 30.8); the effect of inflammation was minimal. Knowledge that first grade UDM flour and the grey loaf are fortified was reported by 32.1% (CI: 29.9, 34.3) of women, but only 3.7% (CI: 2.8, 4.6) mentioned the benefits. Knowledge about anemia was low; 12.5% (CI: 11.0, 14.0) were able to identify causes.

Conclusions: The NFFP coincided with a substantial decline in the prevalence of anemia. However, the high prevalence of depleted iron stores suggests that women are still not eating enough iron or iron absorption is inhibited. Knowledge about

the NFFP and anemia was low; therefore consumer education should be prioritized. UDM flour must be fortified appropriately and monitored regularly.

Key words: Fortified flour, iron, folate.

PO2379**THE EFFECTS OF VITAMIN E ANALOGS AND METABOLITES ON RAT FATTY LIVER**

C. Muto¹, K. Saito², O. Igarashi¹, C. Kiyose^{1,2}

¹Department of Nutrition and Life Science, Kanagawa Institute of Technology, Kanagawa, Japan

²Department of Applied Chemistry, Graduate School of Kanagawa Institute of Technology, Kanagawa, Japan

Background and objectives: Vitamin E is the term for a group of tocopherols and tocotrienols that has four analogs differing in the number and position of methyl groups on the chroman ring. 2,7,8-trimethyl-2-(2'-carboxyethyl)-hydroxychroman (gamma-CEHC), gamma-tocopherol (-Toc) or gamma-tocotrienol (-T3) metabolite, is known to have a role similar to natriuretic hormone. Therefore, it considers that vitamin E may have a pro-drug action. The aim of this study is to find the novel function of carboxyethyl-hydroxychroman(CEHC). Especially, we investigated the effects of vitamin E analogs and metabolites on fatty liver in vitro.

Methods: Male Sprague-Dawley strain rat (three weeks old) was fed the high fat diet (20% w/w corn oil). After 4 weeks, the hepatocytes were perfused from fatty liver of the rat. The hepatocytes were sown in 60mm dishes or 12 well plates and grown at 37°C in a humidified atmosphere containing 5% CO₂. After 24h, each vitamin E analogs(alpha-Toc, gamma-Toc, alpha-T3, gamma-T3) and CEHCs (alpha- and gamma-CEHC) was added to the fatty hepatocytes (final concentration; 2 micro M), and the medium was changed at 6h. After 8h from the medium change, we measured mRNA expression of microsomal triacylglycerol transfer protein (MTP) and apolipoprotein B (ApoB) in fatty hepatocytes. Furthermore, we determined triacylglycerol (TG) content in fatty hepatocytes after 18h from the medium change.

Results: There were no significant differences in the MTP mRNA expression between all the group. On the other hands, each of ApoB mRNA expressions of gamma-T3 or gamma-CEHC group was remarkably higher than that of control group. However, there were no significant differences in TG content among all groups.

Conclusions: According to these results, we suggested that gamma-T3 and its metabolite (gamma-CEHC) may improve

fatty liver because of up-regulating ApoB mRNA expression in fatty hepatocyte.

Key words: Vitamin E, CEHC, ApoB, primary culture, fatty liver

PO2380

LONG TERM FOLLOW-UP STUDY OF REFINED SUGAR CONSUMPTION FOR CHILDREN AGED 2 TO 5 YEARS IN TAIWAN

L C. Lyu¹, Y C. Yang¹, H W. Yu²

¹Department of Human Development and Family Studies, National Taiwan Normal University, Taipei, Taiwan

²Division of food and nutrition, John Tung Foundation, Taipei, Taiwan

Objectives: The purpose of this study is to examine the consumption of sugar-sweetened beverages (SSB), snacks and desserts among pre-school children and estimate the intake of refined sugar among children aged 2 to 5 by a prospective cohort.

Methods: Total 301 infants were followed up annually to the age of 5 (n=132). The intake of refined sugar is calculated by using 24-hour recalls. Estimated percentages of refined sugar in various food products are used in order to obtain the average daily intakes.

Results: The consumption of SSB among reported children increases with age. Among the SSBs, “flavored and fermented milk” contributes to the highest percentage among children aged 2-5, while the “whole grains drinks” and “tea drinks” showed increased trend in years. For snacks and desserts, “biscuits” contributes to the highest percentage among children aged 2 to 4, with “Chinese sweet soup” showing an upward trend by years while having the highest increasing percentage among children aged 5. The refined sugar intake at age 4 is significantly associated with dietary intakes at 2, 3 and 5, respectively, and weight and height at age 5 ($p < 0.05$), but not associated with BMI at age 5 after controlling for gender and birth weight ($p > 0.05$).

Conclusions: The energy intakes from refined sugar are 5%, 6%, 9% and 8% (p for trend < 0.01) respectively for children aged 2 to 5. Over one-third of 5-year-old children have over 10% calories intakes from refined sugar.

Key words: preschoolers, sugar sweetened beverages, snacks and desserts, refined sugar, prospective cohort study

PO2381

EFFECTIVENESS OF COMMUNITY MALNUTRITION SCREENING FOR CHILDREN AGED 6 TO 59 MONTHS IN THE HEALTH DISTRICT OF DIAPAGA (BURKINA FASO)

E W R. Compaore¹, D. Ouedraogo¹, P A. Nikiema¹, A. Bichard², J. Mouecoucou³, A S. Traore¹

¹Department of Biochemistry-Microbiology, CRS-BAN, University of Ouagadougou, Ouagadougou, Burkina Faso

²Action Contre la Faim, Ouagadougou, Burkina Faso

³Department of Physiology, Universite des Sciences de la Sante, Libreville, Gabon

Background and objectives: Community screening program at health district of Diapaga consists of a systematic screening of malnutrition in order to identify and refer moderated and severely malnourished children to health center (CSPS). The objective of this program is evaluation of the effectiveness of the community malnutrition screening by providing coverage statistics of children by community screening compare to total of children and estimate the referred cases admitted or not at different health center clusters. It's determine the shortcomings of this community screening and provide hypotheses in order to improve the quality and effectiveness of community screening

Methods: It consists of three steps which are: i) Systematic screening by volunteers of all children aged 6 to 59 months in each cluster every 2 months; ii) The listing of all malnourished children screened and referred to CSPS for confirmation; iii) Admission of confirmed cases in the management program. The evaluation was performed using screening available data from August 2010 to March 2011 and from August 2011 to March 2012.

Results: Regarding coverage rate from August 2010 to March 2011 all clusters have targeted 70% of children. For the presence at CSPS, at the same period 90% of clusters are below the limit of 50%. For admission rate 8 clusters (for a total of 10) are below the recommended value which is at 60% to the recommended value. However, from August 2011 to March 2012, 90% of clusters have all indicators placed at the minimum of recommended value.

Conclusions: Community screening help to a better coverage of children of the age group but there are difficulties between the reference and confirmation to CSPS which complicate the rapid management of child malnutrition and limit the results of the community screening.

Key words: Malnutrition, community screening, efficiency

PO2382**MICRONUTRIENT DEFICIENCIES AMONG OVERWEIGHT/OBESE VIETNAMESE WOMEN: AN ISSUE NOT TO UNDERESTIMATE**

A. Laillou¹, E. Yakes², T.H. Le³, F. Weiringa⁴, V.T. Pham³, B.M. Le³, R. Moench-Pfanner¹, J. Berger⁴

¹Global Alliance for Improved Nutrition, Geneva, Switzerland

²University of New Mexico, Departments of Individual, Family and Community Education and Family and Community Medicine, USA

³National Institute of Nutrition, Vietnam

⁴Institut de Recherche pour le Développement, Marseille, France

Background and objectives: There is a growing concern about obesity worldwide. In Vietnam, the prevalence of overweight (BMI > 25 kg/m²) in Vietnamese adults doubled between 1992 and 2002, from 2% to 5.5%, respectively and the double burden of malnutrition is present at national level. The objectives of this study were to assess micronutrient deficiencies among Vietnamese women according to their Body Mass Index.

Methods: A transversal study was conducted in 2010 among 1530 women of reproductive age from 19 provinces of Vietnam. Anthropometry and iron, vitamin A, folate, vitamin B12 and zinc status were assessed.

Results: There was no significant association between BMI category and anemia, iron deficiency (ID), iron deficiency anemia (IDA), deficiencies of vitamin A, zinc and vitamin B12, and marginal/deficient folate status, with similar prevalence of these deficiencies across BMI categories. The prevalence of anemia among overweight/obese women (OW/OB) was 10.0%, and 3.4% had IDA. The prevalence of ID and vitamin B12 deficiency were ≤ 12% among OW/OB women whereas the prevalence of zinc deficiency, and marginal/deficient folate status affected respectively 61.1% and 25.8% of these women, respectively. In contrast, a significant association was observed between BMI category and marginal vitamin A status with higher prevalence of vitamin A deficiency in underweight (19%) compared to OW/OB women (7%, $p < 0.0001$). The odds of marginal vitamin A status and anemia prevalence was 31% among OW/OB women and 66% in underweight women ($p < 0.01$).

Conclusions: This cross-sectional survey demonstrated that micronutrient deficiencies were an issue across the weight spectrum of women in Vietnam. It is therefore essential for Vietnam to actively control for micronutrient deficiencies in women in reproductive age while preventing the increase of overweight and obesity.

Key words: Overweight/obesity, micronutrient deficiencies, double burden, women in reproductive age, Vietnam

PO2383**ASSESSMENT OF A DEVICE TO QUANTIFY IRON CONTENT IN FISH AND SOY SAUCE – A TOOL FOR DAILY MONITORING**

A. Laillou¹, C. Icard-Vernière², I. Rochette², C. Picq², J. Berger², P. Sambath³, C. Mouquet-Rivier²

¹Global Alliance for Improved Nutrition, Geneva, Switzerland

²Institut de Recherche pour le Développement, Marseille, France

³RACHA, Phnom Pen, Cambodia

Background and objectives: In a number of South-East Asian countries and in China, fish and soy sauces produced at industrial level are fortified with iron. Unfortunately some food industries and regulatory agencies implementing fortification programs do not always have the capacity to monitor the programs on an ongoing basis. The objective of the study was to assess a new portable device for the quantitative measurement of iron content of fortified sauces that could be used to control fortification levels.

Methods: Linearity, detection limits, inter- and intra-assay variability of this device were assessed on fish and soy sauce fortified with Fe sulfate (FS), Fe fumarate (FM) and NaFeEDTA; the accuracy of the results was compared to atomic absorption spectrophotometry (AAS).

Results: Measurements required a minimum incubation time of one hour for FS/FM and 24h for NaFeEDTA. Linearity of results ranged from 2 to 10 mg iron/L for FS/FM and from 1-10 mg iron/L for NaFeEDTA, implying the need for proper dilution as iron contents of fortified sauce are usually in the range [150-1000] mg/l. Depending on incubation time, iron compounds and sauces, the coefficients of variation (CV) of intra-assay precision were between 1.5-7.6% and the CV of inter-assay precision between 2.9-7.4%. Comparison with AAS showed high agreement between both methods with $r = 0.93$ and $r = 0.94$ for 10 and 24h incubation times respectively. The Bland and Altman plots showed limits of agreement between the two methods of ± 70 mg/l in the range of fortification levels tested (100-500 mg/l).

Conclusions: This device offers a viable solution for field monitoring of iron fortification of soy and fish sauces after incubation time of 1h for FS/FM and 24h for NaFeEDTA.

Key words: Fish and soy sauce, quality testing, iron, rapid test kit, regulatory monitoring

PO2384**HIGH PREVALENCE OF HYPOVITAMINOSIS D AND MILD HYPOCALCAEMIA CALCIUM AMONG YOUNG VIETNAMESE CHILDREN AND WOMEN**

A. Laillou¹, F. Wieringa², T N. Tran³, V T. Pham³, B M. Le³, S. Fortin², T H. Le³, R. Moench-Pfanner¹, J. Berger²

¹Global Alliance for Improved Nutrition, Geneva, Switzerland

²Institut de Recherche pour le Développement, Marseille, France

³National Institute of Nutrition, Vietnam

Background and objectives: In many developing countries including Vietnam, data are lacking on vitamin D (VD) and calcium deficiencies known to play an important role in the development of bone health. The objectives of this study were to determine the overall prevalence of VD and calcium deficiencies in women and young children and their nutritional related risk factors. A transversal study conducted among 595 women of reproductive age and 532 children <5 years from 19 provinces. Food consumption, socio-economical characteristics and anthropometry were assessed as well as plasma concentrations of calcium (Ca) and VD. Socio-economic status was assessed using the DHS Wealth Index while food consumption was recorded through a 24-hours recall. VD status was assessed by measuring the serum concentration of 25-hydroxyvitamin D and Plasma ionized calcium was measured with an ion-sensitive electrode.

Results: The prevalence of hypovitaminosis D status was high, with the prevalence of VD deficiency [25(OH)D < 30 nmol/l] and insufficiency [25(OH)D between 30–49.9 nmol/l] being 17% and 40% in women and 21% and 37% in children respectively. Using a cut-off of 75 nmol/l, approximately 90% of the women and children had hypovitaminosis D. Overweight/obese women had a 2 times lower risk [OR=0.46, (0.24-0.90)] for VD deficiency their non-overweight/non-obese counterparts. No participant had severe calcium deficiency (Ca<0.8 mmol/l) but moderate (0.8<Ca<0.9 mmol/l) and mild hypocalcaemia (0.9<Ca<1.15 mmol/l) affected respectively 14% and 83% of the women and 97% of children. Women and children intakes was 1% of the IOM recommended nutrient intakes (RNI) for VD and less than 43% of the calcium RNI.

Conclusions: calcium and VD deficiencies would represent a major public health concern in Vietnam due in part to low dietary intakes. Thus, actions to improve the VD and calcium status of the Vietnamese population should be considered.

Key words: Calcium, vitamin D deficiency, daily intake, women, children, Vietnam

PO2385**A REVIEW OF VITAMIN D FORTIFICATION- IMPLICATIONS FOR NUTRITION PROGRAMMING IN SOUTH EAST ASIA**

Z. Yang¹, A. Laillou², G. Smith³, D. Schofield², R. Moench-Pfanner²

¹Nutrition and Food Safety, China Center for Disease Control, Xuanwu, Beijing, China

²Global Alliance for Improved Nutrition, Geneva, Switzerland

³Essential Micronutrients Foundation, Singapore and the International Life Sciences Institute (ILSI), South East Asia Region, Singapore

Background and objectives: Vitamin D (VD) is vital for bone health and has important contributions to non-skeletal health and organ function. Most VD is generated in the body by sunlight exposure with limited amounts added by diet. Despite regular sunshine in South East Asia, VD deficiency or insufficiency is being found more commonly, primarily due to lifestyle reductions to sunlight exposure. Some of these lifestyle changes are unlikely to change, and foods naturally containing VD are not widely consumed, so fortification of foods with VD may raise vitamin D status. The aim of this study was to review of VD fortification and therefore its implications for nutrition programming in South East Asia.

Method: Literature database was searched for fortification studies on VD and we estimated the VD intakes through potential fortified vegetable oil.

Results: Almost all of the studies showed that circulating VD (25OHD) increased in a dose dependent manner based on increased intake of fortified foods. However in a number of the studies, the additional intake was insufficient to increase VD levels to 50 nmol/L. Vegetable oil fortified at the level of 10 µg/100 g, in South East Asia, could provide 10-20% of the IOM estimated average requirement of VD for a woman and 5-15% of the IOM EAR for a child under 5 years of age.

Conclusions: Fortification of widely consumed foods such as edible oil with vitamin D could contribute to improved VD status in SE Asian countries. Intake modeling studies should be conducted to calculate additional resulting intakes, and fortification of additional foods should be considered. More nationally representative studies of vitamin D status in the region are urgently needed.

Key words: Fortification, supplementation, vitamin D, nutrition impact, South East Asia

PO2386**VITAMIN D DEFICIT AND METABOLIC SYNDROME**

I. Gonzalez-Molero¹, G. Rojo¹, S. Morcillo¹, M. Gonzalo¹, M. Domínguez-López¹, C. Gutierrez¹, E. Rubio¹, G. Oliveira¹, M.S. Ruiz de Adana¹, F. Soriguer¹

¹Endocrinology and Nutrition Service, Carlos Haya Hospital, Malaga, Spain

Background and objectives: To assess the relationship between 25-hydroxyvitamin D levels and prevalence and incidence of metabolic syndrome .

Methods:We undertook a population-based cohort study in Spain. At baseline (1996-1998),1226 subjects were evaluated. Follow-up visits were performed in 2002-2004 and 2005-2007. At baseline and follow-up, participants underwent an interview and a standardized clinical examination with an oral glucose tolerance test in those subjects without known diabetes. At the second visit, 25-hydroxyvitamin D levels and iPTH levels were measured.

Results: The prevalence of metabolic syndrome (IDF criteria) at the second and third visit was 29.4% and 42.5 respectively. Mean levels of 25 Hydroxyvitamina D were lower in subjects with metabolic syndrome: 21.7 ± 6.21 ng/ml vs 23.35 ± 6.29 ng/ml, $p=0,001$. The prevalence of vitamin D deficiency (25 hydroxyvitamin D <20 ng/ml) at the second evaluation was 34.7%, with significant differences between subjects with and without metabolic syndrome (34.6 vs 26.5%, $p=0.01$). Women with vitamin D deficiency more frequently had hypertension and metabolic syndrome than women with normal levels. Men with vitamin D deficiency had more frequently hyperglycemia, hypertension, increased waist circumference , hypertriglyceridemia and metabolic syndrome. The number of present criteria was related to the prevalence of vitamin D deficiency so that for 1, 2, 3, 4 and 5 criteria the prevalence were: 31.7%, 32%, 33.5%, 55.4% and 100%. In prospective study, 25 hydroxyvitamin D values <20 ng/ml were not significantly associated with an increased risk of developing metabolic syndrome in the next 4 years (OR=0.99, 95% CI 0,57-1,7, $p=0.97$) after adjusting by sex and age.

Conclusions: Vitamin D deficiency is associated with an increased prevalence but not with increased incidence of metabolic syndrome.

Key words: Vitamin D, metabolic syndrome

PO2387**WEIGHT-FOR-AGE CHARTS AND Z-SCORES DEVELOPED FOR 10-15 YEAR OLD ADOLESCENTS IN NORTH-WEST PROVINCE SOUTH AFRICA**

W. Dube¹, N. Covic¹, A. Van Graan¹, H. Kruger¹

¹Centre of Excellence for Nutrition, Potchefstroom Campus, Northwest University, South Africa

Background and objectives: Monitoring adolescent weight from routine weight measurements at health centres can be an effective screening way to detect overweight or underweight for appropriate and timely referrals. Currently there is no weight monitoring tool for this age group for use in under-resourced health centres in many developing countries where body mass index (BMI) determination is not practical. The objective was to develop a weight-for-age monitoring chart, determine z-scores for adolescents 10-15 years old and make a comparison with the CDC 2000 and WHO 2007 references at 10 years.

Methods: We used age, sex and weight data from a sample of 1114 black North-West province adolescents from a large cross-sectional study. LMSchartmaker® Light was used to develop the charts and determine z-scores. Boys and girls charts were developed with 3rd, 10th, 25th, 50th, 75th, 90th and 97th percentiles.

Results: Our charts had lower weight-for-age at 3rd percentile for 10 year-old boys and girls than the CDC 2000 and WHO 2007 growth charts. We observed lower weight-for-age at the 97th percentile for 10-year old boys than the CDC 2000 and WHO 2007 growth charts. For 10-year old girls, our charts had a similar 97th percentile weight-for-age as the WHO 2007 chart, but lower than the CDC 2000 growth chart. A one-sample mean comparison test showed a statistical significant difference between means on our chart and both the CDC 2000 and WHO 2007 charts ($p<0.05$).

Conclusions: The new growth charts developed from the data may be more context specific and useful to monitor weight-for-age in 10-15 year old adolescents for this group and may detect weight-for-age greater than the 97th percentile at lower weights than the CDC 2000 growth charts. The charts could be used in under-resourced settings where BMI assessment is not practical.

Key words: LMSchartmaker®-Light, weight-monitoring, underweight, overweight, cross-sectional study

PO2388**BODY IMAGE OF ADOLESCENTS AND ITS CORRELATION WITH BODY MASS INDEX***H. Yardimci¹, A O. Ozcelik¹*¹Department of Nutrition and Dietetics, Ankara University, Ankara, Turkey

Background and objectives: There may occur a disposition of losing/gaining weight in the subjects who are in the growth process. The aim of this study is to identify the adolescents' body image and its correlation with body mass index.

Methods: The sample of the study consisted of 815 high school students (male: 287, female: 528). Data collection were made by face to face interviews using a questionnaire and SPSS program has used to evaluate data. WHO data has used to classify percentile values of BMI and chi square test had ran to analyse data.

Results: The mean age of students was 15.70 ± 0.74 years and mean BMI was 20.61 ± 2.60 kg/m². According BMI 68.4% of students were in normal range, 15.7% of them pre-obese, 3.7% of them were obese. Difference between BMI percentile values of age and gender is statistically significant ($p < 0.05$). 87% of the students didn't smoke and 89.1% of them didn't consume alcohol. Female students tended to see themselves fat (17.2%) more than male students did (7.7%). 47.8% of the subjects who consider themselves fat had a normal body weight. Correlation between body image and gender is statistically significant ($p < 0.01$). 43.5% of the subjects who weren't content with their weight ($n=131$) had normal weight. Correlation between being content with weight and gender is statistically significant ($p < 0.05$). 58.8% of the subjects who had a change of weight in the last 6 months stated they gained weight ($n=600$). 33% of them had weight change willingly.

Conclusions: Body weight changes in adolescents may get be affected from social pressure, media or body image issues. Body weight should depend on age and gender in healthy individuals and there has to be cooperation between media and education institutions on this matter.

Key words: Turkey, adolescent, BMI, body image

PO2389**VITAMIN D DEFICIT AND DYSLIPIDEMIA***I. González-Molero¹, S. Morcillo¹, G. Rojo¹, M. Gonzalo¹, M. Domínguez¹, G. Oliveira¹, A. Muñoz¹, F. Soriguer¹*¹Endocrinology and Nutrition Service, Carlos Haya Hospital, Malaga, Spain

Background and objectives: Several studies have investigated a possible action of vitamin D metabolites on different lipid fractions but the possible mechanism by which they could act remain unknown, with varying results in observational and intervention studies. The objective was to study the relation between vitamin D levels and lipids levels.

Methods: We undertook a population-based cohort study in Spain. At baseline (1996-1998), 1226 subjects were evaluated. Follow-up visits were performed in 2002-2004 and 2005-2007. At baseline and follow-up, participants underwent an interview and a standardized clinical examination. At the second visit, 25-hydroxyvitamin D levels and iPTH levels were measured.

Results: The mean levels of total cholesterol (TC) in second study were: 249.73 ± 53.05 ; triglycerides: 111.18 ± 73.21 ; HDL: 66.35 ± 16.38 ; and LDL: 161.6 ± 46.71 mg/dl. In the third study, levels were 201.61 ± 38.11 ; 116.61 ± 78.60 ; 54.78 ± 12.98 ; and 123.58 ± 33.12 mg/dl, respectively. Mean levels of different lipid fractions in the second study depending on the presence or absence of vitamin D deficiency were: TC: 256.68 ± 51.91 vs 246.07 ± 53.37 ($p=0.006$); triglycerides: 87.53 ± 119.94 vs 106.34 ± 63.82 ($p=0.01$); HDL: 68.47 ± 17.50 vs 65.24 ± 15.67 ($p=0.007$); LDL: 120.91 ± 30.76 vs 108.45 ± 25.05 ($p=0.001$); ratio TC/HDL: 3.90 ± 0.96 vs 3.90 ± 0.98 ($p=0.9$); ratio LDL/HDL: 1.69 ± 0.51 vs 1.67 ± 0.53 ($p=0.7$). Mean levels of 25-hydroxyvitamin D were significantly lower in subjects with high TC (22.5 vs. 24.2 ng/ml), high HDL (22.1 vs 23.2 ng/ml) and triglycerides (21.1 vs 23.2 ng/ml). No correlation was found between CT and 25-hydroxyvitamin D ($r=-0.06$, $p=0.08$), but there was a negative correlation with HDL and TG ($r=-0.07$, $p=0.03$ and $r=-0.09$, $p=0.01$) adjusted for age, sex and weight. In the cross-sectional study in the multivariate model we didn't obtained relationship between vitamin D deficiency (<20 ng/ml) and elevated total cholesterol (OR=0.85, 95% CI 0.57 to 1.28) or low HDL (OR=1.42, 95% CI 0.75 to 2.71) after adjustment for age, sex and obesity, but the relationship between vitamin D deficiency and hypertriglyceridemia persisted, so that subjects with deficit of vitamin D were more likely to have high triglycerides (OR=0.68, 95% CI 0.47-0.98, $p=0.03$). In the prospective study, after four years of follow up, patients with or without vitamin D deficit, had similar risk of hypertriglyceridemia adjusted by age, sex and obesity (OR:1.01, $p=0.95$). No relationship was found with other lipid fractions in prospective study.

Conclusions: Vitamin D deficiency is associated with increased prevalence of hypertriglyceridemia but is not related to the incidence of dyslipidemia.

Key words: Vitamin D, dyslipidemia

PO2390**VITAMIN D AND OBESITY**

I. Gonzalez-Molero¹, S. Morcillo¹, G. Rojo¹, M. Gonzalo¹, M. Domínguez¹, E. Rubio¹, C. Gutierrez¹, G. Olveira¹, A. Muñoz¹, F. Soriguer¹

¹Endocrinology and Nutrition Service, Carlos Haya Hospital, Malaga, Spain

Background and objectives: To assess the relationship between obesity and the incidence of hypovitaminosis D and investigate the relationship between 25-hydroxyvitamin D levels and incidence of obesity.

Methods: We undertook a population-based cohort study in Spain. At baseline (1996-1998), 1226 subjects were evaluated. Follow-up visits were performed in 2002-2004 and 2005-2007. At baseline and follow-up, participants underwent an interview and a standardized clinical examination with an oral glucose tolerance test in those subjects without known diabetes. At the second visit, 25-hydroxyvitamin D levels and iPTH levels were measured.

Results: The prevalence of obesity (BMI >30 kg/m²) at the three visits was 28.1%, 36.2%, and 39.5%, respectively. The prevalence of vitamin D deficiency (25 hydroxyvitamin D <20 ng/ml) at the second evaluation was 34.7%. Neither obesity at baseline (OR=0.98, 95% CI 0.69-1.40, p=0.93) nor the development of obesity between baseline and the second evaluation (OR=0.80, 95% CI 0.48-1.33, p=0.39) were significantly associated with vitamin D deficiency at the second evaluation.

Conclusions: Vitamin D deficiency is associated with an increased risk of developing obesity.

Key words: Obesity, vitamin D, prospective study

PO2391**VITAMIN D DEFICIENCY IN MORBID OBESITY BEFORE AND AFTER BARIATRIC SURGERY**

M. Gonzalo-Marín¹, I. González-Molero¹, M. Domínguez-López¹, J.A. García-Arnés¹, J.L. Gallego¹

¹Endocrinology and Nutrition Service, Carlos Haya Hospital, Malaga, Spain

Background and objectives: Patients with morbid obesity may have vitamin D deficiency and bariatric surgery may exacerbate it due to various factors such as lack of dietary compliance, reduced intake, malabsorption, etc. The objective was to study the prevalence of vitamin D deficiency in patients with morbid obesity before and after bariatric surgery and its relationship with other laboratory parameters.

Methods: A retrospective study of 72 morbidly obese patients before and 1 year after surgery (bypass or sleeve). We

collected data about: age, sex, previous comorbidities, physical examination, impedance testing and laboratory parameters (25-Hydroxyvit D, iPTH, Ca, HbA1c, total cholesterol, LDL, HDL, triglycerides, uric acid and leptin).

Results: The mean age of patients was 45.84 ± 10.39 years, 78.4% women. Pre- and postoperatively BMI: 51.51 ± 8.11 and 33.36 ± 5.21 (p=0.00). One year after surgery there were significant decreases in HbA1c, TC, LDL, triglycerides, uric acid, leptin and HDL increase. Mean serum 25-OH vit D pre and post were: 16.96 ± 7.87 vs 22.53 ± 12.44 (p=0.013) and iPTH: 16.9 ± 43.97 vs. 41.79 ± 1, 89 (NS). The percentage of vitamin D deficiency (less than 20 ng / ml) were pre and post: 71.8% vs. 44.9% (p=0.04) and hyperparathyroidism 19.4% vs 14.6% (NS.). Vitamin D levels negatively correlated with preoperative age, body fat percentage and iPTH. Vitamin D levels negatively correlated with postoperative BMI, leptin, total cholesterol and HbA1c.

Conclusions: Patients with morbid obesity have Vitamin D deficiency in 71.8% of cases preoperatively, which should lead us to measure 25-OH vitamin D levels routinely in patients with morbid obesity. After the surgical procedure, despite supplementation with vitamin D, patients maintain a high percentage of vitamin D deficiency (44.9%) and elevated iPTH.

Key words: Morbid obesity, vitamin D

PO2392**ACHIEVING ADEQUATE VITAMIN D STATUS IN GUATEMALAN PRESCHOOL CHILDREN**

M. Bonorden¹, L. Armas², N. Solomons³, L. Hernandez³, S. Salguero³, R. Herreid¹

¹Research and Development, Hormel Foods Corporation, Austin, Minnesota, USA

²Osteoporosis Research Center, Creighton University, Omaha, Nebraska, USA

³Center for Study of Sensory Impairment, Aging, and Metabolism, Guatemala City, Guatemala

Background and objectives: Vitamin D status for inhabitants of tropical countries has been largely ignored. However, recent evidence illustrates the prevalence of sub-adequate vitamin D status in Latin American countries is widespread. For instance, a recent survey revealed 77% of preschool aged children in rural and urban Guatemala had sub-adequate levels of 25-hydroxyvitamin D [25(OH)D]. Here we present data on the response of these children to 12 weeks of supervised oral vitamin D3 supplementation.

Methods: The reported results are part of a larger survey conducted in 2011 documenting concentrations of iron and vitamins D and B12 in children attending one of three daycare centers in the central highlands of the Republic of Guatemala.

Children with sub-adequate vitamin D concentrations (n=67) received supervised supplementation of 2000 IU (50 µg) of vitamin D3 daily with a target of 60 cumulative doses (120,000 IU). Following supplementation 5 mL of venous blood was taken for analysis of 25(OH)D at the Osteoporosis Research Center of the Endocrine Division of Creighton University. Blood values < 30 ng/ml 25(OH)D were considered sub-adequate.

Results: All of the 67 participants received the prescribed 60 doses. Baseline mean 25(OH)D was 23.3 ± 4.4 ng/ml (median 24.0 ng/ml; range 7.9 - 29.9 ng/ml). Participants increased their mean 25 (OH)D levels to 43.3 ± 10.6 ng/ml (median: 41.8 ng/ml; range 26.9 - 85.5 ng/ml). The median increase was 18.4 ng/ml ($p=0.0001$). Following supplementation 98.5% of children achieved adequate levels.

Conclusions: Twelve weekly cumulative doses of 10,000 IU of vitamin D3 was sufficient to achieve adequate 25(OH)D levels in nearly all preschool aged children in Guatemala. Future research should focus on achieving adequate 25(OH)D within a shorter time-frame and in additional population settings.

Key words: Vitamin D, 25-hydroxyvitamin D [25(OH)D], preschool, supplementation, Guatemala

PO2393

QUALITY ASSURANCE OF IODISED SALT AT PRODUCTION END IN INDIA AND PARTNERSHIP OF PRIVATE, NGOS AND GOVERNMENT AGENCIES

K. Yadav¹, R. Kumar², M G. Karmarkar², C S. Pandav¹

¹All India Institute of Medical Sciences, New Delhi, India

²Indian Coalition for Control of Iodine Deficiency Disorders, India

Background and objectives: Quality Assurance (QA) of iodine monitoring laboratories at production end is critical for ensuring adequately iodised salt for target population. Partnership of the private stakeholders (salt producers), non-governmental organizations and government agencies can be used to establish QA Systems. The objective was the: operationalisation of partnership model for establishing QA system in laboratories at salt production end in India.

Methods: Regional iodine monitoring laboratory (RIML) of International Council for Control of Iodine Deficiency Disorders (ICCIDD), South Asia Office developed partnerships to establish QA system in laboratories of small, medium and large scale salt producers and Salt Commissioner's Office, Government of India. The QA protocols included induction training of laboratory personnel, monthly exchange of salt samples for internal and external QA, visits by experts to the field laboratories and refresher training and feedback on QA system.

Results: The QA protocols were successfully established

with nineteen medium and large scale salt producers (who contribute to about 30 percent of total iodised salt production in India) in staggered manner from 1997 to 2005. The 600 small scale producers were enrolled for QA program through a network of Micronutrient Initiative established 17 laboratories in year 2007. The 26 laboratories of Salt Commissioner Office, Government of India monitoring production end salt iodisation and analysing more than one lakh samples annually were enrolled for QA with support of Global Alliance for Improved Nutrition (GAIN) in year 2008. The successful operationalisation of the QA system with diverse range of stakeholders contributed to strengthening of monitoring of salt iodisation and led to increase in adequately iodised salt consumption in India to current level of 71%.

Conclusions: Our study documents successful operationalisation of QA system in laboratory of government regulator, small, medium and large scale salt producers in India.

Key words: Salt iodization, quality assurance, partnership

PO2394

SEASONAL DIFFERENCES OF VITAMIN D STATUS IN AUSTRIAN CHILDREN (7–14 YEARS)

D. Wottawa¹, I. Elmadfa¹

¹Department of Nutritional Science, University of Vienna, Vienna, Austria

Background and objectives: Vitamin D plays an important role in bone and mineral homeostasis. The prevalence of vitamin D deficiency is high in different populations across the world. Body content of vitamin D originates from dietary sources and from the endogenous synthesis initiated by ultraviolet (UV) irradiation of the skin. The endogenous, cutaneous production, which is responsible for 80–90 % of vitamin D in the body, depends on sun exposure, season, skin pigmentation, age and health state. This study should show the importance of the synthesis of vitamin D in the skin and the influence of the season.

Methods: Plasma concentrations of vitamin D (25-OH-vitamin D2 and D3) were measured in 387 children using a HPLC.

Results: The mean 25-OH-vitamin D concentration in spring (March, April, May) was 52.6 nmol/l, in summer (June, July, August) 64.8 nmol/l, in fall (September, October, November) 45.5 nmol/l and in winter (December, January, February) 37.9 nmol/l. The plasma concentration was significantly higher in summer than in spring ($p<0.01$), fall ($p<0.001$) and winter ($p<0.001$). During winter 48 % had deficient (<25 nmol/l), 22 % insufficient (25–50 nmol/L) and 30 % sufficient vitamin D status. During summer 9 % had deficient, 20 % insufficient and 71 % sufficient vitamin D status.

Conclusions: The analysis shows that the endogenous, cutaneous production of vitamin D has a dominant impact on plasma vitamin D level. Therefore it is important to pay attention to sufficient sun light exposure, especially in spring, fall and winter.

Key words: Vitamin D deficiency, season, children

DIETARY PATTERNS AND ANTHROPOMETRIC INDICES AMONG IRANIAN WOMEN WITH MAJOR DEPRESSIVE DISORDER

Z. Kargernovin¹, S. Zareiy², B. Rashidkhani³, B. Pourghassem Gargari⁴, F. Ranjbar⁵

¹Department of Community Nutrition, National Nutrition and Food Technology Research Institute, Faculty of Nutrition Sciences and Food Technology Shahid Beheshti University of Medical Sciences, Tehran, Iran

²Department of Community Nutrition, National Nutrition and Food Technology Research Institute, Faculty of Nutrition Sciences and Food Technology Shahid Beheshti University of Medical Sciences, Tehran, Iran

³Department of Community Nutrition, National Nutrition and Food Technology Research Institute, Faculty of Nutrition Sciences and Food Technology Shahid Beheshti University of Medical Sciences, Tehran, Iran

⁴Of Biochemistry and Diet Therapy, Nutritional Research Center, Faculty of Health and Nutrition, Tabriz University of Medical Sciences, Tabriz, Iran

⁵Department of Psychiatry, Faculty of Medicine, Tabriz University of Medical sciences, Tabriz, Iran

Background and objectives: Major depression is a common mental disorder among women. A number of studies have demonstrated the association between some nutrients and food items with depression, but the studies on the association of dietary patterns with depression, especially in the Middle East, are rare. Further, the literature examining the relationship between anthropometric status and depression are inconsistent.

Methods: In this case-control study, 45 women with major depression and 90 patients with no mental disorder participated. We collected dietary intakes by a semi-quantitative food frequency questionnaire, and measured anthropometric indices (weight, height, waist and hip circumferences). Using factor analysis, two major dietary patterns were extracted: Healthy and Unhealthy.

Results: After adjusting for confounders, individuals who gained higher scores in healthy dietary pattern, had 84% lower odds of major depression; while the odds of major depression in participants who gained higher scores in unhealthy dietary pattern showed no significant association. No significant association was found between anthropometric indices and major depression.

Conclusions: These results suggest that the healthy dietary pattern is significantly associated with lower odds of major depression in adult women. Further researches are needed to confirm these findings.

Key words: Nutrition, factor analysis, weight, body mass index.

PO2396

ASSOCIATION BETWEEN DIET AND CVD AND MORTALITY RISK IN FRANCE AND NORTHERN IRELAND: THE PRIME STUDY

N. McCloskey¹, M C. McKinley¹, D. Arveiler², B. Haas², P. Amouyel³, J. Dallongeville³, J. Ferrières⁴, V. Bongard⁴, F. Kee¹, A. Bingham⁵, P. Ducimetière⁵, J V. Woodside¹

¹Centre of Public Health, Queen's University Belfast, Belfast, Northern Ireland

²MONICA, Strasbourg, France

³MONICA, Lille, France

⁴MONICA, Toulouse, France

⁵INSERM U780, Villejuif, France

Background and objectives: Assessment of overall diet via dietary patterns is considered a complementary approach to examining nutrients or foods in isolation, accounting for synergistic effects of food consumption. The aim of this study was to determine the association between a priori and a posteriori dietary patterns and CVD incidence and mortality in the PRIME prospective cohort study, which included 10600 men aged 50-59 years from Belfast, Northern Ireland and France.

Methods: Four a priori and four a posteriori dietary scores were calculated, based on the 16-item FFQ. A priori scores were: Fruit and Vegetable (FV) Variety Score, Overall Variety Score, Adapted Mediterranean Diet Score (aMDS), and Daily FV Score. Two French and two Northern Irish a posteriori dietary patterns were calculated; "Healthy" and "Unhealthy", "Vegetables and Nuts", and "Fruit, Vegetables and Fish" respectively. Cox's Proportional Hazard Regression was used to determine if all-cause mortality or CVD incidence was associated with dietary patterns.

Results: After full adjustment for country, age, and other biological and lifestyle variables four scores were significantly associated with overall mortality. In the highest fourth, showing

greatest adherence to diet pattern: the “Fruit, Vegetable and Fish” Score and “Healthy” Score were associated with reduced overall mortality [HR 0.74 (95% CI: 0.57-0.96), ptrend=0.049 and HR 0.74 (95% CI 0.57-0.96), ptrend=0.02, respectively]. Daily FV Score and MDS were also associated with reduced overall mortality [HR 0.75 (95% CI: 0.57-0.99), ptrend=0.03 and HR 0.73 (95% CI: 0.50-1.05), ptrend=0.049 respectively]. The other scores were not associated with overall mortality. No dietary patterns were associated with CVD incidence after adjustment.

Conclusions: Adherence to healthy dietary patterns is associated with a reduction in all-cause mortality risk of around 25%. Higher intakes of fruit, vegetables and fish may have a protective effect on all-cause mortality in middle-aged men.

Key words: Dietary patterns, CVD, mortality risk

24.10) kg/m², without significant differences between GDS/FAST stages of dementia, except in palliative patients (mean: 19.85; CI95%: 78.3-83.0 kg/m²). Subjects in GDS/FAST stages 5, 6 y 7a-b showed a Fat Mass Index (FMI) Z-Score next to 0 DS, and a Fat Free Mass Index (FFMI) Z-Score next to -1 DS. This results are consistent with a condition of sarcopenic obesity. Both indexes were significantly lower in patients at GDS/FAST $\geq 7c$ (palliative patients).

Conclusion: Analysis of body composition should be included in the Geriatric Nutritional Assessment always. Otherwise it wouldn't be possible to identify sarcopenic obesity conditions, which are highly prevalent in the elderly with these features.

Key words: Nutritional Assessment. Body Composition. Malnutrition. Dementia. Mini Nutritional Assessment.

PO2397

CHANGES IN BODY COMPOSITION IN RELATION TO THE STAGE OF DEMENTIA IN A GROUP OF INSTITUTIONALIZED ELDERLY

M C. Martin¹, B. de Mateo Silleras¹, I. Carreño Enciso¹, S. de la Cruz Marcos¹, I. Domínguez Gutierrez², S. Barrera Ortega², A. Mijan de la Torre¹, M P. Redondo del Rio¹

¹Area de Nutricion y Bromatologia, Departamento de pediatria, Facultad de Medicina, Universidad de Valladolid, Valladolid, España

²Area Psicogeriatrica, Centro Asistencial San Juan de Dios, Palencia, España

Background and objectives: Changes that occur in body composition during ageing can promote malnutrition, but there is no much information about relationship between body composition and the evolutionary stages of dementia. Objective. To assess the nutritional status in a group of institutionalized elderly with dementia, analyzing changes in body composition according to their stage of dementia.

Methods: A cross-sectional study was conducted from May 2010 to September 2010. The study included 63 institutionalized elderly with dementia, at evolutionary stages of 5, 6, and 7 of GDS (Global Deterioration Scale) and FAST (Functional Assessment Staging) scales. We utilized the MNA (Mini Nutritional Assessment), anthropometry, and hand-to-foot bioelectrical impedance (50 kHz) to assess the nutritional status. The results were analyzed by ANOVA or Kruskal-Wallis tests, and the Scheffé's posteriori contrasts. Significance was considered at $p < 0.05$.

Results: The mean age of the patients was 80.6 (95%CI: 78.3-83.0; Range: 51-95) years. The MNA assessment categorized 38.1% of the group as malnourished, 60.3% as at risk, and 1,6% as well nourished. The mean BMI was 23.06 (22.01-

PO2399

TRENDS IN PERCENT CONTRIBUTION OF CARBOHYDRATES, PROTEINS AND FATS TO ENERGY INTAKES AND ITS ASSOCIATION WITH BODY MASS INDEX CATEGORIES

B. Nagalla¹, B. Varanasi¹, A. Nimmathota², M. Indrapal Ishwarji², M R. Kodavanti², L. Avula²

¹Department of Bio-statistics, National Institute of Nutrition, Hyderabad, India

²Department of Community studies, National Institute of Nutrition, Hyderabad, India

Background and Objectives: Prevalence of underweight in rural India is decreasing and overweight /obesity was increasing as per National Nutrition Monitoring Bureau (NNMB) surveys. The aim of the study was to deduce a trend with regard to percent contribution of macronutrients such as carbohydrate, fats and proteins to energy intake and association with BMI among rural population over the periods.

Methods: Data represents adults aged ≥ 18 years from 9 NNMB states of Rural India. A sample of 11884 in 2001, 14384 in 2006 and 25543 in 2012 was covered. BMI has been graded as underweight (<18.5), normal (18.5-25) and overweight/obese (>25). Intakes of carbohydrate, fat and protein were generated from 24 hour recall method. Adjustment for confounders has been made by regression analyses.

Results: Increase in prevalence of obesity from 5.3 to 10.2% in men and 8.9 to 14.5% in women was observed over a period of time. The percentage of energy contribution from carbohydrates, decreased from 77 to 75%, and for protein it was more or less similar at 11%. In case of fat, there was an increase from 12% to 14%. Percent contribution of carbohydrates and proteins to energy in underweight and normal groups was found to be similar and a notable decrease in overweight/obese group

was observed at each time point. In case of fats, the increase was significant ($p < 0.05$) across the groups. Energy intake decreased over a time across BMI groups. Percent contribution of energy from proteins was inversely related to percent contribution from carbohydrates (-0.596 to -0.867) and fats (-.273 to -.683) at different times after adjusting confounders.

Conclusions: A significant decline of energy intake in various BMI categories and increase in prevalence of overweight/obesity over the periods. Percent energy from fat increased significantly across BMI categories.

Key words: Energy intake, body mass index

PO2400

COMPILATION OF A PROVISIONAL TABLE ON COPPER AND MANGANESE CONTENT OF FOODS FOR USE IN EPIDEMIOLOGICAL STUDIES IN SPAIN

A. Farran¹, R. Montserrat¹

¹Department of Nutrition and Food Sciences, Universitat de Barcelona, Barcelona, Spain

Background and objectives: There is a serious lack of data on copper (Cu) and manganese (Mn) content of foods in Spanish food composition tables, and very often these values are borrowed from foreign tables. Consequently, estimations of Cu and Mn dietary intake performed in Spanish population using these limited data are unreliable. The objectives of this study were to collect documented data on copper and manganese content of Spanish foods, and to evaluate the need of further information. With this aim, a search in scientific literature was performed.

Methods: Values and metadata were extracted from selected papers and documents, scrutinized and aggregated. The resulting data matrix was completed with data from European and USDA food composition data bases. This final database was used to estimate the copper and manganese intake of a sample ($n=334$) of adults (18-80 years) from Barcelona from which food consumption data was obtained using a 24 hours food recall.

Results: The food composition database finally compiled contained data for 579 foods. Values coming from published papers and monographs that included chemical analysis of Spanish foods constitute a 34% (Cu) and 21% (Mn) of total values. Values estimated or calculated using recipes were 10% and 11%, respectively. Assumed zero values were 3,4% and 6,7%, respectively. Values coming from foreign databases were 53% and 60%, respectively. Estimation of Cu and Mn intake in the Barcelona adult sample gave values of 1,81 mg/day (SD: 1,116) and 3,01 mg/day (SD: 1,472) respectively.

Conclusions: Cereals, ready-to-serve foods and vegetables accounted for 50% of the Cu intake. In the case of Mn, cereals

and fruits were the main contributors. Reliable data for these food groups are essential to improve the precision and accuracy of dietary intakes for these two minerals.

Key words: Copper, manganese, food composition data bases, nutrient intake

PO2401

ON THE ACCUMULATION PROCESSES OF IRON, MAGNESIUM, MANGANESE AND ZINC DURING THE GROWTH OF HIJIKI PLANTS

M. Katayama¹, M. Kasama¹, Y. Sugawa-Katayama¹

¹Department of Health and Nutrition, Osaka Aoyama University, 2-11-1 Niina, Minoo, Osaka, Japan

Background and objectives: Hijiki (*Sargassum fusiforme*) is a seaweed, rich in nutritionally beneficial minerals, such as iron (Fe), magnesium (Mg), manganese (Mn) and zinc (Zn). The authors intended to know their accumulation processes to explain the variation of their concentrations in different samples. Hijiki plants begin to germinate in autumn, grow until the following summer, and eventually become floating seaweeds.

Methods: Between November and the following April, sample plants were harvested, and cut into 10 cm sections from the underneath filamentous holdfast to the upper apex. All the sections were separated into stalks and leaves. The samples were washed thoroughly and lyophilized. Portions of the respective samples were ashed with a conc H₂SO₄-HNO₃ mixture on a furnace, and the contents of Fe, Mg, Mn and Zn were determined by atomic absorption spectrophotometry.

Results: The concentration of Mg increased with time gradually first in the leaves, then in the stalks, but it eventually reached similar levels in both tissues. The accumulation of Fe occurred during the earlier period and leveled off thereafter. During the early period of growth, the concentrations of Mn and Zn in the respective sections were not correlated to each other. Later, their concentrations, although greatly varied in their levels, showed a correlation between Mn and Zn with a coefficient of 0.9 in both stalks and leaves.

Conclusions: The accumulation rates and patterns of Fe, Mg, Mn and Zn differed from each other, thus the harvest time should be selected accordingly.

Key words: Hijiki(*Sargassum fusiforme*), growth; minerals.

PO2402**SEGMENTAL BIOELECTRICAL IMPEDANCE ANALYSIS IN NORTHERN THAI SECONDARY SCHOOL-AGE STUDENTS (PCCCR)**

P. Leelahagul¹, K. Klawisait², P. Kongpun², J. Udomlap², G. Janthranant², K. Hoiyeephoo²

¹Graduate Program in Nutrition, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand

²Princess Chulabhorn's College Chiangrai, PCCCR, (Regional Science School), Chiangrai, Thailand

Background and objectives: Body composition is an important indicator of health and nutritional status of adolescents. Accurate and reliable anthropometric and body composition measurements require the proper equipment and techniques. Through the use of 8 polar electrodes, the Tanita BC-418 segmental body composition analyzer can show separate body mass for the right arm(RA), left arm(LA), trunk(TR), right leg (RL) and left leg (LL). The objectives were to study the mass compositions of each arm, each leg, and trunk of Northern Thai secondary school-age students according to their sex, age, and body weight status. A cross-sectional study.

Methods: At the beginning of each academic year during 2009 – 2010, 391 Princess Chulabhorn's College Chiangrai students : 61.9% female, 38.1% male, aged 12-17 years were assessed segmental body compositions by use of Tanita BC-418.

Results: From 2009-2010, in total subjects there were significant increases of these following parameters: BMI, total fat mass (FM), RL predicted muscle mass (RLPMM), LLPMM, RAPMM, and TRPPM. No significant differences in fat percentage of each segmental body part during 1 year. Throughout the study, there were no significant differences of BMI between female and male subjects, whereas other segmental body composition parts showed significant differences between sex. Mean fat percentage of each part in female subjects were significantly higher than those in male subjects, opposite results were observed in fat-free mass percentage of each part. One year follow-up, prevalences of obesity classified by excess percentage total body fat were significant decrease, 3.6% to 2.3% of total subjects, whereas fat percentage of each part of such subjects increased, especially percentage TRF, 37.3% to 38.9%.

Conclusions: Thus the segmental body composition analysis gave more accurate and reliable body composition assessment which result in higher effective nutritional therapy.

Key words: segmental, body composition, fat, adolescents

PO2403**INSIGHT IN IODINE INTAKE IN THE NETHERLANDS: ESPECIALLY CHILDREN OF LOWER EDUCATED PARENTS AT RISK OF INADEQUATE IODINE INTAKES**

J. Verkaik-Kloosterman¹, E J M. Buurma-Rethans¹, A L M. Dekkers¹, M C. Ocké¹

¹National Institute for Public Health and The Environment (RIVM), Bilthoven The Netherlands

Background and objectives: Low iodine intake is associated with goiter, impaired brain development and reduced mental functioning. The Netherlands has a long history of iodization of bread salt to correct the low natural iodine content of food. Since 2008, other foods may also be fortified with iodine. To prevent excessive intakes, the iodine levels in bread salt were reduced. This study aims to investigate current levels of iodine intake, its main dietary sources and its association with socio-demographic and lifestyle factors.

Methods: Dutch national food consumption survey 2007-2010 (2 non-consecutive 24-hr recalls; n=3,819, age 7-69 yr.) and Dutch food composition database 2011 were combined to estimate total iodine intakes. Contributions of different sources to total observed iodine intake and food groups to natural iodine intake were calculated. Associations between natural iodine intake or bread intake with socio-demographic and lifestyle factors were examined with multiple linear regression models.

Results: The habitual total iodine intake was adequate for the majority of the population ($\geq 99\%$); With 232 $\mu\text{g}/\text{d}$ for men and 194 $\mu\text{g}/\text{d}$ for women; median intake was 20-25% lower than before 2008. Main source was iodine added by food manufacturers (43%), of which 90% originated from bread. Followed by iodine naturally present in foods (40%), with as main contributors dairy (31%) and non-alcoholic beverages (13%). Iodine intake increased with age. Children of higher educated parents had a 10% higher intake of natural iodine and bread compared to those of lower educated parents.

Conclusions: The iodine intake in the Netherlands is still adequate, but decreased since 2008. Bread is the main source of added iodine. With future successful decrease in (iodized) salt intake, especially children of lower educated parents are at risk of inadequate iodine intakes, due to lower intake of natural iodine and bread.

Key words: Iodine, dietary sources, socio-demographic, salt

PO2404**FOOD CONSUMPTION SURVEY IN A GROUP OF ADULTS AT RISK OF POVERTY IN LITHUANIA: DAILY INTAKE OF ENERGY AND NUTRIENTS**

V. Hendrixson¹, J. Abaravicius¹, Z. Kucinskiene¹, I. Masliukaite¹, J. Andrikonyte¹, S. Deduchova¹, V. Jablonskiene¹, A. Kaminskas¹, R. Stukas¹, A. Barzda^{1,2}, R. Bartkeviciute^{1,2}, R. Levuliene³

¹Faculty of Medicine, Vilnius University, Vilnius, Lithuania

²Center of Health Education and Disease Prevention under the Lithuanian Ministry of Health, Vilnius, Lithuania

³Faculty of Mathematics and Informatics, Vilnius University, Vilnius, Lithuania

Background and objectives: Nutritional research in Lithuania is scarce, especially research targeting people with lower income. This study aimed to provide detailed information on daily intake patterns of nutrients in a group of adults at risk of poverty (ROP) in Vilnius, Lithuania, in 2012 (EU funded FP7 project CHANCE).

Methods: The survey was conducted among adults who were aged 25–65 and at ROP (the recruitment criterion was set at 40–60 % of the national equivalised household median income). The study also recruited affluent participants (AFF) who served as a control group (the income ranged from 1 to 1.67 times the national equivalised household median income). The sample size was 150 respondents (92 ROP and 58 AFF persons). The 24-hour dietary recall method was used during the face-to-face interviews.

Results: High intake of fat (40.57 % of energy for ROP and 37.2 % for AFF people), insufficiency of carbohydrates (45.63 % and 47.0 % of daily intake of energy from carbohydrates for ROP and AFF respondents respectively), and excess of sugars in both groups (comprising 14.63 % of energy for ROP and 17.35 % for AFF people) were found. The insufficiency of some dietary vitamins and minerals was found in both groups, with the highest risk of inadequate intake for biotin, folic acid, pantothenate, vitamin D, calcium, iodine and iron.

Conclusions: There is an actual need for a shift between different sources of energy intake, particularly from fat to carbohydrates. Special attention should be brought to the enhancement of adequate micronutrient intake, particularly in the ROP group.

Key words: Nutrients, intake, risk of poverty

PO2405**COULD LEAFY VEGETABLES BE USEFUL TO FIGHT AGAINST IRON DEFICIENCY IN SUB-SAHARAN AFRICA?**

C. Mouquet-Rivier¹, C. Icard-Vernière¹, F. Olive¹

¹IRD UMR 204 Nutripass « Prévention des Malnutritions et des Pathologies associées, France

Background and objectives: To help fighting against micronutrient deficiencies, the diversification of the diet towards micronutrient-rich foods should be promoted. In sub-Saharan Africa, cereal-based foods are eaten daily, along with a wide variety of sauces. The potential of leafy vegetable (LV) sauces to cover iron requirements of young children from Burkina Faso is assessed.

Methods: Traditional recipes of LV sauces were reformulated to increase their iron contents and decrease their chelating factor contents. Iron bioaccessibility was then estimated by in vitro dialyzability measurements on blanched leaves, on traditional and improved sauces, and on a typical Burkinabe meal constituted of millet tô, a thick paste, plus sauce. Sauce and tô intakes were measured on 12-17 month-old children (n=12) in Ouagadougou.

Results: Sorrel, amaranth and jute leaves were selected for their high iron content. In blanched leaves, iron dialyzability was much lower for jute than for other leaves, what was attributed to their slimy texture. Cooking into sauces decreased iron dialyzability for sorrel and amaranth. Sauce reformulation increased iron dialyzability only for amaranth sauce but finally, for both sorrel and amaranth sauces, the dialyzable iron content was substantially improved. This positive effect was attenuated by blending the sauces with tô. There were no significant differences between intakes of the different sauces by young children [mean intake per meal: 66 ± 11g of sauce; 84 ± 3g of tô], but improved sauces allowed a higher coverage of iron daily requirements compared to the traditional ones.

Conclusions: Improved amaranth and sorrel sauces contained more dialyzable iron than the traditional ones and consequently allowed a higher potential coverage of iron needs. This must be checked through an absorption study in human before promoting their regular consumption.

Key words: Iron; bioaccessibility; leafy vegetables

PO2406**NUTRITIONAL ASSESSMENT OF UNIVERSITY STUDENTS OF UNIVERSITY OF MURCIA (LORCA, SPAIN)**

J.A. Latorre¹, P. Jimeno¹, V. Garcia-Valverde¹, F.J. Garcia-Alonso¹, M. Mariscal-Arcas¹

¹School of Health Science, Department of Food Technology, Nutrition and Food Science, University of Murcia, Lorca-Murcia, Spain

Background and objectives: It is necessary to collect information to planning actions for a positive impact on human nutritional health. The objective of this study was to know the nutritional status of the university students of the University of Murcia.

Methods: Population: 161 students (37 males, 124 females) of the School of Health Science of University of Murcia (Lorca). Mean males corporal composition data were 22,70 yrs (SD: 4.90), 75,32 kg (SD: 9.48), 177,89 cm (SD: 7,34) and BMI of 23.77 kg/m² (SD: 2,27). Mean females corporal composition data were 26.20 yrs (SD: 9.99), 60.20 kg (SD: 11.11), 164.62 cm (SD: 5.40) and BMI of 22.20 kg/m² (SD: 3.83). Data Collection: Semiquantitative questionnaire of food frequency consumption (FFQ). R24 hours (R24h) and lifestyle questions. Interviews were conducted by personnel trained. All study people signed informed consent. This study was approved by the Ethics Committee of the University of Murcia. Software's: Diet source and SPSS 19.0 (SPSS Inc , Chicago, IL, USA).

Results: Mean estimated energy was 2003 kcal/day (SD: 235.01). 47.01% of carbohydrates, 35.15% of lipids and 17% of proteins. Fatty acids were distributed as 16.07% MUFA, 10.32% SFA and 3.91% PUFA.

Conclusions: According to BMI, both males and females classify as normal weight. There is an imbalance of energy profile with a high protein intake at the expense of carbohydrates, so it is recommended to increase the % of energy from carbohydrates. There is an imbalance of lipid profile with a high % of SFA derived PUFAs detrimental, so it is recommended to increase the % of energy from PUFAs.

Key words: Nutritional assessment, diet, university students

PO2407**EVALUATION OF MEDITERRANEAN DIET QUALITY INDEX (KIDMED) IN STUDENTS OF UNIVERSITY OF MURCIA (LORCA) AND THEIR ADHERENCE TO MEDITERRANEAN DIET PATTERN**

P. Jimeno¹, J.A. Latorre¹, V. Garcia-Valverde¹, F.J. Garcia-Alonso¹, M. Mariscal-Arcas¹

¹School of Health Science, Department of Food Technology, Nutrition and Food Science, University of Murcia, Lorca-Murcia, Spain

Background and objectives: The pattern of the Mediterranean diet is considered the best for the countries of southern Europe. Besides the Murcia region produces some of the staples of this pattern as vegetables, fish and olive oil. The objective of this study was to determine the adherence to Mediterranean pattern of students from the University of Murcia using KIDMED diet quality index.

Methods: Population: 161 students (37 males, 124 females) of the School of Health Science of University of Murcia(Lorca). Mean males corporal composition data were 22,70 yrs (SD: 4,90), 75,32 kg (SD: 9.48), 177,89 cm (SD: 7.34) and BMI of 23.77 kg/m² (SD: 2.27). Mean females corporal composition data were 26,20 yrs (SD: 9.99), 60,20 kg (SD: 11.11), 164.62 cm (SD: 5.40) and BMI of 22.20 kg/m² (SD: 3.83). Semiquantitative questionnaire of food frequency consumption (FFQ) and lifestyle questions. Comparison of the data with the Mediterranean pattern by KIDMED(Trichopoulou 1995, Serra 2004, Tur 2005, Mariscal-Arcas 2007). Interviews were conducted by personnel trained. All study people signed informed consent. This study was approved by the Ethics Committee of the University of Murcia. Software: SPSS 19.0 (SPSS Inc,Chicago,IL,USA).

Results: The KIDMED index classification was 'good' in 27.5% of the population, 'average' in 61.8% and 'poor' in 10.8%. Males showed a mean index of 6.2 (SD: 2.2), females showed a mean index of 5.9 (SD: 2.3) with no significant difference between gender.

Conclusions: The nutritional behaviour of the present population of university students is similar to that found in others KIDMED studies (Mariscal-Arcas 2007). Adherence to the Mediterranean Diet pattern of students from School of Health Science (University of Murcia,Lorca) is decreasing, spite of being health science students.

Key words: Mediterranean diet, KIDMED, diet quality index

PO2408**CHANGES IN BODY COMPOSITION IN ONCOLOGY PATIENTS AFTER ABDOMINAL SURGERY***E. Peklaj¹, D. Mlakar-Mastnak¹*¹Institute of Oncology Ljubljana, Clinical Nutrition Unit, Ljubljana, Slovenia

Background and objectives: Rationale body composition after surgery is usually altered and total body protein during the two postoperative weeks is diminished. The aim of the study was to compare pre-operative (PR-OP) with post-operative (PO-OP) changes in body composition, phase angle (PA) and illness marker (IM) in oncology patients undergoing major abdominal surgery using bioelectrical impedance analysis (BIA).

Methods: 85 patients with colon cancer (61 % men, 24 % women) were included in the study in year 2012. According to an established PR-OP clinical pathway all patients received enteral or in case of severe malnutrition parenteral nutrition support. Patients' nutritional status was assessed two times, PR-OP in the month before surgery and in the second PO-OP week. At both visits BIA was performed and venous C-reactive protein (CRP) was measured.

Results: Average involuntary weight loss in last 6 months PR-OP was $6.7\% \pm 6.5$ PR-OP average weight was 79.6 ± 14.1 kg, average PO-OP weight was 80.2 ± 13.2 kg ($p=0.137$). PO-OP there was some dry lean mass (DLM) gain from 12.5 ± 4.7 kg to 12.7 ± 5.5 kg ($p=0.077$) and an increase in fat free mass index (FFMI) from 12.5 ± 4.7 kg/m² to 12.7 ± 4.5 kg/m² ($p=0.215$). The changes in total body water (TBW), extracellular water (ECW) and intracellular water (ICW) weren't statistically relevant, but TBW, ECW and ICW compared to reference value were decreased ($p=0.000$). PO-OP illness marker (IM) increased from 0.815 ± 0.044 to 0.828 ± 0.036 ($p=0.004$) and PA decreased from $5.2 \pm 1.6^\circ$ to $4.8 \pm 1.1^\circ$ ($p=0.009$). PO-OP CRP increased from 15 ± 31 mg/l to 54 ± 35 mg/l ($p=0.000$).

Conclusions: With early PR-OP nutrition intervention patients were able to maintain or increase their DLM and FFMI, although PO-OP acute phase protein response occurred (increased CRP), PA diminished and IM rose.

Key words: Body composition, oncology patients, abdominal surgery

PO2409**A RELIABLE METHOD OF EVALUATING NUTRITIONAL INTAKE OF MALE MINeworkERS RESIDING IN MINE ACCOMMODATION ON A PLATINUM MINE (SOUTH AFRICA)***M. Marais¹, E. Bredenhann², S. Kassier³*¹Division of Human Nutrition, Stellenbosch University, Tygerberg, Western Cape, South Africa²Consultant dietitian, Mining Industry, North West Province, South Africa³Discipline of Dietetics and Human Nutrition, University of KwaZulu-Natal, Pietermaritzburg, KwaZulu-Natal, South Africa

Background and objectives: The Mining Charter stated that measures must be established for improving nutrition of mineworkers yet no nutritional indicators are defined. The aim was to develop of a simple, cost effective method to monitor food and nutritional intake of mineworkers.

Methods: A cross-sectional, observational study with an analytical component was conducted over five days (including one weekend day) on male mineworkers ($n=700$) that primarily perform underground tasks and reside in mining accommodation. Census sampling was used to recruit study participants. Food inventory data was recorded as food quantities used for food preparation. The yield of the prepared food and expected meal participation was used to calculate mean intake according to the household record method. Meal as well as food item participation was recorded while production and plate wastage was determined to assess actual food intake (individual data). Food and nutritional intake between group and individual data was compared.

Results: The study recorded a 96% meal participation measured against the planned participation figures with 74% participating in all menu items. Plate wastage represents 9% of the food served. A t-distribution test showed that the values for selected nutrients fell within the 95% confidence interval demonstrating that the planned values were within those values observed during the study. The following equation can be adopted to calculate food intake: Food consumed/ mineworker = $\{(\text{Raw issue} \times \text{cooking/preparation factor}) \times \text{participation factor}\} - (\text{edible} + \text{inedible wastage})$.

Conclusions: Household data can be used as a tool to monitor average individual food and nutritional intake of mineworkers if identified indicators are considered. This tool can be adapted to be used in industrial catering units to monitor food and nutritional intake, which will enable identification of food or nutrient deficiencies and timeous implementation of intervention strategies.

Key words: Mineworkers, nutritional intake, food wastage

PO2411**A SCREENING TOOL FOR EARLY DETECTION OF MALNUTRITION IN INDIVIDUALS WITH INTELLECTUAL DISABILITY IN A PSYCHIATRIC HOSPITAL (SOUTH AFRICA)***M. Marais¹, M. Nel², S. Potgieter¹*¹Division of Human Nutrition, Stellenbosch University, Tygerberg, Western Cape, South Africa²Nutrition Department, Carletonville Hospital, Carletonville, Gauteng, South Africa

Background and objectives: Early detection and diagnosis of malnutrition is essential in individuals with intellectual disability (ID), considering the risk factors, prevalence of malnutrition and feeding problems. Objectives were to determine the degree of malnutrition, which degree of ID was more prone to malnutrition, to investigate different risk factors for malnutrition, and to adapt a screening tool for easier identification of malnutrition.

Methods: A descriptive, cross-sectional study, with an analytical component, was conducted. Prevalence of malnutrition was determined by taking anthropometric measurements of all adults with ID who complied with the inclusion criteria. These results combined with other possible factors such as medication and co-morbidities were used to adapt an existing malnutrition screening tool.

Results: Anthropometric measurements of 244 individuals with ID indicated that 38,1% (n=93) was at risk of or undernourished and 10,0% (n=24) was at risk of or over nourished. Men were more prone to be or become undernourished (48,0%, n=73). Individuals with mild ID were more likely to become obese (19,4%, n=6), while individuals with profound ID were more prone to being underweight (57,1%, n=8). A significant difference was found between increased waist circumference (WC) and the severity of ID [Pearson Chi-square test (p=0,00)]. Other risk factors that influence nutritional status in this population included hypertension (13,0%, n=32), epilepsy (46,0%, n=112), and polypharmacy (71,7%, n=175). An existing screening tool was adapted by addition of prevalent factors (WC, epilepsy and medications) as well as through adaptation of the scoring system. The adapted screening tool was more sensitive than the original tool in identifying individuals who were at risk of malnutrition, or who were already malnourished in this study population.

Conclusions: This research can help health care professionals to be more aware of the interaction between the severity of ID and malnutrition.

Key words: Intellectual disability, screening tool, malnutrition

PO2412**ABSENCE OF GEOGRAPHIC-SETTING CONTRASTS IN BODY COMPOSITION ACROSS STUNTED AND LOW-STATURE GUATEMALAN PRESCHOOLERS OFFERED COMMON DIETARY FARE***M J. Soto-Méndez¹, N W. Solomons¹, K. Schümann², A. Gil³*¹Center for Studies of Sensory Impairment, Aging and Metabolism -CESSIAM-, Guatemala²Molecular Nutrition Unit, ZIEL, Research Center for Nutrition and Food Science, Technische Universität München, Germany³Department of Biochemistry and Molecular Biology II, University of Granada, Granada, Spain

Background and objectives: Guatemala has the highest rate of stunting in the hemisphere, and a recent CeSSIAM experience documented comparable degrees of short-stature in both an urban and rural setting among preschool children offered largely similar dietary fare. We sought to explore in more detail the nature of any body-proportion differences that might exist.

Methods: Heights and weights were measured and birthdates obtained in 20 participating preschoolers (aged 2-7 years) at one urban government-supported day-care center in Quetzaltenango in the Western Highlands (U1), 24 in a second urban center (U2), and 43 in a rural center (RC). At all locations, two meals and two snacks from a common 40-day rotating menu were offered daily over 8-week periods over the 10-month annual operation. Data were evaluated using Z-scores and other references to the WHO growth curves (2008) for this age band.

Results: Respective prevalence of stunting (<-2SD HAZ) were: 35%; 63%; and 81%. Analyses then focused exclusively on U2 vs RC. Respective M/F ratios were 1.40 and 0.87, and median ages, 50 and 49 months. Median WHZ were, respectively, -0.16 and -0.07, with median statures of 95 and 92 cm. The only suggestion of intergroup indicator variance was with the WAZ, showing "underweight" in 17% of U2 and 37% of RC. Nevertheless, BMIs averaged 15.6±1.1 and 15.8±1.1 kg/m² in the respective sites (p=0.54). BMIs beyond the 75th percentile, adjusted for age and sex, constituted 21% in U2 and 28% in RC; respective rates below the 25th percentile were 12% and 9%.

Conclusions: Two groups of urban and rural Guatemalan-highland preschoolers had comparable and elevated rates of stunting, common to the region. Detailed comparison of measurements and adjusted indicators failed to uncover any differences reflected at the level of body composition.

Key words: Children, stunting, Guatemala

PO2413**THE INFLUENCE OF VITAMIN A STATUS ON IRON-DEFICIENCY ANAEMIA IN ANAEMIC ADOLESCENT SCHOOLGIRLS IN MYANMAR**

M K. Htet^{1,2,3}, U. Fahmida¹, D. Dillon⁴, A. Akib⁴, B. Uto-mo⁵, D. Thurnham⁶

¹South East Asian Ministers of Education Organization, Regional Center for Food and Nutrition, University of Indonesia, Indonesia

²Department of Health, Ministry of Health, Myanmar, Indonesia

³Research Institute Trisakti University, Indonesia

⁴Faculty of Medicine, University of Indonesia, Indonesia

⁵Faculty of Public Health, University of Indonesia, Indonesia

⁶Northern Ireland Centre for Food and Health, School of Biomedical Science, University of Ulster, Coleraine, UK

Background and objective: Recent studies showed anemia is a major nutritional problem among adolescent schoolgirls in the Ayeyarwady Division of Myanmar however there is a lack of information available to explain the high prevalence. The study was conducted to investigate reasons for high prevalence of anaemia. In addition, we explored the role of vitamin A in contributing iron deficiency anaemia among the girls.

Methods: We screened for anemia (haemoglobin (Hb) < 120 g/L) among 1269 subjects. All the anaemic subjects (n= 391) were further assessed for their iron, vitamin A and sub-clinical inflammation status. Iron and vitamin A status were compared between iron deficient and non-deficient groups as well as between those girls with and without inflammation (Student 't' tests). Logistic regression was done to determine whether vitamin A status and SCI were the risk factors for iron deficiency. The differences in iron status among tertiles of vitamin A were assessed with ANOVA.

Results: One third of the anaemia (30.4%) was due to iron deficiency (IDA). Low vitamin A status (serum retinol < 1.05 µmol/L) was 31.5%. Iron and vitamin A status were significantly different between the IDA and non-IDA groups and also based on their inflammation status. Logistic regression showed low vitamin A status was a significant predictor for being iron deficient (OR [95%CI] were 1.9 [1.09-3.13] and 2.3 [1.32-4.02] in the middle (1.056-1.298) and low (≤ 1.056 µmol/L) vitamin A tertiles respectively). ANOVA showed better iron status was associated with higher concentration of serum retinol but only in those with IDA.

Conclusions: Iron deficiency is not the main cause of anaemia among the girls. The role of other micronutrients should be taken into account in addressing the problem of anaemia.

Key words: Anemia, iron deficiency, vitamin A, Myanmar

PO2414**INTRODUCING INFANT AND YOUNG CHILD FEEDING INDICATORS INTO NATIONAL NUTRITION SURVEILLANCE SYSTEMS- LESSONS FROM VIETNAM**

N. Hajeebhoy¹, P H. Nguyen², D T. Tran³, T D. Le³, M. de Onis⁴

¹FHI 360, Hanoi, Vietnam

²International Food Policy Research Institute (IFPRI), Hanoi, Vietnam

³National Institute of Nutrition, Hanoi, Vietnam

⁴Department of Nutrition for Health and Development, WHO, Geneva, Switzerland

Background and objectives: A comprehensive set of infant and young child feeding (IYCF) indicators exists but is not widely used hampering collection of comparable data on IYCF practices. Vietnam incorporated the WHO-IYCF indicators into the National Nutrition Surveillance system (NNSS) since 2010. We describe the process and lessons learned.

Methods: The Vietnam NNSS was established in the 1980s. While anthropometric indicators based on international standards were shared with stakeholders in a timely and systematic manner, data on IYCF did not enjoy this level of rigor and dissemination. In 2009, Alive and Thrive and UNICEF supported the National Institute of Nutrition to incorporate the WHO-IYCF indicators into the NNSS. The process included a review of the existing tool, preparation of an additional questionnaire that was piloted in 10 provinces, revision of the tool based on the pilot experience, and nationwide roll-out of the revised tool.

Results: The current surveillance tool comprises a four-page questionnaire that enables collection and generation of valid comprehensive data on nutrition and IYCF. The tool has the flexibility to generate data on other relevant activities (e.g mass media interventions, food security) as the last page is adapted yearly on request from planners. Data from 2010 are available in attractive provincial profiles and a national report with maps illustrating IYCF practices across Vietnam. Importantly, the data have been used in the development of provincial plans for nutrition, policy advocacy (e.g. maternity leave legislation, advertisement law) and monitoring of trends.

Conclusions: Adoption of the WHO-IYCF indicators was a successful experience. Strategic timing, buy-in from stakeholders and capacity building at all levels was critical to ensure high quality and use of data. Further revisions to the existing surveillance system (e.g sampling methodology) will be important to ensure validity and reliability of indicators.

Key words: Infant feeding practices, child nutrition, surveillance, Vietnam

PO2415**INTERACTION OF PARASITE PREVALENCE AND LINEAR GROWTH IN PRESCHOOL CHILDREN ATTENDING DAY-CARE CENTERS IN THE WESTERN HIGHLANDS OF GUATEMALA?**

J. Alvey¹, M J. Soto-Méndez¹, M E. Romero-Abal¹, N W. Solomons¹, K. Schümann², A. Gil³

¹Center For Studies of Sensory Impairment, Aging and Metabolism -CESSIAM-, Guatemala

²Molecular Nutrition Unit, ZIEL, Research Center for Nutrition and Food Science, Technische Universität München, Germany

³Department of Biochemistry and Molecular Biology II, University of Granada, Granada, Spain

Background and objectives: Infections, including gastrointestinal infections, can negatively affect growth. As Guatemala has the highest rate of stunting in Latin America, we aimed to determine rates of stunting and parasitic infection among children attending government-sponsored day-care centers and receiving a common diet from a pre-established, rotating menu, subsidized by the Secretariat of Beneficial Works of the First Lady of Guatemala (SOSEP).

Methods: Fecal samples were collected and heights measured in 85 preschoolers (aged 2-7 years) at three participating SOSEP centers in Quetzaltenango, a province in the Western Highlands of Guatemala. Two fecal samples were collected from 7th-8th week, respectively, of the 8-week rotating-menu from 20 children at one urban center (U1), 24 in a second urban center (U2), and 41 in a rural center (RC). Fecal samples were analyzed at local laboratory for protozoal cysts and helminthic ova. Anthropometric data were evaluated using HAZ-scores (WHO, 2008).

Results: The prevalence of stunting (<-2SD HAZ) in the day-care centers was respectively: 35%; 63%; and 81%. Eight different parasite species, including *Ascaris lumbricoides* and *Hymenolepis nana* (worm), and *Entamoeba histolytica*, *Entamoeba coli*, *Endolimax nana*, *Blastocystis hominis*, *Chilomastix mesnili* and *Giardia intestinalis* (protozoa), were observed in single or multi-organism infections. In the RC, only 20 (49%) were found to have fecal parasites, whereas frequencies were 11 (55%) in U1 and 20 (83%) in U2. In RC and U1, with their balance of parasitized and non-parasitized subjects, we used Chi-square to explore for stunted vs. parasitized interactions. We found no evidence of interaction ($p=0.13$ and $p=0.28$, respectively).

Conclusions: A wide range of elevated stunting frequencies were found across geographical settings in the Western Highlands, somewhat matching parasite infection in almost half or more, but without any significant mutual association.

Key words: children, stunting, parasites, Guatemala

PO2416**ASSOCIATION OF A POTENTIAL BIOMARKER OF INTESTINAL GIARDIAL-INFESTATION INTENSITY AND GROWTH AMONG INFECTED PRESCHOOLERS IN THE WESTERN HIGHLANDS OF GUATEMALA**

J. Alvey¹, M J. Soto-Méndez¹, N W. Solomons¹, K. Schümann², A. Gil³

¹Center For Studies of Sensory Impairment, Aging and Metabolism -CESSIAM-, Guatemala

²Molecular Nutrition Unit, ZIEL, Research Center for Nutrition and Food Science, Technische Universität München, Germany

³Department of Biochemistry and Molecular Biology II, University of Granada, Granada, Spain

Background and objectives: Guatemala has the highest rate of under-five stunting in the hemisphere, and the contributing factors are considered to go beyond dietary deficiencies to environmental exposures that produce immunological or oxidative stress. Infection with the protozoa, *Giardia intestinalis*, has been documented by CeSSIAM to be pervasive in day-care centers in Guatemala. We sought to explore any association of body-composition with prevalence or intensity of *Giardia* infection.

Methods: Heights and weights were measured and birth-dates obtained in 20 participants (3-7 years) at one urban government-supported day-care center in Quetzaltenango in the Western Highlands (U1), 24 in a second urban center (U2), and 43 in a rural center (RC). At all locations, two meals and two snacks from a common 40-day rotating menu were offered daily over 8-week periods. Data were evaluated using Z-scores derived from the WHO growth curves (2008). Faecal samples were twice collected and assessed by an ELISA method (ProSpecT[®], Lenexa, KS, USA). For positive samples, the absorbance values were regarded as a scaling-proxy for the faecal intensity of the protozoal organisms, using the higher of the two samples.

Results: Global ($n=87$) rates of stunting (<-2SD HAZ), underweight (<-2SD WAZ) and wasting (<-2SD WHZ) were, respectively: 66%; 23%; and 2%. 2x2 contingency-table analyses, based on positive or negative stool *Giardia* versus above or below median Z-score values, were across indices. The respective probability values for Chi-square were: HAZ ($p=0.48$); WAZ ($p=0.04$); and WHZ ($p=0.20$). The respective Spearman correlation coefficients for the association of Z-score values and faecal absorbance levels among *Giardia*-positive children ($n=48$), were HAZ ($r=-0.28$, $p=0.05$); WAZ ($r=-0.28$, $p=0.05$); and WHZ ($r=-0.08$, $p=0.59$).

Conclusions: Both *Giardia* prevalence and *Giardia* intensity (gauged by absorbance scaling-proxy) were negatively associated with specific growth variables.

Key words: *Giardia intestinalis*, stunting, preschoolers, Guatemala

PO2417**RELATIONSHIP OF RBC MEMBRANE OMEGA-3 AND OMEGA-6 FATTY ACIDS TO INFLAMMATORY BIOMARKERS IN A GUATEMALAN POPULATION ON THE PACIFIC COAST**

R. Campos¹, M J. Soto-Méndez¹, M E. Romero-Abal¹, C. Martínez², E. Bailey³, Jr. N. Salem³, K. Kraemer⁴, N W. Solomons¹

¹Center For Studies of Sensory Impairment, Aging and Metabolism -CESSIAM-, Guatemala

²Instituto de Nutrición de Centro América y Panamá -INCAP-, Guatemala

³DSM Nutritional Lipids, USA

⁴Sight and Life, Switzerland

Background and objectives: Studies suggest that polyunsaturated fatty acids (PUFA) modulate inflammation. Omega-6 PUFA are generally considered as pro-inflammatory, with omega-3 PUFA as generally anti-inflammatory. Literature describes competitive interactions where omega-3 mitigate pro-inflammatory effects of omega-6 fatty acids. Having observed relatively low total omega-3 PUFA contribution to total RBC membrane fatty acid profiles in coastal Guatemalans, we sought to describe the association of these PUFAs with inflammatory biomarkers measured concurrently in our sample.

Methods: 271 blood samples were collected from 148 women and 123 schoolchildren. The red cell sediment was BHT-protected and stored at -80°C pending the RBC fatty acid assays (expressed in weight-percentage {wt%}), including calculation of total omega-6 and omega-3 PUFA. We measured C-reactive protein (CPR) and alpha-1-glycoprotein (AGP) in the supernatant plasma.

Results: 20% of the women and 14% of the schoolchildren had elevation of one or another of the inflammatory biomarkers. With respect to PUFA status, total omega-6 values constituted 37.0 ± 1.3 wt% in women and 37.3 ± 1.4 wt% in schoolchildren, whereas the corresponding contribution for total omega-3 were 5.3 ± 0.6 wt% and 5.5 ± 0.6 wt%, respectively. In the remaining population without elevated inflammatory indicators, omega-6 contributions were 37.0 ± 1.5 wt% and 37.4 ± 1.1 wt% in the respective subsamples, with omega-3 values of $5.5\% \pm 0.8$ and $5.3\% \pm 0.6$, respectively. no differences existed between the wt% of interest across inflamed and non-inflamed subjects by subgroup by Student t-test for either class of PUFA. Refined ANOVA analyses also failed to detect difference comparing the non-inflamed subjects to each subgroup with specific biomarker elevations, alone or combined.

Conclusions: Not unexpectedly, observed relationships between the principal classes of omega PUFA provide no indications of any role in protection from inflammation as it occurs in our sample.

Key words: Omega-6, omega-3, inflammation, Guatemala

PO2418**PROTEIN-ENERGY AND MINERAL NUTRITIONAL STATUS OF SOLDIERS SERVING IN THE CAVALRY SQUADRON OF THE POLISH ARMED FORCES REPRESENTATIVE BATTALION**

J. Bertrandt¹, A. Klos¹, B. Bertrandt²

¹Military Institute of Hygiene and Epidemiology, Warsaw, Poland

²Military Researching and Deployment Center For Food Sevcies, Warsaw, Poland

Background and objectives: Cavalry Squadron is a sub-unit of the Representative Battalion of the Polish Army, which soldiers participate in all official state, military, religious and patriotic ceremonies during the year. The aim of the work was to assess the protein-energy and mineral nutritional status of soldiers serving in the Cavalry Squadron.

Methods: Total of 25 soldiers, men aged 26.5 ± 4.0 years underwent the examination. Measurements of the following parameters: body height, weight, arm circumference and thickness of 4 selected skin folds: on biceps, triceps, under scapula and over iliac were carried out among examined soldiers. Values of body weight and height were the basis for calculation of the Body Mass Index (BMI). Assessment of the bone mineral density was carried out by the densitometric method on a non-prevailing upper limb forearm bone, using the EXA 3000 apparatus. Bone calcification was evaluated based on the T-score value.

Results: The average height and body mass of examined soldiers amounted to 179.8 ± 5.9 cm and 80.4 ± 12.3 kg respectively. The arm circumference of the subjects amounted to 32.0 ± 3.1 cm. Average BMI was 24.9 ± 3.2 kg/m². Overweight was found among 36% of men and one person was obese. The skin folds thickness was as follows: on biceps - 2.54 ± 0.45 mm, on triceps - 2.82 ± 0.46 mm, under scapula - 15.3 ± 6.43 mm and over iliac - 23.79 ± 10.2 mm. Calculated total fat content amounted to 16.7 ± 4.4 kg, while lean body mass was 66.6 ± 7.8 kg.

Conclusions: The T-score value characteristic of osteopenia was found among 20.8% of examined men while 4.2% of subjects indicated values characteristic of osteoporosis.

Key words: Military service, nutritional status, obesity, osteoporosis

PO2419**CAN MOBILE PHONES BE USED TO ROUTINELY MONITOR NUTRITION INDICATORS? EXPERIENCE FROM LIBERIA**

A. Guyon¹, A. Bock², L. Buback³

¹Research & Training Inc., Arlington, USA

²John Snow Inc., Monrovia, Liberia

³John Snow Inc, Arlington, USA

Background and objectives: In Liberia, malnutrition is a major public health problem due to inadequate access to food and nutrients and sub-optimal care of mothers and children, with under-five children stunting rate at 39%. Also, according to the 2007 Liberia Demographic and Health Survey (LDHS), 29% of children are exclusively breastfed for the first 6 months, and only 13% of children 6-23 months received minimum acceptable diet (MAD). Most of internationally recognized nutrition indicators typically require data collection through resource-intensive household surveys.

Methods: The Essential Nutrition Actions (ENA) framework was applied by maximizing contacts through multiple program opportunities within existing health systems and community care groups to promote and provide support for key nutrition actions to be taken at crucial contact points in the life cycle. In order to strengthen the frequency and efficiency of tracking progress, an electronic monitoring system was designed to collect information using smart phones. At strategic points, trained staff conduct interviews with pregnant and lactating women and mothers with children under two, using the LDHS "24 hours recall." Data, collected by a mobile phone application, is sent to a cloud-based database, where it is analyzed and made available to managers on a quarterly basis.

Results: Results indicate that exclusive breastfeeding, iron folic acid supplementation, and maternal diet have all improved. The information also allows the project to respond quickly by targeting practices that show little improvement, for example reemphasizing the importance of dietary diversity to improve MAD for children 6-23 months. Conclusions. The use of mobile-based collection combined with an adapted methodology makes nutritional information traditionally available only from household surveys obtainable and compatible for better program management. This innovation represents a breakthrough in allowing nutrition programs to access routine data to measure key nutrition interventions outcomes.

Key words: Smart phones, monitoring, nutrition, Liberia

PO2420**INFLUENCE OF DIET AND BLOOD LOSS ON THE IRON STATUS OF AUSTRALIAN PREMENOPAUSAL WOMEN**

K. Lim¹, A. Booth¹, E. Szymlek-Gay¹, C. Nowson¹, L. Riddell¹

¹Centre for Physical Activity and Nutrition Research, School of Exercise and Nutrition Sciences, Deakin University, Burwood, Victoria, Australia

Background and objectives: The combined influence of blood loss and iron intake on iron status remains unclear in premenopausal women. The purpose of this study is to investigate whether blood losses (excluding blood donations) and iron intake affect the iron stores of women of childbearing age.

Methods: A total of 150 premenopausal women (who have not donated blood in the past 12 months) will be recruited from Melbourne, Australia. Participants will be asked to complete a validated questionnaire quantifying menstrual losses and history of nosebleeds, complete a food frequency questionnaire estimating dietary and supplemental iron intake, and provide a fasting venous blood sample analysed for serum ferritin, haemoglobin, and ultrasensitive C-reactive protein (CRP). Multivariate linear regression will be used to assess relationships between ferritin, as an indicator of iron stores, and blood loss and iron intake.

Results: In preliminary analysis of 58 participants (mean age 29.7 (SD 9.3) years), three women had elevated CRP (>10 mg/L) and were excluded. Median ferritin was 36 (IQR 23-60) µg/L and mean haemoglobin was 135.5 (SD 8.4) g/L. Eleven percent of women had low ferritin (<15 µg/L); no women were anaemic (haemoglobin<120 g/L). Linear regression with log-transformed ferritin indicated that total iron intake $r=-0.0004$, $p=0.98$, menstrual losses ($r=-0.012$, $p=0.10$), and nosebleeds ($r=0.458$, $p=0.16$) were not associated with iron stores. There were also no associations with ferritin when iron from meat/fish/poultry and supplement use were entered in the regression model in place of total iron intake (iron from meat $r=0.040$, $p=0.36$; supplement use $r=0.462$, $p=0.07$; menstrual losses $r=-0.011$, $p=0.11$; nosebleeds $r=0.444$, $p=0.16$).

Conclusions: Iron intake and blood loss did not predict iron status in premenopausal women. Potentially, genetic factors, such as expression of the hormone hepcidin, have more influence than intake and blood loss.

Key words: Iron intake, serum ferritin, blood loss, women

PO2421**ROLE OF NUTRITIONISTS/DIETITIANS FOR SELF-CARE TO PREVENTION OF CHRONIC DISEASES**

S. Nopchinda¹, S. Taechagnam², C. Pachotikarn²

¹Research Center, Ramathibodi Hospital, Mahidol University, Bangkok, Thailand

²Institute of Nutrition, Mahidol University, Bangkok, Thailand

Background and objectives: Thailand today is the second most aged country in Southeast Asia (next to Singapore). Over 10 % of the population is now over 60. The proportion of older persons in total population will increase to 14 % in 2015, 19.8% in 2025 and nearly 30% by 2050. However, we still do not have a good caring system for our senior citizen. These people need good healthcare, both in term of medical treatment and nutritional support. Both dietitians and nutritionists have a major role in this regard, otherwise these people will suffer from many kinds of diseases such as infections, autoimmune diseases, CNS abnormalities and even cancer. This research was to determine the prevalence of risk factors for chronic diseases among the dietitians and nutritionists attending the 8th Annual Meeting of the Thai Dietetic Association in 2012.

Methods: The questionnaires were analysed by SPSS programme.

Results: Most of them were female and not smoking. There age were 23-50 years (86%). BMI was over 25 Kg/m²(21.2%); total cholesterol >200 mg/dL was 11.8%; LDLcholesterol >130 mg/dL was 4.8 %; Triglyceride > 150 mg/dL was 4.7 % and must be warned to take good care of themselves.

Conclusions: These nutritionists/dietitians had to control their body weight and reduce high fat intake including increased exercise.

Key words: Nutritionist, dietitian, cholesterol

PO2422**IODINE DEFICIENCY DISORDER AND IODIZED SALT CONSUMPTION IN THE PHILIPPINES**

L. Perlas¹, J. Marcos¹, J. Desnacido¹, J. Juguan¹

¹Food and Nutrition Research Institute, Bicutan, Taguig City, Philippines

Background and objectives: In the Philippines, in response to the increasing goiter rates from 3.5% in 1987 to 6.7% in 1993 among Filipinos 7 years and older, an Act for Salt Iodization Nationwide (ASIN Law) was passed in 1995. This paper presents results of surveys on IDD and salt consumption and salt iodine levels through the years.

Methods: Data on UIE and salt iodine levels were taken from the 1998, 2003 and 2008 NNS. UIE was determined using

the acid digestion method of Dunn et al. Presence of iodine in salt was determined using RTK while WYD was used to determine iodine concentration in household salt. All statistical analysis were done using SPSS version 9 and STATA version 7UIE was evaluated using WHO/ICCIDD criteria.

Results: Awareness of iodized salt increased from 67.3% in 1998 to 78.9% in 2008 and consumption of iodized salt based on household salt testing positive to RTK also increased from 24.8% to 81.1% for the same period. Results of WYD indicate that the proportion of households with adequately iodized salt (20-70 ppm), was only 19.5%. On the other hand, median UIE levels among school children increased from 71 ug/L to 132 ug/L also from 1998 to 2008. Results on consumption and median UIE levels were not in accordance with actual consumption since sources of iodine, i.e. processed foods, were not accounted for.

Conclusions: Based on UIE levels among school children, iodine status of Filipinos has shifted from mild deficiency in 1998 to optimal nutrition in 2008. Improvement of iodine status among Filipinos did not conform with the actual consumption of iodine from household salt.

Key words: Iodine deficiency disorder salt consumption

PO2423**FACTORS ASSOCIATED WITH DETERIORATION OF MINI NUTRITIONAL ASSESSMENT-SHORT FORM STATUS OF NURSING HOME RESIDENTS DURING A 2-YEAR PERIOD**

S. Izawa¹, H. Enoki², J. Hasegawa³, T. Hirose⁴, M. Kuzuya³

¹Department of Health and Nutrition, Faculty of Psychological and Physical Science, Aichi Gakuin University, Nisshin, Aichi, Japan

²Department of Sports and Health Sciences, Faculty of Health and Medical Sciences, Aichi Shukutoku University, Nagoya, Aichi, Japan

³Department of Community Healthcare and Geriatrics, Nagoya University Graduate School of Medicine, Nagoya, Aichi, Japan

⁴Department of Comprehensive Community Care Systems, Nagoya University Graduate School of Medicine, Nagoya, Aichi, Japan

Background and objectives: A number of other studies have been conducted to verify the Mini Nutritional Assessment (MNA) or the MNA short form (MNA-SF) as a nutritional assessment/screening tool in various clinical settings or communities. However, there are few longitudinal studies using these tools to analyze which factors affect the incidence of deteriora-

rating nutritional status. We tried to identify the factors associated with deterioration of MNA-SF status of nursing home residents during a 2-year period.

Methods: Participants were 392 people with a mean age of 84.3 in 12 nursing homes in Japan. The factors associated with deterioration in MNA-SF categories during the study period compared to stable/improved MNA-SF categories were identified.

Results: At baseline, 19.9% of the participants were malnourished and 60.2% were at risk of malnutrition, according to the MNA-SF classification. After 2 years, 66.3% participants maintained and 6.1% participants improved their nutritional status according to the MNA-SF classification, while 27.6% showed deterioration in MNA-SF status. Multivariate analysis indicated that basic activities of daily living (basic ADL) impairment, poor chewing ability, and hospitalization during the follow-up period were associated with declining MNA-SF status.

Conclusions: Poor basic ADL status, poor chewing ability and hospitalization during the follow-up period were associated with malnutrition and risk of malnutrition as assessed by MNA-SF of nursing homes residents during a 2-year period.

Key words: The factors associated with deterioration of Mini Nutritional Assessment-Short Form stage, frail elderly, nursing home

PO2424

CORRELATION BETWEEN MACRONUTRIENT INTAKES BASED ON FOOD FREQUENCY QUESTIONNAIRES AND 24-HOUR RECALLS: RESULTS FROM A BREAST CANCER SURVIVORS INTERVENTION STUDY.

N. Travier¹, G. Buckland¹, L. Lujan-Barroso¹, I. Peiró¹, L. Hurtós¹, L. Arribas¹, A. Agudo¹

¹Catalan Institute of Oncology (ICO-IDIBELL), Barcelona, Spain

Background and objectives: The use of food frequency questionnaires (FFQ) to assess dietary intake has been omnipresent in epidemiology for decades, nevertheless, studies based on 24-hour recalls (24HR) or biomarkers have shown discrepancies between these tools. The aim of the present study was to assess the correlation between macronutrient intakes derived from the 136-item validated FFQ used in the Seguimiento Universidad de Navarra (SUN) project and the mean of three 24HRs.

Methods: This analysis was performed on baseline data from 42 women, aged 33 to 70, who participated in a lifestyle intervention designed to induce weight loss in breast cancer survivors. Macronutrient intakes derived from a FFQ and three 24HRs obtained at recruitment were calculated as a function

of energy density (g/day per 2000kcal). Intraclass correlation coefficients (ICC) and deattenuated (corrected for within-person variability) Pearson correlation coefficients (r) were respectively used to assess the reliability of the 24HRs and the magnitude of the correlation between the FFQ and the mean of the 24HRs.

Results: Macronutrient intakes based on FFQ information were on average 65% higher than those obtained from 24HRs. The ICC between 24HRs was rather low and ranged from 0.14 for lipids to 0.22 for proteins. While the deattenuated correlation coefficients for carbohydrates, lipids and proteins showed very high correlations (r ranging from 0.61 to 0.82), the deattenuated correlation coefficient for saturated fat was much lower (r=0.13).

Conclusions: In general, the present study showed high correlation levels between macronutrient intakes obtained from the SUN FFQ and from three 24HRs. Nevertheless, results based on saturated fat intakes need to be interpreted cautiously as the FFQ and the 24HRs showed poor agreement for this macronutrient.

Key words: Dietary assessment, FFQ, 24HR, reliability

PO2425

GROWTH MONITORING AND PROMOTION PRACTICES IN PRIMARY HEALTH CARE FACILITIES IN THE WESTERN CAPE PROVINCE, SOUTH AFRICA

R. Blaauw¹, L M. Du Plessis¹, H E.K. Koornhof¹, M L. Marais¹, D G. Nel², J. Visser¹, M E. Visser¹

¹Division of Human Nutrition, Faculty of Medicine and Health Sciences, Stellenbosch University, Cape Town, South Africa

²Centre for Statistical Consultation, Stellenbosch University, Cape Town, South Africa

Background and objectives: The South African Department of Health incorporated the WHO growth standards into a new screening and monitoring tool (SMT) for young children. This provided an ideal opportunity to adapt the growth monitoring and promotion (GMP) practices in primary health care (PHC) facilities to include a more comprehensive array of measurements. The objectives were to assess the knowledge and practices of health care workers (HCWs) on anthropometric measurements in PHC facilities.

Methods: A proportional stratified sample of 80 PHC facilities was selected. HCWs completed a self-administered questionnaire and their consultations with caregivers of children (0-12months) were observed. Standard weights were used to assess scale accuracy.

Results: Data was collected from 1019 infant-caregiver pairs and 145 HCWs from 69 facilities. Seventy-seven per

cent (112/145) of HCWs received official training on the new SMT and the majority could correctly identify criteria for underweight (71.7%; 99/138), but not for stunting (51.6%; 65/126) or wasting (31.7%; 40/126). The majority (90%; 914/1011) of children were weighed during consultations and weight measurements were correctly plotted (73.8%; 639/866). Head circumference measurements were only performed in 13.8% (11/80) of children. Height and mid-upper arm circumference (MUAC) measurements were performed in 6.5% (22/337) and 10.7% (36/338) of children respectively. Most of the HCWs positioned the measuring tape correctly for a MUAC measurement (78.5%, 106/135), but struggled to interpret the correct cut-off value for classification of malnutrition (43.7%, 60/137). A significant difference was demonstrated between the 5 kg standard weight and weight measurements taken at 68 facilities ($P=0.02$).

Conclusions: Optimal GMP practices should be emphasized at PHC facilities. Attention should not only be focused on performing the measurements, but also on correct documentation and interpretation of findings, as well as appropriate action. Renewed training of HCWs should lead to more accurate and early identification of malnourished children in SA.

Key words: Growth monitoring

PO2426

INNOVATION ON DEVELOPMENT, RELIABILITY AND VALIDITY TEST OF DIGITAL INFANT LENGTH MEASURER WITH SONAR SENSOR PRECISION

A. Syafiq¹, S. Fikawati¹

¹Department of Nutrition, Faculty of Public Health, University of Indonesia, Indonesia

Background and objectives: Length measurement was usually conducted using instrument that was not very accurate, bulky, and impractical. There is a need to develop an instrument to measure length more accurate and more precise to minimize measurement error. This study was aimed at developing digital length measurer employing sonar sensor (P2B2D Version 1.0) by considering accuracy and precision of length measurement, portability, and comfort of infant during measurement. Other aim of the study was to conduct reliability and validity test of the instrument.

Methods: Three sonar sensors were applied to detect if crown of the head, calf, and heel have been positioned properly. Those sensors will activate led light on the digital display panel of the instrument when touched. Thus, measurement could only be made after all lights were on. Intra-method reliability test was conducted through inter-examiner reliability test involving three examiners. Inter-method reliability was tested by comparing result of P2B2D to results of other instru-

ments (wood and mica lengthboards). This study involved 53 infants measured by three examiners. Reliability and validity coefficients were produced using Pearson correlation method. Analyses were also conducted to measure examiner's precision and accuracy and error variability or error margin in anthropometry by calculating Technical Error of Measurement (TEM).

Results: The reliability coefficients of P2B2D calculated by different methods ranged from 0.747 (inter-method reliability against mica length-board using TEM analysis) to 0.966 (inter-method reliability against wood length-board using Pearson correlation analysis). The corresponding validity coefficients were 0.864 and 0.963, respectively.

Conclusions: Those coefficients indicated that P2B2D Version 1.0 reliability and validity could be considered as substantial to excellent. It is recommended to improve this instrument by minimizing possible source of error related to decreasing accuracy due to Doppler effect, for example by experimenting different types of sensor.

Key words: Length measurement, validity, reliability

PO2427

GLUTEN INTAKE IN SPANISH INFANTS AS ASSESSED BY SPECIFIC DEVELOPED FOOD FREQUENCY QUESTIONNAIRES

P. Crespo¹, J. Calvo¹, E. Donat¹, J.M. Adrián², E. Masip¹, C. Ribes-Koninckx¹

¹Pediatric Gastroenterology unit, La Fe University Hospital, Valencia, Spain

²Statistical Institute of Research Foundation, La Fe University Hospital, Valencia, Spain

Background and objectives: To develop adequate tools for the assessment of gluten consumption (FFQ-gluten) in Spanish children aged 7-36 months.

Methods: 2 different FFQ's including all the gluten containing products identified in a preliminary survey were elaborated: one for 7-12-month-old infants and another for children aged between 12-36 months. For validation, the results from the FFQs were compared with results of a 2-day and 7-day food record (DR).

Results: The sample was composed by 342 healthy children. No gluten consumption was referred below the age of 6 months, and at the age of 9 months all of them had introduced gluten in their diet. Eighty-three parents filled in the 2DR and the FFQ, and Forty-five parents filled in the 7DR and the FFQ. The mean gluten consumption between both DR and the FFQs in the two age range groups was compared by a paired t-test. For the first age group there are no significant differences between DR and FFQs (p -value >0.05 in both cases). Results for the second age group reflect significant differences between the FFQs and the

2DR (p-value of 0.007) but not for the 7DR (p-value of 0.47). The Bland-Altman plot, with limits of agreement between 2DR and FFQs and between 7DR and FFQs, reinforces the results obtained by paired t-test.

Conclusions: Reliable and precise information on gluten consumption is crucial to conduct epidemiological studies in the field of coeliac disease and specifically to study the impact of gluten introduction and intake in disease development. Our new gluten-FFQs are the only validated specifically developed questionnaires to determine the amount of gluten consumed by Spanish children. They are easy to use and offer excellent instruments to assess gluten intake for children up to 36 months of age, thus allowing comparison of gluten consumption in different countries.

Key words: Food-frequency-questionnaires, gluten, coeliac.

PO2428

IS THE BMI A GOOD PREDICTOR OF ADIPOSITY IN HEALTHY PEOPLE?

S. de la Cruz¹, B. de Mateo Silleras¹, M A. Camina Martín¹, L. Carreño Enciso¹, P. Redondo del Río¹

¹Department of Nutrition and Bromatology, Faculty of Medicine, University of Valladolid, Valladolid, Spain

Background and objectives: BMI is the mainly used nutritional status indicator, but this is not a body composition index. The aim of this study was to compare different methods to assess the adiposity in a group of healthy subjects.

Methods: Fifty five healthy volunteers (BMI < 25 kg/m², 20-50 y.) participate in this cross-sectional study. BMI, circumferences measurements, and hand-to-food BIA (50 kHz) were employed to assess nutritional status and body composition. We compared three different index to assess adiposity: BMI, waist circumference (WC) and % fat mass (Deurenber's formula, based on BIA). Results are expressed as mean (SD) or n and %.

Results: The mean age of the subjects was 33.4 (8.6) years. The mean BMI showed healthy weight in our sample (22.11 Kg/m²; SD: 1,85). According to the new IDF cut-off points values for WC, only five women are abdominal overweighted. According to SEEDO cut-off points values for % fat mass (FM), 13 men (50%) are overweighted and 5 men (19.2%) are obese, and 6 women (20.7%) are overweighted and 18 women (62.1%) are obese. WC does not classified correctly at 6 (20.7%) and 13 (50%) overweighted women and men, respectively, and at 14 (48.3%) and 5 (19.2%) obese women and men, respectively.

Conclusions: The BMI is not an accurate index to determine adiposity. The use of different specific index for evaluate adi-

posity is mandatory for an adequate assessment of nutritional status, as adiposity is a major risk factor for several diet-related chronic diseases.

Key words: BMI, adiposity, nutritional status, waist circumference, fat mass.

PO2429

IMPLICATION OF THE APICAL SODIUM-DEPENDENT BILE ACID TRANSPORTER IN THE UPTAKE OF FAT-SOLUBLE VITAMINS

A. Goncalves^{1,2}, J. Khoury¹, M. Nowicki¹, A. Dhaussy², A. Huertas², M J. Amiot¹, E. Reboul¹

¹NORT, UMR 1062 INSERM / 1260 INRA / Université d'Aix-Marseille, Marseille, France

²Lesieur, Asnières-sur-Seine, France

Background and objectives: Since 2005, we have demonstrated that the absorption mechanisms of fat-soluble vitamins are more complex than previously assumed. Indeed, intestinal cholesterol transporters have been recognized as involved in vitamin D and E absorption. Our aim is now to identify other possible fat-soluble vitamin transporters. A new promising candidate is the apical sodium-dependant bile acid transporter (ASBT), responsible for bile acid reabsorption, since it represents a potential drug target to reduce plasma cholesterol levels. The objective of this study is thus to determine if ASBT is involved in the intestinal absorption of vitamin A, D, E and K.

Methods: The uptake of vitamins A, D, E and K was measured using differentiated Caco-2 cells grown on filters. Cells were incubated for 1 hour with mixed micelles containing each of the vitamins, with or without an ASBT inhibitor, such as statins (simvastatin and fluvastatin) or thioridazin hydrochloride. **Results:** ASBT expression was previously confirmed in differentiated cell monolayers by qPCR. Statins significantly decreased vitamin D, E, K uptake (up to -38%) but did not affect vitamin A uptake. Thioridazin hydrochloride had a significant similar effect (up to 59% inhibition of vitamin D, E and K uptake). To conclude, the inhibition of ASBT led to a decrease in the uptake of some fat-soluble vitamins.

Conclusion: These data suggest that ASBT is involved in the intestinal transport of vitamin D, E and K, but not in vitamin A transport. Further studies are in progress on transiently transfected cells overexpressing ASBT, mice intestinal explants and in vivo experiments to confirm the results.

Key words: Apical sodium-dependent bile acid transporter, caco-2 TC-7 cells, intestinal absorption, fat-soluble vitamins

PO2430**IMPACT OF NUTRITION EDUCATION PROGRAMME ON NUTRITIONAL STATUS OF CHILDREN AGED 3 TO 5 YEARS IN OF LIMPOPO PROVINCE**

L. Mushaphi¹, A. Dannhauser², C. Walsh², X. Mbhenyane¹

¹Department of Nutrition, University of Venda, South Africa

²Department of Human and Dietetics, University of Free State, South Africa

Background and objectives: Globally, the prevalence of acute malnutrition and micronutrient deficiency is high in young children, especially in developing countries. The objective of the study was to determine the nutritional status of children aged 3 to 5 years at baseline and post intervention.

Methods: A pre-test–post-test control group design was chosen. Data was collected from eight villages (four villages in from each group (experimental (E) and control group (C)). Dietary intake was determined using 24-hour recall. Anthropometric measurements were taken on the same day of interview while blood samples were taken on the following week.

Results: At baseline, 15% (E) to 22.4% (C) of children were stunted baseline. Very few children were underweight in both groups (E = 2.5%; C = 8.2%) at baseline. Only 2.5% of children wasted in the experimental group at baseline. The nutritional status of children did not improve significantly at post intervention in both groups. At baseline, a few children in both groups (E = 38.5%; C = 30.8%) had marginal vitamin A status (100 to 199.9 µg/L), while a few children in the experimental group (E = 7.7%) had vitamin A deficiency (< 100 µg/L). According to the categories for iron status indicators, the number of children that were in the adequate categories for serum iron, serum ferritin, serum transferrin and % transferrin saturation did not change in both groups at post-intervention. The median carbohydrate and protein intake was adequate when compared to EAR/RDA in both groups at pre- and post-intervention. The intake of iron and folate had increased significantly in both groups, while zinc intake increased significantly in the control group.

Conclusions: The nutritional status of children did not significantly changes after intervention in both groups especially weight and height.

Key words: Nutritional status, micronutrient status, children

PO2431**PREVENTING ACUTE MALNUTRITION THROUGH VOLUNTEERS COMMUNITY HEALTH WORKER IN CONAKRY, GUINEA 2008-2011**

M. Sanchez¹, I. Zuza¹

¹Accion Contra El Hambre, Madrid, Spain

Background and objectives: For long time nutrition services at Health Centres (HC) in the Community of Matoto in Conakry were little visited. ACF-E decided to put in place Community Health Worker (CHW) in order to increase screening in the community and to refer all children with acute malnutrition detected to the Health Centres.

Methods: CHW were selected in coordination with community leaders and the chiefs of HC. CHW were trained to search for malnutrition children aged between 6 and 59 months by measuring the middle upper circumference through a MUAC tape and detection of bilateral pitting oedemas. Children identified as acutely malnourished were automatically transferred with a « reference card » to the nearest CS for adequate care. Data was recorded and analysed at monthly basis by the head of project.

Results: Between september 2008 and may 2011, the CHW monitored 305.948 infants. 3.8% of them (10637) were transferred to HCs, and 6.307 were admitted into acute malnutrition programmes. In the last phase of the nutrition program (from Sep 2010 to March 2011), 87% (1029/1189) of children admitted into the Moderate Malnutrition program, and 73% (318/435) of children admitted into Severe Malnutrition program were transferred by the CHW. It shows a great improvement because without the support from the CHW only 13% (160/1189) and 27% (117/435) would have been arrived to the moderate and severe malnutrition programmes respectively.

Conclusions: The established community health agents enrolled in health issues are a key factor in the detection and monitoring of malnutrition, and cooperation with health and community authorities is needed for the sustainability of these activities.

Key words: CHW, screening, MUAC, acute malnutrition

PO2432**IODINE INTAKE IN SCHOOLCHILDREN IN POLAND**

K. Stos¹, B. Krygier¹, A. Glowala¹, M. Jarosz², M. Oltarzewski²

¹Department of Food and Food Supplements, National Food and Nutrition Institute, Warsaw, Poland

²Department of Nutrition and Dietetic with Clinic of Metabolic Diseases and Gastroenterology, National Food and Nutrition Institute, Warsaw, Poland

Background and objectives: Polish territory has been classified as an iodine-deficient area. In 1997 the national programme of obligatory iodisation of household salt was implemented. Household salt should contain 2.3 ± 0.77 mg iodine in 100 g of salt. The aim of the study was to assess iodine content in daily diets of schoolchildren from North and South of Poland

Methods: The study was carried out in 2006, 2008, 2009 and 2010 among 708 boys and girls aged 9-13 years with the use single 24 hour recall. The data on iodine content in food products were based on the National Food Composition Tables. The mean dietary intake of iodine as well as 5th and 95th percentiles (P5, P95) were calculated including iodised salt. The mean intake was compared to the Estimated Average Requirements (EAR), and the P95 intake to the Tolerable Upper Levels (UL).

Results: The mean daily iodine intake in the group of schoolchildren was 104 μg (134% EAR) and ranged from 100 μg (girls) to 108 μg (boys). Household salt was the main source of iodine (67%) in boys and girls diets. The mean iodine content in daily diets excluding the iodised salt ranged from 33 μg (girls) to 36 μg (boys). The P95 intake of iodine ranged from 209 μg in girls to 214 μg in boys and was below the UL.

Conclusions: The average daily iodine intake in studied groups of schoolchildren living in Poland covers 134% of EAR. Household salt is the main source of iodine in daily diets. Model of iodine deficiency prophylaxis based on obligatory iodisation of household salt is effective. However, iodisation of the household salt is still needed in Poland.

Key words: Iodine, intake, iodised salt, schoolchildren

PO2433**SEVENTH NATIONAL NUTRITION SURVEY, PHILIPPINES 2008: ZINC STATUS OF FILIPINOS BY SERUM ZINC LEVEL**

J. Marcos¹, L. Perlas¹, P. Trio¹, J.R. Ulanday¹, R. Cheong¹, J. Desnacido¹, M. Capanzana¹

¹Department of Science and Technology, Food and Nutrition Research Institute, Taguig City, Philippines

Background and objectives: Zinc is an essential nutrient for humans and deficiency in this nutrient is an important and widespread risk to human health. To date, global prevalence remains unknown as zinc status data using serum zinc level are still very limited. This study aims to determine serum zinc levels and magnitude of deficiency among all Filipino age/physiologic groups.

Methods: Serum zinc was determined by atomic absorption spectrometry (AAS) and prevalence and magnitude of zinc deficiency was evaluated using IZiNCG's suggested lower cut-offs and guidelines for public health concern, respectively.

Results: The national estimate of zinc deficiency in the Philippines was 30.0%, with a mean serum zinc level of 84.0 ± 0.5 $\mu\text{g}/\text{dl}$. Zinc deficiency was observed in 21.6% of preschool children, 30.8% in school children, 28.9% in adolescents, 31.0% in adults, 28.4% in elderly, 21.5% in pregnant women and 39.7% in lactating women, with a mean serum zinc level (\pm SE) of 94.5 ± 0.9 $\mu\text{g}/\text{dl}$, 79.9 ± 0.8 $\mu\text{g}/\text{dl}$, 85.2 ± 0.9 $\mu\text{g}/\text{dl}$, 84.2 ± 0.6 $\mu\text{g}/\text{dl}$, 91.4 ± 1.1 $\mu\text{g}/\text{dl}$, 75.1 ± 1.7 $\mu\text{g}/\text{dl}$ and 72.7 ± 1.1 $\mu\text{g}/\text{dl}$, respectively. Zinc deficiency was considered of high magnitude (>20%) in all Filipino population groups. The highest prevalence was noted among lactating women, the extent of deficiency was highest among those in the 1st 6 months of lactation. Males predominantly presented higher deficiency rates than females, except in adults, 20 – 29 and 30 – 39 y-old groups.

Conclusions: Zinc deficiency was generally of significant public health concern (>20%) in the Philippines, both in the national level and in different age/physiologic groups. Lactating women was the most at-risk group to zinc deficiency. Males were generally more at-risk than females. With funding assistance from the World Health Organization (WHO)

Key words: Zinc deficiency, zinc status, IZiNCG

PO2434**IRON BIOAVAILABILITY FROM NUTRITION ENTERAL THERAPY MEASURED IN ADULTS THROUGH SERUM IRON LEVELS**

J E. Dutra-De-Oliveira¹, M V. Junqueira-Morandi¹, J S. Marchini¹, F. Barbosa Jr²

¹Medical School of Ribeirão Preto, Department of Medicine, University São Paulo, São Paulo, Brazil

²Pharmaceutical School of Ribeirão Preto, University São Paulo, São Paulo, Brazil

Background and objectives: It is of importance to measure in clinical nutrition the intestinal absorption of nutrients from food, diets and from formulated enteral therapies. The interaction of nutrients may increase, decrease or block their absorption. The aim was to evaluate the influence of extra iron and vitamin C on the iron absorption from nutritional formulations through serum iron levels measurements.

Methods: Iron absorption from enteral formula containing multiple nutrients was evaluated in 13 healthy adults: Group EN 4 volunteers received oral enteral nutrition formula; Group EN+FeSO₄ - 4 volunteers received the enteral formula plus 120mg of ferrous sulphate (120mg) and Group EN+Vit C 5 volunteers received the enteral formula plus a capsule of vitamin C (60mg). After 8 hours fast, basal (T₀) blood samples were collected: basal (T₀), 1 hour (T₁) and 3 hours (T₂) after oral administration of formulas for analysis of serum iron levels. Iron was determined by inductively coupled plasma mass spectrometry. The results was analyzed with statistic program, applying the Kolmogorov-Smirnov test for normality, variance analyze and Dunnet's test applied to compare the treatment means (p<0.05).

Results: The means of iron absorption of EN Group (T₀=1.15 mg/l, T₁ =0.92mg/l and T₂=1.97mg/l) compared with the other two groups did not differ statistically, the means of EN-VitC Group (T₀=1.52 mg/l, T₁ =1.86mg/l and T₂=2.5 mg/l) was different from EN+FeSO₄ Group(T₀=0.90 mg/l, T₁ =0.72mg/l and T_{3h}=1.10 mg/l) in T₁ and T₂.

Conclusions: The extra ferrous sulfate added of the nutritional formula had a negative effect on iron absorption and Vitamin C had a positive effect on iron absorption from the nutritional formula.

Key words: Iron, nutritional formulation, biological availability

PO2435**IMPACT OF BODY COMPOSITION METHODOLOGY ON THE COMPOSITION OF WEIGHT LOSS AND WEIGHT GAIN**

M. Pourhassan¹, B. Schautz¹, W. Braun¹, C C. Gluer², A. Bosy-Westphal¹, M.J. Müller¹

¹Institute of Human Nutrition and Food Science, Christian-Albrechts University, Schleswig-Holstein, Kiel, Germany

²Clinic for Diagnostic Radiology, University Medical Center, Schleswig-Holstein, Kiel, Germany

Background and objectives: We intended to (i) to compare the composition of weight loss and weight gain using densitometry, deuterium dilution, D₂O, Dual X-ray absorptiometry, DXA, Magnetic resonance imaging, MRI and the 4C model and (ii) to compare regional changes in fat mass (FM), fat free mass (FFM) and skeletal muscle mass as assessed by DXA and MRI.

Methods: 83 study participants aged between 21 and 58 years with a BMI range of 20.2-46.8 kg/m² had been assessed at two different occasions with a mean follow up between 23.5 and 43.5 months. Body weight changes within <3 % were considered as weight stable, a gain or a loss of > 3 % of initial weight was considered as a significant weight change.

Results: There was a considerable bias between the body composition data obtained by the individual methods. When compared with the 4C model, mean bias of D₂O and densitometry was explained by the erroneous assumption of a constant hydration of FFM, thus, changes in FM were underestimated by D₂O but overestimated by densitometry. Because hydration does not normalize after weight loss all 2 component models have a systematic error in weight reduced subjects. The bias between 4C-model and DXA was mainly explained by FM% at baseline whereas FFM hydration contributed to additional 5%. As to the regional changes in body composition, DXA data had a considerable bias and, thus, cannot replace MRI.

Conclusions: To assess changes in body composition associated with weight changes, only the 4C model and MRI can be used with confidence.

Key words: Body composition, weight change, regional body composition, four compartment model

PO2436**EFFECT OF TERMAL PROCESSING ON FAT SOLUBLE VITAMIN CONTENTS IN BLACK SEA SHAD (ALOSA PONTICA)***M. Stancheva¹, D. Dobрева¹, B. Galunska¹*¹Medical University of Varna, Varna, Bulgaria

Background and objectives: Fishes are regarded as important natural food sources of fat soluble vitamins, which are necessary for healthy diet. Temperature processing of fish tissue enhances its taste, inactivates pathogenic microorganisms and increases its shelf life. The fat soluble vitamins (vitamins A, D3 and E) are considered to be especially susceptible to oxidation during heating (cooking) process - steaming, boiling, grilling, baking and frying before consumption. The aim of the present study was to evaluate the effect of steaming (10 min at 90°C) and grilling (7 min on each side) on retinol (vitamin A), cholecalciferol (vitamin D3) and alpha-tocopherol (vitamin E) contents in Shad fillets.

Methods: The sample preparation procedure includes saponification and extraction of fat soluble vitamins with n-hexane. The extract was dried under nitrogen flow and redissolved in methanol. HPLC analysis was performed on ODS2 Hypersil (250 x 4.6, 5µm) column with a mobile phase of methanol:water = 97:3.

Results: The retinol, cholecalciferol and alpha-tocopherol content in fresh fish fillets are 4.4 ± 0.1 µg/100 g, 45.1 ± 1.5 µg/100 g and 1971.0 ± 62.9 µg/100 g, respectively. The amount of vitamin A in steamed fillets decreases significantly (~ 40%), when compared to its content in the raw samples. In contrast vitamin D3 and vitamin E remain almost unchanged. Among three fat soluble vitamins, the grilling process affects significantly only vitamin A (~ 70%) and vitamin E (~ 12%) content.

Conclusions: Black Sea Shad tissue is a good source of vitamin D3 and vitamin E. After steaming and grilling process there were almost no losses in the contents of cholecalciferol and alpha-tocopherol, while retinol was reduced nearly a half.

Key words: *Alosa pontica*, alpha-tocopherol, cholecalciferol, HPLC, retinol

PO2437**FATTY ACID COMPOSITION OF BLACK SEA SHAD (ALOSA PONTICA) UNDER DIFFERENT COOKING PROCESSES***M. Stancheva¹, A. Merdzhanova¹, L. Makedonski¹*¹Medical University of Varna, Varna, Bulgaria

Background and objectives: In Bulgarian cuisine the fish traditionally is steamed or grilled before consumption. Temperature processing of fish tissue enhances its taste, inactiva-

tes pathogenic microorganisms and increases its shelf life. The way of cooking may influence the content of fatty acids in fish tissue. The aim of this study was evaluate the effect of different cooking methods (steaming, grilling) on lipid content and fatty acid profile of edible part of commercially important Black Sea shad (*Alosa pontica*).

Methods: Sample treatment procedure: steaming (over boiling water, 10 min, 90°C) and grilling (7 min, 220°C). Total lipid content in fish tissue was gravimetrically determined after extraction, according to Bligh and Dyer procedure. Fatty acid methyl esters were determined by GC/MS.

Results: The thermal processing of raw fish tissue results in reduction of total lipid content: by 21.28% after steaming and 36.17% after grilling. The steaming tends to increase the saturated fatty acid levels (by 12%), compared to raw samples. In case of grilling there was increase in monounsaturated fatty acids (by 10%). The steaming process, results in significant decrease ($p < 0.001$) in omega-3 (by 18%) and omega-6 (by 16%) fatty acids (FA) levels. After grilling the omega-6 amounts remain almost unchanged, whereas the omega-3 polyunsaturated fatty acids were significantly decrease ($p < 0.001$) by 14%.

Conclusions: The process of steaming affects in higher extent the both omega groups of FA, whereas after grilling only omega-3 FA was changed. In general, the fatty acid composition of Black Sea shad tissue did not reveal great losses in biologically important omega-3 FA after heat treatment. Thus we can conclude that both methods of cooking are suitable for preserving the biological active FA components in Black Sea shad.

Key words: *Alosa pontica*, grilling, omega-3, omega-6, steaming

PO2438**EVALUATION OF HACETTEPE UNIVERSITY DEPARTMENT OF NUTRITION AND DIETETIC FEMALE STUDENTS' EATING ATTITUDES AND HEALTHY LIFESTYLE BEHAVIORS***A. Cakmak¹, F. Tamer¹, N. Ersoy¹, S.B. Alkan¹, G. Ersoy¹*¹Hacettepe University, Health Science Faculty, Nutrition and Dietetics Department, Ankara, Turkey

Background and objectives: This study is planned and applied with the aim of evaluation of Hacettepe University Department of Nutrition and Dietetics female students' eating attitudes and healthy lifestyle behaviours.

Methods: This study has been carried out on 160 volunteer female students who are studying at Hacettepe University Department of Nutrition and Dietetics. A survey sheet including students' demographic socio-cultural characteristics, dietary habits, anthropometric measurements (body weight, height, waist circumference) and 24-hour physical activity record, Ea-

ting Attitudes Test-40 (EAT-40) and Health Promotion Life-Style Profile Scale (HPLP) have been used and research data have been collected by face-to-face application of survey by a researcher. The analyses have been performed with SPSS 19.

Results: The mean of the EAT-40 and HPLP score of the students was 13.6 ± 7.4 , 124.1 ± 16 respectively. The prevalence of abnormal eating behaviours was 2.5% among students and the mean age was 20.5 ± 1.7 years. Students were grouped by some features and compared in terms of their groups in the score averages. EAT-40 scores of students who had a disease, went on diet and dissatisfied with body weight were significantly high ($p < 0.05$). Health responsibility scores of students who had a disease, went on diet, nutrition scores of students who didn't skip main meal, whose BMI evaluated as normal were significantly high ($p < 0.05$).

Conclusions: The prevalence of abnormal eating behaviours among female students of Hacettepe University Department of Nutrition and Dietetic was found low. The mean HPLP score of the students was found higher than results of most researches which carried out on university students in Turkey.

Key words: Eating attitudes, healthy life style behavior

PO2439

NUTRITION SITUATION IN THE OCCUPIED PALESTINIAN TERRITORY: REVIEW AND NUTRITION ASSESSMENT

*E. Rivero*¹

¹Acción Contra El Hambre, Madrid, Spain

Background and objectives: The current crisis that affected the West Bank and Gaza Strip is affecting the health and nutrition status of the population. This assessment aimed to analyse the current state of nutrition in the Occupied Palestinian territory (oPt) and to make recommendations for Action Against Hunger's positioning in the country and potential nutritional interventions.

Methods: This assessment was based on a deep search and analysis of relevant secondary information on a national level that was gathered and analysed before and during field visits to the different oPt areas. Qualitative data gathering was carried out using several different techniques, in order to better understand the nutritional situation in potentially selected areas and the factors/causes related to the nutritional status of children under five years of age and PLW.

Results: Micronutrients deficiency is a concern in oPt contributing to the prevalence of stunting found in the country. Iron deficiency, anaemia and vitamin A deficiency constitute a serious public health problem, despite the fact that the MoH has protocols on management and provides supplements free of charge. However, the non-compliance to current supple-

mentation programmes is a critical concern regarding public health. Vitamin D deficiency is also present in some areas in West Bank and iodine deficiency was also a serious public health problem in the oPt. The lack of awareness and the limited access to healthcare lead to insufficient coverage and no compliance with the micronutrients supplementation.

Conclusions: Nutrition protocols, the follow-up and supervision system all need to be strengthened and changes to providing multiple micronutrients should be considered. An integral strategy to combat and control anaemia and other micronutrients deficiencies was recommended. The main recommendations were: dietary enhancement and diversification, food fortification, vitamin and mineral supplementation and global public health and disease control measures.

Key words: Nutrition, occupied Palestinian territories, assessment

PO2440

FOLATE STATUS OF FILIPINO WOMEN OF CHILDBEARING AGE

*J. Desnacido*¹, *L. Perlas*¹, *R. Cheong*¹, *J. Marcos*¹, *J. R. Ulanday*¹

¹Food and Nutrition Research Institute, Taguig City, Philippines

Background and objectives: Folic acid (FA) is a B-vitamin required for proper cell growth and development of the embryo to ward off major birth defects of the brain and spine, known as neural tube defects (NTD's). FA is required for the production of DNA, which is necessary for the rapid cell growth needed in the development of fetal tissues and organs in early pregnancy. The Philippine Health Statistics (PHS) listed congenital anomalies as the 5th leading cause of infant mortality which included NTD's, spina bifida, and hydrocephalus among others. The objective of the study was to assess the folate status of Filipino women of childbearing age

Methods: A cross-sectional sample of 2119 Filipino women of reproductive age ranging from 15 to 45 years from the 7th National Nutrition Survey (NNS) were included. Serum and red cell folate were analyzed using radioimmunoassay (RIA)

Results: Based on red cell folate (< 175 ng/ml), about 20.9% were folate deficient while based on serum folate (< 3.0 ng/ml), which is a measure of recent intake, the prevalence was 38.7%. On the regional level, the highest prevalence of serum and red cell folate was recorded in National Capital Region with 62.6% and 48% prevalence rates, respectively. On the other hand Northern Mindanao had the lowest prevalence of 10.7% for serum folate, while CAR and Cagayan Region had the lowest prevalence of 1.2% for RBC folate.

Conclusions: The high percentages of subnormal values of serum and red cell folate indicate alarmingly high prevalence of folate deficiencies among Filipino women of childbearing age. The findings strongly suggest the need for awareness and campaign for all women of childbearing age on the importance of taking folic acid every day to reduce the risk of having a pregnancy affected by neural tube defects.

Key words: Folate deficiency, Philippines childbearing age

PO2441

COMPARISON OF THE DESCRIPTION LEVEL OF FOOD CONSUMPTION DATA COLLECTED FROM 24-HOUR DIETARY RECALLS AND A 7-DAY FOOD RECORD

S. Havard¹, C. Dubuisson¹, J.L. Volatier²

¹Dietary Survey Unit, French Agency for food, Environmental and Occupational Health Safety (ANSES), Maisons-Alfort, France

²Office of Scientific Support for Risk Assessment, French Agency for food, Environmental and Occupational Health Safety (ANSES), Maisons-Alfort, France

Background and objectives: As recommended by the European Food Safety Agency, the food consumption data of the next French national dietary survey (INCA3) will be collected using the computerized-assisted 24-hour dietary recall (24-HDR) program EPIC-Soft. To estimate the benefits in terms of food description generated by the change of dietary assessment method from the previous INCA surveys, we compared the level of detail and the quality of dietary data collected from two non-consecutive 24-HDRs using EPIC-Soft and a 7-day food record (7-dFR) in the French part of the European Food Consumption Validation (EFCOVAL) project and the French INCA2 survey respectively.

Methods: The French EFCOVAL study was conducted in Southern France on 113 volunteers aged 45-65 years in 2008. Each food reported during the 24-HDR interviews was described through a system of "facets/descriptors" representing different characteristics of food (eg. preservation method, production method). The INCA2 survey was performed on 2624 adults aged 18-79 years in 2006-2007. The subjects were asked to describe precisely all food and beverages consumed for one week (eg. brandname, preservation method). We assessed the description level of food data collected from both dietary assessment methods and compared when it was possible, the proportion of "undefined" (or missing) data.

Results: Overall, a higher level of detail concerning food description was collected from the 24-HDRs. Compared to

the 7-dFR, additional information on packaging material, skin consumption or cooking method was automatically gathered for relevant foods. Information on some characteristics (eg. fat content, fortification, preservation method) was also more accurately detailed from the 24-HDRs. Nevertheless, overall, the quality of data collected from these both methodologies seemed relatively comparable in terms of proportion of undefined data.

Conclusions: Using 24-HDR interviews with EPIC-Soft in the next INCA3 survey should ensure higher accurate and standardized dietary data collection.

Key words: EPIC-Soft, 24-HDRs, 7-Dfr

PO2442

EFFICACY OF FERROUS GLUCONATE AND FERROUS BISGLYCINATE CHELATE AS FORTIFICANTS IN MAIZE-BASED COMPLEMENTARY FOOD ON IRON STATUS IN CHILDREN 24-59 MONTHS

O. Sinisterra¹, F. Fontes¹, Y. Carrasco¹, E. Pons¹, D. Ulloa¹, L. Lay¹, I. Rios-Castillo^{2,3}, M. Olivares³

¹Department of Nutrition, Direction of Provision of Services of Health, Ministry of Health, Panama

²World Food Programme, Regional Bureau for Latin America and the Caribbean, Panama

³Micronutrient Laboratory, Institute of Nutrition and Food Technology, University of Chile, Chile

Background and objectives: Iron Deficiency (ID) is the most common Micronutrient Deficiency (MND) in the world. Food fortification is an important long-term strategy for addressing MND. The objective of the study was to evaluate the efficacy of two iron fortificants (ferrous gluconate and ferrous bisglycinate chelate) in a maize-based complementary food (Nutricrema®) on iron status in children 24-59 months.

Methods: A prospective, double-blind, cluster-randomized trial conducted in a rural and indigenous area of Panama. The sample was 254 children with age mean 44 ± 10 months (51% male). During a six month period, 36 rural community soup-kitchens were divided into two groups randomly assigned to receive either: Group-A (n=125): 90 g of Nutricrema® with 10 mg of iron as ferrous gluconate; or Group-B (n=129): 90 g of Nutricrema® with 10 mg of iron as ferrous bisglycinate chelate. We measured Hemoglobin (Hb) before and after and ran descriptive and comparative analysis (ANCOVA, Chi2).

Results: Mean \pm SD of Hb before and after in group A was 113 ± 10 and 113 ± 8 g/l, respectively; and in group B was 111 ± 10 and 116 ± 7 g/l, respectively; mean \pm SD of delta-Hb in group A and B was -0.2 ± 10 and 5 ± 10 g/l, respectively (AN-

COVA, treatment effect $p < 0.05$, after adjusting for Hb baseline, sex and age). The prevalence of anemia before and after in group A was 43(34%) and 40(32%), respectively; and in group B was 61(47%) and 25(19%) (Chi2, $p < 0.05$).

Conclusions: We can conclude that a maize-based complementary food, fortified with 10 mg of iron as ferrous bisglycinate chelate is effective to increase hemoglobin concentration and decrease prevalence of anemia among preschool-age children when compared with ferrous gluconate.

Key words: Indigenous population, child, anemia, malnutrition.

PO2443

MICRONUTRIENT STATUS AND INTAKE IN OMNIVORES, VEGETARIANS AND VEGANS IN SWITZERLAND

I. Aeberli¹, R. Schüpbach¹, R. Wegmüller¹, C. Berguerand², M. Bui²

¹Human Nutrition Laboratory, ETH Zurich, Zurich, Switzerland

²Swiss Vitamin Institute, Epalinges, Switzerland

Background and objectives: Following a vegetarian or vegan diet may lead to deficiencies of some micronutrients but information on direct associations in adults living in Switzerland is lacking. The aim of this study was therefore to assess the vitamin and mineral status of vegetarian and vegan adults living in Switzerland.

Methods: Healthy adults between 18 and 50 years consuming an omnivorous ($n=100$), vegetarian ($n=53$) or vegan ($n=53$) diet since at least 1 year were recruited. Weight and height were measured and plasma concentration of the vitamins A, C, E, B1, B2, B6, B12, folic acid, pantothenic acid, niacin, biotin and β -carotene as well as Fe, Mg and Zn was determined. Dietary intake was assessed using 3-day weighed food records and physical activity and lifestyle characteristics by questionnaires.

Results: Omnivores had the lowest intake folic acid, Mg, vitamin C, E and niacin. Vegans reported low intakes of Ca, vitamin D and B12. Despite a similar intake of total energy, BMI was significantly lower in vegans as compared to vegetarians and omnivores. Prevalence of folic acid deficiency was highest in omnivores (58%), while vegetarians showed the highest prevalence of vitamin B6 and niacin deficiency (58% and 34% respectively). Among vegans, 47% were Zn deficient. The prevalence of vitamin B12 deficiency was very low in all groups. Fe status indicators were comparable across the diet groups. More vegans (29%) than vegetarians (6%) and omnivores (3%) reported not to drink any alcohol. The groups did not differ regarding tobacco consumption and physical activity.

Conclusions: Even though the groups differed substantially regarding micronutrient status and intake, deficiency prevalences were similar except for Zn, vitamin C, B6, niacin and folic acid. This indicates that vegetarians and vegans living in Switzerland are well informed and consume a diversified, well-balanced diet.

Key words: Micronutrients, vegetarians, vegans, dietary intake

PO2444

THE USUAL DIET IS CAPABLE OF MAINTAINING THE APPROPRIATE LEVEL OF VITAMINS IN THE NORTH AMERICAN POPULATION?

R. Lima¹, G. Brito¹, W. Conde¹, V. Souza¹

¹Nutrition department, Universidade of Sao Paulo, Sao Paulo, Brasil

Background and objectives: Relationship among food nutrient composition and micronutrients biomarkers is an improbable way to associate serum levels of micronutrients and diet. Establishing dietary patterns by multivariate analysis is best to do that and provide a view of diet as a whole, since they characterize the habitual food intake of individuals. The objective of the study was to estimate association among dietary patterns and serum micronutrients.

Methods: Data comes from NHANES 2005-2006. We used Principal Component Analysis (PCA) to estimate dietary patterns from Food frequency questionnaire (FFQ) data. We retained PCA components with eigenvalues > 1 and chose characterize them by variables with loads $\geq |0.30|$. PCA components were interpreted as dietary patterns and their scores were calculated. To associate dietary patterns with serum levels of micronutrients we performed linear regression. Statistical significance was set at p values < 0.05 . Analysis were done in STATA (version 11).

Results: We identified five dietary patterns characterized as: Pattern 1: milk and milk drinks, cheese, grain mixtures; Pattern 2: eggs and legumes; Pattern 3: eggs, legumes, milk and milk drinks (exclusion of soups/gravies with meat, meat substitutes); Pattern 4: legumes, alcohol (exclusion of meat and non-alcoholic beverages); Pattern 5: fruits and alcoholic beverages (exclusion of soft drinks). All patterns showed a positive association to serum vitamin A. Patterns characterized by legumes and lower consumption of meat were negatively associated to the serum levels of Iron and B vitamins, patterns composed of alcohol were associated negatively to the serum Folic Acid and Vitamin E. Vitamin D is not associated with patterns that showed little variation of food. Beta coefficients of Pattern 1 were similar to all serum micronutrients.

Conclusions: Patterns characterized by larger food diversity were positively and equi-associated with serum micronutrients biomarkers.

Key words: Micronutrients dietary patterns biomarkers

PO2445

VITAMIN D STATUS AMONG FAMILIES IN DENMARK: BASELINE DATA FROM THE VITMAD STUDY

K H. Madsen¹, H. Mejborn¹, I. Tetens¹, E W. Andersen², C. Mølgaard³, R. Andersen¹, L B. Rasmussen¹

¹Division of Nutrition, National Food Institute, Technical University of Denmark, Kongens Lyngby, Denmark

²Department of Applied Mathematics and Computer Science, Technical University of Denmark, Kongens Lyngby, Denmark

³Department of Nutrition, Exercise and Sports, Faculty of Science, University of Copenhagen, Copenhagen, Denmark

Background and objectives: The beneficial effect of vitamin D in bone health is acknowledged and the vitamin has also been associated with several chronic diseases. It is therefore relevant to determine the prevalence of vitamin D insufficiency in different groups, and vitamin D statuses within families have not been studied previously. The objective of the present study was to evaluate serum 25-hydroxyvitamin D (25(OH)D) concentrations among families in Denmark (56 °N) after seasonal UVB peak and to ascertain determining factors.

Methods: Cross-sectional study with 755 children and adults (4–60 y) recruited as families in the VitmaD study. Blood samples were collected in September–October 2010, and vitamin D status was measured as serum 25(OH)D concentration by LC-MS/MS. Vitamin D intake and life style factors were assessed in self-administered questionnaires. Determinants of vitamin D status were identified in a linear mixed model with family as a random variable.

Results: Mean (±SD) serum 25(OH)D concentration was 75 ± 20 nmol/l (range 9–162 nmol/l) and only 10 % had 25(OH)D <50 nmol/l. Determinants of serum 25(OH)D were age (p=0.036), BMI class (p=0.001), multi vitamin use (p=0.033), sun behaviour (p=0.005), outdoor stay (p=0.033), sun vacation (p<0.001), and physical activity (p=0.040). Gender (p=0.692) and vitamin D intake (p=0.238) were not associated to serum 25(OH)D.

Conclusions: The prevalence of vitamin D insufficiency among families in Denmark was low after seasonal UVB peak. Sun vacation was the strongest determinant for vitamin D status at this time of the year.

Key words: Vitamin D status, 25(OH)D, families, UVB peak.

PO2446

GROWTH ATTAINMENT AND HEMATOLOGICAL STATUS OF LOW-INCOME PRESCHOOL CHILDREN OF METROPOLITAN GUATEMALA CITY

J. Casimiro de Almeida¹, A C. MacNott Ramos, M. Olbert, N W. Solomons², K. Schumann¹

¹Hildegard Grunow Foundation, Munich, Germany

²Center for Studies of Sensory Impairment, Aging and Metabolism (CeSSIAM), Guatemala City, Guatemala

³MBR Optical Systems, Wuppertal, Germany

⁵Molecular Nutrition Unit, ZIEL, Research Center for Nutrition and Food Science, Technische Universität München, Freising, Germany

Background and objectives: Young children in the rapid-growth period belong to a high-risk group for iron deficiency anemia (IDA), especially in low-income societies. The growth attainment achieved, however, is also a function of the adverse environmental circumstances and exposures in deprived settings. Guatemala has the highest rate of stunting in the Western Hemisphere. We sought here to quantify growth attainment and anemia in preschool children from low-income communities in metropolitan Guatemala City.

Methods: Anthropometric data, hemoglobin (Hb), ferritin, a marker of iron status, and white blood cell count (WBC) and C-reactive protein (CRP) as inflammatory biomarkers were determined in 175 children (age 18.6 ± 0.9 months; range: 6–47 months). Z-scores for common anthropometric indices were calculated using the WHO growth standard (2006).

Results: The mean weight was 10.1 ± 2.5 kg (median: 9.1 kg; range: 4.3–17.7 kg). The range of weight-for-age (WAZ) Z-scores varied from -3.03 to +1.47. The mean length/height range was 78.2 ± 9.2 cm (median: 72.9 cm; range: 62.5–101.0 cm). Height-for-age (HAZ) Z-scores varied from -3.67 to +1.97. In total, 29 children (16.7%) were stunted (Z-score: <-2.0), 5 of them (2.9%) severely (z-score: <-3.0). The mean Hb was 12.3 ± 1.3 g/dl (median: 11.0 g/dl; range: 8.7–18.6 g/dl), with 27% showing anemia by an altitude-adjusted criterion (<11.7 g/dl). Ferritin ranged from 1.4 to 115.4 ng/ml, with 27.5% having ferritin <20 ng/ml, after adjusting for elevated CRP in 8 children with values >5 mg/l. WBC exceeded 10,800/mm³ in 68 (40.7%) of subjects.

Conclusions: The rate of stunting in this low-income urban sample from the nation's capital city is less than a third of the national, under-five average of 54% from the 2009–10 survey. Our anemia rate is 19 percentage-points below the 46% average for urban children in the same survey.

Key words: Anthropometry, young children, low-income, Guatemala

PO2447**DEVELOPMENT AND COMPARISON OF AN ONLINE DIETARY ASSESSMENT TOOL FOR USE IN THE FOOD4ME STUDY**

H. Forster¹, R. Fallaize², C. Gallagher¹, C. O'Donovan¹, C. Woolhead¹, M. Walsh¹, A L. Macready², J. Lovegrove², L. Brennan¹, E R. Gibney¹, M.J. Gibney¹

¹Institute of Food and Health, University College Dublin, Ireland

²Hugh Sinclair Unit of Human Nutrition and Institute for Cardiovascular and Metabolic Research, University of Reading, UK

Background and objectives: Online dietary assessment tools have the potential to become invaluable methods of assessing dietary intake for personalised nutrition services. The aim of this study was to develop an online food frequency questionnaire (FFQ) for dietary data collection in the Food4me study and compare this with the validated European Prospective Investigation of Cancer (EPIC) paper FFQ.

Methods: The Food4me-FFQ consists of 157 food items and was developed to include standardised colour photographs to quantify portion size for each food item. Subjects completed the FFQ online and for most food items, subjects were requested to choose their usual serving size among seven possibilities. Subjects were recruited in two centres (Dublin and Reading) and each received the Food4me-FFQ and EPIC-FFQ in random order. Participants with more than 4 weeks between completing both FFQ's were excluded from the analyses.

Results: 113 subjects were recruited with a mean age 30 ± 10 years (41% males, 59% females). The Food4me-FFQ estimated significantly higher mean energy intakes than the EPIC-FFQ ($p < 0.0001$). After energy adjustment mean total fat intakes remained significantly different, however, there were no significant differences for protein or carbohydrate intakes between the two methods. Crude unadjusted correlations for macronutrients ranged between 0.43 (% energy from polyunsaturated fatty acids) and 0.72 (% energy carbohydrate). For micronutrients, unadjusted correlation coefficients were lowest for thiamin (0.46) and highest for vitamin C (0.69). Bland and Altman plots indicated good agreement between the two methods for assessing macronutrient intakes.

Conclusions: Results demonstrate that the online Food4me-FFQ has good agreement with the EPIC-FFQ, particularly for macronutrients and many of the key micronutrients. The ability of the Food4me-FFQ to categorise nutrient intakes as low, recommended or high makes it a useful tool for personalised nutrition.

Key words: FFQ, online dietary assessment tool, personalised nutrition

PO2448**STUNTING AND WASTING ASSOCIATED WITH MICRONUTRIENT DEFICIENCIES IN NORTHERN ETHIOPIA**

L. Fernández-de Armas¹, E. Gadisa², L. Sordo³, I. Cruz⁴, J. Moreno⁴, C. Cañavate⁴, A. Aseffa², A. Buño⁵, R. Gómez-Rioja⁵, J M I. Ituarzeta⁵, E. Custodio⁶

¹Escuela Nacional de Sanidad, Instituto de Salud Carlos III, Madrid, Spain

²Armauer Hansen Research Institute, Addis Abeba, Ethiopia

³Centro Nacional de Epidemiología, Instituto de Salud Carlos III, Madrid, Spain

⁴Servicio de Parasitología, Centro Nacional de Microbiología, Instituto de Salud Carlos III, Madrid, Spain

⁵Servicio de Análisis Clínicos, Hospital Universitario La Paz, Madrid, Spain

⁶Centro Nacional de Medicina Tropical, Instituto de Salud Carlos III, Madrid, Spain

Background and objectives: Macro- and micronutrient deficiencies are public health concerns in most developing countries, including Ethiopia. However, there is little information available on micronutrient status of school-aged Ethiopian children. The present study aims to assess copper, zinc, vitamin A and vitamin D deficiencies and evaluate how they relate to nutritional status measured by anthropometry.

Methods: We conducted a cross-sectional study in Libo Kemkem and Fogera districts in Amhara State, Ethiopia. Sampling was carried out by multistage cluster survey. 886 children aged 4 to 15 years were recruited. Anthropometric data, and blood samples from 330 selected children, were collected. Copper and zinc serum concentrations were measured by atomic absorption spectroscopy, serum vitamin A by high-performance-liquid chromatography, and serum vitamin D by immunoassay. Internationally agreed cut off points were used for assessing micronutrient deficiencies. Stunting and thinness were defined as Height-for-Age and Body-Mass-Index-for-Age Z scores < -2 standard deviations (SD) in relation to the WHO 2007 Reference. Descriptive analyses and a stratified analysis by nutritional status were performed.

Results: Stunting prevalence was 40% (354/886) and wasting prevalence 21.4% (190/886). Overall, copper, zinc, vitamin A and vitamin D deficiencies were seen in 1.5% (5/326), 10.1% (31/305), 32.3% (106/330) and 15.4% (46/296) of the children, respectively. Mean zinc serum levels were significantly lower in stunted children compared to non-stunted (91.5 µg/dl, SD 18.5 versus 85.8 µg/dl, SD 17.2), $p = 0.03$. Wasted children had lower vitamin A serum concentration levels than non-wasted children (0.31 µg/ml, SD 0.17 versus 0.27 µg/ml, SD 0.11), $p = 0.014$.

No differences were found in the levels of copper or vitamin D between malnourished and not malnourished children.

Conclusions: Stunting, wasting and vitamin A deficiency should be considered severe public health problems in this area. Stunting is associated with low levels of zinc and wasting with low levels of vitamin A.

Key words: Malnutrition, micronutrients, vitamin A, Ethiopia

PO2449

IMPACT OF DIFFERENT SUGARY BEVERAGES ON THIRST

P. Carvalho¹, M. Sousa², R. Barros¹, P. Padrão^{1,3}, P. Moreira^{1,3,4}, V. Teixeira^{1,4}

¹Faculdade de Ciências da Nutrição e Alimentação, Universidade do Porto, Porto, Portugal

²Centro de Investigação Formação Inovação e Intervenção em Desporto, Faculdade de Desporto, Universidade do Porto, Porto, Portugal

³Instituto de Saúde Pública, Universidade do Porto, Porto, Portugal

⁴Centro de Investigação em Atividade Física Saúde e Lazer Faculdade de Desporto, Universidade do Porto, Porto, Portugal

Background and objectives: To determine the impact of sugary beverages on thirst sensation and in physiological parameters involved in their regulation.

Methods: 32 subjects (15 women), mean age of 22.3 ± 1.97 with BMI between 18.5–25 kg/m², were included in a crossover clinical trial at the same day of 4 consecutive weeks. Standardized breakfast was served and 1 hour after, 330ml of water(W), non-fat milk(NFM), orange juice(OJ) and iced tea(IT) were ingested. The same lunch was served 2h30 after preload. Thirst, desire to drink and mouth dryness were measured at baseline and every 30 minutes until the end of lunch. Glycaemia, plasmatic sodium and osmolality were measured at the beginning and at the end of protocol. Ad libitum water intake at lunch was measured, and a food diary was taken to participants to record all food and fluid intake until 00.00 that day.

Results: A main effect of time ($p < 0.001$) but no effect of beverage ($p > 0.05$) were observed for all motivational ratings. Only in men a main effect of beverage was noticed ($p = 0.01$) with NFM leading to a non-significant increase in thirst sensation face to W ($p = 0.068$) and IT ($p = 0.053$). Water ingestion at lunch showed a main effect of beverage ($p = 0.018$) with NFM tend to higher ingestion face to W ($p = 0.095$) and IT ($p = 0.071$). No changes were observed in osmolality but glycaemia decreased – more pronounced with sugary preloads – and plasmatic

sodium increased ($p < 0.001$). No differences in energy, sugar and sugary beverages intake throughout day were observed between beverages.

Conclusions: Milk revealed a tendency to higher water intake in a subsequent meal and to an increase of thirst sensation in men. Osmolality and sodium did not differ between beverages as well as energy, sugar and sugary beverages intake throughout day.

Key words: Thirst, sugar, milk, orange juice, iced tea

³Instituto de Saúde Pública, Universidade do Porto, Porto, Portugal

⁴Centro de Investigação em Atividade Física Saúde e Lazer Faculdade de Desporto, Universidade do Porto, Porto, Portugal

Background and objectives: Determine the impact of the morning ingestion of sugary and sweetened beverages on energy and fluid intake throughout the day.

Methods: 24 subjects (11 women), mean age of 21.5 ± 2.33 y with BMI between 18.5–25 kg/m², were included in a crossover clinical trial at the same day of 3 consecutive weeks. Standardized breakfast was served and 1 hour after 500 ml of water(W), sugar sweetened pineapple soda(PS; 11% sugar) and sucralose sweetened pineapple diet soda(PDS; 1% sugar) were ingested. The same lunch was served 2h30 after preload. After lunch, a food diary was taken to participants to record all food and fluid intake until 00h00 of that day. Energy and nutritional intake were estimated using an adapted Portuguese version of the nutritional analysis software Food Processor 10.0. Data analysis used a general linear model with repeated measures with beverage as within-subjects factor and sex as the between-subjects factor.

Results: No main effects of beverage ($p > 0.05$) or beverage*sex interactions were observed for total energy, fluid and sugar intake. An interaction beverage*sex ($p = 0.043$) was observed for the amount of sugary beverages ingested and a main effect of beverage ($p = 0.049$) was registered in men, with

PS (637 ml ± 408) leading to a higher but non-significant ingestion of sugary beverages than W (406 ml ± 269, p=0.342) and PDS (343 ml ± 201, p=0.115). A main effect of beverage (p=0.047) and an interaction beverage*sex (p=0.023) was also observed for sugar ingested from sugary beverages with PS (65.2 g ± 45.1) leading to higher sugar intake compared to W (32 g ± 23.9, p=0.165) and PDS (29.2 g ± 27.5, p=0.068).

Conclusions: Morning ingestion of sugary and sweetened beverages leads to similar energy, fluid and total sugar intakes throughout the day. A tendency to a higher intake of sugary beverages throughout the day was observed with sugary soda preload.

Key words: Sugar, beverages, energy intake, morning

⁴Zone Sanitaire Natitingou, Ministère de la Santé, Cotonou, Benin

Background and objectives: Iron biofortification of pearl millet (*Pennisetum glaucum*) is a promising approach to combat iron deficiency in millet consuming communities in developing countries. In this study, the potential of iron-biofortified millet to provide additional bioavailable iron in comparison to regular-iron and post-harvest iron-fortified millet was evaluated by measuring iron absorption from composite meals based on the three millet types.

Methods: Iron absorption from multiple composite meals was measured as erythrocyte incorporation of stable iron isotopes. The study was conducted in 20 Beninese women with marginal iron status (plasma ferritin < 25 µg/l).

Results: Fractional iron absorption from meals based on regular-iron millet (7.5%) did not differ compared to iron-biofortified millet meals (7.5%; p=1.0) resulting in a higher quantity of total iron absorbed from the iron-biofortified millet meals (527 µg vs. 1125 µg; p<0.0001). Fractional iron absorption from post-harvest iron-fortified millet meals (10.4%) was

higher than from regular-iron (P < 0.05) and iron-biofortified millet meals (p<0.01). Total iron absorbed from the post-harvest iron-fortified millet meals (1500 µg) was higher than from the regular-iron (p<0.0001) and iron-biofortified millet meals (p<0.05).

Conclusions: Results indicate that iron-biofortified and post-harvest iron-fortified pearl millets have the potential to provide additional bioavailable iron compared to regular-iron pearl millet and could be effective to combat iron deficiency in millet consuming population.

Key words: Iron biofortification, Iron bioavailability, Iron fortification, pearl millet

PO2452

MICRONUTRIENTS AND PREGNANCY; EFFECT OF SUPPLEMENTATION ON PREGNANCY AND PREGNANCY OUTCOMES: A SYSTEMATIC REVIEW

T. Alemu¹, H. Taddese²

¹Dilla University, Dilla, Ethiopia

²Addis Abeba University, Addis Abeba, Ethiopia

Background and objectives: Every year more than 20 million infants are born with low birth weight worldwide. About 3.6 million infants die during the neonatal period. More than one third of child deaths are thought to be attributable to maternal and child under nutrition. The objectives of the study were to systematically review the effect of supplementing various combinations and types of micronutrients on the course and outcomes of pregnancy.

Methods: Electronic search of Medline, Pub Med, Health Internetwork access to Research Initiative, and Google Scholar databases was conducted. Outcomes of interest were birth weight, low birth weight, small size for gestational age, prenatal mortality and neonatal mortality. After exclusion of irrelevant / incomplete ones, 17 out of 115 articles were considered for the final analysis.

Results: Majority of the articles reviewed favored the supplementation of micronutrients to pregnant mother. Some studies suggested calcium supplementation is associated with a significant protective benefit in the prevention of pre-eclampsia. The remaining articles reviewed, showed significant benefit of multiple micronutrients supplementation during pregnancy in reducing low birth weight, small for gestational age births as compared to the usual iron-folate supplements.

Conclusions: Supplying micronutrients, mainly multiple micronutrients have beneficial effect in reducing the risk of low birth weight and other complications. Further studies at various combination and doses of micronutrient supplements are recommended.

Key words: Micronutrients, pregnancy outcomes, supplementation

PO2453**REVIEW OF THE STATE OF MICRONUTRIENT FORTIFICATION OF WEANING FOODS IN GHANA AND THE WAY FORWARD***R. Pobe¹, W. Plahar¹*¹CSIR-Food Research Institute, Accra, Ghana

Background and objectives: Weaning is a critical period during which the nutritional needs of the young child should not be compromised. International organizations and local researchers have made attempts to improve on the complementary foods fed to infants from 6 months upwards. This paper reviews articles on micronutrient fortification of food in Ghana and proposes a way forward.

Methods: Literature search was done on Google Scholar, Sciencedirect and Agora on publications of weaning food formulations and nutritional intervention studies with micronutrients. Both published articles and on-going work in the CSIR-Food Research Institute were reviewed.

Results: Over the years, Ghana has improved its weaning formulations from traditional cereal-based weaning foods from maize, millet or sorghum which had low energy and protein density and contributed to protein-energy malnutrition, to formulations of complementary foods based on cereal-legume blends. This makes the porridge rich in energy and protein but deficient in important micronutrient such as iron and vitamin A and high in phytate which compromises on nutrient bioavailability. In recognition of this drawback, various attempts have been made to fortify weaning foods with micronutrient powders both at community levels through community based milling and fortification, to household fortification of complementary foods with Sprinkles (SP) powder, crushable Nutritabs (NT) tablets, or energy-dense (108 kcal/d), fat-based Nutributter (NB). However, intervention studies with micronutrients dominate weaning food formulations with micronutrient. Micronutrient powder is very expensive and difficult to sustain in developing countries including Ghana. The proposed strategy is the use of different blends of locally available foods that are rich in specific micronutrients.

Conclusions: Food-based strategies for the solution of micronutrient deficiency problems are more sustainable because of availability and low cost.

Key words: Micronutrients, fortification, weaning, foods, Ghana

PO2454**ANTIOXIDANT ACTIVITIES OF DIFFERENT FRUITS CULTIVATED AND MARKETED IN ANDALUCIA***C. Rodríguez-Pérez^{1,2}, A. Morales-Soto^{1,2}, C. Jiménez-Sánchez^{1,2}, M L. Cádiz-Gurrea^{1,2}, A. Segura-Carretero^{1,2}, A. Fernández-Gutiérrez^{1,2}*¹Department of Analytical Chemistry, Faculty of Sciences, University of Granada, Granada, Spain²Functional Food Research and Development Center, Health Science Technological Park, Granada, Spain

Background and objectives: There is mounting evidence of the health-protective role of the consumption of fruits and vegetables, which are the major contributors to dietary polyphenol intake. Some fruits are considered as natural functional foods because they are the important sources of exogenous antioxidants. In this context, it has been suggested that an intake of a rich antioxidant diet is inversely associated with a risk to develop some pathologies like cardiovascular diseases, cancer as well as aging. Fruit are also one of the largest contributors to total dietary antioxidant capacity, which is considered a dietary quality indicator. The objective of this work is contributing to the improvement of the quality of the food composition tables.

Methods: Fifteen different varieties of fruits cultivated and harvested in different periods of time in the Mediterranean area were fully studied. These fruits included watermelon, mango, medlar, persimmon, pomegranate, sapo melon, cantaluz melon, galia melon, custard apple, quince, red grape, fine lemon, pimarfió lemon, smooth avocado and coarse avocado. Three different assays based on Electron Transfer (ET) and Hydrogen Atom Transfer (HAT) reactions were employed: Trolox Equivalent Antioxidant Capacity (TEAC), Ferric ion Reducing Antioxidant Power (FRAP) and Oxygen Radical Absorbance Capacity (ORAC). Results. The antioxidant activity varies considerably from variety to variety. This variability among the same vegetable can be apparently explained by the influences of location, and harvest season, etc. Lemon, red grape and pomegranate showed the most antioxidant activity while persimmon, quince and melon showed the less antioxidant activity.

Conclusions: A complete set of antioxidant assays was performed in order to do more comprehensive the antioxidant potential of these typical fruits to complete and improve the food composition tables.

Key words: Fruits, antioxidant activity, ORAC, TEAC, FRAP.

PO2455**WATER FROM FLUIDS IS THE MAIN DRIVER OF TOTAL WATER INTAKE IN HEALTHY FRENCH ADULTS***E. Perrier¹, I. Guelinckx¹, A. Klein¹*¹Danone Research, Palaiseau, France

Background and objectives: Various international organizations have set daily reference values for total water intake (TWI), which includes water from beverages (total fluid intake, or TFI) as well as food moisture. To-date, the relative contributions of various beverage categories and food moisture to TWI are not well-described. The objective of this analysis was to determine the relative contribution of TFI and moisture from food to TWI.

Methods: 190 healthy French adults (age: 25-40 years; BMI: 18.5-29.5 kg/m²) completed online food and fluid diaries over three consecutive weekdays. TWI was determined from fluids in 7 categories (plain water, flavored water, milk products, still sweetened beverages, carbonated sweetened beverages, hot drinks, and alcohol), and water from food was determined using a database of food moisture for over 1300 generic foods.

Results: TWI was 2.80 ± 1.30 l/day, with 1.91 ± 1.19 l coming from TFI. TFI explained 91% of the variance in TWI (Pearson's $r=0.95$; $p<0.001$), while water from food was highly variable and only moderately correlated to TWI ($r=0.43$; $p<0.001$). On average, 65% ± 15% of TWI came from fluids. Moreover, linear regression demonstrated that the percentage of TWI obtained from fluids increased as a function of TWI ($p<0.001$), with the lowest deciles of TWI obtaining a lower percentage of water from fluid than the highest deciles.

Conclusions: Water from fluids is the main driver of total water intake, with plain water as the major contributor to water from fluids. Furthermore, water from food moisture is highly variable between individuals and varies as a function of total water intake. This suggests that individuals who consume high fluid volumes also consume more foods that are high in moisture content, such as fruits and vegetables.

Key words: Total water intake, fluids, healthy adult French

PO2456**VALIDATION OF A FOOD FREQUENCY AND PHYSICAL ACTIVITY QUESTIONNAIRE IN KILIMANJARO REGION, TANZANIA***A. Fongar¹, C. Ludwig¹, M E. Swai², M B. Krawinkel¹*¹Institute of International Nutrition, Justus-Liebig-University Giessen, Hesse, Germany²Kilimanjaro Christian Medical Centre, Moshi, Kilimanjaro Region, Tanzania

Background and objectives: Dietary and physical assessment tools depict useful methods to capture lifestyle changes and can provide ideas for prevention of lifestyle-related diseases. Such tools should be validated for each country and region to be culturally sensitive. The current study aimed to validate a semi-quantitative food frequency questionnaire (FFQ) and physical activity questionnaire (PAQ) for the Kilimanjaro Region, Tanzania.

Methods: A cross-sectional study was performed in two urban and three rural areas in Kilimanjaro Region, 2012. The study included 117 participants between the age of 18 and 65 with no diagnosed diseases. A semi-quantitative FFQ, which assessed the food intake of the previous month, was validated against two 24h dietary recalls (DR). A PAQ, which assessed the activity of the previous week, was validated against two 24h physical activity recalls (PA). Data were analyzed with Nutri-survey and SPSS. Paired sample t-test was used for validation and Krippendorff's alpha to test data compliance.

Results: A total of 98 FFQ and 77 PAQ were included into the validation. Mean energy intake was 2864.47 kcal (± 931.01) based on FFQ. Mean PAL, based on PAQ was 1.8 (± 0.34). According to paired sample t-test, mean nutrient intakes significantly differed between FFQ and 24h dietary recall. Same was true for mean physical activity PAQ and 24h physical activity recall. Krippendorff's alpha comparison showed no agreement in both tools (FFQ and 24h DR $r=-0.13$; PAL and 24h PA $r=0.2$).

Conclusions: Reported dietary intake and physical activity differed between the assessment tools. Overestimation seemed to be frequent in both FFQ and PAQ, whereas underreporting was in the 24hr-recalls. Further adjustments and possible simplification of the FFQ and PAQ have to be done for improving the assessment tools which are used to monitor dietary intake and lifestyle patterns.

PO2457**BODY COMPOSITION IN RELATION TO MICRONUTRIENT STATUS IN CAMBODIAN INFANTS: THE WINFOOD PROJECT**

C. Chamnan¹, J.K.H. Skau², N. Roos², M.A. Dijkhuizen², J. Berger³, H. Friis², K.F. Michaelsen², F.T. Wieringa³

¹Dept of Fisheries Post-harvest Technologies and Quality Control (DFPTQ), Fisheries Administration, Ministry of Agriculture Forestry and Fisheries, Phnom Penh, Cambodia

²Dept of Human Nutrition, Faculty of Life Science, Copenhagen University, Copenhagen, Denmark

³Institut de Recherche Pour le Développement (IRD), Paris, France

Background and objectives: Malnutrition in infancy and early childhood is responsible for over 3 million child deaths yearly. Moreover, malnutrition in early childhood predisposes to a higher risk for non-communicable diseases such as obesity and cardio-vascular diseases later in life through metabolic alterations which are still not fully understood. Rapid growth during the first 2 years of life and fat mass at 2 yrs of age are strong predictors for later obesity. This paper investigates body composition in early childhood in relation to micronutrient status.

Methods: Anthropometry (weight, height, MUAC, skinfolds), body composition (deuterium dilution) and micronutrient status (iron, zinc, vitamin A) were measured at 6 mo and 15 mo of age. The infants were participating in the WinFood project which studied the effectiveness of fortified complementary foods (FCF) in improving health and growth.

Results: From 269 Cambodian infants data on body composition and micronutrient status were available for both time points. Lean body mass increased with 1.96 ± 0.59 kg, whereas the percentage of body fat decreased from 21.7% to 14.9% over the study period ($p < 0.001$). At 6 and 15 mo of age, body fat was strongly correlated to ponderal growth (WHZ, $p < 0.01$) but not to length growth (HAZ) or gender. Vitamin A and zinc status were not related to fat mass. Iron status at 6 and 15 months of age significantly correlated with body composition, with infants with no iron stores at endpoint having a higher fat mass (14.0% vs 15.5%, $p = 0.02$).

Conclusions: Iron status, but not vitamin A or zinc status, was related to body composition in Cambodian infants. FCF aimed at improving micronutrient status in early childhood may have long term health benefits.

Key words: Body composition, iron, infants, obesity

PO2458**NUTRITIONAL STATUS IN CHILDREN WITH SICKLE CELL DISEASE**

P. Mataratzis^{1,2}, D. Lino^{1,2}, F. Bezerra^{1,2}, M. Citelli^{1,2}, A. Freitas^{1,2}, K. Souza^{1,2}, R. Capone³, D. Capone³, J. Valle^{1,2}, C. Cople-Rodrigues^{1,2}

¹Institute of Nutrition, State University of Rio de Janeiro, Rio de Janeiro, Brazil

²Reference Center on Nutritional Surveillance of Hemoglobinopathies, Nutrition in Hematology clinic, Pedro Ernesto's Hospital, Rio de Janeiro, Brazil

³Radiology setor, Pedro Ernesto's Hospital, Rio de Janeiro, Brazil

Background and objective: Sickle cell disease (SCD) is the world's most common hereditary hemoglobinopathy. Poor nutritional status and delayed skeletal development have been recognized in children with SCD. The goal was to evaluate the associations between nutritional status, hematological parameters and bone age.

Methods: Children between 24-70 months old with SCD-SS from Rio de Janeiro participated in the study. Age and gender-specific z scores for BMI, weight, height and weight/height and adequacy for mid-upper arm circumference (MUAC), triceps skinfold and mid arm muscle circumference (MAMC) were determined in all subjects. Blood samples were obtained to determine hemoglobin, hematocrit, reticulocyte count, lactate dehydrogenase (LDH), hemosedimentation velocity (HSV) and serum calcium and magnesium. Bone age and relative bone age (difference between bone age and chronological age) were also assessed.

Results: 74 children were evaluated (60.8% male). Mean chronological age and relative bone age were 46.6 ± 14.9 and -8.9 ± 10.7 months, respectively. 9.5% were at risk of overweight, 4.1% presented overweight and 2.7% were undernourished. 9.5% presented low height-for-age and 1.4% had very low height-for-age. Stunting was greater than weight deficit: 4.1% presented low weight-for-age. BMI-for-age and weight-for-age z scores were correlated with hematocrit ($r > 0.29$, $p < 0.038$). Weight-for-age was also associated with hemoglobin ($r = 0.31$, $p < 0.022$) and inversely associated with HSV ($r = -0.34$, $p < 0.018$). MUAC and MAMC's adequacy were associated with hemoglobin ($r > 0.34$, $p < 0.014$) and hematocrit ($r > 0.35$, $p < 0.010$). Relative bone age was associated with hemoglobin ($r = 0.38$, $p < 0.011$), serum calcium ($r = 0.37$, $p < 0.029$), BMI-for-age ($r = 0.31$, $p < 0.028$), weight-for-age ($r = 0.42$, $p < 0.002$), height-for-age ($r = 0.31$, $p < 0.029$) and weight-for-height ($r = 0.33$, $p < 0.037$) z scores. Bone age was inversely associated with serum magnesium ($r = -0.40$, $p < 0.010$). No correlations between LDH and nutritional status were observed.

Conclusions: Our results indicate transition in nutritional status in children with SCD-SS with presence of overweight.

Poor nutritional status was associated with worse hematological parameters that may contribute to higher delayed bone age.

Key words: Sickle-cell-disease, growth, children

PO2459

NUTRITIONAL STATUS AND DIETARY INTAKE IN CHILDREN WITH SICKLE CELL DISEASE

P. Mataratzis^{1,2}, D. Lino^{1,2}, F. Bezerra^{1,2}, M. Citelli^{1,2}, A. Freitas^{1,2}, K. Souza^{1,2}, J. Valle^{1,2}, C. Cople-Rodrigues^{1,2}

¹Institute of Nutrition, State University of Rio de Janeiro, Rio de Janeiro, Brazil

²Reference Center on Nutritional Surveillance of Hemoglobinopathies, Nutrition in Hematology Clinic, Pedro Ernesto's Hospital, Rio de Janeiro, Brazil

Background and objectives: Children with sickle cell disease (SCD) homozygous type (SS) usually present poor nutritional status due decreased appetite, inadequate dietary intake and increased energy expenditure. The goal was to evaluate the associations between nutritional status and dietary intake.

Methods: Children (2-5y) with SCD-SS from Rio de Janeiro participated in the study. Age and gender-specific Z-scores for body mass index (BMI), weight, height and weight/height and adequacy for mid-upper arm circumference (MUAC), triceps skinfold and mid arm muscle circumference (MAMC) were determined. Dietary intake was evaluated by two 24-hour recall to assess estimated energy intake (EEI), carbohydrate, protein, total fat, calcium, phosphorus and magnesium.

Results: 40 children were evaluated (65% male), 15% were at risk of overweight and 2.5% presented overweight. Height-for-age and weight-for-age Z-scores were low in 12.5% and 2.5%, respectively. Mean EEI was 1399 ± 414 kcal/d provided from carbohydrate (58%), protein (15%) and total fat (27%). Mean total fat intake was low in 72% children under 3y, according to DRI. EEI was associated with adequacies of MUAC ($r=0.41$, $p<0.008$) and MAMC ($r=0.38$, $p<0.017$), weight-for-age ($r=0.40$, $p<0.011$) and height-for-age ($r=0.32$, $p<0.046$) Z-scores. Carbohydrate, protein and total fat intake were correlated with adequacies of MUAC ($r>0.34$, $p<0.032$) and MAMC ($r>0.33$, $p<0.038$). Carbohydrate intake was also associated with weight-for-age ($r=0.41$, $p<0.009$) and height-for-age ($r=0.37$, $p<0.020$) Z-scores. Protein intake was associated with weight-for-age ($r=0.40$, $p<0.011$) and weight-for-height ($r=0.41$, $p<0.024$) Z-scores. Total fat intake was associated with triceps skinfold's adequacy ($r=0.37$, $p<0.019$). Calcium intake was below DRI in 78% of the children. Calcium and phosphorus intake were correlated with adequacies of MUAC ($r>0.44$, $p<0.005$) and MAMC ($r>0.54$, $p<0.000$), BMI-for-age ($r>0.49$, $p<0.001$), weight-for-age ($r>0.60$, $p<0.000$), height-for-age ($r>0.42$, $p<0.005$) and weight-for-height ($r>0.51$, $p<0.004$) Z-scores.

Conclusions: Adequate dietary intake was associated with better nutritional status. Nutritional following is necessary to improve nutritional status in SCD-SS children.

Key words: Sickle-cell-disease, dietary intake, nutritional status

PO2460

NUTRITIONAL STATUS AND BODY COMPOSITION OF UGANDAN WOMEN LIVING WITH HIV/AIDS

H. Namusoke¹, A. Hills², N. Byrne²

¹Mwanamugimu Nutrition Unit, National Referral, Mulago Hospital, Kampala, Uganda

²Queensland University of Technology, Kelvin Grove Campus, Brisbane, Australia

Background and objectives: Antiretroviral therapy (ART) increases chances of survival, with concerns regarding fat redistribution; linked to protease inhibitors (PIs), in addition to older age and being female. We assessed physical characteristics using a comprehensive anthropometric protocol and to predict body composition.

Methods: 211 (88 ART-naïve), 15-49 year-old women, through cross-sectional approach, with information on disease and medication status.

Results: 34.1 ± 7.65 years old, 4.63 ± 4.78 years with infection and 2.8 ± 1.9 years on ARVs, 8.1% received PIs and 26% of them had ever changed regimen. Mean nutritional status and predicted percent body fat values was acceptable; different for participants receiving ARVs and the HIV-infected ART-naïve. Fat (%) estimated by BMI and skinfold thickness and BIA was similar to that by deuterium oxide dilution technique. Using BMI, 7.1% of patients were underweight (<18.5 kg/m²) and 46.4% were overweight/obese (≥ 25.0 kg/m²). Waist circumference characterized 40% as centrally obese. Deuterium dilution technique showed no between-group difference in body composition ($p=0.045$), with a very small effect (0.021). Older age ($r=0.430$, $se=0.089$, $p=0.000$), time spent receiving ARVs ($r=0.972$, $se=0.089$, $p=0.006$), time with the infection ($r=0.551$, $se=0.089$, $p=0.000$) and receiving ARVs ($r=2.940$, $se=1.441$, $p=0.043$) were independently associated with %fat. Older age was the greatest single predictor of body fat. BMI gave better information than weight alone could; in that, mean %fat per unit BMI ($n=192$) was significantly higher in patients receiving treatment (1.11 ± 0.31) vs. the exposed group (0.99 ± 0.38 , $p=0.025$).

Conclusions: There were more overweight/obese participants than in the general Ugandan population, associated with ART status.

Key words: Nutritional status, body composition, Ugandan women, HIV/AIDS

PO2461**PLASMA SOLUBLE TRANSFERRIN RECEPTOR CONCENTRATION IS ASSOCIATED WITH ABSOLUTE RETICULOCYTE COUNTS, INFLAMMATION, AND MALARIA INFECTION IN URBAN CAMEROONIAN CHILDREN**

R. Engle-Stone¹, A. Ndjebayi², M. Nankap², A. Tarini², M. Gimou³, J. Erhardt⁴, K. Brown¹

¹Program in International and Community Nutrition, University of California, Davis, CA, USA

²Helen Keller International, Yaoundé, Cameroon

³Centre Pasteur, Yaoundé, Cameroon

⁴VitA-Iron Lab, Willstaett, Germany

Background and objectives: Several studies have reported greater prevalence of iron deficiency (ID) as measured by plasma soluble transferrin receptor (pTfR) compared with ferritin (pF), even after correcting for inflammation. Because pTfR can reflect both rate of erythropoiesis and tissue iron demand, we examined factors associated with pTfR in a malaria-endemic setting.

Methods: In a representative, cluster survey of 306 pairs of children 12-59 mo and women 15-49 y in urban Cameroon, we collected blood samples to assess absolute reticulocyte counts (ARC, an indicator of erythropoiesis), hemoglobin and malaria infection, and plasma indicators of iron status (pF and pTfR) and inflammation (C-reactive protein and α 1-acid glycoprotein).

Results: Anemia and inflammation were present in 48% and 46% of children and 44% and 22% of women, respectively; 8% of children and 5% of women had malaria. The apparent prevalence of ID ranged from 9.1% (inflammation-adjusted pF <12 μ g/l) to 24.7% (pTfR >8.3 mg/l) among children and from 8.7% (pTfR >8.3 mg/l) to 16.8% (adjusted pF <15 μ g/l) among women. Children with elevated pTfR (n=71) had greater ARC (median: 50.0 vs 36.0 cells/nl), lower hemoglobin (106 vs 112 g/l), and greater risk of malaria (19.7 vs 4.2%), inflammation (60.5 vs 41.7%), and low adjusted pF (27.3 vs 3.2%) than children with low pTfR (P<0.01, controlling for age). Compared to women with low pTfR, women with elevated pTfR (n=26) had lower hemoglobin (106 vs 122 g/l) and were more likely to have low adjusted pF (61.7 vs 12.5%, p<0.001), but ARC and presence of malaria, inflammation, and pregnancy did not differ.

Conclusions: In this setting, elevated pTfR is associated with increased erythropoiesis, inflammation, and malaria among children, so pTfR may overestimate the prevalence of ID. Among women, elevated pTfR represents mainly ID, possibly because infection prevalence was low.

¹Jivita Project, Gaibandha, Bangladesh

²Center for Human Nutrition, Johns Hopkins University, Baltimore, USA

³Partnership for Population Development, Dhaka, Bangladesh

Background and objectives: It has been observed that South Asians have a higher percent body fat at a given body mass index (BMI) than Western populations. We explored the relationship between percent body fat (%BF), estimated by bioelectrical impedance analysis (BIA) and skinfold measurements, and BMI to establish cutoff levels of BMI for defining obesity based on %BF in rural Bangladeshi women of reproductive age.

Methods: A community-based assessment of nutritional status was conducted at 3 months postpartum, representing a point in time when maternal nutritional status is comparable to periconceptional status, in 1555 women who participated in a placebo-controlled, antenatal, weekly vitamin A or beta-carotene supplementation trial. Anthropometric measurements (height, weight, triceps and subscapular skinfolds) were taken and resistance at 50 kHz was measured using single frequency BIA. Percent body fat was calculated from skinfold thickness' using the Siri equation and from resistance using a previously validated BIA equation for predicting body fat in this population.

Results: Mean (SD) weight was 42.8 (5.9) kg, height was 149.1 (5.3) cm, BMI was 19.2 (2.2) kg/m², and %BF was 23.7 (4.8) and 23.3 (4.9) by skinfold and BIA methods, respectively. Receiver operating characteristic (ROC) curve analysis showed that a BMI of 21.5 kg/m², versus a conventional cutoff of 25 kg/m², optimized sensitivity (82.5%) and specificity (90.8%) and minimized misclassification of subjects with %BF >30, the standard definition of obesity.

Conclusions: In Bangladesh, the conventional BMI cut-off of 25 kg/m² markedly underestimated the prevalence of obesity (BF>30%). Rather, in this rural Bangladeshi setting, women are obese, in terms %BF, at a lower BMI than in non-South Asian populations.

Key words: Bioelectrical impedance analysis, body mass index, fat percent, Bangladesh, women

PO2463**ADEQUACY TO FIBER INTAKE ACCORDING TO BODY MASS INDEX IN ADULT POPULATION OF ROSARIO (ARGENTINA)**

M.E. Zapata^{1,2}, R. Bufarini¹, N. Lingiardi¹, M.M. Bibiloni², J.A. Tur²

¹Licenciatura en Nutrición, Facultad de Química, Universidad del Centro Educativo Latinoamericano, Rosario, Santa Fe, Argentina

²Grupo de Investigación en Nutrición Comunitaria y Estrés Oxidativo and CIBERobn CB12/03/30038 Fisiopatología de la Obesidad y la Nutrición, Instituto de Salud Carlos III, Universitat de les Illes Balears, Palma de Mallorca, Illes Balears, España

Background and objectives: The non-communicable chronic diseases are a key public health problem in low-middle- and high-income countries, and incidence and mortality rates are rapidly increasing in many previously low-risk countries. Epidemiological studies suggest that dietary fiber intake help maintain a healthy body weight. The aim of this study was to assess the dietary fiber adequacy of adults from Universidad del Centro Educativo Latinoamericano (UCEL) of Rosario, Argentina, and to describe the adequacy according body mass index.

Methods: A cross-sectional study was carried out and evaluated 88 students and employees of UCEL (34.1 ± 12.8 years). Food intake was assessed through four 24-hour recall along a year. Adequacy of fiber intake was calculated according to Dietary Reference Intakes (FNB-IOM, 2002/2005) by sex and age. Prevalence of overweight and obesity were calculated according to the WHO classification (overweight: BMI >25 - <30 kg/m²; obesity: BMI >30 kg/m²).

Results: The mean of dietary fiber adequacy was $62.3 \pm 21.6\%$ (CI 95% 57.7-66.8). The prevalence of overweight and obesity was 44.3%. Significant differences ($p < 0.001$) in dietary fiber adequacy by BMI classification were found, with high adequacy in normal-weight ($70.2 \pm 22.3\%$; CI 95% 63.8-76.6) than in overweight/obesity ($52.4 \pm 16.2\%$; CI 95% 47.1-57.6) subjects.

Conclusions: It has been suggested that enough fiber in the diet will tend to prevent excessive food intake, so it is necessary to encourage adequate consumption of whole cereals, fruits, vegetables and pulses to increase the contribution of fiber to the diet and prevent weight increase.

Key words: Fiber intake, body mass index, adults

PO2464**MICRONUTRIENT STATUS IN DIABETIC RETINOPATHY**

G.B. Reddy¹, A. Satyanarayana¹, N. Balakrishna¹, M. Sivaprasad¹, P.Y. Reddy¹, P. Lopamudra¹, P. Suryanarayana¹, K. Viswanath², R. Ayyagari³

¹National Institute of Nutrition, Hyderabad, India

²Pushpagiri Vitreo Retina Institute, Hyderabad, India

³University of California, San Diego, USA

Background and objectives: Multiple factors are likely to be involved in predisposing diabetic subjects to diabetic retinopathy (DR), as evidenced by the fact that many but not all diabetic patients develop DR. In this study we have evaluated the micronutrients status in DR with an ultimate goal to understand the role of genotype-nutrient interaction in DR.

Methods: A hospital based cross-sectional case-control study was conducted with 300 type-2 diabetic subjects with retinopathy (DR) (n=200) and without retinopathy (DNR) (n=200) along with 100 normal control (CN) subjects based on strict inclusion and exclusion criteria. Diabetic subjects on nutritional supplements and history of nephropathy and other complications were excluded. Based on ophthalmic examination including FFA, patients were classified as DNR or DR. In addition to regular clinical profile, the blood levels of all the vitamins and trace elements were analyzed by HPLC, atomic absorption, spectrophotometric methods.

Results: Among trace elements, an inadequacy in blood levels of manganese, cobalt and zinc was found in DR patients compared to CN and DNR. Excepting vitamins folic acid B6, B12 and D, blood levels of all the vitamins were not different between the groups. While, levels of vitamin B6, folic acid and vitamin D were significantly lower in diabetic groups as compared to controls, there was no difference between DNR and DR groups. This study revealed a significantly lower level of plasma vitamin-B12 in DR patients compared to CN and DNR groups. While plasma homocysteine levels were found to be higher in diabetes patients compared to control subjects, homocysteine was further higher in DR group.

Conclusions: These results suggest an association between vitamin-B12 deficiency and hyperhomocysteinaemia in DR and further indicate that vitamin-B12 deficiency could be an independent risk factor for DR.

Key words: Diabetic retinopathy, micronutrients, vitamin B12, homocysteine

PO2465**EFFECT OF IRON FORTIFIED COWPEA FLOUR ON IRON STATUS STATUS OF SCHOOL CHILDREN IN NORTHERN GHANA**

A R. Abizari^{1,2}, D. Moretti², M. Zimmermann^{2,4}, M. Armar-Klemesu³, I. Brouwer²

¹University For Development Studies, School of Medicine and Health Sciences, Tamale, Ghana

²Division of Human Nutrition, Wageningen University, Wageningen, The Netherlands

³Department of Nutrition, Noguchi Memorial Institute for Medical Research, University of Ghana, Legon, Ghana

⁴Human Nutrition Laboratory, Institute of Food Science and Nutrition, Swiss Federal Institute of Technology, Zurich, Switzerland

Background and objectives: Cowpeas, like other legumes, contain high amounts of native iron but are rich in phytic acid and polyphenols inhibiting iron absorption. NaFeEDTA may overcome the combined inhibitory effect of phytic acid and polyphenols. Our objective was to test the efficacy of NaFeEDTA fortified cowpea meal in improving iron status of school children in a malaria endemic area.

Methods: We conducted a double-blind controlled trial with 5 – 12-y-old school children from two rural communities in northern Ghana (n = 241). Eligible children were randomly assigned to two treatment groups to receive either cowpea meal fortified with 10 mg Fe/meal as NaFeEDTA, or an identical but non-fortified cowpea meal. Meals were provided 3 d/wk for a period of about 7-mo under strict supervision. Mass deworming and malaria antigenemia screening and treatment were carried out at baseline and 3.5-mo into the trial.

Results: Consumption of cowpea flour fortified with NaFeEDTA resulted in significant improvement of Hb (p<0.05), SF (p<0.001) and body iron stores (p<0.001) and reduction of TfR (p<0.001) compared to non-fortified flour. Fortification resulted in 30% and 47% reduction in the prevalence of iron-deficiency (ID) and iron-deficiency anemia (IDA) (p<0.05), respectively.

Conclusions: The results indicate that fortification of cowpea flour with NaFeEDTA overcomes the combined inhibitory effect of phytic acid and polyphenols and, when used for targeted school-based fortification of cowpea flour, is effective in reducing the prevalence of ID and IDA among school children in malaria endemic rural northern Ghana.

Key words: Fortification, iron-deficiency, schoolchildren, Ghana

PO2466**SUB-CLINICAL INFLAMMATION AND EFFECT OF IRON SUPPLEMENTATION IN UNDER-TWO-YEAR-OLD INDONESIAN CHILDREN**

U. Fahmida¹, M K. Htet^{1,2}, D. Thurnham³

¹SEAMEO-RECFON, Regional Center for Food and Nutrition, University of Indonesia

²Research Institute Trisakti University, Indonesia

³Northern Ireland Centre for Food and Health, School of Biomedical Science, University of Ulster, Coleraine, UK

Background and objectives: Sub-clinical inflammation (SCI) influences iron indicators and hemoglobin levels, while studies have reported anti-inflammatory role of long-chain polyunsaturated fatty acids (LCPUFA). However, there is limited information on the influence of SCI and EPA/DHA supplementation on effectiveness of iron supplementation. This study aims to investigate the influence of SCI and EPA/DHA supplementation on effect of iron supplementation to improve hemoglobin and iron status.

Methods: A randomized, double-blinded controlled trial was conducted in Lombok, West Nusa Tenggara Province, Indonesia (ClinicalTrials.gov Identifier: NCT01504633). There were four groups: placebo, Fe (16 mg elemental iron/day), EPA/DHA (20 mg/100mg per day) and Fe+EPA/DHA (n=60/group). Indicators of SCI (CRP, AGP), iron status (serum ferritin/SF, transferrin receptor/sTfR, body iron store/BIS) and hemoglobin were assessed at baseline and after 24-week supplementation (endline).

Results: SCI was associated with higher SF and lower BIS at baseline. However in groups who received iron, there was no difference in improvement of hemoglobin, SF, sTfR, BIS between SCI groups (18.7 g/l, 53.6 µg/l, -2.7 mg/l, 6.6 in SCI and 14.7 g/l, 41.9 µg/l, -2.6 mg/l, 7.0 in non-SCI respectively). In both stratum with and without SCI, improvement in hemoglobin, SF, sTfR and BIS was significantly better in groups who received iron. The same pattern was observed when stratified by with and without DHA supplementation.

Conclusions: Within the regime of iron dosage used in this study (equivalent to 2 mg/kg.day) iron supplementation improved hemoglobin and iron status regardless of SCI status and EPA/DHA supplementation.

Key words: EPA/DHA, iron status, iron supplementation, sub-clinical inflammation, under-two-year-old children

PO2467**A PROSPECTIVE STUDY OF NUTRITIONAL STATUS OF PATIENTS WITH CHRONIC MALNUTRITION UNDER DIETARY TREATMENT***R. Popova¹, D. Popova¹, B. Strahilova¹*

¹Medical University, University Hospital 'Queen Giovanna - ISUL', Clinic of Metabolic Diseases and Dietetics, Sofia, Bulgaria

Background and objectives: Patients with chronic malnutrition have bad quality of life with diminished capacity of working and deteriorated social status. The aim of our study is to assess the effectiveness of different therapeutic approaches on patients with chronic malnutrition, who were admitted at the Clinic of metabolic diseases and dietetics.

Methods: We analyze the results of 52 malnourished patients with different etiology. They have: 1primary anorexia or/and bulimia nervosa 2secondary anorexia with depressive syndrome 3chronic gastrointestinal diseases 4status after surgery Patients are reviewed two times – at the beginning of the study and after 24 months. We measure the body composition with bioelectrical impedance analyser „Tanita TBF – 401A” and the muscle strength with dynamometer “SAEHAN”. We test the cognitive function by Mini Mental State Examination and investigate their usual nutritional habits using standard questionnaire. We build up an individual therapeutic plan with a diverse nutritional support according to the unique metabolic status.

Results: After 24 months we have been established that muscle strength is mostly improved. All the patients show better results by dynamometry and they remark improving quality of life by the questionnaire. We find out that patients with depressive syndrome and patients after surgery show better results after 2 years, compared to those with anorexia nervosa and chronic gastrointestinal diseases. Patients with anorexia nervosa show the worst compliance and those with chronic gastrointestinal diseases don't have adequate food intake in relation to constant gastrointestinal symptoms and impaired nutrient absorption.

Conclusions: The results of our 24 months study confirm the necessity of systematical individual approach of the nutritional therapy of malnourished patients. It is obligatory to monitor the patients' status during the therapy and to adjust if it's necessary.

Key words: Chronic malnutrition, nutritional assessment, therapeutic approach, monitoring

PO2468**FOOD LIMITS THE RESPONSE OF CIRCULATING NON-TRANSFERRIN-BOUND IRON (NTBI) TO ORAL IRON SUPPLEMENTATION IN YOUNG CHILDREN***M. Orozco¹, M E. Romero-Abal¹, N W. Solomons¹, G. Weiss², K. Schümann³*

¹Center for the Studies of Sensory Impairment, Aging and Metabolism (CESSIAM)

²Department of Internal Medicine I, Clinical Immunology and Infectious Diseases, Medical University of Innsbruck, Innsbruck, Austria

³Research Center for Nutrition and Food Science (ZIEL), Freising-Weihenstephan, Germany

Background and objectives: Malaria in children can be more virulent in the context of 12.5-mg oral Fe supplementation, as shown in a trial on the Zanzibari island, Pemba. A leading candidate as a virulence factor is the loosely-bound circulating Fe (NTBI), which enters the circulation after supplementation. It is recommended that, if oral Fe is to be given, it should be consumed along with food to limit the intravascular exposure to NTBI. We hypothesized that the circulating NTBI would be associated with the serum Fe concentration and that consuming food with the Fe would limit the NTBI response.

Methods: Forty subjects, aged 24-36 months, were assigned to one of four groups (G): GI received oral Fe solution at time zero with blood extraction 180 min later; GII received water with sampling at 270 min; GIII received oral iron with blood extraction 270 min later; GIV received water with sampling at 270 min. Oral iron was 13 mg of Fe as FeSO₄ syrup, with a snack based on 4 ounces of gelatin or flan plus juice served within 30-min of dosing. Serum Fe was measured with a photometric colorimetric test and NTBI by a fluorometric competitive binding assay.

Results: The Spearman correlation coefficient of NTBI vs serum Fe was $r=0.15$ ($p=0.32$, $n=38$). Pooled serum Fe was 28.1 ± 15.5 $\mu\text{g}/\text{dl}$ with iron plus food ($n=19$) vs 17.6 ± 7.6 $\mu\text{g}/\text{dl}$ without oral Fe ($n=20$) ($p=0.01$). Corresponding circulating NTBI averaged 0.37 ± 0.35 and 0.31 ± 0.37 $\mu\text{g}/\text{dl}$ ($p=0.61$) respectively, with 25% undetectable NTBI in the iron and 35% in the placebo groups.

Conclusions: Despite the close proximity of the oral supplement dose to a meal, significant Fe uptake into the circulation can be detected, whereas NTBI concentrations remained at basal levels in this meal-feeding situation.

Key words: Children, iron-supplementation, non-transferrin-bound iron, malaria, Guatemala

PO2469

VALIDATING ESTIMATES OF TRADITIONAL FOOD INTAKE IN THE CREE AND INUIT POPULATIONS OF NORTHERN CANADA

L. Johnson-Down¹, G M. Egeland¹

¹Centre For Indigenous Peoples' Nutrition and Environment, School of Dietetics and Human Nutrition, McGill University, Montreal, Quebec, Canada

Background and objectives: Hunting and gathering patterns vary throughout the year as a result of animal migration and weather patterns. Due to the seasonal nature of consumption, estimates of traditional food (TF) in indigenous populations in northern climates are difficult to obtain. Validation of TF reported on a food frequency questionnaire (FFQ) used a ratio of estimated energy intake (EI) to basal metabolic rate (BMR).

Methods: FFQ recorded year-long TF intake from the "Nituuchischaayihitaa Aschii: A Multi-Community Environment-and-Health Longitudinal Study in Iiyiyiu Aschii" and the International Polar Year (IPY) Inuit Health Survey (IHS). Two hundred and one adult Cree participants (aged 18 and above) and 2081 participants from the IHS responded to a FFQ aimed at obtaining all TF over the previous 12 months. Average portion size using standard portion models (Santé Quebec, Canada) was obtained along with the frequency. Using this data, daily energy from TF was calculated. EI from TF was compared to estimates of BMR to determine the validity of reports.

Results: The energy reported from TF on FFQ was 4995 ± 6412 and 1263 ± 3216 and BMR was 1800 ± 281 and 1555 ± 262 in the Cree and Inuit respectively. The ratio of reported energy intake from TF to BMR in the Cree was 2.48 ± 3.57 with a maximum of 22.0. In the Inuit population, the ratio was 0.80 ± 1.96 with a maximum of 43.9.

Conclusions: Given ratios of total daily energy intake to BMR of 1.4-1.9 established by the WHO, and because TF represents only a fraction of the diet of our participants, this would indicate a clear overestimation of total TF intake. Although it is important to get an estimate of intakes of TF in indigenous populations, investigators need to be aware of the limitations of the methods they are using.

Key words: Traditional food, indigenous, food frequency, validation

PO2470

RECEIVER OPERATING CHARACTERISTIC CURVE ANALYSIS OF ANTHROPOMETRIC MEASUREMENTS VERSES BODY FAT ASSESSED BY AIR DISPLACEMENT PLETHYSMOGRAPHY IN INDIAN WOMEN.

D S. Varghese¹, S. Surampudi¹, B. Nagalla², V R. Yagnambhatt¹

¹Department of Work Physiology and Sports Nutrition, National Institute of Nutrition (ICMR), Hyderabad, Andhra Pradesh, India

²Division of Bio-Statistics, National Institute of Nutrition (ICMR), Hyderabad, Andhra Pradesh, India

Background and objectives: Optimal fatness is a key to healthy and longer life. Assessment of fatness with a better accuracy using simple and cost effective tools is important to curtail the consequences of excess body fat. A study was carried out to assess the relative ability of anthropometric indicators of fatness as compared to the percent fat measured by Air displacement plethysmography (ADP) in Indian adult women.

Methods: Sixty-six healthy women aged between 30 and 60 years having normal BMI as per WHO classification (BMI, 18.5 - 24.9 kg/m²) were included in the study. Body composition was assessed using Air Displacement Plethysmography (BodPod, LMI, USA) to obtain percent body fat (%BF). Height, Weight, Skinfold thickness (SKF) at four different sites (triceps, biceps, sub-scapula and supra-iliac) and circumferences at seven position viz upper-arm (AC), neck, chest, waist, hip, thigh and calf were measured using standard procedures. BMI, WHR, Waist- Stature-Ratio (WSR) and Hip-to-Height-Ratio (HSR) were calculated. The Receiver Operative Characteristic (ROC) analyses were done and areas under the curves (AUC) were used to compare the relative accuracy of each indicator to assess the fatness, where fat above 30% was considered as excess fatness.

Results: The mean fat percentage was found to be 34.4 ± 6.7 . All the measured circumferences and SKFs, BMI, WSR and HSR were positively correlated with fat percentage at 0.01 significance level. The probability of detecting fatness expressed by the AUC was found to be higher for triceps (0.970), BMI (0.934) and AC (0.927), hence, can be considered as better predictors for fatness among the indicators studied. The AC can be considered as an accurate indicator of fatness which is cost effective.

Conclusions: Amongst the indicators studied, triceps, BMI and AC were found to be better indicators of fatness.

Key words: ROC curve, fat percentage, air displacement plethysmography, triceps, BMI

PO2471

PROVITAMIN-A-CAROTENOIDS AND RETINOL ACTIVITY EQUIVALENTS: APPARENT BIOAVAILABILITY OF ALPHA-CAROTENE AND BETA-CRYPTOXANTHIN IS GREATER THAN THAT OF BETA-CAROTENE IN SPANISH SUBJECTS

B. Olmedilla-Alonso¹, R. Estevez-Santiago¹, B. Beltrande-Miguel², C. Cuadrado Vives²

¹Department of Metabolism and Nutrition, Institute of Food Science and Technology, Spanish National Research Council (ICTAN-CSIC), Madrid, Spain

²Department of Nutrition and Bromatology, Faculty of Pharmacy, Universidad Complutense of Madrid, Madrid, Spain

Background and objectives: Current assumptions about RAE (international standard of measure for vitamin-A) are based on the supposition that the absorbabilities of the provitamin-A-carotenoids are the same. Beta-carotene is assigned the maximum contribution to retinol intake, and this has been established on the basis of its bioavailability from foods. The other two provitamin-A-carotenoids are considered to have the same bioavailability and potential for conversion to retinol, which is half that of beta-carotene. Objective: Assessment of provitamin-A-carotenoids (alpha-carotene, beta-carotene, beta-cryptoxanthin) and retinol in serum and diet and comparison of their apparent bioavailabilities in Spanish subjects.

Methods: Subjects: n= 108 (54 men), aged 20-35 y and 45-65 y (n=54/group). Normal serum cholesterol and BMI, consumption of varied diet and no nutritional supplements were selected as Inclusion criteria. Dietary assessment: 3-day food records questionnaires and carotenoid data-base of food composition (Beltrán et al Nutr. Hosp 2012). A validated HPLC method for serum carotenoids and retinol (Olmedilla et al Clin.Chem 1997). Apparent bioavailability calculated dividing the blood level of each carotenoid by its intake.

Results: Serum beta-carotene and beta-cryptoxanthin concentrations are close, but in diet, that of beta-carotene is more than 6-fold-higher than that of beta-cryptoxanthin or alpha-carotene. Beta-carotene represents 76% of all the provitamin-A-carotenoids consumed (both groups of age) but, in contrast, in serum, the percentage of beta-carotene is closer to that of beta-cryptoxanthin (51-55% vs 37%). The apparent bioavailability of alpha-carotene was twice that of beta-carotene, and that of beta-cryptoxanthin was close to that of alpha-carotene. Bioavailabilities of alpha-carotene and beta-cryptoxanthin compared with that of beta-carotene (as standard) are 1,3 and 4,6 (median values) respectively. The contribution of these two provitamin-A-carotenoids to the vitamin-A intake could be greater than that considered currently (RAE).

Key words: Carotenoids, serum, diet, bioavailability

PO2472

BODY FAT DISTRIBUTION OF CHILDREN AND ADOLESCENTS IN ABEOKUTA, SOUTHWEST NIGERIA

I. Senbanjo¹, K. Oshikoya¹, O. Njokanma¹

¹Department of Paediatrics and Child Health, Lagos State University College of Medicine, Ikeja, Lagos State, Nigeria

Background and objectives: Excessive central fat in children and adolescents is a risk factor for cardiovascular and metabolic disorders. The aims of this study were to compare the body fat distribution patterns of children and adolescents in Abeokuta, Nigeria with an international reference standard and to determine the prevalence of general and central obesity.

Methods: Five hundred and seventy children aged 5 to 19 years were selected from seven schools using multi-stage random sampling. Extensive anthropometric measurements were made. Values obtained for Nigerian children were compared with corresponding values for the African-American children.

Results: Females had higher mean BMI, TSF, SSF, WC, HC, WHR and WHtR, while males had significantly higher STR. The mean BMI, WC, TSF and SSF values were lower for our subjects than for African-American subjects at all ages. On the other hand, in both sexes, STR was higher among Nigerian than African-American subjects up to 12 years old. Thereafter the values were similar. The mean WC was similar to those reported for African-American males up to 8 years, and females up to 7 years of age; thereafter, African-American had higher values. According to NCHS/WHO criteria based on BMI, 10 (1.8%) of the children were overweight, seven (70%) of whom were females. The only obese child (0.2%) in the study was female. The prevalence of central obesity using WC and WHtR measures was 4.4% and 5.8% respectively.

Conclusions: Subjects had relatively high central body fat despite their low mean BMI.

Key words: Overweight, central obesity, children, adolescents, Nigeria

PO2473**COEXISTENCE OF STUNTING AND THE RISK OF OVERWEIGHT/OBESITY AMONG PRESCHOOL CHILDREN ATTENDING A PERI-URBAN DAYCARE CENTER IN METROPOLITAN GUATEMALA CITY?**

S. Salguero¹, L. Hernández¹, M.J.L. Bonorden², K. L. Sheldon², R. M. Herreid², N. W. Solomons¹

¹Center for Studies of Sensory Impairment, Aging and Metabolism (CeSSIAM), Guatemala

²Hormel Food Corporation, Austin, USA

Background and objectives: Much of the developing world is passing through a so-called “nutrition transition” and double-burdens of malnutrition. Stunting is a form of undernutrition. Meanwhile, we are seeing the emergence of overweight/obesity on the excess side. Our objective here was to see if stunting and overnutrition coexist in a peri-urban day-care center in Guatemala City.

Methods: Heights and weights were measured and birthdates obtained in 174 participating preschoolers (aged 3-6 years) at Fe y Alegría in the community of Peronia, 16 km from the capital. We transformed the measurement into Z score of height-for-age (HAZ), defining stunting as < -2SD and calculated body mass index (BMI), with overweight defined as 85th-96.9th percentile and obesity as ≥97th. Our reference was ANTHRO v3.2.2 and ANTHRO-Plus v1.04 (WHO, Geneva).

Results: The mean age in years was 5.1 ± 1.0 , with 52.3% boys. The overall mean HAZ was -1.0 ± 0.9 (median:-1.0; range:-3.2 to +1.1), with corresponding descriptive statistics for boys of -0.8 ± 0.9 (median:-0.9; range:-3.2 to +1.1) and for girls -1.2 ± 0.8 (median:-1.2; range:-3.1 to +0.9) ($p=0.02$). The overall stunting prevalence was 12.1%, with 12.1% for boys and 12.0% for girls. Overall prevalence of overweight was 12.1% and obesity, 2.0%. By sex, they were 14.3% and 2.3%, and 9.6% and 1.2%, respectively. The prevalence of overweight/obesity in stunted children ($n=1$) is 5.6%, and that in non-stunted subjects ($n=23$) is 13.2% ($p=0.346$).

Conclusions: The 12.1% stunting prevalence here must be considered as mild, well below the national rate of 49.8% for under-fives. Similarly, the 14% of combined overweight/obesity practically superimposes on the fraction of a population encompassed between 85th and 100th percentiles. Coexistence of under- and over-nutrition is minimal in this setting.

Key words: Children, anthropometry, stunting, overweight/obesity, Guatemala

PO2474**PSYCHOSOCIAL FACTORS ASSOCIATED WITH LOW ENERGY REPORTING IN MALE AND FEMALE MALAYSIAN UNIVERSITY STUDENTS**

W Y. Gan¹, M T. Mohd Nasir¹, M S. Zailah¹, A S. Hazizi¹

¹Department of Nutrition and Dietetics, Universiti Putra Malaysia, Serdang, Selangor, Malaysia

Background and objectives: This cross-sectional study aimed to identify potential psychosocial factors associated with low energy reporting in Malaysian male and female university students.

Methods: A total of 806 university students (39.7% males and 60.3% females), aged 19 to 24 years ($M = 20.7$, $SD = 1.9$), from six randomly selected universities completed the Multidimensional Body Image Scale, Eating Attitudes Test-26, Depression Anxiety Stress Scale, International Physical Activity Questionnaire, and a two-day 24-hour dietary recall. Body weight and height were measured. The ratio of total energy intake to estimated basal metabolic rate (EI:BMR) and the Goldberg cut-off point were used to classify participants into under-reporters and adequate reporters of EI.

Results: About 30.9% of the males and 33.3% of the females were under-reporters. Significantly higher proportions of male and female under-reporters of EI were overweight and obese than adequate reporters. Multiple linear regression analysis revealed that lower EI:BMR values were associated with higher BMI ($r = -0.257$, $p < 0.001$), higher body dissatisfaction ($r = -0.299$, $p < 0.001$), higher depression $r = -0.169$, $p = 0.004$), and lower stress ($r = 0.185$, $p = 0.005$) in females, whereas with higher BMI ($r = -0.378$, $p < 0.001$) in males. Other factors were also included in the models but they were not significantly associated with EI:BMR (i.e physical activity, anxiety, and disordered eating). These final models explained 24.5% of variance in females and 17.6% in males.

Conclusions: Factors associated with low energy reporting differed according to sexes among university students. Thus, programs targeting these students should consider these differences.

Key words: Low energy reporting, psychosocial factors, university students

PO2475**DIETARY PATTERNS IN AN ADULT POPULATION FROM ARGENTINA**

N. Elorriaga¹, D. Defagó¹, L. Gutierrez¹, H. Desimone¹, R. Poggio¹, V. Irazola¹

¹Institute for Clinical Effectiveness and Health Policy IECS, Argentina

Background and objectives: Dietary patterns (DP) have been used to identify different combinations of foods that may be associated with mortality and risk of chronic disease. The objective of this study was to identify DP in the adult population of Argentina, and explore associations with socio-demographic features.

Methods: We defined DP among 3,000 adults between 35 to 74 years old, participating in CESCAS I, a population-based cohort study carried out in two cities in Argentina, Marcos Paz and Bariloche. Data on food intake was obtained from a validated self-administered food frequency questionnaire. Principal component Analysis (PCA) was used to identify DP. A summary score for each pattern was then derived and used in multiple regression analysis to examine the relationship between DP and socio-demographic variables.

Results: Using PCA, we identified 3 major eating patterns. The first factor (Traditional dietary pattern), was characterized by a high intake of refined grains, red meat, whole fat dairy products, vegetable oils, and “mate”, a traditional South American infused drink frequently consumed in Argentina; the second factor (Healthy dietary pattern), was characterized by a high intake of vegetables, fruit, low fat dairy products, whole grains, and legumes; the third factor (Processed-food dietary pattern) consisted mainly of processed meat, snacks, pizza, and “empanadas”, a stuffed bread baked or fried. After adjusting for energy intake, we found that DP were associated with age, gender, and educational level. Healthy DP score was higher among women and high educational level ($p=0.001$) while men and young people scored significantly higher in the Processed-food DP ($p=0.01$).

Conclusions: Local DP has been identified in our population. This study will provide useful information to set priority targets for nutrition interventions, and promote healthy policies based on local food habits.

Key words: Dietary patterns, Argentina, adults.

PO2476**ASSESSMENT OF DIFFERENTIAL ITEM FUNCTIONING IN THE HOUSEHOLD FOOD SECURITY SCALE MODULE WITHIN A DISADVANTAGED AUSTRALIAN POPULATION**

R. Ramsey¹, D. Gallegos¹

¹Queensland University of Technology, Brisbane, Australia

Background and objectives: Food insecurity is the limited availability of or access to nutritious, safe and culturally-appropriate food, or inability to access these foods by socially acceptable means. Monitoring and surveillance of food insecurity is imperative for the development of policy and interventions to address the issue. The measurement of food insecurity in Australia is limited, relying on a single item that underestimates its prevalence. Recently, countries have been adopting the more comprehensive United States Department of Agriculture Household Food Security Survey Module (HFSSM). However, it is unknown whether items in the HFSSM are perceived differently between groups, for example ethnic minorities and women, which may confound or complicate the interpretation of sub-group differences.

Methods: We examined differential item functioning of the ten USDA-FSSM adult-related items, based on gender, country of birth (COB) and presence of children in the household. Data were collected via mail-based survey among a cross-sectional sample of 487 low-income households in Brisbane, Australia and analysed using jMetrik freeware.

Results: Items did not function differently based on COB. Between genders, moderate levels of differential functioning were evident for only the item pertaining to hunger. Items functioned differently between households with and without children, with six of ten items displaying moderate differential functioning and a further three revealing large amounts of differential functioning. This is likely due to item bias, reflecting confounding with presence of children in a household. Care should be taken with the interpretation of results between households with and without children. Alternatively a separate measure of food insecurity may be constructed, however this may complicate comparisons between other groups and studies.

Conclusions: Differences in item function in the HFSSM exist between households with and without children. Care should be taken in the interpretation of results between these sub-groups.

Key words: Food security, food insecurity, measurement

PO2477**ASSESSMENT OF HOUSEHOLD FOOD SECURITY: DESIGN OF A STANDARDIZED APPROACH AT THE WORLD FOOD PROGRAMME**

D. Rose¹, S. Hollema², A. Mathiassen³, A. Wadhwa³, J. Luma³

¹Department of Global Community Health, Tulane University, New Orleans, USA

²Asia Regional Bureau, United Nations World Food Programme, Bangkok, Thailand

³Food Security Analysis Service, United Nations World Food Programme, Rome, Italy

Background and objectives: The World Food Programme (WFP) operates throughout the world, providing emergency relief and food assistance to the most needy. Information on household food security, a key determinant of diet and nutrition outcomes, is used to guide program activities. This paper describes results of the design phase of a project to improve and standardize reporting of food security indicators across countries.

Methods: A mixed-methods approach included an extensive review of documents from international food and nutrition agencies and scientific literature from the nutrition, health, agriculture, and economics disciplines. Key stakeholder input was obtained from a working group of WFP staff in 17 countries and the headquarters' teams of the Food Security Analysis Service (FSAS). Empirical testing was conducted with FSAS household datasets from South Sudan, Nepal, Tajikistan, El Salvador, Guatemala, and Djibouti.

Results: The new approach provides a framework for combining and reporting food security indicators on current food consumption, such as the WFP Food Consumption Score. It also includes indicators on income status and asset depletion, which affect a household's ability to feed itself in the face of future shocks. Household status is reported across four categories: food secure, and mild, moderate, and severe food insecurity. Comparison with previous approaches showed similar prevalence rates of the two most severe categories, but significant differences with the 'secure' category across all countries tested.

Conclusions: New to this approach was the use of four categories of food security, allowing for distinction between 'secure' and 'mildly food insecure' households. This can be useful for WFP programming on school feeding, nutrition, and other efforts to protect livelihoods. More importantly, calculation of a summary indicator of household food security in a standardized and transparent way can improve communication with relevant actors, and facilitate effective action.

Key words: Food security, assessment, households, food programs

PO2478**DEVELOPMENT AND VALIDATION OF AN INFANT COMPLEMENTARY FEEDING INDEX**

S. Godakandage¹, W. Gunathunga², R. Jayatissa³

¹Family Health Bureau, Colombo, Sri Lanka

²Department of Community Medicine, Faculty of Medicine, University of Colombo, Colombo, Sri Lanka

³Department of Nutrition, Medical Research Institute, Colombo, Sri Lanka

Background and objectives: Childhood malnutrition is a priority health problem in Sri Lanka, and suboptimal complementary feeding practices is considered a major contributor. In order to address this issue, frontline healthcare workers need to conduct rapid assessment of feeding practices of infants and young children, and intervene if necessary. The objective of this study was to develop an index which can be used by frontline healthcare workers to conduct a rapid quantitative assessment of complementary feeding practices of infants at individual level.

Methods: The development of the index was carried out involving eight experts in the fields of public health, paediatrics, medical nutrition and biochemistry, using the Delphi technique. Indicators belonging to the seven domains of milk feeds, meal frequency, food variety, nutrient density, food hygiene, responsive feeding and miscellaneous were given scores by the experts, depending on their relative importance for the age groups 2.0-3.9, 4.0-5.9, 6.0-8.9, and 9.0-11.9 months. The first age group was included to capture premature introduction of solids. The construct validity of the index was assessed against anthropometric parameters of a sample of 624 infants.

Results: The Infant Complementary Feeding Index developed consists of 25 variables, which ranged from 2-5 in each of the seven domains. The scores received for each domain of complementary feeding practices of infants in the sample were significantly associated ($p < 0.05$) with their z-scores for weight for age and height for age, when assessed using the multiple regression method, after controlling for the confounding variables of sex, birth weight, maternal age, maternal education, father's occupation and family income.

Conclusions: The index developed is a valid tool for a quantitative assessment of infant complementary feeding practices.

Key words: Infant complementary feeding, infant nutrition, nutrition assessment, feeding index

PO2479**GROWTH AND DEVELOPMENT OF CHILEAN ADOLESCENTS BELONGING TO A COHORT OF CHILDREN BORN PRETERM**

M A. Gonzalez¹, C. Muñoz¹, A. San Martín¹, A. Rodríguez¹

¹Departamento de Nutrición y Salud Pública, Facultad Ciencias de la Salud y de los Alimentos, Universidad del Bio-Bio, Biobío, Chile

Background and objectives: Catch-up growth in children born preterm occurs in the first months of life; it can be slow and progressive and, in some cases, growth recovery takes place in adolescence. The objective was to study the growth and development of adolescents born preterm and compare them to term-born adolescents.

Methods: A sample of 91 children was taken from a cohort born preterm between January 1995 and December 1996 with birth weight <2500 g and gestational age <37 weeks residing in the urban areas of Chillán and San Carlos in the Bio-Bio Region, Chile. This sample was compared with 91 term-born children matched for gender, age, and attendance at the same educational institution. Assessment included BMI-for-age and height-for-age based on CDC/NCHS standards, Tanner puberty scale for development stages, body composition by skinfold, and percentage body fat with Slaughter's formulae. Blood pressure and waist circumference were calculated to estimate cardiovascular risk.

Results: Overweight and obesity according to BMI-for-age was 23.0% and 24.1% in adolescents born preterm and term-born, respectively; 25.5% of adolescents born preterm and small for gestational age and 14.5% adequate for gestational age were overweight. Lower height was observed in 16.5% and 5.5% of the sample and control, respectively, according to height-for-age; a higher proportion of girls had lower height ($p < 0.04$). A higher proportion of excess fat mass was found in adolescents born preterm than in the control, particularly in the suprailiac skinfold. No significant differences were found in blood pressure and waist circumference.

Conclusions: There is a group of preterm children who do not recover height during adolescence, especially girls. Cardiovascular risk is similar in both groups.

Key words: Adolescents born preterm, body composition, cardiovascular disease, growth recovery.

PO2480**TOLEDO AREA STUDY: ASSESSMENT OF GLYCEMIC INDEX IN ADOLESCENTS AND THEIR PARENTS.**

J M. Martínez-Sesmero¹, T. Guillén³, A. Aragonés², S. Bastida³, F J. Sanchez-Muniz³

¹Pharmacy Department, Virgen de la Salud Hospital, Toledo, Spain

²Department of Pediatrics, Virgen de la Salud Hospital, Toledo, Spain

³Nutrition Department Faculty of Pharmacy, Complutense University of Madrid, Madrid, Spain

Background and objectives: The Toledo Area Longitudinal Study (TALS) examines the influence of dietary, anthropometric and metabolic parameters at birth and their parents about different cardiovascular risk factors in children and adolescents of Toledo Health Area. Glycemic load (GL) estimates the impact of carbohydrate consumption. Glycemic load control appears to be beneficial in dietary programs targeting metabolic syndrome, insulin resistance, and weight loss. The objectives are to determine GL and to evaluate the correlation between parents and adolescents. Methods. In a sub-sample of 53 adolescents TALS (16-17 years old) and their parents we measured GL (by multiplying Glycemic Index value by the grams of available carbohydrates in their diets) and the GL/1000 kcal. Descriptive statistics (median and interquartile range) and analytical (nonparametric tests) were performed by SPSS® 15.0.

Results: In adolescents GL= 127.7 (36), GL/1000 kcal= 61.9 (11); in fathers GL= 109.3 (49), GL/1000 kcal= 50.6 (13); in mothers GL= 98.3 (45), GL/1000 kcal= 56.1 (12). There was statistically significant difference between parent and adolescents in GL and GL/1000 kcal in ($p=0.040$ and $p=0.038$, respectively), but there was not between parents ($p=0.128$, $p=0.245$ respectively). There were statistical significant correlations between father GL and adolescent GL ($r=0.331$, $p=0.030$), father GL/1000 kcal and adolescent GL/1000 kcal ($r=0.392$, $p=0.009$), father GL/1000 kcal and mother GL/1000 kcal ($r=0.366$, $p=0.016$).

Conclusions: Despite the correlation between GL and GL/1000 kcal in fathers and adolescents, there were high levels of GL and GL/1000 kcal in the adolescent sample, which may lead to premature insulin resistance and increased diabetes risk.

Key words: Diet quality, adolescents, parents, glycemic index

PO2481**VITAMIN B12 INTAKE AND STATUS IN CROATIAN CELIAC PATIENTS ON A GLUTEN-FREE DIET**

M. Bituh¹, I. Panjkota Krbavcic¹, V. Zizic², N. Vukelic³, I. Colic Baric¹

¹Department of Food Quality Control and Nutrition, Faculty of Food Technology and Biotechnology, University of Zagreb, Zagreb, Croatia

²Department of Laboratory Diagnosis, Children's Hospital Zagreb, Croatia

³University Department of Chemistry, Sestre milosrdnice University Hospital, Zagreb, Croatia

Background and objectives: Adequate vitamin B12 status is necessary for many biological functions in the body. It is well known that patients with untreated celiac disease have low serum vitamin B12. However, inadequate serum vitamin B12 was also observed among celiac patients adhering gluten-free diet. Since gluten-free diet excludes only plant origin foods which contain gluten, the food of animal origin, as a good dietary source of vitamin B12, should not be reduced in celiac patients on a gluten free diet. The aim of this study is to determine vitamin B12 intake and its correlation with vitamin B12 status in celiac patients adhering gluten-free diet.

Methods: The survey was carried out on a 33 celiac patients (19-69 years) adhering gluten-free diet in average 8.9 years, who were not taking vitamin B supplements. Vitamin B12 intake was calculated based on a seven-day food record using food composition tables. Fasting venous blood samples were drawn from all subjects to determine serum Vitamin B12 concentration by radioimmunoassay.

Results: Median intake of vitamin B12 was 3.3 µg/day and in all subjects exceeded 100 % EAR (102-597 % EAR). Although none of the subjects had inadequate vitamin B12 intake suboptimal status of vitamin B12 (<208 pg/ml) was found in 18 % of subjects. Significant positive correlation was found between vitamin B12 intake and status (p<0.05).

Conclusions: Long life gluten-free diet is necessary for celiac patients to prevent malabsorption; however it seems that these patients are still at risk for some nutritional deficiency, such as vitamin B12, even after long adherence to a gluten free-diet. Monitoring of Vitamin B12 status should be a routine even in celiac patients on a long life gluten-free diet.

Key words: Celiac disease, vitamin B12

PO2482**NUTRITIONAL AND SAFETY EVALUATION OF LEGUME-BASED COMPLEMENTARY FOODS CONSUMED BY YOUNG CHILDREN IN NORTH WOLLO, ETHIOPIA: A DIFFICULT COMPROMISE**

K. Baye¹, J. P. Guyot², C. Icard-Verniere², C. Mouquet-Rivier²

¹Center for Food Science and Nutrition, Addis Ababa University, Addis Ababa, Ethiopia

²IRD UMR 204 Nutripass «Prévention des Malnutritions et des Pathologies Associées», IRD/UM1/UM2, Montpellier, France

Background and objectives: In developing countries, a significant share of the complementary foods is legume-based. This study aimed to identify the most frequently consumed legumes; to quantify the corresponding nutrient intakes by young children in North Wollo, northern Ethiopia; and to estimate iron and zinc bioavailability of the legume-based foods.

Methods: A cross-sectional study, using two in-home, 24h-recalls was conducted among 12-23 months-old breast-fed children (n=76) in two rural villages in North Wollo. The household processing of legume-based foods was observed and samples were collected for analyses of iron, zinc, calcium, phytate, and polyphenols.

Results: The contribution of legume-based foods to the total intake (estimated need) was 17% (12%) for energy, 28% (77%) for protein, 20% (6%) for calcium, 38% (16%) for vitamin A, 29% (38%) for iron, and 21% (9%) for zinc. Grass peas, broad beans and field peas were the most frequently consumed legumes, in the form of shiro stew -mostly prepared from blends of grass pea and broad beans- and split field pea stew (SFP). Processing comprised: roasting, splitting and cooking with oil and spices. Both stews had similar zinc contents (~3.2 mg/100 g DM), but shiro had higher iron (1.8 x) and calcium (1.5 x) and lower phytate contents than SFP stews. Consequently, much lower phytate:Fe and phytate:Zn molar ratios were observed in shiro compared to SFP stews suggesting a better mineral bioavailability. However, grass pea consumption was associated with a significant intake (25 mg/day) of the neurotoxin β-ODAP (β-Oxalyldiaminopropionic acid).

Conclusions: Mineral contents and estimated iron and zinc bioavailability in shiro were higher than in SFP stews. However, the risk of neurotoxicity associated to grass-pea consumption should be assessed, particularly in young children. Further investigations to reduce toxin levels through optimized processing are of interest.

Key words: Complementary foods, grass pea, β-ODAP, mineral bioavailability

PO2483**IMPACT EVALUATION USING CHILD ANTHROPOMETRY: TECHNICAL ERROR OF MEASUREMENT MATTERS**

E. Becquey¹, C.T. Ouedraogo³, S.Y. Hess², N. Rouamba³, J.B. Ouedraogo³, K.H. Brown^{1,2}

¹Helen Keller International, New York, NY, USA

²Department of Nutrition, University of California, Davis, CA, USA

³Direction Régionale de l'Ouest, Institut de Recherche en Sciences de la Santé, Bobo-Dioulasso, Burkina Faso

Background and objectives: Precision of anthropometric measurements is affected by human error and instrument quality, which influence the magnitude of detectable changes over time and in response to intervention. However, measurement error is rarely reported or even assessed in child growth studies.

Methods: As part of a longitudinal trial to evaluate the impact of zinc supplementation among Burkinabe children 6-30 mo old, 4 teams of 2 anthropometrists were trained to measure height, weight and mid-upper arm circumference (MUAC) according to WHO recommendations. Throughout the 15 mo of study, regular retraining and 13 standardization sessions were completed by recruiting 10-12 children measured twice by each team. The square root of the measurement error variance defined the technical error of measurement (TEM).

Results: TEM for child length across all standardizations (n=132 children) was 0.43 cm; this fluctuated between 0.27 and 0.67 cm throughout the study and permitted detection of a true change of 1.2 cm (range: 0.8-1.9) with 95% confidence (95%DC). The TEM for weight was 45 g (range: 30-105; 95%DC range: 86-297) and for MUAC was 2 mm (range: 1-4; 95%DC range: 2-10). During the intervention, 10,333 16-wk growth intervals and 2,547 48-wk intervals were assessed. TEM accounted for 38%, 19% and 213% of the mean 16-wk changes in length, weight and MUAC, respectively; and 12%, 6% and 69% of the respective mean 48-wk changes.

Conclusions: Regular training, supervision and standardization throughout a 48-wk trial increased the precision of anthropometric measures used for impact evaluation. Despite this, MUAC was inappropriate to measure 16-wk changes. TEM results can be used to select proper outcome indicators, evaluate staff/instrument performance and compare efficiencies of using longer time intervals versus larger sample sizes in planning trials with growth outcomes.

Key words: Anthropometry, child, measurement error

PO2484**NEW DOMESTIC PROCESSING METHODS: EFFECT ON POTATO NUTRITIONAL COMPOSITION**

C.S.P. Santos¹, S.C. Cunha¹, J.A. Pereira², S. Casal¹

¹REQUIMTE, Faculty of Pharmacy, Oporto University, Porto, Portugal

²CIMO, School of Agriculture, Institute of Bragança, Bragança, Portugal

Background and objectives: Potatoes nutritional and bioactive features are influenced by thermal processing conditions, defining its nutritional composition and health impact. Consumers seek increasingly for faster domestic cooking methods, such as microwave cooking in alternative to current frying or baking. Also, several devices are being commercialized for healthier frying simulation, without a documented characterization of the final processed food nutritional data. Thus, this study aimed to assess and compare the influence of these domestic processing methods on the quality of potatoes processed with olive oil.

Methods: Potatoes were processed by frying, baking, microwave and a low-fat frying device, with equivalent shape and olive oil amounts, except frying. Samples were evaluated for crude fat, fatty acid composition, vitamin E, total carotenoids and total phenols.

Results: Microwave cooked potatoes presented similar fat contents as standard frying, higher than those achieved by baking or with the low-fat frying device tested, but the fatty acid composition was similar. Vitamin E loss was comparatively higher after frying but no significant differences were found for total carotenoids. Potatoes phenolic compounds were partially lost during cooking, being apparently higher after baking.

Conclusions: The distinct nutritional features obtained highlight for the importance of detailing the food compositional tables regarding each processing method, including the "new" domestic methodologies, increasingly used by consumers.

Key words: Potatoes, extra virgin olive oil, domestic cooking, food composition.

PO2485**SODIUM AND POTASSIUM STATUS IN AUSTRIAN CHILDREN: IS THERE A CORRELATION BETWEEN THESE PARAMETERS?**

T. Kuen¹, I. Elmadfa¹

¹Department of Nutritional Sciences, University of Vienna, Vienna, Austria

Background and objectives: The boom in semi-prepared foods has led to high levels of salt consumption. Salt consumption is associated with raised blood pressure, cardiovascular diseases and high NaCl intake is linked to increased risk of stroke. The objectives of the study were the evaluation of sodium (Na) status (salt intake) and potassium (K) status and to investigate if plasma K status correlates with urine Na concentration in austrian children.

Methods: Data were collected within a cross sectional study in 400 children (7–14 years) which was conducted 2010/12 to prepare the Austrian Nutrition Report 2012307 spot urine and blood samples were collected, salt intake was estimated from data based on 24h urine (Na steady state was assumed). K concentration was evaluated in blood plasma and Na concentration in urine.

Results: Na/g Creatinine: <100 mmol/g: 45.7%, 100–150 mmol/g: 23.6 %, >150 mmol/g: 30.7 %. Calculated salt intake: <6 g/d: 22.8 %, 6–10 g/d: 39.7 %, >10 g/d: 37.4 % Potassium: <4.1 mmol/l: 36.5 %, 4.1–4.7 mmol/l: 52 %, >4.7 mmol/l: 11.5 % A weak negative correlation between plasma K level and Na/g Creatinine status could be shown (rs=-0.11, p<0.05).

Conclusions: It was demonstrated, that slightly higher urine Na status correlates with lower plasma K status. It was shown that 77.1 % of austrian children consumed >6 g/d of salt. More than one third showed K concentrations under reference levels, most of these had marginally lowered K levels (2.5–4.1 mmol/l), no child showed serious K deficiency (<2.5 mmol/l). Even if there is no alarming K deficiency, salt consume in austrian children should be reduced.

Key words: sodium, potassium, salt, children

PO2486**FOOD GROUP INTAKE AMONG HEALTH-CARE PROFESSIONALS, UNIVERSITY OF ANTIOQUIA, COLOMBIA**

J M. Monsalve-Álvarez^{1,2,3}, L I. González-Zapata^{1,2,3}, G. Deossa¹, J. Díaz-García^{1,3}, N. Babio^{3, 4}, J. Salas-Salvadó^{3,4}

¹School of Nutrition and Dietetics, University of Antioquia, Medellín, Colombia

²Research Group in social determinants of nutrition and health status, Medellín, Colombia

³Latin American network for the study of Metabolic Syndrome –RIBESMET

⁴Human Nutrition Unit, Research Institute Pere i Virgili, Universitat Rovira i Virgili; and CIBERobn, Institute Carlos III, Spain

Background and objectives: The importance of healthy foods intake in order to maintain a good health and nutrition has long been recognized and health-care professionals are expected to do so. The objective is to characterize the intake of some food groups (dairy, vegetables, fruits, sugary drinks) among health-care professionals at University of Antioquia, according to sociodemographic and anthropometric variables.

Methods: Cross-sectional study derived from Latinmets Colombia 2010-2011. The Food Frequency Questionnaire validated for the PREDIMED study and adjusted to Latinmets Multicenter was applied to 283 volunteers (professors and students) 18-65 years old. Foods were grouped up for the analysis and food intake was converted to times a day. Results were compared to Colombian guidelines intake recommendations. A descriptive analysis and Spearman correlation coefficient with $\alpha=0.05$ were performed. SPSS-v.18.

Results: Dairy: 25.8% have two servings a day, 63% of them are middle-class, 35,6% are 18-24 years old and 65.7% have a normal BMI. Vegetables: 36.7% fulfill the requirements, 62.2% of them are middle-class and 66.3% have a normal BMI. Fruits: 18.4% fulfill the requirements. 40% have sugary drinks once a day or more. A direct association between fruit and vegetables intake and socioeconomic status and age was found (p<0.05), sugary drinks intake was inversely associated to age.

Conclusions: Some sociodemographic variables such as socioeconomic status and age influenced fruit, vegetables, and sugary drinks intake among health-care professionals. Surprisingly, dairy products, fruit, vegetables, and sugary drinks intake among this population was not as expected.

Key words: Food frequency questionnaire, healthcare personnel, food intake.

PO2487

HIGH SODIUM AND LOW POTASSIUM INTAKE AMONG YOUNG URBAN WOMEN IN SRI LANKA: NEED FOR EDUCATIONAL INTERVENTION

T. Anirtha¹, P. Lanerolle¹, T. Thoradeniya¹

¹Department of Biochemistry and Molecular Biology, Faculty of Medicine, University of Colombo, Colombo, Sri Lanka

Background and objectives: Current evidence supports the need to reduce Na and simultaneously increase K intakes to reduce hypertension and cardiovascular diseases. No recent data exists on Na/K intake in Sri Lanka. This study determined Na and K intake by 24-hour urinary excretion method, and validated dietary tools; 24-hour dietary recall (24hDR), food frequency questionnaire (FFQ) to assess Na/K intake in women.

Methods: Two-stage cluster sampling enrolled 83 apparently healthy women (18-30 years) from Colombo Municipality, Sri Lanka. Pre-tested questionnaires assessed general information, dietary Na/K intake, knowledge, attitudes and practices (KAP) related to salt and physical activity. Na and K intakes were measured by 24-hour urinary excretion (52 satisfied urine collection criteria) against which, dietary tools were validated. Scores were calculated for knowledge and attitudes.

Results: The mean excretion of Na and K over 24-hours and the K:Na ratio were $3.14 \pm 1.12\text{g}$ ($8.0 \pm 2.8\text{ g salt}$), $1.3 \pm 0.6\text{ g/day}$ and 0.25 ± 0.11 respectively. None of the women met the joint dietary guidelines for Na ($<2\text{g/d}$) and K ($>3.51\text{g/d}$). Knowledge and attitudes were poor, with 58.2% and 54% women below the mean scores for knowledge; 7.0 ± 3.4 ; and attitudes; 21.2 ± 3.7 respectively. The main source of Na was added salt during cooking (68%) and of K were oily foods (22%; 90% of that from coconuts). Bland Altman analysis found 24hDR for Na intake (mean bias -0.02g ; 96% of estimates within the limits of agreement) and FFQ for K intake (mean bias -0.08g ; 94% of estimates within the limits of agreement) to be comparable with 24-hour urinary excretion measurements.

Conclusions: Na and K intakes did not meet guidelines and most women had inadequate KAP related to salt necessitating public health oriented educational interventions. 24hDR and the FFQ respectively are accurate in assessing Na and K intake in young women at group level.

Key words: Salt intake, women, dietary tools

PO2488

THE CORRECTION OF UNDERESTIMATION OF ENERGY INTAKE BY USING NEURAL NETWORKS

J.W. Szczepanska¹, L. Wadolowska¹

¹Department of Human Nutrition, University of Warmia and Mazury, Olsztyn, Poland

Background and objectives: Underestimation of energy intake (EI) in a dietary record is often a problem in nutritional assessment. The aim of the study was to improve the value of EI according to the fundamental principles of energy physiology by using neural networks.

Methods: The study included 450 women aged 20-45 with BMI $>18.5\text{ kg/m}^2$. A three-day dietary record was used. For analysis were taken two working days and one day off. The underestimation of the EI was verified by the Goldberg method (Goldberg et al. 1991). The data with sufficient energy estimation (according to body fat and age) was used for training neural networks. We searched for the best models with the use of regression analysis in linear (Multilayer perceptrons – MLP) and non-linear (Radial Basis Function - RBF) mapping. To further statistical analysis the best five models with different number of neurons were selected (from 2 to 14).

Results: Only 14% of the women had a correct estimation of EI. After calculating the energy values by neural networks, the adequate energy to the nutritional status had 69-75% of women. Using neural networks improved the values of EI and increased the relation between EI and nutritional status. EI corrected by RBF models correlated slightly better to output of EI than MLP (mean: 0.32 vs. 0.26). EI changed by MLP compared to RBF and unchanged EI gave higher correlation coefficients for the body fat (0.79 vs. 0.48 vs. 0.17, respectively) and the sum of the thickness of skin-folds (0.91 vs. 0.57 vs. 0.25).

Conclusions: Neural networks allowed to reduce a number of women with underestimation of energy intake and to qualify more women to further analysis.

Key words: Energy, nutritional assessment, neural networks

PO2489**GROWTH AND BODY COMPOSITION FROM BIRTH TO 6 MONTHS IN INFANTS BORN TO PREGNANT MOTHERS AT RISK OF GESTATIONAL DIABETES***N. Kizirian¹, S. Garnett^{2,3}, J. Brand-Miller¹*¹Human Nutrition Unit, The University of Sydney, Sydney, NSW, Australia²Institute of Endocrinology and Diabetes, The Children's Hospital at Westmead, Sydney, NSW, Australia³The Children's Hospital at Westmead, Clinical School, University of Sydney, Sydney, NSW, Australia

Background and objectives: Fetal overnutrition, due to maternal obesity and/or gestational diabetes mellitus (GDM) may "program" the fetus to obesity and metabolic disturbances in later life. Adiposity in early life, independent of birth weight, might predict future disease risk. We investigated the adiposity and growth trajectory of infants born to mothers at risk of GDM, for the first 6 months of life.

Methods: This study is part of a clinical trial comparing two diets during pregnancy on offspring birth weight and pregnancy outcomes. Body composition was measured at birth and at 3 months of age by air-displacement plethysmography. Infants' anthropometry was assessed every month, for the first 6 months. Children more than 1SD weight-for-length (WHZ) are considered "at risk of overweight" and those more than 2SD WHZ are "overweight" (World Health Organization).

Results: Mean maternal (n=139) age and pre-pregnancy BMI were 34.7 + 0.4 years and 25.2 + 0.4 kg/m², respectively. 32 infants (15 males) had body composition measured at both time points. Median percentage [range] fat mass (%FM) at birth and at 3 months was 8.7% [2.5 to 17.6] and 26.2% [19.4 to 32.3] in males and 12.0% [3.8 to 18.7] and 23.0% [14.8 to 33.2] in females. At 3 months of age, 9.5% of the children measured (Nn=43) were at risk of overweight and 2.4% were overweight. At 6 months of age, 9.1% (n=33) were at risk of overweight.

Conclusions: %FM significantly increased in male and female, from birth to 3 months of age (p<0.001). This study provides gender-specific data on growth trajectory and body composition in infants born to mothers at risk of GDM, who are potentially at risk of developing obesity in later life.

Key words: Growth, body composition, GDM, obesity

PO2490**COMPARISON OF FORMULAS FOR ESTIMATING WEIGHT AND HEIGHT WITH ANTHROPOMETRIC REAL MEASURES OF ADULTS AND ELDERLY***C. Freiberg¹, A. Morais¹*¹Centro Universitário São Camilo, Paraíso, Cachoeiro de Itapemirim, Sao Paulo, Brazil

Background and objectives: Body weight and height measures are essential for the construction of indicators that participate in the establishment of nutritional diagnosis, besides being essential for dietary and pharmacological prescription. The accuracy of anthropometric measurements is important for nutritional diagnosis more reliable. The objectives were to evaluate the feasibility of applying the formulas for estimating weight and height with anthropometric measurements obtained directly from adults and the elderly.

Methods: Check measurements of weight and height obtained directly, and compare with the measures set and measures estimated by various formulas checking the feasibility of their applications. We evaluated 169 individuals aged between 18 and 87 years.

Results: When comparing the results of estimated weight with the actual weight in 9.5% of the value estimated weight was exactly equal to the actual weight. Compared the estimated height with the actual height, was found that 5.3% of the population actual height value is exactly equal to the estimated height. The height values were calculated using formulas very close to the actual values, differing 1 or 2 cm. Calculating the standard deviation, the height estimated by the amplitude arm varied more than the other, indicating that the Chumlea's equation is more stable. Regarding the measures referred to in both genders, individuals who were between 50 and 59 years overestimated their weight 2.89 kg, while the others tended to underestimate, highlighting the younger, who underestimated their weight with a difference of 1, 57 kg unless mentioned. Among the means of self-reported height and actual results are statistically identical.

Conclusions: Knowing the accuracy of these equations is critical to verify its applicability in clinical practice. Validation studies can contribute to the correct diagnosis and the most appropriate interventions mainly in individuals unable to be measured and more accurate estimates of weight and height were needed.

Key words: Nutritional assessment

PO2491**MONITORING THE NUTRITIONAL COMPOSITION OF PROCESSED FOODS: THE ARGENTINEAN EXPERIENCE**

L. Allemandi¹, L. Garipe¹, V. Tiscornia¹, N. Samman², V. Schoj¹

¹Fundacion InterAmericana del Corazon-Argentina, Buenos Aires, Argentina

²Universidad de Jujuy, Jujuy, Argentina

Background and objectives: In Argentina, cardiovascular disease causes about 100,000 deaths and 250,000 events every year at a cost of more than one billion dollars. In 2011, the Ministry of Health agreed with the food industry to reduce sodium content in processed foods. Also, a modification in the Codex Alimentarius will decrease TFA to less than 5% of total fat in processed foods by 2014. Our objective is to build an Argentinean food composition database as part of the Global Food Monitoring Group led by The George Institute, Australia in order to have an independent source of nutritional information to monitor food composition changes over time.

Methods: This is a descriptive study to capture a full listing of all processed food products for sale in Argentina. This includes in-store collection of nutritional information from the foods labels of products. Processed foods will be categorized into food groups and food categories for the primary analyses which will compare mean levels of nutrients.

Results: Advanced smartphone technology developed by The George Institute to collect the nutritional information has been piloted and used in our country. Baseline data collection was performed from december 2012 to january 2013. We have collected a total of 1179 products from 12 food groups: bread and bakery products, cereals, cheese, meat and meat products, soups, sauces, canned foods, confectionary, fish and fish products, snacks, sauces, and drinks. For each group we collected information for 33 categories and 188 sub-categories.

Conclusions: The use of standardized methodology in conjunction with a collaborative approach to collect and share data will enable low-cost tracking of processed food composition around the world. This project represents a major step forward in transparently monitoring industry and government commitments to improve the food supply in Argentina.

Key words: Food database, nutritional composition, processed foods

PO2492**LOW WEIGHT FOR AGE ACCORDING TO WHO IN PRETERM NEONATES FROM A HIGH RISK MONITORING PROGRAM "KANGAROO" FROM HOSPITAL UNIVERSITARIO DEL VALLE IN CALI, COLOMBIA**

¹Universidad del Valle, Cali, Colombia

Introduction: Ponderostatural recovery is critical for the premature (PreT) neonate development at risk of stunting and > mortality. Objective: To determine the prevalence of low weight for age (LWA) according to WHO, in very low birth weight PreT (VLBW) at the Hospital Universitario del Valle in Cali, Colombia, and potential associations. Methodology: Prevalence study in 63 PreT of VLBW (<1500 g) from a High Risk Monitoring Program "Kangaroo". Sociodemographic, maternal and neonatal variables were considered. According to WHO, it was considered LWA = >-2 SD. Statistical analysis included prevalence estimation of LWA in PreT and corresponding confidence interval 95%, the estimate of other descriptive measures of interest and association analysis by multiple logistic regression.

Results: In these PreT mean age 23.4 ± 6.2 months, mean birth weight 1132.1 ± 223.6 grams, found a prevalence of 20.6% of LWA to following between 11 and 33 months and male predominance. Association analysis showed > LWA opportunity by origin, education, multiple pregnancies, maternal diseases other than diabetes, hypertension and syphilis, and weight for gestational age. Finally associated factors were desired pregnancy, partner and final height.

Conclusion: Only about 20% of PreT of VLBW (<1500 g) followed between 11 and 33 months, showed LWA, being associated with sociodemographic variables as desired pregnancy and partner and neonatal variables as final height.

PO2493**PREVALENCE OF SARCOPENIA IN YOUNG ADULTS FROM TABASCO MEXICO**

A E. Sierra-Ovando¹, M F. López-Fernández¹, A I. Hernández-Hernández¹, L A. Sánchez-Romero¹, L F. Trujillo-Castillo¹, E. Pichardo-Ontiveros², J C. López-Alvaranga³, X. Formiguera Sala⁴

⁴Institut Català pel Tractament i Recerca de l'Obesitat, Barcelona, España

Background and objectives: Sarcopenia (S), is defined as the degenerative loss of skeletal muscle mass normally occurring during aging. However, there are reports of young adults with muscle loss, even though that S is a late manifestation; its earliest beginnings are probably to occur with a sedentary lifestyle and poor nutrition. The aim of this study was to investigate the prevalence of S in a sample of young adults of Villahermosa (Tabasco, Mexico).

Methods: The study subjects were assessed by bioelectrical impedance (Tanita BC-418) and were administered the IPAQ questionnaire of physical activity. The Presence of Sarcopenia was assessed by measuring the skeletal muscle mass index (SMMI), which is calculated dividing appendicular skeletal muscle mass (ASMM) by height (m²).

Results: 198 subjects were included (24.75% male and 75.25% female) with a mean age of 30.46 ± 10.95 years. Sarcopenia was found in 33.3% of the sample, from which 3.5% presented severe sarcopenia and 29.8% moderate sarcopenia with greater presence in males (81.6% men and 18.4% women). Of the subjects with Sarcopenia, 60.9% had a minor physical activity.

Conclusions: The presence of Sarcopenia is not restricted to geriatric persons as it also occurs in young adults. Therefore, it's necessary to carry out strategies for prevention and timely diagnosis of these conditions in young people, to improve their quality of life and productivity.

Key words: Sarcopenia, aging, young adults.

PO2494**RELATIONSHIP BETWEEN SALTY TASTE ACUITY AND ZINC NUTRITIONAL STATUS IN KOREAN YOUNG ADULTS**

H. Noh¹, H.Y. Paik¹, J. Chung²

¹Department of Food and Nutrition, College of Human Ecology, Seoul National University, Seoul, Korea

²Department of Food and Nutrition, College of Human Ecology, Kyung Hee University, Seoul, Korea

Background and objectives: Zinc nutritional status has been associated with variation in taste perception. In this study, we examined whether salty taste perception is related to zinc nutritional status in young adults.

Methods: 207 free-living healthy young adults aged 20-29yrs were recruited, and salty taste acuity was evaluated by determining salty taste threshold using sensory test. Zinc nutritional status was examined by measuring dietary zinc, serum zinc and the expression level of leukocyte zinc transporters gene.

Results: Among various zinc transporters examined, ZnT1, ZnT6, ZnT9, Zip1, Zip6 and Zip7 were abundantly expressed in the leukocytes. In particular, the level of leukocyte Zip7 mRNA had significantly positive correlation with zinc intake in female ($r=0.23$, $p<0.05$). In male, dietary zinc and serum zinc had no association, but the level of leukocyte ZnT9 mRNA had negative association with salty taste threshold (standardized $\beta=0.048$, $p=0.03$). On the other hand, available zinc intake had negative association with salty taste threshold (standardized $\beta=0.467$, $p=0.04$) in female. Furthermore, the level of leukocyte Zip7 mRNA had negative association with the salty taste threshold (standardized $\beta=0.479$, $p<0.01$), and this relationship was maintained after adjustment for available zinc intake (standardized $\beta=0.414$, $p=0.01$).

Conclusions: Our data shows that zinc nutritional status is associated with salty taste acuity, especially in female. Further, our study results suggest that dietary zinc affect the gene expression of Zip7, which may lead to altered taste perception for salt.

Key words: Salty taste acuity, zinc status

PO2495**ANEMIA AND MICRONUTRIENT STATUS AFTER MICRONUTRIENT POWDER SUPPLEMENTATION AMONG MALNOURISHED AND WELL-NOURISHED CHILDREN IN AN URBAN SLUM OF DHAKA**

M. Mahfuz¹, M. Islam¹, M I. Hossain¹, D. Mondal¹, F. To-fail¹, R. Haque², T. Ahmed¹

¹Centre for Nutrition and Food Security, icddr,b, 68, Shaheed Tajuddin Ahmed Sarani, Mohakhali, Dhaka, Bangladesh

²Centre for Vaccine Sciences, icddr,b, 68, Shaheed Tajuddin Ahmed Sarani, Mohakhali, Dhaka, Bangladesh

Background and objectives: Anemia and micronutrient deficiency is very common among children with undernutrition. This study aimed to assess the effect of daily 2 months micronutrient powder (MNP) supplementation on anemia and micronutrient status of malnourished and well-nourished children in an urban slum of Dhaka, Bangladesh.

Methods: MNP supplementation was provided daily to a total of 392 children aged 6-24 months, including 223 malnourished children (Weight-for-age-z-score, WAZ <-2 sd) and 169 well-nourished children (WAZ >-1 sd). The research staff directly observed the consumption of MNP. Venous blood was collected during enrollment and 5 months after enrollment. Haemoglobin (Hb), serum retinol and serum zinc levels were measured. Anemia was defined as Hb concentration of <11 g/dl and the cut-off values used for vitamin A deficiency and zinc deficiency were serum retinol level of <20 µg/dl and serum zinc concentration of <65 µg/dl.

Results: Anemia prevalence had significantly reduced from 65.1% to 51.7% (p=0.01) in malnourished children after MNP supplementation but no significant change was observed in well-nourished children. Low serum retinol level (<20 µg/dl) was observed 38.8% and 35.5% in malnourished and well-nourished children, respectively, at baseline which then reduced to 36.7% and 30.9% at end-line, respectively. However, serum zinc deficiency (<65 µg/dl) had deteriorated from 15.9% and 14.5% to 31.6% and 21.1% during trial period among mal-nourished and well-nourished children, respectively.

Conclusions: In this study MNP supplementation was more effective in malnourished children in reducing anemia. Vitamin A status had also improved. However, zinc deficiency further deteriorated. Further evaluation is needed for the well-nourished children as because 2 months MNP supplementation may not be optimum for improving their anemia status.

Key words: MNP, malnutrition, children, Bangladesh

PO2496**DEVELOPMENT OF DATA COLLECTION TOOLS TO BE USED DURING FOOD INTAKE STUDIES IN ILLITERATE, LOW-INCOME COMMUNITIES**

H. Schonfeldt^{1,2}, M. Bester^{1,2}

¹Institute of Food, Nutrition & Well-being, University of Pretoria, Pretoria, South Africa

²Department of Animal and Wildlife Science, University of Pretoria, Pretoria, South Africa

Background and objectives: Nationally representative food intake data is needed to determine the effect of the consumption of animal products on human dietary exposure (in terms of both over- and undernutrition), as well as to extrapolate the burden which the industry has on the environment. However, to provide correct data towards the development of policies and programmes specifically aimed at malnutrition in low and very low socio-economic households, intake data specific to each socio-economic group is needed. Due to the complex demographics of the population, highly divergent economic circumstances and low level of literacy amongst lower socio-economic groups, the collection of certain data amongst these groups have proved to be a challenging task for researchers due to a lack of appropriate tools.

Methods: To enable the collection of correct data in low and very low socio-economic groups, specific pictorial tools were developed. To translate product consumed to nutrients ingested, data on actual edible portion of each food portion is required. Physical dissection of the specific foods included in the pictorial tool was dissected into meat and non-meat components. The nutritional contribution of low-cost or wild animal foods, often consumed as an alternative to high-end animal products by these low socio-economic households, was determined.

Results: A pictorial tool was developed based on research conducted on the current eating habits of low socio-economic consumers in South Africa, including the types of animal foods often consumed (including indigenous species such as insects and rodents), preparation techniques employed, and usual portion sizes.

Conclusions: This tool enables researchers to visually question illiterate consumers on what type and quantity of animal foods they consume.

Key words: Animal protein consumption, portion sizes, pictorial research tool

PO2497

A NUTRIENT PERSPECTIVE ON CLIMATE CHANGE AND SUSTAINABLE RED MEAT PRODUCTION AND CONSUMPTION

H. Schonfeldt^{1,2}, I. Rajput^{1,2}

¹Institute of Food, Nutrition and Well-being, University of Pretoria, Pretoria, South Africa

²Department of Animal and Wildlife Science, University of Pretoria, Pretoria, South Africa

Background and objectives: In order to determine the impact of livestock production and the effect of the consumption of animal products on human dietary exposure (in terms of both nutrient and anti-nutrients), as well as to extrapolate the burden which the industry has on the environment (sustainability and green economy), correct intake data is required for the complete and diverse South African population. By uncovering relevant information on the consumption and perceptions of animal-derived protein foods, the relevant industries can be equipped with information to re-align production, processing, policy development as well as consumer education. Towards this aim a study was formulated to investigate the perceptions and utilization of animal product by different socio-economic groups in South Africa.

Methods: Adapted questionnaire-based personal interviews were performed in three different socio-economic groups from 3 of the 9 provinces of South Africa.

Results and Conclusions: Although animal products are consumed by all (from high to low socio-economic groups), the nutritional contribution from certain low-cost animal products such as meat-bones, chicken feet and insects are questionable. Results will be presented and critically discussed.

Key words: Climate change, red meat consumption, sustainability

PO2498

RELATIONS BETWEEN NUTRITION FOR GAME PERFORMANCE IMPROVEMENT AND AROMA FOR FATIGUE REDUCTION DURING SPORTS

K. Kanbe¹, S. Nakata², H. Nakayama², M. Yamamoto³, S. Muto⁴

¹Department of Food and Nutrition, Junior College, Nihon University, Japan

²Tokyo Denki University School of Science and Engineering, Tokyo, Japan

³Tokyo Polytechnic University Faculty of Engineering, Japan

⁴Laboratory of Health Information Science, Kagawa Nutrition University, Japan

Background and objectives: Proper nutritional intake in each game is necessary for good physical performance. It has been reported that fragrance elements of aroma are effective in mental care before games and fatigue recovery after games. We examined the relations between the effect on fatigue reduction by aroma and nutritional intake during exercise aimed to improve game performance.

Methods: A total of 17 male collegiate students from the athletic club participated. Students chose voluntarily their favorite aroma. The bike-riding exercise test was carried out in two ways by smelling a preferable aroma (exercise with aroma) and by not smelling aroma (exercise without aroma). The oxygen intake was measured using a gas mask. The examinees were asked to point the finger at a certain rating of perceived exertion (RPE) during the test. After the experiments, the mood states questionnaire with/without aroma was administered. The food intake frequency method was used by the self-administered questionnaire before the experiments. Respective data with/without aroma was analyzed statistically.

Results: 'Exercise with aroma' test showed significantly low in terms of RPE. Also, in the questionnaire after the experiments, 'Feeling tired' item was significantly different, and 'Fatigue' item was low level. Although only two students reported suitable amount of nutritional intake, seven students showed that the animal protein ratios were high. As for the energy per weight, only 'exercise without aroma' group showed significantly higher ratios in 'bad feeling', 'lack of concentration' and 'fatigue' among energy deficiency group than among the energy sufficiency group.

Conclusions: This study indicated that the use of aroma during exercise eased the fatigue. Glycogen exhaustion causes the decline of athletic ability. Therefore, further research is needed to verify that the combination of proper nutritional intake and aroma usage leads to game performance improvement.

Key words: Aroma, nutrition intake, fatigue reduction, glycogen exhaustion

PO2499**ISSUES IN CHARACTERIZING RESTING ENERGY EXPENDITURE IN OBESITY AND AFTER WEIGHT LOSS**

A. Bosy-Westphal¹, W. Braun², B. Schautz², M.J. Müller²

¹Institut für Ernährungsmedizin, University Hohenheim, Stuttgart, Germany

²Institut für Humanernährung, Christian-Albrechts-University Kiel, Kiel, Germany

Background and objectives: Normalization of resting energy expenditure (REE) for body composition using the 2-compartment model (fat mass, FM; fat-free mass, FFM) may lead to erroneous conclusions when comparing REE in people with a wide range of adiposity as well as before and after substantial weight loss.

Methods: Different methods of REE normalization were compared: (i) normalization for FFM and FM (ii) by the inclusion of %FM as a measure of adiposity and (iii) based on organ and tissue masses. Results were compared between healthy individuals with different degrees of adiposity as well as within subject before and after weight loss.

Results: Normalizing REE from an “REE vs. FFM and FM equation” that (i) was derived in obese participants and applied to lean people or (ii) was derived before weight loss and applied after weight loss leads to the erroneous conclusion of a lower metabolic rate (i) in lean persons and (ii) after weight loss. This is revealed by normalization of REE for organ and tissue masses that was not significantly different between lean and obese or between baseline and after weight loss. We found evidence for an increasing specific metabolic rate of FFM with increasing %FM that was explained by a higher contribution of liver, kidney and heart mass to FFM in obesity. Using “REE vs. FFM and FM equations” specific for different levels of adiposity (%FM) eliminated differences in REE before and after weight loss in women.

Conclusions: Normalization of REE based on FFM and FM may lead to spurious conclusions about metabolic rate in obesity and the phenomenon of weight loss-associated adaptive thermogenesis. Using %FM-specific REE prediction from FFM and FM in kg may improve the normalization of REE when subjects with wide differences in %FM are investigated.

Key words: Body composition, resting energy expenditure, obesity, weight loss

⁹Department of Paediatrics, University of Zaragoza, Zaragoza, Spain

Background and objectives: Multiapproach interventions appear to achieve the most beneficial effects in the treatment of obese adolescents. They include management protocols involving behaviour modifications, family support and lifestyle, requiring the input of multidisciplinary professional teams. Aim of this study was to assess body composition changes after twelve months of a multiapproach therapy including diet, exercise and behavioural modification in obese adolescents. Materials and

Methods: One hundred and one Spanish male and female adolescents aged 13 to 16 years with overweight and obesity, were included in a multicenter intervention study. Anthropometry was assessed by weight, height, BMI and skinfolds. Friedman test was used to compare anthropometric measure-

ments during follow up, and post hoc comparisons with Wilcoxon signed-rank test was conducted with Bonferroni correction applied.

Results: In males, we observed, after one year, significant changes in weight (-4.1 kg), height (+2.1 cm), BMI (-2.9 kg/m²), sum of 6 skinfolds (-25.4 mm), fat free mass (+2.9 %), waist circumference (-11.1 cm) and waist to height ratio (-0.07). In females, there were significant changes fat mass index (-2.2 kg/m²), fat mass percentage (+1.1%), sum of 4 skinfolds (-14.8 mm), hip circumference (-1.9 cm) and waist to hip ratio (-0.06). Changes in weight, height, BMI, sum of 6 skinfolds, fat free mass, waist circumference and waist to height ratio were higher in males than females.

Conclusions: Body composition changes after a multidisciplinary intervention were observed in both genders, but changes were higher in males than in females. Acknowledgements: Funded by Spanish Ministry of Health and Consumption (PI 051080, PI 051579), and GENUD Research Group is funded by European Regional Development (MICINN-FEDER). We gratefully acknowledge all adolescent and their families who participated in the study.

Key words: Body composition, intervention study, fat mass, fat free mass

PO2501

ELECTRIC BIOIMPEDANCE VERSUS FLUID BALANCE METHOD FOR HYDRATION STATUS EVALUATION IN HOSPITALIZED ELDERLY PATIENTS.

T K. Weber¹, B López-Plaza¹, L M. Bermejo¹, S. Palma-Milla¹, A. Lisbona-Catalan¹, C Gómez-Candela¹

¹Clinical Nutrition Department, University Hospital La Paz, La Paz Institute For Health Research (IdiPAZ), Madrid, Spain

Background and objectives: Dehydration is a common condition and frequent cause of hospitalization in older people, being associated with higher mortality and morbidity. The evaluation of those different methods to evaluate the hydration status of elderly people may be important. The study aimed to properly assess hydration status among hospitalized elderly patients by using two different methods electric bioimpedance (BIA) and Fluid Balance (FB).

Methods: Fifty patients aged ≥ 65 years of all departments in a tertiary hospital were included according to admission time. Patients on critical care and renal insufficiency were excluded. 48 to 72 hours after admission, hydration status was measured by BIA according to $\text{Standardized Bioelectromogram}$, allowing patient's classification in: normally hydrated, dehydrated and hyper-hydrated and FB was estimated by counting of all liquids lost and taken in from the body.

Results: The mean age of patients (48% men) was 76.5 \pm 6.5 years. According to BIA 18% (9/50) of patients presented dehydration, 58% (29/50) normal hydration status and 24% (12/50) hyper-hydration. The percentage of patients with negative FB was significantly higher in dehydration group (78%, 7/9) compared with normal hydration (30%, 9/29) and hyper-hydration (20%, 2/12). An association between dehydration status measured by BIA and negative FB has been observed ($p < 0.01$). However, a high percentage of patients without dehydration by BIA presented a negative FB (26.8%, 11/41).

Conclusions: A high percentage of elderly patients had an abnormal hydration status. Despite of the association between BIA and FB method, only negative FB could be considered in clinical practice in order to detect and prevent future dehydration in these patients.

Key words: Dehydration, elderly, bioimpedance, fluid balance

PREVALENCE OF MICRONUTRIENT DEFICIENCIES AND ANTHROPOMETRIC STATUS OF WOMEN AND PRESCHOOL CHILDREN IN RURAL BURKINA FASO

L. Nikiema¹, Y. Martin-Prevel², M. Moursi³, G. Ouedraogo¹, I. Kossivavi-Ayassou², H. Lanou¹, P. Allemand², F. Moura³

¹Institut de Recherche en Sciences de la Santé (IRSS), Ouagadougou, Burkina Faso

²UMR 204 Nutripass, IRD-UM2-UM1, Institut de Recherche pour le Développement, Montpellier, France

³HarvestPlus, IFPRI/CIAT, Washington D.C, USA

Background and objectives: In Burkina Faso, the nutritional situation is characterized by high prevalence of malnutrition and micronutrient deficiencies among women and children, but only scarce data are available. This study aimed at determining the prevalence of anemia, low serum concentration of retinol, iron, ferritin and zinc among mothers and preschool children in two rural provinces of the country.

Methods: A cross-sectional survey was carried out in December 2010 in the two provinces. A representative sample of 240 mothers and their 36-47 month-old children were randomly selected. Anthropometric measurements were performed using WHO procedures. A sub-sample of 90 mothers and 90 children had venous blood sampling. Haemoglobin (Hb) was measured using a Hemocue201 system. After centrifuged, sera were frozen at -20°C until analyses were performed. Ferritin, serum transferrin, CRP and AGP were measured by ELISA

technique. Serum iron content was measured by colorimetric method, serum zinc by atomic absorption and retinol by HPLC system.

Results: Underweight concerned 14.1% [10.9-17.3] of women and 31.3% [25.6-37.0] of children were stunted. The prevalence of anemia (Hb<110 g/l) was 35.7% [28.6-42.8] in women and 72.4% [65.6-79.2] in children, respectively. Low serum iron concentration (<8 µmol/l) concerned 20.1% [14.2-26.1] of women and 53.9% [46.2-61.6] of children. Low body iron stores was detected in 7.6% [3.5-11.6] and 5.1% [1.6-8.6] of women and children, respectively. Prevalence of low ferritin adjusted for inflammation was 3.2% [0.4-6.1] in women and 2.0% [0.0-4.2] in children. Zinc deficiency affected 38.6% [31.3-46.0] of women and 64.3% [57.0-71.7] of children. The prevalence of vitamin A deficiency was 13.3% [8.4-18.3] among women and 33.9% [26.6-41.1] among children.

Conclusions: Micronutrient deficiencies were at a high level in this area, and constantly higher among children than among women. Preventive measures such as micronutrients supplementation or food fortification are needed.

Key words: Malnutrition, anemia, zinc, vitamin A, Africa

PO2503

VITAMIN A, IRON AND ZINC CONTENT OF COMMERCIAL MAIZE MEAL AND BREAD SAMPLED AT HOUSEHOLD LEVEL IN SOUTH AFRICA

P. Van Jaarsveld¹, M. Faber¹, M. Van Stuijvenberg¹

¹Nutritional Intervention Research Unit, Medical Research Council of South Africa, Cape Town, South Africa

Background and objectives: In 2003, a national mandatory food fortification programme was introduced in South Africa. Bread wheat flour and maize meal are fortified with various micronutrients, including vitamin A, iron and zinc. The aim of this study was to determine the vitamin A, iron and zinc content of maize meal and bread sampled at household level in two urban and two rural sites.

Methods: Maize meal (250 g) and/or supermarket/local shop bread (three inner slices) were collected from 50 randomly selected households from each study site. Maize meal samples were reduced to 10 composite samples per site, each consisting of five randomly selected samples. Bread samples were composited similarly; bread slices were kept intact; one composite sample consisted of 15 slices; over all, eight composite samples were obtained for both brown and white bread. Maize meal and bread samples were analysed by the Southern African Grain Laboratory for vitamin A, iron, zinc and moisture content.

Results: Based on 12.5% moisture, 100 g uncooked maize meal contained 105.7 to 183.3 µg RAE vitamin A, 3.0 to 4.2 mg iron and 1.8 to 2.1 mg zinc across the four study sites; representing 56-97% of the minimum fortification level as per legislation for vitamin A, 76-108% for iron and 89-100% for zinc. Mean content of brown bread, per 100 g and based on 39% moisture, represented 57%, 197% and 167% of the minimum fortification level for vitamin A, iron and zinc, respectively; white bread represented 89%, 222% and 207% for vitamin A, iron and zinc, respectively.

Conclusions: Vitamin A, iron and zinc content in uncooked fortified maize meal sampled at household level was lower than the legislated requirement; bread vitamin A content was lower, and iron and zinc content higher than the legislated requirement.

Key words: Maize meal, bread, micronutrient content

PO2504

NUTRITIONAL INTEREST OF NA, K, CA, MG, FE, MN, CU, ZN, CR AND MO LEVELS IN DARK BEERS

C. Rubio¹, A. Ravelo¹, A J. Gutiérrez¹, D. González Weller¹, A. Hardisson¹

¹Toxicology Department, University of La Laguna, La Laguna, Santa Cruz de Tenerife, Spain

Background and objectives: Dark beer is a type of German lager with a strong flavour and dark in colour. Spain was the fourth largest beer producer in the European Union in 2010. The objectives of this study were to determine the concentrations of Na, K, Ca, Mg, Fe, Mn, Cu, Zn, Cr and Mo in dark beers and also to evaluate the contribution of moderate consumption of dark beers to the recommended daily intakes (RDI) set for the Spanish adult population.

Methods: 28 samples of dark beers commercialized in Tenerife were analyzed. Samples were degassed with ultrasounds (5 min) and placed in porous porcelain crucibles (25 ml). Subsequently, samples were passed through a water bath (100°C/30 min), heater (80°C/24 h) and muffle furnace (±450°C/48 h). The obtained ashes were diluted with 1.5% HNO₃ to a volume of 50 ml. Metal determination was performed by atomic emission spectroscopy with inductively coupled plasma (ICP-AES).

Results: The metal mean values were: 67.92 mg/l of Na, 342.25 mg/l of K, 54.81 mg/l of Ca, 86.51 mg/l of Mg; 0.187 mg/l of Fe, 0.157 mg/l of Mn, 0.229 mg/l of Cu, 0.093 mg/l of Zn, 0.011 mg/l of Cr and 0.011 mg/l of Mo. The estimation of the contribution of moderate dark beer consumption (330 ml for women and 660 ml for men) to the RDIs revealed the following data: Na (1.49 - 2.99%), K (3.64 - 7.29%), Ca (2.01 - 4.02%), Mg (9.52 - 16.31%), Fe (0.34 - 1.37%), Mn (2.88 - 4.51%), Cu

(6.87 - 13.74%), Zn (0.44 - 0.65%), Cr (14.52 - 20.74%) and Mo (8.07 - 16.13%) for women and men, respectively.

Conclusions: Moderate consumption of black beer contributes significantly to the Cr, Mg, Mo and Cu daily dietary recommendations.

Key words: Dark beer, metals, RDI, ICP-AES

PO2505

ESSENTIAL METALS AND TRACE ELEMENTS IN YOGURTS. NUTRITIONAL EVALUATION.

C. Rubio¹, G. Luis¹, C. Revert¹, Á J. Gutiérrez¹, C. Hernández Sánchez¹, D. González Weller¹, A. Hardisson¹

¹Toxicology Department, Faculty of Medicine, University of La Laguna, La Laguna, Santa Cruz de Tenerife, Spain

Background and objectives: Milk and dairy products are a group of foods widely consumed by the population, contributing to the intake of essential elements, mainly Ca. The objectives of this study were to determine the concentrations of Na, K, Ca, Mg, Cu, Fe, Mn, Zn, Cr and Mo in two types of yogurt (plain and flavoured) marketed in Tenerife (Spain) and also to evaluate the contribution of the intake of a yogurt/day (125 g) to the established RDI for adults.

Methods: 36 samples of two types of yogurt (plain and flavoured) were purchased in supermarkets in Tenerife and analyzed. 20 g were weighed in a porous porcelain crucible, dried in a heater (70Å°C/72 h) then in a muffle oven (450Å°C/48 h). The obtained ashes were dissolved in HNO₃ at 1.5% to a volume of 25 ml. Metals were analyzed by the ICP-AES technique (inductively coupled plasma atomic emission spectroscopy).

Results: The mean concentrations in the yogurts were: 454.5 mg Na/kg, 1,101 mg K/kg, 1,018 mg Ca/kg, 115.1 mg Mg/kg, 0.268 mg Cu/kg, 0.327 mg Fe/kg, 0.023 mg Mn/kg, 2.785 mg Zn/kg, 0.021 mg Cr/kg and 0.035 mg Mo/kg. The consumption of 125 g of yogurt/day contributes to 14.14% of the RDA of Ca in women, 10.48% of the RDA of Cr in adult males, 9.71% of the RDA of Mo in adults and 4.97% of the Zn RDA for adult males, among others.

Conclusions: Daily consumption of yogurt contributes to the dietary intakes of essential metals and trace elements.

Key words: Inductively coupled plasma spectrometry, intake, metals, yogurt

COMPARISON OF EQUATIONS TO PREDICT BODY WEIGHT AMONG ADULTS IN A TERTIARY HOSPITAL

E. Rabito¹, T. Oliveira¹, A. Marcadenti², B S. Alves², D. Ferreira², S P. Souza²

¹Department of Nutrition, Universidade Federal de Ciências da Saúde de Porto Alegre, Porto Alegre, Brazil

²Division of Nutrition, Hospital Nossa Senhora Conceição, Porto Alegre, Brazil

Background and objectives: Body weight is very important to monitoring the nutritional status during hospitalization but cannot always be detected by conventional methods; therefore, researchers have developed equations to estimate it. The aim of this study was to evaluate the concordance of equations for estimating weight.

Methods: Cross-sectional study conducted among 200 inpatients, aged 18 to 59 years, both sexes. Patients were stratified in two groups according to gender and there were evaluated five equations to estimate body weight: two by Chumlea and three by Rabito. The concordance between all equations and the weight detected by scales was performed using Bland and Altman and intraclass correlation coefficient (ICC). Student's t test was used for comparisons.

Results: Mean age among men was 46.8 years and among women 43.1 years ($p < 0.01$). Chumlea equations for weight prediction among Caucasians (which uses arm circumference and knee height) showed a concordance interval -23.5 to 1.4 kg (ICC= 0,75) among men and concordance interval -17.2 to 16.6 kg (ICC= 0,82) among women. Equations developed for black people showed a concordance interval -25.6 to 12.2 kg (ICC= 0,71) among men and a concordance interval -18.3 to 16.7 kg (ICC= 0,83) among women. Rabito's equations (which uses arm, calf and abdominal circumferences plus sub scapular skin fold) showed ICC= 0,91 (concordance interval -12.9 to 8.7 kg); ICC= 0,88 (concordance interval -10.1 to 16,8 kg). Finally, the Rabito equation which uses three circumferences and gender showed ICC= 0,91 (concordance interval -12.4 to 10.1 kg; ICC= 0,90 (concordance interval -13.7 to 12.5 kg), for men and women, respectively.

Conclusions: Although the equations developed by Rabito showed a better agreement when compared with the weight detected by scales among adults inpatients, the difficulty to obtain anthropometric measurements should be considered by professionals to choose an equation to be applied.

Key words: Weight, equations, adults

PO2507**MICRONUTRIENTS ADEQUACY AND FOOD PATTERN OF INDONESIAN YOUNG CHILDREN***H. Hardinsyah¹, T. Tecco¹, L. Amalia¹*

¹Food and Nutrition Society of Indonesia, and Department of Community Nutrition, Bogor Agricultural University, Kampus IPB, Jl Raya Darmaga, Bogor, Indonesia

Background and objectives: The basic health survey called Riskesdas 2010 is the first nation-wide survey that collected individual food intake data in Indonesia, but no one has analyzed the data for micronutrient adequacy and food pattern of young children – a vulnerable group. Besides, micronutrients intake information from large nation-wide survey in Asian developing countries is very limited. This study analyzes micronutrients adequacy and food pattern of young children aged 1-3 yrs (YC) of Indonesia.

Methods: The electronic files of the Riskesdas 2010 data were used and analyzed. The cleaned data consisted of 1868 YC covering 33 provinces. The food data were collected using a 24-hour recall method. Calcium, phosphorus, iron, zinc, and vitamin A, B1, B9, and C intake were analyzed by using food composition tables. The food patterns were analyzed based on quantity and participation rate of 10 food groups consumed.

Results: Among the micronutrients analyzed, the mean adequacy level less than 70% requirement was zinc, iron, calcium and folic acid. This occurred until the third economic quintile. The higher the father education and family economic levels the higher the micronutrient adequacy of YC. Each of micronutrients adequacy levels among stunted and among rural YC was lower compared to normal and urban YC. The mean intake of cereals, tubers, bean, meat, eggs, fish, vegetables, fruit, milks, street foods were 278.2, 6.1, 18.5, 8.4, 21.9, 28.7, 48.9, 11.0, 37.9 and 37.1 g, respectively. All the food groups except cereals had a low participation rate. The stunted YC consumed fewer amounts of cereals, fruit, bean, milk and animal foods.

Conclusions: Most Indonesian YC especially from middle-low socioeconomic level had low intake of zinc, iron, calcium and folic acid, and more likely suffering from stunting. There is a need to increase the intake of foods rich in these micronutrients.

Key words: Micronutrient, food pattern, stunting, children

PO2508**CORRELATION BETWEEN 24-HOUR AND SPOT/VOID URINE SAMPLES FOR THE PURPOSE OF POPULATION SALT INTAKE ASSESSMENT***P. Jeffery¹, M A. Land^{2,3}, L. Riddell¹, J. Shaw⁴, J. Webster^{2,3}, J. Chalmers³, W. Smith⁵, V. Flood⁶, M. Woodward³, B. Neal^{2,3}, C. Nowson¹*

¹Deakin University, Melbourne, Australia

²The University of Sydney, Sydney, Australia

³The George Institute for Global Health, Sydney, Australia

⁴Baker IDI Heart and Diabetes Institute, Melbourne, Australia

⁵New South Wales Health, Sydney, Australia

⁶The University of Wollongong, Wollongong, Australia

Background and objectives: Spot urine samples have been investigated for population salt intake assessment with the sample standardised to 24 hours by measuring spot urinary creatinine, however diurnal variation affects results. The objective of this study was to assess spot and void urine samples collected after the evening meal and before bedtime, as these collection times have not previously been assessed for estimating population salt intake.

Methods: 605 adults living in Australia were enrolled, with a mean age of 56.5 ± 12.1 (SD) years (range 21 to 78) and 54% women. Participants provided a 24-hour urine sample and as part of the 24-hour sample, either: 1) a urine sample consisting of one complete void of the bladder, collected in the evening following a main meal (EVENINGMEAL), or 2) a spot sample collected immediately before bedtime (BEDTIME).

Results: Mean sodium excretion was 137 ± 57 mmol/day. Pearson's correlation, comparing the measured 24-hour urinary sodium versus the sodium-to-creatinine ratio of the spot/void sample was: $r=0.48$ ($p<0.0001$) (EVENINGMEAL), and $r=0.51$ ($p<0.0001$) (BEDTIME). This compares with the results of Mann and Gerber (2010) who found correlations of: $r=-0.01$ ($p=0.97$) (random collection time), $r=0.14$ ($p=0.42$) (morning collection), and $r=0.67$ ($p<0.001$) (evening collection prior to meal).

Conclusions: Significant correlations were found between measured 24-hour urinary sodium and spot/void sodium-to-creatinine ratio for urine samples collected after the evening meal and before bedtime. Further analysis is required to determine if these correlations at an individual level translate to estimation of population salt intake using predictive equations.

Key words: Sodium, salt, spot, assessment, population Mann, SJ & Gerber, LM 2010, 'Estimation of 24-hour sodium excretion from spot urine samples', Journal Of Clinical Hypertension (Greenwich,Conn.), vol.12, no.3, pp.174-80.

PO2509**TIME SINCE VITAMIN A SUPPLEMENTATION (VAS), POLIO VACCINE DISTRIBUTION AND OTHER FACTORS AFFECT THE VALIDITY OF VAS POST-EVENT COVERAGE ASSESSMENT**

C T. Ouedraogo^{1,2,3}, E. Becquey^{2,3}, S Y. Hess³, L. Prince⁴, N. Rouamba¹, J.B. Ouedraogo¹, S.A. Vosti⁴, K.H. Brown^{2,3}

¹Direction Régionale de l'Ouest, Institut de Recherche en Sciences de la Santé, Bobo-Dioulasso, Burkina Faso

²Helen Keller International, USA

³Department of Nutrition, University of California, Davis, USA

⁴Department of Agricultural and Resource Economics, University of California, Davis, USA

Background and objectives: Information on coverage of high-dose VAS programs relies on administrative tally sheets or post-event coverage surveys, but the validity of these reports has rarely been assessed. In a longitudinal study, we investigated factors related to false positive VAS survey responses.

Methods: 6,365 parents of children aged 6-30 mo participated in a longitudinal study, during which two semi-annual VAS campaigns occurred. Every 4 wks, caregivers were shown a photo of VAS capsules and asked if their child received VAS in the previous 4 wks. After 6 mo, a photo of the locally administered oral polio vaccine (OPV) was also shown. A positive response for VAS was considered valid during the 4 wks following each VAS campaign. Positive responses during the remaining periods were considered false positives as VAS was not available elsewhere.

Results: During 38,958 interviews that took place >4 wks after a VAS campaign, 13.6% reported that their child received VAS (false positive). The odds of false positives increased with shorter time since the last VAS campaign (OR=8.00 if interview was 4-6 wks from previous VAS campaign compared to >3 mo; $p<0.0001$); when OPV were distributed in the reporting period (OR=3.46; $p<0.0001$); when no photo of OPV was shown (OR=1.28; $p<0.0001$) and when the interview took place earlier in the longitudinal study ($p<0.0001$). Other factors associated with false positives included the relationship of respondent to the child, the age of the child, place of residence, ethnicity, mother's occupation (all $p<0.0001$) and mother's marital status ($p<0.0042$).

Conclusions: Post-event VAS coverage surveys should be scheduled as soon as possible following VAS campaigns, and pictures should be shown of both VAS and any oral vaccines distributed during the same period.

Key words: Burkina Faso, vitamin A supplementation, survey

PO2510**VALIDITY AND RELIABILITY OF BIOELECTRICAL IMPEDANCE ANALYSIS TO ESTIMATE BODY FAT COMPARED TO AIR DISPLACEMENT PLETHYSMOGRAPHY AND DUAL-ENERGY X-RAY ABSORPTIOMETRY**

C. Conlon¹, M. Ingram¹, D. Walsh², P. von Hurst¹, R. Kruger¹, W. Stonehouse¹

¹Institute of Food, Nutrition and Human Health, Massey University, Auckland, New Zealand

²Institute of Information & Mathematical Sciences, Massey University, Auckland, New Zealand

Background and objectives: Body fat percentage (BF%) is most accurately predicted using air displacement plethysmography. Dual X-ray Absorptiometry (DXA) and Bio-Impedance Analyser (BIA) also predict BF%, but have not been validated against air displacement plethysmography in a large sample of healthy adults. The objective was to assess the validity of BIA and DXA for assessing BF% against air displacement plethysmography, and to test the repeatability of each method.

Methods: BF% of 164 adults (18-70 y) was assessed twice within 5 days using air displacement plethysmography, DXA and BIA. Validity was determined by comparing methods (t-test), Pearson's correlations, linear regression and method of triads. Repeatability was assessed by Pearson's correlations and comparing first and second measurements.

Results: Overall, there was a good relationship between BIA and air displacement plethysmography ($r^2=0.88$). Mean BF% difference for air displacement plethysmography - BIA was 2.04% [95% CI 1.68-2.40]. Half of BIA measurements ranged from 4.6 below to 0.4 above air displacement plethysmography (median 2.00; 25th, 75th percentile: -0.4, 4.6). Mean BF% difference for air displacement plethysmography - DXA was 0.39% [95% CI 0.02-0.77]. DXA BF% from 20% - 40% had a good relationship with air displacement plethysmography ($r^2=0.78$, intercept=-0.02, slope=1.03), but BF% <20 and >40 were lower and higher than air displacement plethysmography, respectively. Method of triads showed strong correlations between both BIA and DXA and the 'truth' (validity coefficient =0.967 and 0.974, respectively). For repeatability, within-subject correlations were strong for all methods (air displacement plethysmography 0.9898; DXA 0.9951; BIA 0.9953). Analysis of differences between visits show most were <1%, but up to 5.6% (air displacement plethysmography).

Conclusions: On average, air displacement plethysmography BF% can be predicted from BIA readings by adding 2%. DXA compares well to air displacement plethysmography from 20-40% body fat, but underestimates BF% <20 and overestimates >40.

Key words: Body fat, air displacement plethysmography

PO2511**NUTRITIONAL STATUS AND DIETARY INTAKE IN CHILDREN WITH SICKLE CELL DISEASE**

P. Mataratzis^{1,2}, F. Bezerra^{1,2}, D. Lino^{1,2}, M. Citelli^{1,2}, A. Freitas^{1,2}, K. Souza^{1,2}, J. Valle^{1,2}, C. Cople-Rodrigues^{1,2}

¹Institute of Nutrition, State University of Rio de Janeiro, Rio de Janeiro, Brazil

²Reference Center on Nutritional Surveillance of Hemoglobinopathies (CENUTHEM), Nutrition in Hematology Clinic, Pedro Ernesto's Hospital, Rio de Janeiro, Brazil

Background and objectives: Children with sickle cell disease (SCD) homozygous type (SS) usually present poor nutritional status due decreased appetite, inadequate dietary intake and increased energy expenditure. The goal was to evaluate the associations between nutritional status and dietary intake.

Methods: Children (2-5 y) with SCD-SS from Rio de Janeiro participated in the study. Age and gender-specific Z-scores for body mass index (BMI), weight, height and weight/height and adequacy for mid-upper arm circumference (MUAC), triceps skinfold and mid arm muscle circumference (MAMC) were determined. Dietary intake was evaluated by two 24-hour recall to assess estimated energy intake (EEI), carbohydrate, protein, total fat, calcium, phosphorus and magnesium.

Results: 40 children were evaluated (65% male), 15% were at risk of overweight and 2.5% presented overweight. Height-for-age and weight-for-age Z-scores were low in 12.5% and 2.5%, respectively. Mean EEI was 1399 ± 414 kcal/d provided from carbohydrate (58%), protein (15%) and total fat (27%). Mean total fat intake was low in 72% children under 3 y, according to DRI. EEI was associated with adequacies of MUAC ($r=0.41$, $p<0.008$) and MAMC ($r=0.38$, $p<0.017$), weight-for-age ($r=0.40$, $p<0.011$) and height-for-age ($r=0.32$, $p<0.046$) Z-scores. Carbohydrate, protein and total fat intake were correlated with adequacies of MUAC ($r>0.34$, $p<0.032$) and MAMC ($r>0.33$, $p<0.038$). Carbohydrate intake was also associated with weight-for-age ($r=0.41$, $p<0.009$) and height-for-age ($r=0.37$, $p<0.020$) Z-scores. Protein intake was associated with weight-for-age ($r=0.40$, $p<0.011$) and weight-for-height ($r=0.41$, $p<0.024$) Z-scores. Total fat intake was associated with triceps skinfold's adequacy ($r=0.37$, $p<0.019$). Calcium intake was below DRI in 78% of the children. Calcium and phosphorus intake were correlated with adequacies of MUAC ($r>0.44$, $p<0.005$) and MAMC ($r>0.54$, $p<0.000$), BMI-for-age ($r>0.49$, $p<0.001$), weight-for-age ($r>0.60$, $p<0.000$), height-for-age ($r>0.42$, $p<0.005$) and weight-for-height ($r>0.51$, $p<0.004$) Z-scores.

Conclusions: Adequate dietary intake was associated with better nutritional status. Nutritional following is necessary to improve nutritional status in SCD-SS children.

Key words: Sickle-cell-disease, dietary intake, nutritional status

PO2512**OSMOLALITY OF 50 BEVERAGES THAT ARE COMMERCIALLY AVAILABLE IN SAN FRANCISCO**

J. Stookey¹, J. Hamer¹, V. Ng², A. Higa²

¹Children's Hospital Oakland Research Institute, Oakland, USA

²Children's Hospital & Research Center Oakland, Oakland, USA

Background and objectives: Beverage osmolality (solute concentration) is a key determinant of a beverage's absorption and impact on cell hydration and metabolism. Food composition tables, diet analysis software, and beverage labels do not report beverage osmolality.

Methods: This study described the osmolality of 50 beverages available for purchase at supermarkets in San Francisco, USA. Beverage osmolality was measured by freezing-point depression osmometer at room temperature. Beverage pH was measured by pH meter. Beverages with an osmolality above the normal concentration of blood and threshold for cell shrinkage-stimulated anti-diuretic hormone release (ADH) (280 mmol/kg) were distinguished from those below this threshold.

Results: Beverage osmolality ranged from 0 to 1130 mmol/kg. The majority (70%) of beverages sampled had an osmolality above 280 mmol/kg.

Conclusions: The majority of beverages sampled had an osmolality over the threshold for ADH release. Further work is needed to pursue the implications of beverage osmolality for consumers.

Key words: Beverage, osmolality, hydration, food composition tables

PO2513**HOSPITAL MALNUTRITION, PREVALENCE AND ECONOMIC IMPACT**

G. Lobo Tamer¹, A. Pérez de la Cruz¹, D. Ruiz López², A. Fernández Valdivia¹, A M. Trigo Fonta¹, M^a J. Romero Capilla¹, C. Caro Morente¹

¹Hospital Universitario Virgen de las Nieves, Granada, Spain

²Departamento de Nutrición y Bromatología, Universidad de Granada, Granada, Spain

Background and objectives: Among the diseases caused by a lack of nutritional content, due to the impact and the effects it produces, stands out the malnutrition. In the last few years, malnutrition acquired a special significance within the hospital environment and it is known now as an entity called 'Hospital

malnutrition'. Our objectives were (i) to determine the prevalence and incidence of malnutrition in our area, quantifying the costs they impose; (ii) to analyze the connection between hospital malnutrition, average stay (EM) and premature reentry.

Methods: We carried a cohort study in order to assess the nutritional status of patients admitted to a hospital in third level. To all the patients, selected at random, a nutritional assessment protocol was applied in order to determine the weight, height, arm circumference, skinfold thickness, and serum concentrations of albumin, transferrin and prealbumin. The quantification of the costs included drugs, diet (basal, therapeutic and artificial), hospital stay and costs according to diagnosis-related groups (DRGs).

Results: We included 817 subjects (average age 50.9 ± 18.5 years), males accounted for 62.9%, and women for 37.1%. 45.9% of subjects (n=375) suffered from malnutrition. Seven days later, the prevalence of malnutrition was 58.7%; those patients that were admitted already malnourished suffered a deterioration of the 59.9% on their nutritional status in comparison to their baseline. Males were the most affected. There was an increase in costs related to malnutrition in association with the length of hospital stay (68.04% more) and use of medications. The average stay (EM) and premature readmission rate were higher in subjects admitted in the hospital with malnutrition.

Conclusions: The high prevalence and the impact of malnutrition require the proposition of mechanisms that may allow us to reveal their true reach and to develop the necessary programs to its solution.

Key words: Undernutrition, prevalence, costs

PO2514

DIETARY DIVERSITY IS A GOOD INDICATOR OF MICRONUTRIENT INTAKE AMONG KENYAN WOMEN IRRESPECTIVE OF SEASON

S. Ngala¹, M. Tembo¹, A. Mwangi², F. Kok¹, I. Brouwer¹

¹Division of Human Nutrition, Wageningen University, Wageningen, The Netherlands

²Department of Food Science, Nutrition and Technology, Nairobi, Kenya

Background and objectives: Food seasonality has been shown to affect dietary diversity and nutrient adequacy, however, the direction of this effect and impact on the association between diet variety and adequacy is not known. To ensure that dietary diversity can be used as indicator of micronutrient adequacy irrespective of season, we examined the seasonal variations in dietary diversity and micronutrient adequacy, and their association among Kenyan women of reproductive age.

Methods: We used repeated non-consecutive 24 hr-recalls during post-harvest (period 1, Oct, 2007, n=75) pre-harvest (period 2, April, 2008, n=205) and post-harvest (period 3, Oct,

2008, n=187) seasons, constructing dietary diversity scores (DDS) based on 13 food groups with minimum intake of 15 g and calculated mean probability of adequacy (MPA) for 11 micronutrients. Correlations and regression analysis tested the association between DDS and MPA and effects of season on this association. Sensitivity/specificity analysis detected low and high nutrient adequacy.

Results: DDS ranged from 4.3 ± 1.2 in period 1 to 3.1 ± 1.2 in period 3, indicating a low diverse diet mainly based on starchy staples with little or no organ meat and fish. MPA ranged from 0.50 ± 0.06 in period 1 to 0.24 ± 0.05 , period 3. DDS and MPA were significantly associated in all periods, highest association in period 3 ($r=0.54$). A cut-off of DDS of 3 maximized sensitivity/specificity in all periods, detecting low adequacy (MPA<40%).

Conclusions: DDS and MPA are sensitive to seasonal and annual fluctuations, but seasonality does not affect their association. DDS can be used as simple indicator for micronutrient adequacy irrespective of season.

Key words: Dietary diversity score, nutrient adequacy, women, season

PO2515

VITAMIN K2 ALTERS BONE METABOLISM MARKERS IN HIGH FAT DIET-INDUCED OBESE MICE

C. Sohn¹, M. Kim¹, W. Na¹, E. Kim¹, Y. Jeong¹, O. Kim²

¹Department of Food & Nutrition/Wonkwang University, Iksan, Republic of Korea

²Center for Animal Resources Development/Wonkwang University, Iksan, Republic of Korea

Background and objectives: There are several reports that obesity is a risk factor for osteoporosis. Vitamin K is essential for α -carboxylation of certain glutamic acid residues of vitamin K-dependent proteins. More recently, it became apparent that vitamin K can increase bone mineralization and decrease bone resorption in in vitro studies. The aim of this study was to examine the effects of menaquinone supplementation on prevention of bone loss in high fat diet-induced obese model.

Methods: A total of 21 four-week-old C57BL/6J male mice were divided into three groups: the 10% kcal fat control diet group (CD, n=7), the 45% kcal fat diet group (HFD, n=7), and 45% kcal fat with 200 mg/1000 g menaquinone-4 (vitamin K2) diet group (HFD+vitamin K2, n=7) for 12 weeks. Serum levels of bone metabolism markers, including osteoprotegerin (OPG), osteocalcin, and receptor activator of nuclear factor kappa-B ligand (RANKL) and bone mineral density were measured.

Results: Serum levels of osteocalcin in the HFD+K2 group (51.01 ± 7.33 ng/ml) was higher than those of the HFD group (41.84 ± 1.524 ng/ml). Serum OPG of CD group, HFD group,

and HFD+K2 group were 1.47 ± 0.42 ng/ml, 2.31 ± 0.31 ng/ml and 2.90 ± 0.11 ng/ml ($p < 0.05$), respectively. Serum RANKL of HFD group (0.40 ± 0.060 ng/ml) was significantly higher than the HFD+K2 group (0.21 ± 0.03 ng/ml) ($p < 0.05$). Moreover, both the CD and HFD groups had a significantly higher serum RANKL to OPG ratio compared to HFD+K2 group ($p < 0.05$). BMD of HFD+K2 group was higher than the other groups.

Conclusions: Present study demonstrates that vitamin K2 supplementation had favorable effect on bone mineralization and increased osteoblast over osteoclast activity in mice fed a fat diet. Our findings support a potential beneficial effect for vitamin K2 on reduction of osteoporosis risk in obese mice.

Key words: Menaquinone, bone mineral density, osteocalcin

PO2516

MEASUREMENT OF ENERGY REQUIREMENT BY HEART RATE METHOD AND PWC170 FOR YOUNG ACTIVE AND SEDENTARY WOMEN

M. Chopra¹, A. Siddhu

¹Lady Irwin College, Delhi University, Delhi, India

Background and objectives: The energy expenditure of individuals and groups are of vital interest to nutritionists for policy, therapeutic and research purposes. Heart rate monitoring with individual calibration has been advocated for assessing energy expenditure in field studies and has been compared with the 'gold standard' techniques of doubly labelled water and indirect calorimetry. The broad objective was to determine the energy requirements by heart rate method and Physical Work Capacity (PWC170) for young active and sedentary women.

Methods: A cross-sectional study on 30 collegiate young women (18-23 years) was conducted. Young active women (Group A) ($n=15$) and age matched sedentary women (Group S) ($n=15$) were selected. Group A selection was based on an inclusion criterion. Institutional ethical clearance was obtained. Data was collected on general information, anthropometry, blood pressure, body composition, PWC170, HR-VO2 relationship, dietary and physical activity to compute energy requirements.

Results: Mean total daily energy expenditure (TDEE) by factorial method for Group A was 2256 ± 246 Kcal and for Group S was 1772 ± 163 Kcal. Mean TDEE by heart rate method of Group A was 1952 ± 68 Kcal and of Group S was 1579 ± 116 Kcal. TDEE by factorial method gave nearly 16% higher values ($p < 0.05$) for Group A and 12% higher values ($p < 0.05$) for Group S than the heart rate method. PAL for Group A was nearly 32% higher as compared to Group S. Mean PWC170 values for Group A and Group S were 94.8 ± 6.9 and 93.5 ± 13.9 watts respectively.

Conclusions: The heart rate technique is a useful tool for computing energy requirement of active groups because of its

simplicity and potential use in free living conditions. More research is needed to measure TDEE on India's growing sedentary population.

Key words: Energy requirement, heart rate method, PWC170, factorial method, TDEE

PO2517

PERCEPTION OF CURRENT BODY SIZE OF RESTAURANT'S WORKERS IN RIO DE JANEIRO: BRAZIL

T W G. Guedes¹, O B. Aguiar¹, F B. Kraemer¹, M J M. Fonseca²

¹Department of Applied Nutrition, State University of Rio de Janeiro, Rio de Janeiro, Brazil

²Department of Epidemiology, National School of Public Health, Brazil

Background and objectives: Current body size (CBS) refers to a picture that someone has in mind about body size, image, and shape. Our objective was to analyze the perception of CBS in relation to body size and shape as to be normal, real and ideal using informed and measured weight and height and the drawings scale of silhouettes.

Methods: A sectional study with 272 workers, 37 ± 11 years (57% men), in seven restaurants of Rio de Janeiro State, Brazil. The Stunkard's figure rating scale was used for measuring the perception of CBS; height and weight were self-reported and measured by trained interviewers; nutritional state was calculated by BMI. For comparisons between sexes the Mann-Whitney test was employed for $p < 0.05$.

Results: In the evaluation of regular diet, 73% informed to be unsatisfied with the composition and regularity of feeding. The referred BMI classified as normal weight and overweight between 49.3% to 50.7% for men and 40% to 60% for women, respectively. Measured BMI positioned men from 40.3% to 59.7%, and women from 20.9% to 79.1%, as normal weight and overweight, respectively. Regarding satisfaction with BMI, 43% of men and 14% of women reported to be satisfied, and 76% of women reported the wish to reduce silhouette. When CBS perception is compared to measured BMI, 26.3% of men and 15% of women see themselves as how they really wanted to be on the rating scale. Women showed a greater overweight prevalence as compared to men ($U=259438.91$; $p=0.0001$).

Conclusions: The majority of workers reported to be dissatisfied with CBS and diet, mainly women who expressed a desire to have a different silhouette. Emphasis must be taken in CBS approach for a individualized practice of health professionals.

Key words: Obesity, body image, nutritional status

PO2518**DEVELOPMENT AND VALIDATION OF A COMPUTER-NUTRITION CALCULATION (CNC) PROGRAM BASED ON KOREAN FOOD BALANCE PAGODA***S.H. Lee¹, H.J. Lim¹, J.L. Kim¹*

¹Center for Health Promotion, Samsung Medical Center, Seoul, Republic of Korea

Background and objectives: This study was performed to evaluate the validity of a computer-nutrition calculation (CNC) program based on Korean Food Balance Pagoda, which is being used at the Samsung Medical Center (SMC) in Seoul.

Methods: CNC was developed to calculate the number of representative nutrient value of the food groups. 136 participants (72 males, 64 females) were recruited from participants at the health promotion center of SMC. Daily dietary intakes were interviewed using 24 hour recall method and CNC. Dietary intakes were calculated with Can-pro 3.0 (2005, Korean Nutrition Society). Pearson's correlations were used to identify the relationship between 24 hour recall method and CNC.

Results: The Pearson's correlation coefficients for nutrients ranged from 0.27 (vitamin A) to 0.94 (energy) with a mean of 0.44. The kappa value ranged from 0.15 (vitamin C) to 0.57 (protein) with a mean of 0.35. More than 51.3% of the subjects were classified into the same quartiles.

Conclusions: Therefore, our CNC program is considered a briefly proper method to assess nutrient intakes in healthy Korean adults. It was expected that the CNC program can be useful for nutritional counseling.

Key words: Validation, Korean Food Balance Pagoda

PO2519**NUTRITIONAL ASSESSMENT BY ANTHROPOMETRY, FROM THE USERS OF THE "BOM PRATO" PROJECT***A. Murakami Y Cruces¹, J. Almeida dos Santos¹, M Y. de Camargo¹, T. Sandoval¹, C. Freiberg¹*

¹Centro Universitário São Camilo, Ipiranga, São Paulo, Brazil

Background and objectives: To face the hunger and malnutrition problem in the low income population in Brazil, the Government of the State of São Paulo, aligned with the actions of the "Fome Zero" (Zero Hunger) Program, has created initiatives such as "Bom Prato" (Good Meal) Project, to offer complete, balanced and high-quality meals to low income families (elderly, unemployed, underemployed, homeless and itinerant). In spite of having a low cost (about US\$ 0,50), the meals

have a high caloric value (400 kcal for breakfast and 1200 kcal for lunch). Our objective was to assess the nutritional status of "Bom Prato" Project users by anthropometry.

Methods: 315 people between 19 and 59 years old, who reported going to the restaurant at least three times a week, have been evaluated by measures on weight, height, waist and neck circumference and applying questionnaire about lifestyle.

Results: It refers to an overweight population of both genders, noticing that 42.7% were overweight and 17.2% were obese, judged by BMI (Body Mass Index). The risk of cardiovascular disease evaluated by several parameters was high: by the waist circumference (38.4%), the hip-waist relation (13.3%) and the conicity index (29.2%), it showed a strong relationship with overweight. The abdominal obesity is considered an important risk factor for cardiovascular diseases, diabetes, dyslipidemias and metabolic syndrome. Smoking habit showed an inverse correlation with body weight in the sample. Physical inactivity was shown in evidence, since only 35.2% do regular physical activity.

Conclusions: Despite the adoption of projects related to the alimentation and nutrition field in the country, we found a low income population, with overweight and prone to develop chronic diseases, according to the demonstration by the nutritional transition. Lifestyle changes are the key for the obesity control and prevention of those diseases. Therefore, this kind of project is very important to offer nutritionally appropriate meals for urban population.

Key words: Obesity, nutritional assessment, cardiovascular diseases

PO2520**THE ASSOCIATIONS BETWEEN MEAL FREQUENCY AND BODY COMPOSITION IN ADULTS***M. Bas¹, E. Sezer¹, S. Yilmaz¹*

¹Baskent University, Faculty of Health Science, Department of Nutrition and Dietetics, Ankara, Turkey

Background and objectives: This research was done in order to investigate the effects of meal frequency on body composition with the use of various parameters. The participants of this research are 300 people.

Methods: all the participants were required to record two week days and one weekend day meal consumption in order to determine their meal frequency. The participants recorded the time they started eating and finished eating.

Results: There was a negative relation between average number of meals consumed and body mass, BMI, waist circumference, fat body mass, lean body mass ($p < 0.001$). The difference between classification of BMI and average number of meals consumed is determined as statistically important by

the researcher ($p < 0.001$). A negative relation between average number of meals consumed and energy consumed, total body fat, saturated fatty acid and monounsaturated fatty acid intake is found ($p < 0.05$). A positive relation between average number of meal consumed and fiber, some vitamins, minerals and water intake was found ($p < 0.05$).

Conclusions: This preliminary investigation suggests that eating more frequently, characterized by an eating pattern of approximately three meals and two snacks, was related to lower BMI and maintenance of weight loss. However, as this investigation also found that greater frequency of snack episodes were positively related both to energy intake and physical activity, additional research is needed to examine the role of eating frequency and physical activity in weight loss maintenance.

Key words: Meal frequency, BMI, body composition

PO2521

BRAZILIAN FOOD COMPOSITION DATABASE (TBCA-USP): UPDATE ON VITAMIN DATA

F. Grande¹, E.B. Giuntini¹, F.M. Lajolo¹, M.C.T. Dan¹, J.A.E. Negrini¹, E. Wenzel de Menezes¹, P. Baldan-Pineda¹

¹Food and Nutrition Research Center/University of São Paulo (NAPAN/USP), FoRC/CEPID/FAPESP and Department of Food and Experimental Nutrition, Faculty of Pharmaceutical Sciences, USP, São Paulo, Brazil

Background and objectives: Several studies have been carried aiming to quantify vitamins in Brazilian foods; however, this information is dispersed in many publications. The goal of the present work was to elaborate a database regarding the composition of vitamins A, C and E in Brazilian foods, aiming to make it available to the population and scientific community.

Methods: For elaborating the vitamin database, data originated from validated methodologies for each compound were compiled, whereas the vitamin A database includes data on retinol and on seven types of carotenoids (α -carotene, β -carotene, β -criptoxantin, lycopene, lutein, violaxantin and zeaxantin), while the vitamin C database includes data on ascorbic and dehydroascorbic acids. For the vitamin E database, data on all available tocopherols and tocotrienols were compiled. The total content of vitamin A was calculated both as Retinol Equivalent (RE) and as Retinol Activity Equivalent (RAE); total vitamin C total was calculated through the sum of ascorbic and dehydroascorbic acids; and, for vitamin E, total values were expressed both as α -tocopherol Equivalents and γ -tocopherol.

Results and Conclusions: Data search was done throughout national and international journals, dissertations and thesis, in a total of 383 references published between 1975 and

2011. From the total references, 148 were compiled and 235 discarded, mainly due to the lack of mandatory information, such as validation of analytical methods. The vitamin database provides information on vitamin A (825 foods), vitamin C (517) and vitamin E (66). Most part of the compiled foods belong to the vegetables group (32%) and fruits group (29%), which represent the foods that are most purchased by the Brazilian population. The data about 1,408 compiled foods generated the vitamin database, and will be available in the TBCA-USP (www.fcf.usp/tabela) as well as in the NAPAN and FoRC platforms.

Key words: Database, food composition, TBCA-USP, vitamins

PO2522

USE OF PREDEFINED DIET QUALITY SCORES IN THE CONTEXT OF CARDIOVASCULAR DISEASE RISK DURING URBANISATION IN THE SOUTH AFRICAN PURE STUDY

R. Dolman¹, E. Wentzel-Viljoen¹, J. Jerling¹, E. Feskens², A. Kruger³, M. Pieters¹

¹Centre of Excellence for Nutrition, North West University, Potchefstroom, South Africa

²Division of Human Nutrition, Wageningen University, Wageningen, The Netherlands

³Africa Unit for Transdisciplinary Health Research (AUTHer), North West University, Potchefstroom, South Africa

Background and objectives: Urbanisation is generally associated with increased cardiovascular disease (CVD) risk and accompanying dietary changes. Little is known regarding the association between increased CVD risk and dietary changes using approaches such as diet quality. The relevance of predefined diet quality scores (DQS) in non-Western developing countries has not yet been established.

Methods: The association between dietary intakes and CVD risk factors was investigated using two variations of DQS, adapted to the black South African diet. Dietary intake data were collected using a quantitative food frequency questionnaire (FFQ). CVD risk was determined by analysing known CVD risk factors. The setting was urban and rural areas in North West Province, South Africa. Apparently healthy volunteers from the South African PURE study population were studied ($n=1710$).

Results: CVD risk factors were significantly increased in the urban participants, especially the women. Urban men and women had significantly higher intakes of both macronutrients and micronutrients, with macronutrient intakes well within

the recommended CVD guidelines. While micronutrient intakes of the urban groups were generally higher than the rural groups, intakes of selected micronutrients were low in both groups. Both variations of DQS indicated improved diet quality in the urban groups and showed good agreement between the scores although they seem to measure different aspects of diet quality.

Conclusions: The apparent paradox between improved diet quality and increased CVD risk in the urban group can be explained when interpreting the cut-offs used in the scores against the absolute intakes of individual nutrients. Predefined DQS as well as current guidelines for CVD prevention should be interpreted with caution in non-Western developing countries.

Key words: CVD, diet quality scores, urbanisation

PO2523

DELAYED GROWTH IN COLOMBIAN SCHOOL CHILDREN WITH FUNCTIONAL GASTROINTESTINAL DISORDERS

L. Valencia¹, N. Muñoz¹, C. Velasco¹

¹Universidad del Valle, Cali, Colombia

Background and objectives: It is possible that delayed growth (DG) of children with functional gastrointestinal disorders (FGDs) is reflected in their height. Objective: To determine DG according to the WHO in school children in Cali, Colombia with functional gastrointestinal disorders (FGDs) and establish associations. Methodology: Case (n=111) and controls (n=111) study in school children from a public school in Cali, Colombia with functional constipation (FC) (n=48), irritable bowel syndrome (IBS) (n=25), functional abdominal pain (FAP) (n=9), aerophagia (AE) (n=8), functional dyspepsia (FD) (n=7), abdominal migraine (AM), and FAP syndrome (FAPS), respectively (n=5), cyclic vomiting syndrome (CVS) (n=2) and non-retentive fecal incontinence (NRFI) and adolescent rumination syndrome (ARS), respectively (n=1), identified by the Rome III Criteria (Spanish version) in whom the following were considered: sociodemographic (age, gender), familial (single child, family dysfunction, parents with FGDs) and infectious (prior dengue) variables. The statistical analysis included estimation of FGDs prevalence, its corresponding 95%CI; estimation of other descriptive measurements of interest and association analysis through multiple logistic regression.

Results: In this population of school children with a mean age of 12.3±2.5 years (range 8 and 18), prevalence was found at 26.58% for FGDs, predominance of female gender and family dysfunction. FGDs was associated to gender (OR 1.00 CI95% 0.53-1.91 p=0.00). Age was the factor finally associated (OR 1.12 CI95% 0.99-1.26 p=0.05).

Conclusion: Nearly one third of the Colombian school children presented FGDs: 48 with risk of low height, 9 with low height, and 2 with severe low height; with older age being a risk factor.

Key words: Delayed growth, Functional gastrointestinal disorders, School children

PO2524

FIBER INTAKE IN COLOMBIAN SCHOOL CHILDREN WITH FUNCTIONAL GASTROINTESTINAL DISORDERS

C. Alvarez^{1,2}, C. Arajo¹, C. Velasco¹

¹Grupo de Investigación GASTROHNUP, Universidad del Valle, Cali, Colombia

²Pontificia Universidad Javeriana, Cali, Colombia

Background and objectives: The low fiber intake has been associated with functional gastrointestinal disorders (FGDs) such as functional constipation (FC) and irritable bowel syndrome (IBS). Our objective was to determine fiber intake through nutritional survey among Colombian school children with FGDs and associations.

Methods: Case (n=23) and control (n=46) study among school children in a private school in Cali, Colombia with IBS (n=15) and FC (n=8) identified by the Rome III Criteria (Spanish version). Nutritional (crude and dietetic fiber intake), demographic (age, sex, origin), and family (single child, parents with FGDs) variables were considered. Statistical analysis included estimation of the prevalence of malnutrition (MNT), its corresponding 95% CI, estimation of other descriptive measures of interest and association analysis by multiple logistic regression.

Results: Mean age 11.1 ± 2 years; prevalence for MNT of 64%; predominantly males and originating in Cali, Colombia, and low crude fiber (1.8 ± 0.8 g) and dietetic fiber (1.2 ± 0.8 g) intake. In association analysis we found a greater chance of low fiber intake in single child (p=0.00) and associated factors were finally sex (p=0.13) and low crude fiber intake (p=0.18).

Conclusions: All Colombian school children with FGDs showed low fiber daily intake and more than half of them had malnutrition, being risk factors sex and crude fiber intake.

Key words: Fiber intake, functional gastrointestinal disorders, school children

PO2525**NUTRITIONAL SURVEY IN COLOMBIAN SCHOOL CHILDREN WITH FUNCTIONAL GASTROINTESTINAL DISORDERS**

C. Alvarez^{1,2}, C. Velasco¹, C. Arajo¹,

¹Grupo de Investigación GASTROHNU, Universidad del Valle, Cali, Colombia

²Pontificia Universidad Javeriana, Cali, Colombia

Background and objectives: Nutritional status may be disrupted in school children with functional gastrointestinal disorders (FGDs). The objective is to determine the prevalence of malnutrition (MNT) for body mass index (BMI) in Colombian school children and associations.

Methods: Case (n=23) and control (n=46) study among school children in Cali, Colombia with FGDs identified by the Rome III Criterie (Spanish version). Nutritional (calories, carbohydrate, protein, fats, zinc), demographic (age, sex, origin) and family (single child, parents with FGDs) variables were considered. Statistical analysis included estimating the prevalence of MNT, its corresponding 95% CI, estimating of other descriptive measures of interest and association analysis by multiple logistic regression.

Results: Mean age 11 ± 2 years; prevalence for MNT of 63%, predominantly males, being natives of Cali, Colombia and consuming a low calorie, carbohydrate, protein, fats and zinc diet. The MNT was associated with the presence of FGDs (p=0.02), but not with the nutritional, demographic and family variables (p>0.05). In association analysis it was found greater chance of MNT in the male gender, being single child and younger. Finally associated factors were age and low zinc intake daily.

Conclusions: More than half of the Colombian school children with FGDs demonstrated MNT: 27 at risk of overweight, 12 overweight and 6 with risk of thinness, being risk factors the younger and low zinc intake daily.

Key words: Nutritional survey, functional gastrointestinal disorders, school children

PO2526**THE EFFECT OF BREEDING AND RETAIL PRACTICES ON THE NUTRIENT PROFILE OF BEEF**

N. Hall^{1,2}, H. Schonfeldt^{1,2}

¹Institute of Food, Nutrition and Well-being, University of Pretoria, Pretoria, South Africa

²Department of Animal and Wildlife Science, University of Pretoria, Pretoria, South Africa

Background and objectives: Due to the increased awareness of the global obesity epidemic, red meat is often seen as a culprit in weight gain and obesity. As a result the global meat industry has responded by decreasing the total fat content of red meat. Actions include breed selection, feed manipulation, and retail and food preparation practices, such as trimming. Consistency with the changes in carcass characteristics and retail and food preparation practices need to be maintained in order to reflect true composition. The composition of SA beef cuts with subcutaneous fat removed has not been determined before. The accurate composition data on what is actually consumed (trimmed cuts) will aid in consumer education, in-line with current nutri-marketing trends, to further the image of South African beef as part of a healthy diet.

Methods: An updated nutritional profile of three South African beef cuts (prime-rib (n=72), rump (n=72) and shoulder (n=72)) from four age groups according to the national classification system, cooked and raw, with and without subcutaneous fat, was determined. Nutrients determined include protein, fat, cholesterol and the fatty acid profile among others. Results and

Conclusions: The results have been applied towards: 1) Determining the changes in the nutrient composition of South African beef over time (since the previous composition study was done in 1990); 2) Determining the effect of age and feeding regime on the composition beef; 3) Determining the effect of retail trimming on carcass composition.

Key words: Nutrient content, beef, red meat

PO2527**NUTRITIONAL ADEQUACY OF MINERAL CONTENTS OF ORAL DIETS FOR RENAL PATIENTS PREPARED IN A HOSPITAL OF BELO HORIZONTE, MG, BRAZIL**

K. Diego Quintaes¹, J. David Silva¹, D C. Faria Moreira¹, J S. Manzoli de Sá¹, A S. Aguiar Nemer¹, M A. Morgano²

¹Ouro Preto Federal University, Nutrition School, MG, Brazil

²Institute of Food Technology, Quality and Control Center of Foods, SP, Brazil

Background and objectives: Chronic renal failure (CRF) is an illness of high morbidity and mortality, and the chemical composition of the diet is fundamental to manage the pathology. This study aimed to assess the nutritional adequacy of Ca, Cu, Fe, K, Mg, Mn, Na, P, Zn and Se contents in oral hospital diet and in artisanal food oral complement (OFC) for renal patients prepared in a hospital in Belo Horizonte, MG, Brazil.

Methods: About 14% of the hospital menu served to renal patients had the mineral content analyzed by inductively coupled plasma optical emission spectroscopy (ICP OES). The samples were collected in duplicate during the months of May and September, 2010 and January, 2011. The results were evaluated with regard to nutrition mineral recommendations for adult and elderly patients, from both genders, with chronic renal insufficiency (CRI).

Results: Renal oral diets presented deficit of Ca and Fe in all times studied, reaching on average 31 and 58% of recommendation, respectively. On the other hand, the levels of Se and Na exceeded the maximum considered safe (UL) in 145 and 1409%, respectively, getting worse when diet was associated with OFC. The amount of K and P exceeded the recommendation in 119 and 114%, respectively, while Mg content did not reach the minimum recommended for adult and elderly men in any time. The amount of Mn satisfied the recommendations, while Cu and Zn were 95 and 90% below the recommended, respectively, in September.

Conclusions: The use of OFC in association with oral renal diet contributes to achieving the recommended levels of Cu and Mg, but at the same time increases the risk of Na and Se toxicity. It is necessary a better balance of mineral nutrient contents in oral diets for CRI patients.

Key words: Dietotherapy, food analysis, nutritional recommendation, mineral nutrition

PO2528**BODY COMPOSITION OF KUWAITI CHILDREN; ESTABLISHMENT OF A STABLE ISOTOPE FACILITY FOR ASSESSMENT OF TOTAL BODY WATER IN KUWAIT**

T. Al-Ati¹, T. Preston², S. Al-Hooti¹, N. Al-Hamad³, J. Al-Ghanim¹, F. AlKhulifi¹, B. Al-Lahou¹, A. Al-Othman¹, L. Davidsson¹

¹Kuwait Institute for Scientific Research, Safat, Kuwait

²University of Glasgow, Scottish Universities Environmental Research Center, Scotland, UK

³Food and Nutrition Administration, Ministry of Health, Safat, Kuwait

Background and objectives: Assessment of body composition provides a much needed tool to monitor and evaluate interventions to combat obesity, in particular during childhood. Stable isotope technique to estimate total body water (TBW) is the golden standard technique for body composition. The aims of this study were to install the technique for TBW and assess body composition of Kuwaiti children.

Methods: The Isotope Ratio Mass Spectrometer (IRMS) was calibrated with defined international reference water standards. 75 boys and 83 girls (7-9 years) participated in the study. A dose of deuterium oxide (1-3 g) was consumed after an overnight fast and deuterium enrichment in baseline and post dose urine samples was measured. TBW was calculated and used to estimate fat free mass (FFM). Fat mass (FM) was estimated by difference (body weight minus FFM).

Results: IRMS measurements were confirmed to be accurate and precise. Children were classified as normal weight, overweight or obese according to the World Health Organization (WHO) based on BMI-for-age z-scores. Statistically significant differences in body composition were observed between normal weight boys and girls while only minor differences were found in overweight and obese children. Of particular interest is the finding that both boys and girls children classified as normal weight or overweight had high % body fat, over 35% and 40 % respectively.

Conclusions: The introduction of state-of-the-art technology for assessment of body composition provides an opportunity to explore a wide range of applications, within Kuwait as well as in the Gulf region.

Key words: Body composition, stable isotopes, childhood obesity, IRMS, deuterium dilution, Kuwait

PO2529**EVALUATION OF DIET QUALITY WITH CHINA DIET BALANCE INDEX AMONG RESIDENTS IN JIANGSU, CHINA***S. Zhen¹, Y. Dai¹, Q. Zhu¹, B. Yuan¹*¹Department of Nutrition, Jiangsu Center For Disease Prevention and Control, Jiangsu, China

Background and objectives: To evaluate diet quality among residents in Jiangsu by using China diet balance index (DBI-07).

Methods: A multistage stratified cluster random scheme was used to draw the sample in Jiangsu for the China Health and Nutrition Survey cohort. Dietary intake data were determined by three consecutive 24-hour recalls and food weighing method. Blood pressure and anthropometric data were measured with standard protocols. Dietary quality was evaluated by using DBI-07 method.

Results: Intakes of fruits and vegetables, milk, and beans are insufficient whereas intakes of red meats, edible oil, and salt intake were excessive. Excessive intakes of energy and fat and imbalanced diet were more common among men than among women. Insufficient nutrients intakes were more severe in rural areas than in urban areas and in age group of 40-50 than in all other age groups.

Conclusions: Insufficient and excessive intakes of nutrients coexist in Jiangsu. Nutritional interventions need to target at people in rural areas, particularly people at age of 40-50 years.

Key words: Dietary balance index, dietary quality, dietary evaluation

PO2530**DETERMINANTS OF CALCIUM INTAKE IN CHINESE ADULT IN BEIJING***L. Lu¹, F. Wang¹*¹Department of Nutrition and Food Safety, Xicheng District Centre For Disease Prevention and Control, Beijing, China

Background and objectives: Calcium intake is low and calcium deficiency is prevalent in Chinese adults, but its determinants are unknown.

Methods: Data on a total of 1,086 participants in Beijing from the China Health and Nutrition Survey were used. Dietary intake data were determined by three consecutive 24-hour recalls and food weighing method. Multivariate linear regression was used to determine the association between calcium intake and some key demographic factors and dietary behaviors.

Results: The average calcium intake was 516.9 mg/day. It was higher among men than among women but the difference was not significant (544.1 mg/day vs. 491.6 mg/day, $p=0.19$). 87.8% of participants did not reach the intake level (800 mg/day) recommended by Chinese Nutrition Society. Calcium intake increased with age ($r=0.127$, $p<0.001$), and was not significantly associated with smoking status ($p=0.876$) and body mass index ($p=0.146$).

Conclusions: The proportion of people reaching the recommended calcium intake level in Beijing, China, is low, particularly among young adults.

Key words: Calcium intake, adult, determinants, China

PO2531**ASSESSMENT OF IODINE INTAKE AND EXCRETION AMONG ADULTS***S. Zou¹, J. Zang¹, C. Huang¹, M. Mi¹, W. Li², H. Ni³, Z. Zhu¹, A. Shi¹, P. Jiang¹*¹Department of Nutrition Hygiene, Shanghai Municipal Center for Disease Control and Prevention, Shanghai, China²Department of Environmental Health, Jinshan Center for Disease Control and Prevention, Shanghai, China³Department of Public Health, Jingan Center for Disease Control and Prevention, Shanghai, China

Background and objectives: Few studies explored iodine nutritional intake and excretion in adults in normal dietary situation. The aim of this research is to evaluate iodine intake and urinary excretion by using the duplicate-portion technique.

Methods: 8 healthy men and 8 healthy women aged 18-60 years were randomly selected to participate in this study. Amount and types of daily drinking water and beverages were recorded for three consecutive 24 hours by using a quantitative measurement. 24-hour urine samples were collected on the same day when the water and food consumption were assessed. Food samples and urine samples were collected and measured by using 3-day duplicate portion technique. Iodine content in water, food, and urine was analyzed subsequently.

Results: Median iodine intake was 196.1 $\mu\text{g/day}$ among men and 171.0 $\mu\text{g/d}$ among women. Among the 16 participants, 12 reached the recommended iodine intake level and 3 below 80% of the recommended level. The median proportions of iodine intake from food were 86.2% among men and 85.1% among women. 87.3% of iodine was excreted from urine. Urine iodine excretion was significantly associated with iodine intake ($r=0.873$, $p<0.001$).

Conclusions: Dietary iodine intake may be a good indicator of nutritional iodine status.

Key words: Iodine intake, urinary excretion, duplicate-portion technique

PO2532

CHANGES IN BODY MASS INDEX AMONG YOUNG ADULTS IN HUBEI, 1991-2009

Y. Song¹, M. Cheng¹, S. Liu¹, J. Li¹, C. Gong¹

¹Institute of Health Surveillance, Analysis and Protection, Hubei Center for Disease Control and Prevention, Hubei, China

Background and objectives: To study the distributions and trends of body mass index (BMI) among young adults aged 20 to 45 years old in Hubei province.

Methods: A subsample of adults aged 20-45 years (n=675 at baseline) from the China Health and Nutrition Survey was used. Anthropometric data were measured with standard protocols. Gender- and age-BMI percentage curves were constructed by using the LMS (lambda, mu, sigma) method.

Results: The prevalence of overweight or obesity increased by 13.9% in men and 12.0% in women during the 18 follow-up years. The increase in the prevalence of overweight and obesity was far greater than the decrease in underweight (by 4.0% in men and 3.7% in women). Age- and gender-specific percentile curves showed that BMI increased faster in men than in women. Compared to the distribution in 1991, BMI distribution curves flattened at higher levels of BMI in both men and women.

Conclusions: Body mass index and prevalence of overweight and obesity are increasing quickly among young adults in Hubei. Overweight and obese adults have gained more weight than their normal weight peers in past two decades.

Key words: Adults, body mass index, overweight, obesity

PO2533

TRENDS AND PATTERNS OF ENERGY INTAKE AMONG ADULTS IN SHANDONG PROVINCE, 2000-2009

J. Zhang¹, S. Li¹, D. Liu¹

¹Department of Nutrition and Food Safety, Shandong Center for Disease Control and Prevention, Shandong, China

Background and objectives: Economic development in Shandong province, one of the largest provinces in China has affected dietary patterns. We explore the patterns and trends of energy intake and composition among Shandong adults from 2000 to 2009.

Methods: Two waves of data from the China Health and Nutrition Survey in Shandong Province conducted in 2000 (1142 subjects aged 18 and above) and 2009 (1095 subjects) were used. T-test analysis of pooled data was performed.

Results: In 2000, the average energy intake was 9089.2 kJ (2164.1 kcal), with 13.0%, 28.9% and 58.1% derived from protein, fat and carbohydrate, respectively. In 2009, the energy intake significantly increased to 12223.26 kJ (2910.3 kcal) (p<0.01). Energy from protein and fat significantly increased to 14.0% and 33.2%, respectively (p<0.01), while energy from carbohydrate significantly decreased to 52.8% (p<0.01).

Conclusions: During the past decade, fat and energy intake have shifted to being much higher than the Chinese reference nutrient intake levels (RNI).

Key words: Energy intake, fat, energy from fat

PO2534

VALIDATION STUDY OF ESTIMATION ERRORS IN VARIOUS PATTERNS OF RICE PHOTOGRAPHS

S. Kato¹, S. Nakamura¹, K. Waki², S. Osada³, N. Tomizawa², H. Fujita²

¹Department of Nutrition Science, Faculty of Nursing and Nutrition, University of Nagasaki, Nagasaki, Japan

²Department of Ubiquitous Health Informatics, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan

³Department of Food and Nutrition, Junior Collage of Kagawa Nutrition University, Tokyo, Japan

Background and objectives: A method to use photographs has been considered as a useful tool for dietary assessment. However, estimation errors in different angles or dishes have not been sufficiently examined. We validated estimated volu-

mes about staple foods, rice in this study, changing that layout and volume. It is important for exact calculating of staple foods because they are largely composed energy intakes.

Methods: Fourteen patterns of rice photographs were prepared for the study. It changed volume (100 g, 150 g, 200 g, 250 g and 300 g), layout (e.g. normal, almond-shape, rice ball) and dishes (e.g. rice bowl, gratin dish, plate, lunch box). Standard rice was 150 g in regular size rice bowl. Dishes were put on plaid tablecloth then took right above or skewed angle by digital camera. Thirty-six of dietitian-course students estimated volumes from test images compared with standard image.

Results: The variability of all rice samples showed positive correlation with actual and estimated volumes from right above ($r=0.50$, $n=504$) and skewed angle ($r=0.54$, $n=540$). Serve in rice bowl samples indicated a high correlation with actual and estimated volumes in both angle, above ($r=0.89$, $n=108$) and skewed angle ($r=0.87$, $n=144$). Percentages of estimations within 20% of the actual volume were high in 200 g of rice bowl (above 82.8% and skewed angle 88.9%) and low in 150 g of gratin dish (above 30.6% and skewed angle 27.8%). Angle difference within 20% of the actual volume between above and skewed angle in 200 g rice on curry plate was 50.5% and 80.6%, respectively ($p<0.01$). Many participants commented, it was difficult to estimate volume when different dishes or unclear dish height.

Conclusions: Using food photographs to make better estimation for dietary assessment should need supplementation with some standard patterns.

Key words: Dietary assessment, photograph, staple food

PO2535

THERAPEUTIC USE OF VANADIUM FOR TREATMENT OF NON-INSULIN DEPENDENT DIABETES MELLITUS

*S. Athimoolam*¹

¹North East Regional Institute of Education, National Council of Educational Research and Training, Umiam, India

Background and objectives: Diabetes mellitus is a heterogeneous metabolic disorder characterized by hyperglycaemia due to defective insulin secretion, insulin resistance or both and controlled by vanadium in animals and humans. Evaluating vanadium's glucose-enhancing potential, biodistribution, bioavailability, biomolecular transformation, and mechanisms of action is essential for therapeutic relevance.

Methods: literature search.

Results: Gene expression, using Affymetrix arrays, was examined in muscle from streptozotocin-induced diabetic and normal rats treated with oral vanadyl sulfate. Genes for oxi-

dative stress were identified and related with known oxidative properties, thereby implying that early transition metals formed from their chemical interactions with other metabolites may act as general transcription modulators. Vanadium compounds activate Akt signaling through inhibition of protein tyrosine phosphatases with consequent increment in insulin sensitivity in diabetics. A transmission electron microscopic study indicated that vanadyl sulphate through preserving islet beta cell ultrastructure, reversed diabetic symptoms in streptozotocin-treated rats. The blood glucose lowering properties of vanadium-vitamin B(12) bioconjugates and combined micronutrients (Cr, Se & V) were reported. Supplementation of *Coprinus comatus* and *Cordyceps sinensis*, rich in vanadium, decreased blood glucose and glycohemoglobin levels and increased glycogen synthesis in alloxan-induced hyperglycemic mice. Oral administration of vanadate in *S. Bunge* herbal decoction produced a stable blood glucose status and alleviating vanadium toxicity in rat. But other study reported gastrointestinal intolerance in type 2 diabetics after 6 weeks of vanadyl sulfate treatment at 150- and 300-mg doses. Bioavailability of vanadyl compounds is another required characteristic for supplementation and organic compounds are preferred to inorganic forms.

Conclusions: It is concluded that diabetics are not vanadium-deficient, since no difference in levels between diabetics and controls. Vanadium compounds are effective as antidiabetic at high concentrations and in organic forms, but ineffective when the treatment is withdrawn. Chronic consumption may cause vanadium bioaccumulation, therefore, large-scale randomized controlled trials are needed for recommending routine vanadium medication.

Key words: Vanadium, therapeutic use, diabetes mellitus

PO2536

RELATIONSHIP BETWEEN DIETARY NUTRIENTS AND OXIDATIVE STRESS MARKERS

*K. Tomioka*¹, *C. Mizote*¹, *M. Tabuchi*¹, *T. Kawakami*¹, *S. Haisa*², *Y. Takahashi*¹

¹Department of Nutritional Science, Okayama Prefectural University, Soja-shi, Okayama-ken, Japan

²Okayama Citizens' Hospital, Okayama-shi, Okayama-ken, Japan

Background and objectives: Oxidative stress is associated with many lifestyle-related diseases. Breakdown of the balance between oxidative stress and antioxidant processes in the body is now recognized as an emerging health risk factor. Unhealthy dietary habits can cause cardiovascular disease and diabetes. However, the assessment of oxidative stress and antioxidant capacity measurement, nutrition management and therapy

are not well used in Japan. Therefore, we performed reactive oxygen metabolite (d-ROMs) tests and OXY-adsorbent (OXY) tests. The subjects were 30 middle-aged Japanese males (age: 49.7 ± 7.7) who underwent a health check-up at a Health Administration Center.

Methods: The Free Radical Elective Evaluator *carpe diem* (FREE, Wismerll Laboratory) was used to measure the levels of d-ROMs, reflecting active oxygen metabolites, and the levels of OXY, reflecting total antioxidant capacity. Habitual food intake, dietary energy and nutrients were determined using a quantitative food-frequency questionnaire.

Results: The levels of d-ROMs were 320 ± 78 U.CARR (mean \pm SD) (normal range: 200-300). The levels of OXY were 355 ± 68 fmol/ml (normal range: $350 <$). Dietary intake of calcium and magnesium, zinc and saturated fatty acids (SFA) correlated negatively with serum d-ROMs (Ca: $p < 0.01$, Mg, Zn and SFA: $p < 0.05$). Dietary intake of folic acid correlated positively with serum OXY ($p < 0.05$). OXY/d-ROMs ratio (potential antioxidant ability) correlated positively with dietary Ca and Mg, vitamin K and folic acid ($p < 0.05$).

Conclusions: The levels of d-ROMs of the subjects were around the upper border of the normal range. Oxidative stress markers (d-ROMs, OXY, OXY/d-ROMs) were related to exogenous antioxidants in dietary nutrients, which is useful information for the primary prevention of lifestyle-related diseases and nutrition management.

Key words: Oxygen metabolite (d-ROMs) tests, OXY-adsorbent (OXY) tests, dietary nutrients, primary prevention, lifestyle-related diseases

PO2537

VALIDITY OF POPULATION LEVEL ASSESSMENT OF PLASMA AND MILK RETINOL CONCENTRATIONS USING THE ICHECK FLUOROMETRIC DEVICE IN INDONESIA

M. Mardewi¹, A D. Priamsari¹, M. Bloem¹, P. Gupta¹, A. Roshita², E. Ermayani², A. Osei³

¹Helen Keller International, Indonesia Office, Jakarta, Indonesia

²Southeast Asian Ministers of Education Organization Regional Center for Food and Nutrition (SEA-MEO RECFON), Jakarta, Indonesia

³Asia Pacific Regional Office, Helen Keller International, Phnom Penh, Cambodia

Background and objectives: Vitamin A (VA) deficiency remains an important public health problem globally. One of the key challenges to providing appropriate VA interventions, targeted to the right population is the availability of accurate and

logistically feasible methods for VA assessments under remote field settings. Our objective was to compare plasma and milk retinol concentrations assessed on site by the portable iCheck fluorometric device to plasma retinol concentrations of the same population as determined by HPLC. This is one of the few studies to validate the iCheck device in a population.

Methods: Blood samples taken from 347 children (6 – 59 months) and 96 of their mothers were analyzed for hemoglobin, retinol and C-reactive protein concentrations. Milk samples taken from the mothers who had babies aged 3 – 11 months were analyzed for retinol concentration. Plasma retinol concentrations for each subject were assessed both at the field using iCheck fluorometric device and in laboratory using HPLC. Milk retinol concentrations were assessed at the field using the iCheck device. Statistical analysis comparing plasma and milk retinol concentrations from iCheck to retinol by HPLC using correlations and Bland Altman analysis is currently underway and results will be ready at the time of the congress.

Results: To be submitted before the congress.

Conclusions: The findings from this study will demonstrate the validity of using the iCheck fluorometric device for population level assessment of serum and milk retinol concentrations in remote settings. The advantage of the iCheck device method is that it simplifies the logistics of blood and milk collection and analysis protocols in field settings.

Key words: Vitamin A, retinol, iCheck, HPLC, Indonesia

DISCREPANCIES IN ASSESSMENT OF IODINE SALT CONTENT BETWEEN A RAPID TEST KIT AND TITRATION METHOD: EXPERIENCE FROM GHANA

J. Knowles¹, C. Northrop-Clewes¹, S. Newton², E. F. Amoah³, P. Jooste⁴, F. Rohner¹, S. Jungjohann¹

¹Global Alliance for Improved Nutrition (GAIN), Geneva, Switzerland

²Kintampo Health Research Center, Ghana Health Service, Accra, Ghana

³Nutrition Department, Ghana Health Service, Accra, Ghana

⁴Nutritional Intervention Research Unit, Medical Research Council, Cape Town, South Africa

Background and objectives: A national survey in Ghana in 2009-10 included determination of iodine in household salt. Objective: To assess salt iodine content using a semi-quantitative and a quantitative method, with the aim of evaluating the validity of the semi-quantitative test for field-based quality control of salt iodisation in Ghana.

Methods: Salt samples were tested at the household using a rapid test kits (RTK) to obtain semi-quantitative results (0 ppm, <15 ppm or >15 ppm) for iodine. An additional sample of salt was collected for analysis of iodine content by titration. Negative and positive predictive values as well as sensitivity and specificity results were calculated for the presence of any iodine (>0 ppm) and for adequate iodine (>15 ppm).

Results: Salt was available from 1,206 households for analysis by both methods. The RTK results indicated that 61.8% of salt samples were not iodised and 21.4% were adequately iodised, compared with 8.3% and 48.2%, respectively by titration. The negative predictive value (NPV) of the RTK was 11.3% for any iodine in salt and 63.2% for adequately iodised salt. The specificity and sensitivity of the RTK for any iodine were 84.0% and 40.2% respectively. For adequately iodised salt, RTK specificity was 95.8% and sensitivity was 39.9%. The validity and predictive value of RTK results improved with improved salt quality.

Conclusions: The RTK showed poor predictive value for non-iodised salt when compared with titration. Potential reasons for this and its implications for field-based quality control of iodised salt and for interpretation of past and future survey results in Ghana will be discussed.

Key words: Iodine, salt, titration, rapid test kit

PO2539

MONITORING THE COMPLETENESS OF ADULTS' AND CHILDREN'S 24-HOUR URINE COLLECTIONS USING PABA

L. Cox¹, T. Steer¹, K. Guberg¹, S. Young¹, P. Page¹, A. Prentice¹

¹MRC Human Nutrition Research, Cambridge, UK

Background and objectives: p-aminobenzoic acid (PABA) excretion is a well-established method of assessing the completeness of 24-hour urine samples collected by adults. The inter-individual variability led us to investigate whether those at the lower end of the distribution were continuing to excrete PABA over a longer period. We also investigated the applicability of these limits to children's urine collections.

Methods: To establish the reference range of PABA excretion consistent with a complete 24 hour urine collection we recruited 50 healthy, well-motivated adults; each took 3 x 80 mg tablets at intervals during a single day and 24-hour urine collections were made on the study day and the day following. To compare PABA excretion kinetics in young children with adults, PABA present in individual urine samples passed during the 8 hours after ingestion of one tablet was determined in 15 children aged 4-10 years and in 15 adults. This approach was preferred to a 24-hour collection in order to minimise the bur-

den for child volunteers. PABA was measured by an in-house HPLC method utilising methanol in the mobile phase.

Results: The range of PABA excretion representing a complete collection in adults was determined for our HPLC assay to be 70-104% of the 240 mg dose (mean \pm 2SD). Only traces of PABA were excreted the following day. PABA excretion by young children showed a similar pattern to adults, with excretion of a single tablet complete within 8 hours by all adult and child participants.

Conclusions: This study established limits for PABA excretion in complete 24-hour urine collections from adults, and demonstrated consistent kinetics which indicate that the limits are also applicable to children.

Key words: PABA, 24-hour urine, completeness, child

PO2540

AVOIDING MISLEADING CALCIUM MEASUREMENTS IN BLOOD PLASMA – A RAPID MANUAL ASSAY TO DETECT EDTA

L. Cox¹, A. Prentice¹

¹MRC Human Nutrition Research, Cambridge, UK

Background and objectives: Ethylenediaminetetraacetic acid (EDTA) is a commonly-used anticoagulant (eg. for haematology) which chelates divalent cations. Traces of EDTA contamination in plasma invalidate colorimetric measurement of calcium and other divalent cations, also enzymes such as alkaline phosphatase (ALP) which depend on them for activity. Procedures are commonly in place to avoid such contamination during clinical phlebotomy and sample processing, and high-throughput automated screening assays are available to detect this. In nutritional surveys and studies this issue is not always recognised. Trace contamination during phlebotomy or blood separation can give rise to misleading results. We aimed to develop a manual method to detect EDTA contamination in plasma, in order to identify and discard affected results.

Methods: A published automated assay for EDTA using pyridylazonaphthol (PAN) was adapted for manual use in microplate format, suitable either for spectrophotometry at 530 nm or for screening visually. The relevant range of EDTA concentrations was determined by spiking plasma with EDTA and measuring Ca, Mg and ALP colorimetrically.

Results: Using a 10 minute incubation and 20 μ l sample in duplicate, a nonlinear calibration curve was obtained (530 nm) between 80 and 400 mg EDTA/l. This covered the range where EDTA caused a 10% error in Ca measurement (90 mg/l) and in ALP measurement (250 mg/l).

Conclusions: The small volume required makes this rapid manual assay appropriate for plasma samples of insufficient volume for automated instruments, and for research and lower-

throughput laboratories where such instruments are not available. The assay facilitates the exclusion from datasets of plasma Ca and ALP concentrations which because of EDTA interference do not reflect the in vivo concentration. This emphasises the importance of avoiding cross-contamination between samples from different phlebotomy tubes.

Key words: EDTA, calcium, plasma, interference

PO2541

INADEQUATE AMOUNT OF SLEEP AS ONE OF THE RISK FACTORS OF OVERWEIGHT AND OBESITY IN POLISH MALES

M. Jarosz¹, I. Sajór¹

¹Department of Dietetic and Nutrition in Hospitals with Clinic of Metabolic Diseases and Gastroenterology, National Food and Nutrition Institute, Warsaw, Poland

Background and objective: Increasing prevalence of overweight and obesity in Polish population stimulated research on potential risk factors of this unfavourable phenomenon. The results of recently published studies suggest that aside from nutritional factors, also the duration of sleep can have a role in the emerging epidemic of obesity. The aim of study was to verify if there is a relationship between the presence of overweight or obesity and the duration of sleep in Polish population.

Methods: Questionnaire survey, anthropometric measurements (body weight, body height, waist circumference), and analysis of body composition (body fatness, basal metabolic rate) were conducted in 257 individuals, among them 110 men and 147 women. On the basis of declared duration of sleep, the participants were classified as “short sleepers”, i.e. sleeping ≤ 6 hours per day, “normal sleepers” (7-8 hours per day), and “long sleepers” (≥ 9 hours per day). The results were subjected to statistical analysis.

Results: Mean values of body weight, waist circumference, BMI, and body fatness in male „short” and „long sleepers” were significantly higher than in the „normal sleepers” (body weight: 86.5 kg and 81.7 kg vs. 78.2 kg, $p=0.022$; waist circumference: 102.4 cm and 102.9 cm vs. 94.8 cm, $p=0.003$; BMI: 28.5 kg/m² and 27.5 kg/m² vs. 25.8 kg/m², $p=0.009$; body fatness: 26.9% and 29.9% vs. 23.4%, $p=0.008$). The duration of sleep in women did not influence any of analysed parameters.

Conclusions: Both deficiency and excess of sleep can represent risk factors of overweight and obesity in Polish males.

Key words: overweight, obesity, body fat mass, sleep duration

PO2542

INFANT BODY COMPOSITION IS INFLUENCED BY BREAST MILK LEPTIN CONCENTRATIONS

E P. Rezende¹, A C. Chain¹, M E L. Diogenes^{2,3}, M F S S. Taveira¹, P. Normando¹, F F. Bezerra¹

¹Instituto de Nutrição, Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil

²Instituto de Química, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil

³Instituto Nacional do Cancer (INCA), Rio de Janeiro, Brazil

Background and objectives: The presence of leptin in breast milk suggests its involvement in infant growth and development and may represent a link between breastfeeding practices and the regulation of energy balance in the first months of life. The aim of this study was to investigate the main determinants of leptin concentrations in breast milk of lactating adolescents and its relationship with infant body composition.

Methods: Lactating adolescents (14-19 y, $n=53$) were recruited from a public prenatal clinic in Rio de Janeiro. Maternal serum and breast milk concentrations of leptin were assessed by ELISA. Infant and maternal body composition were determined by dual-energy X-ray absorptiometry at 5 ± 1 wk postpartum.

Results: Leptin in breast milk (0.49 ± 0.37 ng/ml) was much lower ($p<0.001$) than serum leptin (18.3 ± 11.9 ng/ml). Serum and breast milk leptin concentrations were positively associated (Pearson's correlation, $r = 0.38$, $p<0.05$). The most powerful determinants of breast milk leptin were investigated by a stepwise linear regression considering maternal serum leptin concentrations, total body mass, BMI at lactation, pre-gestational BMI, gestational weight gain, total body fat and period postpartum (in days) as potential independent variables. Maternal total body fat played the primary role in predicting breast milk leptin ($R^2=0.31$). Pre-gestational BMI was second in importance increasing the cumulative partial R^2 by 0.20. After adjustment for days post partum by partial correlation, leptin in breast milk was positively associated ($p<0.05$) with infant total fat mass ($r=0.39$) and percent fat mass ($r=0.43$).

Conclusions: Our results suggest that maternal body composition appears to influence the concentration of leptin in breast milk, which in turn may have implications for infant growth and development.

Key words: Leptin, breast milk, infant body composition

PO2543**APPLICATION OF ESTIMATED BODY WEIGHT EQUATION USING MID-UPPER ARM CIRCUMFERENCE (MUAC) AND CALF CIRCUMFERENCE FOR INDONESIAN POPULATION**

N N. Wirawan¹, R. Diana N¹, Harijanto²

¹Department of Nutrition, University of Brawijaya, Malang, Indonesia

²Department of Medicine, University of Brawijaya, Malang, Indonesia

Background and objectives: Body weight is one of the most important anthropometric parameters in assessing nutritional status before the appropriate nutrition care is given to patients. Therefore, provision of the accurate information is a must. However, due to specific conditions of the patients, direct standing weighing sometimes is impossible to be done. In developed countries, this condition raised no problem by the availability of other weighing instruments such as wheelchair scale, bed scale, pod scale, and other that allow direct weighing. However, in developing countries such as Indonesia, most of the hospitals do not have such instruments. Therefore, in order to assess body weight, the estimation needs to be done by using available formula. Parameter mostly used to estimate body weight is Mid-Upper Arm Circumference (MUAC) and Calf Circumference (CC). However, the available equation was developed among Caucasians and Blacks. Therefore this study aims to validate the Chumlea I equation and develop the new locally specific formula.

Methods: A cross sectional study was carried out among healthy Indonesian adults aged 20-49 years old with normal BMI. Measurements of actual body weight, MUAC and CC was done to 194 subjects (97 males and 97 females). Estimated body weight was calculated using equation of Chumlea I and compared to their actual body weight.

Results: The mean actual body weight is 55.74 ± 6.06 kg for males and 48.37 ± 3.98 kg for females. The mean estimated body weight is 61.64 ± 6.17 kg and 51.04 ± 4.56 kg for males and females respectively. The overestimation is higher in male than female (5.9 kg and 2.67 kg respectively). The mean estimated using newly equation is 55.74 ± 4.56 kg for male and 48.37 ± 2.72 kg for female.

Conclusions: To estimate the body weight the locally specific equation should be used.

Key words: Body weight, MUAC, calf circumference

PO2544**BODY COMPOSITION OF ADULTS WITH SICKLE CELL DISEASE**

K. Cordovil¹, M. Citelli², G. Pinheiro³, C. Cople-Rodrigues⁴

¹Master student, Medical Sciences Post Graduation, Faculty of Medical Sciences Institute of Nutrition, State University of Rio de Janeiro, Rio de Janeiro, Brazil

²Associate Professor, Institute of Nutrition (INU/ UERJ), Rio de Janeiro, Rio de Janeiro, Brazil

³Associate Professor, Faculty of Medical Sciences, State University of Rio de Janeiro (FCM/UERJ), Rio de Janeiro, Rio de Janeiro, Brazil

⁴Associate Professor, Institute of Nutrition (INU/ UERJ), Coordinator of Reference Center for Nutritional Surveillance in Hemoglobinopathies (CENTHEM / INU / UERJ), Rio de Janeiro, Rio de Janeiro, Brazil

Background and objectives: Sickle cell disease (SCD) is one of the most common genetic disorders in the world. It is characterized among other things by the presence of hypermetabolism that impacts on body composition. The aim of this study was to assess nutritional status and body composition in Brazilian adults with SCD.

Methods: We evaluated SCD patients of both genders, 39 years old or older. Anthropometric measurements (body mass index (BMI), Calf, Fist, Abdominal and Hips circumferences) were performed, as well as skinfold measurement obtained from each separate observation was based on the sum of 4 skinfold sites (bicep, triceps, subscapular and suprailiac (Lohman, 1986)). The body composition (Durnin and Womersley, 1974) and determination of body fat (%BF) (Siri, 1968) were evaluated. All analysis was conducted in SPSS 19.0 (level significance was 5%).

Results: Among the 52 patients studied, mean age of 50.5 ± 6.1 (SD) years, 51% were classified as eutrophic ($n=27$), 28.8% overweight ($n=15$) and 13.5 % of obese subjects ($n=7$). Mean BMI was 24.3 ± 4.6 (SD) kg/m^2 , average BF was 26.85 ± 8.5 (SD) %, fat mass (FM) and lean mass (LM) were 17.9 ± 7.8 (SD) and 47.5 ± 9.4 (SD) kg, respectively. Men ($n=21$) had lower mean BMI ($p<0.059$), %BF ($p<0.000$) and FM ($p<0.003$). Females ($n=31$) had lower average LM ($p<0.043$). Patients had skinfold measurements and circumferences smaller ($p<0.000$) than those standards. There was a direct association between BMI and %BF ($p<0.011$), FM kg and BMI ($p<0.000$) and LM ($p<0.003$).

Conclusions: This sample of Brazilian SCD patients had a propensity for a nutritional profile of excess body fat among women and men with lower values for necessary interventions differentiated between both genders.

Key words: Sickle cell disease, body composition, nutritional status

PO2545

ASSESSMENT OF THE GROWTH DEVELOPMENT OF CHILDREN UNDER 5 YEARS OLD IN LEBANON

J. Najjar¹, Z. Mansour², B. Gerbea³

¹World Vision, Beirut, Lebanon

²Consultancy for Research and Development, Beirut, Lebanon

³Lebanese Pediatric Society, Beirut, Lebanon

Background and objectives: Many morbidities and mortalities arise from poor growth during infancy, along with psychological impairment and delay in intellectual development. Regular assessment of growth patterns among pre-school children is an essential preventive method. However, in Lebanon, national growth charts have not yet been established and data is scarce on children under 5 years old. Given the vulnerability of this age group and the window of opportunity it presents, it is important to construct national growth standards to provide reference child growth curves for clinical, epidemiological and research purposes as well as becoming the base for future trends assessments.

Methods: A cross-sectional descriptive analytical study was carried out using the standard WHO two-stage Cluster approach. The study targeted children 2040 under 5 years old (free from chronic illness) through a household survey questionnaire in the different Caza in Lebanon, administered by trained data collectors. The household survey questionnaire was complimented by a self completed structured survey questionnaire with 104 pediatricians.

Results and conclusions: The interesting finding in the current assessment is that breastfeeding was highly encouraged by Pediatricians and was seen to be practiced by the parents surveyed: 47.1% reported practicing exclusive breastfeeding up to 5 months. The results showed that the majority of the children under 5 years old sampled have a normal growth pattern, with less than 2.4% being stunted. In addition, the growth curves that resulted from this study are similar in pattern and distribution as that obtained by WHO with the growth curves of this study showing mild obesity.

Key words: Child nutrition, growth monitoring, Lebanon

PO2546

USING HOMESTEAD FOOD PRODUCTION PROGRAM AS A PLATFORM TO DELIVER MULTIPLE MICRONUTRIENT POWDERS TO INFANTS AND YOUNG CHILDREN IN NEPAL

A. Osei¹, P. Pandey², D. Adhikari³, J. Nielsen⁴, D. Davis²

¹Helen Keller International, Asia Pacific Regional Office, Phnom Penh, Cambodia

²Helen Keller International, Nepal Country Office, Kathmandu, Nepal

³US Agency for International Development, Kathmandu, Nepal

⁴Helen Keller International, New York, USA

Background and objectives: Anemia affects 46% of preschool children in Nepal. Micronutrient powders (MNP) are mainly distributed through the health platform. We assessed the value added in using Homestead Food Production program (HFP), as a platform to deliver MNP to children in Baitadi district, Nepal.

Methods: In this cluster-randomized controlled study, 330 children aged 6-9 months were enrolled into one of three study groups: 1) HFP + MNP 2) HFP or 3) control. The HFP + MNP group received 60 sachets of MNP every 6 months, over 12 months. The MNP contained 15 vitamins and minerals, including 10 mg iron, 4.1 mg zinc, 400 g vitamin A, 150 g folic acid and 30 mg vitamin C. Hemoglobin and anthropometry were measured at baseline and post-MNP supplementation.

Results: Baseline mean hemoglobin concentrations were similar for all groups (HFP + MNP = 105.8 g/l; HFP = 107.2 g/l and control = 107.3 g/l). Hemoglobin increased significantly in all groups, with a higher change in the HFP + MNP and HFP compared to the control (difference in difference: 3.9 g/l HFP + MNP vs. control; 3.3 g/l HFP vs. control; and 0.6 g/l HFP + MNP vs. HFP). However, these differences were not significant. Anemia decreased in all groups, with no significant benefit of the interventions, although the change was higher in the HFP + MNP (51.5 percentage points [pp]) than the HFP (48.6 pp) and control (39.6 pp). Stunting increased similarly in all groups and underweight increased in the HFP + MNP and control, but not the HFP group. There was no change in wasting among all groups.

Conclusions: The study showed that HFP can be used as a platform for MNP distribution in Baitadi district, Nepal. HFP alone had a potential of yielding similar benefits on anemia resolution as providing HFP + MNP. Further studies are required to confirm these findings.

Key words: Anemia, micronutrient powders (MNP), Nepal, children

PO2547**WHICH DIETARY DIVERSITY INDICATOR IS THE BEST TO USE IN YOUNG CHILDREN?**

N. Steyn¹, J.H. Nel², D. Labadarios¹, E.M. Maunder³, H.S. Kruger⁴

¹Population Health, Health Systems and Innovation, Human Sciences Research Council, Cape Town, South Africa

²Department of Logistics, University of Stellenbosch, Stellenbosch, South Africa

³University of Bournemouth, England, UK

⁴Nutrition Centre of Excellence, North West University, Potchefstroom, South Africa

Background and objectives: Due to rapid urbanization in many developing countries, street foods (SFs) have become increasingly important as an income generating strategy and as a fast and economical meal option. There is however, a paucity of data on the nutritional contribution of SFs to the diet. The aim of this study was to review studies which had determined the nutritional value of street foods (SFs) and their contribution to the diet of consumers in developing countries.

Methods: The electronic databases of Pubmed/Medline, Web of Science, Proquest Health, and Science Direct were searched according to predetermined search criteria.

Results: From a total of 639 articles, 23 studies were retained since they met the inclusion criteria. In summary, daily energy intake (EI) from SFs in adults ranged from 13% EI to 50.3% EI and in children from 13% EI to 40% EI. Although the amounts differed from place to place, even at the lowest values of the percent energy range, energy contribution from SFs made a significant contribution to the diet. Furthermore, the majority of studies suggest that SFs contribute significantly to the daily intake of protein, often at 50% of the recommended dietary allowance (RDA). The data on fat and carbohydrate intakes are of some concern because of the assumed high contribution of SF to the total intake of fat, trans fats, salt and sugar in numerous studies and their possible role in the development of obesity and non-communicable diseases. Few studies have provided data on the intake of micronutrients, but these tended to be high for iron and vitamin A, but low for calcium and thiamine.

Conclusions: Street foods make a significant contribution to energy and protein intake of people in developing countries and their use should be encouraged if they are healthy traditional foods.

Key words: Street food, urbanization, dietary intake, macronutrients

PO2548**IGROW: BRINGING TECHNOLOGY TO COMMUNITY-BASED GROWTH PROMOTION TO IMPROVE IMPLEMENTATION**

M. Griffiths¹, M. Antal¹, T. Schaetzel¹, N. Shah¹

¹The Manoff Group, Washington, USA

Background and objectives: Community-based growth promotion (CBGP) is practiced to help community workers better support families and detect childcare problems before they lead to undernutrition. Typically, community volunteers or health workers weigh a child monthly and check weight gain against a standard to judge growth adequacy. Based on the determination, they provide tailored counseling and other services to support continued good care or suggest needed changes. An easier and quicker method for accurately determining growth status could improve CBGP effectiveness and simplify training and supervision. Our objective was to identify an mHealth solution to improve the ability of community workers to accurately determine the adequacy of a child's growth and to offer prompts for the counseling.

Methods: We reviewed existing technology packages and determined the need to design a new package and to test it in a program with 1) a functional recording system 2) good monthly attendance 3) a good counseling system and 4) consistent use of growth information by community leaders and health workers to determine actions to improve nutrition.

Results: An mNutrition solution, iGrow, was constructed to record monthly weight per child, automatically calculate progress, and give instant feedback to prompt counseling. The system will aggregate growth information automatically at the community and district levels and be accessible to all stakeholders.

Conclusions: iGrow will enable accurate assessment of child growth, provide instant feedback for health workers who are freed up to focus on counseling, and ensure timely access to aggregated information for decision making by community leaders and district program managers.

Key words: Community based growth promotion, Health

PO2549**VALIDATION OF SKINFOLD THICKNESS EQUATIONS WITH AIR DISPLACEMENT PLETHYSMOGRAPHY FOR ESTIMATION OF BODY COMPOSITION AMONG ADOLESCENTS***Y N. Ang¹, K Q. Chan², B K. Poh¹, M N. Ismail³*

¹Nutritional Sciences Programme, School of Health-care Sciences, Faculty of Health Sciences, Universiti Kebangsaan Malaysia, Kuala Lumpur, Malaysia

²Department of Sports and Exercise Science, School of Arts and Science, Tunku Abdul Rahman College, Kuala Lumpur, Malaysia

³Department of Nutrition and Dietetics, Faculty of Health Sciences, MARA University of Technology, 42300 Puncak Alam, Selangor, Malaysia

Background and objectives: With the rising trend of obesity among adolescents, it is imperative to be able to measure body composition accurately. Hence, this study aimed to validate conventional skinfold thickness (SKF) equations for measuring body composition among adolescents with a criterion method.

Methods: A total of 126 adolescents (50 boys; 76 girls) aged 12 to 18 years old from Kuala Lumpur participated in this study. Anthropometric measurements included body weight, height, and skinfolds. Body composition was determined by Durnin and Rahaman (1976), Slaughter et al. (1988) and Deurenberg et al. (1990) skinfold equations. The criterion method employed was air displacement plethysmography (ADP) technique using BodPod GS.

Results: Mean weight, height and body mass index (BMI) were 54.7±17.1 kg, 159.2±8.4 cm and 21.4±5.7 kg/m², respectively. Mean body fat percentage from Bod Pod GS was 25.5±10.8%. Significant difference ($p<0.05$) was found between Bod Pod GS and Durnin and Rahaman (1976) (2.0±7.0%), Slaughter et al. (1988) (4.3±6.9%) and Deurenberg et al. (1990) (5.6±8.1%) equations. The SKF equations underestimated body fat percentage and fat mass but overestimated fat free mass (FFM). Nevertheless, there were significant correlations ($p<0.01$) between SKF with ADP for body fat percentage, fat mass and fat free mass. The highest correlation for body fat percentage with Bod Pod GS was Durnin and Rahaman (1976) ($r=0.825$, $p<0.01$), followed by Slaughter et al. (1988) ($r=0.824$, $p<0.01$), and Deurenberg et al. (1990) ($r=0.802$, $p<0.01$). Bland-Altman plots showed good agreements between all equations with Bod Pod GS but Durnin and Rahaman (1976) was the best.

Conclusions: We suggest that the Durnin and Rahaman (1976) equation for estimating body composition is the most appropriate for use in future studies among adolescents.

Key words: body composition, skinfold equations, air displacement plethysmography. Financial Disclosure: This study

PO2550**IRON AND ZINC SUPPLEMENTATION IN YOUNG ADULT CAMEROONIANS IN POOR VITAMIN A DIETS***M M. Kana Sop¹, I. Gouado¹, E. Tetanye², P H. Amvam Zollo³, D. Oberleas⁴, J. Van Camp⁵*

¹University of Douala Faculty of Science, Department of Biochemistry, Douala, Cameroon

²University of Yaoundé, Faculty of Medicine and Biomedical Sciences, Yaoundé, Cameroon

³University of Ngaoundéré, Ngaoundéré, Cameroon

⁴Texas Tech University, Emeritus, Lubbock, Texas

⁵University of Gent, Gent, Belgium

Background and objectives: Minerals and vitamin A deficiencies coexist in Cameroon in all age groups. However, natural sources of Vitamin A are available and could be used to reach all the whole population. This study aims at assessing the serum levels of zinc and iron after 11 days supplementation with 20mg of zinc and iron, taken alone, together or at different times in free or low vitamin A diets.

Methods: Thirty two men aged 18 to 33 years, divided into 6 groups of 5 or 6 persons, were enrolled in the study and distributed as follow: groupe1: 5 persons not supplemented; groupe2: 5 persons supplemented with iron; groupe3: 6 persons supplemented with zinc; groupe4: 6 persons supplemented with zinc and iron together; groupe5: 5 persons supplemented with iron and zinc separately; groupe6: 5 persons supplemented with vitamin A the last day. The 5 last days, participants were put on free or poor vitamin A diets. Sera were collected at day 1, day 5 and day 11 for analyses of Zn and Fe levels by atomic absorption spectrophotometry.

Results: Highest serum iron and zinc concentrations were observed in groups either supplemented with zinc or with iron given alone. In those two groups, serum Zn concentrations increased from 0.69 ± 0.02 to 0.95 ± 0.13 (groupe2), from 0.48 ± 0.06 to 0.97 ± 0.11 (groupe3); and serum Fe concentrations from 1.49 ± 0.54 to 3.49 ± 1.01 (groupe2); and from 1.42 ± 0.45 to 3.41 ± 0.81 (groupe3) respectively.

Conclusion: Supplementation with Fe or Zn alone increased both Fe and Zn serum levels participants. Further studies on a larger population are necessary to confirm that supplementation with zinc or with iron alone could raise both zinc and iron levels in serum simultaneously.

Key words: Supplementation, Iron, Zinc, Young-adults, Cameroon

PO2551**EFFECT OF GROUP GUIDANCE ON NUTRITION TO PATIENTS WITH CHRONIC RENAL FAILURE***H. Ikeda¹, I. Shiba², C. Kashiwabara², T. Iwamoto²*¹Nihon University, Tokyo, Japan²Saiseikai Yokohama-city, Nanbu Hospital, Japan

Background and objectives: The principles of dietary measures for chronic renal failure before starting dialysis are to reduce salt, restrict protein and ensure sufficient energy. For the purpose, it is essential to use the special foods for remedy whose constituents are uniquely regulated. The special staple foods of rice, noodle and bread that contain less protein are particularly required for implementation of dietary measures. Our hospital has organized the group guidance to explain how to use the special foods for easy practice of the measures since its opening in 1983 and held the 162th class in December 2012. In this study, the subjects were the patients who participated in the group guidance. Regular surveys on their attitude to diet had been conducted since 1991 and our objective was to compare the results of 2002 and 2011.

Methods: The anonymous questionnaire sheets were distributed to the patients before each guidance and filled and collected on the spot.

Results: There was no significant difference between men and women in both years. (1) The patients whose dietary method was measurement and calculation nearly every day to keep the instructed amounts were 45.0% in 2002 but significantly decreased to 18.4% in 2011. In contrast, those with rough estimate were 15.0% in 2002 and significantly increased to 44.7% in 2011. (2) The patients who bought the special foods from a dispensary near the hospital were 17.5% in 2002 and 40.9% in 2011, which was a significant rise.

Conclusions: A diverse variety of special foods have been developed recently to facilitate implementation of dietary measures. Understanding and continuation of the complex diet can eventually lead to self-management with rough estimate instead of precise measurement of food and nutrient calculation. In addition, the pharmacist of the dispensary where the special foods were dealt with always attended to the group guidance and sold them.

Key words: Nutrition, chronic renal failure, group guidance

PO2552**DEVELOPMENT OF RECIPE DATABASE FOR BREADS AND CAKES FOR PROCESSING DIETARY INTAKE SURVEY DATA***J. Nam¹, J. Y. Lee¹, Y. Lee¹, E. Koh¹, D. Kim¹, M. Yon¹, S. J. Park¹, M. Jo¹, S. Kweon², K. Oh², C. I. Kim³*¹Nutrition Policy Team, Korea Health Industry Development Institute (KHIDI), Chungbuk, Korea²Division of Health and Nutrition Survey, Korea Centers for Disease Control and Prevention, Chungbuk, Korea³Department of Health Industry & Policy, KHIDI, Chungbuk, Korea

Background and objectives: This study was performed to develop a representative recipe database for breads and cakes as a part of on-going work of building recipe database to be used in processing dietary intake survey results from the Korea National Health and Nutrition Examination Survey (KNHANES).

Methods: Frequently consumed breads and cakes were sought using dietary intake data from KNHANES 2009 to make a list for recipe collection. Out of the 10,944 bakeries located in seven metropolitan cities and Gyeonggi province in Korea, 500 bakeries were selected by probability proportional to size sampling and systematic sampling. More than 7,610 recipes for breads and cakes were collected by trained dietitians from 504 bakeries responded to the face-to-face interview in 2011. For each bread or cake, ingredient foods reported from different bakeries were pooled and sorted by appearing frequency and amount used. Ingredients with frequency less than 10% or weight less than 1% of total ingredients weight were excluded and weights of remaining ingredient foods were divided by number of recipes included to make a preparatory recipe for each bread or cake.

Results: We produced a representative recipe database for 103 breads and cakes with recipes from 11 or more bakeries and these were subject to experimental cooking to delineate the relationship between prepared dish volume and amount of ingredients with final adjustment, if necessary.

Conclusions: This database will be used in estimating ingredient food intake from breads and cakes intake reported in volume in KNHANES. In addition, it will be incorporated into the fundamental nutrition database used in the processing dietary intake survey data of KNHANES and consequently enable the more reliable estimation of food and nutrient intake of the Korean population.

Key words: Recipe database, bakeries, breads, cakes

PO2553**MEASURING THE VALIDITY OF DIETARY ASSESSMENT INSTRUMENTS: THE METHOD OF TRIADS***F. Bageherzadeh¹, S. Nabavi¹, S. Edalati¹, K. Aslani¹*¹Students' Research Committee, Faculty Nutrition, Tabriz University of Medical Sciences, Tabriz, Iran

Background and objectives: Assessment of long-term dietary intake has commonly been associated with significant measurement errors. Measurement error is a common source of bias in epidemiological studies, particularly for laboratory tests or questionnaires that are not considered to be a gold standard. These measures could be inaccurate if the two methods have correlated errors or if one of them has repeated measurements. Here, we suggest an approach to validate these measurements that is known as the method of triads.

Methods: We performed a literature search in the MEDLINE and PubMed databases for studies published in English between 1995 and 2012, using a database searching filter and manual selection as needed.

Results: The number of published studies is still small and methodological differences related to population, the type of questionnaire and the reference method hamper the comparability of the results.

Conclusions: The method of triads is a simple technique for assessing validity and reproducibility of continuous exposure measurements.

Key words: Dietary assessment, method of triads, validity

PO2554**ENERGY INTAKE UNDERREPORTING OF ADULTS FROM A HOUSEHOLD SURVEY IN NITERÓI, RIO DE JANEIRO, BRAZIL***D. Souza¹, V. Wahrlich¹, L. Anjos¹, M. Vasconcellos²*¹Departamento de Nutrição Social, Universidade Federal Fluminense, Niterói, Brasil²Escola Nacional de Ciências Estatísticas, Fundação Instituto Brasileiro de Geografia e Estatística, Rio de Janeiro, Brasil

Background and objectives: Dietary surveys generally include energy intake (EI) as a valuable tool in assessing the nutritional status of populations. Thus, it is crucial that it be measured as accurate as possible. The objective of the present study was to identify the underestimation of EI, assessed by 24-hour dietary recall, using the EI to basal metabolic rate (BMR) ratio (EI/BMR) in a probability sample (n = 1726) of the adult population (≥ 20 years) of Niterói, Rio de Janeiro, Brazil.

Methods: BMR was estimated by the FAO/WHO recommended equations (Schofield - BMR_SCH) and by sex-specific equations recently developed and validated for the Brazilian population (BMR_BRA).

Results: Mean (SE) EI was 1570.9 (24.1) and 2188.8 (46.1) kcal/day for women and men, respectively. BMR_SCHO yielded significantly higher values than BMR_BRA (1512.2±7.1 and 1256.1±5.8 kcal/day). The overall EI/BMR_SCH ratio was 1.18 (0.02) and 1.28 (0.02) for women and men, respectively, and the underestimation, using the Goldberg cut-off, was 80.4 and 72.6%. The same values using the EI/BMR_BRA ratio were 1.40 (0.02), 1.56 (0.03), 66.1 and 55.6%. The lowest EI/BMR_SCH ratios occurred in the 50-60y age group (1.06±0.03 and 1.19±0.05) and in the obese (BMI ≥ 30 kg/m²) group (1.01±0.03 and 1.12±0.06, for women and men, respectively).

Conclusions: The data indicate important underestimation of EI, especially in individuals with excess body weight, which is higher if the internationally recommended BMR equations (BMR_SCH) are used.

Key words: Energy intake, Brazil, Basal metabolism

PO2555**APPENDICULAR LEAN MASS DETERMINED BY AN OCTOPOLAR BIA SYSTEM AND DXA IN MIDDLE-AGED AND AGED SUBJECTS FROM NITERÓI, RJ, BRAZIL***V. Wahrlich^{1,2}, L. Anjos^{1,2}, L. Canto², M. Frota¹*¹Departamento de Nutrição Social, Universidade Federal Fluminense, Niterói, Brasil²Pós-graduação em Saúde Coletiva, Universidade Federal Fluminense, Niterói, Brasil

Background and objectives: Appendicular lean mass (ALM) is important to derive skeletal muscle index, a variable used for screening of sarcopenia. Usually ALM is obtained by gold standard body composition methods that are cumbersome to apply in field and clinical studies. An alternative is the bioelectrical impedance analysis (BIA) using eight electrodes that can estimate the composition of the limbs. Our objective was to compare ALM estimated by octopolar BIA (OBIA) and obtained by dual x-ray absorptiometry (DXA) of middle-aged and aged subjects enrolled in the Programa Médico de Família (Family Physician Program) of Niterói, Rio de Janeiro, Brazil.

Methods: A total of 135 subjects over 45 years of age (99 women) participated in this cross-sectional study. ALM was obtained by the sum of arm and leg lean mass determined by DXA (GE IDXA) (ALM_DXA) and by OBIA (TANITA BC 418) (ALM_OBIA). Body mass and stature were also measured and body mass index (BMI) was calculated.

Results: Average \pm SD age was 59.3 ± 10.0 years and 58.4 ± 9.1 for women and men, respectively. On average both sexes were overweight (BMI= 27.9 ± 4.5 kg/m² in women and 27.2 ± 4.4 kg/m² in men) but women had significantly higher percent body fat than men (40.3 ± 5.6 vs $30.2 \pm 5.7\%$). The sample comprised 75.4 and 72.0% of overweight + obesity (BMI >25 kg/m²) women and men. Mean ALM_OBIA was significantly different from ALM_DXA in women (17.2 ± 2.3 and 16.7 ± 3.0 kg, respectively) and men (24.2 ± 3.4 and 23.4 ± 3.6 kg) but represented a relatively low overestimation percentagewise (3.9 ± 7.7 and $3.8 \pm 8.2\%$). ALM was only accurately estimated in obese (BMI > 30 kg/m²) individuals (mean difference of 0.2 ± 1.5 kg).

Conclusions: ALM was significantly overestimated by OBIA for the whole sample but was accurately estimated in obese individuals. Studies with a broader BMI distribution sample should be carried out to ascertain the validity of OBIA to estimate ALM in Niteroian adults.

Key words: Body composition, Brazil, validation studies

PO2556

FUNCTIONAL CAPACITY AND ITS ASSOCIATION WITH NUTRITIONAL STATUS IN THE ELDERLY

T. Menezes¹, N. Silva¹, K. Brito¹, D. Pedraza¹

¹State University of Paraíba, Paraíba, Brazil

Background and objectives: The aging process causes biological changes such as neurological and musculoskeletal disorders, leading to a progressive and irreversible loss of function in systems, interfering with functional capacity and nutritional status of the elderly, exposing him to a state of vulnerability and loss of independence. The aim of this study was to verify the association between functional capacity and nutritional status in an elderly population.

Methods: This is a cross-sectional home-based study with elderly individuals (60 years or more) of both sexes enrolled in the Family Health Strategy of Campina Grande-PB. Variables indicative of functional capacity (handgrip strength (HGS), flexibility/mobility and balance) and nutritional status (NS) (body mass index (BMI), arm muscle circumference (AMC) and corrected arm muscle area (CAMA)) were assessed. The association between functional capacity variables and NS was verified using the Chi-square (χ^2) test. The potential risk factors associated with functional capacity were verified by multivariate logistic regression, adopting a significance level of $p < 0.05$.

Results: The study included 420 elderly subjects (68.1% women). The results of the association between variables indicative of functional capacity and NS showed that elderly people with good HGS were mostly overweight/obese and showed muscle reserve indicative of eutrophy. No significant associa-

tion was observed between the mobility test and NS. Variables AMC and CAMA were associated with balance. In the multivariate logistic regression analysis, the eutrophic condition, verified by the AMC, was a risk factor for poor balance (OR 2.14, 95% CI 3.78 to 1.21).

Conclusions: The influence of nutritional status on the functional capacity in the elderly in this study indicates the importance of studies evaluating factors related to functional loss in this population.

Key words: Elderly, functional capacity, nutritional status

PO2557

PREDICTING OBESITY AMONG DIFFERENT 2 MAJOR ETHNICS IN EAST JAVA

N.N. Wirawan¹, W. Rahmawati¹, S. Andarini², U. Khasanah¹, P.M. Sari¹

¹Department of Nutrition, University of Brawijaya, Malang, Indonesia

²Department of Medicine, University of Brawijaya, Malang, Indonesia

Background and objectives: Asians have a greater percentage of body fat (BF) and abdominal adipose tissue at lower Body Mass Index (BMI). The use of cut-off specific to ethnic groups is recommended. East Java, as one of the most population-dense province in Indonesia, hosts 2 major ethnics: Javanese and Maduranese. Therefore this study aims to assess obesity of both ethnics by using some indicators.

Methods: A cross sectional study with the total of 225 subjects aged 20-49 years old was recruited purposively. Anthropometric measurement includes weight and height for BMI calculation using Asian cut-off, %BF based on 4-sites skinfold thickness (triceps, biceps, suprailiac and subscapular) and digital body fat analyzer, waist circumference (WC) and hip circumference to calculate waist-hip ratio (WHR).

Results: One hundred and thirty seven respondents are Javanese, 88 respondents are Maduranese with 56 (24.9%) are male and 169 (75.1%) are female, aged 33 ± 8.76 years. Mean of all indicator is significantly higher among Maduranese compare to Javanese with $p < 0.05$ (84.71 ± 10.55 and 81.9 ± 60.6 cm for WC, 1.00 ± 1.21 and 0.88 ± 0.64 for WHR, 25.65 ± 4.44 and 22.79 ± 3.61 kg/m² for BMI, 33.40 ± 6.96 and 27.2 ± 7.83 % for %BF, respectively). Based on %BF, more Fat and obese among Maduranese compared to Javanese (57.7% and 85.2% respectively). This is in agreement with the classification using BMI, where more Maduranese were categorized as obese compared to Javanese (65.9% and 35.8% respectively). Maduranese also had more central obesity compared to Javanese (63.6% and 25.5% for WC, 72.7% and 39.4% for WHR respectively).

Conclusions: There is agreement between all indicators in classifying that Maduranese have higher body size and body fat particularly abdominal obesity compared to Javanese in East Java.

Key words: Abdominal obesity, Maduranese, Javanese

PO2558

EVALUATION OF NUTRIENT INTAKE AND DIET QUALITY INDEX-INTERNATIONAL (DQI-I) IN KOREAN GASTROINTESTINAL CANCER PATIENTS

H. Lim¹, S. Kim², E. Shin³, G. Cho³, G. Jeong³

¹Department of Clinical Nutrition, Soonchunhyang University Bucheon Hospital, Gyeonggi-do, South Korea

²Department of Food Sciences & Nutrition, Soonchunhyang University, Asan, South Korea

³Department of Surgery, College of Medicine, Soonchunhyang University, Asan, South Korea

Background and objectives: It is suggested that evaluation of diet quality may be a great indicator of nutritional assessment. The purpose of this study was to investigate the nutritional status, dietary habits, and dietary quality for Korean gastrointestinal cancer patients.

Methods: This survey was conducted through anthropometric data, food frequency questionnaires and diet record survey to 339 cancer patients (colorectal cancer; n=143, stomach cancer; n=196) from February 2007 to December 2012.

Results: Most of the cancer patients (81.6%) were well-nourished, and 18.4% of the cancer patients were malnourished at preoperative status, respectively. The number of nutrients in Index of Nutritional Quality (INQ) < 1.0 of colorectal cancer patients were significantly higher than that of stomach cancer patients. The Korean's Dietary Diversity Score (KDDS) of colorectal cancer and stomach cancer patients were 3.6 and 3.8, respectively. The average Diet Quality Index-International (DQI-I) of colorectal cancer and stomach cancer patients were 67.7 and 62.5, and there was significant difference.

Conclusions: The proper dietary management should be needed for cancer patients.

Key words: Diet quality, nutritional status, colorectal cancer, stomach cancer

PO2559

CALCULATING CHILD AGE WITHOUT BIRTH RECORDS: VALIDATION OF A NEW METHOD FOR ESTIMATING DATE OF BIRTH

J. Waid¹, A. Kader¹

¹Helen Keller International, Dhaka, Bangladesh

Background and objectives: Because accurate child age in days is vital for assessing child nutritional status and adequate feeding practices and no comprehensive method of estimating date of birth without birth records was indentified, the Food Security and Nutrition Surveillance Project developed a new method of estimating child birthdates. While this method has proven easy to use in the field, the quality of the data returned by the method has not yet been validated.

Methods: Results from this method were compared to assumptions of a uniform distribution of child birthdates across weekdays/days of the month and the outcomes of anthropometric indicators derived from these birthdates were examined. The performance of this new method of birthdate calculation, was compared to the results from surveys in Bangladesh which did not use this method. Repeated subsamples of surveyed children drawn from both the new method and other surveys are used to estimate the variation of the observed distribution from what is expected.

Results: The seasonality of birth as measured through this new method shows high congruence between years and fits with the fertility cycle in Bangladesh. Simulation results indicate that the new system presents a better fit for a random uniform distribution model than the birthdates from other surveys in Bangladesh. Furthermore, the new methodology provides a lower proportion of outliers in weight-for-age and height-for-age estimation. This method maintains a low deviation from a uniform distribution even when used in short-term survey projects.

Conclusions: Based on the success of this model in enabling data collectors to record birthdates for children without birth records with little signs of surveyor preference or bias, this method should be used more widely in Bangladesh and scaled up and tested in other locations which have low coverage birth registration systems.

Key words: Anthropometry, date of birth, household survey

PO2560**SERUM RESPONSE TO A SINGLE DOSE OF DIETARY CAROTENOIDS FROM STEAMED, FRIED AND STEAM-DRIED SQUASHES PULP (CUCURBITA SPP)**

A D M. Funkeu¹, I. Gouado¹, F. Schweigert², F. Tchounguep³

¹Department of Biochemistry, University of Douala, Douala, Cameroon

²Institute of Nutritional Science, University of Potsdam, Potsdam, Germany

³Department of Biochemistry, University of Dschang, Dschang, Cameroon

Background and objectives: Data on bioavailability of carotenoids are necessary for dietary recommendation. The objective of this study was to assess the serum response to a single dose of dietary carotenoids from steamed, fried and steam-dried pulp of *C. maxima*, *C. pepo* and *C. moshata*.

Methods: Three groups of 10 healthy volunteers aged 21-28 years with BMI 16.61-17.51 kg/m², were fed respectively with *C. maxima*, *C. moshata* and *C. pepo* pulp processed in 3 different forms: steamed, fried and steam-dried. After 5 days of poor carotenoids and retinol diet, fasting subjects ate meals containing one of the forms of processing squashes (providing 8 mg β-carotene) with roasted hulled groundnut paste. Blood samples were collected before, 4 h and 8 h after the meal. Carotenoids and retinol content of the serum samples was analyzed by HPLC method. Triglycerides content was also evaluated.

Results: Considerable inter-individual variation was observed between serum response of carotenoids, retinol and triglycerides. Mean serum level of triglycerides increased significantly 4 h or 8 h after the test meal no matter the form of processing and the species. No significant difference was observed for all carotenoids and retinol values before and after the test meal at 4 h or 8 h. However, 27/29, 26/29 and 23/29 subjects had serum increment of provitamins A and 22/29, 16/29 and 12/29 subjects had increments of non provitamins A after consumption of steamed, fried and steam-dried squashes respectively.

Conclusions: Carotenoids of steamed squash had the best bioavailability followed by those of fried form and then steam-dried form. However, association of the three forms can efficiently contribute to improve vitamin A status of the population.

Key words: Squashes pulp, steamed, fried, steam-dried, carotenoids bioavailability

PO2561**BODY COMPOSITION IN AMATEUR AND PROFESSIONAL BOXING VERSUS PHANTOM**

A. Witriw¹, M. Iglesias¹, C. Rellecati¹, V. Santamaria¹, C. Schattner¹

¹School of Nutrition, Faculty of Medicine, University of Buenos Aires, Buenos Aires, Argentina

Background and objectives: Boxing is a sport divided by categories according to body weight. One of its main objectives is to achieve proper weight and body composition. Full knowledge of body composition allows that at the time of competition boxers have components sufficiently balanced to reach maximum performance.

Methods: Twenty six boxers of the Argentine Box Federation, both amateur (n=19) and professional (n=7), were evaluated using the "Anthropometric Fractionation" (ENFA) method proposed by Drinkwater and Ross and modified by Basaluzzo, JM., that determines five components (muscle, fat, skeletal, visceral and residual masses), including both protein and calorie reserves (muscle/skeletal mass and fat mass/skeletal mass) and somatotype. Mean values and deviations of each variable were calculated for both categories, and were compared with sedentary subjects (Phantom).

Results: When comparing the profile of a boxer, both amateur and professional with a reference population, it is found that there are significant differences in body mass level, showing a predominance of muscle and skeletal mass and a decrease in fat mass. In bone diameters, increased diameter values were observed in wrist, humerus, ankle and anteroposterior (AP) chest, while bitrochanteric and bi-iliac diameter presented reduced values in both categories. Muscle perimeters show increased values in relaxed bicep, forearm, calves and chest in amateurs and professionals. The somatotype shows a meso-endomorph profile in amateurs and balanced mesomorph in professionals. The calorie reserve in professionals was found decreased: moderately in 3 subjects and severely in 4, while in amateurs, 2 had normal reserve, 9 moderately decreased and 8 severely decreased. Protein reserve was found decreased in 3 of 7 professionals and 5 of 19 amateurs.

Conclusions: This last situation is remarkable as decreased protein reserves may result in a reduced performance. It emphasizes the importance of assessing body composition in this sport.

Key words: Boxing, body composition, anthropometry, ENFA, somatotype

PO2562**PHYLLUQUINONE CONTENT OF VEGETABLES AND DIETARY VITAMIN K1 INTAKE IN CHINESE ELDERLY PEOPLE**

X.H. Wang¹, B. Zhou¹, L.Y. Guo¹, Z. Zhang¹, C. Xu¹

¹Department of Nutrition and Food Hygiene, Shenyang Medical College, Shenyang, Liaoning, PR China

Background and objectives: Phylloquinone (Vitamin K1) plays an important role in bone and vascular health. However, there is no data of phylloquinone in the Standard Tables of Food Composition in China. The objective of the present study was to obtain a closer estimate of dietary intake phylloquinone.

Methods: Phylloquinone contents in vegetables samples (47 food items) were determined by a high-performance liquid chromatography method. Complete 3-d weighed dietary records were obtained from 138 participants aged 60-92 years living in northern China. Vitamin K1 intakes were assessed using phylloquinone contents here and Japanese data of the phylloquinone.

Results: Phylloquinone was widely distributed in green leafy vegetables (80 °C 638 µg/100 g wet weight) and the highest amount was found in celery leaf. The amount of the traditional wild vegetable in chicory, dandelion and shepherd's purse was 211, 354 and 459 µg/100 g, respectively. The vitamin K1 intake of all subjects was 229.7 ± 87.1 µg/d (83.0-575.0 µg/d) and 91.7% of participants met the adequate intake (AI) of vitamin K1 for adult in China. 18.8% of subjects had a vitamin K1 intake higher 300 µg/d. The contributions of green leafy vegetables, other vegetables, plant oil to total vitamin K1 intake were 53.8%, 21.0% and 16.1, respectively. Chinese cabbage larger (80 µg/100 g wet weight) provided 34 % of total vitamin K1 intake.

Conclusions: The present study shows that habitual vitamin K1 intakes in old adults living in northern China were high. Phylloquinone from green leafy vegetables were the major contributors to the total vitamin K1 intakes.

Key words: Vitamin K, phylloquinone, food composition, dietary intake, elderly

PO2564**EFFECTS OF ZINC DEFICIENCY ON TISSUE MINERAL DISTRIBUTION AND BONE METABOLISM**

T. Suzuki¹, H. Inoue¹, M. Uehara¹, K. Suzuki¹

¹Department of Nutrition Science, Faculty of Applied Bio-Science, Tokyo University of Agriculture, tokyo, Japan

Background and objectives: Zinc is an essential nutrient that is required in humans and animals for many physiological functions. Furthermore, zinc has been demonstrated to have a stimulatory effect on osteoblastic bone formation and mineralization. However, very few studies have documented the relationship between tissue mineral distribution and bone metabolism by zinc deficiency in rats. We hypothesized that zinc deficient diet induces mineral alteration in several organs, and affects negatively bone metabolism in rats.

Methods: Four-week-old male Wistar rats were assigned to three different dietary groups: a zinc adequate diet (zinc, 30 ppm) group (C), a zinc adequate diet (zinc, 30 ppm) and pair fed group (PF), and a zinc deficient diet (zinc, 1 ppm) group (ZD). The rats were fed their respective diets for 4 weeks.

Results: After 4 weeks of feeding, weight gain and food efficiency were significantly decreased in the ZD group compared to the two zinc adequate groups. Serum zinc concentration was significantly lower in the ZD group than in the C and PF groups. Compared to the C and PF rats, the ZD rats showed significantly low mean values in tibial bone mineral density (BMD) and bone strength. Additionally, serum osteocalcin, a bone formation marker, was lower in the ZD rats than in the C and PF rats. Urine deoxypyridinoline (DPD), a bone resorption marker, was higher in the ZD rats than in the C and PF rats. Interestingly, magnesium concentration in femur and tibia was increased in the ZD rats compared to the PF and C rats. Moreover, iron and copper concentrations in liver were significantly higher in the ZD rats than in the PF and C rats.

Conclusions: These findings in the present study suggest that several mineral alterations may affect indirectly bone fragility by zinc deficiency.

Key words: Zinc deficiency, bone, magnesium

PO2565**EVALUATION OF MINERAL STATUS IN RHEUMATOID ARTHRITIS PATIENTS***S. Cozzolino¹, K. Callou¹, G. Silva¹, D. Pollak²*

¹Department of Food and Experimental Nutrition, Faculty of Pharmaceutical Science, University of São Paulo, São Paulo, Brazil

²Department of Rheumatology, Faculty of Medicine, Federal University of São Paulo, São Paulo, Brazil

Background and objectives: Pathogenic events such as inflammatory cascades and cell damage are caused by reactive oxygen species (ROS), but they could be decreased with an adequate nutritional selenium (Se) and zinc (Zn) status. These minerals function as a component of antioxidant enzymes (glutathione peroxidase and superoxide dismutase), protecting cells from oxidant damage. Large amounts of ROS are produced in patients with rheumatoid arthritis contributing to the pathogenesis of the disease. Then, the present study aimed to evaluate selenium and zinc status in patients with rheumatoid arthritis (RA).

Methods: Sixteen RA patients, aged 30-65 y and attending clinical treatment in São Paulo Hospital, were included in this study. Plasma samples were collected and the determination of Se and Zn concentration was carried out by hydride generation atomic absorption spectrometry (HG-AAS) and flame atomic absorption spectrometry, respectively. Minerals intake was assessed through three 24-hour recalls using Nutwin software and GPx and SOD activity, using the kits Randox and Ransod, respectively.

Results: All patients presented decreased plasma Zn ($52.4 \pm 7.5 \mu\text{g Zn/l}$) and Se concentrations ($46.5 \pm 14.0 \mu\text{gSe/l}$), except for two of them for Se. These data were positively correlated to Se and Zn intake ($r=0.4082$, $r=0.4553$; $p<0.05$) and neither of the patients achieved the Dietary Reference Intake. Zn and Se intake were adjusted for energy. Se intake above daily requirement leads to an insufficient GPx activity ($45.68 \pm 21.67 \text{ U/g Hb}$) as shown in Pearson correlation ($r=0.666$, $p<0.05$). Besides that, SOD activity varied among patients ($1503.5 \pm 581.2 \text{ U/g Hb}$).

Conclusions: Preliminary results indicate that our patients with rheumatoid arthritis are nutritional deficient in Se and Zn and this fact could compromise antioxidant defense system.

Key words: Selenium, zinc, rheumatoid arthritis, antioxidant defense system

PO2566**EFFECTS OF FOOD MATRIX AND COOKING PROCESS ON MINERAL BIOACCESSIBILITY OF ENTERAL NUTRITION FORMULAS***M G. Galan^{1,2}, S R. Drago^{1,2}*

¹Instituto de Tecnología de Alimentos, Facultad de Ingeniería Química, Universidad Nacional del Litoral, Santa Fe, Argentina

²CONICET, Buenos Aires, Argentina

Background and objectives: In order to avoid monotony when enteral formulas (EF) are used in prolonged treatment as feed supplement, a common practice is their incorporation into foods. However, nutritional properties of EF could be modified by food matrices and cooking processes. The objective of this study was to evaluate the *in vitro* bioaccessibility of Fe, Zn and Ca (%DFe, %DZn, %DCa) from EF and the impact upon their incorporation into sweet preparations.

Methods: Twenty commercial EF, both powder and liquid (EFP, EFL) were evaluated. Sweet preparations were: rice pudding (RP), banana smoothie (BS), tea (T) and chocolate dessert (CD). Mineral content was determined by atomic absorption spectrophotometry. Mineral bioaccessibility was estimated by the percentage of dialyzate mineral after a digestion process that simulates gastrointestinal processes. Also mineral potential supply of 200 g serving was analyzed.

Results: Fe, Zn and Ca dialyzability from EF was variable and generally low. The mean and range of mineral dialyzability were: %DFe: $2.38 \pm 1.36\%$ (0.36–5.48%), %DZn: $4.8 \pm 3.1\%$ (0.2–12.0%), %DCa: $9.5 \pm 4.6\%$ (3.8–18.1%). The EFL showed higher Fe dialyzability than EFP, which may be related to the processes carried out during the drying of the formulations for later reconstitution. However, no significant differences were observed in the cases of Zn and Ca dialyzability among EFP and EFL. Heating during EF-sweet food preparation (T and CD) lowered by 44.1 %DFe, possibly due to degradation of vitamin C, and by 52.7 %DZn and 25.3 %DCa, due to interaction with food components. EF and EF-sweet foods did not make a good supply of Fe, Zn and Ca, as it is recommended.

Conclusions: This study demonstrated how the bioaccessibility of these minerals is affected for food matrix in which EF is included as well as the heating during food preparation.

Key words: Enteral formulas, bioaccessibility, minerals, iron, zinc, calcium

PO2568**DIET ANALYSIS OF ELDERLY PEOPLE: DEVELOPMENT OF A FOOD LIST**

A M P. Freitas¹, S T. Phillippi², S M L .Ribeiro³

¹Post Graduate Program in Applied Human Nutrition (PRONUT) / School of Arts, Sciences and Humanities/University of São Paulo - USP / Brazil - São Paulo

²University of São Paulo - USP/ Department of Nutrition/ School of Public Health/ São Paulo - Brazil

³University of São Paulo - USP / School of Arts, Sciences and Humanities/ São Paulo, Brazil

Background and objectives: Despite the phenomena of population aging, studies describing the feeding practices of elderly individuals are scarce. Our aim was to develop a list of the most ingested foods from community-dwelling elderly persons and to analyze the foods that contribute most to relevant health-related nutrients of these individuals.

Methods: The study was performed with 100 individuals aged 60 years and above, registered at a local reference center. To describe the nutritional status, the weight and stature were measured and the BMI- body mass index was calculated. To develop the food lists, two 24 h food recalls were applied, during two different seasons of the year. The food recalls were analyzed for food intake frequency and for percentage contribution of each food and each nutrient: energy, macronutrients, calcium and vitamin D.

Results: The participants were classified as following: 52% with BMI < 28 kg/m²; 15% with BMI between 28 and 30 kg/m²; 26% between 30 and 35 kg/m² and 7% presented BMI > 35 kg/m². The positive aspects related to food intake were rice, bean and green vegetable consumption. As negative aspects, we observed that the diet pattern was repetitive, since few foods contributed to a high number of nutrients. Furthermore, a high ingestion of refined carbohydrates was observed instead of whole foods.

Conclusions: The food lists allowed reflecting on educative interventions, and also allow future development of different food frequency questionnaires that are specific for this group.

Key words: Elderly, nutrition assessment, diet analysis

PO2569**BODY COMPOSITION AND PATTERN OF FAT DISTRIBUTION IN SCHOOL CHILDREN OF RURAL AND URBAN PLACES OF VENEZUELA**

B. Infante¹, R. Cordero², M. Zabala³, I Hagel⁴

¹Department of Basic Science, Universidad Central de Venezuela, Caracas, Venezuela

²Department of Biochemistry, Universidad Central de Venezuela, Caracas, Venezuela

³Department of Public Health, Universidad Central de Venezuela, Caracas, Venezuela

⁴Biomedicine Institute, Universidad Central de Venezuela, Caracas, Venezuela

Background and objectives: The pattern of central fat distribution is associated with atherogenic processes in childhood. Our aim was to evaluate body composition, muscle area (MA), fat area (FA) and the pattern of fat distribution in school children in Rural Areas (RA) and Urban Areas (UA) of Venezuela.

Methods: The research was exploratory descriptive. 458 children aged 4-14 years old in RA (58.9%) and UA (41.1%) were studied. Anthropometric variables were used to determine MA and FA and the distribution of adiposity by the Centripetal Index (CI) and Sestri (ST). For the categorization of MA and FA the national reference was used, a ST > 1 indicates tendency towards centralization and < 1 towards peripheral distribution. Data descriptive statistic, 't' Student test, analysis of variance and 95% significance level were used.

Results: RA children had higher values of MA, CI and ST than UA children and only FA was lower for RA. An increase of the variables according to subject age was observed, detecting significant increase in girls of RA in relation to UA. UA boys showed higher proportion of low MA and high FA; meanwhile the distribution pattern of peripheral adiposity was higher for the AU and the central adiposity distribution for RA. The older children tend to increase the central adiposity distribution more in boys than in girls in UA.

Conclusions: The body composition and the pattern of adiposity distribution differ between children living in rural and urban areas; this could be conditioned by socioeconomic variables, dietary habits, environmental, and physical activity.

Key words: Anthropometry, body composition, fat distribution

PO2570**DEVELOPMENT AND VALIDATION OF A SEMI-QUANTITATIVE FOOD FREQUENCY QUESTIONNAIRE FOR YOUNG SCHOOL-AGED CHILDREN**

V. Bountziouka², P. Farajian¹, G. Risvas¹, O. Malisova¹, D. B. Panagiotakos², A. Zampelas¹

¹Department of Food Science and Technology, Unit of Human Nutrition, Agricultural University of Athens, Greece

²Department of Nutrition-Dietetics, Harokopio University, Athens, Greece

Background and objectives: Accurate assessment of food intake in children and adolescents is an essential prerequisite for conducting epidemiological and clinical research on the links between diet and health. The objective of the present study was to examine the validity for estimating energy and macronutrients intake of a newly developed picture aid, semi-quantitative food frequency questionnaire (FFQ) for Greek children and preadolescents.

Methods: Sixty nine children, aged 10-12 years old (48% boys) were voluntarily enrolled in the study (86% participation rate). Children were asked to complete a 48 food items and 11 more supplementary questions, picture aid, FFQ as the test instrument and a 3-day dietary record (3DD) as the reference method. Anthropometric and lifestyle characteristics were also measured to evaluate the factors that may be related with reporting the dietary intake. The Bland and Altman method and the Wilcoxon signed rank test were used to evaluate the degree of agreement between the FFQ and the 3DD.

Results: The two methods were found to agree in terms of mean energy intake according to the Bland and Altman method, although a trend in overestimating energy intake was found as the intake increases. Additionally, results of the Wilcoxon signed rank test revealed the similarity of the distribution in energy intake as estimated from the FFQ and the 3DD (median (IQR): 2038 (1264 - 2651) kcals for the FFQ vs. 1902 (1583 - 2324) kcals for the 3DD, $p=0.33$). Concerning macronutrients intake, the agreement was also considered adequate as the mean difference for each nutrient was < 1 SD of the same nutrient intake as estimated from the reference method.

Conclusions: The FFQ can be used to estimate mean daily energy intake in children, as well as to estimate macronutrients intake at the group level.

Key words: Nutritional assessment, food frequency questionnaire, validation, children

PO2571**THE INFLUENCE OF DIETARY FAT ON THE FAECAL EXCRETION OF ZINC AND IRON**

N. Stroebinger¹, S M. Rutherford¹, S J. Henare¹, J F. Pérez², P J. Moughan¹

¹Riddet Institute, Massey University, Palmerston North, Manawatu, New Zealand

²Animal Nutrition and Welfare Service (SNIBA), Universitat Autònoma de Barcelona, Bellaterra, Spain

Background and objectives: It has been reported that consuming diets high in saturated fatty acids leads to a greater faecal calcium excretion, presumably due to the formation of insoluble Ca-fatty acid soaps. In contrast, the impact of dietary fat on other divalent cations, such as zinc or iron, has received little attention, even though zinc or iron deficiency is prevalent. This study aimed to determine the faecal excretion of the latter micro-minerals from diets rich in either saturated or polyunsaturated fatty acids using the growing pig as a model for the adult human. Soybean oil and tallow were used as fat sources as they contain large amounts of available (present in the sn1 and sn3 positions and therefore available for soap formation) unsaturated and saturated fatty acids respectively.

Methods: Pigs received semi-synthetic wheat starch-based free phytate diets containing either soybean oil or tallow as the sole fat source (130 g/kg). The concentration of all other nutrients was equivalent across diets. Faeces were collected over a 72 h period after a 6 day acclimatisation period. Apparent faecal mineral flows were determined based on an indigestible marker (titanium dioxide).

Results: The faecal flows of zinc for pigs fed the tallow-based diets (220 ± 13.9 mg/kg) were significantly ($p<0.001$) higher compared to those for pigs receiving the soybean oil-based diets (163 ± 4.3 mg/kg). In contrast, the faecal flows of iron (224 ± 17.4 mg/kg) were not different ($p>0.05$) across dietary treatments. The fact that zinc, but not iron, was excreted to a greater extent in the presence of dietary saturated fatty acids supports the hypothesis that fatty acid soap formation may occur with minerals other than calcium and that not all minerals behave in the same way.

Conclusions: These results may have implications for diets for humans that are high in saturated fat even if zinc is present in adequate amounts.

Key words: Excretion, zinc, iron, saturated fat

PO2572**DEVELOPMENT OF ENGLISH HOMEPAGE OF NUTRITIONAL INFORMATION ON KOREAN FOOD FOR INTERNATIONAL INFORMATION EXCHANGE***M.H. Kim¹, S.N. Kim², Y.S. Cho²*

¹Department of Food and Nutrition, Kangwon National University, Samcheok, Korea

²Department of Agrofood Resources, NAAS, RDA, Gyeonggi, Korea

Background and objectives: In 2002, the FAO/INFOOD designated Korea's Rural Development Administration (RDA) as a representative institute for the food composition database in Korea. Korea's RDA has published food composition tables since 1970 and recently published the 8th edition of food composition tables including 2,757 kinds of foods and 22 kinds of nutrients. These Korean food composition tables are written in Korean but also include English subtitles. Despite the English translation, the homepage with the Korean food composition tables was only recently provided by Korea (<http://koreanfood.rda.go.kr/>). For this reason, the tables are quite limited for internationals who are concerned about the Korean food composition database. Therefore, it is urgent that Korea's RDA provide the tables through an English homepage. The purpose of this study is to develop an English homepage which can provide convenient access to nutritional information on Korean food.

Conclusions: This homepage service will contribute to an international information exchange about Korean Food.

Key words: English homepage, nutritional information, Korean food, international information exchange

PO2573**STATUS OF SERUM 25 (OH)-VITAMIN D IN ELDERLY IRANIAN SUBJECTS AFTER ONE YEAR SUPPLEMENTATION WITH VITAMIN E AND C***M. Srour¹, A.M. Alavi Naeini¹, I. Elmadfa¹*

¹Department of Nutritional Sciences, University of Vienna, Vienna, Austria

Background and objectives: Elderly patients with MCI (Mild Cognitive Impairment) show different levels of serum 25 (OH)-vitamin D. Vitamin D status especially in the elderly may be influenced by different factors. There is no data about how the serum 25 (OH)-vitamin D levels could be influenced by supplementation with antioxidants. In this study the impact of one year intervention with vitamin E and C on the status of 25 (OH)-vitamin D was assessed.

Methods: A double-blinded, placebo-controlled, study was conducted in 60 elderly Iranian subjects with MCI aged bet-

ween 60-75 years (30 women and 30 men). Divided into two main groups, the intervention group included 30 subjects who were given a daily dose of 300 mg vitamin E (alpha-tocopheryle acetate) and 400 mg vitamin C (ascorbic acid) and the other 30 subjects (Control group) received specially designed placebo. All subjects were not taking any drugs that might interfere with vitamin D status. Serum 25 (OH)-vitamin D levels were assessed in all subjects at baseline, 6 and 12 months of intervention using 25 (OH)-vitamin D direct ELISA kit.

Results: Results show there was a significant difference between males and females both in the control and supplemented groups at six months of intervention: Control, males/females 72.1 ± 22.9 units; 158.3 ± 26.1 units, $p < 0.019$, and Supplemented, males/females 64.2 ± 19.2 units; 136.3 ± 26.6 units, $p < 0.036$, respectively. At the end of the intervention there was no significant difference between males and females in Supplemented group (67.5 ± 21.6 units; 137.7 ± 30.8 units, $p < 0.073$).

Conclusions: One year of antioxidant supplementation with vitamin E and C in elderly subjects with MCI did not influence on the serum 25 (OH)-vitamin D levels.

Key words: Serum 25(OH)D, antioxidants, MCI, elderly

PO2574**THE QUALITY OF FOOD INTAKE OF FILIPINO HOUSEHOLDS: PROGRAMMATIC IMPLICATIONS***M.A. Constantino¹, I. Angeles-Agdeppa¹, J. Platon¹, M. Balitaon¹, M. Capanzana¹*

¹Department of Science & Technology, Food & Nutrition Research Institute, Taguig, Philippines

Background and objectives: Food Consumption Survey is one of the components of the National Nutrition Survey conducted by the Food and Nutrition Research Institute. Food consumption data provides updates on the dietary intakes of Filipino households. Results are used to track changes in food and nutrient intake and serve as basis in formulating plans and programs to address malnutrition, food security and diet-related chronic diseases. This study aims to describe the food intake of the Filipino households and the proportion of households below the Estimated Energy requirement.

Methods: Using the data from the 2008 National Nutrition Survey, about 4,880 randomly selected households were included in the study. One-day food consumption data were collected using the food weighing method. Conversion of food intake to energy and nutrients was based on the Philippine Food Composition Table, and the energy and nutrient intakes were assessed using the recommended intake for energy and protein and the Estimated Average Requirements (EARs) for the rest of the nutrients.

Results: Results revealed a rice-fish-vegetable diet dominate the meal matrix of an average Filipino. Total food consu-

med was 861 g and energy intake was 1867 kcal per capita per day. About 40% of the households met the estimated average requirement (EAR) for nutrients like protein, calcium, iron, thiamine, riboflavin and ascorbic acid. Only niacin intake was high meeting 93% EAR. A declining trend was noted in the consumption of major food groups since 1978 to 1993 but an increasing intake of rice, fish and poultry was observed from 2003 to 2008.

Conclusions: Nutrition education on improving the quality of diet of Filipinos must be intensified and agricultural planners should consider the availability of variety of foods which are accessible and affordable by all Filipinos to reduce the rate of undernutrition in the country.

Key words: Food intake, nutrient, EAR

PO2575

A COMPARATIVE STUDY ON THE INFANT AND YOUNG CHILD FEEDING PRACTICE AND NUTRITION STATUS AMONG 6-23 MONTHS AGE GROUP CHILDREN

T. Khatun¹, S. Matabbar², M R. Sarker³, A. Hoque¹

¹Department of Community Nutrition, Bangladesh Institute of Health Sciences (BIHS), Dhaka, Bangladesh

²Nutrition specialist, MDG-F project, Shushilan, Beijing, China

³Bangladesh Institute of Health Sciences BIHS, Dhaka, Bangladesh

Background and objectives: Child nutritional status is an essential component of a country's overall human development. Inappropriate feeding practices are linked with the malnutrition, overweight and obesity that may develop beyond the age of 2 years. The present study was aimed to assess the infant and young child feeding practice and nutrition status among 6-23 months age group children in nutrition intervention and non-intervention areas.

Methods: It was a comparative cross-sectional study. 350 subjects among age group of 6-23 months children. Anthropometric data were collected by standard techniques. Nutritional status was measured using Z score according WHO classification. χ^2 test, independent t test, Pearson's correlation, multiple regression and logistic regression was performed as $p < 0.05$ level of significance.

Results: Initiation of breast feedings within an hour were 68% and 59.4% among NNP (National Nutrition Program) and non-NNP ($p < 0.000$) area. Prelacteal fed were 34% in NNP and 37% in non-NNP area. Exclusive breast fed were 54.3% and 44% in NNP and non-NNP area ($p < 0.034$). It was found that

appropriate complementary feeding practice were 51.4% and 38.9% in NNP and non-NNP area. In NNP area, severe wasted, stunted and underweight was 3.42%, 6.28% and 10.28% respectively. In non-NNP area, severe wasted, stunted and underweight was 8.0%, 16.0% and 18.9% respectively. Significant difference was found between NNP and non-NNP areas of initiation of breast feeding ($p < 0.000$), exclusive breast feeding ($p < 0.034$) and complementary feeding practice ($p < 0.034$). In Pearson's correlation there was found positive relationship between NNP and non-NNP area according to mean intake of energy, carbohydrate and fat ($p = 0.000$, $p = 0.021$ and $p = 0.001$, respectively).

Conclusions: This study showed that the infant and young child feeding practice and nutritional status are better in nutrition intervention area. Appropriate feeding practice plays an important role in their good nutrition status.

Key words: IYCF and nutrition, nutrition intervention, Z-score

PO2577

WATER AND BEVERAGE INTAKE IN HEALTHY SUBJECTS FROM EUROPEAN COUNTRIES

M. Nissensohn^{1,2}, I. Castro-Quezada¹, L. Serra-Majem^{1,2}

¹Department of Clinical Sciences, University of Las Palmas de Gran Canaria, Las Palmas de Gran Canaria, Spain

²Ciber Fisiopatología Obesidad y Nutrición (CIBERO-BN, CB06/03), Instituto de Salud Carlos III, Malaga, Spain

Background and objectives: Intake of water is done mainly through consumption of drinking water and beverages plus water contained in food. Sometimes, the use of information from different sources and different methodological characteristics raises issues of comparability that are difficult to address. The main objective of this review was to examine the available techniques in assessing hydration status in epidemiological studies in Europe and describe which was the best and most frequently method applied to assess liquid intake in populations.

Methods: Sources of data on beverage intake available from European surveys and nutritional epidemiological investigations were selected from grey literature. With the average of intake of water, soft drinks and alcohol beverage intake, we calculated total fluid intake, reported in g/day.

Results: Twelve articles were included and all relevant data regarding beverage consumption was extracted. Beverages studies were carried out on healthy adults by different types of assessment. The averages of total beverage intake vary from 941 g/d for Spain to 2659 g/d for men in Germany.

Conclusions: From the limited data available, the results show that the average consumer is so different between countries. These differences derived from the methodology used. To our knowledge, there have not been developed recent epidemiological studies that focus on beverage intake in Europe. Further investigation into beverage intake is necessary to clarify what is the real amount of beverage intake in European population, which is the best tool for the evaluation, and to derive the standardized, harmonized and integrated results in reliable recommendations.

Key words: Water, beverages, epidemiological European studies

PO2578

DIFFERENTIAL RELATIONSHIPS BETWEEN FRIED FOODS INTAKE ESTIMATED BY SELF-REPORTED DIETARY INSTRUMENTS, THE MULTIPLE SOURCE METHOD, AND WEIGHT GAIN DURING PREGNANCY

D. Sartorelli¹, P. Barbieri²

¹Department of Social Medicine, University of Sao Paulo, Sao Paulo, Brazil

²Post-Graduation in Community Health, University of Sao Paulo, Sao Paulo, Brazil

Background and objectives: Studies suggest that the Multiple Source Method (MSM) is a useful statistical technique to estimate usual food intake for individuals and populations. The aim of the present study was to compare the associations between fried foods intake estimated by the MSM, and two self-reported dietary instruments, in relation to excessive weight gain during pregnancy.

Methods: A prospective study was conducted among 88 adult pregnant women. Excessive weight gain during pregnancy was defined as > 0.51 kg/week, according to the Institute of Medicine criteria. Fried foods intake during pregnancy was assessed by a validated 85-item quantitative food frequency questionnaire (FFQ), 3 dietary recalls (24hR), and the MSM. Adjusted linear regression models were applied to assess the relationships between fried foods intake estimated by distinct approaches and excessive weight gain during pregnancy.

Results: The mean \pm SD age of participants was 25 ± 5 years old, and 41% had excessive weight gain during pregnancy. The mean \pm SD fried foods intake were 95 ± 64 , 101 ± 64 , and 84 ± 41 units estimated by the FFQ, 24hR, and the MSM, respectively. For every 100 g increment of fried foods intake, the β 1 (95% CI) for excessive weight gain was 1.2 (0.3, 2.1) for the MSM estimates, after adjustment for by maternal age, education, duration of follow-up, and gestational age at the last interview. No associations were found for fried foods intake estima-

ted by the FFQ [0.4 (-0.28, 1.0)], and by the 24hR [0.3 (-0.34, 0.93)] and weight gain.

Conclusions: These data provides support for the use of the MSM approach estimates for usual food intake while evaluating diet-disease relationships during pregnancy. The results suggest a positive association between fried foods intake and excessive weight gain during pregnancy.

Key words: Multiple source method, excessive weight gain during pregnancy, self-reported dietary instruments

PO2579

PREVALENCE OF OVERWEIGHT AND OBESITY AMONG ADOLESCENTS IN SECONDARY SCHOOLS IN ABA SOUTH L.G.A ABIA STATE

O. Onuoha¹, P. Eme¹

¹University of Nigeria, Nsukka, Nigeria

Background and objectives: Adolescent obesity is a serious public health problem because of its strong association with adulthood obesity and the related adverse health consequences. The published literature indicates a rising prevalence of adolescent obesity in both developed and developing countries. Our aim was to determine the prevalence of overweight and obesity among adolescents in secondary schools in Abia State, Nigeria.

Methods: A cross-sectional school-based survey was conducted to determine the prevalence of overweight and obesity in adolescents of Aba South L.G.A. A probability proportional to size was used to select 10 schools where 600 participants, aged 10-19 years were selected. Their weight, height, waist, hip, body mass index and triceps skinfold were assessed. Overweight and obesity was defined using IOTF, CDC and NHANES III cutoff points. Waist-Hip Ratio (WHR) was compared with the WHO standards. Data was analysed using descriptive statistics. Chi-square analysis was used to test the categorical variables at $p < 0.05$.

Results: The prevalence of overweight seems high in both genders (3.0% and 6.7% in males and females respectively) ($p=0.005$) while obesity prevalence was low (1.0% and 2.5% in males and females respectively) ($p=0.085$). More female adolescents (1.2%) than males (0.3%) were classified as obese when triceps skinfold was used as a measure of obesity. About 36.0% of the adolescents were at high health risk when WHR was used as a measure of classification.

Conclusions: Based on the findings, it was concluded that there is need for ongoing individualized dietary education among adolescents in secondary schools in Nigeria.

Key words: Prevalence, overweight, obesity, adolescents, Abia State

PO2580

THE NUTRITIONAL CHARACTERIZATION OF RICE VARIETIES CONSUMED IN PORTUGAL

C. Mota¹, M. Coelho¹, A. Nascimento¹, S. Gueifão¹, I. Coelho¹, M. Cabral², D. Torres², I. Castanheira¹

¹National Health Institute Doutor Ricardo Jorge, Department of Food and Nutrition, Lisboa, Portugal

²Faculty of Nutrition and Food Sciences of the University of Porto, Porto, Portugal

Background and objectives: Portugal has the largest consumption of rice 15.8 kg/capita/year, in Europe. The present work aims to evaluate: rice nutritional profile, namely proximate, amino acid and mineral composition; arsenic content, as the most abundant contaminant and, compositional differences between varieties, year and place of harvest.

Methods: Samples were collected from the most representative national rice producers. Analysis was carried out by the following analytical methods: proximate by AOAC methods; amino acids by UPLC-DAD; starch, and amylase by enzymatic methods; mineral analysis by ICP-OES including copper, manganese, iron, zinc, magnesium, calcium, sodium, phosphorus and potassium and arsenic content by ICP-MS.

Results: Analyzed rice showed higher amylopectin (54.7 ± 7.3 g/100g) content than amylose (33.5 ± 3.8 g/100g) and total protein content of 7.1 ± 0.3 g/100g a low content of fiber and fat (<1 g/100 g) was found. The most abundant essential amino acids were aromatic amino acids with a 7.5% of total protein. The most abundant minerals were potassium and phosphorus with levels ranging from 91 mg/100 g to 107 mg/100 g. The arsenic content was determined by ICP-MS and the values were below 600 µg/kg.

Conclusions: Crop place showed to be the major source of variation in amino acid content. With respect to protein quality, cysteine, lysine, sulfur amino acids and isoleucine were considered limiting with protein digestibility corrected amino acids scores (PDCAAS) lower than 1. To assure the nutritional requirements for amino acids and subsequent protein synthesis, rice consumption must be followed by other food groups (e.g pulses, meat products) in order to provide the other essential amino acids. Rice contribution for mineral intake ranged from 3% DRI (iron and potassium) to 36% DRI (manganese). In this study, a very weak correlation between arsenic levels and amino acid content was observed.

Key words: Rice, food composition, data quality

PO2581

INTER-RELATIONSHIPS AMONG ZINC, HEMOGLOBIN, AND SELENIUM STATUS OF RURAL MALAWIAN WOMEN

E. Siyame¹, R. Hurst², A A. Wawer², S D. Young³, M R. Broadley³, A D C. Chilimba⁴, E L. Ander⁵, M J. Watts⁵, B. Chilima⁶, J. Gondwe⁶, D. Kang'ombe⁷, A. Kalimira¹, S J. Fairweather-Tait², K B. Bailey⁸, R S. Gibson⁸

⁶Community Health Sciences Unit, Ministry of Health, Private Bag 65, Lilongwe, Malawi

⁷Nutrition Unit of Ministry of Health, Lilongwe, Malawi

⁸Department of Human Nutrition, University of Otago, Dunedin, New Zealand

Background and objectives: Evidence of interactions between Zn and haemoglobin (Hb) and Zn with Se prompted a cross-sectional study to investigate possible predictors of Hb and plasma Zn in rural women living in low or high soil Se districts in Malawi.

Methods: Data on socio-demographic status and 1-d duplicate diet composites analyzed for Fe, Zn, Se and phytate (Phy) were collected from rural Malawian women aged 18-50 y from a low (Zombwe) (n=60) and high (Mikalanago) (n=60) Se district. Non-fasting blood samples were collected for Hb, plasma biomarkers of Fe, Zn, and Se status, and C-reactive protein and α -1-glycoprotein (AGP) for inflammation.

Results: The prevalence of Zn deficiency (plasma Zn <10.7 µmol/l) was high in both districts ($>90\%$) and much greater than anemia (Hb <120 g/l) (21%), storage iron depletion (ferritin <12 µg/l) or tissue iron deficiency (transferrin receptor >6.8 mg/l) (both $<16\%$). This finding was attributed to the low Zn content of diets (median 5.7 mg/d) and high Phy:Zn molar ratios (20.0), and high total Fe content (21.0 mg/d). Regression analysis with Hb as the dependent variable showed that plasma Zn was the most important explanatory variable with the largest standardized coefficient (0.299), followed by log ferritin (0.248) and log AGP (0.175). Zombwe women had lower ($p<0.05$) intakes of Zn (4.8 vs. 6.4 mg/d) and Se (6.5 vs. 55.3

µg/d) and plasma Se (0.72 vs. 1.60 µmol/l) than Mikalanago women; plasma Zn did not differ (8.60 vs. 8.87 µmol/l). Correlations between plasma Zn and Se were positive ($r=0.253$; $p=0.052$) in Zombwe, but negative in Mikalanago ($r=-0.273$; $p=0.035$).

Conclusions: Plasma Zn was a more important predictor of Hb than log ferritin and was also associated with the women's Se status in both districts, albeit by different mechanisms.

Key words: Malawi, women, plasma Se, Zn, haemoglobin

PO2582

FOOD FORTIFICATION STRATEGY TO CONTROL MICRONUTRIENT DEFICIENCIES IN SENEGAL

N F. Ndiaye¹, M. Sadjji¹, A. Ndiaye², B. Ndiaye³, A T. Guiro⁴

¹Institut de Technologie Alimentaire (ITA), Dakar, Senegal

²Helen keller International, Dakar, Senegal

³Micronutrient Initiative, Dakar, Senegal

⁴Université Cheikh Anta Diop, Faculté des Sciences et Techniques, Laboratoire de Nutrition, Dakar, Senegal

Background and objectives: Micronutrient deficiencies such as iron, folic acid, vitamin A, zinc, iodine are widespread in Africa and affect people of all ages and socio-economic groups. The primary cause being insufficient intake of bioavailable minerals and vitamins from foods generally high in inhibitors of micronutrients absorption. Programs such as dietary diversification, breastfeeding, supplementation and food fortification are strategies available for controlling and preventing micronutrient deficiencies. In Senegal, after food fortification was made mandatory by the Government, a National Fortification Alliance (COSFAM) was created with a national strategic plan.

Methods: The operational approach was based on fortified foods production, distribution, quality control and social marketing. A FRAT based survey to find the suitable vehicles in order to reach the target groups was conducted. A second survey on food recalls was made, and data on iron, zinc, folic acid and vitamin A status were collected in women of child-bearing age and children from 12 to 59 months. A social marketing campaign was launched on the concept at national level. The whole program was strengthened through capacity building for the technical staff on quality control.

Results: Wheat flour and edible oil were identified as foods vehicles. Currently, industries are producing fortified foods that are being commercialized and there is a progressive adhesion of populations. The baseline status of micronutrients in women of child-bearing age and children from 12 to 59 months of age is known. These data will allow a long-term assessment of the effect of the program.

Conclusions: The program helped in setting important health indicators of the selected vulnerable groups and allowed to develop a good strategy to progressively eradicate micronutrient deficiencies. However it is critical to have good inspection, monitoring and evaluation systems of the production and distribution lines for sustainable results.

Key words: Micronutrient deficiencies, strategy, food fortification

SMARTPHONE BASED VITAMIN D MONITORING

M. Mancuso¹, S. Li², S. Mehta³, D. Erickson²

¹Department of Biomedical Engineering, Cornell University, Ithaca, NY, USA

²Sibley School of Mechanical and Aerospace Engineering, Cornell University, Ithaca, NY, USA

³Division of Nutritional Sciences, Cornell University, Ithaca, NY, USA

Background and objectives: In developed nations such as the United States, over 75% of the population is deficient for vitamin D, leading to a number of complications including bone health problems like rickets and osteomalacia, and more prevalent diseases including depression and cancer. While treatment for micronutrient deficiencies is simple even in developing nations, nutritional assessment of them are both time and cost prohibitive. We develop a point of care diagnostic for vitamin D monitoring that is unique through its synergy with an already ubiquitous technology, the smartphone.

Methods: The smartphone based monitoring system is composed of an "accessory" which connects to an Android smartphone or tablet and consumable "cartridges" that take finger prick blood samples. The accessory acts as a bridge between the smartphones communications, data, location, and display capabilities, and the microfluidic and health related technologies of the inserted cartridge. The cartridge processes the blood sample similar to the steps proceeding an immunoassay (extraction, separation, etc.), and then performs a gold nanoparticle based colorimetric reaction that measures the concentration of vitamin D present.

Results: The assay is optically read out by the accessory, and the results are communicated to the smartphone. Data is then simply displayed to the user who can monitor their levels overtime, or aggregated from multiple collection points and exported for further spatiotemporal analysis. Other users both at computers and in the field with tablets can view maps generated from the data and locate and track regions where malnutrition is worst. Sensitivity is similar to that of current immunoassays.

Conclusions: This work represents one of the earliest works of direct blood micronutrient detection on smartphone and tablet technology. By leveraging these new devices unique data and communications capabilities a new level of nutrition surveillance is possible.

Key words: Vitamin D, diagnostics, nutrition, nutrition assessment, micronutrients

²Australian Red Cross Blood Service, Operating Division of the Australian Red Cross Society, 17 O'Riordan Street, Alexandria, NSW 2015, Australia

³Department of Human Nutrition, University of Otago, PO Box 56, Dunedin 9054, New Zealand

Background and objectives: Lingonberry (*Vaccinium vitis-idaea* L) is a popular edible berry in Scandinavian countries and is increasing in popularity across Europe. Lingonberry possesses a complex polyphenolic profile consisting of a mixture of anthocyanins, phenolic acids, flavonols and proanthocyanidins which is of interest due to their putative anticancer activity. After consumption, phenolic compounds are subject to digestive conditions within the gastrointestinal tract which alter their structures and potentially their bioactivity. Given limited bioavailability in the small intestine, a substantial portion of berry phenolic compounds are likely to pass into the colon where they are degraded by the colonic microbiota. Therefore, it is reasonable to infer that the colonic epithelium is exposed to both the parent phenolic compounds and their degradation products. Our aim was to evaluate the impact of digestion and colonic fermentation on phenolic components and bioactivity of a lingonberry extract (LE).

Methods: LEs were produced by in vitro digestion and subsequent faecal fermentation and characterised by LC-MS and GC-MS. Bioactivity was tested using a physiologically relevant dose range (0-50 µg/ml phenols) with a 24 hour exposure in in vitro models representing key stages in colon carcinogenesis namely initiation (comet assay, HT29, mutagenicity assay HT29G17neo) and invasion (Matrigel invasion assay, HT115).

Results: LC-MS and GC-MS analysis confirmed digestive and fermentation processes altered the polyphenol composition relative to the original LE with the levels of simple aromatic components increased in the fermented extract. Digested and fermented LE exhibited significant anti-genotoxic ($p < 0.05$), anti-mutagenic ($p < 0.05$) and anti-invasive ($p < 0.05$) effects compared to the appropriate controls (ANOVA, Post Hoc Dunnett T test) in all in vitro models.

Conclusions: This study indicates that despite extensive structural modification following digestion and fermentation, lingonberry extracts retain their ability to modulate cellular processes associated with colon cancer.

Key words: Lingonberry, phenolics, fermentation, anticancer

PO2586

DEVELOPMENT OF PREDICTIVE EQUATIONS FOR FAT BODY SEGMENTS IN SEROPOSITIVE HIV PATIENTS

R A. Beraldo¹, H S. Vassimon¹, A M. Navarro¹, M C. Foss-Freitas¹

¹Department of Internal Medicine, University of Sao Paulo, School of Medicine of Ribeirao Preto, Ribeirao Preto, Sao Paulo, Brazil

Background and objectives: With the advent of highly active antiretroviral therapy (HAART), HIV seropositive patients began to present themselves clinically stable. However, changes in body composition called lipodystrophy and metabolic syndrome are observed. The central point of the syndrome are changes in body composition that mainly involve the loss of fat in the limbs and face (lipoatrophy) and/or fat gain in the abdominal region and back neck (lipohypertrophy). To date, the determination of fat per body segment in this group can be obtained by imaging methods such as X-ray absorptiometry (DXA) but not by anthropometric measures, which would be more feasible to be used in practical clinic. It is important to monitor the amount of fat per segment using simple and low cost methods in order to optimize treatment of this group. Our aim was to develop equations by linear regression to estimate fat in each segment (arm, leg and trunk) considering anthropometric and bioelectrical impedance analysis (BIA) variables in HIV seropositive patients on HAART.

Methods: We measured circumferences (arm, waist, hip, thigh, calf), skinfolds (biceps, triceps, subscapular, suprailliac) and conducted examinations of segmental BIA and DXA in 100 HIV seropositive men. These variables were used to develop equations to estimate fat segments (arm, leg and trunk).

Results: We developed two models for estimation of arm fat and 2 for the trunk fat using only anthropometric measurements and two models for leg fat using BIA and anthropome-

tric variables. The coefficients of determination for models of arm, torso and legs were 0.66 and 0.66, 0.76 and 0.75, 0.5 and 0.45, respectively.

Conclusions: The developed equations allow the assessment of fat per body segment (legs, arms and trunk) through evaluation methods accessible, accurate and reliable used in clinical practice.

Key words: HIV, equations, body segments

PO2587

PROPOSED CUTOFF FOR OBJECTIVE DIAGNOSIS OF LIPODYSTROPHY IN HIV SEROPOSITIVE BRAZILIANS

R A. Beraldo¹, H S. Vassimon¹, A M. Navarro¹, M C. Foss-Freitas¹

¹Department of Internal Medicine, University of Sao Paulo, School of Medicine of Ribeirao Preto, Ribeirao Preto, Sao Paulo, Brazil

Background and objectives: The group of body composition and metabolic changes found in seropositive for HIV is called lipodystrophy syndrome. The central point of the syndrome are changes in body composition that mainly involve the loss of fat in the limbs and face (lipoatrophy) and/or gain fat in the abdominal region and back neck (lipohypertrophy). Large discrepancies in the reported incidence of lipodystrophy in scientific studies occur due to a lack of homogeneity of criteria for diagnosis. The fat mass ratio (FMR) was first proposed by Bonnet et al (2005) using an objective index of the X-ray absorptiometry (DXA) to identify lipodystrophy. FMR is defined as the ratio between the percentage of fat in the trunk and lower limbs. Our aim was to propose cutoff points for FMR in order to classify the lipodystrophy in male patients.

Methods: DXA and clinical examination was performed in 100 men on highly active antiretroviral therapy (HAART) and the FMR was calculated. ROC curves were constructed using clinical examination to identify the sensitivity and specificity to propose the cutoffs.

Results: The area under the curve (AUC) observed was 0,74 and the optimal cutoff point was 1.26, with a sensitivity of 73.63% and specificity of 72.2%. The FMR was significantly correlated with the time of HAART, age, CD4 and triglycerides.

Conclusions: FMR can be used to help in the diagnosis of lipodystrophy contributing to a more accurate diagnosis and early intervention, in order to avoid major changes in body composition.

Key words: HIV, lipodystrophy, diagnosis, DXA

PO2588

A BRIEF USER FRIENDLY TOOL TO ASSESS PATIENTS' NUTRITIONAL STATUS, DIETARY & EXERCISE PATTERNS

N T. Adikari¹, R. Vasini¹

¹Wayamba University, Kuliypitiya, Sri Lanka

Background and objectives: Nutrition plays a vital role in the healthcare process. Nutrition management involves dietary modifications and physical activity recommendations. There are several barriers for nutritional management at hospital settings including lack of resources, lack of time, and lack of knowledge about nutrition. Available nutritional screening tools for identifying patients at nutritional risk have a number of drawbacks. Therefore the objective of this study was to develop a brief user friendly tool to assess patients' nutritional status, dietary and exercise patterns.

Methods: Available nutritional screening tools for hospitalized patients were gathered from the reviewing the literature and conducting a preliminary survey. The "Pocket card" model was selected as a user friendly tool. The contents, wording and the figures of the tool were reviewed by three experts in the field of nutrition and dietetics. Ten healthcare professionals who are dealing with nutritional care process justified the format, contents and the presentation of the information in the tool. According to the comments of experts and professionals, the modifications were done and the final version of the "Pocket Card" tool was developed.

Results: The "pocket card" was developed as a user friendly tool. The size of the card was 5.83" inch in width and 8.27" inch in length. The tool was formatted as A5 size one page (front and back side) pocket card. Both sides of the tool were used and one side included assessment components while other side included recommendations for each component of the assessment. Assessment components as well as recommendation components were presented under the four sections named as Nutritional Status, Food Consumption Practices, Eating Behavior and Physical Activity Pattern.

Conclusions: The developed "pocket card" was a simple tool for assessing the nutritional status, dietary and exercises patterns of patients.

Key words: Patients, nutritional status, tool

PO2589**ASSOCIATION BETWEEN SERUM 25-HYDROXY-VITAMIN D LEVEL AND (FEATURES OF) THE METABOLIC SYNDROME: A CROSS-SECTIONAL STUDY IN THE NETHERLANDS**

M A H. Hendriksen¹, C J M. Rompelberg¹, W M M. Verschuren¹, D L. Van der A¹

¹National Institute for Public Health and the Environment, Bilthoven, The Netherlands

Background and objectives: Vitamin D deficiency has been associated with an increased risk of type 2 diabetes mellitus, obesity and the metabolic syndrome (MetS). The mechanisms underlying these associations are not well understood. We aimed to assess the association between serum 25-hydroxyvitamin D (25-OHD) levels with MetS, and its different components in a national sample of Dutch men and women aged 19-70 years.

Methods: Serum 25-OHD levels and MetS components were measured in 2,102 individuals participating in the health examination survey 'Measuring the Netherlands' (2009-2011). Metabolic syndrome was defined as having at least three of the following five risk factors: abdominal obesity, hypertension, low HDL-cholesterol, elevated glucose level and/or elevated triglycerides. Multivariate logistic regression models, adjusted for age, sex, education, ethnicity, smoking, alcohol, physical activity, season, and, if applicable, other MetS components, were used to assess the cross-sectional association between serum 25-OHD levels and MetS (features). Prevalent CVD and diabetes cases were excluded from the analyses. The final sample consisted of 1,899 individuals.

Results: The prevalence of MetS was 25%. Participants in the lowest (<52.9 nmol/l) and middle (52.9-71.1 nmol/l) tertiles of serum 25-OHD had a significantly higher prevalence of MetS compared to those in the highest tertile (>71.1 nmol/l): odds ratios (OR) (95% confidence interval): 1.63 (1.23-2.17) and 1.44 (1.09-1.90), respectively; $p=0.0008$). Following adjustment for potential confounders, serum 25-OHD was also inversely associated with abdominal obesity (OR=1.76 (1.32-2.35), lowest versus highest tertile; $p=0.0001$). In multivariate models, no statistically significant association was observed with any of the other MetS components.

Conclusions: In Dutch adults, lower 25-OHD levels were significantly associated with a higher prevalence of MetS and abdominal obesity, but not with prevalence of hypertension, low HDL-cholesterol, hyperglycemia and hypertriglyceridemia.

Key words: Vitamin D, metabolic syndrome, obesity, risk factors

PO2590**LEVEL OF ANAEMIA AMONG PREGNANT WOMEN IN TRIBAL INDIA**

J B. Singh¹, S. Sharma¹, R. Rani¹

¹Institute of Health Management Research, Jaipur, India

Background and objectives: Anaemia in pregnancy is a common and serious problem especially in developing countries. It is estimated that almost twenty percent of maternal deaths are directly caused by anaemia and causes of another fifty percent of maternal deaths are associated with anaemia in the world. India is one of the countries with the largest prevalence of anaemia.

Methods: A cross sectional study was done in three blocks of Udaipur, Rajasthan, India covering a sample size of 699 pregnant women. Reference values for anaemia detection were taken as per international standards (UNICEF) and Indian (NFHS III 2005-06). The levels of anaemia were defined as per the values i.e. haemoglobin (Hb) above 11 g/dl (normal level), 10.0-10.99 g/dl (mild anaemia), 7.0-9.99 g/dl (moderate anaemia) and below 7.0 g/dl (severe anaemia).

Results: It is worrisome to note that 87 percent of the sample pregnant women were found to be suffering from any form of anaemia. This was found to be much higher than the national figures (59%). Nearly three-fifths of the pregnant women pregnant women suffer from moderate to severe anaemia (57%). The mean value Hb was found to be 9.7 g/dl with a standard deviation of 1.34 g/dl.

Conclusions: There is high prevalence of anaemia among pregnant women and this continues unabated despite multi fold programmes by the Government and interventions continuing for a long time.

Key words: Nutrition, pregnant women, India

PO2591**VALIDATION OF A SEMI-QUANTITATIVE FOOD FREQUENCY QUESTIONNAIRE FOR SRI LANKAN ADULTS**

R. Jayawardena¹, S. Thennakoon¹, P. Katulanda¹, N. Byrne², M. Soares³, A P. Hills⁴

¹Diabetes Research Unit, Faculty of Medicine, University of Colombo, Colombo, Sri Lanka

²Institute of Health and Biomedical Innovation, Faculty of Health, Queensland University of Technology, Brisbane, Queensland, Australia

³Curtin Health Innovation Research Institute, School of Public Health, Faculty of Health Sciences, Curtin University, Perth, WA, Australia

⁴Mater Mother's Hospital, Mater Medical Research Institute and Griffith Health Institute, Griffith University, Brisbane, Queensland, Australia

Background and objectives: Sri Lanka is undergoing nutritional transition and diet-related chronic diseases are emerging as an important health problem. Currently, no validated food frequency questionnaire (FFQ) exists to measure habitual dietary intake of Sri Lankan adults. The aim of this study was to evaluate the validity of a newly developed FFQ for this population.

Methods: Dietary intake was measured using a FFQ and 7-day weighed food intake (7DWR). The FFQ consisted of 8 food groups containing the main foods comprising the diet of Sri Lankan adults, a total of 85 items and 12 color photographs to identify serving size. One hundred healthy adults were randomly recruited from a community sample and administered the FFQ. Participants were then asked to record weighed food intake for seven days. Paired sample t tests and Pearson's correlation coefficients were conducted to determine whether the two instruments reported similar values for energy and nutrients.

Results: Eighty two subjects completed FFQ and 7DWR. Estimated mean energy intake \pm SD from FFQ and 7DWR were 1794 ± 398 kcal and 1698 ± 333 kcal, respectively. Whilst the FFQ overestimated the energy intake when compared with 7DWR and 24DR the FFQ was significantly associated with 7DWR and 24DR for energy. We found a significant positive correlation between the FFQ and 7DWR for energy ($r=0.39$), percentage of energy from carbohydrate ($r=0.40$), percentage of energy from protein ($r=0.52$), percentage of energy from fat ($r=0.34$), carbohydrate ($r=0.42$), protein ($r=0.26$) and dietary fiber ($r=0.32$).

Conclusions: Based on these findings, the FFQ appears to be an acceptable tool for assessing the energy and nutrient intakes in this population.

Key words: Sri Lanka, food frequency questionnaire, validation, FFQ

PO2592**TRADITIONAL INDONESIAN FOOD HAS LOWER ENERGY DENSITY BUT NOT ENERGY PER PORTION THAN MODERN FOOD, STUDY IN MALANG INDONESIA**

N.N. Wirawan¹, W. Rahmawati¹, D. Handayani¹

¹Department of Nutrition, Faculty of Medicine, University of Brawijaya, Malang, East Java Province, Indonesia

Background and objectives: National Survey in Indonesia shows that prevalence of obesity and non-communicable disease in Indonesia has increased gradually. This condition can be caused by the shifting of life style from traditional into modern, including the food consumption. This research was aimed to identify the difference of the energy density, dietary fiber content, and energy per portion between Indonesian traditional food and modern food in Malang, Indonesia.

Methods: Sample was collected using purposive sampling for traditional food ($n=19$) and modern food ($n=8$). Energy content was analyzed in Laboratory of Research Institute in Legumes and Tubers (Laboratorium Balai Penelitian Kacangkacangan dan Umbi-umbian/BALITKABI) Kendalpayak Malang, Indonesia. Analysis of dietary fiber content was calculated using NutriSurvey for Windows version 2004 with Indonesian Food Database. Statistical analysis was performed using SPSS software for windows.

Results: Indonesian traditional food has higher dietary fiber content than modern food (3.38 ± 0.97 grams vs. 1.51 ± 1.52 grams), and it has lower energy density than its counterpart (1.61 ± 0.58 kcals/grams vs. 3.14 ± 1.40 kcals/grams). However, traditional food has bigger size per portion than modern food (439.52 ± 126.45 grams vs. 175.94 ± 104.14 grams). It might be the reason why total energy per portion was not significantly different between traditional and modern food ($662,48 \pm 217.27$ kcals vs 489.33 ± 196.20 kcals (Mann Whitney test)).

Conclusions: Dietary fiber content contributes to lower energy density. However, energy density alone was not the only predictive factor to total energy intake, since it should be combined with portion size.

Key words: Traditional food, energy density, fiber

PO2593**IODINE STATUS IN SPANISH WOMEN OF CHILDBEARING AGE**

L. González Rodríguez¹, B. Navia¹, C. Peñas¹, E. Rodríguez-Rodríguez¹, A. López-Sobaler¹

¹Department of Nutrition, Faculty of Pharmacy, Complutense University of Madrid, Madrid, Spain

Background and objectives: Women of childbearing age may be at risk of iodine deficiency in pregnancy and breastfeeding. An adequate maternal iodine status is essential for the correct thyroid function and the appropriate development of the central nervous system of the fetus and infant. The aim of the present study was to assess the nutritional status of iodine in women of childbearing age in Spain.

Methods: 157 women of childbearing age (18-44 years) were studied. Iodine status was assessed by the iodine concentration in urine over 24 hours and was determined by inductively coupled plasma mass spectrometry. Urinary iodine concentration (UIC) ($\mu\text{g/l}$) and iodine/creatinine ratio (I/Cr ratio) ($\mu\text{g/g}$) were categorized according to the cut-off points established by the World Health Organization. All calculations were made using SPSS (v19.0). Statistical significance was set at $p < 0.05$.

Results: The median UIC among childbearing age women was $169.5 \mu\text{g/l}$ and the I/Cr ratio was $147.7 \mu\text{g/g}$. Considering UIC and I/Cr ratio 0% and 1.5% had severe deficiency ($< 20 \mu\text{g/l}$), 2.9% and 3.0% moderate deficiency (20-49 $\mu\text{g/l}$), 18.4% and 21.5% mild deficiency (50-99 $\mu\text{g/l}$), 41.2% and 37.8% adequate nutrition (100-199 $\mu\text{g/l}$), 14.0% and 14.1% was categorized as in risk of iodine-induced hyperthyroidism (200-299 $\mu\text{g/l}$) and 23.5% and 22.2% as in risk of adverse health consequences ($> 300 \mu\text{g/l}$), respectively.

Conclusions: The 26% of women of childbearing age presented some type of iodine deficiency, but it was also noted that 36% of women had urinary iodine values indicative of risk of hyperthyroidism or adverse health consequences. The results of the present study suggest the need to monitor the iodine nutritional status in women of childbearing age.

Key words: Urinary iodine, status, childbearing women

PO2594**NOURISHMENT AND ITS RELATION WITH IMMUNOLOGY IMMUNITARY RESPONSE AND OXIDATIVE STRESS**

E. Castellanos¹

¹Department of Allergy and Immunology, University Hospital, La Habana, Cuba

Abstract These last decade's articles were reviewed, all related to the topic and written in English and Spanish, well available at the Infomed intranet.

Background and objectives: It is a systematic bibliographic review about nutrition. Nutrients are classified as proteins, carbohydrates, fat, vitamins and minerals, needed in diet for the well functioning of the human being briefly discuss the design of the study/ program and how it was conducted. We would like to develop some projects of investigation to establish a useful therapeutic conduct which allow the patients to take the appropriate diet and prevent lots of disorders in the immunological system.

Methods: We performed a wide and systematic bibliographic revision about nutrition immunity and oxidative stress; on the second place we compiled and prosecuted the information.

Results: An analysis is done about the main antioxidants ingested by diet, due to the harmful effect that free radicals cause in the organism; on the other hand it is explained how nutritional manipulation of immunity may have clinical (cellular immunodeficiency, humoral and phagocytic weakness), biological and therapeutic implications. Besides, it is approached the effect that an adequate nutrition may have on the main defense mechanisms of the organism, present the main results with appropriate statistics/data analysis and pertinent discussion.

Conclusions: We analyzed the information of all current studies and in this bibliographic review, it is deducible the importance of an adequate nutrition to maintain a proper physical appearance and to diminish the oxidative stress mechanisms and improve our defenses.

Key words: Immunonutrition, antioxidants, oligoelements, immunodeficiencies

PO2595**THE RELATIVE VALIDATION OF EASY DIETARY ASSESSMENT TOOL USING URINE SODIUM AND NORMALIZED PROTEIN NITROGEN APPEARANCE AS BIOMARKERS**

A. Saetie¹, C. Pachotikarn¹, S. Taechangam¹, T. Jiamjariyaporn², Y. Cherdrungsi¹, S. Vuttisinaksara¹, W. Pongreuk³

¹Institute of Nutrition, Mahidol University, Bangkok, Thailand

²Bhumirajanakarindra Kidney Institute, Lungdond Kezon, Philippines

³Thai Dietetic Association, Manila, Philippines

Background and objectives: To delay the progression of chronic kidney disease (CKD), the reduction of sodium and appropriate protein and energy intake are recommended. Therefore, the suitable dietary assessment tool is necessary to monitor responses to therapeutic nutrition interventions in patients. Easy Dietary Assessment (EDA) was developed by Dr. Chanida Pachotikarn from Thai Dietetic Association and endorsed by the Nephrology Society of Thailand and Thai Nephrology Nurses Association to use as the tool to evaluate nutrient intake among CKD patients. The accuracy of EDA tool was assessed by comparison with the biomarkers.

Methods: Thirty participants who were not on anti-diuretic drugs were asked to record their 24 hour dietary intake and collect their 24 hour urine. The estimation of sodium, protein and energy intake using EDA tool were compared with urine sodium, normalized protein nitrogen appearance (nPNA) and INMU – Cal program.

Results: Positive significant correlation between total energy intake using EDA tool and INMU-Cal program were found ($r=0.796$; $p<0.01$). The results also demonstrated the significant correlation between dietary protein intake and nPNA ($r=0.431$; $p<0.05$). However, sodium intake was not associated with urine sodium ($r=0.338$; $p=0.067$).

Conclusions: EDA could be used as the dietary protein and energy assessment tool among Thai population with CKD. Conversely, this study indicates a limitation in using EDA to evaluate sodium intake.

Key words: Validation, CKD, protein intake

PO2596**FOLATE STATUS OF FILIPINO WOMEN OF CHILDBEARING AGE**

J. Desnacido¹, L. Perlas¹, R. Cheong¹, J. Marcos¹, J. Ulanday¹

¹Food and Nutrition Research Institute, Bicutan, Taguig City, Philippines

Background and objectives: Folic acid (FA) is a B-vitamin required for proper cell growth and development of the embryo to ward off major birth defects of the brain and spine, known as neural tube defects (NTD's). FA is required for the production of DNA, which is necessary for the rapid cell growth needed in the development of fetal tissues and organs in early pregnancy. The Philippine Health Statistics (PHS) listed congenital anomalies as the 5th leading cause of infant mortality which included NTD's, spina bifida, and hydrocephalus among others. Our objective was to assess the folate status of Filipino women of childbearing age.

Methods: A cross-sectional sample of 2119 Filipino women of reproductive age ranging from 15 to 45 years from the 7th National Nutrition Survey (NNS) were included. Serum and red cell folate were analyzed using radioimmunoassay (RIA).

Results: Based on red cell folate (<175 ng/ml), about 20.9% were folate deficient while based on serum folate (<3.0 ng/ml), which is a measure of recent intake, the prevalence was 38.7%. On the regional level, the highest prevalence of serum and red cell folate was recorded in National Capital Region with 62.6% and 48% prevalence rates, respectively. On the other hand Northern Mindanao had the lowest prevalence of 10.7% for serum folate, while CAR and Cagayan Region had the lowest prevalence of 1.2% for red blood cell folate.

Conclusions: The high percentages of subnormal values of serum and red cell folate indicate alarmingly high prevalence of folate deficiencies among Filipino women of childbearing age. The findings strongly suggest the need for awareness and campaign for all women of childbearing age on the importance of taking folic acid every day to reduce the risk of having a pregnancy affected by neural tube defects.

Key words: Folate deficiency, Philippines, childbearing age

PO2597**BODY COMPOSITION ASSESSMENT DURING REHABILITATION OF MALNOURISHED INFANTS AND CHILDREN IN A CLINICAL SETTING**

A. Badaloo¹, T. Forrester¹, C. Taylor-Bryan¹, F. Jahoor², S. Wootton³, A. Jackson³

¹Tropical Metabolism Research Unit, University of the West Indies, Kingston, Jamaica

²Children's Nutrition Research Center, Baylor College of Medicine, Houston, Texas, USA

³Southampton NIHR Biomedical Research Centre, University of Southampton/Southampton University Hospital NHS Foundation Trust, Southampton, UK

Background and objectives: Management of severe acute malnutrition (SAM) according to WHO guidelines reduces case-fatality but the use of enriched diets to promote rapid catch-up-growth after clinical stabilization may be associated with excess adiposity and poor lean deposition. We aimed to determine changes in body composition during rehabilitation of childhood SAM managed in accordance with WHO guidelines to assess whether achieved proportions of lean and fat are within reference range.

Methods: Forty male and female children with oedematous and non-oedematous SAM, aged 3 to 32 months were recruited. Measurements were conducted during the stabilization period (S1), catch-up growth at 50% weight repletion (S2) and at recovery on achieving at least 90% of reference weight-for-length (S3). Lean mass (LM) was determined using deuterium dilution in accordance with IAEA protocol.

Results: Data are mean \pm SD. Weight-for-length Z-scores at S1 (non-oedematous: -3.0 ± 0.2 ; oedematous: -2.1 ± 0.2) improved to -0.48 ± 0.2 at S3. After stabilization on a maintenance diet, intake increased to 685 ± 101 kJ/kg/d and 3.7 ± 0.6 g protein/kg/d resulting in rapid weight gain (16.5 ± 5.1 g/kg/d) over 20 ± 10 d. TBW (% body weight) at S1 (67 ± 8) and S2 (67 ± 6) were higher than at S3 (63 ± 4), repeated ANOVA, $p < 0.03$. Some estimates of TBW at S1 appeared unphysiological challenging the methodological assumptions applied in their derivation. At recovery, LM was consistent with reference values (71 to 92 % of body weight and 11 to 15 kg/m²).

Conclusions: Insecurity of estimates of TBW and LM at S1 limits the ability to capture changes in lean and fat during rehabilitation. However, rapid weight gain promoted by the enriched diet resulted in body composition within reference range.

Key words: Childhood malnutrition, rehabilitation, body composition

PO2598**DIFFERENCES BETWEEN VEGETARIAN AND NON-VEGETARIAN DIETARY PATTERNS AND THEIR NUTRIENT PROFILES STRATIFIED BY SEX AND RACE**

N. Rizzo¹, K. Jaceldo-Siegl¹, G. Fraser²

¹Department of Nutrition, School of Public Health, Loma Linda University, Loma Linda, California, USA

²Department of Epidemiology, Biostatistics and Population Medicine, School of Public Health, Loma Linda University, Loma Linda, California, USA

Background and objectives: Dietary patterns are of great interest as they reflect choices of food combinations. A description of major nutrient intakes by dietary pattern can help elucidate their possible contributions to the prevention of disease. The purpose of the study was to describe the associations between dietary patterns and nutrient intakes stratified by sex and race.

Methods: A cross-sectional study of 71751 subjects (mean age 59 years, 65% women, 76% white) from the Adventist Health Study-2 with data collected between 2002 and 2007. Participants completed a 204-item validated semi-quantitative food frequency questionnaire. Five dietary patterns were established: non-vegetarian, semi-vegetarians, pesco vegetarians, lacto-ovo vegetarians and strict vegetarians. ANCOVA analysis was used to determine differences in nutrient intakes by dietary patterns. Differences in non-dietary variables, such as age, BMI, smoking and physical activity are also reported.

Results: Mean nutrient intakes varied markedly between dietary patterns. Nutrient intakes were more similar for men and women than for blacks and whites. Supplement intakes were often markedly higher in women than in men and higher in whites than in blacks. Blacks had lower values of nutrients often associated with dairy intake and higher values of soy protein and marine fatty acids.

Conclusions: Nutrient intakes vary markedly between dietary patterns, more so than between the sexes or between blacks and whites. These differences may have health implications.

Key words: Diet, micronutrients, macronutrients, supplements, nutrient deficiencies

PO2599**COMPARISON OF CORRECTION FACTORS FOR EFFECTS OF SUBCLINICAL INFECTION ON PLASMA FERRITIN, BASED ON CROSS-SECTIONAL (INTER-GROUP) VERSUS LONGITUDINAL (INTRA-INDIVIDUAL) DATA**

R. Wessells¹, S. Hess¹, N. Rouamba², Z. Ouédraogo², J. Ouédraogo², J. Peerson¹, K. Brown¹

¹Department of Nutrition, University of California, Davis, Davis, CA, USA

²Institut de Recherche en Sciences de la Santé, Bobo-Dioulasso, Burkina Faso

Background and objectives: Subclinical inflammation and malaria parasitemia affect iron status biomarkers. To remove confounding effects of inflammation, a correction method has been proposed, based on ratios of plasma ferritin concentration (pF) among groups with different stages of infection, as classified by acute phase proteins (APP): elevated C-reactive protein only (CRP;G1); elevated α -1-acid glycoprotein (AGP) and CRP (G2); elevated AGP only (G3); and non-elevated CRP and AGP (G4). However, this method assumes that infected and non-infected individuals have the same nutritional status, which may not be the case.

Methods: Two blood samples were obtained 21 d apart from 412 asymptomatic Burkinabe children 6-23 mo old. Regression coefficients for pF by APP status were calculated independently using cross-sectional and longitudinal ANCOVA models, which capture inter-group versus intra-individual effects of APP on pF, and compared with F tests.

Results: Correction factors (CF) for pF from cross-sectional models (0.47;0.23;0.46;1, G1-G4, respectively) over-adjusted for the effects of APP on pF compared to longitudinal models (0.60;0.30;0.53;1, $p=0.013$); adjusted prevalence of iron deficiency ($pF < 12 \mu\text{g/l}$) was 44.6% and 40.4%, respectively (unadjusted, 27.8%). Results suggest that pre-illness iron status was higher in children with subclinical inflammation than without, or that APP did not fully capture inflammatory effects. When pF was additionally adjusted for asymptomatic malaria (plasma histidine-rich protein II, HRP2), CF from cross-sectional and longitudinal models were not significantly different (APP, $p=0.76$; HRP2, $p=0.23$).

Conclusions: Basing CF on cross-sectional data in this population approximates the true effect of inflammation in an individual when both APP and malaria status are known. However, as prevalence estimates of iron deficiency were similar between APP-only models, cross-sectional adjustments may be adequate for survey data collection and programmatic decisions in this population.

Key words: CRP, AGP, ferritin, malaria

PO2600**COMPARATIVE STUDY OF THE ORAL ABSORPTION OF MICROENCAPSULATED FERRIC SACCHARATE AND FERROUS SULPHATE IN HUMANS**

³Dirección General de Deportes, Comunidad Autónoma de la Región de Murcia, Spain

Background and objectives: Iron is an essential trace metal whose absorption, extracellular concentration and body stores are efficiently regulated. According to the World Health Organization, iron deficiency is the most common nutritional disorder in the world. Because of dietary recommended iron intake is difficult to achieve from food alone, strategies for preventing iron deficiency have focused on food fortification with iron salts. Ideal iron fortificants should permit supplementing high doses of iron in food without changing their physical, chemical, or sensory properties. A microencapsulated ferric saccharate form (MFS) trademarked as AB-Fortis® has recently been developed, designed to produce no organoleptic or aspect changes during storage of fortified food even at high doses. The present work compared the absorption of iron from MFS to Ferrous Sulfate (FS) in healthy volunteers.

Methods: The study was a randomized cross-over, double-blind and postprandial intervention. Seventeen healthy adults from both sexes participated in the study. On each intervention day, after an overnight fast, the volunteers consumed either product, and blood sampling was carried out. The primary outcomes of the study were total serum iron and transferrin saturation.

Results: Transferrin saturation significantly increased after the intake of both products ($p < 0.005$), reaching a peak value between hours 2 and 4. No significant differences were detected between MFS and FS, suggesting that iron absorption from MFS is equivalent to absorption from FS. No significant differences could be observed in serum iron concentration during the 6-h postprandial study.

Conclusions: MFS is a new ingredient with similar absorption to FS that allows the fortification of a wide range of food products with excellent stability, including cooked and non-acidic products.

Key words: Iron deficiency, microencapsulated ferric saccharate, ferrous sulphate, fortified milk

PO2601**DIETARY DIVERSITY AND ITS DETERMINANTS IN RURAL SOUTH-EAST PERUVIAN HIGHLAND***U. Chavez Zander¹, A. Mujica Sanchez², M. Krawinkel¹*¹Justus Liebig University of Giessen, Giessen, Germany²Universidad Nacional del Altiplano UNA, Puno, Peru

Background and objectives: Dietary diversity (DD) is a key concept for nutrition security in resource-poor populations but may be influenced by seasonal food availability. Several studies have applied qualitative food scores as a proxy indicator of diet quality in Asian and African settings, but less is known in Latin America. The aim of this study was: A) To evaluate DD across three seasons: rainy (rain-S), post-harvest (post-S), and farming (farm-S) periods. B) To examine demographic and socio-economic determinants of DD.

Methods: A longitudinal study was carried out with 147 women aged 15 – 49 in three different seasons during 2007. Individual dietary diversity (DDS) and food variety scores (FVS) were calculated based on three qualitative 24 h dietary recalls. Demographic and socioeconomic information was collected using individual questionnaires.

Results: FVS but not DDS varied across seasons ($p=0.006$). Dietary patterns were similar between survey periods, and food scores differed according to agro-ecological zones ($p=0.000$). Less than half the women consumed animal products, fruits and dark green leafy vegetables over the year. Adjusted for age, wealth and housing, and the number of household members, access to local markets was associated with higher food scores in all seasons ($p<0.01$). In addition, income sources determined DD during rain-S ($p<0.05$), while the educational level of household's head ($p<0.01$) and crop production ($p<0.05$) played the main role during post-S.

Conclusions: DD as measured with food scores is able to reflect the dietary quality and is sensitive to socio-economic factors. Access to markets might improve food diversification, since own food production does not supply the household with an adequate variety of foods. The production of indigenous plants and animal farming should be encouraged to ensure a balanced diet even in more distanced areas.

Key words: Dietary diversity, indigenous, food scores

PO2602**ASSESSMENT OF SELENIUM INTAKE FROM GRAIN IN KOREAN ADULTS***O. Lee¹, J. Moon², Y. Chung²*¹Yongin University, Kyonggi, province, Korea²Korea Atomic Energy Research Institute, Daejeon, Korea

Background and objectives: Selenium is an anti-oxidative mineral and essential nutrient for the risk reduction of oxidative degenerating diseases, which is rapidly increasing among Korean. Therefore, the assessment of Korean selenium intake is very important. However, the selenium intake level of Korean is not known until now because of the insufficient selenium food database on Korean food. Grain and legume intake of Korean is higher compared to western countries as they are staple food in Korean diet and major source for carbohydrate and vegetable protein. In this study, the selenium consumption of Korean adults through these plant foods such as grain, starch, and potatoes was assessed.

Methods: The original data set was chosen from 2010 5th KNHANES dietary data and was analyzed using SAS (ver 9.1).

Results: The Korean adult consumed grain and legume selenium with an amount of 11.9 $\mu\text{g}/\text{d}$. The highest contributing grain type in selenium intake of Korean diet was wheat supplying selenium of 5.2 $\mu\text{g}/\text{d}$, followed by rice with 4.2 $\mu\text{g}/\text{d}$. In regard to food item, rice was the highest supplier of selenium in Korean diet, followed by loaf bread.

Conclusions: Together with our prior study on the meat intake, this study shows that Korean people seem to be not at risk of selenium deficiency on average.

Key words: Selenium, Korean adult, grain

PO2603**NECK CIRCUMFERENCE AS A PREDICTOR OF OBESITY IN ADOLESCENTS UNDER AGE AND PUBERTAL STAGES***R.L. Ferretti¹, I.P. Cintra¹, M.A.Z. Passos¹, M. Fisberg¹*¹Department of Pediatrics, Federal University of São Paulo, São Paulo, Brazil

Background and objectives: Obesity has a strong impact in many countries, causing many metabolic diseases. Central obesity is more strongly correlated to the risk of these diseases. In adults, Neck Circumference (NC) has been used as a screening tool for overweight. The aim of this study was to determine the cutoff points for NC identifying obesity in adolescents, according to age and pubertal stage.

Methods: Cross-sectional study that assessed adolescents from 10 to 17 years. Trained researchers took all anthropometric measurements, as weight and height, to calculate BMI, and NC. Obese adolescents ranked above +2 z-score of BMI according to the World Health Organization, 2007 were considered. The pubertal stage was assessed by Tanner boards. To compare the variables between the sexes the Mann-Whitney test was used, and significance was set at $p < 0.001$. Receiver operating characteristic (ROC) analyses were used to determine the predictive validity of NC as well as evaluate optimal cutoff values for identifying obese adolescents.

Results: Among 1668 adolescents assessed 54.92% were female. It was found that 7.56% of girls and 10.51% of boys were obese. The mean values of NC (cm) were 30.33 for females and 33.19 for males ($p < 0.001$). The cutoff points of the NC identifying obesity according to age for females and males were: 10-12 years (30.95 and 30.20), 13-15 years (32.60 and 33.55), 16-17 years (32.45 and 38.45), and according to pubertal stage: prepubertal (29.75 for both), pubertal (31.15 and 37.95) and post-pubertal (32.65 and 33.90). Girls had better Area Under the Curve (AUC) of NC according to pubertal than boys.

Conclusions: These data allow the assessment of central obesity in adolescents according to pubertal stage, using NC, a tool easier and with less margin for error than other measures, permitting identification and early intervention in the treatment of obesity in this population.

Key words: Neck circumference, obesity, adolescents

PO2604

VITAMIN A, ANEMIA, ZINC STATUS AND PARASITIC INFECTION IN MEXICAN SCHOOL CHILDREN

M.I. Grijalva-Haro¹, J. Yañez-Baca¹, E. Artalejo-Ochoa¹, J.A. Ponce-Martínez¹, O. Tortoledo-Ortiz¹, A. Nieblas-Almada¹, A. Robles-Sardin¹, M.N. Ballesteros-Vasquez¹

¹Coordinación de Nutrición, Centro de Investigación en Alimentación y Desarrollo, A.C. Hermosillo, Sonora, México

Background and objectives: Micronutrient deficiency is a global health problem and it has been called the hidden hunger, because mild and moderate manifestations cannot be detected at a glance. Vitamin A, anemia and zinc deficiency have been reported as main nutritional deficiencies among school children. The aim of this study was to assess the biochemical status of vitamin A, anemia and the presence of parasitic infection in school children living in northwest Mexico.

Methods: One hundred sixty-eight school children that attended public elementary schools were evaluated; 104 of them were beneficiaries of a public nutrition aid program called Programa de Desayunos Escolares (PDE), and 62 were not benefi-

ciaries (Reference group, GR). Measurements were taken at the start and at the end of the 2010-2011 school year. Anthropometric measurements, BMI, serum retinol, zinc and hemoglobin, as well as the presence of parasitic infections were evaluated.

Results: The prevalence of obesity was 27.5%. In the PDE group, 45.2% of children had low levels of serum retinol, as 42.4% had vitamin A deficiency (DVA, 0.35-0.7 mmol/l), and 2.8% presented severe deficiency (< 0.35 mmol/l); at the end of the school year, 17.3% of children recovered from DVA and no severe deficiency was found ($p < 0.001$). Anemia (Hb < 11.5 g/dl) was detected in 6.8% of children and it decreased to 2.9% ($p < 0.01$). In the GR group, 74.1% of children presented DVA, and it decreased to 62.8% at the end of the school year ($p > 0.05$). The proportion of anemia decreased from 4.8% and to 1.6%. Zinc deficiency was not found in any of the two groups. Fifty percent of the children presented parasitic infection, and Giardia lamblia prevailed.

Conclusions: Vitamin A deficiency and anemia is a public health problem in northwest Mexico and the Desayunos Escolares Program may help to improve this deficiency.

Key words: Deficiency, vitamin A, anemia, zinc, México

PO2605

THE DEVELOPMENT AND VALIDATION OF FOOD PHOTOGRAPHS IN THE ONLINE HELLENIC HEALTH FOUNDATION (HHF) DIETARY ASSESSMENT TOOL

A. Naska¹, M. Saradopoulou², G. Pounis², P. Orfanos¹, E. Valanou², A. Trichopoulou²

¹Department of Hygiene, Epidemiology and Medical Statistics, National and Kapodistrian University of Athens, Athens, Greece

²Hellenic Health Foundation, Athens, Greece

Background and objectives: Food photographs are widely used in large-scale surveys. Picture series presenting Greek foods and dishes were developed and validated. They were integrated in the online dietary tool (HHF Nutrition Tool), which is used in the Greek national nutrition and health survey (HYDRIA).

Methods: Six pictures per each of 170 foods or Greek dishes were prepared. The 5th and 95th percentiles of portions previously reported by 28572 Greek adults (ages 20-86 years) were used as the smallest and largest portions. Based on perceptual research, the weights of intermediate portions were defined as equal increments on log scale. Densities of foods were calculated. Photos were taken in a setup ensuring technical standards and were integrated in the online dietary tool. The respondents' perception of the quantities displayed online was validated. For this, 106 individuals (37% males and 64% females, mean age 45

± 23 years) were invited to participate based on convenience sampling. Attention was given to cover different educational backgrounds and include at least 25 individuals aged 70 years and more. Dishes displayed included quantities either equal to those of the pictures or between adjacent pictures. Pictures from the same series were validated by respondents of different age, gender and education.

Results: More than 2,200 selections of the corresponding picture were performed. Based on the distribution of reported differences, 75% of the picture series performed well. According to κ -statistic, the agreement between true and selected pictures was very good in 18% and fair in 73% of the picture series. Series that did not perform well included salads, sweets and three soup dishes.

Conclusions: The use of pictures displaying foods and Greek dishes, with which survey participants are familiar, is expected to increase the reliability of the national nutrition survey.

Key words: Food pictures, Greece, HYDRIA

PO2606

IS INFLAMMATION CORRECTION NECESSARY TO ESTIMATE THE PREVALENCE OF IRON DEFICIENCY AMONG 3-12 Y-OLD THAI CHILDREN?: THE SEANUTS STUDY

N. Rojroongwasinkul¹, P. Winichagoon¹, S. Senaprom¹, W. Wimonpeerapattana¹, A. Boonpraderm¹, U. Yamborisut¹, P. Kunapan¹, I. Khouw²

¹Institute of Nutrition, Mahidol University, Phuttamonthon, Thailand

²Friesland Campina, Amersfoort, The Netherlands

Background and objectives: While anemia is still prevalent in women and children in Thailand, there is limited data on iron deficiency (ID). We investigated the prevalence of ID and iron deficiency anemia (IDA) among Thai children using different approaches to correct for inflammation.

Methods: Blood samples from 496 children aged 3-12.9 y were assessed for hemoglobin (Hb), ferritin, transferrin receptor (TfR), TfR/ferritin index (TFI). Inflammation was determined by C-reactive protein (CRP) and α -1-acid glycoprotein (AGP). Acute phase protein (APP) was used (CRP > 5 mg/l and/or AGP > 1 g/l) and defined four groups of inflammation status: reference (normal CRP and AGP), incubation (raised CRP and normal AGP), early convalescence (raised CRP and AGP), and late convalescence (normal CRP and raised AGP). Ratios of geometric means of iron indicators for each inflammation group to reference group were used as correction factors (CF) to adjust iron values.

Results: Prevalence of infection was 7.3% and 31.7% based on CRP and AGP, respectively. Using ferritin, TfR and TFI, prevalence of ID was 1.8, 33.9 and 5%, respectively, and for IDA was 1.2, 5.9, and 1.8 %, respectively. Prevalence of ID increased after adjusting for APP (ferritin (3%)), but almost no change by TfR (33.5%), and TFI (5.4%). Percent anemia attributable to ID based on unadjusted vs APP adjusted ferritin values were 13.2 vs 15.4%; no change using TfR (64.8%) or TFI (19.8%). Using higher ferritin cutoff (< 30 μ g/l) resulted in ID prevalence of 19-22.6%.

Conclusions: Adjustment for infection the prevalence of ID increased when ferritin was used, but no effect when indicators using TfR as iron status indicators. Discrepancies in prevalence of ID and IDA using ferritin versus TfR or TFI needs to be further explored.

Key words: Iron deficiency, anemia, inflammation, correction factor

PO2607

A WEEKEND-DAY IN FOOD RECORDING COUNTERS DECREASING ENERGY REPORTING OVER THREE DAYS IN SCHOOL CHILDREN

F. Wenhold¹, U. MacIntyre¹, P. Rheeder¹

¹University of Pretoria, Pretoria, South Africa

Background and objectives: Food records are considered the most accurate dietary assessment method, using at least three days and including a weekend-day. This poses challenges, particularly amongst children, yet the school context may offer opportunities. Within a validation project, this quality control sub-study aimed to determine amongst grade 6 learners whether there is a difference in mean reported daily energy intake over three consecutive days of food recording, and whether there was a difference in mean energy intake in three different consecutive-day recording periods (Sunday-Monday-Tuesday [SMT] vs. Tuesday-Wednesday-Thursday [TWT] vs. Thursday-Friday-Saturday [TFS]).

Methods: As part of a mathematics assignment the 108 children from three classes were randomly divided into three recording periods (SMT: n=22; TWT: n=49; TFS: n=22) for weighing their total food and drink intakes with a digital food scale. For 93 children (50 girls, 43 boys; mean age 12.3 years) parental consent and child assent for research and useable data were received. Food records were analysed using FoodFinder™. Energy intake to resting expenditure ratios were calculated (EI/REE). Differences in mean energy intake over the three days of recording and the three recording periods were determined using the Friedman two ways analysis of variance with multiple comparisons.

Results: Mean body mass index z-score was 0.42 ± 1.1 . Mean EI/REE was 1.45 ± 0.4 . Overall there was a statistically

significant difference ($p=0.03$) in energy intake between day 1 and day 3. In the SMT and TFS groups there was no significant difference in energy intake over the three days.

Conclusions: The reported energy intake for the group over the three consecutive days was credible, but decreased, except when a weekend-day was part of the period. Food recording in school context is feasible, but should include a weekend-day.

Key words: key words apply: Dietary assessment; children; food records; weekend-day; validity

PO2609

BODY COMPOSITION AND WEIGHT CHANGES DURING PREGNANCY: A STUDY FROM NANJING, CHINA

M. Miao¹, Y. Dai¹, Y. Zhang¹

¹Department of Nutrition, Nanjing Maternity and Child Health Care Hospital, Nanjing, China

Background and objectives: Maternal body composition undergoes a deep adaptative change during the course of pregnancy. Fat mass, fat-free mass and total body water increase in different ways and their effects on pregnancy outcome represent a field of major interest in perinatal medicine. The present study was aimed at investigating changes in body composition characteristics and weight gain during pregnancy.

Methods: A total of 5186 healthy, pregnant women aged between 20 and 44 years participated in the study. Pregnant women were recruited from the outpatient department of Nanjing Maternity and Child Care Hospital, China. Maternal height and weight were measured digitally in a standardized way and Body Mass Index (BMI) was calculated. Maternal body composition was measured using segmental multifrequency Bioelectrical Impedance Analysis (BIA). Subjects were categorized into three trimester groups: Group I (<12weeks), Group II (13-26weeks) and Group III (27-39weeks). Descriptive statistics such as mean and standard deviation (SD) were calculated separately for three groups. Comparison of groups for variables was done using analysis of variance (ANOVA) with Scheffe post-hoc test.

Results: The mean change in maternal weight from the first to the third trimester was 10.32 kg. The mean fat mass for three groups (Groups I, II and III) was 17.21 ± 6.50 kg, 21.18 ± 5.76 kg and 22.50 ± 5.64 kg, respectively; fat-free mass was 40.19 ± 2.80 kg, 42.17 ± 2.85 kg and 43.98 ± 2.82 kg, respectively; total body water was 28.87 ± 3.58 l, 31.56 ± 3.54 l and 32.54 ± 3.52 l, respectively.

Conclusions: The findings could represent more exaggerated physiological responses to the pregnant state in the primiparous and provide reasonable and effective guidance on maternal nutrition and exercise.

Key words: Body composition, pregnancy, bioimpedance

PO2610

WAIST CIRCUMFERENCE AS A SCREENING MEASUREMENT FOR CENTRAL OBESITY AMONG EGYPTIAN ADOLESCENTS

D. Shehab¹, N. Aboul Ella¹, M. Ismail¹

¹National Nutrition Institute, El Cairo, Egypt

Background and objectives: Childhood obesity has become an ever-increasing problem and is now considered to be a disease of epidemic proportion. Early childhood obesity enhances its adulthood risk. The aim of the study was to validate waist circumference (WC) as a screening measurement for central obesity among Egyptian adolescents with using of body mass index (BMI) as a golden standard test.

Methods: A random stratified multistage cluster-sampling design of preparatory and secondary school students was used. Four governorates from Upper Egypt and three from Lower Egypt were selected. Weight, height, and WC were measured and BMI was calculated and categorized according to national center for health statistics and national center for chronic disease prevention and health promotion (2000). By using receiver operating characteristic (ROC) analysis, the ROC curve of waist was drawn to show how well it could separate subjects into groups of \leq with or without; \pm overweight or obesity, with BMI being the gold standard test.

Results: 6018 adolescents were recruited in this study (aged from 11 to 18 years with a mean value of $14.2 \text{ yr} \pm 1.16$, with no significant difference on sex-based comparison). Females formed 51.0% of participants. Overweight was reported among 13% and obesity proportion was 7.8%. Waist cutoff for overweight/obesity with maximum sensitivity; 89.0%, was recorded among male-adolescents aged 16+ yr and maximum specificity; 87.0%, was recorded among male-adolescents aged ≥ 13 yr and < 16 yr. Estimated frequencies for male adolescents at risk followed closely the 75th percentile of British data reference while those for female were midway between 75th percentile of British and American data references.

Conclusions: WC as a screening measurement for central obesity with using of BMI as a golden standard test can be relied upon to some extent among adolescents as age advances.

Key words: Central obesity, waist circumference, ROC curve

PO2611**ASSOCIATION BETWEEN DIETARY DIVERSITY AND PERCEPTION BASED MEASURES OF FOOD INSECURITY: DOES SEASONALITY AND FOOD PRICE CHANGE THE RELATIONSHIP?***J. Waid*¹¹Helen Keller International, New York, USA

Background and objectives: Dietary diversity has been shown to be closely correlated with both household wealth and calorie and micronutrient adequacy. However changes in seasonal dietary patterns and differences between populations with divergent culturally-based food patterns can complicate the interpretation of this indicator. The relationship between dietary diversity and perception based measures of food security has not been fully examined.

Methods: Seasonal, cross-sectional data from two years of the Food Security and Nutrition Surveillance Project was aggregated (six surveillance rounds), resulting in a data set of 53,515 households. The relationship between perception based food security indicators and individual dietary diversity and household food frequency measures was examined.

Results: Notably, as the price of rice fell over the time periods covered by the dataset, diets grew slightly less diverse even as reports of food insecurity fell. Additionally, seasonal variation in estimates of household food insecurity differed depending on if the indicators were based on dietary diversity of households and adult women or based on behavioral responses to food insecurity. Household food frequency scores were highly correlated with the Household Food Insecurity Access Scale, but this relationship differed by season and was greater during the monsoon season. This same pattern was observed for women's dietary diversity scores.

Conclusions: Dietary diversity and food frequency measures are important indicators of food security, but they should be interpreted in light of seasonal and cultural norms in the area under consideration.

Key words: Food security, dietary diversity, food frequency

PO2612**ANTHROPOMETRIC MEASURES, NUTRITIONAL STATUS, COGNITIVE RESTRAINT AND EMOTIONAL EATING PATTERNS IN FEMALE UNIVERSITY STUDENTS***A. Witriw*¹, *C. Drolas*¹, *A. Calviño*²¹School of Nutrition, Faculty of Medicine, University of Buenos Aires, Buenos Aires, Argentina²Faculty of Pharmacy and Biochemistry, IQUIMEFA-CONICET, University of Buenos Aires, Buenos Aires, Argentina

Background and objectives: Cognitive restraint and emotional eating involved in eating behaviors, may modify body composition and the nutritional status. The aims of this study were to assess the nutritional status and body composition of university students, and to analyze the possible links between measured cognitive restraint (CR) and emotional eating (EE) and nutritional reserves derived from anthropometric fractionation of body mass.

Methods: 175 females (24.57 ± 3.54 years), undergraduate students at the Medical School of Nutrition and Faculty of Pharmacy and Biochemistry of the University of Buenos Aires, were involved. Body composition was determined by the anthropometric fractionation method, consisting of 25 surface measurements (eight bone diameters, seven fat folds, eight muscle perimeters, seated and standing height). Caloric (CRv) and proteic (PRv) reserves were derived from fat/skeletal mass ratio and muscle/skeletal mass ratio, respectively. From the three factor eating questionnaire, the CR subscale (6 items) and EE (3 items) were assessed to know eating behaviors. They have Cronbach's alphas of 0.75. Correlation analysis, cluster analysis and analysis of variance (ANOVA) were performed.

Results: Both CRv and PRv normal values were shown in 41.1% of the cases (n=72), while 35.4% presented only normal CRv, 13.1% showed only normal PRv and a 10,3% showed both reserves out of standards. Thus, four clusters explained distributions of nutritional status. CRv was significantly correlated with both CR and EE scores (p<0.01) and PRv only showed a slight correlation with CR scores (p<0.05). ANOVA and post-hoc LSD comparisons support the effects of both EE and CR on anthropometric measures.

Conclusions: Emotional and restraint behaviors under study are related mainly to CRv and very slightly to the PRv, we believe that diminished proteic reserve could be associated with poor food intake and/or sedentary life style.

Key words: Body composition, young females, eating behaviors, caloric reserve, proteic reserve

PO2613**ADOPTING STANDARDIZED EUROPEAN DIETARY METHODOLOGY (EPIC-SOFT) FOR RESEARCH AND DIETARY SURVEILLANCE IN KOREA**

M.K. Park¹, J.Y. Park¹, G. Nicolas¹, J. Kim², N. Slimani¹

¹Dietary Exposure Assessment Group, International Agency for Research on Cancer, Lyon, France

²Molecular Epidemiology Branch, National Cancer Center, Goyang-si, Republic of Korea

Background and objectives: During the past three decades, the economy has grown with great rapidity and a parallel rapid nutritional transition has been observed in Korea. In order to better understand dietary patterns in Korean population and its association with cancer and other non-communicable diseases, well-established dietary methodologies to guarantee standardization in the procedures are required. We therefore aimed to develop a Korean version of the computerized 24-hour dietary recall (EPIC-Soft) and its complementary tools and facilities, developed at the International Agency for Research on Cancer (World Health Organization).

Methods: The creation of about 70 interrelated databases on foods, recipes, dietary supplements, quantification methods and coefficients was needed. Parts of these databases were classified as common databases (i.e backbone to standardize data within and between countries). The other part was country specific (i.e structured databases that have flexibility for capturing the difference in diet across countries) and additional work was done to input the databases, usually based on the data available in Korea. Furthermore, an adapted version of the EPIC-Soft picture book was made, with inclusion of new pictures and portion sizes.

Results: This work provides the first Asian version of the EPIC-Soft with over 70 databases being customised and translated. **Conclusions:** The EPIC-Soft Korean version will be available for the future research and dietary surveillance in Korea. Ultimately, we will have an opportunity to evaluate the feasibility of expanding the EPIC-Soft methodology to other Asian countries. This could offer a unique opportunity to provide a common dietary methodology and increase data comparability across Asian countries where the rapid nutritional transitions have occurred.

Key words: EPIC-Soft, computerized dietary assessment, 24-HDR

PO2614**PROTEIN QUALITY OF PROCESSED CONOPHOR NUT USING RAT BIO-ASSAY**

A. Esekheigbe¹, I. Onimawo¹

¹Ambrose Alli University, Ekpoma, Nigeria

Background and objectives: The objective of this study was to evaluate the quality of the protein from differently processed conophor nut (*Tetracarpidium conophorum* Mull. Arg.) which is known to be rich in proteins.

Methods: Mature conophor nuts were divided into four portions. A portion was deshelled and milled raw while the other three portions were fermented, cooked and roasted respectively before milling. 36 weanling male albino rats were divided into six groups of six rats each on the basis of initial body weight. The animals were fed for 28 days on separate diets containing 10% protein by weight of casein (control), raw, cooked, fermented, roasted conophor nut and a nitrogen-free (basal) diet. Daily records of food consumed and weight changes were kept. Faeces and urine were collected in the last week for nitrogen analysis.

Results: Rats fed on the raw, cooked and fermented conophor nut-based diets had protein efficiency ratios (PER) of 2.24, 2.43 and 2.35, respectively, which were not significantly ($p>0.05$) different from the 2.74 obtained for casein (control) when subjected to one way ANOVA and LSD test. However, animals in the roasted category recorded significantly ($p<0.05$) lower PER of 2.01. Animals in this group also showed a significantly ($p<0.05$) lower biological value of 67.82% compared to the 70.12%, 75.31%, 72.40% and 78.05% obtained for the raw, cooked, fermented conophor and casein diets respectively. Protein digestibility was also lower in the roasted conophor-based diet. However, there were no significant ($p>0.05$) differences in the net protein utilization values.

Conclusions: The quality of conophor nut protein was reduced by roasting.

Key words: Conophor nut, protein quality, casein

PO2615**DIETARY SELENIUM/VITAMIN E AT SUPRANUTRITIONAL DOSES AMELIORATE EFFECT OF HEAT STRESS ON PHYSIOLOGICAL PARAMETERS AND ACID BASE BALANCE IN SHEEP***S.S. Chauhan^{1,2}, P. Celi^{2,3}, B.J. Leury², F. Liu², F.R. Dunshea²*¹Department of Animal Husbandry, Himachal Pradesh, Shimla, (HP) India²Melbourne School of Land and Environment, The University of Melbourne, Parkville, Australia³Faculty of Veterinary Science, University of Sydney, Sydney, Australia

Background and objectives: Heat stress (HS) affects the physiological and biochemical processes of the animal and can create acid-base imbalance. The objective of this study was to elucidate the potential of supranutritional doses of selenium (Se) and vitamin E to ameliorate the effect of HS on physiological parameters and acid-base balance of sheep.

Methods: Thirty two Merino x Poll Dorset ewes were housed in one of 2 climatic chambers maintained at either thermoneutral (TN) (18-21°C and 40-50% relative humidity (RH)) or HS (28-40°C and 30-40% RH) conditions. Sheep were allocated in 2x2 factorial design to different levels of Se (0.24 (LS) and 1.20 (HS) mg Se (as SelPlex™) kg-1 DM) and vitamin E (10 (LV) and 100 (HV) I.U. vitamin E kg-1 DM). Physiological parameters were recorded three times a day (0900, 1300 and 1700 h), blood samples collected on day 1 and 7 of treatment.

Results: Average respiration rate (169 vs. 78 breaths/min) and rectal temperature (40.10 vs. 39.47°C) were increased ($p < 0.001$) during HS. Although there were no overall effects of vitamin E on physiological parameters, there were interactions ($p < 0.001$) between vitamin E and temperature such that vitamin E decreased respiration rate (157 vs. 182 breaths/min) and rectal temperature (40.26 vs. 40.54°C) during HS but not TN conditions. Se decreased respiration rate (165 vs. 174 breaths/min) during HS but not TN. Ewes given HSHV diet had a lower respiration rate (191 vs. 232 breaths/min, $p = 0.012$) and rectal temperature (40.33 vs. 40.58°C, $p = 0.039$) under peak HS (1300 and 1700h) compared to those on the LSLV diet. Blood pH was elevated ($p = 0.007$) and bicarbonate reduced ($p = 0.049$) under HS in LSLV but not in HSHV.

Conclusions: These data demonstrate that effects of HS on physiological parameters and acid-base balance are ameliorated by high levels of Se and vitamin E.

Key words: Heat stress, antioxidant, sheep

PO2616**NUTRITIONAL CHARACTERISTICS IN A MEDITERRANEAN COMMUNITY AMONG PROCREATING MOROCCAN WOMEN***M. Mziwira¹, M. El ayachi¹, D. Lairon², R. Belahsen¹*¹Training and Research Unit on Nutrition & Food Sciences, Chouaib Doukkali University, School of Sciences, El Jadida, Morocco²INSERM, UMR476, «Nutriments Lipidiques et Prévention des Maladies Métaboliques»; INRA 1260; Univ Aix-Marseille 1 & 2, Faculté de Médecine, IPHM-IFR 125, Marseille, France

Background and objectives: To assess and describe the dietary intake levels and major food sources of energy and nutrients for selected women from an agricultural region of Morocco.

Methods: A total of 191 adult women subjects aged 18–55 years resident in urban areas in the province of El Jadida. Dietary habits were assessed by means of 24-h recall during 3 non consecutive days and a semi quantitative food-frequency questionnaire.

Results: Alimentary habits were characterized by a large consumption of cereals, meat and poultry, fish and sea foods, eggs, fruits and vegetables, but a low intake of olive oil. We observed an excess of total calories not balanced by a high degree of physical activity levels, a low calories from lipids intake but high in saturated fat (39 %). This result is reflected in the higher PUFA/SFA ratio (0.76 ± 0.62), a high consumption of total carbohydrates (61 % of daily energy) although this is accompanied by a lower fiber intake 18.07 ± 11.44 g. Furthermore we found a significant higher saturated and monounsaturated fat in the youngest individuals and in people with higher educational levels. Except intake of phosphorus and sodium, all minerals and vitamins assessed are below or close to the recommended dietary allowance (RDA) while all vitamins are consumed at rates below two-third of RDA by a high percentage of women.

Conclusions: Examination of available data revealed a shift of dietary habits from traditional Mediterranean diet to industrial food; a change in lifestyle, recent urbanization could explain, in part, the nutritional and metabolic disorders reported in this population. Adoption of preventive measures by educating women in terms of nutrition are to be undertaken to reverse this picture and avoid health consequences.

Key words: 24h recall, food frequency, Mediterranean diet, nutrients, Morocco

PO2617**IDENTIFICATION OF PROBLEMS OF NUTRITIONISTS IN USING EXISTING FOOD COMPOSITION TABLE AND DEVELOPMENT OF NEW FOOD COMPOSITION TABLE FOR PAKISTAN***S. Aftab*^{1,2}

¹Department of Health and Hospital Management, Institute of Business Management, Karachi, Sindh, Pakistan

²P.E.C.H.S. Government College for Women, Education and Literacy Department of Sindh, Government of Pakistan

Background and objectives: Nutritionists in Pakistan are not satisfied with the current Pakistan's Food Composition Table (FCT) because of limited nutritional information on limited foods and use foreign FCT for the nutrient intake assessment and face a number of problems. The objective of the study was to determine the views and expectations of nutritionists about existing and upcoming FCT respectively to develop a new FCT for Pakistan.

Methods: Cooked foods, to be included in the upcoming FCT, were identified from previous research studies with their standardized recipes. The ingredients with quantities in each food were fed on Microsoft Excel to determine the nutritive value of whole cooked food. Data were gathered from forty-eight nutritionists through interview-cum-questionnaire method regarding their view and expectations about FCTs and were analyzed statistically using SPSS 11.0 version.

Results: United States Department of Agriculture (USDA) FCT was the most preferable FCT because of its authentic and updated data and easy online access followed by Pakistan's FCT, Indian FCT and then International Nutrient Databank. Nutritionists were not satisfied with nutritive values, given per 100 grams of edible food portion, limited nutritional data on locally consumed foods, infant foods and nutritional supplements. Nutritionists expected to have soft and hard copy of FCT with authentic nutritive values on regional and ethnic dishes with different fat versions and consistencies in portion sizes or metric measures. Urdu names of food items were expected to be mentioned. Revision of FCT was expected to be done after every three years. All nutrients along with types of fats, fiber, oxalate, caffeine, amino acid and fatty acid content in food were expected to be present in the upcoming FCT.

Conclusions: Nutritionists need an updated and customized FCT for accurate nutrient intake assessment of population in Pakistan.

Key words: Food composition table, nutritionist, assessment, nutrient

PO2618**SALT PREFERENCE AND SODIUM INTAKE OF KOREAN NORMOTENSIVE FEMALE ADULTS***H.Z. Kim*¹, *J.Y. Lee*², *D.S. Cho*³

¹Department of Food and Nutrition, Daejeon Health and Sciences College, Daejeon, Korea

²Food & Nutrition Major, Eulji University, Seongnam, Korea

³Nursing Department, College of Nursing, Eulji University, Seongnam, Korea

Background and objectives: This study was done to explore the correlation between Korean female adult's salt preference and their sodium intake.

Methods: 156 young women and 77 middle-aged women without hypertension or any current medication were recruited. Body mass index, waist hip ratio and blood pressure were measured from each subject. Salt usage behaviors were surveyed with questionnaire, sodium intake with 24-hr recall method, and sodium excretion with spot urine. Salt preference and sodium intake were analyzed to compare the difference between young and middle-aged women.

Results: Middle-aged women were more obese than young women according to body mass index and waist hip ratio. Blood pressure was significantly higher for the middle-aged. Young women consumed more fats and middle-aged women more carbohydrates. Middle-aged women consumed more sodium and potassium, and excreted more sodium. Among questionnaire items, kimchi, soup or pot stew, or salted vegetables were found to be related with high sodium diet. Salted vegetables and salted nuts and potato chips were significantly correlated with young women's high sodium diet, while soy sauce on fried food, kimchi, salted vegetables accounted for middle-aged women's high sodium diet.

Conclusions: Middle-aged women had higher risk of metabolic syndrome, such as higher BMI, WHR and blood pressure. It was correlated with higher sodium intake of middle-aged women. As women goes aging, reducing sodium intake and maintaining normal BMI and WHR becomes more important to support their health.

Key words: Sodium intake, middle-aged women, blood pressure, salt preference

PO2619**PREVALENCE OF VITAMIN B12 AND FOLATE DEFICIENCY IN LATIN AMERICA AND THE CARIBBEAN**

A. Brito^{1,2}, M. Olivares¹, M F. Mujica¹, D. López de Romaña^{1,3}, L H. Allen²

¹Micronutrients Laboratory, Institute of Nutrition and Food Technology (INTA), Universidad of Chile, Santiago, Chile

²USDA, ARS, Western Human Nutrition Research Center (WHNRC), University of California, Davis, USA

³The Micronutrient Initiative, Ottawa, Ontario, Canada

Background and objectives: There is no systematic review examining the pre-post era of folic acid (FA) fortification on B12 and folate deficiency prevalence in Latin America and the Caribbean (LAC). Our objective was to examine prevalence data on B12 and folate deficiency in LAC since 1990.

Methods: A systematic review was conducted in 2012. Studies using biochemical biomarkers and conducted in apparently healthy individuals were included.

Results: A total of 817 studies were identified. The final numbers of selected studies were 46. The prevalence of B12 deficiency in nationally representative samples was: in Argentina (prevalence 12% adult women, 18% in pregnant; plasma B12<111 pmol/l), Chile (9% elderly; plasma B12<148 pmol/l), Colombia (0%, 3%, 13%, 19% for infants, school-children, adult women and pregnant, respectively; plasma B12<148 pmol/l), Costa Rica (5% lactating women; plasma B12<148 pmol/l), Mexico (7.7% 1-6y; plasma B12 <149 pmol/l) and Venezuela (11% <7y; plasma B12<148 pmol/l). For folate deficiency there are national samples indicating its prevalence before FA fortification in Chile (11% adult women; RBC folate <181 nmol/l), Costa Rica (4% adult women, 2% <6y, 49% lactating women; serum folate <6.8 nmol/l), Venezuela (31% 6m-7y, 36% <14y Gran Caracas; serum folate <6.79 nmol/l) and Mexico (10% <4y, 5% 4-11y, 5% adult women, respectively, serum folate <5.8 nmol/l); and after FA fortification in Argentina (1% adult women, 3% pregnant; serum folate <6.79 nmol/l), Chile (<1%, >65y; serum folate 12 nmol/l, 0% adult women; serum folate <3.2 nmol/l) and Mexico (3.2%, 1-6y; <9.0 nmol/l).

Conclusions: B12 deficiency appears to be mild to moderate public health problem, while folate deficiency is not a public health problem (<5%) in any of the Latin American countries with nationally representative samples available after FA fortification.

Key words: Vitamin B12, folate, folic acid, prevalence, Latin America

PO2620**SELENIUM CONTENT IN COWPEA (VIGNA UNGUICULATA) IN THE STATE OF CEARÁ - BRAZIL**

P P. Pessoa¹, W R. Santiago¹, C F. Barroso¹, L B. Santos², A. Pimente¹, S M F. Cozzolino², J G. Reges¹, M Y P. Teixeira¹, L S. Ressurreição¹, N M. Martins¹, R C A. Silva¹, L M S. Castro¹, C S C. Maia¹

¹State University of Ceara, Ceara, Brazil

²University of Sao Paulo, Sao Paulo, Brazil

Background and objectives: The mineral selenium (Se) is part of the enzyme glutathione peroxidase (selenoenzyme), which participates in the antioxidant defense system of cells. Depending on geological factors Se is distributed by land surface. The geochemical distribution of Se makes vulnerable the studies of food consumption in all parts of the world, because the soil at each site determines the concentration of this mineral in foods. The state of Ceara (Brazil) has been prominent regarding the amount of selenium in its soil which is higher than the states in the Midwest, Southeast and South. The aim of this study was to determine the concentration of Se in cowpea (*Vigna unguiculata*) produced in different geographical regions of the state of Ceará (Brazil).

Methods: The cowpea was chosen because it is a food typical and widely consumed in the state. The method selected for determining the concentration of selenium was atomic absorption spectrophotometry for the generation of hydrides coupled quartz cell (HGQTAAS). Samples were collected from seven geographical regions of the state, harvests in 2010, 2011 and 2012.

Results: The average Se cowpea from around the state was 23,71 mcg Se/100 g of raw food, ranging from 5,70 mcg Se/100 g to 56,44 mcg Se/100 g. We perceive the upper middle of Se in bean comparing our state to the value of Se in beans marketed in other Brazilian cities where the average was 1 mcg Se/100 g of raw food.

Conclusions: We conclude that the cowpea can be an ally to the contribution of the supply of Se in the diet of Ceará.

Key words: Selenium, soil, Brazil, beans

PO2621**TOTAL AND HAEM IRON IN FRESH ANGUS STEERS MEAT FROM NATURAL PASTURES TO CONCENTRATED-BASED FEEDING SYSTEMS IN URUGUAY***M.C. Cabrera^{1,2}, M. Pereiro¹, A. Saadoun²*¹Facultad de Agronomía-Universidad de la República, Montevideo, Uruguay²Facultad de Ciencias-Universidad de la República, Montevideo, Uruguay

Background and objectives: Iron deficiency, a important health problem related to the diet, causes anemia and impairs cognitive performance in children. Bovine meat, an expensive food, is a key source of iron and haem iron, a biologically important iron containing compound, but content could vary with animals diet, breed and muscle type. In this work we determine the content of total and haem iron in bovine meat produced in different feeding systems, pasture, pasture and grains and concentrated-based, in three muscles of high (h), middle (m) and low (l) commercial value.

Methods: Fresh muscles Longissimus dorsi (LD; h), Biceps femoris (BF; m) and Triceps brachi (TB; l) from Angus steers fed with pastures, pastures and grains or concentrated (10 steers each one). Iron was determined by flame atomic absorption spectrophotometer in samples previously dried, ashed and solubilized. Total haem pigments were determined as hemin after extraction with acidified acetone, quantified in a spectrophotometer at 640 nm and haem iron content calculated (0.0882 g iron / g hematin). Data were analyzed by GLM procedure for feeding system and muscle type as main effects followed by Tukey-Kramer test ($p < 0.05$).

Results: Meat from pasture-based feeding systems has a significantly higher iron content (26 ppm; $p < 0.05$) than meat from concentrated-based feeding systems (21 ppm). BF and TB iron was significantly higher (25 ppm; $p < 0.05$) than LD (21 ppm). Meat from pasture or pasture and grains-based feeding systems has a significantly higher haem iron content ($p < 0.05$) related to concentrated-based feeding (20.9, 20.7 y 16.5 ppm, respectively). TB has a high haem iron content (21.8 ppm) as LD (20.3 ppm) but haem/iron is 87% for TB and 96% for LD.

Conclusions: We conclude that pasture meat or a low cost cut as TB are nutritionally valuable source of haem/iron.

Key words: Haem iron, bovine meat, pasture-based meat

PO2622**SELENIUM, ZINC, COPPER AND MANGANESE IN FRESH ANGUS STEERS MEAT FROM PASTURES TO CONCENTRATED-BASED FEEDING SYSTEMS IN URUGUAY***M.C. Cabrera^{1,2}, A. Ramos^{1,2}, A. Saadoun²*¹Facultad de Agronomía-Universidad de la República, Montevideo, Uruguay²Facultad de Ciencias-Universidad de la República, Montevideo, Uruguay

Background and objectives: Mineral deficiencies in humans are common world-wide and there are evidences which suggest that deficiencies may play a negative role in children's development, pregnancy and elderly health. Se, Cu, Zn and Mn are keys for the enzymatic system that counteract the free radicals in the organism. Red meat is a major source of essential minerals, of high bioavailability to human nutrition and its consumption can be a good way to respond qualitatively and quantitatively to the mineral requirements. The objective of this work was to assess the mineral content in bovine meat produced in pasture, pasture and grains and concentrated-based systems, in three muscles of high, medium and low commercial value.

Methods: Fresh muscles, Longissimus dorsi, Biceps femoris and Triceps brachii from Angus steers fed with pastures, pastures and grains or concentrated (10 steers each one) were used. Determination of Cu, Zn, and Mn were performed by flame atomic absorption spectrophotometer and Se was analyzed by graphite furnace atomic absorption. Data were analyzed by GLM procedure for feeding system and muscle type as main effects followed by Tukey-Kramer test ($p < 0.05$).

Results: Se and Mn content in pasture-based meat was significantly higher ($p < 0.05$) than pasture and grains and concentrated-based meat. Meat from pasture and pasture and grains systems was more rich ($p < 0.05$) in Zn than the intensive system. Feeding system has not effect on the Cu level in meat, but Triceps brachii accumulated significantly more Cu ($p < 0.05$) than the other muscles. A high cost muscle as Longissimus dorsi is more rich ($p < 0.05$) in Zn than the Biceps or Triceps muscles. Medium and low cost muscles as Biceps femoris and Triceps brachii, have higher content of Se ($p < 0.05$) than Longissimus independently of feeding diet.

Conclusions: Bovine meat from pasture based-system contain high levels of Se, Mn and Zn but its varies with the muscle type.

Key words: Minerals, selenium, bovine meat, pasture-based meat

PO2623**FATTY ACID COMPOSITION OF MEAT FROM HERFORD AND BRAFORD BREED PRODUCED ON PASTURE IN URUGUAY**

A. Saadoun¹, A. Terevinto^{1,2}, M.C. Cabrera^{1,2}

¹Facultad de Ciencias-Universidad de la Republica, Montevideo, Uruguay

²Facultad de Agronomía-Universidad de la República, Montevideo, Uruguay

Background and objectives: In Uruguay, meat production is principally based on extensive system which includes pasture as food. The Uruguayan herd is constituted principally by Hereford (H). However, nowadays new breed are considered in way to enhance the rusticity of H animals. In this sense, the crossing between H and Brahman, called Braford (B), is considered promising. In regard to the health concerns associated to the type of fatty acids present in meat, it's important to consider this point when new meat products are offered to consumers.

Methods: Fatty acid composition of H (n=12) and B (n=12) Longissimus dorsi muscle, before and after ageing during 14 days at 2°C in vacuum, was compared in animals (steers, 24-26 months of age) fed exclusively pasture. The fatty acids were determined by GC/FID using a CLARUS 500 and capillary column cpsil-88 equipment.

Results: Based on GLM statistical comparison, the saturated fatty acids (SAT), principally palmitic and stearic acids, showed neither breed nor ageing main effect. The monounsaturated fatty acids, principally oleic acid, showed a main breed effect ($p < 0.01$; H>B) but not an ageing effect. For polyunsaturated fatty acids (PUFA), principally linoleic and linolenic acids, a main breed effect was observed ($p < 0.05$; H 0.40).

Conclusions: The meat from B could be considered as very interesting in regard to the fatty acid composition and the PUFA/SAT health indices. The crossing between H breed and Brahman breed could be considered as advantageous, and a way to obtain a healthy meat for consumers.

Key words: Bovine meat, fatty acids, pasture, health indices

PO2624**EVALUATION OF NUTRITIONAL QUALITY IN THE POPULATION AT HIGHEST RISK OF POVERTY IN SERBIA**

M. Glibetic¹, R. Novakovic¹, M. Nikolić¹, J. Milešević¹, A. Kadvan¹, M. Đekić¹, S. Petrovic¹, S. Rankovic¹, M. Guri-novic¹

¹Centre of Research Excellence in Nutrition and Metabolism, Institute for Medical Research, University of Belgrade, Belgrade, Serbia

Background and objectives: Nutritional criticalities in population at the highest risk of poverty (PHRP) have not been evaluated in Serbia. The objective of this comprehensive study was to identify this population group/s in Serbia, to define nutritional criticalities and analyze the nutrition quality.

Methods: To identify the population in the highest risk of poverty (PHRP), indicators were used and data analyzed based on EUROSTAT publication. Population specific nutritional criticalities were identified by systematic review (SR) of literature from Medline and Web of Science (WoS) databases and from the grey literature sources. Food intake was assessed by use of two days 24h recall and FFQ in 500 participants. Intake was studied by the use of nutritional software DietAsses and Serbian food composition data base.

Results: Adults aged 25-65 years and young adults (18-25 years) were identified as populatons at the highest risk of poverty in Serbia. The results of SR indicated lower intake of fruit and vegetables in this groups, especially in the group of young male adults as was confirmed by intake analysis. In general, PHRP groups consume more than 15% less fruits than recommended by the WHO. Also, the contribution of dairy products to total energy intake is lower, which reflects an insufficient calcium and fat soluble vitamins intake in these population groups. Besides adequate protein intake, low intake of fiber was also detected. In contrast, total fat intake is excessive and contributes 8% more to total energy intake (TE) than recommended by the WHO.

Conclusions: In identified PHRP groups in Serbia the main nutrition criticalities are the high intake of total fat, lower intake of dairy product, fruit, fibre and complex carbohydrates and contribute to development of diet-related diseases.

Key words: Risk of poverty, nutrition criticalities, nutrient intake

PO2625**NUTRITION ASSESSMENT OF DOWN'S SYNDROME CHILDREN IN EGYPT**

S. Khairy¹, Z. Abu El-Gheat¹, H. Fadel¹, A. Abd Allah¹, S. Abdel Haleem¹

¹National Nutrition Institute, El Cairo, Egypt

Background and objectives: Down's syndrome (DS) is the most common chromosomal disorder. The aim of this study was to evaluate the nutritional status of DS children.

Methods: The study was conducted on 241 children with DS. Their age ranged from 6-18 years old, from six governorates in Egypt. All children were subjected to clinical examination, anthropometric assessment and sub sample was taken for laboratory tests. Food history was taken using 24 h recall method for about 50% of the sample.

Results: The mean of hemoglobin concentration for the sample was 12.2%, the prevalence of anemia was found among 61.3%. Plasma estimation for micronutrients indicated that 36.4% had low Mg and 33% had low Cu. Approximately 40% of the sample had insufficient energy. The mean intakes for calcium (Ca) and iodine (I) were around half the requirements (53.3% and 48.39% of RDI values respectively), while 84.2% and 83.2% of the total sample had insufficient Ca and I intakes. The mean intake of Vit A was 74% of the RDIs while about half of the sample (45.54%) had insufficient Vit A intake. The other micronutrients (Fe, Cu, Vit B1, B2 and Vit C) had mean intakes over the RDIs.

Conclusions: Re- planning the daily diets to contain more carbohydrates, calcium, zinc, iodine and iron according to RDIs. The suggested dietary sources are legumes, cereals, milk and dairy products, and intake the iodized salt.

Key words: Down's, anthropometry, anemia, diet intake

PO2626**EFFECTS OF FORTIFIED FLOUR CONSUMPTION ON SERUM FOLATE AND HOMOCYSTEINE IN CHILDBEARING-AGED WOMEN IN HIGH PREVALENCE REGIONS OF NEUROTUBE DEFECT**

H. Jian¹, S. Jing¹, H. Junsheng¹, L. Wenxian¹, C. chun-ming²

¹National Institute For Nutrition and Food Safety, Chinese CDC, China

²ILSI Focal Point in China

Background and objectives: To observe the effects of fortified flour consumption on serum folate and homocysteine levels in high prevalence regions of neurotube defect.

Methods: 218 childbearing aged women, aged from 18-39, were voluntarily selected as subjects from 13 townships in Lvliang cities, Shanxi province. Intervention group with 155 subjects had been supplied with fortified flour for 20 months while control group with 63 subjects consumed no fortified flour. Fasting venous blood samples were collected after the intervention and contents of serum folate and homocysteine were measured. According to the different consumption of fortified flour, intervention group was divided into three subgroups: group 1 (less than 200 g/d), group 2 (200-300 g/d) and group 3 (more than 300 g/d).

Results: The fortified flour consumption of group 1, 2 and 3 were 170.2 ± 29.3 g/d, 278.4 ± 25.0 g/d and 389.0 ± 54.2 g/d, respectively. Levels of serum folate and homocysteine were significantly different from intervention and control groups ($p < 0.05$). Serum folate levels in control group, intervention group 1, group 2 and 3 were 8.1 ± 2.1 ng/ml, 10.6 ± 3.6 ng/ml, 11.7 ± 3.3 ng/ml, 11.3 ± 3.5 ng/ml, and serum homocysteine levels were 21.77 ± 11.93 mol/l, 15.69 ± 9.87 mol/l, 12.21 ± 7.00 mol/l, 10.44 ± 4.28 mol/l. Prevalence of folate deficiency and high homocysteine in control group, intervention group 1, group 2 and 3 were 12.9% and 68.9%, 9.5% and 35.7%, 3.0% and 20.0%, 2.4% and 17.1%, respectively.

Conclusions: The study showed that folic acid fortified flour can significantly improve the folate status of childbearing aged women, and presented the consumption-effect relationship.

Key words: Fortified flour, serum folate, serum homocysteine, childbearing aged women, neurotube defect

PO2627**ENRICHMENT OF BOVINE MEAT BY ORGANIC SELENIUM**

A. Saadoun¹, F. Graziano¹, M.C. Cabrera^{1,2}

¹Facultad de Ciencias-Universidad de la Republica, Montevideo, Uruguay

²Facultad de Agronomía-Universidad de la República, Montevideo, Uruguay

Background and objectives: Meat is an important source of nutrients which improve and maintain health. On the other hand, selenium is a versatile mineral which acts as cofactor in physiological functions, for example as cofactor for enzyme glutathione peroxidase (GPx), a firewall against the oxidative stress caused by free radicals. Meat could be enriched in selenium by feeding the animals with an adequate source of selenium. In this sense, the use of selenium-enriched yeast could be an interesting way to improve its content in selenium. Furthermore, the selenium acts as a component which protects meat from lipids oxidation, which increase the lifetime and quality of the product to be consumed.

Methods: In the present investigation Aberdeen Angus steers (n=20; 24-26 months aged) were fed during 90 days a concentrate diet without added selenium (CG; 0.1 mg Se/kg dry matter) or supplemented (SG) with selenium-enriched yeast contained 0.3 mg selenium/kg dry matter. The content of selenium was determined in fresh meat by atomic absorption spectrophotometer (Analyst 300, Perkin Elmer) in Longissimus dorsi (LD) and Psoas major (PM) muscles. Also, lipids oxidation (TBARs) and the GPx activity were determined during the usual ageing of meat. This process consisted in the conservation of meat at 2°C in vacuum during a time between 14-60 days before consumption. In the present work the lipids oxidation and the activity of GPx were determined after 14, 21, 28 and 60 days of ageing.

Results: SG showed more selenium ($p<0.001$) incorporation than CG and a muscle main effect ($p<0.003$; $PM>LD$). Also, a reduced lipids oxidation was observed in SG ($p<0.05$) and showed a main muscles effect ($p<0.05$; $PM>LD$). GPx activity was similar in both muscles.

Conclusions: The enrichment of meat in selenium has been obtained and was accompanied by a reduction of lipids oxidation.

Key words: Meat, selenium, oxidation, GPx

PO2628

NUTRITIONAL POTENTIALITY OF THREE PARTS OF YAM (DIOSCOREA SPP.) TUBER DURING THE GROWTH PERIOD

D.C. Kouadio¹, N.G. Amani¹

¹Food Science and Technology, University of Abobo-Adjame, Abidjan, Côte d'Ivoire

Background and objectives: Yam (*Dioscorea* spp.) is a staple food for developing countries. It meets the assent of the population for its good taste and technological aptitude favorable for traditional feed. Yam tuber presents a longitudinal gradient of maturity in which the distal part is less firm than the median and proximal sections. Also the harvest period of the tuber, done after the leaves drying did not generally correspond to the high level of nutriment content. So, the aim of this investigation is to show the nutritional importance of yam tuber parts during the growth time.

Methods: Two varieties of *Dioscorea cayenensis*: kponan and kangba were cultivated in experiment farm of Abobo-adjamé University (Abidjan, Côte d'Ivoire). Tuber pieces about 754 g were planted in nursery gardener sachet (40 cm x 40 cm) filled up with forest soil then enriched with droppings and arranged (1 m x 0.5 m). Six tubers were harvested randomly at 16, 18, 20, 22, 24 and 26 weeks after planting date. Each tuber was measured and sectioned into three parts (proximal, middle

and distal). The batch of tuber part was transformed into flour. Crude protein content and simple sugars were determined respectively by kjeldhal and enzymatic (Kit Magazyme) methods.

Results: The crude protein of tuber sections varied weakly during the maturity period with a decreasing at 20 to 24 weeks after the planting date. Protein content of the distal (6.52 %) part was higher than the two over parts (4.91 %) ($p<0.05$). It decreased during the tuber maturity. Glucose, fructose and sucrose content decreased considerably during the tuber maturity. At maturity the median and distal parts contained high glucose and low fructose ($p<0.05$).

Conclusions: The nutritional compounds (glucose, fructose and sucrose) of yam tuber were appreciable at early stage of tuberization. The distal part contained appreciable amount of protein at maturity and must be considered as the two over parts.

Key words: Flour, tuber parts, growth period, yam.

PO2629

MICRONUTRIENT POWDER DISTRIBUTION TO YOUNG CHILDREN: SECONDARY ANALYSIS OF ANAEMIA DATA AND PROGRAMMATIC EXPERIENCE IN HIGH ANAEMIA BURDEN REFUGEE SETTING

M.M. Rahman¹, D. Gazarwa¹, N. Zari², C. Wilkinson³, S. de Pee⁴, P. Spiegel³, M. Tondeur³

¹Sub-Office of the United Nations High Commissioner for Refugees, Cox's Bazar, Bangladesh

²Action Contre la Faim, Cox's Bazar, Bangladesh

³Office of the United Nations High Commissioner for Refugees, Geneva, Switzerland

⁴Office of the World Food Programme, Rome, Italy

Background and objectives: Anaemia measured as a proxy for micronutrient malnutrition is a persistent public health problem in refugee populations. Blanket micronutrient powder (MNP) distribution to children 6-59 m was initiated in August 2008 in the two Rohingya refugee camps in Bangladesh managed by UNHCR. This secondary analysis aimed to assess trends in anaemia prevalence from 2008-2012 and to review the MNP programme experience.

Methods: Prevalence of total anaemia, anaemia categories and mean haemoglobin (Hb) from yearly, routine cross-sectional nutrition surveys were analysed in children 6-59 m and disaggregated by age (6-23, 24-59). Monthly coverage and consumption at the household level were reviewed. The MNP programme strengths and challenges were assessed.

Results: The combined camp anaemia prevalence results using $Hb<11$ g/dl and $Hb<10$ g/dl were 47.5% and 23.2% in Fe-

bruary 2008, 28.9% and 9.6% in May 2009, 50.2% and 11.3% in April-May 2010, 36.1% and 8.9% in May 2011, and 29.8% and 4.9% in May 2012, respectively in children 6-59 m. Anaemia levels were significantly higher among children 6-23 m compared to those 24-59 m in most years. Coverage was consistently high while consumption at the household level fluctuated and reached low levels at times. The main strength was the monitoring data collection process. The three most important challenges were: community acceptability of the product, supply issues, and a short-term switch of product from August 2009-January 2010 for children 6-35 m replacing MNP to a lipid-based nutrient supplement.

Conclusions: MNP distribution appears to be associated with a reduction in anaemia, especially in its more severe forms, in children 6-59 m. Additional efforts are needed to further reduce anaemia in children 6-23 m. These results need to be interpreted in consideration of the challenges encountered and the other anaemia reduction activities implemented between 2008-2012. MNP programme implementation is a demanding process for field staff.

Key words: Micronutrient powder, micronutrient malnutrition, anaemia

PO2630

PREVALENCE OF INADEQUATE INTAKE OF ANTIOXIDANT NUTRIENTS FOR PATIENTS UNDERGOING DIALYSIS TREATMENT AT A CLINIC IN FORTALEZA, BRAZIL.

A. Fernandes¹, C.F. Barroso¹, G.N. Arajo¹, C.S.C. Maia¹

¹State University of Ceará, Ceara, Brazil

Background and objectives: The oxidative stress can be associated with chronic renal patients on hemodialysis (HD) as a result of increased pro-oxidant activity and reduced antioxidant systems. Thus, the objective of this study was to analyze the prevalence of inadequate intake of antioxidant nutrients in patients undergoing dialysis treatment at a clinic in Fortaleza, Brazil.

Methods: The study was done with 36 patients on hemodialysis, aged 18 years and not suffering from other chronic diseases, all insured at a specialist clinic. All participants signed a consent form. For food intake assessment 24 hours recall method was used, being collected in two non-consecutive weekdays and one weekend day. We analyzed the nutrient selenium, zinc and vitamins A, C and E through NutWin program, version 2.5. The database software was fed with data from the National Database for Standard Reference Nutrient Department of Agriculture of the United States.

Results: Analysis of the data showed that the mean consumption of selenium was $77,24 \pm 31,22$ μ g and 16,66% of pa-

tients had intake below the EAR, the average zinc was $7,38 \pm 3,22$ mg, with 61,11% of inadequacy, vitamin A, on average $471,67 \pm 671,58$ μ g, with 80,55% of inadequacy, vitamin E, on average $4,6 \pm 2,14$ mg, 100% and average mismatch of vitamin C was $169,49 \pm 680,45$ mg, with 72,22% of inadequacy. The study of Sahni et. al. (2012), who analyzed the intake of zinc, vitamin A and C in patients with severe renal disease found intake of $5,42 \pm 1,74$ mg zinc, $190,31 \pm 63,69$ μ g of vitamin A and $17,9 \pm 10,6$ mg of vitamin C, below the results found in this study.

Conclusions: The data obtained show that the risk of inadequate consumption of antioxidant nutrients by these patients is high and that the diet should be implemented.

Key words: Intake, antioxidant nutrients, dialysis

PO2631

PREVALENCE OF VITAMIN A DEFICIENCY IN LATIN AMERICA AND THE CARIBBEAN: A SYSTEMATIC REVIEW UPDATE

G. Cediell¹, M. Olivares¹, A. Brito^{1,2}, H. Cori³, D. López de Romaña^{1,4}

¹Institute of Nutrition and Food Technology (INTA), University of Chile, Santiago, Chile

²USDA-ARS, Western Human Nutrition Research Center, Davis, California, USA

³DSM-Nutritional-Products, Santiago, Chile

⁴Micronutrient Initiative, Ottawa, Ontario, Canada

Background and objectives: A significant effort has been made in Latin America and the Caribbean (LAC) to control and prevent vitamin A deficiency (VAD). Therefore, updating the prevalence data available on VAD is necessary. Objective: To examine available data on the prevalence of VAD in LAC since 2000.

Methods: A systematic review was conducted using Pubmed, LILACS, SciELO and also WHO, Nutrinet and websites of Health Ministries. Studies that biochemically measured VA status were included. VAD was defined as serum VA <20 μ g/dl. The public health problem (PHP) magnitude was defined in accordance with IVACG/WHO criteria.

Results: Twelve countries with National Representative Survey (NRS) of VAD in preschoolers (<6y) were found. Guatemala (<1%) does not have PHP in VA, Costa Rica-(3%), Cuba-(4%), Guyana-(4%), Nicaragua-(9%), and Panama-(9%) have a mild-(≥ 2 -<10%) PHP; Honduras-(14%), Peru-(13%), Brazil-(16%) and Argentina-(14%) have a moderate-(≥ 10 -<20%) PHP; Colombia-(24%) and Haiti-(32%) have a severe PHP-(≥ 20 %). A NRS indicated 22% VAD in Mexican children aged <12y. Moreover, some countries showed moderate VAD in pregnant women, such as Peru-(10%), Brazil-(12%) and Nicaragua-(11%).

Conclusion: The available NRS suggests that the magnitude of VAD fluctuates from mild to moderate in preschoolers and pregnant women. Alarming figures were reported in Colombian and Haitian young children and in Mexican children and adolescents. Although this information indicates that VAD is still a PHP in some countries, no regional extrapolations to the entire LAC should be done due to lack of NRS in several countries. Funded by DSM Nutritional products.

PO2632

EFFECT OF SHIFT WORK ON THE FEEDING PRACTICES OF CHILDREN (0-24 MONTHS).

A. Kesinro¹, O B. Ogunba¹

¹Department of Family, Nutrition and Consumer Sciences, Faculty of Agriculture, O.A.U, Ile-Ife, Osun State, Nigeria

Background and objectives: For many women today, work is essential for the economic survival of their families while they also fulfill their role of providing optimum nutrition to their babies. This study examines the effect of shift work on the feeding practices for children aged 0-24 months.

Methods: Using stratified random sampling, 110 women, shift workers (nurses) and non-shift workers (artisans) were interviewed from Ile-Ife Central LGA, Osun State, Nigeria about breastfeeding and complementary feeding practices. Data was analyzed using descriptive and inferential analysis.

Results: Shift workers (69.1%) spent 8 hours at their workplace while non-shift workers (89.1%) spent 5-10 hours. 27.3% of the women started breastfeeding immediately after delivery while 30.9% started after 1-2 hours and only 10% (shift workers) of the women practiced exclusive breastfeeding. Non-shift workers (32.5%) and shift workers (50.9%) planned to terminate breastfeeding between 6-12 months and 13-18 months respectively. Complementary foods were introduced between 4-6 months for non-shift workers (36.4%) and shift workers (48.2%). Out of the 48.2% women that used infant formula, 34.5% used feeding bottles, 3.6% used cup and spoon and 10% used both for feeding. Home-made complementary foods were given by the mothers, non-shift workers (45.5%) and shift workers (58.2%).

Conclusions: The shift work of the mothers had no effect on the feeding practices of their children. Health workers, including doctors, nurses and nutritionists should emphasize the importance of breastfeeding and complementary feeding to mothers during antenatal and postnatal period.

Key words: Shift work, breastfeeding, complementary feeding

PO2634

ASSESSMENT OF MAXIMAL OXYGEN UPTAKE IN IRON-DEFICIENT RWANDAN WOMEN

S. Luna¹, L. Pompano¹, M. Lung'aho², J B. Gahutu³, J. Haas¹

¹Division of Nutritional Sciences, Cornell University, Ithaca, NY, USA

²CIAT, Kigali, Rwanda

³Faculty of Medicine, National University of Rwanda, Huye, Rwanda

Background and objectives: Iron-deficiency has been shown to impair physical performance beyond its effects on hemoglobin (Hb) and oxygen-carrying capacity (VO₂). As part of a larger study to analyze the efficacy of biofortified beans on improving iron status in iron-deficient Rwandan women, baseline blood and physical performance data were collected. The objective of the current analysis is to describe the relationship between iron status and physical performance of iron-depleted Rwandan women. We hypothesize that the women with the poorest iron status will have lower maximum oxygen uptake (VO₂max).

Methods: A sample of 158 female Rwandan university students (18-27yrs) provided venous blood samples and completed submaximal physical performance test on a cycle ergometer. Heart rate and VO₂ were measured by the breath-by-breath Cosmed K4B2 system. Iron status was assessed by plasma ferritin (Fer), transferrin receptor (TfR), and hemoglobin (Hb). VO₂max was predicted from extrapolation of VO₂ to predicted maximum HR (220 bpm-age) and compared with various classifications of iron status.

Results: 135 subjects were iron-depleted (Fer<20 µg/l) and 23 were iron-replete. For subjects who were iron depleted, 27% were anemic and 41% had TfR>8.3 mg/l. Predicted VO₂max was marginally lower in iron-depleted subjects compared to iron-replete subjects (31.4 ml O₂/kg/min and 33.7ml O₂/kg/min, respectively; p=0.10). Iron-depleted anemic subjects had lower VO₂max compared with iron-depleted non-anemic subjects (29.4 ml O₂/kg/min versus 32.2 ml O₂/kg/min; p=0.02). Tissue iron-deficient subjects (TfR>8.3 mg/l) had lower predicted VO₂max than subjects with TfR<8.3 mg/l though the difference was not significant (30.4 ml O₂/kg/min versus 32.2 ml O₂/kg/min; p=0.08).

Conclusions: For Rwandan university women, VO₂max was compromised by iron deficiency anemia and to a lesser degree by iron depletion without anemia.

Key words: Iron-deficiency, Rwanda, physical performance

PO2635**CALCIUM INTAKE AND BONE MINERAL DENSITY IN YOUNG MEN WITH DIFFERENT LEVELS OF PHYSICAL ACTIVITY**

J. Nyisztor¹, D. Carías¹, Y. Velazco²

¹Laboratorio de Nutrición, Universidad Simón Bolívar, Caracas, Venezuela

²Escuela de Nutrición, Universidad Central de Venezuela, Caracas-Venezuela

Background and objectives: Calcium is the most abundant mineral in the body. Being very important for skeletal structure and strength, most calcium (99%) is stored in the skeleton. Continuous low calcium intake weakens bones, makes them fragile, and can lead to osteoporosis. The aim of the present study was to evaluate the calcium nutritional state in young men with different physical activity levels, through calcium intake and mineral density estimation, in order to make recommendations that could reduce the risk of developing osteoporosis.

Methods: A cross-sectional study was designed with 80 men aged from 25 to 50 years and with different levels of physical activity. Bone mineral density (BMD) was estimated through DEXA densitometry (Dual Energy X-ray Absorptiometry). A semi-quantitative food frequency questionnaire was designed to assess calcium intake. Physical activity levels were evaluated through IPAQ (International Physical Activity Questionnaire).

Results: 84% of the participants reported appropriate calcium intake. Major calcium consumption was observed among individual with high physical activity levels. 24% of the participants reported BMD values below the expectancy to their age and gender. BMD was positively associated with calcium intake and negatively with age. No association was found between BMD and physical activity level.

Conclusions: Low values of bone density found in the population under study suggest that it may be important to evaluate risk factors associated with lifestyle, such as calcium intake and the physical activity.

Key words: Bone mineral density (BMD), calcium, men, physical activity, osteoporosis

PO2636**EARLY PEAK HEIGHT VELOCITY IS ASSOCIATED WITH CARDIOVASCULAR DISEASE MORTALITY IN A COHORT OF ICELANDIC WOMEN**

C M. Imai^{1,2}, I. Gunnarsdottir^{1,2}, V. Gudnason^{3,4}, T. Aspelund^{3,4}, B E. Birgisdottir^{1,2}, I. Thorsdottir^{1,2}, T I. Halldorsson^{1,2}

²Faculty of Food Science and Nutrition, School of Health Sciences, University of Iceland, Reykjavik, Iceland

³Icelandic Heart Association, Kopavogur, Iceland

⁴Faculty of Medicine, School of Health Sciences, University of Iceland, Reykjavik, Iceland

Background and objectives: Among girls, early puberty has been associated with increased risk of markers for cardiovascular disease. The aim of this study was to quantify the associations between timing of peak height velocity (PHV), derived from growth measures, and cardiovascular disease (CVD) mortality.

Methods: Prospective population based cohort study of 973 Icelandic women born 1921-1935. Childhood growth measures were collected in regular intervals from ages 8 to 13 and subjects were later recruited into the Icelandic Heart Association longitudinal Reykjavik study from 1968-1991. We used Cox proportional hazard model to estimated hazard ratios of cardiovascular disease mortality from recruitment until 31 December 2009.

Results: A total of 86 women died from CVD, of which 42 deaths were from coronary heart disease (CHD). Compared to girls with PHV after age 12, those with PHV identified prior to age 11 and between ages 11 to 12 years were at greater risk of overall CVD mortality (hazard ratio 1.93, 95% confidence interval 1.11 to 3.36) and (2.61, 1.56 to 4.39), respectively. Comparable associations were observed when restricting the analyses to CHD cases (2.47, 1.27 to 4.78) as well as non-CHD CVD cases (2.22, 1.17 to 4.20) when comparing girls with PHV after vs. prior to age 12. Timing of PHV was not associated with traditional CVD risk factors in mid-life including body mass index and adverse lipid profiles.

Conclusions: Earlier timing of PHV in girls may increase the lifetime risk of CVD mortality with slightly stronger associations with CHD mortality. Our results suggest that early height acceleration among girls may be an important determinant for later cardiovascular health.

Key words: cardiovascular diseases, coronary disease, epidemiology, mortality, risk factors

PO2637**OVERALL PLATE WASTE DETERMINATIONS AT PRIMARY SCHOOLS' CANTEENS: A COMPARISON OF TWO METHODS**

M. Liz Martins^{1,2}, L.M. Cunha^{2,3}, S.S.P. Rodrigues^{1,2}, A. Rocha^{1,2}

¹Faculty of Food Science and Nutrition, University of Porto, Portugal

²REQUIMTE, University of Porto, Portugal

³DGAOT, Faculty of Sciences, University of Porto, Portugal

Background and objectives: Schools have been concerned about nutritional, economic, environmental and social impact of plate waste. Physical measurements have been used to evaluate plate waste at schools, however the logistic disadvantages of this method leads to indirect alternatives such as the visual method. The present study aims to evaluate accuracy of visual estimation in comparison with weighing on food waste determination considering meals served at school canteens.

Methods: Plate waste at school lunch was collected for 484 individual servings distributed by 10 menus (mixed and non-mixed), using two different methodologies: weighing and visual estimation. Weighing of individual meals and leftovers was performed and plate waste was calculated by the ratio of food discarded to food served. At the same time, a six-point visual estimation scale developed by Comstock (1981) was used to determine plate waste. Scores on the Comstock scale were converted into weights of plate waste for all servings evaluated based on initial weights. Pearson correlations were computed between the plate weighing and visual determinations of meal waste for total food and for each menu.

Results: Mean plate waste was 50.0 g for weighing method and 59.2 g for visual estimation, and global correlation between them showed a strong association ($r=0.86$, $p<0.01$). Furthermore, when comparing those methodologies with different menus, correlation values ranged from 0.54 to 0.95, all significant at a 99% confidence level, being the mixed meals those with higher values. This indicates that visual estimation could be misleading for non-mixed meals since weaker associations between the two methods were found.

Conclusions: Weighing of food waste seems to be a more sensitive instrument for plate waste determinations. However, lower cost and greater convenience of visual estimation is a determinant for using this method, when plate waste evaluation of a greater number of meals is required.

Key words: Plate waste, school lunch, visual estimation, weighing

PO2638**PREDICTING POTENTIAL BENEFIT FROM IRON INTERVENTIONS: RESULTS OF A RANDOMIZED CONTROLLED TRIAL OF DOUBLE-FORTIFIED SALT IN FEMALE INDIAN TEA PLUCKERS**

J. Hammons¹, S. Venkatramanan², S. Mehta¹, J. Haas¹

¹Division of Nutritional Sciences, Cornell University, Ithaca, New York, USA

²Department of Dietetics and Human Nutrition, McGill University, Ste Anne de Bellevue, Quebec, Canada

Background and objectives: Iron deficiency (ID) primarily affects infants, children, and women of reproductive age. ID is the most common micronutrient deficiency in the world, and is especially prevalent in India. A randomized, double-blinded, placebo controlled trial was conducted in female tea pluckers on a tea estate in West Bengal, India to test the efficacy of double-fortified salt (DFS) as a vehicle of iron delivery. The present analyses examine predictors of response to the intervention.

Methods: Mixed models were used to assess the effect of DFS on the change in iron indicators (hemoglobin, serum ferritin, soluble transferrin receptor, total body iron) and other micronutrient indicators (urinary iodine, serum folate, serum vitamin B12). Predictors of ID resolution were identified using logistic regression models.

Results: Changes in ferritin and body iron were significantly ($p<0.05$) higher, whereas changes in transferrin receptor were significantly lower in the DFS group versus controls. Hemoglobin was only marginally increased by DFS, and DFS did not affect urinary iodine, serum folate, or serum vitamin B12. Resolution of ID and/or moderate ID was predicted by age, height, urinary iodine, and vitamin B12 status, in addition to baseline iron status (hemoglobin, transferrin receptor, and body iron) and treatment group.

Conclusions: DFS improves iron status in female Indian tea pluckers and does not affect the status of other micronutrients, including iodine, folate, and vitamin B12. The potential to benefit from an iron intervention with DFS (i.e. ID resolution and prevention) can be predicted by baseline iron status, as well as age and height. These results may help identify populations likely to respond to future efficacy and effectiveness trials of dietary iron interventions.

Key words: Iron deficiency, dietary intervention, India

PO2639

BODY FAT PERCENTAGE AND BODY MASS INDEX RELATIONSHIP IN A SAMPLE OF ADULTS FROM NITERÓI, RIO DE JANEIRO, BRAZIL

L. Dos Anjos¹, V. Wahrlich¹, L. Canto¹, M. Louzada Macedo¹, T. Miliante Teixeira¹

¹Laboratório de Avaliação Nutricional e Funcional, Departamento de Nutrição Social, Universidade Federal Fluminense, Niterio, Brazil

Background and objectives: Despite its universal use, body mass index (BMI) cut-offs to identify obesity or its risks for associated complications have been shown to be population specific in part due to the difference in its relationship to percentage body fat (%BF) across populations. Our aim was to examine the relationship between BMI and %BF in a sample of Brazilian adults from Niterói, Rio de Janeiro and to validate sex-specific %BF predictive equations based on the inverse of BMI (Inv_BMI) developed with data from a household survey in this population in 2003.

Methods: Body fat (dual-energy X-ray absorptiometry - Lunar iDXA, GE Health Care), body mass and stature were measured in a convenient sample of 674 adult (20.1-91.7 years) subjects (423 women) from Niterói with BMI > 18.5 kg/m². Published predicted %BF equations were: Males, 73.22-(1250.9*Inv_BMI) and Females, 73.72-(876.88*Inv_BMI).

Results: Mean (95% CI) BMI was 26.4 (25.9;27.0) and 28.5 (27.9;29.0) for males and females, respectively. Mean measured %BF was significantly higher than predicted %BF in men (27.9,27.0;28.8 and 24.8,23.8;25.7%) but not different in women (41.4,40.8;42.0 and 41.7,41.1;42.3%). The estimated %BF values for the BMI cut-off values of overweight and obesity (25 and 30 kg/m², respectively) for women (39 and 44) and men (26.8 and 32.8) were somewhat greater than what has been suggested for the American population but resembles, particularly in women, the values previously documented for the adult population of Niterói.

Conclusions: The obesity cut-off values of BMI currently suggested for international use may not be appropriate for the Brazilian population living in Niterói based on the BMI-%BF relationship. The published %BF predictive equations may be appropriate for women of Niterói.

Key words: Body composition, Brazil, BMI

PO2640

CONTRIBUTION TO IMPROVEMENT? POTENTIAL OF NON-TIMBER FOREST PRODUCTS EXTRACTION IN PERIPHERAL AREAS OF PERUVIAN AMAZON.

H. Kotková¹, V. Verner¹, V. Jelínková¹

¹Czech University of Life Sciences, Prague, Czech Republic

Background and objectives: Livelihood of indigenous and traditional communities in remote areas rely primarily on agriculture and non-timber forest products extraction which represents major sources of livelihood and income for some households. High rates of degradation and deforestation of tropical rainforest could threaten rural communities. The aim of the study is to identify collected non-timber forest products, economic potential, role of these products and diversity of collected NTFPs for two different ethnic groups – Shipibo-Conibo and “mestizo”.

Methods: This study presents collection, utilization and market potential of non-timber forest products (NTFPs) used by rural populations from the Peruvian Amazon. Data were collected during September - October 2011 through interviews, semi-structured questionnaires and direct observation. Significance of used NTFPs were determined by cultural and economic values. The inventorial study was conducted with 40 randomly selected ethnic households in three villages of the Abujao river basin.

Results: During the survey, 57 plant-based and 20 animal-based NTFPs were identified. Results show that the Shipibo-Conibo collect higher number of NTFPs, in comparison to the “mestizo” households. Shipibo-Conibo harvests NTFPs particularly for subsistence (64.18%). In contrast, “mestizo” households use 73.77% for auto-consumption. The calculation of cultural and economic values showed higher cultural importance of NTFPs for the Shipibo-Conibo (62.69%) while for “mestizo” households NTFPs are important from the economic point of view (59.02%).

Conclusions: NTFPs gathering represent a daily activity for most households; however, a commercial participation is unachievable for most of them. During the survey it was found out that communities in remote areas have limited access to markets however improvement and availability is desired for most of rural people.

Key words: Commercial potential, cultural value, economic value, Shipibo-Conibo

PO2641**REFERENCES FOR WAIST CIRCUMFERENCE FOR PORTUGUESE ADOLESCENTS**

B. Sousa^{1,2}, B. Mendes de Oliveira¹, M D V. de Almeida¹

¹Faculty of Nutrition and Food Sciences of University of Porto, Porto, Portugal

²Health Service of Autonomous Region of Madeira, Madeira, Portugal

Background and objectives: Waist circumference (WC) is an important parameter to evaluate health conditions and it is essential in the prognostic of the risk of disease not only for adults but also for youngsters. Until 2011 no WC references for the Portuguese adolescents had been developed which constituted a limitation for health assessment. The aim of this study was to analyse and compare the recently developed WC references for age and gender in Portuguese adolescents population in the three main regions: mainland Portugal, Autonomous regions of Madeira (RAM) and of Azores (RAA).

Methods: The references for the Autonomous Region of Madeira (10 to 18 year-old) (Sousa et al, 2011), the references for mainland Portugal (10 to 18 year-old) (Sardinha et al, 2011) and the references for the Autonomous Region of Azores (15 to 18 year-old) (Santos et al, 2011) were compared to identify possible differences between the smoothed percentile curves (P5, P50, P90 and P95) by age and gender.

Results: The references of RAM are similar to those of mainland Portugal but the RAA have much higher values. The differences can sometimes exceed 10 cm, which may lead to different diagnoses, depending on the anthropometric reference which is used. These disparities may be related to the increasing number of overweight subjects in RAA or due to this islander population characteristics as a result of the interactions between genetic and environmental factors.

Conclusions: These WC references constitute a new tool to assess the health and nutritional status of Portuguese adolescents as well as their cardiometabolic risk. However each reference should be used on its own population, namely in the case of the RAA references.

Key words: Waist circumference, references, adolescents

PO2642**INTER-METHOD AGREEMENT OF TWO DIFFERENT ASSESSMENT TOOLS FOR CALCIUM INTAKE REGISTRATION IN ADOLESCENT SWIMMERS**

C. Julián-Almárcegui¹, A. González-Agüero^{1,2}, A. Gómez-Bruton^{1,3}, A. Gómez-Cabello^{1,3}, A. Matute-Llorente^{1,3}, J.A. Casajús^{1,3}, G. Vicente-Rodríguez^{1,3}

¹GENUD (Growth, Exercise, Nutrition and Development) Research Group, Zaragoza, Spain

²Department of Sport and Exercise Science, Aberystwyth University, Aberystwyth, UK

³Department of Physiatry and Nursing, Universidad de Zaragoza, Zaragoza, Spain

Background and objectives: Food frequency questionnaire and 24-hour recall are some of the frequent used methods to register calcium (Ca) intake. The aim of this study was to assess the agreement of two different assessment tools, a 24-hour recall [the Helena-DIAT (Dietary Assessment Tool)] and a self-designed calcium frequency questionnaire (CaFQ), which included the main Ca rich foods.

Methods: Ca intake was evaluated in a total of 22 swimmers (11 females; 14.68 ± 1.73 y). Mean difference, random error and heteroscedasticity were assessed to study the inter-method reliability. For Ca intake estimation, the agreement between the Helena-DIAT and CaFQ was graphically examined by plotting the difference (Helena-DIAT minus CaFQ) against the mean according to the method suggested by Bland and Altman (Bland & Altman, 1986). Difference between Ca intake estimations with Helena-DIAT and CaFQ was analysed with Student's t test. Random error was established as the limits of agreement for the tests, computed as mean difference ± 1.96 standard deviations (of the inter-methods differences). The presence of heteroscedasticity was studied by linear regression analysis.

Results: No significant inter-method difference was found between Helena-DIAT and CaFQ (870.41 ± 355.02 vs. 1009.70 ± 502.29; p=0.3) showing a mean difference of 139.3 mg. The random error was 1025.3 mg. Heteroscedasticity was not detected within the graph (p=0.129) suggesting that relationship between both tools do not change independently of the magnitude of Ca measured.

Conclusions: Although neither significant difference between means nor heteroscedasticity was detected within the plot, the random error resulted high, suggesting that differences between methods present a high variation depending on individual bases. In the case of Ca intake estimation, small changes in food portion reported may be translated in huge differences in Ca calculation. References 1- Bland JM, Altman DG. (1986). *Lancet*, 1, 307-310.

Key words: Registration, calcium intake, assessment

PO2643**DAILY INTAKE OF VITAMIN D AND ITS INFLUENCE ON BONE MASS IN ADOLESCENT SWIMMERS. PRELIMINARY RESULTS**

C. Julián-Almárcegui¹, A. Gómez-Cabello^{1,2}, A. González-Agüero^{1,3}, A. Gómez-Bruton^{1,2}, A. Matute-Llorente^{1,2}, J.A. Casajús^{1,2}, G. Vicente-Rodríguez^{1,2}

¹GENUD (Growth, Exercise, Nutrition and Development) Research Group, Universidad de Zaragoza, Zaragoza, Spain

²Department of Physiatry and Nursing, University of Zaragoza, Zaragoza, Spain

³Department of Sport and Exercise Science, Aberystwyth University, Aberystwyth, UK

Background and objectives: Swimming is a non-osteogenic sport that could not be beneficial for bone acquisition in childhood and adolescence (1). Vitamin D (VitD) insufficiency may have long-term skeletal consequences as VitD affects calcium absorption, bone mineralization and bone mass attainment (2). Therefore, we aimed to describe the VitD intake of a group adolescent swimmers and study its influence on bone mass.

Methods: 22 adolescent swimmers (11 females; 14.68 ± 1.73 y) were evaluated by the Helena-DIAT (Dietary Assessment Tool) to register their daily VitD intake. Dual energy X-ray absorptiometry (DXA) was used to evaluate bone mineral content (BMC) and density (BMD) at subtotal (whole body less head), trochanter, interthrocanter, femoral neck, Wards triangle, total hip and lumbar spine sites. Relationships between VitD intake and bone-related variables were examined by partial correlation analyses after controlling for age, height and subtotal lean mass.

Results: None of the adolescent swimmers reached the daily VitD recommendations (15 µg). The total daily average VitD intake was 2.43 ± 2.36 µg. No significant correlations were found between VitD intake and bone-related variables.

Conclusions: Swimmers did not meet VitD intake recommendations. No correlation have been found between VitD and bone related variables in this specific group. It may be due to the fact that adolescent swimmers did not reach the VitD daily intake. Thus, other factors such as genetic, hormonal balance and other environmental factors like physical activity and daily sun exposure could have an important role on bone acquisition. Further studies should be focused on consequences of a poor VitD intake in performance and health of adolescent swimmers and the design of interventions to achieve dietary guidelines. References 1-Scofield KL et al. (2012). *Curr Sports Med Rep*, 11, 328-342-Pekkinen M et al. (2012)*Plos One*, 7.

PO2647**ASSESSMENT OF BONE BUILDING MINERALS AMONG STUNTED AND NORMAL CHILDREN**

G. Hassan¹, G. Saleh¹, H. Abd sallam¹, H. Fadel¹, A. Abbas¹

¹National Nutrition Institute, El Cairo, Egypt

Background and objectives: Linear growth in children is regulated by complex interaction between an individual's genetic potential, environmental influences and nutrition. The aim of this study was to access the bone building minerals in stunted and normal children.

Methods: The present study is a case control study including one hundred children with delayed linear growth aged 6-12 years old and one hundred age matched children with normal growth randomly assigned. These groups were subjected to medical history, anthropometric measurements and dietary intakes using 24 hours recall method. Laboratory assessment was done for a sub-sample of 50 cases and their control which include serum calcium, phosphorus, magnesium and alkaline phosphatase.

Results: The dietary results showed highly statistical significant differences for energy, protein, calcium and magnesium adequacy between both groups, where their intakes were higher among the normal children. The mean ± standard deviation of serum calcium, phosphorus, magnesium of stunted group were 7.5 ± 1.5 units, 5.6 ± 0.8 units and 2.2 ± 0.2 units respectively compared to 8.7 ± 1.3 units, 5.5 ± 1.1 units and 2.4 ± SD value lacking for the control group respectively with statistical significant difference.

Conclusions: It was concluded that bone building requires adequate intake of protein and micronutrients such as calcium, phosphorus and magnesium since early life to develop normally and to maintain itself after growth.

Key words: Linear growth, bone building mineral, stunted children, 24h recall method

PO2648**EVALUATION OF SOCIODEMOGRAPHIC FACTORS AFFECTING FREQUENCY OF VISITING MATERNAL AND CHILD HEALTH SERVICES AT A WEST AFRICAN CAPITAL (LIBREVILLE) .**

G. Hassan¹, G. Saleh¹, S. Hamoda¹, A. Mareey¹

¹National Nutrition Institute, El Cairo, Egypt

Background and objectives: Access to comprehensive, quality health care services is important for the achievement of health equity and for increasing the quality of a healthy life for everyone (Rose et al 2006).

Methods: The Maternal and Child Health Services (MCHC) of Awendje has received 1417 infants. The group (A) was formed of infants having 9 visits or more (257 infants), the group (B) having less than 4 visits (109 infants). The rest of the cases form group (C) (1056 infants) having a number of visits ranging from 4-9 visits. The study had two components: (i) Comparison of anthropometric measurements of weight and length of enrolled infants by frequency of utilization of maternal and child healthcare services, and (ii) Comparison of demographic factors that promote and prevent the use of the health care services provided by MCHC.

Results: Group A: All infants had weight per age (weight per age z-score \pm 2 SD). The follow up of the group (A) show that 239 infants (93%) have normal linear growth for age the resting, 14 infants Group (B) where the majority 99 infants (91%) had a retarded growth. Only 10 infants (9%) of group (B) has normal linear growth for age. With significant statically difference ($p=0.00$).

Conclusions: The sociodemographic factors have an important impact on the health of the studied infants.

Key words: Anthropometric measurements, demographic factors, MCHC, linear growth

PO2649

QUANTIFICATION OF VITAMIN E IN DEHYDRATED BEE POLLEN OF SOUTHERN BRAZIL

J. Gasparotto Sattler¹, E. Araújo¹, B. Rodrigues Souza¹, M. Braga¹, L. Bicudo de Almeida-Muradian¹

¹Department of Food and Experimental Nutrition, Pharmaceutical Science School, University of São Paulo, Sao Paulo, Brazil

Background and objectives: Bee pollen has become another option for nutritional supplementation in food. From the 90s, studies were initiated for the analysis and verification of therapeutic potential of pollen, with the primary difference being a source of proteins, lipids, minerals and vitamins. Among the vitamins, α -tocopherol (vitamin E) highlights, having the ability to stabilize free radicals responsible for many degenerative diseases characteristic of the aging, which can be either from the outside environment or as a result of natural human metabolism. The southern region of Brazil has a subtropical climate unlike the rest of the country and has different botanical origins not found in other regions. The aim of this study was to obtain analytical data on vitamin E in dried bee pollen from southern Brazil, in order to obtain new information about this product, since the literature data are scarce and mostly from other countries.

Methods: We analyzed 21 samples of dried bee pollen collected in apiaries located in the southern Brazil. The technique used for the analysis of vitamin E was high performance liquid

chromatography (HPLC) as described by Presoto, Rivers and Almeida -Muradian (2000) and Melo (2010).

Results and conclusions: Of the 21 samples analyzed the values of vitamin E ranged from 0.15 to 42.66 $\mu\text{g/g}$ of dehydrated bee pollen. According to the IDR (2000), the recommended daily intake is 15000 $\mu\text{g/day}$ of vitamin E for adults, so the samples were not a source of vitamin E in the range of 25 g a day under the rules of DRI (2000), but other work that includes new botanical sources should be performed to verify the presence of this vitamin in larger quantities.

Key words: Vitamin E, bee pollen, food supplement

PO2650

CLINICAL CASE: SYNDROME WITH MAXILLARY CENTRAL INCISOR UNIQUE MEDIUM WITH LOW WEIGHT AND FEEDING DIFFICULTIES

R. Lladó Padovani¹, L. Lozano Barrón¹, J. Muñoz Rueda¹

¹Child Nutrition Unit, Department of Pediatrics, QUIRON Palma Planas Hospital, Palma de Mallorca, Balearic Islands, Spain

Background and objectives: The medial maxillary central incisor is a complex syndrome consisting of multiple development disorders, primary of the middle line. They are a result of unknown factors and uncertain ethiology. Frequently it is followed by a gross anomaly, holoprosencephaly, as well as: cardiac pathology, lip fissure, hypopituitarism, growth hormone deficiency, hypothyroidism, small penis, slow development and short stature. Assessment and treatment are pillars to ensure nutritional needs for a proper growth. Therefore to be excluded as a risk factor for the failure to thrive.

Methods: A good medical history, nutritional assessment, energy intake evaluation and frequency, nutritional habits, activity and sleep pattern before and after intervention. A nutritional plan was established to cover energetic needs, with a proper macronutrients balance, as well as nutritional supplements to cover energy and micronutrients load. Nutritional education was offered, habits around the table were explained, the child was involved at cooking, and tips were given to introduce solids.

Results: A 8,8% weight gain increase was noticed since the beginning of treatment (eight weeks) comparing to previous periods of time. Better distribution of nutrients was obtained, 50% energy intake increase and a good progress regarding normal feeding habits, gradually accepting more consistent food, solids and a distraction free environment.

Conclusions: Nutritional status assessment, nutrients energy intake study and nutritional education throughout a family context is compulsory to ensure nutritional needs and to exclude it as a risk factor in failure to thrive syndromes.

Key words: Medial maxillary, syndrome, nutritional intervention

PO2651**VITAMIN D INSUFFICIENCY IN RURAL WOMEN LIVING NEAR THE EQUATOR IN SOUTHERN ETHIOPIA***T.G. Egziabher^{1,2}, B. Stoecker¹*¹School of Nutrition, Food Science & Technology, Hawassa University, Hawassa, Ethiopia²Nutritional Sciences, Oklahoma State University, Stillwater, Oklahoma, USA

Background and objectives: Although the photosynthesis and bioavailability of vitamin D are influenced by various factors, vitamin D is produced in the skin by ultraviolet B (UVB) radiation from sunlight. However vitamin D deficiency is being recognized as a common problem even in areas with abundant sunshine. This study assessed serum 25(OH)D concentrations of rural women in southern Ethiopia living in the Rift Valley at 70° 3' N latitude.

Methods: Non-pregnant women (n=202) living in three adjacent rural communities volunteered to participate in this cross-sectional study. Demographic, socioeconomic, health, and food frequency data were acquired by questionnaire. Anthropometric measurements and a fasting venipuncture blood sample were obtained by qualified professionals. Body mass index (BMI) was calculated. ELISA kits from Immuno-Diagnostic Systems were used to determine concentrations of 25(OH) vitamin D with external quality control standards from UTAK Laboratories.

Results: The self-reported mean \pm SD age was 30.8 ± 7.8 years. The mean number of pregnancies was 4.7 ± 2.7 , household size was 6.0 ± 2.6 and BMI was 20.0 ± 2.2 . None of the participants reported ever consuming vitamin D rich foods, fortified foods or dietary supplements. Of the participants 96.7% had 25(OH)D below 75 nmol/l and 76.9% were below 50 nmol/l. All reported substantive sunlight exposure.

Conclusions: Vitamin D insufficiency is a serious problem in the study population, and living near the equator does not assure adequate vitamin D status.

Key words: 25(OH)D, vitamin D status, sunshine, Ethiopia

PO2652**VALIDITY OF INSTRUCTION LEAFLETS FOR PARENTS TO MEASURE THEIR CHILD'S WEIGHT AND HEIGHT AT HOME***I. Huybrechts^{1,2}, C. Beirlaen⁴, E. Schoupe⁴, T. de Vriendt^{1,3}, N. Slimani², P. Pisa², A. de Coene⁵, D. de Bacquer¹, S. de Henauw^{1,6}, J. H. Himes⁷*¹Department of Public Health, Faculty of Medicine and Health Sciences, Ghent University, Ghent, Belgium²Dietary Exposure Assessment Group, International Agency for Research on Cancer (IARC/WHO), Lyon, France³Research Foundation Flanders, Brussels, Belgium⁴KaHo Sint-Lieven, Gebroeders Desmetstraat 1, Gent, Belgium⁵Centre for Pupils Counselling (CLB), Flemish Community Education, Ghent, Belgium⁶Department of Nutrition and dietetics, University College Ghent, Ghent, Belgium⁷Division of Epidemiology and Community Health University of Minnesota School of Public Health, Minneapolis, USA

Background and objectives: Previous research has raised concerns about the validity of parental weight and height reports. Therefore, the authors developed instruction leaflets to instruct the parents how to measure their child's weight and height at home. The aim of this study was to compare the validity of parent-reported height, weight and BMI values of children (4-10 y-old), when measured at home by means of the instruction leaflets in comparison with simple estimated parental reports.

Methods: The subjects were 164 Belgian children (53% male; participation rate 62%). Parents completed a questionnaire including questions about the height and weight of their child. Parents included in the intervention group received instruction leaflets to measure their child's weight and height at home. Classes were randomly allocated to the intervention and control groups. Nurses measured height and weight following standardised procedures. International age- and sex-specific BMI cut-offs were employed to determine BMI categories.

Results: On the group level, small differences in accuracy of reported weight and BMI were identified between parent-reported values, with higher mean differences for the intervention compared to the control group. However, for all 3 parameters, the correlations between parental reports and nurse measurements were higher in the intervention group. Sensitivity for underweight and overweight/obesity were respectively 75% and 60% in the intervention group, and 67% and 43% in the control group. Weighted kappa for classifying children in

the correct BMI category was 0.30 in the control group while 0.51 in the intervention group.

Conclusions: Diagnostic measures were more accurate when parents measured their child's weight and height at home using the instruction leaflets than parental reports without instructions. Therefore, the accuracy of parent-reported weight and height could be improved by encouraging the parents to measure weight and height of their children at home by means of instruction leaflets.

Key words: Instruction folder, BMI, validity, children, parent reports.

(E)-TRAINING: A VITAL COMPONENT IN THE STANDARDIZATION OF INTERNATIONAL NUTRITION STUDIES

I. Huybrechts¹, G. Nicolas¹, S. Crispim¹, M. Niekerk², H. Freisling¹, V. Knaze¹, C. Casagrande¹, N. Slimani¹

¹International Agency for Research on Cancer, Dietary Exposure Assessment Group, International Agency for Research on Cancer (IARC/WHO), Lyon, France

²The National Institute for Public Health and the Environment (RIVM), Bilthoven, The Netherlands

Background and objectives: Although the EPIC-Soft® 24-h dietary recall (24-HDR) programme, used as reference methodology in EPIC and recommended for pan-European dietary surveys, maximizes a structured and standardized recall approach, trained/experienced interviewers are needed to ensure good quality of open-ended interviews. The purpose of this presentation is to report on the experiences of training the trainers for conducting standardized repeated EPIC-Soft 24-HDRs and to notify the importance of e-training tools to facilitate/support such trainings.

Methods: Staff members (in charge of the local EPIC-soft training) of different countries (Bulgaria, Finland, Hungary, Poland and Portugal, Switzerland, Belgium and France) attended the 3-day train-the-trainers course at IARC and/or via an e-training approach using the GoToWebinar system.

Results: Although three training days were the minimum requirement to train-the-trainers who need to organize their local EPIC-soft training in a standardized way, suggestions were made to decrease cost and burden for attendees and course organizers. The e-training system was evaluated positively by all attendees and recommended for future train-the-trainer courses. Via the e-training, attendees were able to access and follow the presentations and make exercises at their own convenience and place. Results obtained via evaluation questionnaires concerning both, the train-the-trainers course at IARC and its e-training approach, will be presented.

Conclusions: The EPIC-soft train-the-trainers course underlined the importance of the e-learning module for future pan-European dietary surveys. More details on limitations and opportunities of the e-training module experienced during the train-the-trainer course will be presented during the presentation.

Key words: Training, dietary assessment, EPIC-Soft

PO2654

NUTRITIONAL ASSESSMENT OF CHILDREN AND TEENAGERS WITH OVERWEIGHT AND/OR OBESITY TO METABOLIC SYNDROME PREDISPOSITION

C. Freiberg¹, D. Nascimento¹

¹Universidade Guarulhos, São Paulo, Brasil

Background and objectives: The prevalence of metabolic syndrome is increasing worldwide, and has followed the global trend to obesity. It is essential to identify and control all the factors that make up metabolic syndrome both in adolescents and in children for the prevention of cardiovascular disease in adulthood. The aim of the study was to assess the nutritional status of children and adolescents who are overweight and/or obese and their predisposition to metabolic syndrome.

Methods: We evaluated 100 patients, age 5 to 18 years, of both genders, in routine clinical care and that were diagnosed with overweight (BMI p 85-95) or obese (BMI p 95) second WHO/2007. We carried out anthropometric measurements, biochemical tests and questionnaires with the mothers.

Results: The study showed that 87% had family history of disease related to nutritional status like hypercholesterolemia, diabetes mellitus and overweight/obesity; 42% started the overweight/obesity under the age of 5 years; 72% don't make any treatment for weight control; 32% eat their meals everyday in front of TV/computer, of these, 45% for more than 4 hours daily; 69% do not do any kind of physical activity outside of school; 57% of the population has no control food intake, consuming them anytime even without being hungry, and 38% eats until feeling sick; 11% have a habit of vomiting inducing after meals showing signs of eating disorders; 39% have high daily consumption of sweets; 74% have cholesterol levels increased considering that this is a population of minors and that many factors are present characteristic of the metabolic syndrome.

Conclusions: To improve the health and nutritional status of children and adolescents is necessary to develop strategies and activities that promote nutrition education, good eating habits and encourage regular physical activity. These actions contribute to the reduction of risk factors for metabolic syndrome.

Key words: Metabolic syndrome

PO2655**THE EFFECT OF TEA CONSUMPTION ON NONHEME IRON ABSORPTION FROM A COMPLETE DIET***M. Reddy¹, J. Cook³, A. Seth²*¹Iowa State University, Iowa, USA²University of Kansas Medical Center, Kansas, USA

Background and objectives: This study was conducted to investigate the effect of tea or coffee consumption on absorption of nonheme iron from a complete diet.

Methods: Four different iron absorption tests were performed in 13 healthy adults (4 males and 9 females) of 19-36y age. Each subject was fed a standard hamburger meal and 3 test diets and nonheme iron absorption was measured using sequential dual radiolabelling method. The 3 tests diets were a typical/usual diet, a diet without tea or coffee, and a diet with maximal intake of tea or coffee and consumed for a 5-day period.

Results: Mean intakes of nonheme iron for the 3 dietary periods were 13.0, 10.8 and 9.7 mg for typical, high tea and no tea diets, respectively. For the high tea period average daily tea consumption was equivalent to 692 mg polyphenols compared to 78 mg with the typical diet. ANOVA showed a significant difference in nonheme iron absorption among the 3 different dietary periods ($p < 0.02$). Mean absorption values were very similar for the typical and high tea/coffee diet (2.99 and 3.37%), but significantly higher for the no tea diet (6.13%).

Conclusions: The results suggest that small amount of tea consumption that was observed in a typical diet can reduce nonheme iron absorption significantly from a complete diet.

Key words: nonheme, absorption, tea, complete diet

PO2656**CUTOFF POINTS FOR THIGH CIRCUMFERENCE TO IDENTIFY OBESITY IN ADOLESCENTS***R L. Ferretti¹, I P. Cintra¹, M A Z. Passos¹, M. Fisberg¹*¹Department of Pediatrics, Federal University of São Paulo, São Paulo, Brazil

Background and objectives: Excess fat in the central region is associated with the development of various diseases. The aim of this study was to determine the sensitivity and specificity of cutoff points Thigh Circumference (TC) that identify obesity in adolescents.

Methods: Cross-sectional study that assessed adolescents from 10 to 17 years. Trained researchers took all anthropometric measurements, weight and height to calculate BMI, and TC. The study considered obese adolescents ranked above +2 z-score of BMI according to the World Health Organi-

zation, 2007. To compare the variables between the sexes the Mann-Whitney test was used. For comparative analysis of the circumference with age, the Kruskal-Wallis test was used. Significance was set at $p < 0.001$. The cutoff points for TC were determined by the Receiver Operating Characteristic curves.

Results: A total of 1668 adolescents, 45.08% male. Obesity was present in 7.56% of girls and 10.51% boys. The mean values of TC (cm) were 48.32 for females and 46.14 for males ($p < 0.001$). The cutoff points of TC identifying obesity in girls was 52.25 with Area Under the Curve (AUC) of 0.825. For boys, the best cutoff point was 50.75, AUC of 0.833. The cutoff points of TC according to age for males and females were 10-12 years (46.95 and 45.30), 13-15 years (55.85 and 50.85), ≥ 16 years (57.95 and 55.9). It turned out better sensitivity and specificity with girls and boys aged 13-15 years, AUC (0.895 and 0.961) respectively. The comparative analysis of CT according to age showed that in both sexes there were significant differences between different age groups ($p < 0.001$).

Conclusions: TC is a great and simple screening tool for identification obesity in adolescents.

Key words: Thigh circumference, obesity, body fat, teens

PO2657**NUTRITIONAL ASSESSMENT AND COUNSELING IN THE OLDER ADULT TO IMPROVE FOOD HABITS AND GENERATE CHANGES IN THE STYLE OF LIFE***F. Chileno Maita¹*¹Internal of Nutrition and Dietetics In The Metropolitan Municipality of Lima University Female Sacred Heart – UNIFE, Lima, Perú

Introduction: In the process of aging, nutrition modulates the functions of the different bodies, therefore, the aging of the population would be a relevant topic for Peru, from the perspective of the nutrition and public health. In Peru the last census, 2007, the adult population (65 years of age and over), in percentage terms has a significant presence in 19 districts in percentages vary between 7.3 % and 17.2 % of the total population. From these data, it can be inferred, that the number of older adults has increased by 50 % since the previous census for the year 1993.

Currently, in our country, there are some studies in health and nutrition in institutionalized older adults, however, there is a lack of studies in the elderly free-living, according to figures available statistics, would represent approximately 90 % of the total elderly. The present investigation poses, such as purpose to characterize a group of people over 60 years of free-living through an anthropometric and dietary evaluation for the modification of the intake

The objective is to measure the needs of energy intake in function of the gender from the age of 60. Methodology: For the nutritional assessment will be used dietary and anthropometric indicators. The methods of assessment of dietary intake at the individual level, are surveys or interviews or dietary food. Prospective: Food Record. Retrospective: 24-hour recall, memory of three days, frequency of consumption of food, dietary history.

Research allows us to conclude that the older adults can modify eating habits, and thus generate a change in your lifestyle to be able to raise both primary prevention, understood as the identification of risk factors in healthy subjects, such as secondary that refers to an early detection of those signs that show the existence of a disease adjacent.

Key Words: elderly, nutritional status, dietary habits, lifestyles.

SELENIUM NUTRITIONAL STATUS IN PATIENTS UNDERGOING DIALYSIS TREATMENT AT A CLINIC IN CEARÁ, BRAZIL

C F. Barroso¹, G N. Araújo¹, S M H A. Araújo¹, C M C. Oliveira¹, L B. Santos³, G. Simeone², S M F. Cozzolino³, M I F. Guedes¹, L V. Pires³, P P. Pessoa¹, C S C. Maia¹

¹State University of Ceara, Ceara, Brazil

²Federal University of Minas Gerais, Belo Horizonte-Brazil

³University of São Paulo, Sao Paulo, Brazil

Background and objectives: The oxidative stress can be associated with chronic renal patients on hemodialysis (HD) as a result of increased prooxidant activity and reduced antioxidant systems. Selenium is an important antioxidant micronutrient. GPx is the main selenoenzyme. Thus, the goal of this study was to analyze nutritional status of selenium in patients undergoing dialysis treatment at a clinic in Ceará, Brazil. Ceará has a selenium soil.

Methods: The study was done with 47 patients on hemodialysis, aged 18 years and not suffering from other chronic diseases, all insured at a specialist clinic. All participants signed a consent form. The dosages of selenium plasmatic were performed by ICP-OES. GPx activity was measured according to Paglia & Valentine (1979).

Results: Selenium plasmatic was $57,32 \pm 5,72 \mu\text{g/l}$ in patients and $72,08 \pm 10,40 \mu\text{g/l}$ in control group ($p < 0,0001$). GPx activity was $42,75 \pm 17,35 \text{ U/g Hb}$ in patients and $43,83 \pm 15,53 \text{ U/g Hb}$ in control group.

Conclusions: The patients are selenium deficient but have normal enzymatic activity.

Key words: Selenium, nutritional status, dialysis, Brazil

PO3367

YEAST SACCHAROMYCES CEREVISIAE AS A SOURCE OF ZINC AND MAGNESIUM AND POTENTIAL SUPPLEMENT IN NUTRITION

D. Urminská¹, S. Illerová¹, T. Bojðanská¹, P. Chlebo¹

¹Slovak University of Agriculture, Nitra, Slovak Republic

Background and objectives: The yeast *Saccharomyces cerevisiae* is the best known microorganism widely used in many branches of industry. It is known as biosorbents, too. Living organisms have always dealt with metals which are very important for enzymatic activities or for proteins structure.

Methods: Experiments were carried out with the yeast *Saccharomyces cerevisiae* Meyen ex E.C. Hansen. The yeast was grown on YPD medium with $\text{Zn}(\text{NO}_3)_2$, ZnSO_4 or ZnCl_2 in final concentrations from 25 to 300 mg per 100 mL of medium; or $\text{Mg}(\text{NO}_3)_2$, MgSO_4 or MgCl_2 in concentrations from 2 to 16 g per 100 mL of medium. After 48 hours cultivation at 30 °C was biomass lyophilized. Zinc and magnesium contents in yeast biomass was analysed by atomic absorption spectrophotometer method.

Results: The highest dose of yeast cells (1.19 g from 100 mL of medium) was obtained by cultivation at 25 mg/100 mL of ZnCl_2 . The highest amount of zinc in yeast cells (18,5 mg/g of dry biomass) was achieved with $\text{Zn}(\text{NO}_3)_2$ cultivation in concentration of 200 mg/100 mL YPD medium. The cells of yeast *Saccharomyces cerevisiae* are capable of accumulation of magnesium and can grow in high concentrations of magnesium, up to 16000 mg of MgSO_4 in 100 mL of medium. The highest amount of magnesium bound in the yeast cells was 6000 mg/kg when added in the form of $\text{Mg}(\text{NO}_3)_2$.

Conclusions: Biosorption is a cost-effective biotechnology. This ability of *Saccharomyces cerevisiae*, industry brewer's yeast, is potential way for food-supplements preparations including high quality proteins, B-vitamins, amino acids and various elements, i.e. Zn and Mg. Acknowledgements: The paper was supported by project: Development of International Cooperation for the Purpose of the Transfer and Implementation of Research and Development in Educational Programs conducted by the Operational program: Education, ITMS code: 26110230085.

Key words: Micronutrients, *Saccharomyces cerevisiae*.

PO3368

BREASTMILK B-VITAMINS CONCENTRATIONS IN HIV-INFECTED MALAWIAN WOMEN ARE INCREASED BY LIPID-BASED NUTRIENT SUPPLEMENTS AND REDUCED BY ANTIRETROVIRAL PROPHYLAXIS

S. Shahab-Ferdows¹, D. Hampel¹, E. York¹, M. Bently², L. Adair², V. Flax², C. van der Horst², D. Jamieson³, G. Tegha⁴, L. Allen¹

¹WHNRC, ARS/USDA, Davis, CA, USA

²School of Public Health/UNC/ Chapel Hill, North Carolina, USA

³CDC, Atlanta, Georgia, USA

⁴UNC Project, Lilongwe, Malawi

Background and objectives: B-vitamins are important for infant growth and development but the infant may become deficient if the mother has low intake or status. Maternal supplementation during lactation may improve the micronutrient status of exclusively breastfed infants. The effect of antiretroviral (ARV) treatments on the micronutrient content of the breast milk is unknown. The objective was to evaluate the effect of Lipid-based Nutrient Supplements (LNS) on breast-milk (BM) B-vitamins in HIV- infected women on ARV prophylaxis vs. control.

Methods: HIV+ mothers in the Breastfeeding, Antiretrovirals and Nutrition Study (BAN) were randomized to LNS, ARV, ARV/LNS and control from 0-28 wk. LNS contained 1 RDA of B-vitamins for lactation. BM samples (n=538) were collected at 2 or 6 and 24 wk postpartum and analyzed for free thiamin, riboflavin, flavin adenine dinucleotide, nicotinamide, pyridoxal, and vitamin-B12. Generalized linear models were used to compare means at 24 wk controlling for 2 and 6 wk values and to test for an LNS-ARV interaction.

Results: At 24 wk, women receiving LNS had higher concentrations of riboflavin, niacin, and pyridoxal and lower concentrations of B12 than the control (All $p < 0.05$). Women receiving ARV had significantly lower concentrations of B12 than the control ($p < 0.05$). ARV also lowered riboflavin and niacin, but ARV/LNS mitigated the decrease in riboflavin. BM B-vitamin in the BAN study were 2-50% below the adequate intake (AI) for infants, even in the LNS group.

Conclusion: BM B-vitamin analyses revealed significant differences in concentrations at the end of the lactation period by study arm. The interaction between ARV and LNS indicated that women treated with ARV had lower BM B2 at 24 wk, but LNS mitigates this effect. Overall, the BM B-vitamin concentrations were below the AI, even after maternal supplementation with LNS containing 1 RDA during lactation.

Key words: B-vitamins, lipid-based nutrient supplements, HIV.

PO3369

COMPREHENSIVE APPROACH TO ENSURE THE QUALITY OF URINARY IODINE DETERMINATIONS

A. Makhmudov¹, K. Caldwell¹, R. Jones¹

¹Inorganic and Radiation Analytical Toxicology Branch, Division of Laboratory Sciences, National Center for Environmental Health, Centers for Disease Control and Prevention, Atlanta, USA

Background and objectives: The accuracy and precision of measurements of iodine is important not only to monitor the status of iodine nutrition of populations around the world, but it is also important for quality assurance to ensure accurate data is collected to document efforts to eliminate Iodine Deficiency Disorders (IDD). Centers for Disease Control and Prevention (CDC), established an External Quality Assurance Scheme (EQAS) program, Ensuring the Quality of Urinary Iodine Procedures (EQUIP) in 2001 to assist laboratories around the world assess the accuracy and precision of their urinary iodine procedures by providing pools of highly characterized urine iodine samples.

Methods: EQUIP urine iodine samples are prepared at CDC and assigned target values using CDC's ICP-MS. Based on the analysis results of the pools and the desired target concentrations, we spike pools using a NIST traceable single element stock standard if necessary, to obtain concentrations ranging from about 10-400µg/L.

Results: Overall participation in this worldwide program is excellent, with 156 reference laboratories from 77 countries. Most of the participating laboratories use spectrophotometric monitoring of the Sandell-Kolthoff reaction with sample digestion accomplished by using either ammonium persulfate or chloric acid. The ICP-MS characterization of the pools provides a measurement standard by which other laboratories can assess accuracy and precision when measuring UI.

Conclusions: Since EQUIP was established, our data shows the program's success, by showing that external quality assurance programs, through inter-laboratory comparisons, are an effective tool for laboratory performance improvement. There have been significant improvements in the quality of data from laboratories measuring urine iodine in different parts of the world as a result of this program. EQUIP will continue to be a tool available to laboratories by encouraging good laboratory practices, providing an assurance of quality data, and also assisting those who are establishing a new laboratory or modernizing old ones.

Key words: Urinary iodine. Iodine Deficiency Disorders. Laboratory Proficiency. Laboratory Methods.

PO3370**INFLUENCE OF VELOCITY OF WEIGHT GAIN IN THE FIRST MONTHS OF LIFE IN THE NUTRITIONAL STATUS OF CHILDREN 4-7 YEARS**

S A. Vieira¹, L F R. Sant`Ana¹, T C A. Magalhães¹, A Q. Ribeiro¹, S E. Priore¹, S C C. Franceschini¹

¹Department of Nutrition and Health, Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil

Background and objectives: Risk factors for the development of overweight were identified in different age groups, especially those where there was a greater acceleration of growth, as the beginning of life. There are studies that show a relationship between the growth rate in the first months of life and risk of obesity later in life. Given the above, the aim of the study was to evaluate the influence of velocity of weight gain (VWG) at 4-6 months in the nutritional status of children aged between 4 and 7 years of Viçosa, Minas Gerais, Brazil.

Methods: Retrospective cohort study, whose sample consisted of 257 children 4-7 years old who were accompanied by Lactation Support Program (PROLAC) in the first months of life. The retrospective data of weight gain were obtained from the records of attendance of PROLAC for calculating the VWG. At ages 4 to 7 years were obtained measures weight and height to calculate body mass index for age (BMI / A). Descriptive analysis, simple and multiple linear regression.

Results: Children assessed, 55,2% were male, mean age of 71,5 (SD = 12,5) months. The prevalence of overweight was observed in 24,9%. In multiple linear regression analyzes, after adjusting for control variables, it was found that increasing the VWG 4-6 months explained the occurrence of higher BMI / A ($\beta = 0,10$, 95% CI = 0,07 - 0,13, $p < 0,001$).

Conclusions: The association between increased VWG in the first months of life and the occurrence of higher values BMI / A at later ages suggests that this criterion can be used to identify children at higher risk for changes in nutritional status throughout life.

Key words: Child, velocity of weight gain, nutritional status.

PO3371**ASSOCIATION BETWEEN IRON STORES AT BIRTH AND TIME OF CORD CLAMPING AND ANEMIA IN CHILDREN AT SIX MONTHS**

F C C. Oliveira¹, S E Priore², L F R. Sant`Ana², A Q. Ribeiro², S C C. Franceschini²

¹Integrated Education in Health Department, Universidade Federal do Espírito Santo, Vitória, Espírito Santo, Brazil

²Department of Nutrition and Health, Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil

Background and objectives: Iron deficiency anemia is the most common nutritional deficiency in children 6-24 months of age and, iron reserves at birth and time of cord clamping are the main determinants of this deficiency. The aim of this study was to evaluate the association between iron stores at birth and time of cord clamping on anemia in the sixth month of life. **Methods:** This is a cohort study conducted in Viçosa, Minas Gerais, Brazil, which were evaluated monthly children from birth to six months. At birth, was measured the time of cord clamping and cord blood collection and in the sixth month, the collection of venous blood. The parameters evaluated were complete blood count, serum ferritin, serum iron and C-reactive protein (CRP). We excluded the results of ferritin in children with abnormal PCR at birth and at six months. The number of children evaluated at birth was 144 and, of these, 64 did the blood collection at six months.

Results: In the sixth month, the incidence of anemia in infants was 56.2% and iron deficiency, 48.4%. Anemic children at six months showed average levels of ferritin at birth lower than non-anemic ($p=0.01$). Children with ferritin values at birth below the 25th percentile (corresponding to 74.9 mg/L) were two times greater risk of developing anemia at six months than those with values exceeding this percentile ($p=0,003$). The clamping time greater than 60 seconds was associated with higher levels of ferritin at six months.

Conclusions: It is clear the importance of prevention maternal anemia and gestational aiming better iron stores for the baby, besides the implementation of the time of cord clamping at least 60 seconds in the guidelines of labor.

Acknowledgements: FAPEMIG e CNPq

Key words: Cord clamping, iron stores, anemia, children, neonate.

PO3372**THE EFFECT OF AN INTERVENTION WITH FISH AND SHELLFISH ON MERCURY, ARSENIC, LEAD, AND CADMIUM LEVELS IN BLOOD**

M. Outzen¹, A. Tjønneland¹, E H. Larsen², K K. Andersen¹, K. Overvad³, A. Olsen¹

¹Unit of Diet, Genes and Environment, Danish Cancer Society Research Center, Copenhagen, Denmark

²Department of Food Chemistry, National Food Institute, Technical University of Denmark, Søborg, Denmark

³Section of Epidemiology, Department of Public Health, Aarhus University, Aarhus, Denmark

Background and objectives: Fish and shellfish are rich in essential nutrients including selenium and iodine. Conversely, consumption of fish and shellfish may also lead to exposure to heavy metals, a potential health risk. This study aimed to investigate the effects of fish and shellfish intake on mercury, arsenic, lead, and cadmium levels in whole blood.

Methods: In this randomised, controlled dietary intervention study, a total of 102 healthy, non-smoking, men and women aged 50-74 years were randomised to an intervention (n=51) or to control (n=51). Intervention participants received one kg fish and shellfish/week for 26 weeks. Control participants received no intervention. Non-fasting blood samples were collected at baseline and after 13 and 26 weeks' intervention. Whole blood levels of mercury, arsenic, lead, and cadmium were determined by inductively coupled plasma-mass spectrometry (ICP-MS). Mean change (SD) between baseline and week 26 was calculated within the two groups using a two-sample t test. Data was collected in a study, where the primary aim was to investigate the effect of the intervention on selenium status.

Results: Data analysis is ongoing, and the results presented in this abstract are preliminary. In total, 84 persons completed the study (n=42, intervention; n=42, control). Mean change (SD) in the intervention group was: 5.6 µg/L (1.8) for mercury, 5.9 µg/L (4.1) for arsenic, 3.7 µg/L (6.3) for lead, and 0.04 µg/L (0.24) for cadmium. In the control group, the mean change was 0.48 µg/L (1.3) for mercury, -1.2 µg/L (5.3) for arsenic, 0.56 µg/L (6.3) for lead, and 0.05 µg/L (0.23) for cadmium.

Conclusions: The preliminary results indicate that 26 weeks' intervention with fish and shellfish increases mercury, arsenic, and lead blood levels in this population.

Key words: Fish, shellfish, intervention, heavy metals.

PO3373**EVALUATION OF NUTRITIONAL STATUS USING ANTHROPOMETRIC AND BIOCHEMICAL INDICES OF COMMUNITY DWELLING OLDER PERSONS**

O. Nzeagwu¹, A. Uwaegbute¹

¹Department of Human Nutrition and Dietetics, Michael Okpara University of Agriculture Umudike, Umuahia, Abia State, Nigeria

Background and objectives: Older persons are on the increase; nutrition and health risks increase with age. Objective: evaluate the nutritional status of community dwelling older persons using anthropometric and biochemical indices.

Methods: Cross sectional study in semi urban and rural communities comprising 600 older community dwellers aged ≥ 65years. Nutritional status was assessed by body mass index (BMI), mid upper arm circumference (MUAC), waist-hip ratio (WHR), waist circumference (WC), calf circumference (CC). Serum haemoglobin (Hb), albumin, ferritin, total cholesterol (TC), low density lipoprotein (LDL), C- Reactive protein (CRP) were assessed for 25% of the subjects using standard procedures and compared with recommended cut-off.

Results: Majority (62.7%) had normal BMI, 21.33% were overweight. 74% were at risk of heart disease with WHR. 75.6% had normal MUAC, 24.33% were malnourished. 69.5% had normal WC and 30.5% had increased risk of abdominal fat adiposity. 56.2% had normal CC, 43.8% were at risk of malnutrition. High prevalence of anaemia as 78% had low Hb. 81% had serum ferritin levels below normal range. About 43.3% had normal albumin level, 56.7% were within abnormal range of either < 35 or > 50g/l. 82.7% were in lower risk category (< 1mg/l) of CRP. 82% had desirable total cholesterol, 53.3% had optimal LDL levels. Age correlated (p<0.05) negatively with CC (r = -0.22), (p<0.01) with MUAC (r = -0.295, positively with albumin (p < 0.05, r = 0.214) in females. Significant relationship (p<0.01) existed between Hb and ferritin for males (r = 0.794) and females (r = 0.839). Negative relationship (p < 0.05) noted for Hb and CRP (r = -0.261). Positive association (p< 0.01) between BMI and CC, MUAC, WC; TC and LDL.

Conclusion: Most had normal BMI; many were at risk of heart disease with WHR. High prevalence of anaemia.

Key words: Nutritional status, anthropometric, older persons.

PO3374**A HEALTHY DIETARY HABITS SCORE IS AN INDICATOR OF DIET QUALITY IN NEW ZEALAND ADOLESCENTS**

J.E. Wong^{1,2}, W.R. Parnell¹, S.M. Williams³, P.M.L. Skidmore¹

¹Department of Human Nutrition, University of Otago, Dunedin, New Zealand

²Faculty of Healthy Sciences, Universiti Kebangsaan Malaysia, Kuala Lumpur, Malaysia

³Department of Preventive and Social Medicine, University of Otago, Dunedin, New Zealand

Background and objectives: Adoption of optimal dietary habits during adolescence may have a protective effect against chronic diseases later in life. This study aimed to examine whether reporting more healthful dietary habits is associated with a better diet quality in New Zealand (NZ) adolescents.

Methods: A 17-item Healthy Dietary Habits Scores for Adolescents (HDHS-A) was developed based on dietary habits information. Using the 2008/09 NZ Adult Nutrition Survey data, adolescents aged 15 to 18 years (n = 694) who completed a single 24-hour diet recall and dietary habits questions were included in this secondary analysis. Post-hoc trend analyses were used to identify the associations between HDHS-A and nutrient intakes estimated by 24-hour diet recalls.

Results: A higher intake of protein, dietary fibre, polyunsaturated fat and lactose, and a lower intake of sucrose were associated with increasing thirds of HDHS-A. Significant positive associations were also found between HDHS-A and most micronutrients (P<0.05).

Conclusions: Reporting of more healthful dietary habits was associated with a more favourable nutrient profile. A healthy dietary habits score may serve as an indicator of diet quality in NZ adolescents.

Key words: Diet quality, adolescents, nutrient intake

PO3375**IODINE STATUS OF NEW ZEALAND ADULTS HAS IMPROVED SINCE MANDATORY FORTIFICATION OF BREAD**

¹Ministry for Primary Industries, Wellington, New Zealand

²Department of Preventative and Social Medicine, University of Otago, Dunedin, New Zealand

³Department of Human Nutrition, University of Otago, Dunedin, New Zealand

Background and objectives: In 2009, mandatory fortification of bread with iodine was introduced in New Zealand to address the re-emergence of mild iodine deficiency that has occurred over the past two decades. The study aimed to measure iodine status and estimate iodine intake of New Zealand adults 18-64 years of age following mandatory iodine fortification of bread.

Methods: A cross-sectional survey of 301 men and women aged 18-64 years living in Dunedin and Wellington was undertaken during February-November 2012. A 24-hour urine collection, demographic questionnaire and iodine-specific FFQ were completed; and height and weight measured. Urine collections were analysed for iodine and reported as median urinary iodine concentration (UIC) µg/L and median urinary iodine excretion (UIE) µg/day. Iodine intakes, with and without discretionary salt use, were estimated using the FFQ.

Results: The median UIC for adults was 73 µg/L, indicative of mild iodine deficiency according to WHO/UNICEF/ICCIDD population iodine status criteria. The mean urinary volume was 2.0L. The median UIE was 127 µg/day and estimated iodine intake using the FFQ, that included discretionary iodised salt use, was 132µg/day. Iodine intake was significantly associated with the UIC (p=0.040) and UIE (p=0.003); however bread iodine intake and iodised salt use were not associated with either the UIC or UIE.

Conclusions: The iodine status of New Zealand adults has improved (from 53 to 73 µg/L) since the introduction of mandatory iodine fortification, however not enough to meet the cut-off of >100µg/L. Caution is advised in applying the WHO/UNICEF/ICCIDD criteria to the New Zealand adult population as it is based on healthy school-aged children >6 years with a mean urinary volume half of that found in this study. The UIE is a better estimate of iodine in this population and suggests that the iodine status of New Zealand adults is now adequate.

Key words: Iodine, bread, fortification, adults.

PO3376**TRANS FATTY ACIDS CONSUMPTION LEVELS OF RESIDENTS LIVING IN THE TOKYO REGION***K. Yoshizawa*¹¹University of Nagasaki, Siebold, Guatemala

Background and objectives: There is evidence indicating that consumption of trans fatty acids (TFA) increases the risk of CHD and diabetes. WHO recommends that the average intake level is less than 1% of the total energy intake. Evaluation of TFA intakes of average people is limited in Japan due to partially lack of information on TFA including the Food Composition Table.

Methods: In 2011 a questionnaire was disseminated by internet to consumer monitors in the Tokyo Region. Inclusion criteria for analyses are male and female aged 10s -60s with 200 persons for each category, who completed the questionnaire, resulting in 1464 persons. The questionnaire consists of a food list, intake frequencies and portion sizes. TFA intake levels were calculated by use of information available in published papers and documents including the USDA food composition database. ANOVA and t-test were used to compare means of different groups.

Results: The mean intake for the total study population is 1.45/day (sd1.56 g/day) with a range 0-16.11 g/day. CV% is 107. The mean intake of the female group is higher than that of the male group (t-value 2.615, p=0.009). Levels of three groups, housewives, students and company employees are 1.79 g, 1.47 g and 1.26 g respectively, showing the intake of housewives (ANOVA, p=0.000) was highest. There was no information on total energy intakes. Therefore the energy level 2000 kcal/day was used to calculate TFA intakes % of total energy intakes. In this study population, 7% people would consume > 1% (4.5 g/day) and 19% would consume >2% (2.25 g/day) of the total energy intakes.

Conclusions: Generalizability from the findings is limited due to the sampling method of this study population: however, the findings suggest some groups are exposed to higher levels of TFA than the threshold.

PO3377**PHYTASE IMPROVES AVAILABILITY OF MINERALS FROM FORTIFIED TODDLER CEREALS – AN IN-VITRO MODEL***V. Elste*¹, *T. Barbara*¹, *K. Vogel*¹, *K. Wertz*¹¹DSM Nutritional Products Ltd., Basel, Switzerland

Background and objectives: Iron deficiency anemia is a major public health problem, and infants are particularly vulnerable. Complementary infant foods are typically based on cereals and legumes, both containing valuable minerals, but also phytate, which binds minerals. Phytate-bound minerals are poorly bioavailable for humans. We used Tolerase™ P phytase as a food processing aid to make two toddler cereals based on various crops, and investigated in an in vitro model, how phytate reduction in the cereals was linked to soluble, hence available, minerals in the cereals.

Methods: For estimation of food mineral bioavailability, soluble minerals and total mineral content were measured in an in vitro model of gastric digestion. The amounts of total vs. soluble iron, zinc, calcium and phosphorus were measured in the cereals treated with phytase, and compared to control cereals with the same composition.

Results: Tolerase™ P phytase increased the levels of soluble, hence available, minerals. Soluble iron increased by 9 fold (0.7 to 6.7 mg/kg), phosphorus by 1.6 fold, calcium by 2 fold, and zinc by 3.5 fold.

Conclusions: Tolerase™ P phytase can remarkably improve the amount of soluble minerals in toddler cereals. The data support using phytase to enhance the bioavailability of essential minerals from cereals, and thus to help cover the physiological mineral requirements toddlers need for healthy development.

Key words: Phytase, minerals, bioavailability, cereals, in-vitro.

PO3378

THE EFFECT OF MATERNAL OBESITY ON IRON STATUS, PLACENTAL TRANSFERRIN RECEPTOR EXPRESSION AND PREGNANCY OUTCOME. RESULTS OF PREOBE-STUDY

L.M. Garcia-Valdes¹, Campoy. C², I. Rusanova², M. Segura², M T. Miranda³, M C. Padilla⁴, A. Marcos⁵, L. Gambling¹, C. Kennedy¹, H E. Hayes¹, H J. McArdle¹

¹Rowett Institute of Nutrition and Health, University of Aberdeen, UK

³Department of Statistics, School of Medicine, University of Granada, Spain

⁴Department of Obstetrics and Gynecology, University Hospital San Cecilio, Granada, Spain

⁵Department of Metabolism and Nutrition, Institute of Food Science and Technology and Nutrition (ICTAN), CSIC, Madrid, Spain

Background and objectives: Obesity is associated with decreased iron status, possibly due to a rise in hepcidin, a regulator of iron absorption. Iron deficiency (ID) during pregnancy has deleterious consequences for mothers and offspring. Leptin up-regulates hepcidin expression and might be part of the aberrant iron metabolism in obesity. The aims of this study are: a) does maternal obesity result in reduced iron status? b) is leptin the link between obesity, hepcidin and decreased iron status? and c) can the placenta compensate the decreased iron status by increasing pTfR levels?

Methods: Iron status from pregnant women was estimated by serum transferrin receptor (sTfR) and ferritin levels (Fnt), serum leptin and hepcidin by luminex assays and pTfR by Western-blotting. Normal (BMI<25 kg/m²; n:126) and obese women (BMI≥30 kg/m²; n:43) were classified according to iron status (IS: Iron sufficiency, Hb>110g/L, Fnt>12mg/L; ID without anaemia, Hb>110g/L, Fnt<12mg/L; IDA: ID with anaemia, Hb< 110g/L, Fnt< 12mg/L) measured at 24, 34 weeks of gestation and at delivery.

Results: ID was more common in obese than in controls (Fnt: 16.31±6.64, n=17 vs 25.60±14.38, n=76; p=0.020; sTfR (27.24±11.49, n=18 vs 21.83±6.71, n=67; p=0.022), with inverse correlation between pre-pregnancy BMI and iron status parameters. Hepcidin levels were significantly higher among obese pregnant women at delivery (23.16±9.96, n=18 vs 16.55±9.68, n=62; p=0.034). Statistically significant correlations were found between pre-pregnancy BMI and hepcidin at delivery (r=0.2, p=0.046), leptin levels (r=0.6; r=0.5, r=0.4, p<0.0001) and leptin cord blood (r=0.3, p=0.007). Significantly pTfR expression was inversely related to maternal iron status, independently of BMI, and positively correlated with serum leptin levels.

Conclusions: Although causality cannot be demonstrated, these data imply altered regulation of iron metabolism in obese women. Importantly, these data also demonstrate that iron levels, rather than other regulators, modulate pTfR expression in the placenta.

Key words: Obesity, iron, leptin, hepcidin, placenta.

PO3379

FOLIC ACID DIETARY STATUS AND B12 DEFICIENCY ARE CRITICAL FACTORS TO EVALUATE HEPATIC AND VASCULAR DAMAGE IN GROWING RATS

T. Partearroyo¹, N. Ubeda¹, E. Sánchez-Campayo¹, G. Varela-Moreiras¹

¹University CEU San Pablo, Madrid, Spain

Background and objectives: Vitamin B12 and folic acid (FA) deficient diets may block the methylation route, by reducing S-adenosylmethionine (AdoMet) concentration, accumulating homocysteine (Hcy) and increase of oxidative stress. Moderate FA supplementation under B12 deficiency status, partially reverts. Therefore, deficient diets in both vitamins potentially may result in liver and/or vascular damage. The study was conducted to evaluate the effect of different dietary FA and vitamin B12 levels on hepatic and vascular parameters during growth.

Methods: Six-week male Sprague-Dawley rats (n=50) divided in four groups were fed during 30 days the following diets: Control B12/Control FA (CBCF): 50 µg vitamin B12/ 2 mg FA Deficient B12/Deficient FA (DBDF): 0 µg vitamin B12/ 0 mg FA Deficient B12/Control FA (DBCF): 0 µg vitamin B12/ 2 mg FA Deficient B12/Supplemented FA (DBSF): 0 µg vitamin B12/8 mg FA We evaluated serum lipid profile (total cholesterol (TC), triglycerides, oxidized low density lipoprotein and high density lipoprotein), apolipoprotein (Apo) A and B, angiotensin converting enzyme and liver function biomarkers (transaminases).

Results: Serum folate and vitamin B12 levels varied according to the dietary treatment. Plasma homocysteine was significantly higher in B12 deficient groups, whereas plasma triglyceride was significantly reduced for the DBSF group. Serum lipoproteins, TC, Apo, ACE and transaminases concentration were unmodified. In previous studies we demonstrated that FA deficiency compromises methionine metabolism, whereas supplementation did not show any additional positive effect compared to a control diet even in a critical physiological process such as growth. In addition, B12 and FA deficiencies increased oxidative stress at liver and plasma.

Conclusions: Vitamin B12 status affects the response to different FA levels through changes in liver methionine cycle and oxidative stress, without modification of the lipoprotein profile, neither other liver biomarkers and/or vascular damage.

Key words: Vitamin B12 status; dietary folic acid; oxidative stress; vascular damage.

HEALTH RISKS OF TOO LOW AND TOO HIGH INTAKE SHOULD BE EQUALLY CONSIDERED WHEN SETTING MICRONUTRIENT LEVELS IN FOOD

M. Bruins¹, K. Klaus²

¹DSM Biotechnology Center, Delft, The Netherlands

²Sight and Life

Background and objectives: Food fortification is a main strategy countries can use to address population-wide vitamin A deficiency. Risk-benefit models can be used to set vitamin A fortification levels. Adverse health consequences of vitamin A intakes below the Estimated Average Requirement (EAR) are very different from those above the Upper Level (UL) both in terms of nature and severity. Risk-benefit methods exist that equally consider the health impact of micronutrient intake at the two ends of the intake spectrum. As example, the net risk-benefit was calculated for country-wide vitamin A-fortification of foods in India among children under five years of age.

Methods: The health impact was calculated for vitamin A fortification (25% of recommended level) of each of following food vehicles: oil, wheat flour and rice, sugar, or milk products. In the first step, current health burden among under-fives was expressed in Disability Life Years (DALYs) lost. In a next step, DALYs to be averted resulting from vitamin A fortification were calculated. The WHO model for calculating DALYs was used. Calculations were built on India's 2010 demographics of under-fives and household intake data. Disability weights for xerophthalmia were used. Relationships between vitamin A intake and xerophthalmia prevalence, mortality rate and possible toxic effects were modeled.

Results: Depending on the food vehicle, up to ~80% of the EAR and ~20% of the dietary gap of under-fives could be met by (25%) vitamin A fortification. The minimal impact would be 10 million DALYs averted. If fortifying all food vehicles at 25%, prevalence of xerophthalmia and mortality could reduce by half with no adverse health effects at the 97th intake percentile.

Conclusion: Estimating the health consequences of vitamin A fortification at both ends of the intake spectrum may assist in making deliberate decisions on food fortification programs.

Key words: Risk-model, fortification, vitamin A, infants.

³Department of Horticulture Crops, Food Technology Institute, Agriculture Research Center, Ministry of Agriculture, Giza, Egypt

⁴Department of Experimental Kitchen, Food Technology Institute, Agriculture Research Center, Ministry of Agriculture, Giza, Egypt

Background and objectives: Recent data supported that diet composition introduced to infants and young children during diarrheal episodes is controversial so it has been the concern of extensive research. Study aimed to formulate and evaluate some proposed formulas for this group during acute diarrhea.

Methods: Six different defatted soy based formulas with yellow carrots, rice, potato starch powder and orange were prepared. Outpatients' infants and young children (140) with acute diarrhea, visiting the Center for Social and Preventive Medicine, Cairo University Children's Hospital, Egypt, were enrolled in the study. Participants were randomly assigned to 7 groups, 20 each. The control group did not receive any dietetic intervention. At the first visit, participant's mother in the other groups randomly received a formula at in a powder form to be dissolved and used at home. Patients were followed up for 2 weeks in two visits (after 5 and 15 days of enrollment) and assessed for diarrhea duration, number of motions/day, stool consistency, weight gain and their acceptability of the formulas. Statistical analysis of the results was performed.

Results: Feeding patients formulas demonstrated insignificant ($p < 0.05$) differences among age, gender, and illness cha-

racterize of cases. The percentages of cases with watery, loose and semi solid stools were greatly reduced after five days in all the groups. Insignificant difference ($p < 0.05$) was found among weights of formulas' groups and control at enrollment, after 5 and 15 days. These groups showed significantly lower mean number of motions per day after getting proposed formulas for 5 days compared to control group ($p < 0.001$).

Conclusions: During diarrhea episodes, feeding participants proposed formula showed better outcome than those not receiving dietetic intervention.

Key words: acute diarrhea, infant, young children, soy based formulas.

DEVELOPMENT OF PROBIOTIC FOOD MULTIMIX (PFMM)

R. Djoulde Darman¹

¹Department of Agriculture Husbandry and By products, The Higher Institute of the Sahel, University of Maroua, Maroua, Cameroon

Background and objectives: The food multimix (FMM) concept is one of the attempts used successfully by international programmes to meet the food insecurity challenges in poor African rural area. Despite its success the current FMM formulation concept target mainly common nutrient as carbohydrates, protein and vitamins thus lacking some bioactive compounds. This paper aims at adding live Bifidobacterium to a FMM formulation to develop a FMM enriched with bioactive compound.

Methods: The FMM were developed using fermented sorghum flour, cowpea, tiger nuts milk, red Hibiscus extracts and Aloe vera extracts. The probiotic were a strain of Bifidobacterium Longum isolated from chocolate bars. The FMM were first prepared and aliquot (102 UFC/g to 1010 UFC/g) of live encapsulated bifidobacterium added. The mixture allowed drying in an oven. The Arrhenius model supplemented by the linear model was used to predict the survival time of bifidobacterium in PFMM stored at ambient conditions.

Results: The proximate composition of developed PFMM shows an energy value of 427.77 ± 23 Kcal/100g, a protein value of 23.4 ± 6 g/100g, and total fats value of 6.29g/100g. Vitamins iron and calcium were also recorded. The survival time experi-

ments indicate an optimal rate of bifidobacterium as 106UFC/g with 30% death after 6 month storage time.

Conclusions: The new probiotic food multimix can be considered as a powerful bioactive enriched meal, with adequate required energy and key nutrients together with live microorganisms for bioactives compound.

Key words: Probiotics, Food multimixt, North Cameroon

BENEFITS OF HYDROLYSED COLLAGEN SUPPLEMENTATION IN SKIN'S PHYSIOLOGY OF MIDDLE-AGED PORTUGUESE WOMEN

N. Tavares¹, C. Rosado¹, L. Rodrigues¹, S. Abreu^{1,2}

¹CBIOS, Escola de Ciências e Tecnologias da Saúde, Universidade Lusófona, Lisboa, Portugal

²Research Centre In Physical Activity, Health and Leisure, Faculty of Sport, University of Porto, Porto, Portugal

Background and objectives: Collagen play a key role in normal dermatologic functioning. However, very few is known about the effects of hydrolysed collagen supplementation on skin's functions. We evaluated the effects resulting from hydrolysed collagen intake in skin's water profile and biomechanics in mature women.

Methods: Using data from measurements of transepidermal water loss, epidermal capacitance and biomechanical behaviour, before and after 30 days of supplementation we evaluated effects on skin's physiology in 18 women, 52.3y (SD±7.3). Volunteer's hydration status was assessed by plasma osmolality. Supplementation consisted in 2,5 g hydrolysed collagen or placebo each day for 30 days. A randomized, placebo-controlled, double-blind trial was chosen.

Results: The marker of hydration status was within the range of normalcy for all women. Hydrolysed collagen supplementation significantly increased skin hydration (p=0.000) and elasticity (p=0.000). Significant variation in transepidermal water loss could not be observed.

Conclusions: In the present experimental conditions, a 2,5 g per day oral hydrolysed collagen supplementation improved skin hydration and elasticity.

Key words: Collagen hydrolysate, supplementation, skin, women

DEVELOPMENT OF TASTY BREAD CONTAINING FUNCTIONAL ULVA PERTUSA POWDER

T. Yamauchi¹, A. Koide¹, K. Matsumoto², K. Mamiya¹, T. Banno², A. Yamamoto³, M. Moriyama⁴

¹Faculty of Human Life and Environmental Sciences, Nagoya Women's University, Nagoya, Aichi, Japan

²Department of Applied Life Studies, College of Nagoya Women's University, Nagoya, Aichi, Japan

³Department of Food Science and Nutrition, Aichi Gakusen College, Okazaki, Aichi, Japan

⁴Faculty of Human Life and Environmental Sciences, Aichi Gakusen University, Okazaki, Aichi, Japan

Background and objectives: Ulva pertusa (Sea lettuce) has not been used as food in Japan due to its tough fibrous texture; however, in light of recent findings that the seaweed contains high levels of iron, calcium, vitamins, and polyphenols, its potential food applications are currently drawing increasing attention. We attempted to develop tasty loaf bread, which is the most regularly consumed type of bread in Japan, containing ulva pertusa powder to utilize the functional components of the plant.

Methods: Bread samples were prepared to contain powdered ulva pertusa (particle size, 250 fÊm) at levels of 0 (control), 1, 2, and 3%, and examined for the contents of vitamin C, chlorophyll, and polyphenols, along with DPPH radical-scavenging activity, specific loaf volume, color, texture (using a creep meter), and sensory attributes (on a five-point scoring system). Data were analyzed by Tukey-Kramer's test (p<0.05).

Results: The contents of vitamin C, polyphenols, and chlorophyll, and the level of DPPH radical-scavenging activity increased with the amount of added ulva pertusa powder. The breads containing 2 and 3% ulva pertusa powder showed a significantly lower specific loaf volume, a significantly higher hardness value, and a significantly lower cohesiveness value than the control. In relation to the amount of added ulva pertusa powder, there was a significant reduction in lightness and a significant increase in greenness and yellowness. The bread containing 1% ulva pertusa powder received significantly higher scores in the sensory evaluation than the other breads.

Conclusions: The contents of the functional components increased with the amount of ulva pertusa powder added, and the bread containing 1% ulva pertusa powder was ranked first in terms of preference. Regular consumption of ulva-pertusa-containing bread could be an effective way to increase the intake of its functional components.

Key words: ulva-pertusa-containing bread, functional components, color, texture, preference

PO2663

ANTIOXIDANT ACTIVITY AND PHENOLICS CONTENT OF SWEET CHERRIES (*PRUNUS AVIUM* L.) FROM NORTHERN SERBIA

M. Popovic¹, D. Prvulovic¹, D. Malencic¹, M. Ljubojevic¹, G. Barac¹, V. Ognjanov¹, B. Popovic¹

¹Faculty of Agriculture, University of Novi Sad, Novi Sad, Serbia

Background and objectives: Sweet cherry is a valuable source of some bioactive compounds important for human health preservation. Recent increasing interest in nutraceuticals and functional foods has led plant breeders to initiate selection of crops with higher antioxidant activity. Red fruits, including sweet cherries, have been reported to contain various phenolics which contribute to total antioxidant activity. Thus, the aim of this study was to determine the fruit content of different phenolic compounds and to estimate their antioxidant activity.

Methods: Red-colored fruits of 15 cultivars were collected from the productive orchard "Sloga" at Ka, in vicinity of Novi Sad. The plants were growing under continental semi-arid agroecological condition typical for the Panonian plain lowlands representing the north of Serbia. The content of total polyphenolics (TP), total tannins (TT), total flavonoids (TF) and anthocyanins (A) has been determined in 70% ethanol fresh fruit extracts. In addition, the DPPH and FRAP antioxidant assays were evaluated, as well.

Results: TP content in the sweet cherries ranged from 7.45-147.31 mg GAE 100⁻¹ g fresh weight (f.w.). Cv. Peter had the highest TP and TT content, followed by Katalin (137.55 mg 100⁻¹ g) and Carmen (126.90 mg 100⁻¹ g). The cultivars with high TF content observed were Peter, Rita and Margit with 41.80, 39.00 and 36.98 mg rutine g⁻¹ f.w., respectively. Sweet cherries cultivars abundant in TP, TT and TF also contained more anthocyanins. The highest content was in the Katalin fresh fruits, 0.69 mg cyanidin-3-glycoside g⁻¹ f.w. The DPPH-values for investigated extracts varied in a wide range between 39.76% and 78.71%.

Conclusions: DPPH activity was found to have a positive correlation with TP (0.771), TT (0.747) and A (0.548). However, the correlations of FRAP values with phenolics were relatively lower.

Key words: sweet cherries, polyphenolics, antioxidant activity

PO2664

PROTECTIVE EFFECT OF LYCOPENE AGAINST ACUTE MYOCARDIAL INFARCTION

Y. Zhang¹, H. Wang², Y. Hou³, Y. Yang², H. Pan¹

¹Department of Nutrition and Food Hygiene, Public Health School of Harbin Medical University, Harbin, China

²The Second Affiliated Hospital of Harbin Medical University, Harbin, China

³Department of Pharmacology, Harbin Medical University, Harbin, China

Background and objectives: The present study has been designed to investigate the preservation of lycopene for acute myocardial infarction in vivo.

Methods: Wistar rats were randomly assigned either to lycopene, acute myocardial infarction (AMI) model and the normal groups. Lycopene group was given lycopene dissolved in olive oil each day, while the model group and normal group were given olive oil in the same amount. After 30 days, rats of lycopene group and model group were performed left anterior descending coronary artery ligation to establish AMI model. The severity of AMI and parameters of oxidative stress were assessed by the serum, histopathological exam and myocardial homogenate.

Results: Pretreatment with lycopene significantly increase the survival rate, reduce the infarct size and amount of myocardial enzymes. The alleviation of coagulative necrosis in ventricle of lycopene group was confirmed by the histopathological exam. The comprehensive oxidative stress assessment indicated lycopene significantly decreased the amount of the products of lipid peroxidation, protein damage, and DNA damage, significantly increased the amount of antioxidative enzymes.

Conclusions: Lycopene had a myocardial preservation and the effect might attenuate the intensified oxidative stress in AMI and stimulate the generation of endogenous antioxidants.

Key words: Lycopene; Myocardial preservation; Acute myocardial infarction; Oxidative stress; Rats

PO2665**ANTIOXIDATIVE AND HEPATOPROTECTIVE EFFECTS OF GLOSSOGYNE TENUIFOLIA ON ACETAMINOPHEN-INDUCED LIVER DAMAGE IN MICE**Y. Lu¹, Y. Tien¹¹Department of Nutritional Science, Fu-Jen Catholic University, New Taipei City, Taiwan

Background and objectives: Acetaminophen (APAP), a commonly used antipyretic and analgesic agent, can cause acute liver failure by overdose. *Glossogyne tenuifolia* (GT), Hsiang-Ju, used to prepare an herbal tea in Penghu, Taiwan, has been shown in recent research to exhibit antioxidative, antic-inflammatory, and anticarcinogenic properties. The present study investigates the antioxidative and hepatoprotective effects of GT against acetaminophen-induced acute liver injury in BALB/c mice.

Methods: The extracts of GT by various solvents (hot water, 50% ethanol and 95% ethanol) were used to compare the DPPH radical scavenging activity, reducing powder, total phenolic contents, and trolox equivalent antioxidant capacity (TEAC).

Results: The results showed that hot water extracts exert an excellent antioxidative capacity and were thus used in the animal experiment. The 30 male BALB/c mice were randomly divided into negative control group (APAP 400mg/kg), positive control group (N-acetylcysteine 600 mg/kg bw) and two GT groups at different dosages (100, 300 mg/kg respectively). After the administration of different oral treatments for one week, APAP was administered to the mice on the seventh day. The results showed that mice treated with GT had significantly decreased serum levels of alanine aminotransferase (ALT), aspartate aminotransferase (AST), and lipid TBARS (thiobarbituric acid-reactive substances), but total antioxidant capacity (TEAC) was not affected. GT-H (300 mg/kg) increased catalase activity in the liver; no prominent effects were demonstrated on superoxide dismutase, glutathione S-transferase, glutathione peroxidase.

Conclusions: In conclusion, hot water extract of GT may have potential antioxidant capacity and exert hepatoprotection in mice.

Key words: acetaminophen, *Glossogyne tenuifolia*, hepatoprotective, antioxidative

PO2666**IN VITRO METABOLISM OF 3,5,6,7,8,3',4'-HEPTAMETHOXYFLAVONE BY RAT LIVER MICROSOMES**N. Koga¹, M. Matsuoka¹, C. Ohta¹, Y. Kato², K. Haraguchi³, O. Kimura⁴, T. Endo⁴¹Faculty of Nutritional Sciences, Nakamura Gakuen University, Japan²Faculty of Pharmaceutical Sciences, Tokushima Bunri University, Japan³Daiichi College of Pharmaceutical Sciences, Japan⁴Faculty of Pharmaceutical Sciences, Hokkaido Health University, Japan

Background and objectives: 3,5,6,7,8,3',4'-Heptamethoxyflavone (HepMF), a polymethoxyflavone present abundantly in the citrus peel, have been reported to show biological properties such as the inhibition of P-glycoprotein and the suppression of growth of tumor cells. However, the mechanism which the activities are exerted by HepMF or its metabolites remains obscure. Therefore, the metabolism of HepMF was investigated using rat liver microsomes and the effects of typical cytochrome P450 (P450) inducers, phenobarbital (PB), 3-methylcholanthrene (MC) and dexamethasone (DEX), were also examined.

Methods: HepMF was incubated for 20 min at 37°C with rat liver microsomes, NADPH-generating system and HEPES buffer (pH 7.4) under aerobic conditions. Rat liver microsomes were prepared from untreated, PB-treated, MC-treated and DEX-treated rats. After incubation, an ice-cold methanol was added and the incubation mixtures were centrifuged. The supernatants were applied to HPLC.

Results: HepMF was metabolized to three major metabolites (M-2, M-3 and M-4) and four minor metabolites (M-1, M-5, M-6 and M-7) by liver microsomes of untreated rats and the amount of M-2, M-3 and M-4 was 0.42, 0.56 and 0.12 nmol/min/mg protein, respectively. PB treatment increased three major metabolites to about 2-fold and M-1 to 4.4-fold of untreated rats significantly. MC treatment increased both M-2 and M-4 to about 3-fold of untreated rats and also accelerated the formation of M-5, M-6 and M-7 to 244-, 16- and 5-fold of untreated rats, respectively. Moreover, DEX showed the similar induction pattern to PB. From the spectral data of MS and 1H-NMR, three major metabolites, M-2, M-3 and M-4, were assumed to be 4'-demethylated (OH), 7-OH and 6-OH metabolites, respectively. The chemical structures of M-1, M-5, M-6 and M-7 remain unclear because of their low yields.

Conclusion: These results suggest that CYP2B, CYP1A and CYP3A enzymes are responsible for HepMF metabolism.

Key words: polymethoxyflavone, metabolism, rat, liver

PO2667

PLANT-BASED FOODS AS A SOURCE OF LIPOTROPES FOR PREVENTING HEPATIC STEATOSIS

Fardet¹, J. Martin¹, J. Chardigny¹

¹Inra, CLERMONT-FERRAND, France

Background and objectives: Lipotropes are food components that limit excessive hepatic triglyceride contents or steatosis. Steatosis is often associated with obesity and type 2 diabetes, and may lead to more serious pathologies such as steatohepatitis, hepatic fibrosis and cirrhosis, or cancer. Yet, whereas steatosis concerns several millions people worldwide, the lipotropic potential of foods has never been studied; and lipotrope-rich foods remain quite unknown. Our objective was to characterize and quantify the lipotropic potential of plant-based foods.

Methods: From lipotrope contents found in literature and nutritional tables, 132 plant-based foods and 8 lipotropes (betaine, choline, myo-inositol, methionine, niacin, pantothenic acid, folates and magnesium) could have been selected. Plant-based food lipotropic potential was expressed into a new index, the Lipotropic Capacity (LC) that integrates the sum of the 8 lipotropic densities relative to a reference food.

Results: Vegetables are the best source of lipotropes on a 100 kcal-basis and plant-based foods are a more diversified source - but complementary - of lipotropes than animal-based products. Technological processes reduce plant-based foods lipotropic potential by around 20%: while refining is the most drastic treatment, fermentations may tend to increase lipotrope densities. By comparing lipotrope consumption via both French standard diet (INCA 2 survey) and Food guide pyramid, we evaluated that our consumption in betaine, choline and myo-inositol may be increased: this can be easily reached by choosing lipotrope-dense foods like beetroot, spinach or coffee. On a one euro-basis, grains products (i.e. cereals, nuts and leguminous and oleaginous seeds) are the best compromise between a high LC and a cheap supply in lipotropes.

Conclusions: The LC allows easily ranking foods according to their lipotropic potential. But, it remains indispensable to carry out studies in humans to relate food LC with prevalence of hepatic steatosis.

Key words: Lipotropes, plant-based foods, lipotropic capacity, technological processes, consumption

NOURISHMENT FUNCTION IMPROVEMENT OF THE WHEAT PRODUCTS BY THE ULVA PERTUSA ADDITION

A. Yamamoto¹, M. Moriyama², A. Koide³, K. Matsumoto⁴, . Mamiya³, T. Yamauchi³

¹Department of Food Science and Nutrition, Aichi Gakusen College, Japan

²Faculty of Human Life and Environmental Sciences, Aichi Gakusen University, Japan

³Faculty of Human Life and Environmental Sciences, Nagoya Women's University, Japan

⁴Department of Applied Life Studies, College of Nagoya Women's University, Japan

Background and objectives: In late years, eating habits were influenced by westernized countries. Lack of a mineral and dietary fiber in meal was related to diabetes mellitus. The meal intake standard of magnesium (Mg) is 370 mg/day, but there are few intakes with 250 mg. We processed *Ulva pertusa* (*Ulva*) which is unused food resources into wheat products. The chlorophyll content of *Ulva* is high and addition of it which is green algae in familiar food served as a source of Mg supply. Noodles and bread were prepared with addition of *Ulva*. Examination of chlorophyll and Mg were done to assess cooking loss and its effectiveness.

Methods: After hanging *Ulva* to a lyophilizer, *Ulva* powder was sieved using 280 microns. *Ulva* noodles were variably added with *Ulva* powder with a density of 0%, 3%, 5%, 8% and 13% while *Ulva* bread addition of *Ulva* powder were 0%, 1%, 2%, and 3% respectively. Ingredient analysis for the quantity of Mg and chlorophyll were performed by Arnon Method and Ion Chromatograph Method.

Results: The chlorophyll content correspondingly increased with *Ulva* density addition. The quantity of Mg in 13% *Ulva* powder noodles increased to 1,030 mg per 100 g. After boiling, Mg quantity was 530 mg. In bread, Mg quantity was 400 mg per 100 g of 3% of *Ulva* powder bread before bake. An amount of 151 mg was obtained after baking. Quantity of Mg in noodles and bread with increasing addition of *Ulva* density was similar in quantity increase of chlorophyll.

Conclusions: Increasing *Ulva* powder density of all wheat products put up a nourishment ingredient than additive-free noodles. It was suggested that it could become a source of Mg supply by the addition of *Ulva*.

Key words: *Ulva pertusa*, Magnesium, Chlorophyll, Wheat products

PO2669**DETERMINATION OF PHENOLIC ACIDS IN INDIGENOUS LEAFY VEGETABLES OF BOTSWANA BY HIGH PERFORMANCE LIQUID CHROMATOGRAPHY***S T P. Matenge¹, N. Dlamini², K. Mathiba²*¹National Food Technology Research Centre, Kanye, Botswana²CSIR, BioSciences Unit (Natural Products and Agro processing Platform), Pretoria, South Africa

Background and Objectives: Plant materials especially green leafy vegetables contain phytochemicals whose consumption has been associated with protecting the human body from chronic diseases.

Methods: With the aim to promote the utilisation of indigenous leafy vegetables, the present study separated, identified and quantified using HPLC-DAD the main phenolic compounds in indigenous leafy vegetables [Amaranth (*Amaranthus* spp.), Spider plant (*Cleome gynandra*), Cowpea leaves (*Vigna unguiculata*) and Black nightshade (*Solanaceae* spp)] of Botswana.

Results: 3,4-dihydroxybenzoic acid (7.56 ± 0.61 mg/100g), chlorogenic acid (12.34 ± 0.95 mg/100g) and ferulic acid (3.63 ± 0.09 mg/g) in *Amaranth* spp., 3,4-dihydroxybenzoic acid (7.25 ± 0.11 mg/100g), 4-hydroxybenzoic acid (3.85 ± 0.14 mg/100g), p-coumaric acid (1.60 ± 0.25 mg/100g) and ferulic acid (4.75 ± 0.25 mg/100g) were found in *Vigna unguiculata*, vanillic acid (1.13 ± 0.09 mg/100g), chlorogenic acid (31.32 ± 4.42 mg/100g) and ferulic acid (2.38 ± 0.09 mg/100g) were found in *Cleome gynandra*, 3,4-dihydroxybenzoic acid (6.68 ± 0.05 mg/100g) and ferulic acid (7.93 ± 0.94 mg/100g) were found in *Solanaceae* spp. Ferulic acid (2.38 ± 0.09 mg/100 – 7.93 ± 0.94 mg/g) appeared in all the samples analysed, however, chlorogenic acid (12.34 ± 0.95 mg/100g – 31.32 ± 4.42 mg/100g) was the most abundant.

Conclusion: Vegetables investigated in this study are shown to be rich sources of polyphenols which contribute to their health promoting properties. Therefore the use of these vegetables as a source of polyphenols could offer enormous opportunities for the functional food industry. In addition, it is critical to create awareness regarding diet related health benefits of these vegetables. This is the first report on identification of phenolic acids in the extracts of four indigenous leafy vegetables grown in Botswana.

Key words: Polyphenols, *Amaranthus* sp., *Cleome gynandra*, *Vigna unguiculata*, *Solanaceae* (nightshade), HPLC

PO2670**INFLUENCE OF PINE BARK EXTRACT POLYPHENOLS ON INTESTINAL MICROFLORA***T. Sanchez Moya¹, R. López Nicolás¹, D. Planes Muñoz¹, P. Peso Echarri¹, C. González Bermúdez¹, V. Gómez Gómez¹, A. López Fernandez¹, L. Fernández Palacios¹, C. Frontela Sasetá¹, C.A. Martínez Graciá¹*¹Department of Food Science and Nutrition, Faculty of Veterinary Sciences of University of Murcia, Murcia, Spain

Background and objectives: Phenolic compounds exert antioxidant properties and beneficial effects on human health, being abundant in fruits and other vegetables, as cereals and legumes. As a concentrated of water-soluble polyphenols, Pine (*Pinus pinaster* Ait) bark extract (PBE) has been demonstrated to have strong antioxidant properties. In this study, the antimicrobial activity of caffeic acid, gallic acid, ferulic acid, chlorogenic acid and taxifolin; and PBE, against *Escherichia coli* O157:H7, *Enterobacter sakazakii*, *Listeria monocytogenes* and *Staphylococcus aureus*, *Escherichia coli*, *Enterococcus faecalis*, and the effect on *Lactobacillus casei rhamnosus* and *Lactobacillus gasseri*, was determined.

Methods: Taxifolin, ferulic, gallic, chlorogenic and caffeic acids, and PBE were analysed by HPLC. Each phenolic compound (1.25, 0.6, 0.3, 0.15, 0.07, 0.04 and 0.02 mg/mL) was tested against different bacterial strains to determine their effects on bacterial growth, using the microtiter plate method.

Results: Increased concentration of phenolics led to an inhibition of bacterial growth with differences depending of the compound. The growth of *S. aureus* and *Lactobacillus gasseri* was inhibited at 0.15 at 1.25 mg/mL and 0.3-0.6 mg/ml of caffeic acid, respectively. Meanwhile *L. casei rhamnosus* was not affected by this compound. Regarding gallic acid, the inhibitory effect was highly significant for *S. aureus* and *E. faecalis*, at concentrations of 0.02-1.25 and 0.04-1.25 mg/mL, respectively. Taxifolin showed antilisterial effect at concentrations of 1.25 mg/mL with growth inhibition values of 97%. The inhibitory effect of PBE was highly significant on the growth of *E. coli* O157:H7. Nevertheless, the growth probiotic bacteria growth was poorly affected by most of tested phenolic compounds.

Conclusion: PBE and its constituents showed selective antimicrobial activity on intestinal bacteria. Moreover, we have demonstrated the protective effect of polyphenols and PBE on probiotic bacteria as *L. casei rhamnosus* and *L. gasseri*.

Key words: pine bark extract, polyphenols, intestinal microflora

SYNERGISTIC ANTIOXIDANT ACTIVITY OF PROTEIN HYDROLYSATES FROM DIFFERENT SOURCES OBTAINED BY ENZYMATIC HYDROLYSIS

R. Castro¹, H. Sato¹

¹Department of Food Science, School of Food Engineering, University of Campinas, Campinas, São Paulo, Brazil

Background and objectives: Soy protein isolate (SPI), bovine whey protein (BWP) and egg white protein (EWP) hydrolysates were prepared using different microbial proteases to produce peptides with antioxidant activity (DPPH radical scavenging).

Methods: The process parameters: enzyme type, substrate and enzyme concentrations, and hydrolysis time were further investigated for each protein source. After defining the most appropriate process parameters for enzymatic hydrolysis, the interactions amongst the hydrolysates with maximal antioxidant activity obtained from the different sources, were studied using a simplex centroid mixture design.

Results: SPI hydrolysates with maximal antioxidant activity were obtained with a substrate concentration of 90 mg.mL⁻¹ and 70.0 U of a commercial protease from *Aspergillus oryzae* per mL of reaction mixture (U.mL⁻¹), with a hydrolysis time between 120 and 180 min. For BWP hydrolysates the hydrolysis parameters were: substrate concentration of 8.0% plus 70.0 U.mL⁻¹ of a protease from *Aspergillus oryzae* produced by solid-state fermentation, and a hydrolysis time in the range from 60 to 240 min. The hydrolysates prepared from 3.0% EWP plus 20.0 U.mL⁻¹ of a commercial protease from *Aspergillus oryzae*, obtained after 120 minutes of hydrolysis time, presented high DPPH radical scavenging. In the antioxidant study of seven formulations containing SPI, BWP and EWP hydrolysates, alone or in combinations, a synergetic effect was found for the ternary mixture. In a mixture composed of SPI (1/3), BWP (1/3) and EWP (1/3), increases of 184.1, 164.7 and 217.5% in DPPH radical scavenging were observed as compared to the respective isolated hydrolysates. However the binary mixture BWP (1/2) plus EWP (1/2), showed an antagonistic effect. The interactions between the binary mixtures: SPI (1/2) plus BWP (1/2) and SPI (1/2) plus EWP (1/2) were not statistically significant ($p < 0.05$).

Conclusions: The results suggest that the enzymatic hydrolysis of proteins from different sources and their mixtures can improve the antioxidant activities.

Key words: protease, protein hydrolysates, antioxidant activity, synergistic effect

PO2672

FUNCTIONAL PROPERTIES AND INHIBITION OF THE RELATIVE LIPID ACCUMULATION OF PROTEIN HYDROLYSATES OBTAINED BY ENZYMATIC HYDROLYSIS USING STATISTICAL MIXTURE DESIGN

R. Castro¹, R. Inacio², A. Oliveira², H. Sato¹

¹Department of Food Science, School of Food Engineering, University of Campinas, Campinas, São Paulo, Brazil

²Department of Anatomy, Institute of Biology, University of Campinas, São Paulo, Brazil

Background and objectives: Statistical design mixtures of soy protein isolate (SPI), bovine whey protein (BWP) and egg white protein (EWP) were used to study the effects of the different protein sources and their mixtures on the functional properties (solubility, heat stability, emulsion activity index and foaming capacity) and inhibition of the relative lipid accumulation (RLA) in 3T3-L1 preadipocytes during differentiation.

Methods: The hydrolysates were prepared in Erlenmeyers flasks containing 50 mL of protein solution (100 mg.mL⁻¹) and a commercial protease from *Aspergillus oryzae*. The solution was incubated for 2h under the optimum pH and temperature conditions for the enzyme (pH 5.0 at 50.0°C).

Results: For functional properties, the enzymatic hydrolysis increased the solubility of the proteins, excepted for EWP and the mixtures containing it. However, the hydrolysates exhibited a tendency to decrease the foaming capacity and heat stability. A synergetic effect was found for the emulsion activity index with two binary formulations and the ternary mixture, with increases of up to 12-fold. The EWP hydrolysates showed the highest RLA suppression (19.7%) followed by BWP (16.4%) and SPI (8.7%). Two binary mixtures and the ternary formulation showed similar RLA suppression compared to the isolated protein sources. The hydrolysates obtained using equal proportions of SPI and BWP, and of BWP and EWP, showed RLA suppressions of 11.5 and 12.8%, respectively, while the ternary mixture containing SPI (1/3), BWP (1/3) and EWP (1/3) showed an RLA suppression of 14.5%.

Conclusions: The results suggest that the enzymatic hydrolysis of proteins from different sources and their mixtures can improve some functional properties and increase the suppression of RLA in 3T3-L1 cell differentiation.

Key words: protein hydrolysis, mixture design, functional properties, relative lipid accumulation, 3T3-L1.

PO2673**IN VITRO METABOLISM OF DIOSMETIN AND HESPERETIN BY RAT LIVER MICROSOMES***C. Ohta¹, Y. Kato², K. Haraguchi³, N. Koga¹*¹Faculty of Nutritional Sciences, Nakamura Gakuen University, Japan²Faculty of Pharmaceutical Sciences, Tokushima Bunri University, Japan³Daiichi College of Pharmaceutical Sciences, Japan

Background and objectives: Flavonoids in fruits and vegetables are transformed to hydroxy-metabolites via hydroxylation and demethylation in animals. To elucidate the relationship between their chemical structures and metabolic patterns, the metabolism of a flavone (diosmetin) and a flavanone (hesperetin) by rat liver microsomes was compared and the effects of inducers and inhibitors of cytochrome P450 (P450) on their metabolisms were examined.

Methods: Rat liver microsomes were prepared from untreated, phenobarbital (PB)-treated and 3-methylcholanthrene (MC)-treated rats. Each flavonoid was incubated for 20 min at 37°C with rat liver microsomes, NADPH and HEPES buffer (pH 7.4) under aerobic conditions. After addition of methanol, the incubation mixtures were centrifuged to remove the denatured protein. For analyses of the metabolites, the supernatants were applied to HPLC. α -Naphthoflavone (α NF), furafylline (FFL) and ketoconazole (KCZ) were used as P450 inhibitors for CYP1A1, CYP1A2 and CYP3A1, respectively.

Results: In untreated microsomes, diosmetin and hesperetin were mainly oxidized to give 4'-demethylated metabolites, luteolin and eriodictyol, with the rates of 0.47 and 0.16 nmol/min/mg protein, respectively. In hesperetin metabolism, three minor metabolites were also formed. PB-treatment showed a slight increase (about 1.5-fold of untreated rats) of both luteolin and eriodictyol, whereas MC-treatment increased both metabolites remarkably to 5.9-fold and 10.9-fold of untreated rats, respectively. However, the amount of eriodictyol formed were 30-64% of that of luteolin formed in all cases. 0.5 mM α NF inhibited the formation of luteolin and eriodictyol to 45% and 18% of control, respectively. 0.25 mM KCZ inhibited both metabolites to 30% of control.

Conclusion: These results suggested that CYP1A and CYP3A enzymes are the most important P450 isoforms in the metabolism of both flavonoids in rat and that diosmetin having the flavone skeleton is a better substrate for CYP1A and CYP3A enzymes than hesperetin having flavanone skeleton.

Key words: flavone, flavanone, metabolism, rat, liver

PO2674**NOVEL ANXIOLYTIC-LIKE PEPTIDE RELEASED FROM ALPHA-S-CASEIN BY GASTROINTESTINAL PROTEASES***T. Mizushige^{1,2}, Y. Sawashi¹, A. Yamada¹, R. Kanamoto¹, K. Ohinata¹*¹Division of Food Science and Biotechnology, Graduate School of Agriculture, Kyoto University, Kyoto, Japan²Research Unit for Physiological Chemistry, C-PIER, Kyoto University, Kyoto, Japan

Background and objectives: Our previous findings demonstrated that dipeptide YL exhibited orally active anxiolytic-like activity comparable to diazepam [1]. The YL sequence is often observed in the primary structure of natural food proteins. We then investigated whether YL analogues are released from bovine alpha-s-casein by gastrointestinal proteases.

Methods: YL analogues in the pepsin-pancreatin digestion of alpha-s-casein were quantified by LC-MS. Synthetic peptides were prepared by the F-moc strategy. We investigated anxiety-like behavior using two behavioral tests, the elevated plus-maze and the open-field, in mice. Peptide or digest dissolved in saline was administered intraperitoneally and/or orally 30 min before the test. Antagonists of neurotransmitters associated with anxiolytic-like activity were co-administered intraperitoneally with peptide 30 min before the test. A percentage of the entry time in open arms or in the center circle was measured.

Results: We found that YLG, corresponding to alpha-s1-casein(91-93), was more effectively released from alpha-s-casein than YL by pepsin-pancreatin digestion, mimicking gastrointestinal enzymatic conditions. Using the synthetic model peptide, we determined that trypsin cleaved the N-terminus of YLG, and elastase and carboxypeptidase contributed to cleavage of the C-terminus of that. YLG as well as YL exhibited potent anxiolytic-like activity after oral administration. The anxiolytic-like activity of YLG was inhibited by WAY100135, SCH23390 or bicuculline, an antagonist of serotonin 5-HT1A, dopamine D1 and GABAA receptors, respectively; however, YLG has no affinity for these receptors. These results suggest that YLG exhibits anxiolytic-like activity via the releases of serotonin, dopamine, and GABA, which are a novel neuronal pathway common to YL. The pepsin-pancreatin digestion of alpha-s-casein also exhibited anxiolytic-like activity.

Conclusions: We found that YLG, a novel anxiolytic-like peptide, released from alpha-s-casein after pepsin-pancreatic digestion mimicking gastrointestinal conditions, exhibits anxiolytic-like activity in mice.[1] Kanegawa N et al. (2010) FEBS Lett 584:599-604.

Key words: emotional behavior, anxiolytic, peptide, bovine milk protein

PO2675**PRODUCTION OF OIL PALM (ELAEIS GUINEENSIS) KERNEL PROTEIN HYDROLYSATES WITH ANTIOXIDANT PROPERTIES AND APOLIPOPROTEIN B SECRETION INHIBITION**

S K. Chang¹, H. Hamajima², I. Amin^{1,5}, T. Yanagita^{2,3}, M E. Norhaizan¹, B. Mohamad Taufik Hidayat⁴

²Jofuku Frontier Laboratory, Saga University, Japan

³Department of Health and Nutrition Sciences, Faculty of Health and Human Welfare Sciences, Nishikyushu University, Kanzaki, Saga, Japan

⁴Department of Human Anatomy, Faculty of Medicine and Health Sciences, Universiti Putra Malaysia, Selangor, Malaysia

⁵Laboratory of Halal Science Research, Halal Products Research Institute, Universiti Putra Malaysia, Serdang, Selangor, Malaysia

Background and objectives: Plant proteins played essential roles in human nutrition. Palm oil was the most important oilseed crops globally. There was 12-16% of crude protein in oil palm kernel. However, little was known about the functional properties of the kernel protein. Hence, this study aimed to produce the protein hydrolysates and characterize its health promoting properties.

Methods: The protein isolate used for the generation of protein hydrolysates was obtained by alkaline extraction and acid precipitation. Then, oil palm kernel protein hydrolysates (OPKH) were produced by protease and pepsin-pancreatin hydrolysis. SDS-PAGE was used for qualitative assessment of its polypeptide profiles. Amid acid profile was analyzed by Pico Tag Amino Acid Analyzer. The effect of both protein hydrolysates (PH) on apoB secretion and lipid metabolism in vitro was undertaken using HepG2 cells in ApoB Microwell ELISA Assay Kit (AlerCHEK). In vitro antioxidant activity (AA) was determined using ferric reducing antioxidant power (FRAP) and 2,2'-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid) (ABTS) assay.

Results: The estimated polypeptide molecular mass of both protein hydrolysates from reducing SDS-PAGE were 7, 8, 11 and 12 kDa while only one protein band was observed from non-reducing SDS-PAGE, 50 kDa. Both protein hydrolysates were richest in Aspartic acid and Glutamic acid (> 35% of total amino acids), followed by sulfur amino acids, lysine and valine. Both PH (1 mg/ml) reduced apoB secretion and its triglycerides and cholesterol synthesis significantly. Protease and pepsin-pancreatin hydrolysates reduced apoB secretion 45.4% and 32.6% respectively compared to control. OPKH (5 mg/ml)

were highly effective in scavenging ABTS radicals and with high reducing power (FRAP) compared to many other seed PH. There was a dose-dependent relationship between both PH and AA.

Conclusions: OPKH have good health promoting properties as a source of nutraceuticals contributed by its lipid lowering and antioxidative properties.

Key words: Oil palm kernel; protein hydrolysates; apoB secretion; antioxidant activity

PO2676**DEVELOPMENT OF A REPORTER ASSAY SYSTEM TO SCREEN FOR CHEMICALS MIMICKING THE ANTI-AGING EFFECTS OF CALORIE RESTRICTION**

T. Chiba¹, T. Tsuchiya², I. Shimokawa²,

¹Biomedical Gerontology Laboratory, Faculty of Human Sciences, Waseda University, Tokorozawa, Japan

²Department of Investigative Pathology, Unit of Basic Medical Science, Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan

Background and objectives: Caloric restriction (CR) in normal mice, and suppression of the growth hormone (GH) / insulin-like growth factor-I (IGF-I) pathway in spontaneous mutant Ames dwarf (DF) mice extends their lifespan and delays the onset of age-dependent disorders. In combination, these two lifespan-extending interventions have an additive effect upon DF mice. In this study, we tried to identify the intracellular signaling pathways of CR beneficial effects and develop a system to screen anti-aging chemicals.

Methods: We previously identified dozens of genes up-regulated in the liver of DF and CR mice by using DNA microarray. Motif analysis was performed to identify consensus sequence motifs in the upstream of these putative pro-longevity genes. We tried to identify binding factors of these motifs using gel shift assay. We also constructed the reporter assay system to screen CR mimetics generating the constitutive cell lines and the transgenic mice harboring the motif sequence.

Results: We found that one of the synthesized sequences of identified motifs bound to hepatocyte nuclear factor-4 (HNF-4) alpha, an important transcription factor involved in glucose and lipid metabolism. When the reporter construct, containing an element upstream of a secreted alkaline phosphatase (SEAP) gene, was co-transfected with HNF-4 and its regulator peroxisome proliferator-activated receptor-gamma coactivator 1 (PGC-1) alpha, activity of SEAP was increased dose-dependently in comparison to untransfected controls. Moreover, transgenic mice established using this construct showed increased SEAP activity both CR and resveratrol-fed mice in comparison to ad

libitum fed mice. Furthermore, oxidative stress resistance was correlated with SEAP activity of these transgenic mice.

Conclusions: These data suggest that our bioassay would be useful to screen for CR mimetic photochemical both in vitro and in vivo.

Key words: Aging, calorie restriction, photochemical, HNF-4, PGC-1

PO2677

MONITORING OF BIOACTIVE COMPOUNDS IN READY-TO-HEAT VEGETABLES: EVALUATION OF CONTENT, STABILITY AND COMPARISON

M I. Alarcon-Flores¹, F. Hernández-Sánchez¹, R. Romero-González¹, P. Plaza-Bolaños^{1,2}, A. Garrido-Frenich¹

¹Research Group Analytical Chemistry of Contaminants, Department of Chemistry and Physics, Research Centre for Agricultural and Food Biotechnology (BITAL), University of Almería, Agrifood Campus of International Excellence, Almería, Spain

²Department of Analytical Chemistry, University of Granada, Granada, Spain

Background and objectives: Bioactive compounds are present in fruit and vegetables and they are recognized for their benefits for health. Because the advantages of ready-to-heat vegetables, as time saving, healthy characteristics and low-cost, this market is currently the fastest growing subsector of food industry. The purpose of this work is the study and comparison of the content of several families of bioactive compounds in ready-to-heat vegetables, as pepper, tomato, carrot, cauliflower and broccoli, before and after applying a microwave heating. In a second step, the evolution of the content of bioactive compounds during shelf life of these products has been evaluated.

Methods: The extraction procedure carried out was based on a solid liquid extraction using methanol:water (80:20,v/v). The extract was injected into the ultra-high-performance-chromatogram coupled to triple quadrupole mass analyzer.

Results: The total content of bioactive compounds in pepper was slightly increased after heat treatment. The content of bioactives was higher when the sample was heated after expiration date. A bag of a mixture of broccoli, cauliflower and carrot was evaluated, although each matrix was always analyzed separately. Caffeic acid appeared after heat treatment, and it must be considered that it was a degradation product of chlorogenic acid. The content of total bioactive compounds in carrots increased after heating. In general, it was observed that expiration date affects more than heat treatment to the total content of bioactives. Nonetheless, differences were not statistically significant in most cases, except for broccoli.

Conclusions: The content of bioactive compounds is affected more by expiration date rather than by heat treatment. It is also interesting to indicate that transfer of bioactive compounds between vegetables during cooking can be observed. **Acknowledgments** The authors thank Andalusian Regional Government (Regional Ministry of Innovation, Science and Enterprise) and FEDER for financial support Project Ref.P11-AGR-7034.

A COMPARISON OF BIOACTIVE COMPOUNDS IN FRESH AND FRESH CUT VEGETABLES

M I. Alarcon-Flores¹, R. Romero-González¹, J L. Martinez-Vidal¹, F J. Egea-Gonzalez¹, A. Garrido-Frenich¹

¹Group "Analytical Chemistry of Contaminants", Department of Chemistry and Physics, Research Centre for Agricultural and Food Biotechnology (BITAL), University of Almería, Agrifood Campus of International Excellence, Almería, Spain

Background and objectives: Consumption of fruit and vegetables could help to prevent diseases. These beneficial effects have been attributed to bioactive compounds. Nowadays, there is an increased interest of the consumers by fresh-cut products. Therefore, it is important to investigate if the minimal processing may provoke losses of important bioactive compounds. The purpose of this work was the comparison of the content of several families of bioactive compounds in fresh and fresh-cut products, as tomato, eggplant, grape, carrot and broccoli, in order to get a comprehensive view of the presence of bioactive compounds in fresh and fresh-cut products. Other variables such as type of cut and shelf life were also evaluated.

Methods: The extraction procedure was based on a simple solid-liquid extraction with methanol:water (80:20,v/v), and the extract was injected into an ultra-high-performance-chromatographic system coupled to triple quadrupole mass analyzer.

Results: Phenolic acids were the most abundant class of phytochemicals in tomato, carrot and eggplant, whereas glucosinolates were majority in broccoli and flavonols in grape. When bioactive compounds contents were compared in fresh and fresh-cut products, the concentrations in fresh products were higher than in fresh-cut, except for phenolic acids in eggplant, although in most cases the difference was not statistically significant. On the other hand, it was observed that phenolic acids were the class most affected by type of cut. Furthermore, it was noted that the storage at lower temperature (4 °C) provides higher levels of the assayed compounds.

Conclusions: Fresh and fresh-cut products have similar beneficial properties with respect to their content in bioactive compounds, except tomato, which contains a higher amount of phenolic acids in fresh products.

Acknowledgments: The authors are grateful to Andalusian Regional Government (Regional Ministry of Innovation, Science and Enterprise) and FEDER for financial support Project Ref.P11-AGR-7034 and to Guzmán-Gastronomía.

PO2680

FUNCTIONAL/NUTRACEUTICAL EVALUATION OF CITRUS PEEL AGAINST DYSLIPIDEMIA

M. Butt¹, H. Ashraf¹, F. Anjum¹

¹National Institute of Food Science and Technology, University of Agriculture, Faisalabad, Pakistan

Background and objectives: Functional/nutraceutical foods are the core element of diet based therapy owing to their health enhancing potential beyond the basic function of supplying nutrients. Citrus peel, a byproduct of food processing industry has group of bioactive components that play a significant role against various physiological threats. The most prevalent polymethoxylated flavones are tangeretin and nobletin that have physiological importance with enormous food and pharmaceutical applications. The present project was designed to establish the dyslipidemic potential of citrus peel extract with special reference to their active ingredients.

Methods: The citrus peel was characterized followed by product development phase and nutraceutical evaluation for the management of dyslipidemia through experimental rats modeling. The citrus peel extracts were prepared by using methanol, ethanol and water and checked for FRAP, DPPH, flavonoids, flavonols and ABTS. Functional/nutraceutical cakes and biscuits were also prepared. Further, the citrus peel extract and powder were assessed for cholesterol, low density lipoprotein (LDL), high density lipoprotein (HDL) and triglycerides (TG) in Sprague Dawley rats.

Results: The citrus peel methanolic extract showed higher total polyphenols, FRAP, DPPH, flavonoids, flavonols & ABTS values in comparison with other extracts. Functional/nutraceutical cakes and biscuits were prepared after adding citrus peel extract and powder. Bioevaluation comprised of three groups of rats feeding on control diet, diet containing 10% citrus peel and diet containing 5% citrus extract. Cholesterol and LDL were significantly reduced ranging from 6.01 to 7.25 and 8.78 and 11.39%, respectively with subsequent rise in HDL. Furthermore, the values for liver and kidney functions tests were within the normal range showing the safety prepared products.

Conclusions: In the nutshell, citrus peel based edibles have potential to curtail different physiological malfunctioning thus should be encouraged in diet based therapy among the vulnerable segments.

Key words: Citrus peel, functional/nutraceutical, dyslipidemia, cholesterol, HDL

PO2681

FAVORABLE EFFECT OF CONSUMPTION OF LILY BULB ON COLONIC LUMINAL ENVIRONMENT IN RATS FED A HIGH-FAT DIET

Y. Okazaki¹, E. Fukuda¹, H. Chiji¹, N. Kato²

¹Faculty of Human Life Sciences, Fuji Women's University, Ishikari, Japan

²Graduate School of Biosphere Science, Hiroshima University, Higashi-Hiroshima, Japan

Background and objectives: The bulbs of lily (*Lilium leichtholmii*) are traditionally consumed in East Asia, including Japan, as both food and oriental medicine. It contains high amounts of starch, protein, and dietary fibers including glucomannan. This study investigated the effect of dietary lily bulb on the colonic luminal environment in rats fed a high-fat (HF) diet.

Methods: In experiment 1, male SD rats were fed a HF diet (30% beef tallow) with or without 5% or 10% raw lily bulb powder for 3 weeks. In experiment 2, rats were fed a HF diet with or without 7% steamed or raw lily bulb powder for 3 weeks. Intestinal luminal variables, including IgA, mucins (indices of intestinal immune and barrier functions, respectively), organic acids and microflora were measured.

Results: In experiment 1, Food intake and growth were reduced in the 10% raw lily bulb group. Dietary raw lily bulb significantly increased fecal IgA and mucins and cecal Lactobacillales in a dose dependent manner. In experiment 2, Food intake and growth were unaffected by the dietary treatment. Fecal IgA and cecal Lactobacillales were significantly elevated in the raw lily bulb group, and similar trends were observed in the steamed lily bulb group. Consumption of both steamed and raw lily bulb markedly elevated fecal mucins, the weight of cecal digesta and cecal organic acids, including lactate, propionate, acetate and butyrate. Compared with the control group, fecal β -glucosidase activity was significantly higher in the raw lily bulb group, but not in the steamed lily bulb group. Dietary steamed lily bulb significantly reduced mesenteric adipose tissue weight and increased fecal triglyceride excretion.

Conclusion: The results suggest a favorable effect of lily bulb on colon health in rats fed a HF diet.

Key words: lily bulb, colonic luminal environment, rats

⁴Unit of Nutrition and Dietetics, Virgen de las Nieves Hospital, Granada, Spain

Background and objectives: Probiotics are microorganisms that provide health benefits to the host when ingested in adequate amounts. We have described the identification and characterization of 3 novel bacterial strains (*Lactobacillus paracasei* CNCM I-4034, *Bifidobacterium breve* CNCM I-4035 and *Lactobacillus rhamnosus* CNCM I-4036), which were isolated from the feces of exclusively breast-fed infants. Prior to its evaluation for beneficial effects in humans, safety of any probiotic strain must be demonstrated. Here we describe a trial with healthy volunteers to test the safety of the aforementioned strains.

Methods: One hundred and three healthy patients underwent a 15-day washout period after which they were randomly and blindly divided to receive a placebo or a daily capsule containing 10^{E10} CFUs one of the 3 strains for 30 days. The intervention period was followed by a second washout of another 15 days. Patients did not take any fermented product for the entire duration of the study.

Results: Three volunteers dropped out of the study. No patient had side effects of any kind. Volunteers that received the placebo showed a decrease in serum IL-12 and IL-4 concentrations, as well as decreased populations of *Atopobium*, *Lactobacillus* and *Bifidobacterium* in feces. IgA concentration and *Clostridium coccoides* population increased in the feces, whereas IL-12 decreased in serum, of patients fed *B. breve* CNCM I-4035. Intestinal colonization occurred in 86% of the patients fed *L. rhamnosus* CNCM I-4036. In these patients, increases in the population of *Clostridium leptum* in feces, and IL-10, IL-4, IL-10/IL-12 in serum, together with decreases in IL-12 and TNF-alpha/IL-10, occurred. Patients fed *L. paracasei* CNCM I-4034 showed augmented IL-10/IL-12 ratio.

Conclusions: Intake of the three novel probiotic strains by healthy patients is safe. Altogether, results obtained warrant the undertaking of similar studies in patients affected of pathologies such as intestinal-related diseases.

Key words: probiotics, safety.

PO2683**DETERMINATION OF THE PHENOLIC COMPOSITION OF GRAPE JUICE AND DIFFERENT TYPES OF WINES FROM MONTEVIDEO AND INTERIOR OF URUGUAY**

M. Panzl¹, F. Noguera¹

¹Department of Nutrition, Catholic University of Uruguay, Montevideo, Uruguay

Background and objectives: Several epidemiological studies have examined the relationship between the consumption of red wine and its derivatives rich in phenolic compounds and cardiovascular disease. That is why we propose the following problem: if the wine contains polyphenols, anthocyanins in them and these compounds provide health benefits, Can grape juice polyphenols present and provide similar benefits? The objectives: Determination of the phenolic composition in grape juice and different types of wines (red, white and pink) from the departments of Canelones, Montevideo and Paysandú in the June-July period of 2011.

Methods: A descriptive cross with a type of non-probability sample of convenience with a total of 67 samples from 20 local wineries. Each sample was analyzed in the total polyphenol index (IPT) and total anthocyanins (At), using the methods of ultraviolet absorbance at 280 nm and 520 nm (nanometers).

Results: The group of red wines showed the highest values in the quantification of total phenolics and total anthocyanins (76.79 and 655.33 mg / l), then follows the grape juice (32.36 and 175.88 mg / l). Thirdly rosés group (14.89 and 74.46 mg / l), and the white wine group has the lowest values (11.90 and 3.28 mg / l).

Conclusions: The grape juice could be considered a food source of antioxidants, which contributes to health, due to the polyphenolic compounds content.

Key words: antioxidant, phenolic compounds, juice.

PO2684**INCREASING THE RESISTANT STARCH CONTENT OF CHICKPEA FLOUR BY ENZYMATIC AND THERMAL TREATMENTS**

A. Guadix¹, R. Morales-Medina¹, M. Munio¹, P. Gonzalez-Tello¹, F. Camacho¹, E.M. Guadix¹

¹Department of Chemical Engineering, University of Granada, Spain

Background and objectives: Resistant starch (RS) is the starch which can not be absorbed in the small intestine of healthy humans. RS has positive effects on diabetes, cardiovascular diseases, colonic health, obesity and osteoporosis.

Considering potential sources of RS, the scientific literature has reported that the starch contained in legumes can be transformed into RS by means of enzymatic and thermal methods. The purpose of this work was to compare the efficiency of both methods intended to increase the RS content of chickpea flour.

Methods: In the case of enzymatic treatment, a suspension of chickpea flour was pre-heated at 100 °C for 15 min. Then, the suspension was hydrolyzed with pullulanase (EC. 3.2.1.41) for 24 h. In the case of thermal treatment, 4 heating-cooling cycles were applied. Each cycle comprised heating at 100 °C for 30 min plus cooling at 4 °C for 24 h. The RS content of the lyophilized samples was determined using the AACC Official Method 32-40, which included a simulated digestion with α -amylase at 37 °C for 16 h.

Results: The initial RS value of the flour (0.88%) improved significantly by the usage of both treatments. Regarding the enzymatic one, after the pre-heating step, the RS amount reached 4.47%. This value was further enhanced up to 7.47% at the end of the hydrolysis. By the usage of the thermal treatment, the RS content increased up to 8.74%, 9.85%, 10.28% and 10.67%, after 1, 2, 3 and 4 cycles, respectively.

Conclusions: Thermal as much as enzymatic treatments were effective in order to enhance the amount of RS which is present in raw chickpea flour. Due to hydrolysis with pullulanase, RS content was multiplied by a factor of 8.5, while executing 4 heating-cooling cycles provided a factor of 12.

Key words: resistant starch, simulated digestion, legume, chickpea.

PO2685

INFLUENCE OF SIMULATED DIGESTION IN THE ACE INHIBITORY ACTIVITY OF GOAT MILK PROTEIN HYDROLYSATES

A. Guadix¹, F.J. Espejo-Carpio¹, M.C. Almecija¹, R. Perez-Galvez¹, P.J. Garcia-Moreno¹, E.M. Guadix¹

¹Department of Chemical Engineering, University of Granada, Spain

Background and objectives: Some peptides derived from food proteins have shown angiotensin converting enzyme (ACE) inhibitory activity, which can be useful in the formulation of functional foods intended for hypertensive individuals. However, these peptides must remain active after the digestion process in order to exert its inhibitory action. The objective of this work was to evaluate the effect of simulated digestion on the ACE inhibitory activity of protein hydrolysates from goat milk.

Methods: Goat milk casein hydrolysates were produced by three different enzymatic treatments, using subtilisin, trypsin and the mixture of both. The hydrolysates were submitted to

a simulated digestion process, which consisted in two consecutive hydrolysis with pepsin (1 hour, 37 °C, pH 2) and pancreatin (2 hours, 37 °C, pH 7.5). The ACE inhibitory activity of hydrolysates was evaluated before and after the simulated digestion by a spectrophotometric assay using 2-furanacryloyl-L-phenyl-alanyl-glycylglycine as substrate.

Results: The values of the IC₅₀ (defined as the concentration of hydrolysate which reduces the ACE activity by 50%) of digested hydrolysates were compared with the values of the initial samples (248 microg/L). When the complete simulated digestion was performed, an increase of 3% in the IC₅₀ only was measured in the case of the subtilisin hydrolysate. For the trypsin hydrolysate, it was reached the highest worsening in the IC₅₀ (53%). Finally, when the mixture of both enzymes was employed, an intermediate increase (16 %) in the IC₅₀ was observed.

Conclusions: The hydrolysis of goat milk caseins with subtilisin, trypsin or a mixture of both enzymes yielded hydrolysates which maintained their ACE inhibitory activity to some extent after being subjected to simulated digestion with pepsin and pancreatin.

Key words: Bioactive peptides, ACE-inhibitory activity, protein hydrolysates, goat milk, simulated digestion.

PO2686

AZUKI(RED) BEANS PASTE: EFFECT OF COOKING TIME ON RESISTANT STARCH CONTENTS AND PARTICLE MORPHOLOGY

A. Kamei¹, R. Atsumi¹

¹Division of Domestic Science Education, Miyagi University of Education, Sendai, Miyagi prefecture, Japan

Background and objectives: Traditional Japanese sweets are very popular and are often eaten by middle-aged and elderly people. A lot of traditional Japanese sweets are made using an Azuki bean paste, so called 'An' in Japanese. Azuki beans are a good source of carbohydrate as well as protein, because they are starchy pulse. Resistant starch (RS) escapes digestion until reaching colon and acts like dietary fiber. Recently, many researchers suggest taking this type of dietary fiber for our health benefits. The purpose of this study was to investigate the effect of different cooking times on the amount of RS and the morphology of 'An' particles.

Methods: Azuki beans were boiled 50, 70, 90 minutes in water. The ratio of Azuki beans to water was one to five. After grinding, each mixture was strained through a sieve in order to remove husk and put into cheesecloth. Then, a 6kg of stone was placed on cheesecloth for 1 hour to discard excess water and to make 'An'. The amount of RS of each 'An' was measured and each 'An' particles was observed by optical microscope.

Results: The amount of RS of 'An' in 50, 70, 90 minutes cooking time were 6.4%, 5.0%, 4.4%, respectively. This result showed that increasing cooking time was decreasing the amount of RS. Optical microscope observation showed that as the cooking time become longer, the ratio of damaged or ruptured 'An' particles increased.

Conclusions: These results indicated that damaged 'An' particles had more digestible starch than intact 'An' particles. One of the possible reasons could be that intact 'An' particles resist digestive enzymes. Another reason might be that a starch in 'An' particles affects its structure during cooking.

Key words: Azuki bean paste 'An', resistant starch, 'An' particles

PO2687

EXTRACTS OF SENEN YEMENI PLANTS WITH ANTIOXIDATIVE AND ANTIBACTERIAL ACTIVITIES

R A S. Thabit¹, X R. Cheng¹, X. Tang¹, J. Sun¹, Y H. Shi¹, G W. Le¹

¹State Key Laboratory of Food Science and Technology, School of Food Science and Technology, Jiangnan University, Wuxi, China

Background and objective: The increasing interest in natural dietary components has focused attention on plants used as food or spices which are a rich source of bio-nutrients or bio-active phytochemicals. The most important of these bioactive compounds of plants are alkaloids, tannins, and phenolic compounds. Herbs and spices have been employed since ancient times as flavouring and storing agents for food, attributing to their antimicrobial and antioxidant components. This study aims to find out the phenolic contents of the most important plants grown in Yemen and their antioxidative and antibacterial activities.

Methods: The total contents of phenolic (TPC), flavonoid (TFC), tannins (TTC), and anthocyanin (TAC) in the extracts of seven Yemeni plants: *Punica granatum*, *Zizyphus vulgaris*, *Ruta graveolens*, *Lavandula officinalis*, *Thymus vulgaris*, *Conyza bonariensis*, and *salavia officinalis* were determined by Folin-Ciocalteu method, flavonoid-aluminium complex method, Folin and Ciocalteu method, and pH-differential method. The antioxidative activities of the extracts were determined by DPPH and β -carotene bleaching. The effects of the extraction on the growth inhibition of some indicators of foodborne illness bacteria were investigated.

Results: There is a great variability in the TPC, TFA, TTC, TAC, inhibition of DPPH radical and β -Carotene bleaching of the extraction obtained from the seven plants. *C. bonariensis* and *P. granatum* presented the best antioxidative activities, had the highest TPC, TFC, TTC, and TAC and strongest inhibi-

tion of DPPH radical and β -Carotene bleaching. Extracts of *C. bonariensis* and *P. granatum* showed inhibitory effects on the gram positive and negative bacteria at all added doses.

Conclusions: Extracts of seven Yemeni plants showed antioxidative and antibacterial activities. Extracts of *C. bonariensis* and *P. granatum* possessed the best activities may attribute to their high content of polyphenols.

Key words: Total phenolic, Antioxidant, Antibacterial, *Conyza bonariensis*, *Punica granatum*

ALGINATE ENRICHED BREAD AS AN OBESITY TREATMENT

D. Houghton¹, M. Wilcox¹, I. Brownlee², C. Seal³, J. Pearson¹

¹ICaMB, Newcastle University, Newcastle Upon Tyne, NE2 4HH, UK

²Food and Human Nutrition Department, Newcastle University office, 180 Ang Mo Kio, Singapore

³Human Nutrition Research Centre, School of Agriculture, Food and Rural Development, Kings Road, Newcastle upon Tyne, UK

Background and objectives: Obesity is a fast growing medical issues worldwide is fast becoming one of the leading causes of mortality. Data from our laboratory have demonstrated that alginate possess the ability to inhibit pancreatic lipase in-vitro. The purpose of the present study was to determine if alginate enriched bread inhibits fat digestion in-vitro and in-vivo.

Methods: Control bread and alginate bread developed by Greggs Plc was used. Trioctanoate and tributyrates were digested in an open model gut system developed within our laboratory which replicates digestion in the mouth, stomach and small intestines. The substrate was added to the model gut alone or with either 5.2 g alginate bread or 5.2 g control bread (n=6). 1ml samples were taken every 15 minutes from 0-180 minutes and analysed for free glycerol. Preliminary data from a double blind study using ileostomy patients (n=13) fed either an alginate bread (105 g) or control bread (105 g) (visits were one month apart), which included 20 g of butter post fasting. Blood samples were taken at baseline and then every 30 minutes. A t-test was used to compare control bread and alginate bread with normal substrate digestion, and to compare total triglycerides in plasma between alginate and control bread.

Results: At 180 minutes there was a significant reduction in fat digestion of 47.7% (1.2) and 32.5% (2.4) for trioctanoate (p>.05) and tributyrates (p>.05) respectively. Data from ileostomy patients indicated a reduction in the total triglycerides in the plasma ranging from 9-34% compared with the control bread, with a significant difference at 210 minutes (p>.05).

Conclusions: This study provides evidence that normal foods supplemented with alginate could be used to treat obesity/overweight. Further analysis is required of a larger group of ileostomy patients and to assess the ileum effluent fluid to demonstrate undigested lipids.

Key words: obesity, digestion, alginate.

PO2689

EFFECTS OF RESVERATROL ON CHANGES INDUCED BY HIGH-FAT FEEDING ON CLOCK GENES IN RATS

J. Miranda^{1,2}, M.P. Portillo^{1,2}, J.A. Madrid³, N. Arias^{1,2}, M.T. Macarulla^{1,2}, M. Garaulet³

¹Nutrition and Obesity Group, Dpt. Nutrition and Food Sciences, Faculty of Pharmacy, University of the Basque Country (UPV/EHU), Vitoria, Álava, Spain
²CIBERobn Physiopathology of Obesity and Nutrition, Institute of Health Carlos III (ISCIII), Madrid, Spain

³Dpt. Physiology, Faculty of Biology, University of Murcia, Murcia, Spain

Background and objectives: In mammals, the main component of the circadian system is the suprachiasmatic nucleus of the hypothalamus, but circadian clocks are also present in most peripheral tissues such as adipose tissue or liver. The purpose of the study was to analyze the potential effects of resveratrol on changes induced by high-fat feeding in the expression of different clock genes and clock-controlled genes (CCG) in white adipose tissue and liver from rats.

Methods: 24 rats were divided into three groups: the control group fed a standard diet and two groups fed a high-fat diet supplemented with resveratrol (RSV) or not (HF). The polyphenol was daily added to the diet in amounts that assured a dose of 30 mg/kg body weight/d. The expression of clock genes (*Bmal1*, *Clock*, *Npas2*, *Cry1* and *Per2*) and CCGs (*PPAR γ* , *Rev-Erba*, *Rora* and *Sirt1*) was analyzed by real time RT-PCR in epididymal adipose tissue and liver.

Results: Final body weight, adipose tissue weights and liver weight were significantly higher in animals from HF groups than those from control group. Resveratrol reduced body weight and the sum of adipose tissues but these parameters did not reach the values observed in control rats. By contrast, resveratrol did not modify liver weight. When compared with the controls, the RSV group showed similar patterns of response to HF group, except for *Rev-Erba*, which was down-regulated in both analyzed tissues.

Conclusions: The effects of resveratrol on changes induced on the circadian clock machinery in adipose tissue and liver by

high-fat feeding, together with the weight loss induced in rats, allow this polyphenol to be proposed as a therapeutic agent in the chronobiological treatment of obesity.

Key words: High-fat feeding, Clock gene, Resveratrol, Rats

PO2690

MALAYSIAN SELECTED LOCAL BASED DISHES: CONTENTS OF MACRONUTRIENT, ISOFLAVONE, TOTAL PHENOL AND ANTIOXIDANT ACTIVITY.

H. Haron¹, L. Siew Fen¹, Y. Zu Wei¹,

¹Nutrition Science Programme, School of Health Care, Faculty of Health Sciences, Universiti Kebangsaan Malaysia, Kuala Lumpur, Malaysia

Background and objectives: Phenolic content in soybean have been identified to prevent chronic diseases through antioxidative activity. This study was carried out to determine the macronutrient, total phenol, isoflavone contents and anti-oxidative activity in selected soy based dishes.

Methods: Eight types of local soy based dishes were bought from restaurants and food stalls located in Kuala Lumpur. Each sample from two different locations were analysed in duplicates. Proximate contents were analysed by using AOAC methods (1997) while carbohydrate content was calculated by difference. Isoflavone content was analysed using High Performance Liquid Chromatography method by Hutabarat et al. (2000). Total phenol content (TPC) was determined using Folin-Ciocalteu method while antioxidant activities were assessed using DPPH radical scavenging assay and B-carotene bleaching assay.

Results: The soy based dishes contained 8.18-161.34 mg total isoflavone/ 100g food sample, 34.91-87.64% moisture, 3.93-13.83% protein, 4.35-32.90% fat, 0.53-41.74% total carbohydrate and 1.20-1.92% ash. Average TPC in all the dishes was in the range of 19.14-62.82 mg of GAE/g wet weight. Antioxidant activities based on DPPH radical scavenging assay and B-carotene bleaching assay were significantly ($p < 0.01$) correlated with TPC. Total isoflavone content was significantly ($p < 0.01$) correlated with TPC ($r=0.711$), DPPH radical scavenging assay ($r=0.720$) and B-carotene bleaching assay ($r=0.720$). Dishes containing tempeh has significantly ($p < 0.05$) higher isoflavone content compared to other dishes containing other type of soy products.

Conclusions: Soy product like egg tofu contained highest moisture but lowest protein and isoflavone contents. Method of cooking such as frying increased the fat content in the dishes. Dishes containing fermented food such as tempeh have high amount of isoflavone and significantly higher antioxidant activity compared to other type of soy products.

Key words: Soy based dishes, Isoflavone, Total phenol content, Macronutrient, Antioxidant activity.

PO2691**COMPARATIVE ANALYSIS OF VOLATILES FROM PLANT CZ BY HDE-GC/MS***K. Chang¹, G. Kim¹*¹Plant Resources Research Institute, Duksung Women's University, Korea

Background and objectives: The purpose of this report was to evaluate and compare the chemical variability of the volatile compositional differences of CZEOS in Korea. Volatile compositional differences of CZEOS prepared via different producing methods (wild-growing and cultivate-growing) were also determined.

Methods: The dried CZ were crushed for 10 sec by a blender (NJ-8060SM, NUC Electronics, Seoul, Korea) and extracted by hydro-distillation extraction (HDE) method for 3 hr using a Clevenger-type apparatus (Hanil Lab Tech Ltd, Incheon, Korea), and analyzed by gas chromatography-mass spectrometry (GC/MS).

Results: Total 57 and 55 volatiles constituents were confirmed in CZEOS from wild-growing and cultivate-growing. Alcohols were predominant in the volatiles of CZ flowers (%): the wild, 37.57; and the cultivated, 30.34.

Conclusions: There was some differences between CZEOS from wild-growing and cultivate-growing; the yields of CZEOS were 0.35 and 0.12%(v/w), respectively. Borneol was the most abundant volatiles in the wild-growing and *f*N-curcumene was the major component in the cultivated.

Key words: volatile composition, producing methods, hydro-distillation extraction borneol, *f*N-curcumene

PO2692**EFFECTS OF SERICULTURAL PRODUCTS ON BLOOD GLUCOSE AND LIPID STATUS IN STREPTOZOTOCIN-INDUCED DIABETIC MICE***S H. Cho¹, S W. Choi¹*¹Department of Food Science and Nutrition, Catholic University of Daegu, Gyeongbuk, Korea

Background and objectives: The effects of four types of sericultural products on the blood glucose and lipid status as well as peroxidative state and muscle glycogen level were investigated under diabetic condition. The four products were silkworms (SW), mulberry leaves (ML), mulberry fruit (MF), and native mulberry fruit (kujippong; NMF).

Methods: Dried powders of the four products were added to diets (AIN-93G) for the corresponding four groups of streptozotocin-induced diabetic mice and fed for four weeks. Non-diabetic (Normal) and diabetic mice fed no test product

(DM-Control) were another experimental groups to compare the effects of test diets.

Results: Compared to the DM-Control (mean; 289.4±23.1 mg/100mL), the NMF group (mean; 255.3±19.9 mg/100mL) increased blood glucose at reduced rate most effectively among the test groups. Serum cholesterol and triglyceride levels were lowest in the ML group (114.2±17.5 and 136.9±14.4 mg/100mL) but those of SW, MF, and NMF groups were tended to be lower than the DM-Control group (159.6±14.7 and 169.0mg±15.1 mg/100mL). Liver cholesterol and triglyceride contents were lower in the MF (12.8±1.2 and 12.9±1.9 mg/g) and the NMF groups (12.9±1.0 and 13.2±1.5 mg/g) than the DM-Control group (16.5±1.3 mg/g, and 21.1±2.3 mg/g). Liver level of thiobarbituric acid reactive substances (TBARS) was lower in the NMF (20.9±1.9 nmol MDA/g) than the other groups while muscle glycogen level was higher only in the MF group than the DM-Control group.

Conclusions: A proper combination of mulberry fruit, kujippong, and mulberry leaves as the ingredients of functional foods helps blood glucose and lipid status maintain proper levels and improves body peroxidation under diabetic state.

Key words: mulberry, blood glucose, lipid, diabetic mice

PO2693**THAI FRUIT SOURCES FOR LUTEIN AND ZEAXANTHIN : PROTECTIVE EFFECTS AGAINST AGE-RELATED MACULAR DEGENERATION (AMD)***N. Vatanasuchart¹, P. Khaiprapai², U. Phukasmas¹*¹Department of Nutrition and Health, Institute of Food Research and Product Development, Kasetsart University, Bangkok, Thailand²Food Quality Assurance Services Center, Institute of Food Research and Product Development, Kasetsart University, Bangkok, Thailand

Background and objectives: Lutein and zeaxanthin play an important role in protecting against age-related macular degeneration (AMD), rising an evidence in the elderly. This study was aimed at determining lutein and zeaxanthin in 170 Thai fruits.

Methods: Fruit sample was extracted with 0.1% BHT in MeOH and analyzed by HPLC.

Results: It showed that lutein was predominately found in Thai fruits about 122 samples or 71.76% of total samples, while zeaxanthin was rarely found about 65 samples or 38.24 %. When fruits were classified according to sugar content, Thai melon (Tangthai) contained the highest lutein of 66.17 ± 26.4 µg/100g in group of sugar < 10%. Among all samples, Tangthai also provided the highest lutein, following with roseapple (Phed), watermelon (Torpedoe and Kinaree), guava (Kimju),

mango (Pramkaymea) and pameló (Kaonumpueng), respectively. In group of sugar between 10-20%, banana (Namwa) contained the highest lutein of $26.04 \pm 6.76 \mu\text{g}/100\text{g}$ following with other banana varieties and sapote (Lamod). In group of sugar > 20%, all jackfruits contained lutein and Sritong variety had the highest lutein of $22.91 \pm 8.25 \mu\text{g}/100\text{g}$. Whereas ripe mangoes and sweet tamarinds did not contain lutein. For determination of zeaxanthin, mango (Munkunsri), in group of sugar < 10% had the highest of $24.93 \pm 49.86 \mu\text{g}/100\text{g}$, following with papaya (Kekdum), mango (Keowsavoy), pameló (Kaonumpueng), mango (Pramkaymea) and pameló (Tongdee), respectively. In group of sugar between 10-20%, Maprang showed the highest zeaxanthin of $27.29 \pm 26.43 \mu\text{g}/100\text{g}$, followed with Mayongchid, mango (keowyai), orange, pineapple and starfruit, respectively. Source of both lutein and zeaxanthin were Tangthai, pameló, roseapple, raw mangoes, Maprang, Mafueng, orange, sapote, purple passionfruit and pineapple.

Conclusions: Thai fruits are important source of lutein and zeaxanthin which should be regularly consumed to promote eye health, particularly for the fruits with low sugar.

Key words: Thai fruits, lutein, zeaxanthin, eyehealth.

PO2694

ADLAY CONSUMPTION AMELIORATED THE PROGRESSION OF ALCOHOLIC LIVER DISEASES

H.Y. Yang¹, W.J. Yeh², H.Y. Weng², C.Y. Chein², J.R. Chen²

¹I-Shou University, Kaohsiung, Taiwan

²Taipei Medical University, Taipei, Taiwan

Background and objectives: Fatty liver has become a health problem in Taiwan and dietary modification may show beneficial effects. Adlay has been reported to exhibit hypolipidemic, antiobesity and antiinflammation effects. Therefore, the aim of the study is to investigate effects of adlay on alcoholic liver disease.

Methods: We fed rats with ethanol liquid diet to induce alcoholic liver disease (group E) and added 22.1 g/L (group A) and 44.2 g/L adlay (group B) powder in diet of rats. After a 12-wk experimental period, rats were sacrificed for blood and liver sample collections.

Results: We found elevation of hepatic index AST and ALT in the ethanol group since the 4th week and adlay consumption attenuated the elevation of hepatic index. At the end of the study, the ethanol group showed hepatic steatosis and higher levels of liver malondialdehyde, tumor necrosis factor- and early fibrosis markers hydroxyproline than the control group and the two adlay groups. We also found that group A had lower cytochrome P450 2E1 protein expression than group E. In the histological analysis, the fatty change scores of both central and portal vein zone of group A were also lower than group E.

Conclusions: These results suggested that dietary adlay consumption may be beneficial in the prevention of alcohol-induced hepatic fat accumulation and inflammation.

Key words: alcohol, fatty liver, adlay, inflammation

PO2695

BENEFICIAL EFFECTS OF SOY PROTEIN AND β -CONGLYCININ ON NONALCOHOLIC LIVER DISEASES VIA AMELIORATING HEPATIC STEATOSIS AND INSULIN RESISTANCE

W.J. Yeh¹, C.Y. Chien¹, H.Y. Weng¹, J.R. Chen¹, H.Y. Yang²

¹Taipei Medical University, Taipei, Taiwan

²I-Shou University, Kaohsiung, Taiwan

Background and objectives: Nonalcoholic fatty liver disease (NAFLD) is the most common liver disorder in the Western world and is related to obesity, insulin resistance, inflammation, and oxidative stress. Nonalcoholic steatohepatitis (NASH) is the most extreme form of NAFLD, and is characterized by steatosis with necroinflammation. This study aims to explore the beneficial effects of soy protein and soy-conglycinin on hepatic steatosis and insulin resistance in NASH.

Methods: Male Wistar rats were induced to have NASH with high-fat-liquid diet for 16 weeks and divided into NASH group (N), soy protein group (S), and β -conglycinin group (B). Experimental diets were based on high-fat-liquid diet with 50% soy protein or equivalent β -conglycinin as substitution of casein for 8 weeks. Plasma and liver samples were collected for analysis of lipid profiles, cytokines and insulin sensitivity, as well as cytochrome P-450 2E1 (CYP2E1) protein expression and pathological analysis in the liver. Feces were assembled for lipid content analysis.

Results: Rats treated with high-fat diet for 16 weeks showed abnormal plasma alanine aminotransferase (ALT) and aspartate aminotransferase (AST) activity, and they also exhibited increasing levels of TG, interleukine(IL)-1 and MDA concomitant with an upregulation of CYP2E1 in the liver. After 8-wk soy protein or β -conglycinin consumption, hepatic TG, tumor necrosis factor (TNF)- and MDA concentrations were lower than those in the NASH group, whereas the systemic insulin sensitivity was also improved by β -conglycinin. We also found improvement of hepatic steatosis in pathological analysis.

Conclusions: Soy protein and soy β -conglycinin may improve the liver function in rats with NASH by lowering lipid levels in the liver and ameliorating inflammation and insulin resistance.

Key words: soy protein, conglycinin, fatty liver, nonalcoholic steatohepatitis

GREEN TEA EXTRACT SUPPRESSES DISUSE MUSCLE ATROPHY IN MICE

H. Tachibana¹, M. Murata¹, R. Kosaka¹, K. Kurihara¹, A. Nesumi², M. Maeda-Yamamoto³, K. Yamada¹

¹Kyushu University, Faculty of Agriculture, Japan

²National Institute of Vegetables and Tea Science, NARO, Japan

³National Food Research Institute, NARO, Japan

Background and objectives: A variety of stresses, including starvation, muscle disuse, systemic illness, and aging cause skeletal muscle atrophy. Loss of muscle protein primarily is a result of enhanced protein breakdown, which is initiated by the activation of the ubiquitin-proteasome pathway. Two muscle-specific E3 ubiquitin ligases, muscle RING finger 1 (MuRF1) and muscle atrophy F-Box (Atrogin-1) are recognized as markers of muscle atrophy since they are expressed at relatively low levels in resting muscle and transcriptionally increased under a variety of atrophy-inducing conditions. In this study, we examined the suppressive effects of green tea extracts on disuse muscle atrophy and its causative genes in mice.

Methods: Tail suspension was maintained for 10 days using the male C57BL6 mouse, and the oral administration of green tea (Sunrouge or Yabukita) extract continued at 48 h intervals during the tail suspension. Gastrocnemius, soleus, plantaris, and quadriceps femoris were extracted, and weight was measured. In each muscles, the expression level of MuRF1 and Atrogin-1 gene was measured.

Results: The tail suspension group had a significantly decreased ratio of gastrocnemius, soleus, plantaris, and quadriceps femoris weight as compared with the ground group. Oral administration of Sunrouge or Yabukita extract suppressed the decrease of muscle weight ratio in the tail suspension group. The tail suspension induced mRNA expression of MuRF1 and Atrogin-1. The green tea extracts significantly suppressed the induction of MuRF1 and Atrogin-1 in the tail suspension group.

Conclusions: The green tea has a potential to attenuate skeletal muscle atrophy. The inhibitory effect of the green tea may

PO2698**TOCOPHEROL CONTENT AND TOTAL ANTIOXIDANT CAPACITY IN EXTRA VIRGIN ARGAN OIL**

C. Cabrera-Vique¹, A. Rueda¹, C. Samaniego-Sánchez¹, R. Giménez¹, M. Olalla¹, I. Seiquer²

¹Departamento de Nutrición y Bromatología, University of Granada, Granada, Spain

²Instituto de Nutrición Animal, Consejo Superior de Investigaciones Científicas (CSIC), Granada, Spain

Background and objectives: Virgin argan oil has been traditionally consumed in the Magreb countries, but recently its consumption has been extended into European, Japan and USA oil-markets. This oil is rich in oleic and linoleic acids (45 and 34%, respectively) and tocopherols. Polyphenols, sterols, carotenoids, squalene, and other minor compounds also contribute to its antioxidant capacity. However, available bibliography on composition data is scarce and contradictory due to the lack of standardization of the oil extraction method. In this study, we selected extra virgin argan oil to determine tocopherols and total antioxidant capacity (AC) in comparison with other edible vegetable oils widely consumed.

Methods: The presence of alfa, beta, gamma and delta-tocopherols were quantified by HPLC following the UNE-EN ISO 9936-2006 method. AC was determined by ABTS, DPPH and FRAP methods previous sample treatment with a mixture methanol/water.

Results: Total tocopherols in virgin argan oil ranged between 342.3–510.6 mg/kg, being gamma-tocopherol the major fraction (78.3%); alfa, beta and delta-tocopherols represents 11.2, 2.1 and 8.5%, respectively. The mean content in extra virgin olive oil (Picual variety) was 244.1 mg/kg and alfa-tocopherol was the major fraction. In virgin argan oil, the AC varied between 0.099-1.052, 0.056-0.257 and 0.179-0.237 mmol Trolox/kg for ABTS, FRAP and DPPH methods, respectively. Statistically significant higher AC values were detected in virgin olive oil but not in other oils such as soy or sunflower oils. Nosignificant correlation was observed between tocopherol content and AC.

Conclusions: The elevated presence of gamma-tocopherol (a potent antioxidant and anti-inflammatory agent) and its major total AC in relation to other oils corroborates the extra virgin argan oil nutritional value and its potential human healthy properties. Present findings may provide additional market opportunities for the food industry to develop new products.

Key words: argan oil, tocopherols, antioxidant capacity, edible oils

PO2699**BIOACCESSIBILITY OF POLYPHENOLS AND ANTIOXIDANT ACTIVITY IN VIRGIN ARGAN OIL. COMPARISON WITH VIRGIN OLIVE OIL**

C. Cabrera-Vique¹, A. Rueda¹, R. Gimenez¹, M. Olalla¹, I. Seiquer²

¹Departamento de Nutrición y Bromatología, University of Granada, Granada, Spain

²Instituto de Nutrición Animal, Consejo Superior de Investigaciones Científicas (CSIC), Granada, Spain

Background and objectives: Phenolic compounds are of essential importance in the nutritional properties of vegetable oils, mainly related with their potent antioxidant activity. Nevertheless, to achieve any *in vivo* effect these bioactive compounds must be bioaccessible, which depend on their release from the food matrix during the digestion process. The aim of this study was to evaluate the bioaccessibility of total phenols and antioxidant properties of extra virgin argan oils (AO) as compared with extra virgin olive oil (OO), using an *in vitro* gastrointestinal digestion method to approach physiological conditions. Results were compared with those obtained in oil extracts before digestion process.

Methods: Chemical extraction of antioxidants from oils was performed by addition of methanol/acetone/water. Moreover, oil samples were *in vitro* digested in two sequential steps to simulate gastric and duodenal conditions, followed by centrifugation. Chemical extracts and supernatants of digested samples (which represent bioaccessible fraction) were used to determine phenolic compounds (Folin-Ciocalteu method) and antioxidant activity (ABTS and FRAP assays).

Results: Phenol content and antioxidant properties were always higher in bioaccessible oil fractions than in chemical extracts. Phenol content in chemical extracts was lower in AO (ranging 193-624 mg/kg) than in OO (1018 mg/kg), but only minor differences were observed in bioaccessible fractions (AO 2440-3008 mg/kg, OO 3618 mg/kg). A similar tendency was observed for the antioxidant activity, and high correlations were shown between phenol content and ABTS and FRAP assays ($p < 0.001$).

Conclusions: Differences of polyphenol content and antioxidant activity found between AO and OO in chemical extracts were attenuated in the bioaccessible fraction obtained after the *in vitro* digestion process, as comparatively higher release of antioxidants due to digestive enzymes activity seem to occur in AO.

Key words: virgin argan oil, polyphenols, antioxidant activity, bioaccessibility.

PO2702**THE NATURAL IMINUSUGAR D-FAGOMINE REDUCES WEIGHT GAIN AND FAECAL ENTEROBACTERIAL POPULATION OF RATS FED AN ENERGY-DENSE DIET**

S. Ramos-Romero¹, E. Molinar-Toribio¹, J. Perez-Jimenez¹, M. Casado², B. Pina², J.L. Torres¹

¹Department of Biological Chemistry and Molecular Modelling, Institute of Advanced Chemistry of Catalonia (IQAC-CSIC), Barcelona, Spain

²Department of Environmental Chemistry, Institute of Environmental Assessment and Water Research (IDAEA-CSIC), Barcelona, Spain

Background and objectives: Increasing evidence reveals that diet induced changes in the composition of gut microbiota are related to fat accumulation, insulin resistance and obesity. Particularly, high consumption of fat and sucrose increases the proportion of intestinal Enterobacteriales. As D fagomine, an iminosugar analogue of D glucose, agglutinates Enterobacteriaceae and inhibits their adhesion to intestinal mucosa in vitro, we hypothesized that it may have a functional effect on the gut microbiota of animals fed an energy-dense diet.

Methods: Rats were fed a standard diet, a high-fat, high sucrose diet and a high-fat, high sucrose diet supplemented with D fagomine (0.065 %) for 5 weeks. Body weight and feed intake were measured at the onset and at the end of the study. Total bacteria, Enterobacteriales and *Escherichia coli* were quantified by quantitative real-time PCR on faecal DNA.

Results: During the nutritional intervention energy intake was independent of the diet. After 5 weeks the mean weight gain of the group fed the high fat, high sucrose diet was ~13 % higher than that of the standard group whereas the gain in the group supplemented with D fagomine was ~7 % higher ($P < 0.05$). All the animals presented similar amounts of total bacteria in faeces. The relative abundance of Enterobacteriales and *E. coli* excreted was significantly higher ($P < 0.05$) in the high-fat, high-sucrose group. The animals supplemented with D fagomine and the standard group presented similar amounts of faecal Enterobacteriales and *E. coli*.

Conclusions: The iminosugar D fagomine reduces the weight gain and the raise in the proportion of faecal enterobacteria associated with an energy-dense diet. The two effects may be related.

Key words: D-fagomine, iminosugars, obesity, microbiota, *Escherichia coli*

PO2703**INHIBITORY EFFECTS OF PHENOLIC EXTRACTS DERIVED FROM JAPANESE APRICOT FRUIT (PRUNUS MUME) ON RAT SMALL INTESTINAL DISACCHARIDASE ACTIVITIES**

K. Kishida¹, Y. Heya¹, Y. Yamazaki¹, A. Horinishi¹, Y. Ozaki¹

¹Department of Science and Technology On Food Safety, Kinki University, Japan

Background and objectives: Japanese apricot fruit (*Prunus mume* Sieb. et Zucc) has been traditionally used as a folk remedy in Japan. We have already established a preparation method for extracting phenolics from 'umezu', exuding juice of salted Japanese apricot fruits. Umezu phenolics (UP) contain about 12% (w/w) polyphenol as gallic acid equivalents and mainly consist of hydroxycinnamic acids (caffeic acid, ferulic acid, p-coumaric acid) and their derivatives. Chlorogenic acid is one of the most abundant phenolics in UP. The aim of this study was to investigate whether UP inhibits small intestinal disaccharidase activities and suppresses the postprandial elevation of blood glucose levels in rats.

Methods: The disaccharidase (maltase, sucrase, isomaltase, glucoamylase, lactase, trehalase) activities were assayed by the Dahlqvist method using rat intestinal mucosa homogenates. A single oral administration of 2 g/kg BW sugars (glucose, maltose, sucrose, starch) was carried out with or without UP and blood glucose levels were measured up to 120 min.

Results: UP inhibited all disaccharidase activities examined in this study although the effects varied among disaccharidases. Inhibitory effect of chlorogenic acid or non-esterified hydroxycinnamic acids at the concentration equivalent to those in UP was relatively low. This may indicate the presence of other unknown derivatives responsible for the inhibition. The blood glucose levels were significantly altered when sucrose was administered to rats. The suppressive effects after other sugar load tests were marginal.

Conclusions: These results suggest that UP could be useful as a food ingredient to reduce risks for diabetes and obesity.

Key words: Japanese apricot, phenolics, disaccharidase, blood glucose.

PO2704**LACTOBACILLUS PARACASEI CBA L74 AND FERMENTED OAT INHIBIT ENTRANCE OF UNDIGESTED GLIADIN PEPTIDES IN CACO-2 CELLS**

M. Sarno¹, M. Nanayakkara¹, M. Cuomo¹, R. Nigro², S. Auricchio¹, M V. Barone¹

¹Department of Pediatrics and ELFID, University of Naples Federico II, Italy

²Department of Chemical Engineering, University of Naples Federico II, Naples, Italy

Background and objectives: Recent reports describe a role of probiotics as therapeutic approach for Celiac Disease (CD). Undigested A-gliadin peptides P31-43 and P57-68 are central to CD pathogenesis, inducing an innate and an adaptative immune response respectively. They enter enterocytes and localize to vesicular compartment to induce their toxic/immunogenic effects. Our aim is to test the effect of Heinz property strain *Lactobacillus Paracasei* (LP) CBA L74 (International Depository Accession Number LMG P-24778, its supernatant and LP CBA L74 fermented oat on P31-43 and P57-68 entrance in Caco-2 cells to verify its protective effect.

Methods: We treated Caco-2 cells with LP CBA L74, its colonies supernatant or with fermented oat for 30 minutes, and then fluorochrome labeled P31-43 or P57-68 were added to cells cultures. We studied entrance of labeled peptides by fluorescence assay.

Results: LP CBA L74 inhibit both P31-43 (FI: 75%) and P57-68 (FI: 50%) entrance respect to control. LP CBA L74 supernatant is also able to induce decrease of both gliadin peptides entrance in Caco-2 cells (FI: 70% and 50% respectively), indicating that this biological effect is due to some product included in LP CBA L74 supernatant. LP CBA L74 fermented oat is also able to reduce P31-43 entrance in Caco-2 cells respect to not fermented oat (FI: 50%).

Conclusions: LP CBA L74, its supernatant and fermented oat, reduce P31-43 and P57-68 entrance in Caco-2 cells. This is the first study that attempts to explain the molecular mechanism of probiotic effects in the prevention of undigested gliadin peptides toxic effects.

Key words: probiotic, celiac disease, oat, LP CBA L74

PO2705**IRON AND CALCIUM BIOACCESSIBILITY FROM CEREAL DERIVATIVES**

A. Cilla¹, Y. Caldera¹, R. Barberá¹, M J. Lagarda¹

¹Nutrition and Food Science Area, Faculty of Pharmacy, University of Valencia, Valencia, Spain

Background and objectives: Cereal flours and derivatives are ideal foodstuffs for mineral fortification with iron (Fe) and calcium (Ca). Iron deficiency is the most prevalent single nutritional deficiency in the world and is related to delayed cognitive development and intellectual impairment in children. Calcium intake during childhood is associated with increased peak bone mass during adolescence, bone fragility and hip fracture prevention and a reduction in the prevalence of osteoporosis. The aim of this study was to determine the bioaccessibility (amount of mineral available for absorption and utilization) of Fe and Ca in six fortified biscuits and bakery products.

Methods: A simulated gastrointestinal digestion with two stages (gastric with pepsin pH= 2 and intestinal with pancreatin and bile salts pH= 6.5) was applied to obtain the soluble mineral (bioaccessible fraction) by centrifugation. Total and bioaccessible iron and calcium were determined by atomic absorption spectrometry after dry mineralization (450°C).

Results: Bioaccessible iron: 0.5-2 mg Fe/100g sample. The highest Fe content was found in the product with one of the lowest Ca/Fe ratios and one of the highest total Fe contents. Negative influence: Ca content (Ca/Fe ratio) and fiber. Positive influence: Fe content. Iron bioaccessibility was > 20% (23-32%). Bioaccessible calcium: 49-79 mg Ca/100g sample. The highest Ca content appeared in the product with less fiber content and more total Ca. There was a trend of less soluble Ca when fiber increases and in the presence of polyphenols used in the ingredients found in the formulation. Calcium bioaccessibility was > 40% (40-70%).

Conclusions: Bioaccessibility results indicate that cereal derivatives fortified with Fe and Ca are suitable complementary sources for meeting the nutritional requirements for these minerals.

Key words: iron, calcium, bioaccessibility, cereal derivatives

PO2706**ANTIOXIDANT AND SCAVENGING CAPACITY OF SERBIAN OAK TREE**

B. Popovic¹, D. Stajner¹, R. Zdero¹, S. Orlovic², Z. Galic², M. Kebert

¹Faculty of Agriculture, Serbia

²Institute of Lowland Forestry and Environment, Serbia

Background and objectives: Quercus trees, commonly known as oaks, belong to the family Fagaceae. They comprise 450 species worldwide. European oak corresponds well with these requirements, and is mainly represented by Quercus robur L. (pedunculate) and Quercus petraea L. (sessile oak). Bearing in mind that antioxidant potential of two major Serbian oaks-Quercus robur L. and Quercus petraea L. has not been studied well enough, especially their leaves and twigs, the aim of this work was to investigate the in vitro antioxidant activities.

Methods: Antioxidant characteristics of leaves, twigs and acorns from Serbian oak species from Vojvodina province (northern Serbia) were investigated. 80% EtOH (in water) extracts were used for antiradical power (ARP) determinations against DPPH, oNO, O₂o- and oOH radicals, ferric reducing antioxidant power (FRAP), total phenol (TPC) and tannin (TAC) contents. Permanganate reducing antioxidant capacity (PRAC) was determined using water extracts. Beside mentioned parameters, soluble proteins, lipid peroxidation (LP), pigment, proline, flavonoid and proanthocyanidine contents were also determined. The data of different procedures were compared and analysed by multivariate techniques (correlation matrix calculation and principal component analysis (PCA)).

Results: Significant positive correlations were obtained between ARP parameters and contents of phenolic antioxidants. Close interdependence was also observed between PRAC and O₂o- ARP, which were totally opposite to LP on the loading plot. PCA found that investigated organs of two different oak tree species possess similar antioxidant characteristics.

Conclusions: The superior antioxidant characteristics showed oak leaves over twigs and acorns and seems to be promising source of antioxidants with possible use in industry and pharmacy.

Key words: antioxidant; scavenging capacity; oak tree; FRAP, DPPH

PO2707**PRODUCTION OF LIPIDS WITH IMPROVED NUTRITIONAL AND BIOLOGICAL PROPERTIES USING ENZYMATIC INTERESTERIFICATION OF VEGETABLES OILS FROM AMAZONIAN AREA**

G. Macedo¹, P. Speranza¹, A. P. Ribeiro², J. Macedo³

¹Food Science Department; UNICAMP - Campinas State University, Campinas, Sao Paulo, Brasil

²School of Applied Sciences, UNICAMP, Limeira, Sao Paulo, Brasil

³Food Nutrition Department, UNICAMP, Campinas, Sao Paulo, Brasil

Background and objectives: Composition and nature of oils and fats used in the preparation of food products is acquiring greater importance. It is now known that the incidence of cardiovascular disease, diabetes and other metabolic syndromes are directly related to the type and amount of lipid consumed. Currently, the search for lipids non-hydrogenated, low cholesterol and rich in polyunsaturated fatty acids is a need for the food market. Therefore, oil industries have focused mainly on upgrading products to better fit the current needs of consumers, who are looking for healthier foods, manufactured with higher quality. Enzymatic interesterification, involving the rearrangement of fatty acids among glycerol backbones, proving to be a good alternative. The changes in the original triacylglycerol composition modified the physical and nutritional properties of restructured triacylglycerol, thus increasing the potential applications of these lipids. The objective of this study was to produce interesterified blends rich in unsaturated fatty acids using different enzymatic systems.

Methods: For the production of these mixtures were used buriti and muru-muru oils, natural riches of the Amazon region, with huge unexplored and nutritional potential.

Results: The results obtained of regiospecific distribution of fatty acids on triacylglycerol (¹³C NMR) indicate the production of oils rich in unsaturated fatty acids at positions sn-1,3 for both enzyme systems tested. The concentration of unsaturated fatty acids at positions sn-1, 3 of triacylglycerol increased from 33.5% in the original mixture to 54.1% in the mixture produced using lipase from Rhizopus sp, and 54.5% in the mixture produced with a commercially available immobilized lipase.

Conclusions: The production of lipids with high content of unsaturated fatty acids in the position sn-1,3 of triglyceride and free of trans fatty acids is of great interest for the development of lipids with high nutritional and biological potential.

Key words: lipase, amazon oils, interesterification.

PO2708**METABOLIC TRANSIT OF N-CARBOXYMETHYL-LYSINE AFTER CONSUMPTION OF MODEL MAILLARD REACTION PRODUCTS**

I. Roncero-Ramos¹, C. Delgado-Andrade¹, F. J. Tessier², C. Niquet-Léridon², C. Strauch³, V. Monnier³, M. P. Navarro¹

¹Instituto de Nutrición Animal, Estación Experimental del Zaidín, CSIC, Spain

²Institut Polytechnique LaSalle Beauvais, Beauvais, France

³Case Western Research University, Cleveland, Ohio, USA

Background and objectives: The purpose of this study was to investigate the intake and excretion of an advanced glycation compound produced in the Maillard reaction, carboxymethyl-lysine (CML), after feeding rats a diet containing Maillard reaction products (MRPs) from the glucose-lysine model system. CML in serum and different tissues was measured to detect target organs.

Methods: Equimolar mixture of glucose-lysine-HCl (GL) was heated (150°C, 90 min) to obtain GL90 sample. It was added to the AIN-93G diet (Control diet) to reach a final concentration of 3% (GL90 diet). Twenty-four weanling rats were distributed into two groups and assigned to dietary treatments for three months, monitoring food consumption and body weights. In the last week, faeces and urine were collected daily and stored as a 1-week pool. After sacrifice, blood was drawn to obtain serum, and some organs removed. CML analysis was performed by HPLC/MS-MS in diets, faeces, urines, serums and tissues.

Results: CML intake increased after GL90 diet consumption (30 vs. 175µg/day for Control and GL90 group), accordingly these animals excreted much more CML in faeces and in urine. As percentage of the intake, faecal CML was 2.5-fold higher in animals fed GL90 diet. However, the rate of urinary CML was lower in them. No changes were found in protein-bound-CML levels in serum whereas CML in bone, tendon and heart increased due to MRPs consumption

Conclusions: Faecal CML excretion is highly influenced by dietary CML levels. The rate of CML excreted in urine was probably limited or saturated depending on the type of compounds ingested. Consumption of assayed MRPs led to a higher CML deposit in heart and tendon, while in bone the increased amounts of CML ought to have an in situ origin as a consequence of a dicarbonyl compounds environment.

Key words: Maillard reaction products; carboxymethyl-lysine; bone; heart; tendon.

PO2709**EFFECT OF GARLIC ESSENTIAL OIL ON PROTEIN OXIDATION IN CHILL STORED PORK PATTIES**

G. Nieto^{1,2}, L. Skibsted², M. Andersen², G. Ros¹

¹University of Murcia, Murcia, Spain

²University of Copenhagen, Denmark, Spain

Background and objectives: Taking into accounts that meat products, such as burger patties, are very susceptible to oxidation as mincing, cooking, and addition of salt promotes the formation of Reactive oxygen species (ROS), the addition of natural antioxidants as essential oil on these meat products could be an interesting strategy to improve their quality. The aim of this study was to determine the effect of garlic (G) essential oil (EO) on protein oxidation in pork burgers manufactured without synthetic additives and stored under retail display conditions.

Methods: For that purpose 3 batches of pork burgers (minced to 5 mm and 2 % salt) were prepared: the control group C; G1 (Level 1: 0.05% EO); and G2 (Level 2: 0.4% EO). The patties were packed with modified atmosphere (70%O₂: 20%CO₂: 10% N₂) (MAP), stored for up to 9 days at 4°C. The oxidative stability was evaluated by the formation of myosin cross-links as analysed by SDS-PAGE, and protein thiol loss as analyzed spectrophotometrically after derivatisation with DTNB.

Results: Results showed that protein thiols were lost to yield myosin cross-links in the pork patties during storage. Garlic was found to promote protein oxidation, as seen by an extreme loss in thiol groups and highly elevated myosin cross-link formation, indicating that G interacts with the thiol groups of the myofibrillar proteins, and thus increases the cross-link formation in pork patties stored in oxygen containing packages.

Conclusions: This study shows that essential oils of garlic should be tested for prooxidant activity before to be used.

Key words: Pork patties; thiol oxidation; protein cross-linking, garlic

PO2710**ANTIOXIDANT AND PROOXIDANT ACTIVITIES OF PHENOLIC COMPOUNDS OF THE EXTRACTS OF ECHINACEA PURPUREA (L.) AND CASTANEA SATIVA MILL**

⁴Zagreb Health School, Zagreb, Croatia

⁵Factory for processing of fruits and vegetables, Orahovica, Croatia

Background and objectives: In recent years, there is a growing interest on natural and safer antioxidants. So far, little is known about the potential of *E. purpurea* and *C. sativa* extracts.

Methods: In order to evaluate its antioxidant activity of extracts investigation had to include the total phenolics content and the scavenging capacity on DPPH radicals. The ability of extracts to scavenge superoxide and hydroxyl radicals were tested using electron paramagnetic resonance (EPR) techniques. Also, the extracts were screened for cytotoxicity using neutral red chemotherapeutic sensitivity assays on human colon cancer cell lines SW480. The cells were exposed to various concentrations of extracts and different treatment times.

Results: The content of total phenolic compounds of extracts of *E. purpurea* and *C. sativa* leaves were 10.57 % GAE and 6.74 % GAE, respectively. The scavenging activity of the radicals was found to exhibit 50% of the inhibition value (IC₅₀ value) at the concentration of 15.67 µg/ml for the investigated of *E. purpurea* and 1.87 µg/ml for *C. sativa* leaves. The ability of *C. sativa* to scavenge hydroxyl and superoxide radicals was at the concentration of 42.3 µg/ml and 8.5 µg/ml. Examination of redox potential *E. purpurea* on cancer cells SW480 was shown prooxidant effect at lower concentrations of extract and shorter incubation period. Treatment of cancer cells with chestnut leaf extract immediately cause a cytotoxic effect with the initial concentration and cytotoxic effect increases as a function of the concentration of the extract. The highest concentration was also the most toxic which is particularly evident in the treatment of 24 hours.

Conclusions: The obtained results shown that investigated extracts have good antioxidant potential. The antioxidant properties of phenolic compounds *C. sativa* leaves extracts was better compared to *E. purpurea*.

Key words: Antioxidants, phenolic compounds, *Echinacea purpurea*, *Castanea sativa*.

PO2711**DOCOSAHEXAENOIC ACID DOWN-REGULATES EGF-INDUCED MATRIX METALLOPROTEINASE-1/-9 AND UPA EXPRESSION VIA DISRUPTION OF INTERACTION BETWEEN EGFR AND ERBB2 AND INACTIVATION OF EGFR/ERBB-2 SIGNALING IN SK-BR3 BREAST CANCER CELLS**

F. Cheng¹, C. Lu¹, C. Li^{1,2}

¹School of Nutrition, Chung Shan Medical University, Taichung, Taiwan

²Department of Nutrition, Chung Shan Medical University Hospital, Taichung, Taiwan

Background and objectives: Matrix metalloproteinase-1 (MMP-1), MMP-9 and urokinase plasminogen activator (uPA) play crucial roles in tumor metastasis. Previous studies showed polyunsaturated fatty acids exhibit an anti-cancer effect in various human carcinoma cells; however, the effect of docosahexaenoic acid (DHA; 22:6, n-3) on metastasis of breast cancer cells is not fully clarified. ErbB2 is overexpressed in 20-30% of human breast cancers and correlates with poor prognosis.

Methods: We used ErbB2-overexpressing SK-BR3 breast cancer cells as cell model, and used Western blotting, real-time PCR, siRNA, and zymography assay to explore the anti-metastasis activity of DHA.

Results: EGF (40 ng/ml) induced MMP-1, MMP-9, and uPA mRNA and protein expression, as well as enzyme activity in both dose- and time-dependent manners, and 100 µgM DHA significantly inhibited EGF-induced MMP-1, MMP-9, and uPA protein expression, enzyme activity, and cell migration. Treatment with SP600125 and PD98059 decreased EGF-induced MMP-1, MMP-9, and uPA protein expression. In addition, EGF-induced MMP-1 and uPA expression was also decreased by SB203580 and LY294002. DHA was shown to inhibit EGF-induced activation of ERK1/2 and JNK. The phosphorylation of EGFR and ErbB2 was induced within 15 min after EGF treatment and the total amount of protein was found to increase after 12 h of EGF exposure. EGF-induced phosphorylation and increased total protein of EGFR and ErbB2 were decreased by DHA. Co-immunoprecipitation analysis showed the interaction between EGFR and ErbB2 was disrupted by DHA. EGFR siRNA mimics the inhibition of EGF-induced MMP-1, MMP-9, and uPA expression as well as enzyme activity by DHA.

Conclusions: Taken together, these results suggest attenuation of EGFR and ErbB2 expression and disruption of protein interaction between EGFR and ErbB2 and their downstream signaling pathways are involved in DHA's down-regulation of EGF-induced MMP-1/-9 and uPA expression in SK-BR3 breast cancer cells.

Key words: Docosahexaenoic acid; MMP; uPA; EGFR; ErbB2; SK-BR3

PO2712**ANTI-OBESITY EFFECTS OF DIETARY D-PSICOSE IN GROWING RAT FED A HIGH-SUCROSE DIET**

M. Ochiai¹, K. Onishi¹, T. Yamada², T. Matsuo¹

¹Faculty of Agriculture, Kagawa University, Japan

²Research and Development, Matsutani Chemical Industry Co., Ltd, Japan

Background and objectives: D-Psicose (D-ribo-2-hexulose), C-3 epimer of D-fructose, is a rare sugar presents in small quantities in nature product. We previously reported that D-psicose provided no energy and had anti-obesity effects in rats, but their detailed mechanisms remain to be elucidated. We here investigated the effects of anti-obesity effects of dietary D-psicose in growing rat pair-fed a high-sucrose diet (HSD).

Methods: Thirty-one male Wistar rats aged 4weeks were divided into two dietary groups: HSD contained 5% cellulose (C, n=21), and HSD contained 5% D-psicose (P, n=10). The rats in the C dietary group were further divided into two groups: rats fed the C diet ad libitum (C-AD group, n=11), and rats pair-fed the C diet with rats in the P group (C-PF, n=10). Each diet was fed for 8 week. At the weeks between 5th and 7th, energy expenditure (EE) was measured. At the end of the test period, all rats were killed by decapitation after 4-hours fasting. The serum and tissues were collected for biochemical analysis.

Results: The food intake was significantly lower in the P and C-PF groups than in the C-AD group. The body weight gain and food efficiency did not differ between the P and C-PF groups. The EE in darkness, lipoprotein lipase activity of the soleus muscle, and hepatic glycogen content were significantly higher, and in contrast, the serum levels of glucose, leptin, and adiponectin, glucose 6 phosphate dehydrogenase activity, body fat accumulation were significantly lower in the P group than in the C-PF group.

Conclusions: The anti-obesity effects of D-psicose could be induced by not only the suppression of food intake, but the increases of EE in rats.

Key words: D-psicose, pair-feeding, obesity, energy expenditure, rat

PO2713**ASPERGILLUS AWAMORI-FERMENTED BURDOCK ELEVATES BIFIDOBACTERIUM AND REDUCES ADIPOSE TISSUE WEIGHT IN RATS FED A HIGH-FAT DIET**

³Yaegaki Bio-industry Incorporated, Japan

⁴Faculty of Human Life Sciences, Fuji Women's University, Japan

⁵Iida Women's Junior College, Japan

Background and objectives: Aspergillus has been used widely for the production of sake, miso, soy source, etc. in Japan. However, there is very limited study on the utilization of Aspergillus for the production of functional foods. Burdock, *Arctium lappa*, is a popular vegetable in Japan, and has been used therapeutically in Asia, Europe, and North America for hundreds of years. Burdock contains high amounts of dietary fibers such as inulin and oligosaccharides as well as polyphenols such as chlorogenic and caffeic acid. Recently, to improve the functional properties of burdock, we have developed a method for producing Aspergillus awamori-fermented burdock. This study was conducted to investigate the effects of dietary supplementation with the fermented burdock powder on colonic luminal environment and body fat in rats fed a high-fat diet.

Methods: Male SD rats (5 weeks old) were fed on a high-fat diet (30% beef tallow) containing 5% burdock powder or 5% Aspergillus awamori-fermented burdock powder for 3 weeks.

Results: Food intake and growth were unaffected by dietary manipulation. Consumption of the burdock and fermented burdock diets significantly elevated fecal IgA and mucins (indices of intestinal immune and barrier functions) and reduced fecal lithocholic acid (a risk factor for colon cancer) ($p < 0.05$). Interestingly, the fermented burdock diet markedly elevated cecal Bifidobacterium and organic acids including lactate, acetate, propionate and butyrate, and reduced fecal deoxycholic acid (a risk factor for colon cancer) and perirenal adipose tissue weight ($p < 0.05$), but the burdock diet did not.

Conclusions: The results suggest that the consumption of fermented burdock improves the colonic luminal environment and suppresses obesity in rats fed a high-fat diet.

Key words: burdock, Aspergillus awamori, Bifidobacterium, obesity, secondary bile acids

PO2714**EFFECTS OF SOY YOGURT ON INTESTINAL AND PLASMA POLYAMINE LEVELS IN YOUNG AND ADULT RATS**

M. Fukuda¹, M. Kobayashi¹, K. Tsuzuki²

¹Department of Food Science and Nutrition, Mukogawa Women's University, Nishinomiya, Hyogo, Japan

²Research Institute, Marusan-Ai Co. Ltd., Okazaki, Aichi, Japan

Background and objectives: Polyamines, putrescine, spermidine and spermine, are important constituents of all mammalian cells and are essentially involved in a variety of regulatory step during normal and malignant cell proliferation. The level of polyamine in the body tends to decrease with age. Recently, a causative role for polyamines in longevity has been noted. Soy foods are rich in polyamines. Soy yogurt was produced from soy by using *Lactobacillus* and was richer in polyamine content than unfermented soy. We investigated the effect of soy yogurt on polyamine levels in intestines and blood of young and adult rats.

Methods: The polyamines in food, intestine and blood were measured as fluorescent derivatives by HPLC analysis.

Results: Spermidine was most abundant polyamine in soy yogurt. The ingestion of soy yogurt induced the increase of mucosal polyamine level in small intestines of young and adult rats. Although the polyamine level in cecum content was significantly increased in both young and adult rats ingested soy yogurt, the polyamine level in large intestinal mucosa was not increased. Soy yogurt intake was effective for polyamine increase of small intestinal mucosa in spite of age. The large intestinal mucosa seems to regulate the polyamine level to prevent own cells from hyperproliferation. The polyamine level in plasma of young rats was not changed by soy yogurt intake, whereas the level in adult rats ingested soy yogurt was significantly increased. Especially, plasma spermidine in adult rats ingested soy yogurt was significantly increased compared with that of control rats, whereas plasma putrescine did scarcely increase in adult rats. It was found that soy yogurt is useful for the recovery of polyamine, especially spermidine, in adult rats.

Conclusions: Soy yogurt is a functional food supplying polyamines to aged animal.

Key words: polyamine, soy yogurt, rat, intestine, blood

PO2715**FRUCTOOLIGOSACCHARIDES ENHANCES THE EFFECT OF A FLAVONOID, α -GLUCOSYL-ISOQUERCITRIN, ON GLUCAGON-LIKE PEPTIDE-1 (GLP-1) SECRETION IN RAT INTESTINE AND ENTE-ROENDOCRINE CELLS**

P. Phuwamongkolwiwat¹, T. Hira¹, H. Hara¹

¹Graduate School of Agriculture, Hokkaido University, Sapporo, Hokkaido, Japan

Background and objectives: Hyperglycemia with insufficient insulin action is a major symptom of diabetes mellitus (DM). Glucagon-like peptide-1 (GLP-1) an incretin hormone released from enteroendocrine cells (L-cells), has received much attention for improving the glucose tolerance but the GLP-1 secretion differs by characteristics of ingested foods. Fructooligosaccharide (FOS) and α -glucosyl-isoquercitrin (Q3GM) in diet are known to improve glucose metabolism. To our knowledge, however, no study is available about the effects of GLP-1 secretion in response to the FOS and Q3GM together. Therefore, we conducted in vivo and in situ rat experiments to investigate the differences in the secretion of GLP-1 in response to oral ingestion or ileal injection of test solutions (i.e., Q3GM, FOS, and Q3GM+FOS).

Methods: Blood samples were collected from jugular vein in vivo, and from portal vein in situ experiments before (0 min) and after (15, 30, 60, 90, and 120 min) oral or ileal administration of test solutions to evaluate plasma level of GLP-1. Direct effects of Q3G with- or without FOS on GLP-1-producing L-cells were also examined through an in vitro study using a murine enteroendocrine cell line, GLUTag.

Results: Q3GM transiently stimulated the secretion of GLP-1 in both in vivo and in situ experiments. Contrariwise, administering Q3GM+FOS significantly enhanced and prolonged the plasma GLP-1 concentrations in both experiments. The plasma GLP-1 concentration however, was higher after the ileal injection (in situ) compared to the oral injection. Likewise, the in vitro experiment using GLUTag showed the direct stimulative action of Q3GM on GLP-1 secretion, whilst FOS enhanced the effect of Q3GM.

Conclusions: Our findings suggest that Q3GM+FOS has the potential for prevention or treatment of DM by enhancement and prolongation of GLP-1 secretion.

Key words: Diabetes mellitus, Fructooligosaccharides, Glucagon-like peptide-1, Glycosyl isoquercitrin

PO2716**FRUCTO-OLIGOSACCHARIDE SUPPLEMENTATION REDUCED FECAL TOXICITY, BILE ACID AND BACTERIAL RISK FACTORS OF COLORECTAL CANCER IN CONSTIPATED OLDER VOLUNTEERS**

H. Chen^{1,2}, C H. Yen^{3,4}, H W. Yu¹, Y W. Kuo¹

³Department of Family and Community Medicine, School of Medicine, Center for Education and Research on Geriatrics and Gerontology, Chung Shan Medical University, Chung Shan, Taiwan

⁴School of Medicine, Chung Shan Medical University, Chung Shan, Taiwan

Background and objectives: The study assessed effects of fructo-oligosaccharide (FOS) supplementation on fecal precancerous risks and preventive factor of colorectal cancer and whether effects of FOS were sustained after its withdrawal in constipated older volunteers.

Methods: Six men and three women (73.4 ± 3.9 y old) participated in a double-blind, placebo-controlled, diet-controlled study that consisted of a 4-wk placebo (3 mL of fructose syrup) period, a 4-wk FOS (10 g/d) and a 4-wk post-FOS period. Stools were collected in the last wk of each period to determine the risk markers of colorectal cancer, such as fecal bacteria enzyme activities, bile acids and toxicity of fecal water on Caco-2 cells, a human colonocyte model, as well as the beneficial factor, short-chain fatty acid.

Results: Fecal activities of β -glucosidase, β -glucuronidase and mucinase, total fecal bile acid, and the proportion of secondary to total bile acid (%) significantly decreased with FOS compared with placebo. In contrast, fecal acetate and butyrate levels increased with FOS. In agreement with the reduced mutagenic markers, the fecal water-induced cytotoxicity and DNA damage towards Caco-2 cells were the lowest in the FOS period. Furthermore, the fecal β -glucuronidase, mucinase, total and secondary bile acid, and fecal water toxicity remained significantly lower in the post-FOS period than that in the placebo period, respectively.

Conclusions: Supplementation of FOS for 4 week significantly reduced fecal precancerous risks related to bacterial metabolism in constipated older volunteers and these effects partially remained at the end of post-FOS period.

Key words: Fructo-oligosaccharide; β -glucuronidase; mucinase; bile acid; toxicity

PO2717**SENSORY CHARACTERISTICS AND ACCEPTABILITY OF SAUSAGES WITH 10 % FAT AND ADDED RYE OR WHEAT BRAN**

¹Department of Nutrition, Exercise and Sports, Faculty of Science, University of Copenhagen, Denmark

²Danish Meat Research Institute, Danish Technological Institute, Roskilde, Denmark

Background and objectives: Improving the nutritional profile of sausages by addition of dietary fibres might influence appetite, sensory characteristics and liking differently depending on the fibre source. The objective of this study was to investigate the sensory characteristics of sausages with 10 % w/w fat and added rye or wheat bran reaching a final dietary fibre content of 2.4 and 3.2 g/100 g respectively. Furthermore consumer liking of the two sausages was assessed among two Danish target groups.

Methods: A trained sensory panel (n=9) evaluated the sausages with rye (RBS) and wheat bran (WBS) using sensory descriptive attributes in terms of odor, appearance, texture and flavor. Commercial 20 % w/w fat sausage (20%S) and 10 % w/w fat sausage (10%S) sausages were also included. Furthermore a consumer test, including a novel method "Holistic by DMRI", was conducted among children (6-9 years old, n=49) and their parents (n=24) to investigate liking of RBS and WBS.

Results: With respect to appearance RBS and WBS differed significantly from the remaining test sausages. They were browner (p>0.001), had the greatest extent of dots (p>0.001) and the coarsest inner structure (p>0.001). WBS differed from all other samples being less juicy (p>0.001) and having a higher intensity of cereal flavour (p>0.001) whereas RBS was similar to the commercial 10%S according to juiciness (p>0.001), fatty mouth feel (p>0.0001) and firmness (p>0.001). The consumer tests showed that liking was significantly lower for WBS than for RBS whereas the latter was not different from the commercial 10%S. Finally RBS was correlated with more positive words compared to WBS although both were correlated with "healthy".

Conclusions: Addition of dietary fibre from rye bran to sausages represents a promising approach to improve the healthiness of conventional sausages while maintaining consumer liking.

Key words: Bran, dietary fibre, sausage, sensory characteristics, consumer liking

PO2718**POTENTIAL APPLICATION OF SOME COMMON INDIAN SPICES AS FUNCTIONAL FOOD ON FISH UNDER REFRIGERATED STORAGE***B. De¹, S. Chatterjee¹*

¹J. D. Birla Institute, Food Microbiology and Biochemistry laboratory, Department of Food Science and Nutrition Management, Kolkata, India

Background and objectives: Spices, popularly used as flavouring agents, are excellent source of phenolic compounds which exhibits good antioxidant activity with health-promoting properties. They may also be used in functionalization and natural preservation of foods.

Methods: Hence potential antioxidant activities of six commonly used spices - fennel, black-pepper, ginger, cinnamon, celery, panchforon (mixture of fennel, celery, cumin, black-cumin, fenugreek), and BHT, a synthetic antioxidant were evaluated and potential to reduce lipid peroxidation was determined post application on homogenized tilapia fish muscle. Antioxidant activity and oxidative stability of fish oil, extracted at interval of one week over a span of six weeks was estimated from amount of total phenol content, inhibition to peroxidation, metal chelating activity, and free fatty acid, peroxide, p-anisidine, thiobarbituric acid (TBA) values.

Results: Contrary to other spices cinnamon and panchforon remarkably could successfully decrease the amount of malonaldehyde accumulation and free fatty acid formation in oil. Peroxidation was effectively controlled by panchforon, fennel and pepper for longer duration. Maximum phenolic concentration was recorded in cinnamon extract and inhibition to peroxidation was high in pepper and celery extract. Phenolic concentration in fish oil was found to be highest in panchforon and pepper. Most effective metal chelating activity of fish oil was found in panchforon, followed by fennel in 4th week.

Conclusions: Cinnamon and panchforon showed maximum efficiency in controlling oxidation whereas panchforon and fennel enriched fish oil exhibited higher antioxidant activity. Antioxidant activity of fish increases on preservation with spices which suggest potential health benefits in human body by inhibiting the lipid peroxidation and arresting the harmful free radicals in addition to imparting flavor to the food.

Key words: antioxidant, lipid peroxidation, phenolic compounds, metal chelating activity, malonaldehyde

PO2719**CHANGES IN BAX, BCL-XL, CASPASE-3 AND 8 CONTRIBUTE TO PHYTIC ACID (IP6) INDUCED APOPTOTIC IN HT-29 CELLS***N. Mohd Esa^{1,2}, N.H. Shafie¹, H. Ithnin³, N. Saad⁴*

⁴UPM-MAKNA Cancer Research Laboratory, Institute of Bioscience, Universiti Putra Malaysia, UPM Serdang, Selangor, Malaysia

Background and objectives: Loss of apoptotic response is a major hallmark of various human malignancies. The mechanism of action of many anti-cancer drugs is based on their ability to induce apoptosis. Previous studies have shown that phytic acid (IP6) can inhibit the growth of various tumor cells in many mechanisms. The cellular and molecular mechanism underlying IP6 induced apoptosis however, have not been well defined. Hence, this study aimed at investigating the expression of the apoptotic-related targets; pro- and anti-apoptotic; Bax and Bcl-xl, respectively and also caspase-3 and 8 caused by IP6.

Methods: HT-29 cells were treated with different concentration of IP6 that was extracted from rice bran for 72 hrs, then total RNA of cells were isolated, and qRT-PCR was performed followed by western blotting.

Results: IP6 showed an extensive significant reduction of anti-apoptotic, Bcl-xl and a coherent increment of pro-apoptotic, Bax at mRNA and protein level. These results showed that IP6 caused a marked increase in apoptosis, which was accompanied by significant increase in mRNA and protein levels of caspase 3 and caspase 8 ($p < 0.05$).

Conclusions: These molecular alterations provide an insight into IP-6 caused apoptotic death of human colon cancer, HT-29 cells.

Key words: Phytic acid (IP6), Bcl-xl, Bax, caspase.

PO2720**SUPPRESSIVE EFFECT OF CRYSTALLIZED CELLULOSE ADDED TO THE LIQUID FORMULA ON POSTPRANDIAL GLUCOSE ELEVATION IN HEALTHY SUBJECTS**

S. Nakamura¹, S. Morita¹, A. Miyahara¹, C. Ushiroda¹, Y. Yamagichi¹, K. Tanabe¹, T. Oku¹

¹Graduate School of Human Health Science, University of Nagasaki Siebold, Japan

Background and objectives: The elderly patients often experience osmotic diarrhea due to the enteral nutrition and also have hyperglycemia. It is important for these patients to develop the liquid formula (LF) which causes the suppressive effect on postprandial glucose elevation and on diarrhea. We have already clarified that dietary fiber materials, especially crystallized cellulose (CC), suppressed osmotic diarrhea induced by sufficient ingestion of nondigestible oligosaccharides. In this study, we investigated that LF containing CC suppress the elevation of postprandial glucose and insulin levels using healthy subjects.

Methods: Study protocol was carried out using a within-subject, repeated measures design and was approved by the Ethical Committee of University of Nagasaki Siebold. A total of 21 healthy subjects (21.7 y; BMI, 21.3 kg/m²) were participated in this study. The criteria were no history of diabetes; the fasting glucose is less than 110 mg/dL; BMI is between 18.5 and 26.0. The LF containing 0.5 g of CC was used as a control (CONT), and compared to the LF containing 1.7 g (CC-1.7) and 1.8 g (CC-1.8) of CC. After the overnight fasting, the subject was examined by the medical doctor, then blood was collected to measure basal level. After the subject ingested the test substance, blood was collected at 30-min intervals for 2 h. The plasma glucose and insulin were measured with Trinder's method and with ELISA, respectively.

Results: When the subject ingested separately CC-1.7 and CC-1.8, the elevations of postprandial glucose and insulin levels were significantly low in comparison with the ingestion of CONT ($p < 0.05$). In addition, no subjects induced osmotic diarrhea.

Conclusions: The LF containing plentiful CC was suppressed the postprandial elevation of glucose and insulin levels. These results can contribute to develop LF with suppressive effect on both osmotic diarrhea and hyperglycemia.

Key words: crystallized cellulose; dietary fiber; suppressive effect on glucose elevation

PO2721**DIETARY POLYPHENOLS PROTECT THE BARRIER FUNCTION OF CACO-2 CELLS EXPOSED TO INDOMETHACIN THROUGH THE MODULATION OF OCLUDIN AND ZO-1 EXPRESSION**

C. Carrasco-Pozo¹, P. Morales¹, M. Gotteland¹

¹Department of Nutrition, Faculty of Medicine, University of Chile, Santiago, Chile

Background and objectives: Dietary polyphenols represent a group of secondary metabolites abundant in fruits and vegetables, which display antioxidant, anti-inflammatory and anti-proliferative properties. We have recently shown in in vitro and in vivo models of gastrointestinal damage induced by the non-steroidal anti-inflammatory drugs, indomethacin, that dietary polyphenols protect against the indomethacin-induced mucosal damage through their ability to regulate mitochondrial function and intracellular calcium mobilization. The aim of this study was to determine whether dietary polyphenols may exert a protective effect against the disruption of the intestinal barrier function induced by indomethacin in Caco-2 cell monolayers.

Methods: The integrity of Caco-2 cell monolayers was determined by measuring their transepithelial electrical resistance (TEER) and permeability to FITC-dextran. The expression of the tight junction proteins occludin and ZO-1 was evaluated by immunofluorescence and RT-qPCR assays. These experiments were carried out in the presence or absence of indomethacin and the polyphenols quercetin, rutin, resveratrol and epigallocatechingallate.

Results: Indomethacin decreased TEER and correlatively increased FITC-dextran permeability in Caco-2 monolayers; these alterations were abolished by all the tested polyphenols but rutin, being quercetin the most efficient. The protective effect of quercetin was associated to its capacity to inhibit the redistribution of ZO-1 protein induced both by indomethacin and by rotenone, an inhibitor of the mitochondrial complex-I, and to prevent the decrease of ZO-1 and occludin expression.

Conclusions: The dietary polyphenols differentially protect Caco-2 barrier function, independently of their antioxidant properties; these findings, in addition to the fact that some of the alterations induced by indomethacin were reproduced by rotenone, suggest that indomethacin exerts its deleterious effect on the intestinal barrier function not only by inducing oxidative stress but also by altering the mitochondrial function.

PO2722**INCREASED ANTIOXIDANT POTENTIAL OF RYE FLOUR BY ENZYMATIC HYDROLYSIS**

J. Macedo², F. Lima¹, G. Macedo¹

¹Department of Science of Food, School of Food Engineering, University of Campinas, Campinas, Brazil

²Department of Food and Nutrition, Faculty of Food Engineering, University of Campinas, Campinas, Brazil

Background and objectives: The consumption of processed grains and vegetables not only improve nutrient utilization, but also act as potential nutraceutical and therapeutic foods for human health. Cereal based foods generally comprise a significant part of daily diets throughout the world. Rye products are particularly known for its high level of dietary fiber and bioactive compounds such as phenolic compounds, phytosterols, minerals, vitamins and tocotrienols. The treatment with tannase enzyme in rye is an alternative to the release of bioactive compounds, such as phenolics, which have antioxidant activity towards oxidative stress in the body. Tannase is an enzyme that hydrolyzes the tannins of grains, increasing the antioxidant activity and the release of gallic acid. In this context, the present study aimed to evaluate the relationship between phenolic compounds released by the action of tannase and antioxidant activity in rye.

Methods: The crude extract of tannase was produced using the *Paecilomyces variotti* in solid-state fermentation. The rye grain was milled in laboratory mill and the enzymatic reaction was performed in a shaken water bath at 40°C and 200 rpm for 2 hours. After that, the flour was frozen, freeze dried and stored at -18°C. The phenolic compounds were determined as gallic acid equivalents (GAE) using the Folin Ciocalteu method. The antioxidant activity was evaluated by scavenging of DPPH radical, the results were expressed as μM of trolox equivalents.

Results: Rye treated with tannase showed an increase in antioxidant activity by 89% and total phenols by 20% compared to the control (without enzyme).

Conclusions: Rye is used as an ingredient in breads, fermented and distilled beverages. The results indicated that the enzymatic treatment is an alternative for improving nutritional value of this grain as an ingredient.

Key words: Antioxidant activity, Phenolic Acids, DPPH, tannase, rye.

Background and objectives: Colonic microbial fermentation is a key function of the microbiota that might contribute to gastrointestinal health as well as overall health. Metabolites are the end-products of metabolic activity and might be most closely related to induction of health effects, therefore some of them are generally accepted as beneficial to the host, whereas others are considered as potentially toxic. The aim of this activity was to evaluate the available evidence for the toxicologic or nutritional properties/relevance of the metabolites of gut microbes on host tissues.

Methods: A literature search was performed to address available evidence for the physiological and nutritional effects of metabolites such as short chain fatty acids. In addition, the evidence of adverse effects of particularly compounds produced during the protein fermentation were assessed. Holistic approaches including biological assays analysing of genotoxicity as well as metabolomics analysis were reviewed.

Results: No formal systematic reviews evaluating the physiological or toxicological properties of bacterial fermentation metabolites were found. Comprehensive reviews and experimental studies indicated that protein fermentation metaboli-

tes, typically considered as harmful metabolites, do not induce toxic effects at the concentration ranges retrieved in the colon. Studies indicate that dietary interventions with prebiotics reduce the incidence of cancer. At present, there is no evidence that these effects are due to reduction in genotoxic compounds, thus limiting the usefulness of genotoxicity assays. Metabolomic analysis has great promise in providing meaningful data related to gut health but there are insufficient data to provide convincing links with different gut conditions or dietary changes.

Conclusions: There are not yet sufficient studies or data to support the established use of any biomarkers of gut health. However the range of concentrations of several metabolites can be established in faeces at in different conditions.

Key words: Gut microbiota, gut functions, digestive health, markers

PO2724

EFFECT OF SARDINE PROTEINS AND CASEIN COMBINED WITH MARGARINE OR MILK LIPIDS ON OXIDATIVE STRESS MARKERS IN HYPERCHOLESTEROLEMIC RATS

A. Benyahia - Mostefaoui¹, F. Dehiba¹, H.M. Khelladi¹, S. Louala¹, M.Y. Lamri - Senhadji¹

¹Département de Biologie, Laboratoire de Nutrition Clinique et Métabolique (LNCM), Université d'Oran, Algérie

Background and objectives: The relationship between dietary fats consumption and the risk of cardiovascular disease (CVD) has been a topic of strong debate over the years because the numerous investigations relating the relationship between margarine and dairy fats intake, and several risk factors associated with CVD have been incoherent. The present investigation was undertaken to study the potential effects of milk lipids compared to margarine combined with sardine proteins or casein on some markers of oxidative stress in rats fed a cholesterol - enriched diet.

Methods: Male Wistar rats (n=32) were fed a 20% sardine proteins or casein combined with 5% milk lipids (SP-milk, CAS-milk) or 5% margarine (SP-margarine, CAS-margarine) and 1% cholesterol for 28 days. Serum total cholesterol (TC), triacylglycerols (TG) and uric acid concentrations were determined. Lipid peroxidation and antioxidant enzyme activities were evaluated.

Results: In CAS-margarine versus CAS-milk, TC level was 2.6-fold lower but TG content was 2.7- higher. Uricemia was decreased in CAS-margarine compared to CAS-milk (2.3-fold) and SP-milk (5-fold). In spite of unchanged antioxidant enzymatic defense (only in aorta), serum TBARS were higher

(1.3-fold) in CAS-margarine versus SP-margarine but lower in CAS-milk versus SP-milk (1.7-fold) and CAS-margarine (2.7-fold). In contrast, serum hydroperoxydes contents were not influenced by the oil and protein origin. In heart, brain and aorta TBARS values were decreased in CAS-margarine versus CAS-milk and SP-margarine versus SP-milk (P<0.001). Indeed, tissues hydroperoxydes values were decreased in SP-margarine than CAS-margarine and SP-milk.

Conclusions: Margarine combined with casein or sardine protein induced a hypocholesterolemic effect and seems to protect some tissues against the cytotoxic action and oxidative stress of cholesterol supplementation in particular, when it is combined with the sardine protein.

Key words: Margarine, milk lipids, sardine protein, oxidative stress, hypercholesterolemia

PO2725

ANTHOCYANIN-RICH GRAPE-BILBERRY JUICE INFLUENCES FAT METABOLISM AND IMPROVES RISK FACTORS FOR CARDIOVASCULAR DISEASES IN FISCHER RATS

D. Graf¹, S. Seifert¹, A. Jaudszus¹, A. Bub¹, B. Watzl¹

¹Department of Physiology and Biochemistry of Nutrition, Max Rubner-Institut, Karlsruhe, Germany

Background and objectives: Cardiovascular diseases (CVD) are a public health problem in Western countries. Diets rich in fruit and vegetables are inversely associated with the risk of CVD. Anthocyanins, a subgroup of flavonoids, are among the bioactive compounds in plant foods, for which a preventive potential for CVD is discussed. Therefore we investigated the impact of an anthocyanin-rich juice on CVD risk factors, while feeding a Western style diet.

Methods: Fischer rats were fed a diet mimicking Western fat intake (34 %kcal fat, rich in saturated fatty acids (SFA)) for ten weeks. Anthocyanin-rich grape-bilberry juice (ARJ) or anthocyanin-depleted grape-bilberry juice (control) were provided ad libitum (n=24/group). After the intervention period parameters of fat metabolism, adipokines, as well as fatty acid composition of plasma were determined.

Results: Intervention with ARJ decreased serum concentrations of cholesterol, leptin, and resistin (p<0.05). Triglycerides tended to be decreased, too (p=0.079), whereas no effects were observed for non-esterified fatty acids, glucose, insulin, and adiponectin. Furthermore, ARJ decreased the amount of SFA in plasma and increased the amount of polyunsaturated fatty acids (PUFA; p<0.05). The ratio of n6:n3 PUFA was not affected.

Conclusions: The results of this study indicate that diets rich in anthocyanins might possess preventive potential for

CVD, even with concurrently high intake of SFA. Especially the increase in plasma PUFA should be investigated further, as health promoting effects for PUFA have been described. So far nothing is known about the mechanisms by which anthocyanins influence fatty acid composition of plasma. This study has been financially supported by the German Federal Ministry of Research and Education (0315379G).

Key words: Anthocyanins, fatty acids, adipokines, lipid metabolism

PO2726

PHENOLIC COMPOUNDS AND ANTIOXIDANT CAPACITY OF FRESH AND DEHYDRATED CHILEAN FRUITS AND VEGETABLES

M. Lutz¹, J. Hernandez¹, C. Henriquez¹

¹CIDAF, Facultad de Farmacia, Universidad de Valparaíso, Chile

Background and objectives: Cardiovascular diseases, cancer, diabetes, among other non transmissible chronic diseases, are the main causes of death worldwide. Numerous epidemiological studies have demonstrated that diets containing high amounts of fruits and vegetables (F&V) reduce risk factors of these diseases, in association with their phenolic compounds content, which possess antioxidant properties. The aim of the study was to characterize the potential healthy value of F&V, fresh and dehydrated, by analyzing their total phenolics content and antioxidant capacity.

Methods: Blackberries, blueberries, eggplants, spinaches, Granny Smith apples, Red Delicious apples, red peppers, green peppers, tomatoes, and carrots, fresh and dehydrated, were analyzed in order to evaluate the effect of drying on their healthy potential. We assayed total phenolic compounds (Folin Ciocalteu), anthocyanins (differential pH), catechin, caffeic acid, and gallic acid (HPLC), vitamin C (HPLC) and antioxidant capacity (DPPH and ORAC).

Results: The highest amount of phenolics was found in blackberries (22.1 mg EAG/g fresh and 126.3 mg EAG/g dry), followed by blueberries. Phenolics correlated positively with antioxidant capacity ($p < 0.01$). The most abundant phenolic compound in F&V was catechin. The highest vitamin C content was observed in fresh peppers and dry Granny Smith apple. Vitamin C did not contribute to antioxidant capacity in the analyzed products.

Conclusions: It is concluded that the amount of phenolic compounds and antioxidant capacity are higher in dehydrated F&V, which constitute an interesting source of potential healthy value ingredients for foods. Funded by FONDEF D09I1222 and CIDAF.

Key words: phenolic compounds, antioxidant capacity, fruits, vegetables, healthy value.

PO2727

ISOFLAVONES CONTENT OF QUINOA GRAINS FROM LOCAL ECOTYPES GROWN IN DIFFERENT CONDITIONS

M. Lutz¹, A. Martinez¹, A. Vega-Galvez², M. Miranda², E. Martinez³

¹CIDAF, Facultad de Farmacia, Universidad de Valparaíso, Chile

²Ingeniería en Alimentos, Universidad de La Serena, Chile

³Centro de Estudios Avanzados de la Zona Arida (CEAZA), Universidad de La Serena, La Serena, Chile

Background and objectives: Quinoa (*Chenopodium quinoa* Willd.) is a typical crop of the Andean zone. The nutritional value of this chenopod is well recognized, however little has been described on its content of bioactive compounds. The aim of this study was to determine the concentration of two "phytoestrogens": genistein and daidzein, in local ecotypes of quinoa from three different geographic zones in Chile (north Altiplane at 19°S, central zone at 34°S and southern region at 39°S) and to evaluate the effects of environmental growing conditions on isoflavones content.

Methods: Daidzein and genistein were determined by HPLC in seeds of three genetic regions of quinoa: from the three Zones in Chile. Grains were collected and daughter seeds were grown and harvested under controlled conditions at 30°S) in an experimental field and the same isoflavones were measured.

Results: Isoflavones contents varied between the quinoa types studied ($p < 0.05$), daidzein was significantly higher than genistein content ($p < 0.05$). Daidzein ranged from $0,54 \pm 0,03$ to $1,80 \pm 0,05$ mg/100 g in the original regional seeds and from $0,73 \pm 0,01$ to $1,08 \pm 0,06$ in daughter seeds, while genistein ranged from $0,36 \pm 0,02$ and $0,48 \pm 0,02$ mg/100 g in the original grains, and from $0,34 \pm 0,00$ to $0,46 \pm 0,05$ in daughter seeds. Interestingly, two farmers' varieties or local ecotypes of daughter seeds exhibited absence of one isoflavone. Northern seeds (a high temperature, low rainfall and deficient soil condition) contain more isoflavones, which decrease when the ecotype is grown in a different environment.

Conclusion: Besides its well recognized nutritional value, quinoa also possesses an excellent potential as a source of health-promoting bioactive compounds such as isoflavones. However, Isoflavones content of quinoa seeds is highly dependent on environmental growing conditions. Funded by FONDECYT 1100638 and CIDAF CID 04/06.

Key words: isoflavones, daidzein, genistein, bioactives, quinoa, ecotypes.

PO2728**APPLYING A BOX-BEHNKEN DESIGN FOR OPTIMIZED EXTRACTION OF AGAVE FRUCTANS (AGAVE TEQUILANA WEBER VAR. AZUL) WITH PREBIOTIC POTENTIAL**

J A. Salazar-Montoya¹, E. Flores-Girón¹, E G. Ramos-Ramírez¹

¹Department of Biotechnology and Bioengineering, CINVESTAV-IPN, México DF, Mexico

Background and objectives: Nowadays there is a great quest for food ingredients that besides of their nutritional function provide benefits to consumer health. The carbohydrates present in Agave tequilana are fructans which have prebiotic potential because they include fructose chains joined by(2-1) linkages, such as those present in inulin. The objectives of the study were establishing the optimum extraction conditions of these compounds by maceration and determine their polymerization degree.

Methods: Factors as temperature, time and solvent:solid ratio for the extraction of fructans were studied in a maceration process of Agave powder using a Box-Behnken design. The Agave powder was obtained by grinding, drying and sieving of the stem of a plant of 7 years. The evaluated response variable was the extraction yield. The fructans extracted were precipitated with ethanol and dried by freeze-drying; the reducing sugars and degree of polymerization (apparent glucose-fructose ratio) were determined.

Results: It was found statistically significant effects ($p < 0.05$) for the three factors studied, like interactions between temperature and solvent:solid ratio, also between solvent:solid ratio and time. A significant quadratic term was determined for the time factor which indicated the presence of a maximum in the range of study. The factor solvent:solid ratio had a positive influence on the performance of response variable. A negative effect was observed in the factor temperature possibly due to a partial hydrolysis of polysaccharides. The $93.72 \pm 2.88\%$ of dry material obtained was carbohydrates with $1.85 \pm 0.08\%$ of reducing sugars. The polymers had an apparent polymerization degree of 29.

Conclusions: The selection of study variables were decisive in extraction yield obtained. The conditions of maximum extraction of fructans were determined with an extraction yield predicted of 37.84%. Fructans with suitable polymerization degree were successfully obtained and being used as prebiotics in dairy.

Key words: Agave, extraction, fructans, prebiotics.

¹Department of Food Science and Nutrition, Mukogawa Women's University, Nishinomiya, Hyogo, Japan

²Research Institute, Marusan-Ai Co., Ltd., Okazaki, Aichi, Japan

Background and objectives: Cardiovascular disease is a severe problem in developed and developing countries. One of the risk factors of atherosclerosis is dyslipidemia. Soy foods have been known to exhibit lipid metabolism-modulating effects. The major bioactive ingredients of soy foods are soy proteins and isoflavones. The ingestion of soymilk has reduced plasma and hepatic lipid levels. As the taste of soymilk is not always favorable for everybody, we prepared fermented soymilk using lactic acid bacteria derived from vegetable food to ingest it more easily. Thus we examined the effects of fermented soymilk on the lipid metabolism in rat liver.

Methods: Male Sprague-Dawley rats aged 7 weeks were fed experimental diets for 1 week or 5 weeks after acclimatization on AIN-93G diet for 1 week. The rats were divided to a control diet (AIN-93) group, soymilk diet (SM) group or fermented soymilk diet (FSM) group. Plasma parameters were measured after fasting for 8 h. The influences of diet on hepatic gene expression in non-fasted rats were investigated.

Results: The hepatic triglyceride and cholesterol contents and plasma cholesterol levels in the SM and FSM groups were significantly lower than those in the control group. The fatty acid synthesis-related genes were down-regulated in the SM and FSM groups after 1 week. The gene of CYP7a1 related to cholesterol catabolism was more markedly up-regulated in the SM and FSM group after 5 weeks. This up-regulation was higher in the FSM group than in the SM group.

Conclusions: The bioactive components produced or increased by lactic acid fermentation seem to induce the up-regulation of hepatic CYP7a1 to reduce the plasma cholesterol level in rats.

Key words: soymilk, lactic fermentation, lipid metabolism, CYP7a1, isoflavone.

PO2730**QUERCETIN INCREASES BILE ACID EXCRETION IN RATS**

C. J. Guo¹, Z. C. Tang¹, B. Meng¹, J. Y. Wei¹, W. N. Gao¹, J. J. Yang¹, L. L. Pu¹, J. Q. Wu¹

¹Department of Nutrition, Institute of Health and Environmental Medicine, China

Background and objectives: previously, we found that dietary supplementation of quercetin increased serum LDL-c concentration significantly in rats. In this study, the effects of quercetin on bile acid excretion was further investigated in order to probe into the action quercetin played on cholesterol metabolism in detail.

Methods: Male Wistar rats were fed AIN-93 diets containing 0%, 0.1%, 0.2%, 0.4%, 0.8% quercetin for 5 weeks, respectively. At the end of experiment, serum lipid profiles were analysed and bile excretion was recorded under sodium pentobarbital anesthetization. Fecal samples also were collected for analysis of bile acids. Hepatic 7 α -hydroxylase activity and mRNA expression were determined.

Results: It was confirmed that serum LDL-c level was increased after quercetin treatment in a dose dependent manner. The bile excretion was not changed, whereas the contents of bile acids in bile and fecal samples were significantly increased in response to quercetin supplementation. The hepatic 7 α -hydroxylase activity was significantly increased in the 0.4% quercetin group compared to the control. However, the mRNA expression of 7 α -hydroxylase gene was not increased after quercetin exposure.

Conclusion: Quercetin may change cholesterol metabolism via the increase of bile excretion and this action is associated with increased activity of hepatic 7 α -hydroxylase.

Key words: quercetin, cholesterol metabolism, bile excretion, 7 α -hydroxylase

PO2731**EFFECTS OF MANGROVE-BARK EXTRACTS ON THE ANTI-TUMOR ACTIVITY IN TUMOR-BEARING C57BL/6 MICE**

J. Nagata¹, K. Kinjyo²

¹Fukuoka Institute of Technology, Japan

²University of the Ryukyus, Japan

Background and objectives: The present study was carried out to examine the effects of mangrove-bark extracts on the anti-tumor activity in tumor-bearing mice.

Methods: Some extracts were prepared with methanol, acetone or ethyl acetate from the bark of mangrove (*Bruguiera*

gymnorhiza or *rhizophora stylose*), and methanol from that of *Heritiera littoralis*, *Exoecaria agallocha* and *Soneratia alba* in the study. C57BL/6 mice were implanted with B16 melanoma cell line and administered intraperitoneally for each sample for 60 days. The survival rate and the tumor growth during experimental periods were observed. Serum IFN-gamma and IL-12 concentrations of mice were also measured using the commercially available ELISA kit. In addition, to estimate the functional component, we estimated the active ingredient of each extracts with TLC and HPLC.

Results: No significant differences were observed in the survival rate of mice and tumor growth among various groups, but the survival rate and the suppression of tumor growth of mice administered ethyl acetate extracts of *Bruguiera gymnorhiza* or *rhizophora stylose* were superior to those of mice administered other extracts. Serum IL-12 concentration of mice administered methanol extracts from the bark of *Bruguiera gymnorhiza* also showed the response of the dose-dependent manner. These extracts contained both some kind of catechin and their polymers.

Conclusions: The results indicate that the administration of ethyl acetate extracts from the bark of mangrove exerts anti-tumor activity in C57BL/6 mice. These effects maybe, in part, depend on the polyphenols containing characteristically in the mangrove bark.

Key words: Mangrove bark extracts, tumor-bearing mice, survival rate, tumor growth.

PO2732**CONTENTS OF QUERCETIN, KAEMFEROL, MYRICETIN, APIGENIN AND LUTEOLIN OF VEGETABLES AND FRUITS IN CHINA AND ESTIMATED DIETARY INTAKE BY CHINESE**

C. J. Guo¹, J. Y. Wei¹, Y. Liu¹, W. N. Gao¹, L. L. Pu¹, J. Q. Wu¹, J. J. Yang¹

¹Department of Nutrition, Institute of Health and Environmental Medicine, China

Background and objectives: It was reported that intake of flavonoids was inversely related to the morbidity and mortality of degenerative diseases, such as cardiovascular diseases and certain type of cancers. In this study, the contents of quercetin, kaemferol, myricetin, apigenin and luteolin in vegetables and fruits sampled in China were analysed and the dietary intake by Chinese was estimated.

Methods: The vegetables and fruits were sampled from Beijing, Tianjin, Shanghai and Hangzhou. A HPLC procedure was developed to analyse the contents of quercetin, kaemferol, myricetin, apigenin and luteolin after acid hydrolysis. Based on the data of Chinese Nutrition and Health Survey 2002, dietary intake by Chinese was calculated.

Results: Total of 46 vegetables and 38 fruits samples were collected. Quercetin was detectable in most vegetables and fruits and most abundant in onion bulb, lotus root, broccoli and scallion in vegetables and pomegranate, hawthorn, date, fox grape in fruits. Kaemferol, myricetin, apigen and luteolin distributed in limited vegetables and fruits. It was calculated that total dietary intake of quercetin, kaemferol, myricetin, apigen and luteolin from vegetables and fruits was not less than 16.7mg, in which 83.2% was from vegetables and 16.8% from fruits.

Conclusions: Quercetin distributes most abundantly and more fruits should be recommended to be consumed by Chinese in order to increase the intake of dietary flavonoids.

Key words: flavonoids, vegetables, fruits, dietary intake, Chinese

PO2733

THE SEPARATION AND PURIFICATION OF ANTIHYPERTENSIVE PEPTIDES FROM JAPANESE CLASSIFIED BARLEY FLOUR

M. Kawaguchi¹, S. Kanetsuki¹, Y. Okada¹, F. Sakai², Y. Yamanaka², H. Doi²

¹Department of Food Design, College of Nutrition, Koshien University, Japan

²Department of Food Science and Nutrition, Mukogawa Women's University, Japan

Background and objectives: Barley is useful as a foodstuff, because it contains high levels of protein, dietary fibers and minerals. We have been attempting to identify the biological active peptides from Japanese barley flour obtained from the outer layer of the grain. Angiotensin 1 converting enzyme (ACE) is important for blood pressure regulation. ACE inhibitory peptides have been derived from many food sources including fish, casein and soybean. In this study, we investigated the ACE inhibitory activity of peptides from Japanese classified barley flour.

Methods: Japanese classified barley flour was extracted in water and the extract was dialyzed with a Cell Sep T1 (nominal MW=3,500). The external solution of dialysis was evaporated and taken to dryness. Then the sample was dissolved in water and subjected to size exclusion chromatography on a Bio Gel P-4 column. The fractions were collected and subjected to HPLC using a CAPCELL PAK C18 column. The molecular weight of these fractions was confirmed by HPLC analysis with Tosoh TSK 3000SW column. The ACE inhibitory activity was measured by the method of Lam et al.

Results: Five fractions (P4-1a, P4-1b, P4-2-2a, P4-2-2b, and P4-3a) were identified by the preceding sequential steps. The molecular weight of P4-1a, P4-2-2a and P4-3a were 407.8,

299.9 and 147.9, respectively. The IC₅₀ values of these peptides were 0.28mM, 4.61mM and 4.39mM, respectively.

Conclusions: From the results of analysis of molecular weight, it was considered that these fractions are short peptides with two to four amino acids. Fraction P4-1a has the strongest ACE inhibitory activity among 3 peptides purified from barley, however, the IC₅₀ value of the peptide is much higher than that of commercialized antihypertensive peptides such as Ile-Phe-Phe.

Key words: antihypertensive peptides, ACE inhibitory activity, barley

PO2734

THE EFFECT OF DIFFERENT HARVEST PERIODS ON THE CONTENT OF RUTOSIDE IN HERB OF THE SELECTED CULTIVARS OF BUCKWHEAT

E. Pisulewska¹, R. Witkowicz¹, Z. Janeczko², S.Z. Suchacki³

¹Agricultural University of Krakow, Poland

²Jagiellonian University in Krakow, Poland

³Maopolska Hodowla Rocelin, Poland

Background and objectives: Tartary buckwheat and buckwheat herb are used in medicine. The raw material contains flavonoids (mainly rutoside), phenolic acids, minerals and fagopyrin. The extracts of herbs are used as a drug regulating the permeability of the capillaries, in the treatment of psoriasis and vitiligo. The aim of this study was to compare the content of rutoside in the leaves and stems of four cultivars of buckwheat: Green Corolla, Kora, Panda, Red Corolla, harvested in two periods: I - phase of intensive growth, II - at the beginning of blooming.

Methods: the experimental material for the analysis came from the two-factor field experiment which was carried out in the locality of Wierzbica (50°29'N, 19°45'E) in 2012. Rutoside was determined on a Dionex liquid chromatograph, with a PDA 100 UV-VIS detector, P 680 pump, TCC 100 thermostat, ASI 100 autosampler, and CHROOMELEON 6.60 control program. The results were calculated using a two-way statistical variance analysis.

Results: The compared buckwheat cultivars significantly differed in rutoside content both in leaves and stems. The rutoside content in the leaves ranged from 2.51 to 4.20%, and in stems from 0.031 to 0.065%. The leaves of Red Corolla cultivar had the highest rutoside content (4.20%), and the Polish cultivar Panda had the lowest (2.51%), as well as Kora (2.54%). Green Corolla cultivar contained rutoside (3.13) at the level of Tatory (3.24). The content of rutoside in buckwheat stems was low and the most of the ingredient was found in Kora cultivar

(0.065%). The first period (period 1 - 3.477%, period 2 - 2.72%) was favourable for harvesting rutoside from the leaves out of the two compared periods. However, the experiment harvest dates had no significant impact on the content of rutoside in the stems (period 1 and 2 - 0.046%).

Key words: buckwheat, leaves, stems, rutoside

PO2735

EFFECTS OF LONG-TERM FEEDING WITH NON-DIGESTIBLE OLIGOSACCHARIDE AND DIETARY FIBER ON AGE-RELATED LEARNING AND MEMORY OF SENESCENCE ACCELERATED MICE

Y. Yamaguchi¹, N. Kondo¹, K. Tanabe¹, S. Nakamura¹, T. Oku¹

¹Graduate School of Human Health Science, University of Nagasaki Siebold, Japan

Background and objectives: Senescence accelerated mouse-prone 8 (SAMP8) is a model of learning and memory disorder. Gut microbiota play more important role in maintaining human health than those previously known. Prebiotics is defined as food-grade components that deliver measurable benefit to the host through the microbiota modulation. However, the effect of prebiotics on learning and memory disorder is not clear. The purpose of this study was to examine the effects of non-digestible oligosaccharide and dietary fiber feeding on learning and memory ability of SAMP8.

Methods: SAMP8 (4wk, n=54) were randomly divided into three groups. AIN93M diet composition was replaced with 5% sucrose (CONT), 5% fructooligosaccharide (FOS) or 5% glucomannan (GM). In addition, senescence accelerated resistant strain mice (SAMR1, n=15) were used as an external control, and fed control diet. Identification of gut microbiota was measured by Mitsuoka's method. The learning and memory ability were evaluated by passive avoidance test (PAT). Total grading score was evaluated by Hosokawa's method. Oxidative stress and amyloid-beta concentration in brain were measured by ELISA method. Serotonin and catecholamine in brain were analyzed by HPLC.

Results: Total bacterial count was higher in FOS than in SAMR1 and CONT groups, and beneficial microbiota increased. PAT was better in FOS than in CONT. Total grading score was lower in FOS and GM than in CONT, although it increased depending on aging in any groups. Amyloid-beta concentration and oxidative stress were lower in FOS and GM compared with CONT. Serotonin and catecholamine concentrations were not significantly different among groups.

Conclusions: Long-term intake of FOS and GM improved intestinal microbiota and also suppressed learning and memory disorder, and delayed the aging of SAMP8. These results may

be caused by the suppression of oxidative stress and deposition of amyloid-beta.

Key words: fructooligosaccharide, glucomannan, senescence accelerated mouse

PO2736

SUPPRESSION ON POSTPRANDIAL BLOOD GLUCOSE AND INSULIN BY INHIBITION OF LOQUAT LEAF EXTRACT FOR DISACCHARIDASE AND GLUCOSE TRANSPORT IN RATS

K. Tanabe¹, C. Ushiroda¹, Y. Yamaguchi¹, S. Nakamura¹, T. Oku¹

¹Graduate School of Human Health Science, University of Nagasaki Siebold, Japan

Background and objectives: Loquat leaf is traditionally used for treating lung and stomach diseases, and diabetes mellitus, and is found to be effective for inflammatory diseases. It contains many biologically active compounds such as polyphenols and triterpenoids. Some of these biological compounds appear to have a hypoglycemic property, as well as Morus alba leaf. The objectives of the present study were to clarify the suppressive effect of Loquat leaf extract (LLE) on the elevation of blood glucose and insulin levels.

Methods: Fresh Loquat leaves were thoroughly extracted with 6-fold of 50% MeOH after drying. The inhibitory effect of LLE on rat intestinal disaccharidases was investigated by the modified Dahlqvist method using glucose oxidase. Transporter-mediated glucose uptake was performed using everted gut sac of rat jejunum. To estimate the suppressive effect on the elevation of postprandial blood glucose and insulin levels, the sucrose (150 mg) or glucose (150 mg) solution (2.5 mL) with or without LLE was administered orally to fasting rats (250 g). Blood was collected from the tail vein before administration and at 30-min intervals for 3 h after administration. Plasma glucose and insulin were measured by Trinder's method and by ELISA kit, respectively.

Results: LLE inhibited strongly the activity of sucrase, maltase, trehalase and lactase, and the inhibitory mode was non-competitive. LLE and phlorizin as SGLT1 inhibitor decreased significantly the uptake of glucose using everted gut sac. Furthermore, when the sucrose or glucose solution containing LLE was orally administered in rats, the elevation of blood glucose and insulin levels were significantly suppressed ($p < 0.05$).

Conclusions: The present study demonstrates that the suppressive effect of LLE on the elevation of blood glucose and insulin levels is caused by the inhibition of both disaccharidase activity and glucose transport in rats.

Key words: Loquat leaf extract; blood glucose; disaccharidase; glucose transport

PO2737**ORAL 2'-FUCOSYLLACTOSE INCREASES ACETYLCHOLINESTERASE LEVELS IN A MODEL OF EARLY DEVELOPMENT IN ZEBRAFISH***A. Barranco¹, E. Vazquez¹, M^a J. Martin¹, R. Rueda¹*¹Discovery R&D, Abbott Nutrition, Granada, Spain

Background and objectives: Research on Human Milk Oligosaccharides (HMO) has intensified in the last decade due to the accelerated improvement in analytical methodology and the availability of large quantities of pure carbohydrate structures. Since 2'-fucosyllactose (2'FL) is one of the most abundant HMO, several groups have focused on this particular trisaccharide. Here, we report the effect of 2FL on Acetylcholinesterase (AChE) activity, which is a commonly used biomarker for patterning of synaptic activity, neuronal growth, and circuitry. We used the Zebrafish model as a tool to assess changes in activity of AChE.

Methods: Zebrafish embryos were grown in water for 96 hours after fertilization. Larvae were transferred into 24-well culture dishes and incubated for 24 hours at 26°C in a water solution of 2'FL (74.73 mg/l). Water was used as negative control and a solution of docosahexaenoic acid (100 mg/l) was the positive control. After incubation, larvae were homogenized and centrifuged and AChE levels and protein were determined in the supernatants. The experiment was conducted twice, each one with two separate assays done in triplicates. Specific AChE activity data were referred to control and analyzed by ANOVA. Dunnett post hoc tests were used for comparisons.

Results: 2'FL induced a significant increase on AChE activity when compared to the negative control and was similar to that of the positive control. Data from the two experiments was similar, suggesting that the observed changes were not artifacts.

Conclusions: This constitutes the first account to provide evidence on the effects of 2'FL on neuronal development and suggests that 2'FL may play a role in the development of neuronal tissues of breast fed infants.

PO2738**PRELIMINARY CHARACTERIZATION OF PHENOLIC AND OTHER POLAR COMPOUNDS IN WATERMELON (CUCURBITACEAE) BY USING LIQUID CHROMATOGRAPHY COUPLED TO TANDEM MASS SPECTROMETRY***I M. Abu-Reidah¹, D. Arraez-Roman¹, A. Segura-Carretero¹, A. Fernández-Gutiérrez¹*¹Department of Analytical Chemistry, University of Granada, Granada, Spain

Background and objectives: Watermelon (*Citrullus lanatus*) is a member of the economically important family Cucurbitaceae. It is a widely cultivated and consumed crop in the world, occupying the first largest production of all cucurbits. Recently, fruits and vegetables have been recognized as important sources for a wide array of phytochemicals that may benefit health. Nevertheless, data about these compounds are lacking so far. The aim of this work was to develop a powerful HPLC-ESI-QTOF-MS method to carry out an expansive characterization of phenolic and polar compounds present in an aqueous-methanolic extract of watermelon.

Methods: 0.5 gram of lyophilized sample was extracted by a methanol/water solution. Then the mixture was vortexed, sonicated for 30 min, and finally centrifuged for 15 min at 4000 rpm. The supernatant was collected in a round bottom flask and thoroughly evaporated. The final extract was resolved in 0.5 ml of methanol/water which was filtered and finally injected in the instrument. The analysis were performed by using an HPLC coupled to QTOF-MS equipped with an ESI interface operating in negative ionization mode using a C18 column and acidified water and acetonitrile as mobile phases at 0.8 mL/min.

Results: The coupling of HPLC to ESI-QTOF-MS has demonstrated to be a useful tool for the tentative characterization of 35 phenolic compounds and other polar compounds; most of them have not been described so far in watermelon.

Conclusions: To our knowledge, this study reports the first characterization work of phenolic compounds and other polar compounds in *Citrullus lanatus*. The obtained data may facilitate the quantitative analysis; also they may be used to improve the food composition tables.

Key words: Watermelon; Cucurbitaceae; Phenolic compounds; HPLC-ESI-QTOF-MS

PO2739**USING OF ULTRA-PERFORMANCE LIQUID CHROMATOGRAPHY COUPLED WITH QUADRUPOLE-TIME-OF-FLIGHT TO CHARACTERIZE UNUSUAL BIOACTIVE PHENOLIC COMPOUNDS FROM GLOBE ARTICHOKE (ASTERACEAE)**

I.M. Abu-Reidah¹, I. Borrás-Linares¹, D. Arraez-Roman¹, A. Segura-Carretero¹, A. Fernandez-Gutierrez¹

¹Department of Analytical Chemistry, University of Granada, Granada, Spain

Background and objectives: Fruit and vegetable intake is inversely correlated with risks for several chronic diseases in humans. Phytochemicals and in particular, phenolic compounds present in plant foods may be partly responsible for these health benefits through a variety of mechanisms. However, detailed information on these bioactive compounds is still needed. In this context, the present study was aimed to develop a reliable method to perform a comprehensive characterization of phenolic and other polar compounds present in the artichoke extract.

Methods: 16 ml of aqueous-methanol solvent was added to homogenize about 0.5 gram of the freeze-dried artichoke sample. Thereafter, the mixture was vortexed, sonicated for 30 min, and finally centrifuged for 15 min at 3750 x g. The supernatant was completely evaporated and the final extract was resolved in 0.5 ml of aqueous-methanol, filtered and finally injected in the instrument. The analysis were performed by using an RP-UPLC coupled to QTOF/MS operating in negative ionization mode using a C18 column and acetonitrile and acidified water as mobile phases at 0.8 mL/min flow rate for a total time of 40 min.

Results: The proposed method has facilitated the tentative characterization of 61 phenolic and other polar compounds of which 33 unusual compounds have been never reported before. Other 28 known compounds of previously described phenolics have also been detected in this work.

Conclusions: As far as we know, a total of 33 new phenolic compounds with their isomers have been tentatively characterized in artichoke for the first time. The obtained data may be used in further quantitative analysis; they may also be used to update the food composition tables.

Key words: Artichoke; Asteraceae; Phenolic compounds; RP-UPLC; QTOF

PO2740**ORAL 2'-FUCOSYLLACTOSE PREVENTS LONG TERM EFFECTS OF EARLY PSYCHOLOGICAL STRESS ON GLIAL CELL CYTOKINE AND STRESS HORMONE RESPONSE**

E. Vazquez¹, A. Barranco¹, M^a J. Martín¹, R. Buck², P A. Prieto², M^a. Ramirez¹, R. Rueda¹

¹Discovery R&D, Abbott Nutrition, Granada, Spain

²Discovery R&D, Abbott Nutrition, Columbus, OH, USA

Background and objectives: 2'-fucosyllactose (2'FL) is the most abundant human milk oligosaccharides (HMO). Several beneficial effects have been ascribed to HMOs, covering aspects as diverse as immunomodulation and regulation of intestinal development. A mouse model of early stress by maternal separation (MS) has been reported to induce permanent changes in the central nervous system resulting in a hyperactive hypothalamic-pituitary-adrenal (HPA) axis. The aim of this work was to determine the ability of orally administered 2'FL to ameliorate the effects of early stress as measured by biochemical markers.

Methods: C57/BL6 mouse pups were daily removed from the dam for 4 hours (days 2 to 14 after birth). Sham animals were kept with their mothers. After weaning, early stressed mice were separated into two groups, one fed on AIN-93G control diet and the other with AIN-93G supplemented with 2'FL (350mg/kg BW per day). After three months of feeding, the basal level of serum corticosterone was measured. Mice were submitted to an acute restraint stress during 20 min and serum corticosterone was measured. Animals were then sacrificed and glial cells were isolated from the brain and cultured in the presence of LPS (1µg/ml). Cytokine levels in supernatants were measured.

Results: The control group had higher serum corticosterone and lower IL-6 and IL-10 secretion from glial cells than the sham group. Dietary 2'FL supplementation restored the level of these parameters to those of sham animals.

Conclusions: Feeding 2'FL prevented alterations induced by stress during early life. This suggests that HMOs may also play a role in the development/function of the central nervous system by modulating the HPA axis.

PO2741**THE EFFECT OF HARVEST TIME ON THE BASIC CHEMICAL COMPOSITION OF DRIED LEAVES OF SOME BUCKWHEAT CULTIVARS***E. Pisulewska¹, E. Pitkowska¹, T. Leszczyńska¹, A. Kopeć¹*¹Agricultural University of Cracow, Poland

Background and objectives: Buckwheat is known as a plant showing functional properties. It reduces the cancer risk and it has anti-allergic and anti-inflammatory properties. The aim of the study was to determine the basic chemical composition of some varieties of dried buckwheat leaves.

Methods: Four varieties of dried buckwheat leaves (Green Corolla, Red Corolla, Kora, Panda) were harvested in June and July. Leaves were shredded and dried. The total amount of nitrogen, fat, ash, dietary fibre and carbohydrates were determined using AOAC methods in dry mass.

Results: In every case, the harvest time had a significant effect on the content of the tested components. It has been shown that the dried buckwheat leaves are an important source of protein (25g/100g). The lowest concentration of those components was in Panda variety harvested in July and the highest was noted in Kora variety collected in June. The dried buckwheat leaves are rich in minerals (ash) (13g/100g). The lowest amount was found in Panda variety from July, the highest in the Kora from June. The buckwheat leaves have low concentration of fat (1g/100g). The average total carbohydrate content was ca. 50g/100g.

Conclusions: The harvest time had a significant effect on the content of the tested components. The researched varieties of dried buckwheat leaves are a valuable source of basic nutrient components and should be considered as the raw material for food production.

Key words: chemical composition, buckwheat, protein

PO2742**INCREASE IN HIPPOCAMPAL LONG-TERM POTENTIATION RESPONSE BY 2'-FUCOSYLLACTOSE AFTER SHORT OR LONG TERM FEEDING IN RODENTS***E. Vazquez¹, A. Barranco¹, J. M^a. Delgado-Garcia², A. Gruart², P. A. Prieto³, R. Buck³, M^a. Ramirez¹, R. Rueda¹*¹Discovery R&D, Abbott Nutrition, Granada, Spain²Department of Neurosciences, University Pablo de Olavide, Sevilla, Spain³Discovery R&D, Abbott Nutrition, Columbus, OH, USA

Background and objectives: The ability of synapses to change their strength is considered one of the major mechanisms that underlie learning and memory. A Long Term Potentiation (LTP) model might replicate cellular changes in synapses that occur during cognitive function. It has been shown that incorporation of fucose into glycoproteins and fucokinase activity increase after induction of LTP or learning tasks. Since 2'-fucosyllactose (2'FL), is the most prevalent human milk oligosaccharides we set to determine its effects on LTP using two different models.

Methods: Experiment 1 (rats): Basal LTP was established in four adult Sprague Dawley rats, which were then fed an AIN-93M diet supplemented with 2FL (350 mg/kg BW/day) for two weeks. LTP was then measured and compared with basal LTP. Experiment 2 (mice): Weanling C57BL/6 mice were divided into 2 groups. Control (n = 10) and FL (n = 10). Animals were fed either AIN-93G control diet or diet supplemented with 2FL (350mg/kg BW per day) from weaning for 12 weeks. LTP was measured at the age of three months. LTP: The animals were surgically implanted with electrodes in the hippocampus (CA3-CA1 area). After application of a high frequency protocol (HFS), field excitatory post-synaptic potentials (fEPSPs) were recorded for each animal. Additional recordings were carried out for 15 min during the 3 following days

Results: In both experiments LTP were evoked following HFS of the hippocampal synapse. Furthermore, LTP evoked after 2 weeks (rats) or 12 weeks (mice) of feeding with 2'FL diets presented significantly larger fEPSPs than basal data (rats) or than control values.

Conclusions: 2-Fucosyllactose increases LTP response regardless of the duration of feeding; this suggests that this human milk trisaccharide plays the role of a molecular mediator in processes of learning/memory.

PO2743**ORALLY GIVEN 2'-FUCOSYLLACTOSE BUT NOT FUCOSE INDUCES AN INCREASE OF THE HIPPOCAMPAL LONG-TERM POTENTIATION RESPONSE IN CONSCIOUS RATS**

E. Vazquez¹, A. Barranco¹, A. Gruart², J M^a. Delgado-Garcia², R. Buck³, P A. Prieto³, M^a. Ramirez¹, R. Rueda¹

¹Discovery R&D, Abbott Nutrition, Granada, Spain

²Department of neurosciences, university Pablo de Olavide, Sevilla, Spain

³Discovery R&D, Abbott Nutrition, Columbus, OH, USA

Background and objectives: Long-term potentiation (LTP) is a long-lasting enhancement in signal transmission between two neurons. LTP underlies synaptic plasticity, and is widely considered one of the major cellular mechanisms involved in learning and memory. It has been postulated that fucosylated proteins are implicated in this process. Direct intrahippocampal injection of L-fucose or the human milk oligosaccharide 2'-fucosyllactose (2'FL) enhances LTP. In previous studies, we have confirmed that feeding with 2'FL enhances LTP in mice after a long period of feeding and in rats after only two weeks. The objective of this work was to determine whether the positive effect of oral 2'FL on LTP is due to its L-fucose content or to the entire 2'FL molecule.

Methods: Adult Sprague Dawley rats (n=10 per group) were fed during 40 days with three diets: a AIN-93M control diet, the same diet supplemented with 2'FL (350mg/Kg BW), or with L-fucose (equimolar to 2'FL). Electrodes were surgically implanted in the CA3-CA1 area. LTP was evoked, using a high frequency protocol HFS and the field excitatory post-synaptic potentials were recorded for 30 min. Additional recordings were carried out for 15 min during the 3 following days.

Results: The 2'FL group presented a significantly larger LTP as compared with the other two groups. Feeding with L-fucose did not modify LTP respect to control group.

Conclusions: The effect of oral 2'FL on the potentiation of hippocampal synapses appears to be independent of the metabolic contribution of its fucose content. This results suggests that either intact 2'FL or one of its structural motifs may play a role in LTP-mediated cognitive processes

PO2744**PHOSPHORUS BALANCE AFTER MODEL MAILLARD REACTION PRODUCTS CONSUMPTION IN YOUNG AND ADULT RATS**

C. Delgado-Andrade¹, I. Seiquer¹, I. Roncero-Ramos¹, A. Haro¹, P. Navarro¹

¹Instituto de Nutrición Animal, EEZ, Consejo Superior de Investigaciones Científicas (CSIC), Armilla, Granada, Spain

Background and objectives: Studies concerning effects of Maillard reaction products (MRPs) on mineral availability have been mainly focused on divalent cations. However, information on MRPs and phosphorus is scarce since it acts as an anion in the biological fluids. Our purpose was to investigate the effects of the consumption of MRPs from glucose-lysine model system heated 150°C-90 min on phosphorus bioavailability and its main metabolic destination, the bone.

Methods: Equimolar mixture of glucose-lysine-HCl (GL) was heated (150°C-90 min) to obtain GL90 sample. It was added to the AIN-93G diet (Control diet) in a concentration of 3% (GL90 diet). Forty-eight rats were distributed into two groups (n=24) and assigned to one of the dietary treatments. Food intake was monitored during the whole experimental period. To investigate the phosphorus balance in different stages of growth, each dietary treatment was divided into two groups (n=12). One of them was sacrificed after three weeks, whereas the other continued the experiment until twelve weeks. In each slaughter 6 animals were destined to the calculation of phosphorus balance, while the remaining 6 animals were used for femur extraction. Phosphorus in diets, whole animals and femurs was colorimetrically determined (vanadomolybdate procedure).

Results: Phosphorus intake was unaffected by the consumption of MRPs after three or twelve weeks. After three weeks, phosphorus body content was increased by consumption of GL90 diet, as well as its global retention and bioavailability. However, considering the twelve-week period these parameters were unchanged. Phosphorus content and concentration in femur did not modify by MRPs consumption in any case.

Conclusions: Consumption of glucose-lysine MRPs by young rats increased phosphorus retention and bioavailability. An adaptation mechanism seems to occur with age, as once rats reach maturity phosphorus bioavailability was unaffected by the intake of these compounds.

Key words: Maillard reaction products; phosphorus; retention; bioavailability.

PO2745**BACTERIAL CELL WALL COMPONENTS AND PROBIOTIC STRAINS INDUCE ALTERATIONS IN DNA METHYLATION OF TNF AND TLR4 IN HUMAN INTESTINAL EPITHELIAL CELLS**

D. Kremenovic², B. Hippe¹, M. Remely¹, L. Giali¹, A. G.Haslberger¹

¹Dep. Nutritional Research, University of Vienna, Vienna, Austria

²Dep. Anthropology, University of Vienna, Vienna, Austria

Background and objectives: Commensal bacterial strains and bacterial cell wall components are proposed to induce differential cell responses regulated by intracellular signalling pathways. Epigenetic modulation of gene expression was recently discussed to be influenced by LPS and probiotic bacteria. The main aim of this study was to investigate promoter methylation in response to probiotic strains in contrast to LPS.

Methods: Upon stimulation of Caco-2-cells with LPS, *Lactobacillus rhamnosus* GG (LGG) and *Lactobacillus delbrueckii* (LD) quantitative DNA methylation of four CpG loci in the TNF- α promoter region and four CpGs of the TLR4 exon were analysed by the pyrosequencing.

Results: Methylation in four analysed TNF- α CpG loci ranged between 70-90% in unstimulated cells. Significant changes in TNF- α methylation over all four CpGs were caused by LGG after 12h of stimulation ($+1.07\pm 0.24\%$, $p=0.048$), LD after 24h ($+1.54\pm 0.3\%$, $p=0.035$) and LPS after 72h ($-0.58\pm 0.05\%$, $p=0.007$). TLR4 methylation was not consistent among cell culture experiments and ranged between 10 and 45% in unstimulated cells. CpG 4 was significantly increased by 12h LPS treatment ($+2.00\pm 0.42\%$, $p=0.041$), CpG 3 was decreased after 72h LGG treatment ($-1.77\pm 0.29\%$, $p=0.027$) and CpG 2 was also decreased after 12h LPS treatment ($-1.62\pm 0.26\%$, $p=0.024$).

Conclusions: The results indicate, that epigenetic regulation of TNF- α and TLR4 contributes to the specificity of inflammatory reactions induced by bacteria and bacterial cell wall components

PO2746**EFFECTS OF ADVANCED GLYCATION COMPOUNDS FROM BREAD CRUST ON IRON METABOLISM AND TISSUE DISTRIBUTION**

C. Delgado-Andrade¹, I. Roncero-Ramos¹, A. Haro¹, M. P. Navarro¹

¹Instituto de Nutrición Animal, Estación Experimental del Zaidín, CSIC, Spain

Background and objectives: Advanced glycation end-products (AGEs) can interfere mineral utilisation, as they can act as anionic polymers which complex minerals. We investigated effects of AGEs from bread crust (BC) on iron bioavailability and tissue distribution in rats, analysing whether effects are related to the molecular weight of AGEs.

Methods: BC was digested with pronase-E, obtaining soluble and insoluble fractions. Ultrafiltration was applied to separate compounds higher and lower than 5kDa (HMW and LMW) from the soluble fraction. BC was added to the AIN-93G-diet (Control diet) to reach a concentration of 10% (BC diet). LMW and HMW fractions were individually added to the AIN-93G-diet in the proportion they were present in BC (LMW and HMW diets). Four groups of rats ($n=12$) were assigned to one of dietary treatments for three months, monitoring food consumption and body weights. Afterwards, animals were sacrificed and iron balance calculated in six individuals of each group (initial-final iron), whereas in the remaining animals different organs were removed. Dietary, faecal, urinary and tissue iron was determined by AAE.

Results: Iron intake did not differ in any dietary treatment, however iron body content and its retention tended to increase by consumption of BC and derivatives, leading to a higher iron bioavailability, only significant in HMW group. Iron body concentration resulted increased after consumption of AGEs-enriched-diets, especially in LMW and HMW groups. BC intake led to higher iron content and concentration in liver and small intestine, while consumption of LMW and HMW fractions conducted to increased iron concentration in spleen and femur. Haemoglobin levels were unaffected.

Conclusions: Consumption of AGEs from BC or its derivatives led to increases on iron bioavailability between 13-33%. A hyperconcentration of iron occurred in the organism, conducting to higher stored iron in organs as liver or spleen.

Key words: AGEs; iron; bioavailability; distribution.

PO2747**POTENTIAL DIETARY HEALTH BENEFITS OF THE UNEXPLOITED SEEDS OF SOME SPECIES FROM THE FLORA OF TUNISIA***N. Nasri¹, W. Elfalleh¹, N. Tlili¹*

¹Department of Biology, Faculty of Sciences of Tunis, University of Tunis-El Manar, Tunisia

Background and objectives: There has been recent growth in research aimed at investigating new sources of plant oils, particularly from unexploited seeds. Samples from *Acacia cyanophylla*, *Juniperus phoenicea*, *Punica granatum* and *Capparis spinosa* were analyzed in order to evaluate the potential nutritional value of their unexploited seeds.

Methods: Samples were collected from different Tunisian geographic locations. Seed oils were extracted and total lipids including polyunsaturated fatty acids, carotenoids, tocopherols and sterols were evaluated. Storage proteins and total phenols were also investigated.

Results: All the studied seeds seem to be quite rich in lipids: from 11% (*A. cyanophylla*) to 33% (*C. spinosa*) and proteins from 8.4% (*J. phoenicea*) to 27% (*C. spinosa*). Lipids are mainly unsaturated (ca.86%). ω 6 PUFAs can reach 63% for *A. cyanophylla* and ω 3 PUFAs average 34% for *J. phoenicea*. Total phenols are highly present for all studied species (reached to 1764 mg Gallic Acid Eq/100 g DW for *J. phoenicea*) and mean free radical scavenging activities can reach 1337 TEAC per 100 g D W for *J. phoenicea*. Tocopherols attained 3 g/ kg of total lipids (*P. granatum*). Carotenoids (mainly xanthophylls) are also quantified and ranged up to 113 mg. kg⁻¹ of total lipids (*A. cyanophylla*). Sterols are also highly present, particularly for *A. cyanophylla* (8.9 g/ kg of total lipids).

Conclusions: All of these findings highlight that these non conventional oils and these unexploited seeds might have a potential nutritional value and encourage researchers to more explore and find developments for these plants for healthy purposes.

Key words: Unexploited seeds, Oils, healthy purposes.

PO2748**GLYCEMIC INDEX OF FONIO (DIGITARIA EXILIS) COUSCOUS WITH OKRA (ABELMONSCHUS ESCULENTUS) AND WHITE BREAD CONSUMED WITH CASHEW NUTS (ANACARDIUM OCCIDENTALE)***A T. Guiro¹, S A A. Diatta¹, A. Faye¹, N. Idohou-Dossou¹, A. Diouf¹, S. Wade¹*

¹Laboratoire de Nutrition, Département de Biologie Animale, Faculté Des Sciences Et Techniques, Université Cheikh Anta Diop (UCAD) de Dakar, Senegal

Background and objectives: Glycemic index (GI) and glycemic load (GL) of foods are interesting tools in the prevention of diabetes. The objective of the study was to measure GI and GL values of Fonio couscous with okra (F-Okra) and white bread (WB) consumed with local cashew nuts (W-Nuts).

Methods: Fifteen (15) healthy men volunteers participated to the experimental study and were randomized into F-Okra group (n=7, mean age=28 y, mean BMI=18.9 kg/m²), and W-Nuts group (n=8, mean age=24 y, mean BMI=20.6 kg/m²). After a 10-12h overnight fast, the subjects received 97 g of WB (equivalent to 50 g of available carbohydrate) as the reference food during 3 consecutive days, and the day after they received either 74.63 g of Fonio mixed with 11 g okra powder, or 97 g of WB consumed with 60 g of cashew nuts. Finger capillary blood samples were collected before the meals (fasting) and at 15, 30, 45, 60, 90 and 120 min. The GI and GL were calculated according to WHO/FAO standards and published tables, respectively.

Results: F-Okra had a GI of 64.9±27.2 and W-Nuts a GI of 60.8±18.6 when WB was used as the reference. After adjusting for glucose, low GIs (<55) were found for F-Okra (49.9±20.9), and W-Nuts (46.7±14.3). The GL corresponding to 150 g of cooked Fonio couscous (WB reference) was 20.3 g. The GL corresponding to 80 g of WB (WB reference) was 24.3 g. Both GL were high and intermediate when adjusted for glucose:15.6 g and 19.2 g respectively.

Conclusions: GIs of these African foods are intermediate and low when adjusted for glucose. Depending on the amount of food consumed, the corresponding GL was high or intermediate. Therefore it's important to consider food GI and GL in nutritional counseling for diabetic patients.

Key words: GI, GL, F-Okra, W-nuts, Senegal

PO2749**SIALIC ACIDS IN HUMAN MILK: IN VITRO ACCESSIBILITY STUDY**

L. Claumarchirant¹, E. Galán¹, G. García-Llatas¹, E. Matencio², A. Alegría¹, M.J. Lagarda¹

¹Nutrition and Food Chemistry, Faculty of Pharmacy, University of Valencia, Spain

²Hero Global Technology Center, Hero Spain, S.A. Alcantarilla, Murcia, Spain

Background and objectives: Sialic acids (N-acetylneuraminic acid-Neu5Ac and N-glycolylneuraminic-Neu5Gc) are bioactive compounds present in human milk that play a role essential in the brain development during the first stages of life. The aim of this study is to assess the precision/variability of simulated gastrointestinal digestion in sialic acids present in human milk and to estimate their bioaccessibility (maximum soluble amount available for absorption).

Methods: The gastrointestinal digestion, with three sequential steps (salivary with neuraminidases, gastric and intestinal-soluble fraction), was applied to a human milk pool (4-7 months of lactation). Aliquots of all the stages of digestion and blanks were hydrolyzed with H²SO⁴ 0.05M, centrifuged (1000xg/4°C/10min), purified by ion exchange (2ml of Dowex 1x8), ultrafiltered (Microcon Ultracel YM-10, 13000xg/4°C/10min) and derivatized (DMB 50°C/2.5h). The Neu5Ac and Neu5Gc contents were determined by HPLC-fluorescence.

Results: Large intraday (n=3, four digestions) and interday (n= 12, three different days) variability for Neu5Ac were observed in salivary (5.2-25.3% and 26.2%), gastric (3.7-15.5% and 11.1%) and intestinal (2.8-10.1% and 21.5%) fractions. No statistically significant differences (p < 0.05) among Neu5Ac contents from all fractions were observed. The percentages of decrease of Neu5Ac in each fraction respect to the average content in human milk without digest (299.9±7.8 mg/L) ranged between 30.47% and 35.74%. Bioaccessibility percentage was 68.1±15%. Neu5Gc was detected only in intestinal fraction with high intraday (14%) and interday (28%) values and contents ranged between detection and quantification limits (0.7 and 2 mg/L, respectively).

Conclusions: It is necessary to standardize simulated digestion models. The salivary digestion with neuraminidases reduced significantly the Neu5Ac content, though the bioaccessibility remained high.

Key words: sialic acid, human milk, in vitro bioaccessibility

PO2750**BULGARIAN MEDICINAL PLANTS WITH A POTENTIAL TO IMPROVE LIPID PROFILE IN HEALTHY VOLUNTEERS**

M. Nashar¹, O. Tasinov¹, D. Vankova¹, Y. Kiselova-Kaneva¹, D. Ivanova¹

¹Department of Biochemistry, Molecular Medicine and Nutrigenomics, Medical University Varna, Bulgaria

Background and objectives: Obesity and diabetes are among the most common and socially significant diseases associated with hyperlipidemia. Plant derived therapeutics have less side effects and often possess higher efficiency, than those derived synthetically. Sambucus ebulus(SE) and Agrimonia eupatoria(AE) are medicinal plants widely used in Bulgarian traditional medicine. They are rich in polyphenols with proven high anti-oxidative and anti-inflammatory activity and possibly play a role for the prevention of obesity-related diseases. With respect to identifying new drug sources, we aimed to compare the effect of SE (fruits) and AE (aerial parts) tea consumption on body mass index (BMI), serum of triacylglycerides (TG), total cholesterol (TC), high-density lipoprotein-cholesterol (HDL-C), low-density lipoprotein-cholesterol (LDL-C) and glucose in healthy volunteers.

Methods: The study involved two groups of healthy volunteers n=22 and n=19 who consumed SE or AE tea 200 ml/day for 30 days. Blood samples were collected at the start and at the end of the study. Plasma lipids and glucose levels were measured using standardized spectrophotometric methods.

Results: Although that AE tea consumption induced an increase in TG and TC (p<0.01), also HDL-C was elevated significantly (p<0.05) contributing thus to elevated HDL/LDL ratio. A slightly different mode of action of SE tea was observed – its consumption induced statistically significant decrease in TG (p<0.01), TC (p<0.001), and in LDL-C (p<0.001), and also a slight increase in HDL-C. Both teas induced elevation of HDL/LDL ratio, the change being significant only in the SE (p<0.01) group. In both groups of volunteers blood glucose levels stayed within the reference values. BMI did not change either.

Conclusions: Apparently both plants have a potential to improve lipid profile, although that SE tea seems to be a better therapeutic source to treat hyperlipidemia and related disorders.

Key words: Sambucus ebulus, Agrimonia eupatoria

PO2751

EFFECT OF SOY ISOFLAVONE, INULIN CALCIUM AND VIT D3 IN THE TREATMENT OF POST-MENOPAUSAL HOT FLUSHES: A CONTROLLED OBSERVATIONAL STUDY

⁸Gynecological Service Fondazione Monasterio Pisa, Pisa, Italy

Background and objectives: Inulin may increase the plasma concentrations of the soybean isoflavones (Am J Clin Nutr. 2007 86:775-80), improving soy isoflavone effect on climacteric symptoms.

Methods: To test this hypothesis, we conducted an observational prospective study. Peri-post-menopausal women observed in seven Italian outpatients gynaecological services from January 2102, aged 45-60 years, reporting 3 or more hot flushes (HF) die, not requiring hormonal therapy (HT) and/or therapy for osteopenia/osteoporosis, were eligible for the study. They gave informed consent to the study. A daily treatment with 55 mcg calcium + 7.5mcg Vit D3+ 3 gr inulina and 40 mg of soy isoflavones per os was proposed to all women. Those who accepted the treatment were included in the treatment group, who did not in the control one. Follow up visits were after 3 and 6 months. In this analysis we present the results available until January 2013, with reference to 3 months follow up visit.

Results: Univariate analysis of variance was used to evaluate the change from baseline of number of HF die. 144 women entered the study, 82 (mean age 53.8, SD 3.8) were in the treatment group and 64 (mean age 53.9, SD 4.4) in the control one. At study entry the mean number/die of HF was 6.1 (SD 4.6) in the treatment group and 5.6 (SD 6.5) in the control one. At the 3-month follow up visit, the mean change of the number of HF was -2.9 (SD 4.0) in the treatment group and +0.2 (SD 4.1) in the control one (P<0.05).

Conclusions: This preliminary analysis shows that 3 months after study entry a daily treatment with 55 mcg calcium + 7.5mcg Vit D3+ 3 gr inulina and 40 mg of soy isoflavones per os lowers the number of hot flushes/die reported by the women. No change was observed in the control group

PO2752

PHENOLIC CONTENT AND ANTIOXIDANT ACTIVITY OF RAW AND PROCESSED ROOTS AND TUBER CROPS

A. Chandrasekara¹, T. Joshepkumar¹, M. Sakthivel¹, V. Marian-Victor¹

¹Department of Applied Nutrition, Wayamba University of Sri Lanka, Makandura, Gonawila, Sri Lanka

Background and objectives: Root and tuber crops which play an important role as a global source of energy, next to cereals are generally peeled and subjected to a hydrothermal treatment before consumption. The objectives of the study were to determine the phenolic contents and their antioxidant activities of several raw tuber crops and their processed counterparts.

Methods: Several roots and tubers, namely cassava (*Manihot esculenta*), potato (*Solanum tuberosum*), sweet potato (*Ipomea batatas*) and elephant foot yam (*Amorphophallus paeoniifolius*), country potato (*Solenostemon rotundifolius*), lesser yam (*Dioscorea esculenta*), arrowroot (*Maranta arundinacea*) and purple yam (*Dioscorea alata*) were studied. Phenolic extracts obtained from tubers and their peeled and cooked counterparts were studied for their total phenolic (TPC) and flavonoid (TFC) content, radical scavenging capacity and reducing power.

Results: The TPC of raw and cooked tubers ranged from 4 to 79 and 1.5 to 48 μ moles gallic acid equiv /g of dry matter for flesh, respectively. For all varieties employed in this study the peel showed the highest TPC and TFC. All roots and tubers exhibited notable 2, 2-diphenyl-1-picrylhydrazyl (DPPH) radical scavenging activity, trolox equivalent antioxidant capacity (TEAC), and reducing power (RP). Peeling and hydrothermal processing affected the TPC, TFC and radical scavenging and antioxidant activities of tubers depending on the variety. In general, peel had higher TPC thus exhibited superior antioxidant activities compared to flesh. Cooking with peel showed a high retention of phenolic compounds in the flesh.

Conclusions: Thus, the present study demonstrated that peeling and hydrothermal treatments affect the phenolic content and antioxidant activities of root and tuber crops. Processing conditions should be optimized to retain natural antioxidants. Peeled tubers as well as peel fraction may serve as natural source of nutraceutical and functional food ingredients in health promotion and disease risk reduction.

Key words: DPPH, Flavonoids, Reducing power, TEAC

PO2754**MUCILAGE OF OPUNTIA STREPTACANTHA: DIETARY FIBER WITH POTENTIAL PREBIOTIC**

E G. Ramos-Ramírez¹, M. Reyes-Reyes¹, L F. Ortiz-González¹, J A. Salazar-Montoya¹, L. Rodríguez-Páez², M P. Méndez-Castrejón¹

¹Department of Biotechnology and Bioengineering, CINVESTAV-IPN, Mexico City, Mexico

²Department of Biochemistry, ENCB-IPN, Mexico City, Mexico

Background and objectives: The mucilage of *Opuntia streptacantha* (OS) is formed mainly by complex carbohydrates which are resistant to digestion and absorption processes of the small intestine. The partial hydrolysis of their sugars produce oligosaccharides, which can be considered as prebiotic active compounds. Therefore the aim of this study was to determine the content of dietary fiber (DF) of mucilage OS and prove the potential prebiotic of oligosaccharide fraction (OF).

Methods: The mucilage was extracted from fresh cladodes of OS and it was determined its DF content. By partial enzymatic hydrolysis, gel permeation chromatography and ethanol precipitation was obtained the OF, and it was determined its molecular weight. Prebiotic potential was evaluated using the OF by an in vitro assay using *Lactobacillus acidophilus*.

Results: Total DF content determined in the mucilage was 57.62%, of which 37.16% were soluble DF; these values are within those reported for other plants such as soy and pulp of cactus pear fruit. In the in vitro assay it was observed that cell growth presented by *Lactobacillus acidophilus* showed no significant difference, compared with the growth shown for a commercial prebiotic (Inulin). Changes in pH were according to the reported for others oligosaccharides.

Conclusions: The mucilage of OS showed a significant content of DF, so that your consumption can generate gastric and/or systemic benefits. In vitro behavior of the OF was similar to that of inulin, so can be considered as a potential prebiotic.

Key words: Mucilage, *Opuntia*, Dietary fiber, Prebiotic, Oligosaccharides.

PO2755**EFFECTS OF SPICE INGREDIENTS ON APOLIPOPROTEIN B48 BY CACO-2 INTESTINAL CELL LINE**

K. Tomishige¹, A. Minato¹, Y. Nakagawa¹, T. Matsushima¹

¹Department of Human Life Science, Jissen Women's University, Tokyo, Japan

Background and objectives: Postprandial hyperlipidemia is considered to be one of strong risk factors for atherosclerosis. Several spice ingredients and food components are of interest, supposed to suppress lipid absorption and hyperlipidemia. Analysis of the secretion and metabolism of chylomicron is important to study postprandial hyperlipidemia. Apolipoprotein B48, a partial peptide of B100 originated from the same gene, is the constitutional protein moiety of chylomicron. We established monoclonal anti-B48 antibody using C-terminal synthetic peptide as antigen and developed ELISA system for B48. Human colon cancer cell line Caco-2 keeps physiological characteristics as normal intestinal cells.

Methods: In this study we cultured Caco-2 cells in permeable membrane insert, where cells are polarized and secrete nutrients absorbed at apical side from upper chamber to lower chamber from basal side.

Results: Caco-2 cells cultured in the medium with lipid micelles secreted considerable amount of apoB48. Addition of 350µM of piperine, 300µM of gingerol and 200µM of curcumin, a spice ingredient of turmeric, decreased apoB48 secretion by 55%, 57% and 85% respectively. Suppression of the secretion of apoB48 from Caco-2 cell is also observed by addition of 200µM of soy isoflavone and wine polyphenol. On the other hand, capsaicin the component of red pepper increased the apoB48 secretion to 135% of control.

Conclusions: Several candidate steps may be responsible for regulation of the secretion of apoB48, such as lipid digestion, absorption, apoB48 messenger editing and triglyceride incorporation into lipoprotein. Some of relevant proteins are under investigation. Spices increase appetite and may lead people to over-eating, but those tested above possibly suppress over-taking of energy by inhibiting absorption and secretion of lipids into blood. When eating fat-rich dishes, taking them with these spices may be beneficial to prevent hyperlipidemia through suppression of the secretion of apoB48 and chylomicron.

Key words: apolipoprotein, chylomicron, cell, spice, hyperlipidemia

PO2756**NATURALLY OCCURRING SPHINGOID BASES REGULATE EXPRESSION OF GENES ENCODING MEDIATORS OF FILAGGRIN DEGRADATION TO NATURAL MOISTURIZING FACTORS IN HUMAN KERATINOCYTES**

T. Hasegawa¹, M. Nakashima¹, Y. Matsuoka¹

¹Shiseido Functional Food Research & Development Center, Yokohama, Japan

Background and objectives: Glucosylceramide (GlcCer) is major sphingolipid of natural products, including those used as daily food sources, such as rice and maize. It has been reported that dietary GlcCer improves skin barrier condition. However, the mechanism involved remains unknown. We previously found that dietary GlcCer enhanced cornified envelope formation and tight junction function, which are essential for the skin barrier function, via induction of transglutaminase-1 and claudin-1 in skin epidermis. On the other hand, filaggrin, which is a key protein for skin barrier function, plays a role in the precursor of hygroscopic amino acids and their derivatives, known as natural moisturizing factors (NMF), in the skin epidermal stratum corneum. The pathway of filaggrin degradation to NMF is also crucial for skin barrier function.

Methods: In this study, we examined whether sphingoid bases generated by metabolism of dietary GlcCer, i.e., sphingosine (SS), sphinganine (SN), phytosphingosine (PS), 4,8-sphingadienine (SD) and 4-hydroxysphingene (4HS), influence the expression of genes encoding factors that mediate filaggrin degradation to NMF, including the filaggrin, caspase-14, calpain-I and bleomycin hydrolase genes, in cultured human keratinocytes by RT-PCR.

Results: As the result, all five sphingoid bases increased the expression of filaggrin mRNA. Among them, only PS increased the expression of caspase-14 mRNA, while SS decreased it. Further, PS and 4HS increased the expression of calpain-I mRNA, and 4HS increased the expression of bleomycin hydrolase mRNA.

Conclusions: Our results indicate that skin barrier improvement by oral GlcCer treatment is at least partly due to modulation of the expression of genes encoding mediators of filaggrin degradation to NMF in human keratinocytes, by sphingoid bases metabolically derived from GlcCer.

Key words: Glucosylceramide; Sphingoid base; Filaggrin; Natural moisturizing factors; Keratinocyte

PO2757**CATECHIN INCREASES THE SEROTONIN RELEASE IN THE RAT HIPPOCAMPUS**

A. Nishimori¹, H. Hirayama², T. Matsuoka¹, R. Nigo², T. Yamato^{1,2}, M. Aomine^{1,2}

¹Faculty of Nutrition Sciences, Nakamura Gakuen University, Fukuoka, Japan

²Graduate School of Health and Nutrition Sciences, Nakamura Gakuen University, Fukuoka, Japan

Background and objectives: Catechin has been reported to be responsible for a lot of physiological functions including central nervous system. However, the effects of catechin on the brain function, especially the central serotonergic systems, remain to be clarified. Therefore, the aim of the study was to examine whether or not the catechin increases serotonin (5-hydroxytryptamine; 5-HT) release from the brain region.

Methods: We used the male Wistar rat and measured the extracellular 5-HT in the hippocampus using in vivo microdialysis techniques. We used five catechin compounds (10 μ M); (+) catechin (CAT), (-) epigallocatechin gallate (EGCG), (-) epigallocatechin (EGC), (-) epicatechin gallate (ECG), and (-) epicatechin (EC). We mainly used CAT because EC was changed to CAT by heating. The effect of CAT was also examined under the conditions of high or low K⁺ and of the presence of tetrodotoxin (TTX, 1 μ M), clorgyline (MAO inhibitor, 1mM) and/or fluvoxamine (serotonin selective reuptake inhibitor; SSRI, 1mM).

Results: All catechin compounds used markedly increased the 5-HT release from hippocampus. EC was most effective in increasing 5-HT release, followed by CAT, EGC, ECG, and EGCG in that order. CAT (1 μ M~1mM) increased the 5-HT release concentration-dependently, and the ED₅₀ was about 0.1mM. The 5-HT release by CAT remained unchanged even in the conditions of low K⁺, high K⁺, or TTX. On the other hand, clorgyline or fluvoxamine also significantly increased the 5-HT release. However, the additional increase of the 5-HT release by clorgyline or fluvoxamine was not observed even in co-existence of CAT.

Conclusions: These findings suggest that catechin may act as an antidepressant, which elevates the 5-HT levels in the brain, thereby permitting the improvement of depression.

Key words: catechin, in vivo microdialysis, 5-HT, hippocampus, antidepressant

PO2758

DIOSCOREA JAPONICA EXTRACT SUPPRESSES THE EXPRESSION OF THE RELATED ENZYMES SYNTHESIZING LIPID MEDIATOR PROSTAGLANDIN E2

I. Tsukayama¹, M. Takafuji¹, S. Tanaka¹, Y. Kawakami¹, Y. Takahashi¹, T. Suzuki-Yamamoto¹

¹Department of Nutritional Science, Okayama Prefectural University, Soja, Japan

Background and objectives: *Dioscorea japonica* is one of wild yams and is a relative of the Dioscoreaceae family native to Japan. For many years, it is believed that *Dioscorea japonica* is good for a nutritional fortification, and has some effects of gastric mucosal protection, digestive enhancement and so on. In some areas, the wild yam has been used as folk medicine against asthma, rheumatoid arthritis, bronchitis, and other disease. However, the detailed physiological effects of the yam have not been clear. In the present study, we focus on the functional effects of *Dioscorea japonica* on the related enzymes synthesizing prostaglandin (PG) E₂. PGE₂ is one of the lipid mediators, and is involved in many pathological conditions such as inflammation and tumorigenesis. PGE₂ is synthesized from arachidonic acid by cyclooxygenase (COX) and PGE synthase (PGES), and the isozymes, COX-2 and mPGES-1 are induced in those diseases.

Methods: The 50% extract of *Dioscorea japonica* powder (DJP) was added to human lung carcinoma A549 cells, human colon carcinoma Caco-2 cells, and lipopolysaccharide (LPS)-induced mouse macrophage RAW264 cells. The expression of COX-2 and mPGES-1 was analyzed by real-time PCR, and COX-2 activity and PGE₂ production were measured. COX-2 promoter activity was analyzed using secreted luciferase reporter gene assay.

Results: In A549 cells and Caco-2 cells, DJP extract dose-dependently suppressed COX-2 and mPGES-1, and inhibited COX-2 activity and PGE₂ production. Additionally, in the inflammation model, LPS-RAW264 cells, it was also confirmed that DJP extract decreased the mRNA levels, and suppressed COX-2 promoter activity.

Conclusions: The present study indicated that DJP extract suppressed the expression of COX-2 and mPGES-1 in the carcinoma models and the inflammation model. Hence *Dioscorea japonica* may contribute to the prevention such as tumorigenesis and inflammation.

Key words: wild yam, cyclooxygenase-2, prostaglandin E₂ synthase-1, carcinoma, inflammation.

PO2759

AMELIORATING EFFECTS OF GREEN TEA ON THE DIABETES-INDUCED OXIDATIVE STRESS

A. Nishimori¹, H. Hirayama², T. Matsuoka¹, R. Nigo², T. Yamato^{1,2}, M. Aomine^{1,2}

¹Faculty of Nutrition Sciences, Nakamura Gakuen University, Fukuoka, Japan

²Graduate School of Health and Nutrition Sciences, Nakamura Gakuen University, Fukuoka, Japan

Background and objectives: Green tea catechins confer potent biological properties including antioxidation and free-radical scavenging. Oxidative stress resulting in reactive oxygen species generation and inflammation play a pivotal role in lifestyle-related disease. Therefore, we examined whether the intake of a catechin-rich beverage, green tea, ameliorates the increased oxidative stress induced by diabetes (DM).

Methods: Eight weeks old-Wistar rats were divided into two groups; DM group and non-DM group. Rat was rendered diabetic by streptozotocin. Both group rats were further divided into three groups, respectively; freely water-intake group, forced intake of catechin-rich beverage (9mg/kg) group (CAT1) and freely intake of catechin-rich beverage group (CAT2). Catechin-rich beverage was intragastrically administered in CAT1 rats one time a day. During these periods, the body weight, water and food intake volumes were observed. After two weeks, the levels of fasting blood glucose, insulin, nitric oxide, oxidative stress, and anti-oxidant capacity were measured in the serum of these rats.

Results: In general, the increase in body weight of both DM and non-DM groups was suppressed by catechin-rich beverage, but the intake of food and water in only DM group was enhanced. Catechin increased the level of insulin in only DM group significantly. The level of oxidative stress was significantly reduced in only DM-CAT2. The anti-oxidant capacity was raised by catechin intake in only DM group.

Conclusions: These findings suggest that the intake of catechin-rich beverage, green tea, may ameliorate diabetic state, because the green tea reduced the level of oxidative stress but increased the anti-oxidant capacity in DM rats. Among the large number of green tea substances, the catechin is thought to be a potent candidate showing the protective health effects of drinking green tea.

Key words: green tea, oxidative stress, diabetes

PO2760**INHIBITORY EFFECTS OF ETHYLACETATE-FRACTION FROM SASA BOREALIS ON ADIPOCYTE DIFFERENTIATION***H.S. Park¹, G.H. Kim¹*

¹Plant Plant Resources Research Institute, Duksung Women's University, Seoul, Republic Korea

Background and objectives: *Sasa borealis* is major source of boomboo leaves for use in traditional medicine in Korea. Obesity is a serious health problem in industrialized countries because it is implicated in various diseases, including type2 diabetes, hypertension, cancer, and coronary heart disease. Recent reports have proposed mechanisms to reduce obesity, decreased preadipocyte differentiation and proliferation. The preadipocytes play a key role by differentiation into mature adipocytes and increasing fat mass. Many of the advances in our understanding of adipogenesis are based on studies in murine 3T3-L1 cells. In this study, we investigated anti-adipogenic effects of crude extract and soluble-fractions of *Sasa borealis*

Methods: *Sasaborealis* were extracted with 70% ethanol and fractionated with n-Haxan, chloroform, ethylacetate, n-butanol, water (SBE). Adipocyte differentiation of 3T3-L1 cells was induced by MDI processes and measured by Oil Red O staining assay. The expression of PPAR α and C/EBP α in 3T3-L1 adipocytes was examined using reverse-transcription PCR

Results: Ethanol-soluble extract (SBE) and ethylacetate-soluble fraction (SBEA) of *Sasa borealis* inhibits intracellular accumulation of lipid droplet in a dose-dependent manner in 3T3-L1 cells. Down-regulation of PPAR α and C/EBP α , transcription factor during adipogenesis, was confirmed by reverse transcription polymerase chain reaction (RT-PCR). Ethylacetate-soluble fraction from *Sasa borealis* attenuated expression of PPAR α and C/EBP α , which act as key trascription factor in adipogenesis.

Conclusion: *Sasa borealis* inhibited adipogenic differentiation by regulating adipogenic transcription factors in of 3T3-L1 cells. Therefore *Sasa borealis* extracts may be a good candidate for management of obesity.

Background and objectives: There is mounting evidence that specific dietary polyphenols can enhance vascular health by augmenting nitric oxide. Our aim was to investigate the acute effects of chlorogenic acid, an important dietary phenolic acid present in coffee, on nitric oxide status, endothelial function and blood pressure.

Methods: Healthy men and women (n=23) were recruited to a randomised, double-blind, placebo-controlled, cross-over trial. The acute effects of chlorogenic acid (400 mg, equivalent to 2 cups of coffee) were compared to a control. Measurements included biomarkers of plasma nitric oxide status, assessed by measuring S-nitrosothiols + other nitroso species (RXNO) and nitrite; endothelial function, assessed by measuring flow mediated dilatation (FMD) and blood pressure.

Results: Chlorogenic acid resulted in significantly higher plasma concentrations of chlorogenic acid (P<0.001). Relative to control, mean post-treatment systolic blood pressure (-2.41 mm Hg, 95% CI: -0.03, -4.78; P=0.05) and diastolic blood pressure (-1.53 mm Hg, 95% CI: -0.05, -3.01; P=0.04) were significantly lower with chlorogenic acid. Markers of nitric oxide status (P>0.10) and the measure of endothelial function (P=0.60) were not significantly influenced.

Conclusions: Chlorogenic acid can lower blood pressure acutely; an effect which if sustained would benefit cardiovascular health.

Key words: Chlorogenic acid, coffee, vascular health, nitric oxide, blood pressure

PO2762**PROTECTIVE EFFECTS OF KOREAN RED GINSENG AGAINST ALCOHOL-INDUCED FATTY LIVER IN RATS***H.J. Lee¹, H.M. Ok¹, G.M. Do¹, O. Kwon¹*

¹Department of Nutritional Science and Food Management, Ewha Womans University, Seoul, Republic of Korea

Background and objectives: Alcohol consumption induces excess adipose lipolysis, thereby increasing fatty acid influx to the liver developing alcoholic fatty liver. This study was carried out to evaluate the protective effects of Korean red ginseng (KRG) against alcohol-induced fatty liver in rats.

Methods: Fifty-nine male Sprague Dawley (SD) rats were randomly divided into six groups and pair-fed Lieber-DeCarli liquid diet with or without 5% (w/v) ethanol for 6 weeks: normal control (CON), ethanol alone (ET), ET + silymarin 100mg/kg (positive control, ETS), or ET + KRG 125, 250 or 500 mg/kg (RGL, RGM or RGH, respectively). Silymarin and KRG were administered by gavage.

Results: Six-week ethanol administration demonstrated a significant increase of free fatty acids (FFA) and a decrease of adiponectin in the blood as compared with CON. We observed that KRG administration slightly retarded decrease in adiponectin and increase in FFA. Changes of gene expression levels in the liver: SREBP-1 expression increased in ET was significantly decreased by KRG administration, whereas CPT and PPAR- γ expressions were increased. FAS expression was also decreased in all doses of KRG compared with ET. Furthermore, all doses of KRG caused increases in levels of AMPK phosphorylation in the liver, while ACC phosphorylation was significantly decreased compared with those of ET. Histological examinations by Oil red O revealed decrease of the large lipid droplets in KRG treated groups.

Conclusion: These results suggest that KRG has a protective effect against alcohol-induced fatty liver, possibly through the regulation of the AMPK-mediated lipid metabolism. Further studies related to the effects of KRG on the balance of lipid metabolism in the liver and adipose tissue are under investigation.

Key words: Korean red ginseng, ethanol, lipid metabolism.

PO2763**QUANTITATION OF GLUCOSINOLATES IN BRASSICACEAE VEGETABLES SOLD IN LATE AUTUMN AND WINTER IN JAPAN***S. Osada¹, Y. Aoyagi²*

¹Department of Food and Nutrition, Junior College of Nutrition University, Tokyo, Japan

²Faculty of Nutrition, Kagawa Nutrition University, Saitama, Japan

Background and objectives: Brassicaceae vegetables contain glucosinolates, and have been known to contribute to health promotion of human beings. Epidemiological studies suggested that dietary Brassicaceae vegetables lower the risk for a number of cancers. The objective of this study was to identify the composition and content of glucosinolates, and to identify the distribution of α -methylsulfinyl, phenethyl, and indolyl-3-methyl glucosinolates, which were the precursors of isothiocyanates which induce phase I enzymes and/or inhibit phase I enzymes, in the 15 species of Brassicaceae vegetables (cabbage, Chinese cabbage, turnip and leaves, komatsuna, qing-geng-cai, potherb mustard, broccoli, cauliflower, field mustard, ta-sai, broccoli sprout, Japanese radish, rocket salad, and watercress) sold in late autumn and winter in Japan.

Methods: We determined quantity according to the ISO9167-1. Glucosinolate profiles were investigated by LC/MS.

Results: 25 species of glucosinolates were identified (aliphatic series; 18, aromatic series; 3, indolyl series; 4). 4-methylsulfinylbutyl glucosinolate was included in broccoli sprouts (111.15 \pm 15.46 μ mol/g DW), broccoli (10.45 \pm 5.05), cabbage (5.05 \pm 5.82), and rocket salad (4.15 \pm 1.83). 5-methylsulfinylpentyl glucosinolate was included in turnip leaves (2.96 \pm 1.39) and field mustard (2.10 \pm 1.73). In watercress, 6-methylsulfinylhexyl (2.96 \pm 0.98), 7-methylsulfinylheptyl (25.08 \pm 5.20), and 8-methylsulfinyloctyl glucosinolate (4.24 \pm 3.07) were included at a higher content than in any other vegetables. Phenethyl glucosinolate was included in many kinds of Brassicaceae vegetables. These were watercress (30.03 \pm 8.88), turnip (5.64 \pm 1.86) and leaves (2.42 \pm 0.17), field mustard (1.73 \pm 0.51), broccoli sprouts (1.47 \pm 0.05), and komatsuna (1.30 \pm 1.12). Indolyl-3-methyl glucosinolate was included in many vegetables excluding Japanese radish and rocket salad.

Conclusion: The results from this study suggested that we could expect to intake more glucosinolates that exert influence of anticarcinoma activity when we ate some Brassicaceae vegetables.

Key words: Brassicaceae vegetables, glucosinolates, LC/MS

PO2764**EFFECT OF THIOSULFINATES DERIVED FROM TEARLESS ONION MODEL ON LIPID METABOLISM IN MICE**

M. Kato¹, J. Shono¹, T. Kamoi¹, M. Aoyagi¹, N. Masamura¹, S. Imai¹

¹Somatech Center, House Foods Corporation, Yotsukaido, Chiba, Japan

Background and objectives: When onion tissue is disrupted, E-S-1-propenyl-L-cysteine sulfoxide (PRENCSO) is transformed predominantly into propanethial S-oxide, a lachrymatory factor, via 1-propenesulfenic acid by the actions of alliinase and lachrymatory factor synthase (LFS). Recent reports showed that suppression of the LFS activity caused a dramatic increase in thiosulfinates named cepathiolanes. Cepathiolanes have been shown to have inhibitory activities *in vitro* against cyclooxygenase-1 and β -glucosidase, and are expected to be helpful in the fight against metabolic syndrome. However, effects of cepathiolanes on lipid metabolism have not been reported yet. In this study, we examined the effects of cepathiolanes on the lipid metabolism in mice.

Methods: C57BL/6N mice were randomly divided into two groups, high fat diet (HF) group and HF + cepathiolanes (HFC) group. The mice were allowed *ad libitum* access to water and diets, and were administered cepathiolanes or mock by oral gavage every morning. Food and water intake and body weight were measured weekly. After six weeks of feeding, triglyceride and cholesterol in the serum and the liver were analyzed. In addition, expression levels of key genes involved in the lipid metabolism in liver were examined by quantitative real-time PCR.

Results: Food and water intake were not difference among groups. In the HFC group, body weight gain tended to be suppressed. Besides, the liver triglyceride and cholesterol were significantly reduced ($P < 0.05$). The gene expression levels of liver X receptor alpha (LXR α), sterol regulatory element-binding protein 1c (SREBP-1c), fatty acid synthetase (FAS), glycerol-3-phosphate acyltransferase (GPAT) and diglyceride acyltransferase 2 (DGAT2) were significantly decreased ($P < 0.05$ or 0.01).

Conclusions: Cepathiolanes would be beneficial for preventing fatty liver by down-regulating a set of lipid synthesis leading to accumulation of triglycerides. Protein expression analysis and metabolome analysis using western blot and CE-TOF-MS are currently underway.

Key words: Lipid metabolism, sulfur compound, onion, CE-TOF-MS

PO2765**INTRAGASTRIC ADMINISTRATION OF ALLYL ISOTHIOCYANATE INCREASES CARBOHYDRATE OXIDATION VIA TRPV1 BUT NOT TRPA1 IN MICE**

N. Mori¹, S. Matsumura², H. Hosokawa³, K. Inoue², T. Fushiki²

¹Department of Food Science and Nutrition, School of Human Cultures, University of Shiga Prefecture, Shiga, Japan

²Division of Food Science and Biotechnology, Graduate School of Agriculture, Kyoto University, Kyoto, Japan

³Department of Intelligence Science and Technology, Graduate School of Informatics, Kyoto University, Kyoto, Japan

Background and objectives: The transient receptor potential (TRP) channel family is composed of a wide variety of cation-permeable channels activated polymodally by various stimuli and is implicated in a variety of cellular functions. TRPV1 and TRPA1 are cation channels belonging to the TRP channel family that are activated by high and low nociceptive temperatures, respectively. These channels are also activated by spicy or pungent compounds in foods. Recent investigations have revealed that activation of TRP channels is involved not only in nociception and thermosensation but also in thermoregulation and energy metabolism. Therefore, we investigated the effect of intragastric administration of TRP channel agonists on changes in energy substrate utilization of mice.

Methods: We used allyl isothiocyanate (a pungent compound in mustard or wasabi, a typical TRPA1 agonist) as a TRP channel agonist. In respiratory gas analysis, the mice (C57BL/6) were kept individually in a chamber for 3 h to attain a constant respiratory exchange ratio. Allyl isothiocyanate was intragastrically administered and the expired air was analyzed. The oxidation of total fatty acids and carbohydrates was computed on the basis of oxygen consumption and carbon dioxide production. To examine whether TRP channels mediate this increase in carbohydrate oxidation, we also used TRPA1 and TRPV1 knockout (KO) mice.

Results: Intragastric administration of allyl isothiocyanate markedly increased carbohydrate oxidation but did not affect oxygen consumption. Intragastric administration of allyl isothiocyanate increased carbohydrate oxidation in TRPA1 KO mice but not in TRPV1 KO mice.

Conclusions: Intragastric administration of AITC increased carbohydrate oxidation in mice and the effects were mediated by TRPV1 but not TRPA1.

Key words: TRPV1, TRPA1, allyl isothiocyanate, energy metabolism, carbohydrate oxidation

PO2766

PREVENTION MECHANISMS OF GLUCOSE INTOLERANCE AND OBESITY BY CACAO LIQUOR PROCYANIDIN EXTRACT

H. Ashida¹, Y. Yamashita¹, M. Okabe², M. Natsume²

¹Department of Agrobioscience, Kobe University, Kobe, Japan

²Food Science Research Labs., Meiji Co., Ltd., Odawara, Japan

Background and objectives: Cacao beans (*Theobroma cacao*) are a major ingredient of cocoa and chocolate and contain polyphenols abundantly. It has been reported that cacao has beneficial effects on health, such as reduced risk of cardiovascular diseases, improvement of lipoprotein profiles, and prevention of diabetes and obesity. However, the molecular mechanisms by which cacao liquor extract prevent hyperglycemia and obesity are not yet fully understood. In this study, we investigated whether cacao liquor procyanidin (CLPr) extract ameliorated hyperglycemia and obesity.

Methods: CLPr used in this study consisted of 4.3% catechin, 6.1% epicatechin, 39.4% procyanidins and others. CLPr was orally given to ICR or C57BL/6 mice, and anti-hyperglycemic effects were investigated.

Results: Single oral administration of CLPr inhibited acute hyperglycemia after the administration of glucose, maltose, or soluble starch in ICR mice. This anti-hyperglycemic effect of CLPr was depending on the promotion of translocation of glucose transporter 4 (GLUT4) in the skeletal muscle, but not on the inhibition of α -glucosidase activity in the small intestine. We, further, investigated the preventive effect of CLPr on obesity and hyperglycemia in C57BL/6 mice fed a high-fat diet for 13 weeks. CLPr suppressed high-fat diet-induced hyperglycemia, glucose intolerance and fat accumulation in white adipose tissue. CLPr also promoted GLUT4 translocation and phosphorylation of AMP-activated protein kinase (AMPK) in skeletal muscle and brown adipose tissue. AMPK phosphorylation was also observed in the liver and white adipose tissue. CLPr up-regulated the gene and protein expression levels of uncoupling protein (UCP)-1 in brown adipose tissue and UCP-3 in skeletal muscle.

Conclusions: CLPr is a beneficial food material for the prevention of hyperglycemia and obesity through AMPK phosphorylation, GLUT4 translocation and up-regulation of UCP expression in skeletal muscle and adipose tissue as the underlying molecular mechanisms.

Key words: AMPK, Cacao liquor procyanidin, GLUT4, UCP

PO2767

4-HYDROXYDERRICIN AND XANTHOANGELOL FROM ASHITABA (ANGELICA KEISKEI) SUPPRESS DIFFERENTIATION OF PREADIPOCYTES TO ADIPOCYTES VIA AMPK AND MAPK PATHWAYS

T. Zhang¹, H. Ashida¹

¹Department of Agrobioscience, Kobe University, Kobe, Japan

Background and objectives: Adipocytes differentiation is deeply involved in the onset of obesity. 4-Hydroxyderricin (4HD) and xanthoangelol (XAG) are chalcones that derived from Ashitaba (*Angelica keiskei*). In this study, we investigated the effects of these chalcones on adipocytes differentiation.

Methods: 3T3-L1 preadipocytes were treated with 4HD and XAG for the first 3 days, lipid accumulation in the cells was estimated by Oil red staining, and cell viability was determined by both WST-1 assay and crystal violet staining assay. Furthermore, we investigated the effects of these chalcones on the expression of adipocyte-specific transcription factors and phosphorylation levels of AMP-activated protein kinase (AMPK) and mitogen-activated protein kinase (MAPK) using RT-PCR and Western blotting analysis.

Results: We found that these two chalcones suppressed intracellular lipid accumulation at 5 μ M without cytotoxicity. They inhibited adipocytes differentiation accompanying by the down-expression of adipocyte-specific transcription factors, C/EBP α , C/EBP β and PPAR α . To obtain insights into the underlying mechanism, the activation of AMPK and MAPK pathways were investigated. 4HD and XAG promoted phosphorylation of AMPK and acetyl CoA carboxylase during differentiation of 3T3-L1 adipocytes accompanied by a decrease in glycerol-3-phosphate acyl transferase-1 and an increase in carnitine palmitoyltransferase-1 mRNA expression. Moreover, these chalcones also promoted phosphorylation of ERK1/2 and JNK, but did not alter phosphorylation of p38. We, further, found that the inhibitors for AMPK and ERK1/2 abolished the chalcones-caused down-expression of C/EBP α , C/EBP β and PPAR α . Treatment with JNK inhibitor abolished the down-expression of C/EBP α and PPAR α , but not C/EBP β .

Conclusions: we found that the inhibitory effect of 4HD and XAG on adipocytes differentiation was involved in the activation of AMPK and MAPK pathways, resulting in the down-expression of adipocyte-specific transcription factors. These results indicated that 4HD and XAG could act as the anti-adipogenic compounds to prevent obesity.

Key words: chalcone; C/EBPs; PPAR α ; AMPK; MAPK

PO2768**INFLUENCE OF ADMINISTRATION OF WHEY PROTEIN CONCENTRATE IN DIABETIC RATS**

C. Nishimura¹, A. Isaka¹, K. Kitamura², E. Suzuki¹

¹Ochanomizu University Human Life and Environmental Sciences Nutrition and Food Science, Japan

²Asama Chemical Co., Ltd., 20-3, Nihonbashi Kodemma-cho, Chuo-ku, Tokyo, Japan

Background and objectives: Lipopolysaccharide (LPS) derives mostly from gram negative bacteria and can increase insulin resistance by bacterial translocation. It increases the blood sugar level. It is reported that the diabetic humans has higher LPS concentration level as compared with the healthy humans, because of aggravation of intestinal bacterial flora. The whey protein concentrate (WPC), a byproduct of cheese and casein during the dairying process, is known to contain LPS antibodies.

Methods: In order to determine the effect of WPC which decreased LPS levels, we tried to use type 2 diabetic model rats (Zucker Diabetic Fatty rat, ZDF). After checking diabetic symptoms of ZDF rats, we added 5% WPC in feed. We collected their blood from jugular vein and feces every week.

Results: The LPS concentration in blood and feces decreased after four weeks at the start of WPC administration as compared with before WPC administration. Furthermore, when the bacteria in feces were counted by FISH, *E. coli* which is gram negative bacteria decreased, and *Bifidobacterium* and *Lactobacillus* increased. *Bifidobacterium* and *Lactobacillus* are gram positive bacteria and can improve mucosal barrier function.

Conclusions: Although change of the blood sugar level by WPC administration was not obtained, the improvement of the intestinal bacterial flora was checked. It was concluded that WPC was able to have a possibility of affecting improvement of insulin resistance. To date, further experiment of WPC is conducted using the diabetic model mouse.

Key words: lipopolysaccharide, whey protein concentrate, type 2 diabetes, translocation

PO2769**THE ANTI-ATHEROGENIC ACTIVITIES OF PERILLA FRUTESCENS**

E. Saita¹, Y. Kishimoto¹, M. Toyozaki¹, N. Sugihara¹, M. Tani¹, K. Kondo¹

¹Institute of Environmental Science For Human Life, Ochanomizu University, Tokyo, Japan

Background and objectives: Perilla (*Perilla frutescens* (L.) Britt.) is a widely cultivated leafy vegetable that is commonly consumed as well as used in traditional medicine in Japan, China and other Asian countries. Atherosclerosis is a complex inflammatory arterial disease. Oxidized low-density lipoprotein (oxLDL) has been shown to induce multiple functional alterations and has been implicated in the pathogenesis of atherosclerosis. The aim of this study was to investigate the inhibitory effect of perilla on LDL oxidation and endothelial dysfunction induced by oxLDL.

Methods: We compared the antioxidant activity of red perilla and green perilla.

Results: Perilla had abundant polyphenol compounds. Perilla dramatically inhibited LDL oxidation by azoradials and human umbilical vein cells (HUVECs)-mediated LDL oxidation. We next examined the antioxidant effects against LDL in human subjects after the consumption of perilla extracts. After the oral intake of red perilla, the LDL oxidation lag time was significantly increased. Also, lipid peroxide formation and the electrophoretic mobility of LDL markedly decreased. Moreover, we examined whether perilla prevented oxLDL-induced vascular endothelial dysfunction. HUVECs were pretreated with perilla extracts and then stimulated with oxLDL. While oxLDL stimulation remarkably increased LOX-1 expression, red perilla treatment significantly suppressed LOX-1 expression. Perilla counteracted oxLDL-induced intracellular ROS generation as well as the downregulation of antioxidant enzymes (SOD and catalase) expression. Perilla also decreased inflammatory cytokines expression and increased eNOS expression. Next, we carried out a static monocyte adhesion assay and measured the expression of adhesion molecules (ICAM-1 and VCAM-1). Red perilla significantly blocked oxLDL-induced THP-1 cells adhesion to HUVECs and suppressed the expression of adhesion molecules.

Conclusions: These results showed that perilla inhibited LDL oxidation in vitro and in vivo and oxLDL-induced inflammatory responses in HUVECs. This suggests that perilla may contribute to prevent atherosclerosis through inhibiting LDL oxidation and oxLDL-induced endothelial dysfunction.

Key words: polyphenol, atherosclerosis, oxLDL

PO2770**THE EFFECTS OF GREEN TEA CATECHIN ON LDL OXIDATION AND ENDOTHELIAL FUNCTION IN HEALTHY SUBJECTS**

N. Sugihara¹, Y. Kishimoto¹, E. Saita¹, M. Toyozaki¹, C. Taguchi¹, M. Kobayashi², H. Niino², Y. Sagesaka², M. Tani¹, K. Kondo¹

¹Institute of Environmental Science For Human Life, Ochanomizu University, Tokyo, Japan

²Central Research Institute, ITO EN, LTD., Shizuoka, Japan

Background and objectives: Epidemiological studies suggest that green tea consumption is associated with a reduced risk of cardiovascular disease. We have demonstrated the inhibitory effects of tea catechin on low-density lipoprotein (LDL) oxidation *in vitro*. The objective of this study was to determine whether tea catechin could improve LDL oxidizability and endothelial function in healthy human subjects.

Methods: Either high (1000 mg) or middle (500 mg) dose catechin (EGCG 48.3 %, ECG 20.4 %, GCG 4.2 %, CG 1.1 %) were examined in a randomized, placebo-controlled, double-blind crossover trial among ten healthy men (aged 35.6 ± 6.5 years, BMI 22.8 ± 2.8). Blood samples were taken from each subject immediately before and 0.5, 1, 2 and 4 h after intake.

Results: A marked increase of the concentration of plasma catechin and metabolites (EGCG, ECG, EGCG3_hMe) was found. EGCG and ECG concentrations were highest at 1 h while EGCG3_hMe concentration peaked at 2 h after tea catechin intake. The total antioxidant capacity of plasma was significantly increased at 1 h after high dose tea catechin intake. High dose catechin significantly prolonged the LDL oxidation lag time, as assessed by lag time assay, relative to placebo. The endothelial function was assessed by brachial artery flow-mediated dilatation (FMD).

Conclusions: These findings suggest that tea catechin could be rapidly absorbed and improve LDL oxidizability in healthy subjects.

Key words: polyphenol, LDL oxidation, endothelial function, FMD

PO2771**EFFECT OF NANNOCHLOROPSIS OCLATA LIPID EXTRACT SUPPLEMENTATION ON LIPID METABOLISM IN EXPERIMENTAL MICE**

N.M. Ibrahim², M.S. Abdul Mutalib¹, S.P. Loh^{1,2}

¹Laboratory of Molecular Biomedicine, Universiti Putra Malaysia, Serdang, Selangor, Malaysia

²Dept of Nutrition & Dietetics, Universiti Putra Malaysia, Serdang, Selangor, Malaysia

Background and objectives: *Nannochloropsis oculata* is a marine microalgae that is usually used in aquaculture as live food for larval of shrimp and mollusks. The influence of supplementing the diet with *N. oculata* lipid extract on lipids and selected gene expression in mice were studied.

Methods: Lipid of *N. oculata* was extracted by using dichloromethane:methanol (2:1, v/v). Mice were divided into 3 groups and fed one of the following diets: a control diet; 10% *N. oculata* lipid extract and 10% *N. oculata* lipid extract + 1% cholesterol over a 8 week period. Plasma lipids, liver lipids and regulation of selected genes (HMG-CoA reductase, LDL receptor, fatty acid synthase, SREBF1, SREBF2, PPAR α , PPAR γ and PPAR δ) were determined.

Results: In the group of mice that was fed with *N. oculata* extract alone, plasma triglycerides increased (6.89%) while plasma total cholesterol, HDL-cholesterol, LDL-cholesterol and LDL/HDL ratio decreased by 16.5, 28.93, 71.84 and 78.1%, respectively. The addition of cholesterol to the diet supplemented with *N. oculata* extract however reduces all the plasma lipids after 8 weeks. No significant changes were observed in liver lipids of all groups. The mRNA levels of all genes were upregulated when treated with *N. oculata* extract except for SREBF2.

Conclusions: The major effect of *N. oculata* lipid extract is in lowering LDL levels as observed from the plasma lipids as well as the regulation of genes related to LDL metabolism.

Key words: *Nannochloropsis oculata*, lipid extract, lipid metabolism, mice

PO2772**EFFECTS OF LYCHEE FRUITS POLYPHENOL ON ENDOTHELIAL FUNCTION AFTER GLUCOSE TOLERANCE IN HEALTHY SUBJECTS**

Y. Kishimoto¹, M. Tani¹, E. Saita¹, N. Sugihara¹, M. Toyozaki¹, C. Taguchi¹, K. Kitadate², K. Wakame², K. Kondo¹

¹Institute of Environmental Science for Human Life, Ochanomizu University, Tokyo, Japan

²Amino Up Chemical Company, Ltd., Sapporo, Japan

Background and objectives: Endothelial dysfunction is now well known to be an initial step for atherosclerosis. We have previously demonstrated that oligomerized lychee fruits polyphenol (OLFP) inhibits LDL oxidation and improves endothelial function in vitro. The objective was to determine whether acute glucose loading attenuates endothelial function and whether OLFP could prevent these postprandial changes in healthy subjects.

Methods: We evaluated the acute effects of oral glucose tolerance (75 g) alone and with OLFP (1 g) in a crossover study of 10 male volunteers (Age: 39.6 ± 2.3 years, BMI: 23.1 ± 0.8 kg/m²). Blood samples were taken immediately before and at 0.5, 1, 2 and 4 h after tolerance. We assessed endothelium-dependent vasodilation by brachial artery flow-mediated dilatation (FMD).

Results: Plasma glucose and insulin levels were rapidly elevated and peaked at 0.5 h after tolerance. Total leukocytes and neutrophils counts and serum sVCAM-1 levels were significantly increased at 0.5 h in both trials. FMD was impaired at 1 h after glucose loading, while co-administration of OLFP improved the FMD attenuation.

Conclusions: Our results demonstrate that postprandial hyperglycemia acutely impaired endothelial function in healthy subjects, which can be prevented by OLFP.

Key words: polyphenol, postprandial hyperglycemia, endothelial dysfunction, FMD

PO2773**EFFECTS OF ORAL INTAKE OF LACTOBACILLUS CORYNIFORMIS CECT5711 ON IMMUNE PARAMETERS IN ADULTS SUFFERING OLIVE POLLEN ALLERGY. A PILOT STUDY**

J A. Maldonado¹, M J. Rojas², M A. Lara², P. Díaz-Ropero¹, M. Olivares¹, J. Fonolla¹, J F. Florido²

¹Nutrition Department, Biosearch S.A., Granada, Spain

²Allergy Service, Complejo Hospitalario de Granada, Spain

Background and objectives: Prevalence of allergic disease has increased dramatically in Western countries. Intestinal dysbiosis has been shown to precede the onset of clinical allergy, possibly through altered immune regulation. A number of clinical studies have investigated the potential of probiotic bacteria to ameliorate the pathological features of allergic disease. The aim of this study was to investigate the immunomodulatory properties of *L.coryniformis* CECT5711 in adults suffering from olive pollen allergy.

Methods: A double-blind, randomized, placebo-controlled study was performed. A group of 20 volunteers with confirmed olive pollen allergy were included in the study and distributed into two groups: control group (CG) who received an oral daily dose of methylcellulose for 8 weeks or probiotic group (PG) who received *L.coryniformis* at a dosage of 3×10^9 CFU/day for 8 weeks. The study was performed from March to June 2012. Blood samples were collected at 0, 4 and 8 weeks for determination of olive pollen-specific IgE, total IgE and total IgA levels. At the same time, cytokine secreted by Treg cells (IL-10, and TGF- β) were also measured.

Results: A significant increase in olive pollen-specific IgE ($p=0.013$) and total IgE ($p=0.025$) in plasma was observed in CG at the end of the study. In contrast, no changes in IgE levels were detected in PG. Changes in other immune parameters were not detected with the exception of an increase in TGF- β levels in active group. That was not observed in CG.

Conclusions: Oral administration of the strain *L.coryniformis* CECT5711 attenuated allergen-specific IgE response in adults with olive pollen allergy. It observes an increase of up to four times in the level of TGF-beta in relation to basal level in patients receiving probiotics. It is possible that a change, dependent Treg cells happens in patients receiving *L.coryniformis* CECT5711.

Key words: Lactobacillus, pollen allergy, immune response.

PO2774

LACTOBACILLUS PARACASEI CNCM I-4034, A NOVEL STRAIN ISOLATED FROM BREAST-FED NEWBORNS, MODULATES PATHOGEN-INDUCED INFLAMMATION IN A NOVEL TRANSWELL CO-CULTURE MODEL

M. Bermudez-Brito¹, S. Muñoz-Quezada¹, C. Gomez-Llorente¹, E. Matencio², M.J. Bernal², F. Romero², A. Gil¹

¹Department Biochemistry & Molecular Biology II, Institute of Nutrition & Food Technology, University of Granada, Armilla, Granada, Spain "José Mataix", University of Granada, Granada, Spain

²Global Centre for Child Nutrition Technology, Hero Group, Alcantarilla, Murcia, Spain

Background and objectives: The network of dendritic cells (DCs) and intestinal epithelial cells (IECs) plays a crucial role in the regulation of gut homeostasis. Our aim is to determine whether a novel strain, *Lactobacillus paracasei* CNCM I-4034, could activate human intestinal DCs through a physical barrier of IECs, and how they response against *Salmonella*.

Methods: A novel in vitro transwell co-culture model was used. Caco-2 cells were cultured on the upper side of membrane. Bacteria were added from the apical side and co-cultured with DCs for 4h. After 20 h, culture supernatants were collected. Different cytokines and chemokines were measured with a MILLIplex kit using the Luminex 200 system. Differences between treatments were assessed by U Mann Whitney test.

Results: DCs challenged with *L.paracasei* increase the release of IL-1 β (14,1%), IL-6 (83%), IL-8 (7,8%) and RANTES (4%) compared to controls (0%). In the presence of *Salmonella*, IECs and DCs release low levels of all pro-inflammatory cytokines, such as IL-1 β (0,8%), IL-8 (1%) and TNF- α (1%). *Salmonella* was not able to induce DCs chemokines, as RANTES. DCs and IECs stimulated with the probiotic and *Salmonella* up-regulate pro-inflammatory cytokines production. This pattern is characterized by a high level of IL-6 (90%) and varying levels of IL-1 β (2,4%), IL-8 (5,9%) and TNF- α (5,4%) secretion. IFN- γ and IL-12p70 could not be detected. Chemokines production is also increased, such as MCP-1 and MIP-1.

Conclusions: IECs and DCs were poorly responsive to *Salmonella*. Hence, IECs act as a barrier against pathogens, avoiding DCs activation and therefore DCs cytokine production. Just caco-2 cells were sensing pathogenic bacteria and releasing cytokines. The greatest amount of IL-6 suggests that this IL may have a key role in immune gut response. As IFN- γ and IL-12 could not be detected, this probiotic may promote regulatory responses.

Key words: Toll-like receptors, probiotics, cytokines

⁴Facoltà Di Farmacia, Università Degli Studi Di Catania, Catania, Italy

Background and objectives: Evidence from several studies has revealed that the protective effects of Extra-Virgin Olive Oil (EVOO) against chronic diseases such as atherosclerosis, cancer, obesity, diabetes, and coronary diseases are related to the phenolic compounds. These compounds exert strong antiproliferative effects in human cancer cell models. However, significant plasma concentrations of these compounds are hardly achieved due to poor absorption, rapid clearance and inactivation by metabolic enzymes. The development of suitable drug delivery systems such as liposomes, may be an appropriate strategy for the effective administration of these compounds. Indeed, liposome increase the half life of many drugs and reduce their clearance. The goal of this work was to develop liposomal formulations containing EVOO phenolic extract in order to improve their bioavailability and their cytotoxic effects on human breast cancer cellular models (JIMT1 and MCF7).

Methods: The degree of incorporation of EVOO polyphenols in liposomes was evaluated by high-performance liquid chromatography coupled to electrospray ionization time-of-flight mass spectrometry (HPLC-ESI-TOF-MS). Tetrazolium salt (MTT)-based cell viability assays was employed to assess the cytotoxic effects of EVOO polyphenols and liposomal formulations.

Results: EVOO polyphenols were efficiently encapsulated into phospholipid vesicles. In particular, acetoxypinoresinol and pinoresinol (lignans); luteolin and apigenin (flavones) and methyl oleuropeinaglycone, oleuropeinaglycone isomers I and II and 10-hidroxy oleuropeinaglycone (carboxymethylsecoiridoids) showed strong affinity for egg yolk phosphatidylcholine (EYPC) vesicles. Liposomal formulations showed a significant decrease of IC50 values in all treatments and consequently, an improvement of therapeutic index.

Conclusions: EVOO polyphenols were efficiently incorporated into EYPC liposomes. Remarkably, breast cancer cell sensitivity was higher against liposomal formulations containing EVOO phenolic extract compared to crude EVOO phe-

nolic extract. Flavones, some oleuropein derivatives and, in a lesser degree, lignans were the candidate compounds for such activity.

Key words: EVOO polyphenols, liposomes, breast cancer, HPLC-ESI-TOF/MS.

Background and objectives: Lettuce (*Lactuca sativa*) is widely consumed in all over the world, fresh cut or minimally processed, and so being an important dietary source of natural bioactive compounds. However, a great number of these metabolites still remain unknown. In this study, reversed-phase ultra-performance liquid chromatography coupled to electrospray ionization-quadrupole-time-of-flight mass spectrometry (RP-UPLC-ESI-QTOF-MS) was applied for the comprehensive profiling of polar and semi-polar metabolites from lettuce varieties cv. baby, romaine, and iceberg.

Methods: Lettuce leaves were lyophilized and extracted by a methanol/water solution (80:20, v/v) previous to their analysis. The MS and MS/MS data obtained were processed through DataAnalysis 4.0 (Bruker Daltonics). Metabolites were characterized by matching their accurate masses and suggested molecular formula with those previously reported in Asteraceae family and their structures were corroborated by the MS/MS data.

Results: The analytical method showed a great resolution to separate isomers and a sensitive detection that allows characterizing 171 compounds, belonging to various structural classes: amino acids (essential and non-essential) and peptides (42), organic acids (11), nucleosides (3), tryptophan derived-alkaloids (2), phenolic compounds (92), sesquiterpene lactones (17), one iridoid and 10 novel structures formed by conjugation of known amino acids and sesquiterpene lactones. To our knowledge, the major part of these compounds has not been reported in lettuce.

Conclusions: Genotype, at least in part, affected the metabolic composition of lettuce. The studied varieties were qualitatively rich in phenolic compounds, especially baby variety, and remarking that lettuce is a good source of natural antioxidants.

In addition, known bioactive alkaloids and sesquiterpene lactones were also characterized. The applied methodology is a good option to develop an exhaustive metabolic profiling of plants that helps to understand their potential biological activities and folk uses.

Key words: Lettuce (*Lactuca sativa*); bioactive phytochemicals; metabolic profiling; phenolic compounds; RP-UPLC-ESI-QTOF-MS

²Functional Food Research and Development Centre (CIDAF), Armilla, Granada, Spain

³UGC Pediatría, Hospital Clínico San Cecilio Granada, Granada, Spain

Background and objectives: The beneficial effects of American cranberry (*Vaccinium macrocarpon*) might at least in part be attributed to the phenolic composition, thus, the evaluation of the physiological behavior of this fraction is crucial. A rapid and sensitive method by reversed-phase ultra-performance liquid chromatography coupled to quadrupole-time-of-flight mass spectrometry (RP-UPLC-QTOF-MS) has been employed to identify phenolic metabolites in human urine after a single dose of cranberry syrup.

Methods: Samples from four subjects were collected before (0 h) and at 2, 4 and 6 h after the consumption of cranberry syrup. Urinary metabolites were extracted by solid-phase extraction (SPE) with LC-18, Isolute ENV+, and Evolute ABN, and analyzed by RP-UPLC-ESI-QTOF-MS in negative and positive ion modes. Their characterization was based on retention time, accurate mass data, isotope function and fragmentation pattern using DataAnalysis 4.0 (Bruker Daltonik). Once then, these metabolites were simultaneous screened by TargetAnalysis (Bruker Daltonik).

Results: Isolute ENV+ SPE was selected for the better extraction of urinary metabolites. Afterwards, they were successfully profiled using RP-UPLC-QTOF-MS. So, it was characterized free phenolic acid derivatives (coumaroyl-hexose, dihydroxybenzoic acid, caffeoyl-glucose and dihydroferulic acid 4-O-beta-D-glucuronide), flavonols (methoxyquercetin

3-O-galactoside, myricetin and quercetin) and a coumarin (scopoletin), together with 23 phase I and phase II metabolites, and including various isomers, hippuric and salicylic acid. Among them, methylated and glucuronide conjugates of quercetin and myricetin were found largely. In general, urinary metabolites reached maximum amounts 4 h after the administration of cranberry syrup.

Conclusions: At least one fraction of the ingested cranberry polyphenols were absorbed intact and could act in vivo in this form prior to excretion, whereas another fraction was absorbed, metabolized, and excreted in urine. Further studies of the biological properties of these metabolites would be helpful to understand the action mechanism of cranberry syrup.

Key words: Cranberry; polyphenols; urinary metabolites; RP-UPLC-QTOF-MS

HEPATOPROTECTIVE EFFECTS OF EXTRACTS FROM PEPPERMINT, LEMON BALM AND ROSEMARY IN LAMIACEAE PLANTS

S. Hironaka¹, M. Akao¹, Y. Matsui², H. Masuda², O. Nishimura², H. Kumagai¹

¹Department of Chemistry and Life Science, Nihon University, Fujisawa-shi, Kanagawa, Japan

²Laboratory of Health Materials, Ogawa & Co., Ltd, Urayasu-shi, Chiba, Japan

Background and Objectives: Spices and herbs often exert various physiological functions such as anti-aging and anti-cancer activities. In our previous study, we examined the antioxidant capacity of 80 kinds of spices including Lamiaceae, Apiaceae, and Myrtaceae plants by the ORAC method, and found that some of the Lamiaceae plants have high antioxidant capacity. The present study aimed to examine the hepatoprotective effect of extracts from peppermint (PE), lemon balm (LB) and rosemary (RM) in Lamiaceae on liver injury induced by foreign compounds such as carbon tetrachloride (CCl₄).

Methods: Male Sprague-Dawley rats were orally administered with each sample dissolved in water for five consecutive days. One hour after the final administration of sample solution, CCl₄ in olive oil was intraperitoneally injected, and acute liver damage was induced. Then, 24 hours after CCl₄ injection, the animals were sacrificed, and determined the specific activities of aspartate aminotransferase (AST), alanine aminotransferase (ALT), and lactate dehydrogenase (LDH) as markers for hepatic injury and the level of thiobarbituric-acid reactive substances (TBARS), the specific activities of detoxification enzymes such as cytochrome P450 2E1 (CYP2E1) and glutathione S-transferase (GST), and those of antioxidant enzymes such as superoxide dismutase (SOD).

Results: Pretreatment with extracts from PE, LB and RM significantly suppressed the elevation in serum AST, ALT and LDH activities, and hepatic TBARS level, and the reduction in hepatic GST and SOD activities although it did not restore the CYP2E1 activity.

Conclusions: These results indicate that PE, LB and RM possess suppressive effect on hepatic injury induced by CCl₄. Their hepatoprotective effect would be attributed to the antioxidant activities. Antioxidants in them would have eliminated active oxygen and free radicals formed by CCl₄, which led to the reduction in lipid peroxidation and oxidative stress.

Key words: Lamiaceae plants, Hepatoprotective effect, antioxidant

PO2779

IN VIVO EVALUATION OF THE REDUCED ALLERGENICITY OF DEAMIDATED WHEAT GLIADIN

S. Shimizu¹, R. Abe¹, M. Akao¹, H. Kumagai², H. Kumagai¹

¹Department of Chemistry and Life Science, Nihon University, Fujisawa-shi, Kanagawa, Japan

²Department of Food Science and Nutrition, Kyoritsu Women's University, Chiyoda-ku, Tokyo, Japan

Background and objectives: Deamidation is the reaction that converts glutamine and asparagine into glutamic acid and aspartic acid. Deamidation of food protein is an effective way to improve their functionalities. Our previous study showed that wheat gliadin was effectively deamidated without peptide-bond hydrolysis just by being mixed with cation-exchange resins of the carboxylate type, and the solubility and digestibility of gliadin were enhanced by deamidation. In addition, the reactivity of wheat gliadin with sera of wheat-allergy patients was reduced by deamidation because some tandem sequence repeats having glutamine residues constitute the primary structure of IgE-binding epitopes in wheat gliadin. Therefore, the allergenicity of deamidated wheat gliadin might be further reduced during digestion when it is orally administered. The present study aimed to evaluate the in vivo allergenicity of deamidated gliadin by using a mouse model of wheat gliadin allergy.

Methods: Mice were sensitized by intraperitoneal injection of untreated gliadin with the presence of aluminum hydroxide as an adjuvant. After the sensitization, untreated or deamidated wheat gliadin were intragastrically administered to mice at 7 times every other day. After the final oral challenge, the peritoneal cells, blood and small intestine were collected. The levels of histamine and gliadin-specific IgE in serum were measured by ELISA. Immunocyte from peritoneal cells were categorized by flow cytometer, and intestinal permeability was determined by a closed loop experiment.

Results: The levels of histamine and gliadin-specific IgE in plasma were lower in deamidated-gliadin group than in untreated-gliadin group. Oral challenge of deamidated gliadin down-regulated the expression of FcεRI on peritoneal mast cells. Untreated gliadin enhanced the intestinal permeability, while deamidated gliadin did not change it.

Conclusions: These results indicate that oral administration of deamidated gliadin did not present the allergic reactions in a mice model of wheat allergy.

Key words: deamidation; wheat gliadin; reduced allergenicity

PO2780

THE SYNERGIC EFFECT OF DAIDZEIN AND KIWI-FRUIT ON BONE LOSS AND EQUOL PRODUCTION IN OVARIECTOMISED RATS.

Y. Tousei¹, F.M. Wolber², W.H. Chua², Y. Ishimi¹, M. Tadaishi¹, Y. Nishide¹, M.C. Kruger²

¹Department of Food Function and Labeling, National Institute of Health and Nutrition, Tokyo, Japan

²Institute of Food, Nutrition and Human Health, Massey University, Palmerston North, New Zealand

Background and objectives: Equol, a metabolite of one of the major soybean isoflavones called daidzein, is produced in the gastrointestinal tract by certain intestinal microflora. Habitual dietary patterns may influence the metabolism of isoflavones and the production of equol, with its production shown to be promoted by dietary fibre. Kiwifruit is a rich source of dietary fibre and there is evidence linking kiwifruit consumption to improved gut health. In this study, we investigated the synergic effects of daidzein, known to affect bone health, and kiwifruit on bone loss and equol production in female rats.

Methods: Female Sprague-Dawley rats, aged 5 months, were randomly assigned to one of five groups and either sham operated (Sham) or ovariectomised (OVX) (n = 15 per group): OVX-control, OVX fed 0.1 % daidzein-supplemented diet (OVX + Dz), OVX fed 0.1 % daidzein- and green kiwifruit-supplemented diet (OVX + Dz + GRK), OVX fed 0.1 % daidzein- and gold kiwifruit-supplemented diet (OVX + Dz + GOK).

Results: Whole body Bone mineral density (BMD) week-8 in the Sham, the OVX + Dz + GRK and the OVX + Dz + GOK groups were not statistically lower compared to baseline. In contrast, whole body BMD was significantly decreased in the OVX and OVX + Dz groups at week-8 compared to baseline. Consequently, Dz and both of the green and gold kiwifruit treatments prevented the OVX-induced decline in BMD. Kiwifruit supplementation however, did not affect serum equol concentrations or the urinary ratios of equol to daidzein.

Conclusions: These results suggest that the combination of daidzein and kiwifruit may prevent bone loss caused by oestrogen deficiency, but it may be not mediated by equol production. Further studies are required to confirm the synergic effect of isoflavones and kiwifruit. Acknowledgements: MBIE NZ; JST; Zespri International Ltd.

Key words: Soy isoflavones, kiwifruit, bone

EFFECTS OF ARTEMISIA CAPILLARIS ON THE DISORDERS OF HEPATIC FUNCTIONS AND LIPID-METABOLISM IN RATS TREATED WITH 2,3,7,8- TETRACHLORODIBENZO-P-DIOXIN

J.H. Lee¹, S.Y. Hwang², C.L. Zhang¹, S.C. Bi¹

¹University of Chungnam National, South Korea

²University of Daejeon, Daejeon, South Korea

Background and objectives: Dioxin that is an endocrine disrupter, causes various diseases to human and intimidates human health. This study was conducted to investigate the effects of *Artemisia Capillaris* (AC) on the disorders of hepatic functions and lipid metabolism induced by 2,3,7,8- tetrachlorodibenzo-p-dioxin (TCDD), using male rats.

Methods: experimental animals (SD, five weeks old) were divided into four groups and were intaked pure experimental diets for three weeks. AC was added as 1.5% or 3% levels to basal diets, respectively. TCDD (40ug/kg B.W) was intraperitoneally injected into rats at the beginning of the experiment.

Results: AC decreased relative liver weights of rats were increased by TCDD. Their thymus were apparently shrunken by about 80% in all rats treated with TCDD. The levels of white blood cells were significantly increased by TCDD tended to decrease by AC diets. The elevation of glutamic oxalacetic transaminase activities by TCDD was diminished by AC diets. Serum HDL-cholesterol levels were significantly elevated by AC diets. The apparent increasing of the triglyceride levels of rat livers induced by TCDD was significantly suppressed by AC diets. The hepatic cytosolic catalase activities were significantly decreased by TCDD, showed recovering trend by AC diets. In histochemical observation, the fat droplets and apoptosis of hepatocytes by TCDD were markedly alleviated by AC diets.

Conclusions: These results indicated that AC could exert recovering effects on some disorders of hepatic functions, lipids metabolism and antioxidant activities by TCDD.

Key words: *Artemisia Capillaris*, TCDD, hepatic functions.

PO2782**ORANGE AND PEACH-APPLE FRUIT JUICES REDUCE CARDIOVASCULAR RISK IN MODERATELY HYPER- AND NORMO-CHOLESTEROLAEMIC IRON DEFICIENT WOMEN**

R. Blanco-Rojo¹, A M. Pérez-Granados¹, L. Toxqui¹, M P. Vaquero¹

¹Department of Metabolism and Nutrition, Institute of Food Science, Technology and Nutrition (ICTAN), Spanish National Research Council (CSIC), Spain

Background and objectives: Hypercholesterolaemia and iron deficiency are very common in Western populations and may affect the same individuals. Our aim was to investigate the influence of the consumption of an iron-fortified fruit juice, known to increase iron status (1), on different biomarkers of cardiovascular risk in a group of iron-deficient women.

Methods: A group of 122 iron-deficient women participated in a randomised double-blind placebo-controlled study of 16-weeks (ClinicalTrials.gov:NCT01135576). They consumed 500mL/day of a placebo fruit juice (P) or iron-fortified fruit juice (F). The beverages were orange and peach-apple juices, 100% from concentrate with no added sugars. Blood lipids and cardiovascular risk indexes were determined at baseline and every 4 weeks. Moderately hypercholesterolemia (MHC) was defined as total cholesterol (T-chol) >200mg/dL.

Results: No differences were found between P and F in lipids changes during intervention. Forty seven women presented MHC (38.5% of total). T-chol levels significantly decreased in MHC from week 4 to 16 (p<0.001) but did not change in normocholesterolaemic (NC) women. LDL-chol decreased in both groups during the study (p<0.001). HDL-chol significantly increased from baseline to the end of the study in NC (p=0.05) but not in MHC women. Serum triacylglycerols did not vary during the intervention. Cardiovascular risk indexes, T-chol/HDL-chol and LDL-chol/HDL-chol, markedly decreased in both groups (p<0.001).

Conclusions: Daily consumption of iron fortified orange and peach-apple juices by both moderately hyper- and normocholesterolaemic iron deficient women could have additional beneficial cardiovascular effects besides improvement of iron status, in the context of a health promoting diet. Supported by Project AGL2009 11437 and Grupo Leche Pascual. Blanco-Rojo R. and Toxqui L. were supported by JAE-predoc grants from European Social Fund. 1Blanco-Rojo R, Perez-Granados AM, Toxqui L, Gonzalez-Vizcayno C, Delgado MA, Vaquero MP. *Br J Nutr.* 2011;105(11):1652-9.

PO2783**INTAKE OF AN IRON OR IRON AND VITAMIN D-FORTIFIED SKIMMED MILK AND IRON METABOLISM IN WOMEN**

L. Toxqui¹, A M. Pérez-Granados¹, R. Blanco-Rojo¹, I. Wright¹, C. González-Vizcayno², M P. Vaquero¹,

¹Department of Metabolism and Nutrition, Institute of Food Science, Technology and Nutrition (ICTAN), Spanish National Research Council (CSIC), Spain

²Clinical Analysis Laboratory, Madrid Salud, Spain

Background and objectives: Iron deficiency anaemia has been identified as one of the most common and widespread disorders in the world. The present assay was designed to know if an iron-fortified flavoured skimmed milk improves iron metabolism in iron-deficient menstruating women and if the supplementation with vitamin D involves an additional effect.

Methods: A randomized, controlled, double-blind, parallel design trial of 16 weeks duration was performed following the guidelines of the Consolidated Standards of the Reporting Trials and registered at ClinicalTrials.gov: NCT01739907. Subjects were randomized into two groups that consumed, as supplement to their usual diet an iron (Fe, n=55) or iron and vitamin D-fortified (Fe+D, n=54) skimmed flavoured milk. The daily portion was 500mL/day, and provided 15 mg iron/day in the form of microencapsulated ferric pyrophosphate. The Fe+D fortified-milk provided 5 µg of vitamin D3/day. At baseline and monthly, dietary intake, body weight, haematological and iron metabolism parameters were determined.

Results: Serum ferritin displayed significant variations during time in Fe and Fe+D groups (p=0.045 and 0.009 respectively) but at the end of the assay it recovered baseline levels. Significant increases (p<0.05) were observed in serum iron and transferrin saturation at week 4, and in erythrocytes, haematocrit and haemoglobin at week 8 in Fe+D group compared to Fe group.

Conclusions: The iron-fortified skimmed flavoured milk did not improve iron status in iron-deficient women. These results are attributed to the presence of casein and calcium in the milk. However, the addition of vitamin D produced a slight improvement in several haematological parameters. This study was financed by Project AGL2009-11437Toxqui L and Blanco-Rojo R were supported by a JAE-predoc grant from CSIC and European Social Found.

Key words: ferric pyrophosphate, fortification, skimmed milk, iron-deficiency, women. Acknowledgments:

PO2784**CHANGES IN BONE REMODELLING IN IRON-DEFICIENT WOMEN BY THE CONSUMPTION OF AN IRON OR IRON AND VITAMIN D-FORTIFIED SKIMMED MILKS**

L. Toxqui¹, A. M. Pérez-Granados¹, R. Blanco-Rojo¹, I. Wright¹, C. de la Piedra², M.P. Vaquero¹

¹Department of Metabolism and Nutrition, Institute of Food Science, Technology and Nutrition (ICTAN), Spanish National Research Council (CSIC), Spain

²Department of Biochemistry Investigation, Fundación Jiménez Díaz, Institute for Medical Research (IIS-FJD), Spain

Background and objectives: Vitamin D is essential for calcium absorption and bone mineralization and a number of new functions have been reported in the last years. Recently, a relationship has been proposed between vitamin D deficiency and iron deficiency anaemia. The aim of this assay was to know if the supplementation with iron or iron and vitamin D involves an effect on bone remodelling in iron-deficient women.

Methods: Young menstruating women with low iron stores (serum ferritin <30ng/mL) and haemoglobin \leq 11g/dL, were included in this study. A randomized, controlled, double-blind, parallel design trial (ClinicalTrials.gov: NCT01739907) of 16 weeks duration was performed following the guidelines of the Consolidated Standards of the Reporting Trials. Serum 25-hydroxyvitamin D (25OHD), as the vitamin status marker and compliance biomarker, parathormone (PTH) and biochemical bone markers (P1NP, NTx), were analysed at baseline and bi-monthly.

Results: A total of 109 women completed the study and consumed 500 ml/day of an iron (Fe group, n=55) or iron and vitamin D-fortified (Fe+D group, n=54) skimmed flavoured milk. Serum 25OHD baseline levels indicate that 34.9% of the women were deficient, 38.5% insufficient and 26.6 % sufficient. In Fe+D group, serum 25OHD significantly increased during the assay and it was higher at weeks 8 and 16 compared to Fe group, indicating a good compliance. P1NP and NTx decreased in the Fe+D group (p=0.004 and p<0.001, respectively) and did not change in the Fe group during the intervention.

Conclusions: The majority of the iron deficient women (73.4%) presented vitamin D deficient or insufficient status and supplementation with an iron and vitamin D-fortified skimmed milk reduces bone remodelling and could improve bone health. Study financed by Project AGL2009-11437L. Toxqui and R. Blanco-Rojo were supported by JAE-predoc grants from CSIC and European Social Found.

Key words: Vitamin D, fortification, bone remodelling, women.

PO2785**LACTOBACILLUS RHAMNOSUS CNCM I-4036 DECREASES INFLAMMATORY CYTOKINE RELEASE IN HUMAN INTESTINAL EPITHELIAL CELLS CHALLENGED WITH SALMONELLA TYPHI.**

⁴Current address: National Agency For Medicines (ANAMED), Santiago, Chile

Background and objectives: Intestinal epithelial cells, as important participants in the mucosal immune response, must respond to a variety of stimuli, including commensal and pathogenic bacteria. Interleukin- 8 (IL-8) and tumor necrosis factor alpha (TNF-alpha) are cytokines produced by macrophages and other cells types such as enterocytes, involved in the mucosal immune response. Probiotic bacteria may provide protection against intestinal damage induced by pathogens, but the underlying mechanisms are still largely unknown. The aim of the present study was to investigate whether Lactobacillus rhamnosus CNCM I-4036, isolated from exclusively breast-feeding infant feces, protected intestinal Caco-2 cells from the inflammation-associated response induced by Salmonella typhi CECT 725, causative agent of typhoid fever, by modulating cytokine secretion.

Methods: Caco-2 cells were exposed to Salmonella or co-incubated with Salmonella and Lactobacillus rhamnosus CNCM I-4036 for 4 hours. IL-8 and TNF-alpha secretion by Caco-2 was measured by immunoassay, with a MILLIplex™ kit using the Luminex 200 system based on the xMap technology. Statistical differences for secreted IL-8 and TNF-alpha between treated and untreated cells were assessed by the U-Mann Whitney test.

Results: Lactobacillus rhamnosus CNCM I-4036 prevented increased secretion of IL-8 and TNF-alpha in human intestinal epithelial cell Caco-2 S. typhi-induced, which was significantly reduced by 99% and 77%, respectively (p<0.05).

Conclusions: The beneficial effects of Lactobacillus rhamnosus seem to be associated with a decrease in the secretion of IL-8 and TNF-alpha levels by enterocytes. This strain showed the potential to protect enterocytes from an acute inflammatory response and is a potential candidate for the development of new functional foods helpful in counteracting enteropathogen infections.

Key words: gut immune response, Lactobacillus rhamnosus, probiotics, typhoid fever

PO2786**ANIOXIDANT EFFECT OF BREAD USING BLACK RICE (ORYZA SATIVA L. JAPONICA VAR. SBR)***M. Hiemori-Kondo^{1,2}, A. Nagayasu²*¹Department of Food Science and Nutrition, Tokushima Bunri University, Tokushima, Japan²Department of Nutrition, Okayama Prefectural University, Okayama, Japan

Background and objectives: Black rice contains a dark purple pigment derived from cyanidin-3-O-beta-D-glucoside (C3G), which is the most abundant form of anthocyanin in foods. C3G has versatile physiological functions including antioxidant, anti-inflammatory, and antiarteriosclerosis effects. Previously, we demonstrated that a large amount of C3G in black rice is degraded to protocatechuic acid (PCA) by heat, suggesting that cooked black rice no longer retains its physiological function. However, the effect of thermal processing on antioxidant effect of C3G in black rice remains to be elucidated. In this study, we investigated the process of baking bread with black rice flour, and studied the change of its antioxidant effect and C3G levels.

Methods: Breads replaced 20% of wheat flour with rice flour (black, pearled and brown rice flours) were prepared. No rice flour bread was also prepared as a control. Acidic ethanol extraction of these breads and its raw materials were subjected to analysis. The amounts of C3G and PCA in the extracts were quantified by HPLC-PDA. Furthermore, total phenol in the extracts was measured with folin-ciocalteu method. Antioxidant effects of the extracts and purified C3G and PCA were evaluated by hydrophilic oxygen radical absorbance capacity (H-ORAC).

Results: H-ORAC value of the extract from black rice flour bread showed the highest value among all extracts. Approximately 80% of C3G in the black rice flour was decreased by baking, whereas PCA was increased. H-ORAC value and total phenol in the extracts indicated positive correlation. Interestingly, the H-ORAC value of purified PCA was higher than that of C3G.

Conclusions: The black rice flour bread has high antioxidant that is attributed to PCA. These findings suggest that black rice flour bread is useful to prevent chronic diseases as a functional food.

Key words: cyanidin-3-O-beta-D-glucoside, protocatechuic acid, antioxidant effect

PO2787**THE INFLUENCE OF DIET WITH ELDERBERRY FRUITS ON MORPHOLOGICAL PARAMETERS IN SERUM OF RATS OVER INTOXICATION WITH LEAD***E. Piatkowska¹, E. Sikora¹, A. Kopec¹, B. Borczak¹*¹Department of Human Nutrition, Agricultural University of Krakow, Krakow, Poland

Background and objectives: The elderberry fruits are a very good source of vitamins (especially vitamin C, B) and biologically active non-nutrient components – polyphenols. These compounds may reduce the harmful effects of various factors. The aim of the study was to determine the influence of diet with elderberry fruits on morphological parameters in serum of rats over intoxication with lead.

Methods: Wistar rats were divided into 4 group (n=6) and fed with experimental diet (I) AIN-93G, (II) AIN-93G with lyophilised elderberry fruits (5%), (III) AIN-93G with lead (0.025 mg/ kg body weight), (IV) AIN-93G with elderberry fruits and lead. After 4 weeks rats were anaesthetized and blood was collected. The morphology (content of red and white blood cells, platelets, hemoglobin and hematocrit) and the content of creatinine, uric acid and bilirubin were measured according to the protocol. Additionally, the activity of asparagine aminotransferase (AST) and alanine aminotransferase (ALT) were measured.

Results: The lead intoxication caused a reduction of hematocrit and decreased the hemoglobin level. The content of creatinine is at about 59 umol. Rats fed AIN-93G diet with lead intoxication had highest urine acid and bilirubin amounts. The addition of elderberry fruits contributed to decreased bilirubin level. The ALT activity declined in the serum of rats fed standard diet with fruits, while AST activity is increased, both in AIN-93G with elderberry fruits and in AIN-93G with fruits and lead.

Conclusions: The addition of elderberry fruits to the experimental diet improves the morphological and selected biochemical parameters in rats' blood. This study was supported by the National Science Centre; decision no DEC-2011/01/B/NZ9/07177.

Key words: rats, elderberry fruits, lead, biochemical parameters.

PO2788**CONTENT OF TOTAL POLYPHENOLS AND ANTI-OXIDANT ACTIVITY OF INFUSIONS FROM SOME VARIETIES OF DRIED BUCKWHEAT'S LEAVES**

E. Piatkowska¹, T. Leszczyńska¹, E. Pisulewska², A. Kopeć¹, R. Witkowicz²

¹Department of Human Nutrition, Agricultural University of Krakow, Krakow, Poland

²Department of Crop Production, Agricultural University of Krakow, Krakow, Poland

Background and objectives: Numerous studies have shown that products made from buckwheat have nutritional, dietary and health benefits. There are no data in the literature on the content of total polyphenols and antioxidant capacity in infusions made from the dried leaves of buckwheat. The aim of the study was to determine the total polyphenols and antioxidant activity of infusions from some varieties of dried buckwheat's leaves.

Methods: Four varieties of buckwheat leaves were harvested in June and July. Leaves were dried, grinded and covered with boiling water. The content of polyphenols in dried leaves and in infusions was determined by Poly-Swain and Hills method and the antioxidant activity was measured by determining the ability of elimination of the free radical ABTS•+.

Results: In any case, harvest time had a significant impact on the content of total polyphenols. It has been shown that dried buckwheat's leaves are rich in polyphenols, especially Panda variety harvested in July (602,4 mg/100 g). The highest antioxidant activity has Green Corolla variety harvested in June (1743,3 μmol Trolox/ 1 g), Red Corolla and Panda variety harvested in June (~1303,1 μmol Trolox/ 1 g). Into infusions goes 80-100% total polyphenols contained in the dried leaves. The largest and at the same time similar antioxidant activity has been demonstrated in the infusions made from Panda and Kora varieties (harvested in July) 402,2 and 409,2 μmol Trolox/ 1 ml respectively.

Conclusions: These investigated varieties of buckwheat's leaves, as a good source of total polyphenols and antioxidant activity, may be a adequate material for making infusions.

Key words: buckwheat leaves, infusions, polyphenols, antioxidant activity

PO2789**THE EFFECT OF SELECTED BIOACTIVE FOOD COMPOUNDS IMPLEMENTATION IN LONG-TERM DIETETIC THERAPY IN PATIENTS WITH OBESITY**

A. Kostrzewa – Tarnowska¹, M. Cztapka - Matysik¹, M. Fejfer¹, J. Mierkiewicz¹, J. Jeszka¹

¹Department of Human Nutrition and Hygiene, Poznan University of Life Sciences, Poland

Background and objectives: The obesity is related to many diseases such as carbohydrate metabolism disorders, dyslipidemia, atherosclerosis or hypertension. In this case some bioactive food compounds may be useful in the weight-loss dietotherapy. *Morus alba* L., *Urtica dioica* L. and *Vicia faba* L. improve glucose tolerance, whereas *Brassica oleracea* L. var. *sabellica* L. and inulinum show serum-lipid lowering properties. The objective of this study was to investigate whether selected bioactive food compounds implementation positively affects metabolism disorders and supports weight-loss.

Methods: The food products with bioactive compounds were selected by nutritive value, composition and glycemic index (GI) and included in the weight-loss diet for obese patients. The weight-loss diet was prepared according to Polish National Food and Nutrition Institute dietary guidelines. The dietary intervention took 9 weeks. The body mass, anthropometric indicators, body composition, and bone density were measured every week. Moreover every patient was obligated to keep a nutrition diary, which was used for nutritional value of daily food ration estimation. The results have been compared to control group which followed low-calorie diet including placebo food products (free from bioactive compounds).

Results: The implementation of bioactive food in weight-loss dietetic therapy enhanced the weight loss and improved lipid and carbohydrate metabolism by lowering total serum cholesterol and blood glucose level.

Conclusions: The results support the correctness of bioactive components' choice for supporting weight loss, as well as lipid and carbohydrate metabolism improvement in obese patients. They also give an impulse to implement bioactive components in 'functional food' production.

Key words: weight-loss therapy, *Morus alba* L., *Brassica oleracea* L. var. *sabellica* L., *Vicia faba* L., *Urtica dioica* L.

PO2790**ANTIOXIDANT PROPERTIES OF BLACK ELDERBERRY (SAMBUCUS NIGRA L.) AND SEA BUCKTHORN (HIPPOPHAË RHAMNOIDES L.) FRUITS***B. Borczak¹, E. Sikora¹, E. Piatkowska¹, A. Kopec¹*¹Department of Human Nutrition, Agricultural University in Krakow, Poland

Background and objectives: Many studies have shown that as a result of environmental factors increases the intensity of free radical reactions in the human body, with all health implications. The aim of this study was to determine the contents of antioxidant components in the wild - grown fruits and their ability to quench free radical ABTS.

Methods: The research material consisted of fresh fruits, gathered in the places free from industrial pollution. Measurements of vitamin C and beta-carotene were performed according to Polish standards [PN-A-04019, PN-90/A-7510112]. The content of anthocyanins was determined by Benvenuti et al., [2004], the ability to quench free radical ABTS by Re, Pellegrini et al., [1999] and the tannin content by spectrophotometric method [Farmakopea, 2002]. Results of the analyses were presented as mean values with standard deviations (sd).

Results: The content of vitamin C [mg / 100 g] in the sea buckthorn fruits (58.72 ± 4.4) was higher than in elderberry fruits (33.99 ± 2.32). The amount of beta-carotene in elderberry fruits (0.28 ± 0.04 mg/100 g) was six times lower than in sea buckthorn (1.75 ± 0.23 mg/100 g), while the tannins content [mg/100g] was higher in elderberry fruits (68.97 ± 0.04), compared to sea buckthorn (63.7 ± 0.05), and anthocyanins [mg/100g] in elderberry fruits (302.88 ± 37.9) exceeded more than two hundreds the content presented in the sea buckthorn (1.25 ± 0.6). Greater ability to quench free radical ABTS [$\mu\text{mol Trolox/g}$] was characterized by elderberry fruits (99.49 ± 0.72), compared with sea buckthorn fruits (10.77 ± 0.3).

Conclusions: The inclusion of elderberry and sea buckthorn fruits or their preparations may help to diversify and increase functional properties of the daily diet. This study was supported by the National Science Centre; decision no DEC-2011/01/B/NZ9/07177.

Key words: wild-grown fruits, bioactive components, antioxidants

PO2791**THE INFLUENCE OF DIET WITH AN ADDITION OF ELDERBERRY FRUITS AND LEAD ON SELECTED BIOCHEMICAL PARAMETERS IN SERUM OF RATS***A. Kopec¹, E. Sikora¹, B. Borczak¹, E. Piatkowska¹*¹Department of Human Nutrition, Agricultural University in Krakow, Poland

Background and objectives: Heavy metals may represent a significant threat to human health and cause an acute poisoning and far adverse effects. The aim of the study was an investigation of lead and elderberry fruits addition to a diet of laboratory rats on the selected biochemical parameters.

Methods: The experimental rats (male, Wistar strain) were divided into four groups (n=6) and fed for 5 weeks with the following diets: (1) AIN-93G as control, (2) AIN-93G with an addition of lead, (3) AIN-93G with an 5% addition of freeze-dried elderberry fruits and (4) AIN-93G with an addition of both, lead and 5% of freeze-dried elderberry fruits. Lead was added to the diet at a dose of 0.025 mg/kg body weight. The contents of total cholesterol and triacylglycerols were measured by using enzymatic kits, while the glucose level was monitored by glucometer.

Results: The body mass gain was highest in rats fed control diet (1), while an addition of lead to the diet (2) caused a decrease in the body mass gain. In the groups of rats fed diets with an addition of elderberry fruits (3,4), the body gains were lowered compared to diets without an addition of this fruit but a decreasing effect of lead on the body gain was not seen. The addition of lead into a control diet (2) led to an increased glucose and triacylglycerols levels, while an incorporation of this metal into a diets containing elderberry fruits (3, 4) did not change those parameters.

Conclusions: The addition of lead to rats' diet contribute to some adverse changes on the tested biochemical parameters, while elderberry fruits seem to possess protective effect in the living organism. This study was supported by the National Science Centre; decision no DEC-2011/01/B/NZ9/07177.

Key words: elderberry, lead, cholesterol, glucose, triacylglycerols

PO2792**COOKING EFFECT ON OXALATE CONTENT IN MALAYSIAN SOY BASED DISHES.***G. Shimi¹, H. Haron¹*

¹Nutritional Sciences Programme, School of Health Care, Faculty of Health Sciences, Universiti Kebangsaan Malaysia, Jalan Raja Muda Abdul Aziz, Kuala Lumpur, Malaysia

Background and objectives: Legumes have been found to contain some inherent anti-nutritional factors which limit their nutritive value by exerting certain deleterious effects. Some studies investigated the effect of food processing and preparation methods on bioactive food components and ingredients such as oxalate. Recently, researches on soy bean products have been attracted by many health and industrial stakeholders. As the first study in Malaysia, this study aimed to determine the effect of cooking on oxalate content and the negative effects of oxalate on calcium availability in eight Malaysian soy based dishes.

Methods: A total of eight types of Malaysian soy based dishes were home cooked. Oxalate was analyzed by using anion-exchange column (AEC), while calcium content was determined using Atomic Absorption Spectrophotometer (AAS).

Results: Oxalate concentration of studied samples was in the range of 6.43-19.40 mg/100 g for whole cooked dish samples, 9.03-11.90 mg/100g for raw soy products and 4.36-7.99 mg/100g for cooked ones. There were 5 out of 12 samples containing oxalate which was significantly lower ($p < 0.05$) in cooked soy products compared to the raw ones. The rest of samples were also lower in oxalate but was not significantly different ($p > 0.05$). Oxalate in raw and cooked fermented soy products (tempeh) was slightly lower compared to the non-fermented ones. However, there was no significant difference ($p > 0.05$) in oxalate content between fermented and non-fermented soy products.

Conclusions: Oxalate/Calcium ratio among all samples was below 1 which showed that oxalate did not have an effect on availability of calcium in studied samples. Thus, cooking and optimal food processing might be effective in reducing oxalate content in soy bean products. As a final point, further researches on the effect of cooking and fermentation on anti-nutrients in other Malaysian soy based dishes may provide more useful information.

Key words: Calcium, cooking, Malaysian, Oxalate, soy products

PO2793**UHPLC-ESI-QTOF-MS TO IDENTIFY PHENOLIC COMPOUNDS FROM A GRAPE (VITIS VINIFERA) SEED EXTRACT***M^a L. Cádiz Gurrea^{1,2}, S. Fernández Arroyo^{1,2}, M^a I. Borrás Linares^{1,2}, A. Segura Carretero^{1,2}*

¹Department of Analytical Chemistry, University of Granada, Granada, Spain

²Research and Development of Functional Food Centre (CIDAF), Granada, Spain

Background and objectives: Grapes (*Vitis vinifera*) are considered as the world's largest fruit crops, with an approximate annual production of 58 million metric tonnes. The presence and distribution of flavonoids of grape seeds have been studied by several authors. Grape seeds are rich sources of monomeric phenolic compounds, such as (+)-catechins, (-)-epicatechin and (-)-epicatechin-3-O-gallate as well as dimeric, trimeric and tetrameric procyanidins. These compounds act as antimutagenic and antiviral agents. Grape seeds are used as a dietary supplement and natural food additive in the USA, Australia, Japan, Korea and in many European countries. There has been an increasing consumer demand for this product due to its powerful antioxidant properties and other beneficial biological activities. The aim of the present study was to characterize phenolic compounds in *Vitis vinifera* seeds extract.

Methods: The characterization was carried out using UHPLC-ESI-QTOF-MS. A reverse phase C18 column was used working in gradient mode using acetic acid 1% in water and acetonitrile as mobile phases. Accurate mass and fragmentation pattern of each peak provided from QTOF instrument were used to determine the compounds.

Results: 25 compounds were identified belonging to various structural classes such as flavonols (quercetin, catechin, myricetin and derivatives), benzoic acids (gallic acid and derivatives) and others organic acids (quinic acids and derivatives).

Conclusions: The method described simultaneously separated a wide range of phenolic compounds and the tentative characterization of the major compounds of this extract was carried out. It is important to highlight that, to our knowledge; this is the first time that the phenolic compounds from *Vitis vinifera* seeds extract have been characterized.

Key words: Grape seeds, phenolic compounds, *Vitis vinifera*, UHPLC-ESI-QTOF-MS.

PO2794

PROTECTIVE EFFECTS OF A COMBINATION OF CITRUS AND ROSEMARY EXTRACTS ON UV-INDUCED DAMAGE IN HUMAN KERATINOCYTES

A. Pérez-Sánchez¹, E. Barrajón-Catalán¹, N. Caturla², J. Castillo³, O. Benavente-García⁵, M. Alcaraz⁴, V. Micol¹

¹Institute of Molecular and Cell Biology, Miguel Hernandez University, Elche, Alicante, Spain

²Monteloeder S.L., Elche, Alicante, Spain

³Nutrafur S.A., Alcantarilla, Murcia, Spain

⁴Radiology and Physical Medicine Department, Faculty of Medicine, University of Murcia, Espinardo, Murcia, Spain

⁵Institute of Research into Aging, University of Murcia, Espinardo, Murcia, Spain

Background and objectives: UV radiation, absorbed by the epidermis, is the major cause of a variety of cutaneous disorders including photoageing and skin cancers. In recent years, an increase in the use of botanicals with antioxidant and anti-inflammatory properties as skin photoprotective agents is emerging. In the present study, a combination of rosemary extract and citrus bioflavonoid extract (NutroxSun) has been challenged to inhibit UV harmful effects using human keratinocytes.

Methods: The protection study was performed determining the viability of HaCaT cells exposed to UVB and their level of DNA damage through MTT and Comet assays. In addition, we evaluated the antioxidant activity and attenuation of oxidative stress on UVB-irradiated cells by the combination extract. Finally, we carried out a human trial, inducing erythema in volunteers, and assessed the skin protective effect against UV radiation.

Results: The combination of the extracts (NutroxSun) exhibited higher protective effects on cell survival upon UV radiation than the individual extracts pointing out potential synergic effects. The combined extract also showed the capacity of scavenging intracellular radical oxygen species, especially hydrogen peroxide, at non-cytotoxic concentrations. The extract was also capable to decrease UV-induced DNA damage as shown by the comet assay. The oral daily consumption of 250 mg of the combination in human volunteers revealed a significant UV protection compared to the first day after 57 days, through the increase of the minimal erythema dose upon UV radiation. Longer treatments achieved stronger protection, probably indicating that longer treatments reach higher steady-state concentrations of the chemopreventive compounds.

Conclusions: These results indicate that the combination of citrus flavanones and caffeoyl derivatives from rosemary (NutroxSun) may be considered as an ingredient for oral photoprotection and their mechanism of action may deserve further attention.

Key words: Botanicals; UV radiation; photoprotection; DNA.

PO2795

PHENOLIC COMPOUNDS IN ROSMARINUS OFFICINALIS L. EXTRACTS AND ANTIOXIDANT ACTIVITIES

M. Bellumori², C. Samaniego-Sánchez¹, M. Innocenti², N. Mulinacci², H. López-García de la Serrana¹

¹Dpto. Nutrición Y Bromatología, Facultad de Farmacia, Universidad de Granada, Granada, Spain

²Department of NEUROFARBA, Division of Pharmaceutical and Nutraceutical, University of Florence, Sesto Fiorentino, Florence, Italy

Background and objectives: *Rosmarinus officinalis* L. (Labiatae) is an aromatic herb used not only to obtain essential oils, but also to prepare various extracts that are increasingly employed to provide natural alternatives to synthetic antioxidant and artificial preservative additives in foodstuffs. The antioxidative properties of the leaves of rosemary are probably due to several phenolic compounds, among them rosmarinic acid, carnosic acid, carnosol, and flavonoids. The aim of this study was to investigate the antioxidant activity of three ethanolic extracts (E-TO, E-PO, E-LI) from rosemary leaves and evaluate the relationship between the observed antioxidant properties and the phenolic content of the extracts.

Methods: The leaves were ground in liquid nitrogen and extracted with ethanol by the alternation of magnetic stirring and sonication in ultrasounds, according to the procedure described in a previous study. The extract E-TO was obtained by this ethanolic extraction, E-PO and E-LI were obtained by purification of this extract using dichloromethane; then the extracts were analyzed by HPLC/DAD/MS. Different radical-scavenging models, DPPH, ABTS, FRAP and DMPD, were used for the characterisation of the activity.

Results: The extracts showed different degrees of radical scavenging capacity and antioxidant activity was dependent on the type of assay used. In most of the assays the extract E-TO, with higher total phenolic content, was superior in activity. The observed antioxidant characteristics were not fully related to the total phenolic content of the extracts in any of the assays, but were presumably strongly dependent on rosmarinic acid concentration, the major phenolic component present in this type of rosemary extract as already described by Dorman et al.

Conclusions: This study indicated that rosemary contains significant free radical scavenging activities suggesting that rosmarinic acid contributes to total antioxidant activities of the extracts.

Key words: Rosemary extract; Rosmarinic acid; DPPH; ABTS; FRAP

PO2796

HIGH-DOSE MUSHROOM INCREASES HEPATIC ACCUMULATION OF TRIACYLGLYCEROL IN RATS FED WITH HIGH-FAT DIET

D. Handayani¹, B. Meyer², J. Chen², S. Brown², T. Mitchell², XF. Huang²,

¹Nutrition Department-Faculty of Medicine, University of Brawijaya, Malang, East Java, Indonesia

²School of Health Sciences and Illawarra Health and Medical Research Institute, University of Wollongong, Wollongong, Australia

Background and objectives: Shiitake mushroom is a functional food that contains active biological components such as beta glucan and eritadenine. The Shiitake has been shown to have health benefits including plasma TAG lowering and the prevention of body weight gain. Yet the underlying mechanisms are largely unknown. The aim of this study was to assess the potential underlying mechanism of Shiitake mushrooms to prevent body weight gain in rats fed a high fat diet (HFD).

Methods: Forty Wistar rats were divided randomly into four groups. Rats in the control group were given HFD only and rats in the treatment group were fed HFD enriched with Shiitake mushroom powder in low dose (LD-M, 0.7% wt:wt), medium dose (MD-M, 2% wt:wt) and high dose (HD-M, 6% wt:wt) for 6 weeks. Diets were isocaloric containing ~50% energy from fat. After 6 weeks' dietary intervention, rats were sacrificed; blood and tissue samples were collected.

Results: The rats fed HD-M showed a significantly higher ratio of liver weight to 100 g body weight ($p < 0.05$), a more severe hepatic steatosis marker such as hepatocyte ballooning ($p < 0.0001$) and more liver triacylglycerol (TAG) content than LD-M and MD-M ($p < 0.05$). HD-M also showed a significantly decreased ratio of phosphatidylcholine (PC) to phosphatidylethanolamine (PE) compared to HFD ($p < 0.05$) but there were no differences compared to HD-M and MD-M. This study also showed a positive association between the dosage, liver TAG and liver ballooning histology. A negative association was found between the dosage of mushroom and the ratio of liver PC to PE.

Conclusion: The study showed that high-dose shiitake mushroom increased TAG accumulation in liver. This could partially explain how consumption of mushrooms lowers blood levels of TAG in rats fed with high-fat diet.

Key words: Shiitake mushroom, Triacylglycerol, Phosphatidylcholine, Phosphatidylethanolamine

PO2797

EFFECT OF IMMEDIATE INTAKE AND SUPPLEMENTATION FOR 6 DAYS WITH BLUEBERRIES ON GLYCEMIA, INSULINEMIA AND REDOX STATUS IN HEALTHY SUBJECTS

X. Palma Molina¹, H. Araya López², J. Codoceo²

¹Departamento de Nutrición y Alimentos, Universidad de Valparaíso, Valparaíso, Chile

²Departamento de Nutrición, Universidad de Chile, Santiago, Chile

Background and objectives: Western diets, rich in fats and rapidly digestible carbohydrates have been associated with an increased risk of chronic diseases. Blueberries have shown different biological activities being one of the most important their effects on glycemic and insulinemic responses. The aim of this study was to evaluate the effect of two different ways to consume blueberries (an immediate intake and a 6-days supplementation) on glycemia, insulinemia and redox state after a glucose load in healthy subjects.

Methods: Ten volunteers (aged 22 – 31 years) consumed 150-g of white bread alone (control), together with a single dose of 150-g of unprocessed blueberries, and after a 6-days supplementation period with the same amount of fruit daily in a crossover design with a minimum 2 wks between sessions. Blood samples were collected at fasting and at 30 min intervals for 120 min from initiated bread ingestion. Glycemia, insulinemia, red blood cell glutathione, plasma malondialdehyde and antioxidant capacity (FRAP) were determined.

Results: Glucose concentrations were significantly lower at 60, 90 and 120 min after immediate intake compared to control ($p < 0,05$) and at 60 and 90 min compared to supplementation ($p < 0,05$). Blood glucose peak was also significantly lower after immediate intake compared to control and supplementation ($102,03 \pm 1,41$ versus $127,99 \pm 7,85$ and $130,39 \pm 7,48$ mg/dL, respectively, $p < 0,05$). Insulin concentrations tended to be lower after both types of blueberries consumption, but there were no significant differences. Redox biomarkers did not significantly differed after blueberries ingestion.

Conclusions: Results suggest that immediate intake of blueberries modulates glucose but not insulin concentrations in response to a 75-g glucose upload in healthy subjects. Anthocyanins actions over carbohydrate digestion enzymes are likely to be responsible.

Key words: Blueberries intake, Glycemic response, Insulinemic response, Redox status

PO2798

RESTRUCTURED SQUID-SURIMI ENRICHED IN GLUCOMANNAN IMPROVES THE ANTIOXIDANT STATUS IN OBESE ZUCKER RATS

M. Vázquez-Velasco¹, L. González-Torres¹, P. López-Gasco², A. Garcimartín¹, M J. González-Muñoz³, J. Benedí², S. Bastida¹, F J. Sánchez-Muniz¹

¹Dep. Nutrición y Bromatología I (Nutrición), Facultad de Farmacia, Universidad Complutense de Madrid, Madrid, Spain

²Dep. Farmacología, Facultad de Farmacia, Universidad Complutense de Madrid, Madrid, Spain

³Dep. Nutrición, Bromatología y Toxicología, Facultad de Farmacia, Universidad de Alcalá, Alcalá de Henares, Madrid, Spain

Background and objectives: Zucker Fa/Fa rat is a commonly used model in Metabolic Syndrome (MS) studies. MS leads to an overbalance of reactive oxygen species net level in comparison to the antioxidant capacity. Glucmannan, a soluble highly fermentable fibre, has been suggested to act as antioxidant. Present study aims to assess the effects of the consumption of a high saturated diet -containing a 30% of restructured squid-surimi enriched with glucmannan- on the antioxidant system of Fa/Fa rats.

Methods: Two groups of eight rats each were fed for seven weeks with Control diet (C, AIN-93M enriched with 30% of restructured squid-surimi) or Glucmannan diet (G, 15% of glucmannan into same restructured surimi). Glutathione levels were assessed in liver following the Hissin & Hilf method. Hepatic superoxide dismutase (SOD), catalase (CAT), glutathione peroxidase (GPx) and glutathione reductase (GR) levels were determined by Western blot and their expression by qRT-PCR.

Results: High saturated C diet produced oxidative stress. G diet increased reduced glutathione ($p < 0.05$), improving redox index ($p < 0.05$). SOD expression and levels were reduced with the G diet (both $p < 0.05$), suggesting a free radical sequestering capacity of the fiber. CAT and GPx expressions or levels were not affected by diet, while GR levels were increased with the G diet ($p < 0.05$), suggesting the stimulation of the glucose-6-phosphate dehydrogenase metabolic pathway due to glucmannan consumption.

Conclusions: Consumption of glucmannan in a squid-surimi matrix exerts an antioxidant effect attending to the observed improvement of some antioxidant status markers. Squid-surimi enriched with glucmannan could be considered as a potential functional food, although more studies are recommended. The present study was supported by the Spanish projects AGL2011-29644-C02-02, Consolider-Ingenio 2010 project # CSD2007-00016, and CONACYT grant.

Key words: Squid-surimi, glucmannan, glutathione, antioxidant-status.

PO2799

IMPROVEMENT OF IN VITRO AND IN VIVO ANTIOXIDANT CAPACITY OF COWPEA (VIGNA UNGUICULATA) BY NATURAL OR CONTROLLED FERMENTATION PROCESS

R. Martínez¹, G. Kapravelou¹, A. Andrade¹, L. Bustos¹, P. Aranda¹, M. López-Jurado¹, F. Arrebola², M. Galisteo³, J M. Porres¹

¹Department of Physiology, School of Pharmacy, Institute of Food Science and Technology, University of Granada, Granada, Spain

²Department of Histology, School of Medicine, Institute of Neurosciences, University of Granada, Granada, Spain

³Department of Pharmacology, School of Pharmacy, University of Granada, Granada, Spain

Background and objectives: Cowpea (*Vigna unguiculata*) is a widely cultivated legume that contains appreciable levels of bioactive non-nutritional compounds which may confer this legume great potential as functional food. Furthermore, certain technological treatments like fermentation may enhance its antioxidant capacity. This study aimed to test the antioxidant properties of *V. unguiculata*, var. Carrilla, and the effect of natural and controlled fermentation with an inoculum of *L. plantarum* combined with a thermal treatment of dry heat.

Methods: Cowpea seeds. *Vigna unguiculata* L. var. carrilla was ground and fermented using the endogenous microbiota present in the seed or with an inoculum of *Lactobacillus plantarum*. Fermented samples were freeze-dried and dry-heated at 120°C, 1 atm during 20 min. Total polyphenol content, reducing capacity, and antioxidant capacity was determined in the different acetone extracts of *V. unguiculata* flours. Animals. 60 Wistar rats were divided in 6 experimental groups ($n = 10$ per group). Each group consumed ad libitum one of the experimental diets formulated to contain raw or fermented cowpea flours as the sole source of dietary protein. Plasma total antioxidant capacity was assessed, and the Liver was selected to determine the activity of GPX, SOD and CAT.

Results: The different fermentation processes increased the total polyphenol content, reducing capacity and antioxidant capacity of cowpea flour extracts. Furthermore, in vivo assessment showed an increase in plasma total antioxidant capacity and in liver GPX, Cu/Zn-SOD, Mn-SOD and CAT activity of rats that consumed fermented cowpea diet when compared to rats that were fed raw cowpea or casein diets.

Conclusions: Fermentation improved the antioxidant capacity of *Vigna unguiculata* var. carrilla flours measured by in vitro or in vivo techniques, thus exhibiting great potential for the preparation of new legume-derived functional foods with enormous benefits for human health.

Key words: *Vigna unguiculata*; antioxidant capacity; functional food; fermentation

PO2800**EFFECT OF DIFFERENT CONCENTRATIONS OF PROTEINS IN A SOLUBLE HIGH FIBER FOOD ON THE SHORT-TERM SATIETY IN HEALTHY YOUNG ADULTS**

M. Oliveri¹, P. Araya¹, H. Araya López²

¹Departamento de Nutrición y Alimentos, Universidad de Valparaíso, Valparaíso, Chile

²Departamento de Nutrición, Universidad de Chile, Santiago, Chile

Background and objectives: The objective of this study was to examine the effect of different concentrations of calcium caseinate on short-term satiety using as a vehicle a food high in soluble fiber.

Methods: The high soluble fiber food was a cake prepared with a mixture whole flaxseed meal and refined wheat meal. 22 healthy young men were selected from students of the University of Valparaíso. Three groups were studied: the control group that consumed the food without protein addition and the other 2 groups received the high fiber food with the addition of a 8% and a 14 % of caseinate, respectively. Short term satiety was determined by two methods one of them used a visual analogue scale (subjective method) and the other applied differential weighing between the amount of foods offered and the left over by the subjects (objective method). Results were analyzed by repeated measures ANOVA, t-paired (parametric) and Kruskal Wallis, Wilcoxon test (nonparametric).

Results: The feeling of satiety during the subjective evaluation was significantly highest when subjects consumed the highest protein preload when compared with the other two preloads and also fullness and reduced hunger and appetite were observed. When the objective method was applied food and energy intakes were significantly lower for the highest protein preload and then satiety was superior.

Conclusions: The results of the study make possible to conclude that addition of proteins to a high soluble fiber food increases satiety response directly related to protein concentration.

Key words: Fiber soluble, caseinate calcium, satiety

PO2802**A NON-BITTER BITTER GOURD DRINK IS READY TO BE TESTED ON HUMANS IN A BLINDED STUDY**

S D. Habicht^{1,2}, H I. Wang¹, M B. Krawinkel², R Y. Yang¹

¹AVRDC – The World Vegetable Center, Shanhua, Tainan, Taiwan

²International Nutrition, Justus Liebig University, Giessen, Hesse, Germany

Background and objectives: Bitter gourd (*Momordica charantia* L.) ameliorates insulin sensitivity in animal studies. However, significant data from human studies are lacking. Its distinctive bitter taste makes it difficult to use bitter gourd in blind placebo-controlled human studies. Therefore, a non-bitter bitter gourd drink (made from bitter gourd powder, a food additive that masks bitterness, and cucumber powder in water) and a placebo (cucumber powder and food additive in water) were developed. These two drinks and one containing only bitter gourd powder were compared for their effect on body weight and blood glucose in mice.

Methods: Forty high fat diet fed mice were treated with water (control), bitter gourd powder in water, non-bitter bitter gourd drink, or placebo. Treatments were given orally six days a week for eight weeks. Bitter gourd dosages were 500 mg/kg body weight, which is equivalent to 150 ml bitter gourd drink for humans.

Results: After eight weeks, average body weight was the highest in the control (35.6 g), followed by 33.9 g after treatment with bitter gourd only, 32.7 g with placebo, and 32.6 g with non-bitter bitter gourd drink. HbA1C levels were 4.7±0.05% and 4.7±0.1% in control and placebo groups, respectively, and 4.6±0.1% in the two bitter gourd groups. Average fasting blood glucose levels were also lower in the groups treated with bitter gourd. **Conclusions:** The food additive seems to prevent excessive weight gain, which led to a lower body weight in mice treated with non-bitter bitter gourd and placebo drinks. The placebo did not show any effect on blood glucose. The bitter taste masking agent did not reduce the antidiabetic effect of the bitter gourd. Thus, recipes for the non-bitter bitter gourd drink and the placebo drink are suitable to be used in a blinded study with humans.

Key words: type-2 diabetes, *Momordica charantia*

PO2804**OYSTER MUSHROOM (PLEUROTUS OSTREATUS) DECREASES BLOOD CHOLESTEROL LEVELS IN DIET-INDUCED HYPERCHOLESTEROLEMIA MICE**

V. Caz¹, C. Soler², M. Taberner¹, F. Marín², G. Reglero², C. Largo¹

¹Experimental Surgery, La Paz Hospital, Madrid, Spain

²Production and characterization of novel foods, Autonoma University, Madrid, Spain

Background and objectives: Cardiovascular disease is the leading cause of mortality in developed countries. Major risk factors include hypercholesterolemia and hyperglycemia. The objective of this study was to investigate the efficacy of *Pleurotus ostreatus* (*Pleurotus*) in lowering total cholesterol concentrations in diet-induced hypercholesterolemia mice.

Methods: For 4 weeks, 16 male C57BL/6J mice were fed a hypercholesterolemic diet (2% cholesterol; 3% fat) with or without 1.5% (wt/wt) *Pleurotus* extract obtained by the ASE (Accelerated Solvent Extraction) method. Blood samples were collected at the end of the experiments for biochemical analysis.

Results: Total plasma cholesterol levels were significantly lower in the group supplemented with *Pleurotus* as compared with the hypercholesterolemic control group, although they did not reach normal values. In the hypercholesterolemic control group, high-density lipoprotein cholesterol (HDLc) levels decreased 18% and low-density lipoprotein cholesterol (LDLc) levels increased 79% compared with the normocholesterolemic control group. HDLc and LDLc levels decreased 38% and increased 56% in the group supplemented with *Pleurotus*, respectively, as compared with the hypercholesterolemic control group. There were no differences in triglycerides and glucose levels between the group supplemented with *Pleurotus* and the two control groups.

Conclusions: Dietary supplementation with *Pleurotus* mushroom extract significantly decreased total plasma cholesterol levels, although not to normal levels, in diet-induced hypercholesterolemia mice. The HDLc-LDLc balance was not improved by *Pleurotus* supplementation. The present study suggests that *Pleurotus* supplementation may provide health benefits, at least partially, by acting on total cholesterol levels in the hypercholesterolemic condition.

Key words: bioactive food components, mushrooms, hypercholesterolemia

PO2805**DETERMINATION OF ANTIOXIDANT POTENTIAL OF SOME TRADITIONAL NON-ALCOHOLIC BEVERAGES IN BOSNIA AND HERZEGOVINA**

J. Djedjibegovic¹, A. Marjanovic¹, M. Sober¹, M. Brcaninovic¹, K. Sinanovic²

¹Department of Pharmaceutical analysis, Faculty of Pharmacy/University of Sarajevo, Sarajevo, Bosnia and Herzegovina

²Department of Physical Chemistry, Faculty of Pharmacy/University of Sarajevo, Sarajevo, Bosnia and Herzegovina

Background and objectives: Oxidative stress is assumed to be one of the risk factors in development of many diseases. In that light antioxidants and functional food containing antioxidants gain rising popularity among consumers. Aside of commercial products some traditionally beverages also have a potential to be classified as functional food. The main aim of our work was to determine antioxidant capacity of some traditional non-alcoholic beverages in Bosnia and Herzegovina.

Methods: Eight samples of traditionally prepared beverages (elder juice with and without lemon, juniper berries juice with and without lemon, blackberry juice, pomegranate juice, and boza). Commercial blackberry juice was also analyzed. The antioxidative effects of fruit juices were determined using the 2,2-Diphenyl-1-picryl hydrazyl (DPPH) assay, and ferric reducing antioxidant power (FRAP) assay. In addition total phenolic content was determined by Folin-Ciocalteu method and anthocyanidines by Vanilin-HCl method. Pure compounds (catechine, ascorbic acid and trolox) were used as control standards.

Results: Total phenolic content was in range of 74.31 mg TEA/L (elder juice with lemon) to 3365 mg TEA/L (pomegranate juice). Anthocyanidines content ranged from 125.27 mg/L (elder juice without lemon) to 1899 mg/L (traditionally prepared blackberry juice). Pomegranate juice exhibited the strongest activity against DPPH radicals (75.29 % inhibition), followed by traditionally prepared blackberry juice (42.86 % of inhibition) with their IC₅₀ values of 5.5 % (v/v) and 6.4 % (v/v), respectively. The DPPH determined antioxidant capacity showed significant positive correlation with total phenolic content as well as with flavonoids content. Analysis by FRAP assay showed stronger antioxidant capacity for most of the samples, compared to ascorbic acid standard.

Conclusions: In conclusion the analyzed traditionally prepared beverages showed strong antioxidant capacity which was even more pronounced than in the commercial juice. Health promotion of potential benefits of such homemade products should be enhanced.

Key words: elder, blackberry, pomegranate, boza, juniper

PO2806**PHYTOSTEROLS OXIDES IN FUNCTIONAL BEVERAGES: MATRIX AND STORAGE INFLUENCE**

M. González-Larena¹, G. Garcia Llatas¹, L M. Sánchez-Siles², G. Clemente³, R. Barberá¹, M J. Lagarda¹

¹Facultat de Farmàcia, Universitat de València, València, Spain

²Hero Global Technology Center, Hero Spain SA

³Departaments Statistics, Polytechnical University, Valencia, Spain

Background and objectives: Plant sterols (PS) are currently used as functional food ingredients because of their ability to reduce low-density lipoprotein (LDL)-cholesterol levels. One way of improving the oxidative stability of PS enrichment in a food would be their inclusion in a matrix with natural antioxidant compounds as fruit & skimmed milk. The aim of this study was to evaluate the influence of food matrix, temperature and storage time in the content of phytosterol oxidation products (POPs) in functional beverages with PS added.

Methods: Three beverages (fruit juice, milk and fruit juice + milk) enriched with PS (0.8 g PS/100 mL beverage) were manufactured in a pilot plant by HERO Spain, S.A. Samples were analyzed just after manufacture (time 0) and were then stored at 4, 24, or 37 °C and analyzed at regular time intervals of 2 months until 6 months.

Methods: After identification and determination of POPs by GC-MS and GC-FID, respectively, a three factor ANOVA was applied to total POPs and a simple regression analysis was performed for determining the evolution of total POPs in each matrix during their storage.

Results: Total POPs content was fruit juice and milk (FM) < fruit juice (F) << milk (M). In the first four months of storage a major increase of the total content is observed and an interaction (time x temperature) was also detected. The predictive models obtained were: FM) Total POPs = 213.627 + 55.5914*sqrt(Time); R² = 71.166 (p = 0.0006); F) Total POPs = 485.821 - 92.8523*sqrt(Time); R² = 71.8914 (p = 0.0005); M) Total POPs = 325.353 + 97.8143*sqrt(Time); R² = 79.0188 (p = 0.0003) .

Conclusions: Association of milk and fruit juice improves the stability of PS.

Key words: phytosterols, POPs, functional food

PO2808**FOOD COMPONENTS WITH EC CLAIMS RELATED TO CORONARY HEART DISEASE SUMMARISED IN A ROUND TABLE MODEL**

M. Ashwell¹, U. Arens¹, S. Gibson¹, A. de la Hunty¹, M. Sadler¹

¹Ashwell Associates, Ashwell St, Ashwell, Hertfordshire, UK

Background, objectives, methods: In 1993 the first Round Table Model of factors relating to coronary heart disease (CHD) was devised [1]. The model is an 'aide memoire' to illustrate the role that many food components play in risk reduction. It consists of a series of concentric circles, representing food components (outer circle) physiological factors (middle circle) and pathological events (inner circle). Each food component occupies a segment in the outer circle, matched to the corresponding physiological risk factor and to a pathological event: i.e. injury to coronary arteries(a), atheroma and fibrous plaque formation and vulnerability(b), and thrombosis(c). Our aim was to update the model and to see how authorised EC health claims relating to CHD reflect the spectrum of beneficial food components and their matching physiological risk factors. **Results and conclusions:** Twenty years later, the model could include early life events as well as genetic factors as 'uncontrollable factors' in adulthood. 'Less controllable' factors could include an excess of visceral and ectopic fat, and possibly the gut microbiota. The physiological risk factors (with related pathological event- a,b,c) would probably now include increased blood pressure(a,b), increased plasma homocysteine(a,c), increased lipid oxidation(a), impaired endothelial function(a,c), increased inflammation(a), poor atherogenic lipid profile(b), pro-coagulant state(b,c), increased insulin resistance(b) and arrhythmia(c). Food components with authorised claims on the EC register include potassium, antioxidant nutrients such as vitamin C and zinc, folate, B vitamins, betaine, choline, mono-unsaturated and poly-unsaturated fatty acids, resistant starch, beta-glucans, insoluble and soluble fibres, plant sterol/stanol esters, glucomannan, chitosan and vitamin K. Matching these, and others, to physiological risk factors reveals many claims showing improvement of the atherogenic profile, with fewer claims relating to many of the other risk factors.

Key words: diet, CHD, risk factors, EC claims [1. Ashwell M et al: Proc Nutr Soc 2000;59:415-416].

PO2809**IN VITRO POTENTIAL PROPERTIES OF CONVENTIONAL AND HERBAL TEAS AGAINST KEY ENZYMES RELEVANT TO ALZHEIMER'S DISEASE***U. Suttisansanee¹, J. Tonglim¹*

¹Institute of Nutrition, Mahidol University, Phutthamonthon, Nakhon Pathom, Thailand

Background and objectives: Conventional tea (*Camellia sinensis*) has been extensively studied for their potential health promotions and benefits. Tea polyphenols possess neuroprotective properties, which can protect brain cells against development of Alzheimer's disease (AD) and related disorders. Acetylcholinesterase (AChE), butyrylcholinesterase (BChE) and α -secretase (BACE1) are key enzymes that control the termination of physiological role of cholinergic synapses and formation of β -amyloid plaque, the systems that suggested possible developments on AD. Therefore, the inhibitors of these enzymes could be targeted as anti-AD's agents. In this study, tea infusions were investigated regarding their inhibitory activities toward cholinesterase and BACE1 in order to extend fundamental knowledge on tea nutraceutical properties and to potentially discover future anti-AD's agents.

Methods: Five conventional teas and fifteen Thai herbal teas were prepared as tea infusions before being investigated their inhibitory properties toward AChE and BChE using an enzymatic coupled assay with 5,5'-dithiobis(2-nitro benzoic acid) (DTNB) and BACE1 using BACE1 activity assay kit (Sigma-Aldrich, Singapore Science Park II, Singapore).

Results: As results, the inhibitory activities of AChE suggested that the conventional teas possessed approx. 70-90% inhibition, while Thai herbal teas exhibited lower and wider range of inhibitory capacity. Among these, tea infusion from *Pandanus amaryllifolius* Roxb. provided the highest yield of approx. 60% inhibition. As well, *Pandanus amaryllifolius* Roxb. and *Zingiber officinale* Roscoe exhibited the highest BChE inhibitory activity (approx. 50%). Interestingly, tea infusion of *Stevia rebaudiana* Bertoni was the only tea extract that exhibited anti-BACE1 activity (20% inhibition).

Conclusions: Thus, *Pandanus amaryllifolius* Roxb., *Zingiber officinale* Roscoe and *Stevia rebaudiana* Bertoni are three herbal teas that possess high potential of anti-AD agents. These in vitro screening potential activities against key enzymes relevant to AD would be useful for future development of anti-AD's food and beverage as well as potentially drug discovery.

Key words: Anti-Alzheimer activities, conventional teas, Thai herbal teas

PO2810**PHENOLIC PROFILE AND CYTOTOXIC ACTIVITY OF PLANTAGO HOLOSTEUM SCOP.***I. Beara¹, M. Francišković¹, N. Mimica-Dukić¹, N. Simin¹, D. Orčić¹, E. Svirčev¹, D. Četojević-Simin²*

¹Department of Chemistry, Biochemistry and Environmental Protection, Faculty of Sciences, Novi Sad, Serbia

²Oncology Institute of Vojvodina, Sremska Kamenica, Serbia

Background and objectives: Ancient use of plantains (genus *Plantago* L., Plantaginaceae) as herbal remedies is a consequence of their astringent, anti-toxic, antimicrobial, expectorant and diuretic properties. While there are no exhaustive data about bioactivity of many plantains, as part of our continuing valorization of medicinal use of *Plantago holosteum* Scop., some tests on cytotoxic activity of methanol extract of this species collected from mountain Kopaonik (Serbia) have been undertaken. As numerous studies showed that phenolics could influence cancer development, phenolic composition of the extract has been evaluated.

Methods: The presence of 44 phenolics was studied using LC-MS/MS, cytotoxic activity was studied by SRB (Sulforhodamine B) assay [1].

Results: 24 Compounds were found, the most dominant being: vanillic and protocatechuic acid (0.5 and 0.8 mg/g of dw, respectively), with apigenin, luteolin and luteolin-7-O-glc (1.12, 1.3 and 3.4 mg/g of dw, respectively). While some of these compounds are known as potent anticancer agents [2], they could be, at least partially, responsible for cytotoxic activity seen in this extract. The extract showed good cytotoxic activity against HeLa (cervix epitheloid carcinoma) and low activity against MCF7 (breast adenocarcinoma) cell lines (IC₅₀=335 and 964 μ g/mL, respectively), but no cytotoxicity against HT-29 (colon adenocarcinoma) and low cytotoxicity against MRC-5 (human fetal lung, IC₅₀=712 μ g/mL) cell lines.

Conclusions: We report for the first time about detailed phenolic profile and cytotoxic activity of *P. holosteum*. Considering previously determined antioxidant and antiinflammatory activity of this species [3], overall results implicate potential use of *P. holosteum* as source of health-beneficial phytochemicals.[1] Beara I. et al. (2012) LWT-Food Sci. Technol. 47: 64-70.[2] Havsteen B.H. (2002) Pharmacol. Therapeut. 96: 67-202[3] Beara I. et al. (2009) Planta. Med. 75: 877-1904. Acknowledgement: The Ministry of Education and Sciences Republic of Serbia (Grant No.172058).

Key words: *Plantago*, phenolics, cytotoxicity.

PO2811**COUNTERACTION OF OXIDATIVE DAMAGE BY POMEGRANATE JUICE. INFLUENCE OF THE CULTIVAR**

¹Interdepartmental Centre for Industrial Agri-Food Research, University of Bologna, Cesena, Italy

²Dipartimento di Colture Arboree, University of Bologna, Bologna, Italy

³Department of Agri-Food Science and Technology, University of Bologna, Cesena, Italy

Background and objectives: Pomegranate (*Punica granatum*) has gained widespread popularity as potential functional food. In different studies, pomegranate juice (PJ) has been shown to exert antiatherogenic, anti-inflammatory, and antioxidant effects, which have been attributed to its high phenolics content. The differences in polyphenols contents and antioxidant activities of commercial PJ, related to cultivar and/or industrial processing [1], must be carefully taken into accounts in evaluating the health effects of PJ. The aim of this study was to rank PJ from different cultivar according to their total phenolic content and antioxidant capacity. According to the ranking three PJ (Wonderful, Hicaz and G2) were then chosen, characterized for their phenolic composition, and used for HepG2 cells supplementation to evaluate their biological protective activity.

Methods: Cells were supplemented with PJ at two different medium concentration, and an oxidative stress was determined in some experiments by cell exposure to H₂O₂. Results obtained in PJ supplemented cells were compared to unsupplemented controls (stressed and not stressed) and to cells supplemented with tocopherol.

Results: In stressed condition, all PJ but Hicaz at the highest concentration counteracted H₂O₂ induced cytotoxicity. Furthermore, the oxidative damage was effectively counteracted by all PJ in a dose and cultivar-dependent manner.

Conclusions: Our results point out the importance of the cultivar in the degree of protection that can be achieved in cells after PJ supplementation, in some cases comparable to vitamin E. This work was in part funded by the TEPASS Project - Technologies for Safe and Sustainable Food, co-financed by the Emilia-Romagna Region within the call 'From Industrial Districts to Technology Clusters' and realized by Interdepartmental Centre for Industrial Agri-Food Research with the support of POR FESR 2007-2013 found for the realization of Emilia Romagna region technopole.[1] Tezcan F. Food Chem. 2009;115:873-7.

PO2812**NATURAL POLYPHENOLS FROM RED PROPOLIS ATTENUATE ANGIOGENESIS IN ATHEROSCLEROSIS**

J. Daleprane¹, C. Costa², A. Rocha², A. Resende², R. Moura², D. Abdalla³

¹Department of Basic and Experimental Nutrition, Institute of Nutrition, State University of Rio de Janeiro, Brazil

²Department of Pharmacology and Psychobiology, State University of Rio de Janeiro, Brazil

³Department of Clinical and Toxicological Analyses, Faculty of Pharmaceutical Sciences, University of São Paulo, Brazil

Background and objectives: Propolis, a polyphenol-rich resinous substance collected by honey bees, is believed to exert health benefits on various conditions including inflammation. We investigated the effects of polyphenols from red propolis (PRP) on angiogenesis in atherosclerosis.

Methods: The LDL receptor gene (LDLR^{-/-}) knockout mice received a cholesterol-enriched diet and PRP (250mg/Kg/day) by gavage during 4 weeks. Migrations of ECs, ECs sprouting from murine aortic rings, formation of new blood vessels in the chorio-allantoic chicken embryo (CAM) and differentiation of stem cell (SCs) in CD-31 positive cells were used as angiogenesis models.

Results: PRP decreased atherosclerosis lesion (AL) area and expression of inflammatory factors in LDLR^{-/-}. Furthermore, the expression of the pro-angiogenic factors FGF, VEGF and PECAM was downregulated by PRP. In angiogenesis model PRP (10 µg/ml) inhibited the angiogenic process in all protocols. Specifically, PRP reduced HIF-1 protein half-life, from ~58 to ~38 min under hypoxic conditions. The reduced protein half-life was due to increased von Hippel-Lindau (pVHL)-dependent proteasomal degradation of HIF-1 α , which was correlated with PRP-evoked downregulation of Cdc42 but a subsequent pVHL increase.

Conclusions: PRP are atheroprotective through mechanisms including modulation of inflammatory and angiogenic factors mainly modulating HIF-1 stabilization.

Key words: polyphenols, red propolis, nutrigenomics, angiogenesis

PO2813**ANTIPROLIFERATIVE ACTIVITY OF BUTTERMILK, MILK FAT GLOBULE MEMBRANE AND ISOLATED LIPID FRACTIONS ON TEN HUMAN CANCER CELL LINES**

²Instituto de Ciencia y Tecnología de Alimentos y Nutrición (ICTAN) CSIC, Madrid, Spain

³Chemical, Biological and Agricultural Multidisciplinary Research Center (CPQBA/UNICAMP), Paulínia, Brazil

Background and objectives: Buttermilk, a by-product obtained during the production of butter, contains high amounts of residual milk fat globule membrane (MFGM) which has been assessed for its immunomodulatory, antimicrobial and anticarcinogenic capacity. Besides glycolipids and membrane specific proteins buttermilk is a major source of milk polar lipids (60-70%), although their proportions vary greatly depending on the milk specie, treatment and the procedure used for the isolation and analysis. The objective of this preliminary study is to evaluate the antiproliferative impact of buttermilk and different fractions isolates on ten human cancer cell lines.

Methods: Antiproliferative capacity of powder buttermilk (PB) and four isolated fractions as MFGM, total lipids (TL), and neutral (NL) and polar lipids (PL) obtained by SPE fractionation, were assayed on up to ten human cancer cell lines. Concentrations between 1 ng/mL and 100 µg/mL of all samples were assayed. Doxorubicin was also included as a positive control at same concentrations.

Results: Lipid classes of the assayed samples, analyzed by HPLC-ELSD, revealed an increased amount of phospholipids percentage, accounted for about 43%, 50% and 72% of the PB, MFGM and NL respectively. The preliminary results of the experiments carried out showed a slight cytotoxicity effect of the studied samples in all cancer cell lines at the concentrations employed.

Conclusions: Under the experimental conditions of this preliminary study, none of the buttermilk and lipid fractions samples assayed confirmed a significant inhibiting proliferation of the ten human cancer cell lines employed. This work has been supported by CENIT-SENNIFOOD and CYTED-IBEROFUN Projects.

Key words: antiproliferative activity, buttermilk, MFGM, cancer cell lines

PO2814**BIOACTIVE FATTY ACIDS OF PUFA-ENRICHED BUTTERS FROM THE PARMIGIANO REGGIANO CHEESE AREA, AND COMPARISON WITH SOME EUROPEAN COMMERCIAL BRANDS**

E. Guerra¹, A. Gori¹, M^a F. Caboni¹

¹Department of Agricultural and Food Sciences (DISTAL), University of Bologna, Cesena, Italy

Background and objectives: Butter is one of the most complex of all edible fats with a wide range of fatty acids (FA) identified to date. The saturated fraction (SFA) account for the majority of all the FA, followed by mono- and poli-unsaturated fraction (MUFA and PUFA). Furthermore, butter contains minor FA considered bioactive for humans for their health giving properties, such as butyric acid, rumenic acid (CLA), the essential linoleic and α -linolenic acid (n-6, and n-3). Their content in dairy fat can be improved mostly by feeding strategies contemplating the supplementation of unsaturated fat sources. The aim of this investigation was to study the FA composition of experimental butters produced in the Parmigiano-Reggiano Cheese Consortium (CFPR) area, in response to extruded linseed supplementation to dairy cows, and compare the ameliorating effect with commercial butters.

Methods: 32 butter samples were analyzed by fast gas-chromatography. Italian and foreign butters, 21 and 7 respectively, were collected at local markets in Europe, while 4 experimental butter samples were produced at a local dairy farm in the CFPR area, from fresh outcrop milk creams obtained by supplementing the traditional diet of dairy cows with 300 g d⁻¹ of extruded linseed.

Results: With the respect to the Italian and foreign butter samples, experimental butter showed a lower content of medium-chain SFA (-8.5% and -8.6%), a better SFA/UFA ratio (1.78), a higher content of CLA (+32% and +15,3%), total n-3 PUFA (+56,4% and +28,8%) and trans fatty acids (+23.8% and +11.1%).

Conclusions: This study support the feasibility for a sustainable production of value-added by-product of dairy industry. The feeding strategy adopted, could be conveniently applied to achieve a high level of bioactive fatty acids, leading to the production of dairy products that may be more beneficial to consumers.

Key words: butters, enrichment, bioactive fatty acids.

PO2815**CHEESE WHEY PROTEINS AND THEIR HYDROLYSATES AS DIETARY SUPPLEMENT TO AGED RATS: MUSCLE PROTEIN, BONE CALCIUM AND BIOCHEMICAL PARAMETERS ANALYSIS**

A J. Goulart¹, J C. Bassan¹, T M S. Bezerra², D P. Marques¹, R. Monti¹

¹Faculdade de Ciências Farmacêuticas - UNESP Univ Estadual Paulista, Brazil

²Instituto de Química - UNESP Univ Estadual Paulista, Brazil

Background and objectives: Cheese whey proteins and their hydrolysates are composed of high biological value due to the presence of bioactive peptides and high concentration of essential amino acids, and different hydrolysates can be obtained depending on the specificity of the used proteases.

Methods: In this work, cheese whey proteins and their hydrolysates of medium and high degree of hydrolysis were used as dietary supplement of aged Wistar rats (age 17 months). It was analyzed the weight gain, muscle mass and bone mass of the animals, as well as biochemical tests for glucose, cholesterol, triglycerides, HDL, TGO, TGP, urea, creatinine and serum calcium. Four experimental groups were used: control group without supplement (G1), supplemented with integral proteins group (G2), supplemented with protein with low degree of hydrolysis (G3) and group supplemented with protein with high degree of hydrolysis (G4).

Results: All supplemented groups presented increase ($p < 0.05$) of total muscle protein and bone calcium. G3 group presented the best results ($6.33 \pm 0.4 \text{ mg}/100 \text{ g}^{-1}$ and $498.87 \pm 6.0 \text{ mg} \cdot \text{g}^{-1}$, respectively). G2 and G3 groups presented a 20% and 17% decrease in triglycerides in relation to control group G1 and G4. HDL, TGO and TGP did not differ between the groups, but it was verified a tendency of increase of HDL in groups supplemented and a tendency of decrease of TGO and TGP, mainly in G3; this same group also showed significant increase in serum calcium compared to other groups (about 15%). Other biochemical analysis did not show changes between G2, G3 and G4 groups compared to G1. By these results we conclude that dietary supplementation for aged rats with cheese whey proteins with medium degree of hydrolysis improved liver functions of the animals; they also showed a gain of muscle mass, suggesting that their use may reduce sarcopenia. Acknowledgements: CNPq, FAPESP, CAPES, PNPd/CAPES

Key words: cheese whey proteins hydrolysates; dietary supplementation; sarcopenia.

PO2816**ORAL ABSORPTION OF RUMENIC, VACENIC AND ALFA-LINOLENIC ACID AFTER DIETARY INTAKE OF MILK FAT NATURALLY ENRICHED IN PUFA**

L M. Rodriguez-Alcalá¹, J. Fontecha¹, M. Juárez¹, A. Anadón², M.A. Martínez², I. Ares², M.R. Martínez-Larrañaga²

¹Instituto de Investigación en Ciencias de la Alimentación (CIAL, CSIC-UAM), Bioactividad y Análisis de los Alimentos, Madrid, Spain

²Universidad Complutense de Madrid, Faculty of Veterinary Medicine, Department of Pharmacology and Toxicology, Madrid, Spain

Background and objectives: Milk fat naturally enriched in PUFAs have been tested in animals and humans reporting a positive effect on cardiovascular risk factors. Despite the evidences, little data exist about oral bioavailability of CLA, trans-vacenic (TVA) and alfa-linolenic (ALA). This knowledge constitutes valuable information to adjust the dosage in future population and clinical studies. The aim of the present research is to know if the Rumenic acid (RA) (major CLA isomer), TVA and ALA of an enriched goat milk fat (EDF) after oral administration in rats are absorbed.

Methods: Goat milk fat (EDF) naturally enriched in RA, TVA and ALA was administered orally by gavage (3g EDF/kg b.w. equivalent to 153 mg TVA/kg b.w., 46.14 mg RA/kg b.w., 31 mg ALA/kg b.w.) to Wistar rats. Serial blood samples were collected after oral administration. Plasma concentrations of RA, TVA and ALA were determined by GC/MS.

Results: TVA, RA and ALA were rapidly absorbed through the gastrointestinal in rats. The plasma concentrations of TVA, RA and ALA appeared to reach maximal concentrations at 2 h. The absorption grade was not dose-dependent. The maximal plasma concentrations were $65.5 \pm 12.5 \mu\text{g ALA}/\text{mL}$, $45.9 \pm 5.9 \mu\text{g TVA}/\text{mL}$ and $21.1 \pm 5.8 \mu\text{g RA}/\text{mL}$. In addition, while both TVA and RA were detected until 24 h after dose, ALA was still present at 48 h showing a plasma concentration of $10.4 \pm 2.2 \mu\text{g}/\text{mL}$.

Conclusions: The present study indicates that when given orally a goat milk fat naturally enriched in RA, TVA and ALA, these components were absorbed and likely distributed throughout the body by the circulation blood to exert systemic effects. Further research is needed to complete the kinetic characteristics of RA, TVA and ALA. Acknowledgements: This work has been supported by CONSOLIDER FUN-C-FOOD Project.

Key words: Milk fat, fatty acid bioavailability

PO2817**EVALUATION "IN VITRO" AND "IN VIVO" OF THE ANTIOXIDANT CAPACITY OF THE BOVINE CHEESE WHEY PROTEINS AND THEIR HYDROLYZATES**

J.C. Bassan¹, O.A. Barbosa¹, A.L.M. Nasser¹, T.B. Cesar¹, R. Monti¹, A.J. Goulart¹

¹Faculdade de Ciências Farmacêuticas, UNESP Univ Estadual Paulista, São Paulo, Brazil

Background and objectives: The whey, a by-product of the manufacture of cheeses, although potent environmental pollutant, has a high nutritional value and an undeniable amount of bioactive peptides. The objective of this work was to evaluate the antioxidant capacity of cheese whey proteins and their hydrolysates and its effects as dietary supplements on oxidative stress in Wistar rats.

Methods: All rats were treated with diet AIN 93M and water ad libitum. Supplemented groups received 110 mg prot/animal/day of integral whey proteins (IWP), or hydrolysates with low or high degree of hydrolysis (LDH and HDH, respectively). The antioxidant capacity of the hydrolysates and four groups of rats blood serum (control, IWP, LDH and HDH) was evaluated by the reduction of 2,2-diphenyl-1-picrylhydrazyl (DPPH) and lipid peroxidation of the serum of these same groups was assessed by thiobarbituric acid reactive substances (TBARS).

Results: The results showed that in spite of the hydrolysates show a tendency to decrease lipid peroxidation, this change was not significant. The antioxidant capacity of LDH and HDH hydrolysates increased 71.4% and 134.1%, respectively, compared to IWP. However, there was a significant decrease (approximately 70%) in the antioxidant capacity of the animals serum treated with LDH and HDH in relation to the control and the IWP groups ($p > 0.05$) after 43 days of supplementation.

Conclusions: These results showed the production of an expressive amount of bioactive peptides and/or amino acid with antioxidant activity by different conditions of hydrolysis, but in the gastrointestinal tract these compounds can be degraded, resulting in the reduction of its antioxidant activity. However, in another work of our group, the amino acids released under these same conditions of hydrolysis showed positive results 'in vivo' for the synthesis of muscle mass. Acknowledgements: CNPq, FAPESP, CAPES, PNPd/CAPES.

Key words: antioxidant capacity; lipid peroxidation, bioactive peptides.

PO2818**PRODUCTION OF MARGARINE AND SOYA/SUNFLOWER OIL WITH LYOPHILIZED TOMATO PEEL POWDER AS A NATURAL ADDITIVE**

³Food Technology Department, ENSA, Elaharrach, Algeria

⁴Food Technology Department Faculty of Engineering Science, Boumerdes University Boumerdes

Background and objectives: Through derived fat products we understand the fats that have a different composition and structure than their original ones. The largest part of the derived fat products can be conditioned through nutritive elements incorporation, colorants, antioxidants, preservatives etc. Such incorporation is not similar to the chemico-structural derivation. Although, the use of the chemicals additives is limited because of their toxic effect. Natural additives are believed to be healthy and are of good quality. The studies have shown that the increased consumption of tomatoes decrease the risk of occurrence of cardiovascular diseases, and prostate, lung and digestive system cancers. The main point of the research was to determine the antioxidant activity of freeze-dried tomato peels and the oxidative resistance of soya/sunflower oil and margarine rich with lycopene tomato peel waste.

Methods: Tomato peel from the industry was freeze-dried, ground with a mill and stored at -10 °C. The margarine was manufactured according to a industrial formula for Fleurial Cevital product: fat (80%) and water (20%). The colour was measured with a Chroma Meter CR-200. The oxidative resistance of soya/sunflower oil and margarine rich in lycopene was measured with rancimat test.

Results: A margarine and soya/sunflower oil enriched in lycopene, of good sensory quality has been produced containing a level of lycopene (0.17-0.45 mg/100g), that can increase the intake of this carotene in the diet.

Conclusions: The direct use of this by-product, avoiding lycopene extraction has obvious advantages. The use of dry tomato peel has successfully inhibited lipid oxidation (2.61 mg malonique dialdehyde/100g), and improved the oxidative resistance (30 % / control) and color of margarine and soya/sunflower oil rich in lycopene during storage, hence possibility of partial replacement of chemical additives (coloring/antioxidant) by tomato peel in margarine and other fat derived.

Key words: tomato peel, lycopene, margarine, edible oil, antioxidant activity

PO2819**A METABOLITE PROFILING APPROACH ALLOWS THE CHARACTERIZATION AND CLASSIFICATION OF THREE COMMERCIAL VARIETIES OF CUCUMIS MELO.**

Background and objectives: A positive correlation between consumption of fruits and protection against chronic diseases has been observed. Fruit represents one of the major source of phytochemicals and other useful compounds such as amino acids and fatty acids. Melon (*Cucumis melo* L.) belongs to the Cucurbitaceae family. It is a typical fruit presents in most of the world diets. In this work, we present a complete and exhaustive metabolite profile of 15 methanolic extracts from three different melon varieties (Piel de sapo, Galia and Cantaluz) collected in different ripening period.

Methods: HPLC-ESI-Q-TOF-MS analyses were carried out to characterize the phenolic and others polar compounds. The mass accuracy and true isotopic pattern in both MS and MS/MS spectra provided by QTOF-MS made possible the tentative identification of many well-known compounds present in melon. Multivariate analysis was carried out using principal component analysis (PCA) to determine which compounds contributed more to draw distinctions within the different varieties.

Results: More than 40 compounds were tentatively characterized. Some of them have never been described before in melon or cucurbitaceae family. PCA showed a separation between the three varieties. In the PCA scores plots (PC1 vs. PC2), the separation of groups according to the varieties may be clearly observed and the loadings plot indicates the masses and retention time values responsible for this separation. In this way, five compounds were found as the main responsible for the groups' segregation.

Conclusions: Those methods have allowed to profundize about the metabolite profile of *Cucumis melo*. To our knowledge, it is the first time in which tandem mass spectrometry is used to characterize melon samples and molecular markers of Piel de sapo, Galia and Cantaluz varieties are established.

Key words: *Cucumis melo*, metabolite profile, PCA.

PO2820**ANGIOTENSIN I-CONVERTING ENZYME INHIBITORY AND ANTIOXIDANT PEPTIDES FROM SALMON PROTEINS OBTAINED VIA HYDROLYSIS AND DIGESTION**

M. Darewicz¹, J. Borawska¹, P. Minkiewicz¹, G. Vegarud², A. Iwaniak¹

¹Department of Food Biochemistry, University of Warmia and Mazury, Olsztyn, Poland

²Department of Chemistry, Biotechnology and Food Science, Norwegian University of Life Sciences, Aas, Norway

Background and objectives: Fish proteins are considered as an interesting source of bioactive peptides. The aim of this study was to identify ACE inhibitory and antioxidant peptides in hydrolysates of salmon myofibrillar and sarcoplasmic proteins, obtained via different ways of human digestive tract conditions simulation.

Methods: The study covered the *in silico* part – with the use of UniProt database, BIOPEP database and tools available within, Fragment Ion Calculator and Sequence Specific Retention Calculator application. The next step was *in vitro* hydrolysis - with the use of commercial enzymes, and *ex vivo* digestion - with the use of human digestive juices isolated from human individuals. Bioactive peptides in the obtained hydrolysates were identified using RP-HPLC with MS detector based on the expected retention times.

Results: Peptide sequences, which from the theoretical point of view, should be released during the hydrolysis, were selected from the results of the *in silico* part of study. The identification of bioactive peptides in hydrolysates of salmon protein isolates was possible via the expected retention times for each of the selected sequence calculation. The comparison of theoretical and experimental retention times of searched peptides was the basis for identification and analysis. For example the predicted retention time of antioxidative peptide FIKK was 19.15 min and the retention time observed during the study was 19.06 min and 20.13 min for *in vitro* and *ex vivo* samples respectively. ACE inhibitory peptides ALPHA, IVY, IW, TVY, HL and antioxidative peptides FIKK, PHL, PW, HL were identified in both kinds of hydrolysates but ACE inhibitory peptides IWHHT and GL were presented only in *ex vivo* hydrolysates.

Conclusions: During *in vitro* hydrolysis and *ex vivo* digestion different products were released. Salmon proteins can be the source of ACE inhibitors and antioxidant peptides.

Key words: bioactive peptides, salmon, digestion, hydrolysis

PO2821**EFFECTS OF STARCH ON THE ANTIOXIDANT CAPACITY OF GUARANA POWDER (PAULLINIA CUPANA) UNDER CONDITIONS OF IN VITRO DIGESTION**

T M N. Mendes¹, L C B. Fontes¹, E A F S. Torres¹

¹Departament of Nutrition, School of Public Health, University of São Paulo (USP), Sao Paulo, Sao Paulo, Brazil

Background and objectives: Epidemiological evidence suggests that the antioxidant properties of polyphenols may impart health benefits, but the information concerning the antioxidant capacity of polyphenols in the presence of dietary nutrients is limited. The aim of this work was to evaluate the effects of starch on the antioxidant capacity of guarana powder (*Paullinia cupana*) under conditions of in vitro gastrointestinal digestion.

Methods: Samples of guarana and guarana associated with starch were subjected to an in vitro enzymatic digestion with pepsin, pancreatin and bile salt (stomach and small intestine). These samples were analyzed for total phenolics (TP) by Folin-Ciocalteu, procyanidins (PC) by butanol-HCl hydrolysis, Trolox equivalent antioxidant capacity (TEAC) assay with ABTS radical anion and oxygen radical absorbance capacity (ORAC) using fluorescein as the fluorescent probe. Analysis of variance (ANOVA) and significance test ($p < 0.05$) were realized using the SAS software.

Results: The yield from enzymatic digestion of guarana powder showed the highest statistically significant values of TP (110.38mg GAE/g) and ORAC (3254.60 μ M Trolox equivalents/g). The decrease in antioxidant capacity observed when guarana was associated with starch, may be attributed to physicochemical interactions of guarana polyphenols and this nutrient. There was no statistical difference between values found of PC from the yield of guarana and guarana associated with starch; probably procyanidins do not interact with starch. However, the highest statistically significant value of TEAC was found in the yield of enzymatic digestion from guarana associated with starch (725.37 μ M Trolox equivalents/g).

Conclusions: The results obtained indicate that starch affect the antioxidant capacity of guarana powder, decreasing to TP and ORAC, increasing to TEAC, but does not affect the bioaccessibility of procyanidins from guarana powder.

Key words: Antioxidant capacity, in vitro digestion, guarana powder, starch.

PO2822**CITRUS FLAVONOIDS INHIBIT LDL OXIDATION AND MONOCYTE ADHESION IN ENDOTHELIAL CELLS**

M. Tani¹, Y. Kishimoto¹, K. Ushioda¹, K. Nomoto¹, E. Saita¹, M. Yoshida², K. Kondo¹

¹Ochanomizu University, Japan

²Tokyo Medical and Dental University, Japan

Background and objectives: LDL oxidation and monocyte adhesion to endothelial cells are critical and initiating factors in the pathogenesis of atherosclerosis. Citrus fruits are one of the most popular fruits in the world, and contain many antioxidants such as flavonoids. In this study, we examined whether citrus flavonoids could inhibit LDL oxidation and monocyte adhesion to endothelial cells.

Methods: The effects of citrus flavonoids on human umbilical vein cells (HUVEC)-mediated LDL oxidation were determined by TBARS production and LDL mobility. The static monocyte adhesion assay was carried out using HUVECs and THP-1 cells. The protein expression of adhesion molecule and eNOS was detected by western blot assay.

Results: Eriodictyol, hesperetin and naringenin inhibited HUVEC-mediated LDL oxidation. Citrus flavonoids decreased TNF- α -induced monocyte-endothelial adhesion (eriodictyol: 61.1 %, hesperetin: 59.8 %, naringenin: 79.5 %). The ICAM-1 protein expression and NF κ B activation were suppressed by citrus flavonoids.

Conclusions: These results suggest that citrus flavonoids may have anti-atherogenic effect through inhibiting LDL oxidation and monocyte adhesion to endothelial cells.

Key words: Flavonoids, LDL oxidation, endothelial cells

PO2823**EVALUATION OF ESSENTIAL OIL-DERIVED COMPONENTS FOR PREVENTION OF LIFESTYLE-RELATED DISEASES TARGETED TO COX-2 AND PPAR**

H. Inoue¹, Y. Takizawa¹, A. Takai¹, A. Itoh¹, S. Yoshii¹, Y. Itoh¹, R. Nakata¹

¹Department of Food Science and Nutrition, Nara Women's University, Japan

Background and objectives: COX-2, the rate-limiting enzyme in prostaglandin biosynthesis, plays a key role in inflammation and circulatory homeostasis. PPARs, ligand-dependent transcription factors belonging to the nuclear receptor superfamily, regulate lipid metabolism, cell proliferation and inflammation, and are involved in the control of COX-2 expression,

and vice versa. Several natural food-derived components such as resveratrol have been identified as suppressors of COX-2 expression and activators of PPARs (Neurosci. Lett. 2003, Nutr. Metab. 2010, Biol. Pharm. Bull. 2012). These two properties targeted to COX-2 and PPARs will be useful in evaluating functional food components against lifestyle-related diseases.

Methods: We evaluated essential oils from various plants using the in vitro cell-based transfection assay, and found that several chemical components have these properties (J. Lipid Res. 2010, Biochim. Biophys. Acta 2010, Biotech. Biochem. Biophys. 2011).

Results: From thyme, lemongrass and rose oils, we identified carvacrol, citral and citronellol/geraniol as major components of the activator of PPAR α and γ and suppressor of COX-2 expression, respectively. PPAR γ -dependent suppression of COX-2 promoter activity was also observed in response to carvacrol and citral treatments.

Conclusions: These results will be important in understanding the anti-lifestyle-related disease properties of food-derived functional components. We are now working on this study from in vitro cell culture to in vivo PPAR γ knockout mice. Supported by Grants-in Aid for Scientific Research (Nos. 24300217 and 21700753) from the Ministry of Education, Culture, Sports, Science, and Technology, Japan.

Key words: COX-2, PPAR, essential oil, anti-lifestyle-related disease

100 ng/ml recombinant human RANKL and 100 ng/ml recombinant mouse M-CSF were added with or without soy isoflavones (daidzein, genistein and R,S-equol) and carotenoids (zeaxanthin and lutein). Cells were stained for tartrate-resistant acid phosphatase (TRAP) after 6 days since induction of osteoclast differentiation by RANKL and M-CSF. TRAP positive cells containing three or more nuclei were counted as TRAP-positive multinuclear osteoclast like cells (MNC).

Results: While addition of genistein and R, S-equol did not have a significant effect, daidzein, zeaxanthin and lutein significantly decreased the number of TRAP-positive MNC in a dose dependent manner. The combination of either 10-5M daidzein or genistein with 10-5M of the carotenoids, enhanced the effect of either compound on the number of TRAP-positive MNC significantly.

Conclusions: It is the first report of possible cooperative effects by soy isoflavones and carotenoids on osteoclast formation. These results suggested that combination of soy isoflavones and carotenoids have the ability to enhance their individual inhibitory effects on osteoclast formation. These findings are of importance indicating a possible effect of functional foods containing these components on bone metabolism and prevention of bone loss. Acknowledgements: JST; MBIE NZ.

Key words: Soy isoflavone, Carotenoid, Osteoclast formation, Bone

Background and objectives: Osteoclasts play a major role in bone resorption. The functional food components that act on bone metabolism are poorly understood. Soy isoflavones and carotenoids are present in food such as soy beans and fruit, respectively, and are reported to inhibit osteoclast formation. Cooperative effects of these components on bone metabolism, however, have not been clarified. Thus, this study aimed to investigate the cooperative effect of soy isoflavones and carotenoids on osteoclast formation in vitro.

Methods: Bone marrow cells (BMC) from ddy mice (male, 6-9 wk old) were cultured in alpha-MEM containing 10% FBS and 1% Penicillin-Streptomycin medium. For osteoclast for-

⁵Department of Sciences of Functional Foods, Graduate School of Agriculture, Shinshu University, Japan

Background and objectives: Fructose consumption has increased in the past three decades due to the use of high-fructose corn syrups as sweeteners in beverages and processed foods.

Excess fructose intake induces adiposity and insulin resistance syndrome, which can lead to non-alcoholic fatty liver disease, diabetes mellitus, and hypertension. Inhibition of fructose absorption may suppress diseases caused by fructose ingestion. It was previously demonstrated that Eucalyptus globulus leaf extract (ELE) inhibited intestinal fructose absorption (but not glucose absorption) in humans and rats. However, the active ingredients in ELE have not yet been identified.

Methods: To identify the constituent that inhibits fructose absorption in the intestine, ELE was subjected to bioactivity-guided fractionation through column chromatography and preparative high-performance liquid chromatography. Further, human intestinal epithelial Caco-2 cells were cultured in vitro on membrane filters and the apical sides were exposed to 1 mM fructose with or without ELE for 4 h. The fructose absorption was measured by analyzing the fructose concentration in the medium on the basolateral side.

Results: A 1 mg/mL dose of ELE inhibited 65% of fructose absorption. A hydrolyzable tannin, tellimagrandin I, was isolated as an inhibitory component (yield, 0.13%) with an inhibition rate of 49% at a dose of 0.005 mg/mL. Related compounds casuarictin, oenothien B, pedunculagin, strictinin, tellimagrandin II, 1,3-O-digalloyl-4,6-hexahydroxydiphenoyl- β -D-glucose, and tri-, tetra-, and penta-O-galloyl- β -D-glucoses exhibited inhibitory activity similar to that of tellimagrandin I. These compounds did not affect glucose absorption. In contrast, the aglycones of these tannins, ellagic acid and gallic acid, and other types of polyphenols (e.g., (+)-catechin, (-)-epigallocatechin 3-O-gallate, and quercetin) showed a low or no inhibitory activity.

Conclusions: Hydrolyzable tannins, such as tellimagrandin I, are the primary constituents of ELE responsible for inhibition of fructose absorption.

Key words: intestinal fructose absorption, eucalyptus, hydrolyzable tannin, glucose transporter, GLUT5

SUBCELLULAR LOCALIZATION OF MIRACULIN AND ITS FUNCTIONAL EXPRESSION IN E.COLI

A. Takai¹, T. Matsuyama¹, M. Satoh¹, A. Ito¹, S. Yoshii¹, Y. Ito¹, R. Nakata¹, T. Aoyama², H. Inoue¹

¹Department of Food Science and Nutrition, Nara Women's University, Nara, Japan

²Institute of Chemical Research, Kyoto University, Uji, Kyoto, Japan

Background and objectives: Losses or modifications of taste and smell are common in the elderly and result from aging and environmental stresses, which also represent risk factors for nutritional and immune deficiencies. However, lit-

le is known about the molecular mechanism of losses or modifications to these tastes. Miraculin isolated from red berries of *Richadella dulcifica*, a native shrub of West Africa, has the unusual property of modifying a sour taste into a sweet one. This homodimer protein consists of two glycosylated polypeptides that are cross-linked by a disulfide bond and belongs to the Kunitz-type soybean trypsin inhibitor (STI) family.

Methods: To clarify the functional relation of miraculin with Kunitz-type STIs, we investigated its subcellular localization and trypsin inhibitory activity.

Results: In transgenic *Arabidopsis thaliana*, miraculin, fused to yellow fluorescent protein, localized to and outside the plasma membrane depending on the putative secretion signal peptide. When transgenic seedlings were cultured in liquid medium, miraculin was present in the supernatant only after cellulase treatment. No trypsin inhibitory activity was detected in native or recombinant miraculin. From these results, miraculin is secreted outside the plasma membrane through the function of a signal peptide, conserved in some Kunitz-type STIs, whereas its trypsin inhibitory activity was lost during its functional evolution related to its dimer formation. Functional expression of miraculin was reported in host cells with the ability to glycosylate proteins, such as lettuce, tomato and the microbe *Aspergillus oryzae*, but not *E. coli*.

Conclusions: Thus, a question remains as to whether glycosylation of miraculin is essential for its taste-modifying properties. We find that recombinant miraculin expressed in *E. coli* has a taste-modifying property as a homodimer, not as a monomer, demonstrating that glycosylation is not essential for the taste-modifying property (J. Biochem. 2009 145, 445-50).

Key words: miraculin, taste, taste-modification, trypsin inhibitor

PO2827

MOLECULAR MECHANISM OF PPAR γ ACTIVATION BY RESVERATROL

Y. Takizawa¹, R. Nakata¹, K. Matsushita¹, S. Hongo¹, A. Matsumoto¹, A. Takai¹, H. Inoue¹

¹Department of Food Science and Nutrition, Nara Women's University, Nara, Japan

Background and objectives: Resveratrol, a phytoalexin and antioxidant polyphenolic compound found in red wine and various plant products, has long been suspected to have cardioprotective effects and to be a contributor to the so-called 'French paradox' (i.e., the relatively low incidence of coronary heart disease in France compared to other developed countries with comparable diets). We found that resveratrol is a triple activator for nuclear receptor PPAR, and, and that daily oral intake of resveratrol protects brain in a mouse ischaemic stroke

model but not in PPAR γ knockout mice (Neurosci Lett 2003 & Nutr Metab 2010). These dates suggested that PPAR γ may be a potential molecular target for the treatment of coronary heart disease and stroke (Biol Pharm Bull 2012).

Methods: We indicated that 4'-hydroxy group of resveratrol plays a key role in activation of PPAR by (1) comparison with structure-activity relationship among various polyphenols and a synthetic resveratrol analogue in cell-based reporter assays, (2) docking mode simulation based on the reported crystal structure of PPAR γ ligand binding domain with its agonist, and the following verifying mutation analyses, and (3) PPAR activation by a resveratrol analogue in vitro and in vivo.

Results: An examination of the structure-activity relationships of resveratrol-related compounds revealed that the 4'-hydroxyl group of resveratrol is functionally important for the direct activation of PPAR γ . This finding was confirmed by a docking model simulation with a subsequent experiment using the crystal structure of the PPAR LBD, as well as by an in vivo investigation of PPAR activation by resveratrol analogs.

Conclusions: These results suggest that PPAR γ is one of the direct molecular targets for resveratrol. Supported by Grants-in Aid for Scientific Research (Nos. 24300217 and 21700753) from the Ministry of Education, culture, Sports, Science, and Technology, Japan.

Key words: resveratrol, PPAR, polyphenol

COOKING PROCESS DECREASES IODINE CONTENT BUT INCREASES PHENOLIC COMPOUNDS IN IODINE SUPPLEMENTED CARROTS

J. Kapusta-Duch¹, R. Bieanowska-Kopeć¹, S. Smoleń², Pysz¹, A. Kopeć¹, E A. Pitkowska¹, R. Rakoczy², A. Koronowicz¹, Ł. Skoczylas²

¹Department of Human Nutrition, Agricultural University in Krakow, Krakow, Poland;

²Department of Soil Cultivation and Fertilization of Horticultural Plants, Faculty of Horticulture, Agricultural University in Krakow, Krakow, Poland

Background and objectives: A lot of people around the world suffer from iodine deficiency. The major reason for iodine deficiency is its low amount in daily diets. The objective of this study was to assess of iodine, phenolic compounds concentration and antioxidant activity of raw and cooked carrots which were biofortified with the iodine during cultivation.

Methods: Carrots (*Ducus carota* L.) were cultivated in heavy soil in 2012; including the following treatments: 1- control (without iodine application), 2- KI fertilization (2.5 kg ha⁻¹ pre-sowing and 2.5 kg ha⁻¹ as a top dressing). Carrots storage roots from both treatments were washed (half of them

was peeled) and cooked for 20, 30 and 40 min. The proportion of water to vegetables was 2:1. The concentration of iodine was determined by the ICP-OES with the use of the cold vapor generator technique. The antioxidant activity was determined by the measurement of the ability of scavenging free radical ABTS. The level of phenolic compounds was measured by the Poly-Swain and Hills method.

Results: Biofortification of carrots with KI significantly increased the concentration of iodine compared to the control. The time of cooking had affected the concentration of iodine in the biofortified carrots (peeled and unpeeled). The lowest concentration of iodine was measured in carrots cooked for 40 min. The highest capacity of scavenging free radicals was found in unpeeled control and biofortified carrots. The concentration of phenolic compounds was higher in control unpeeled cooked for 20 min. carrots.

Conclusions: The best source of iodine is raw carrots but the higher concentration of phenolic compounds was measured in unfortified unpeeled and fortified carrots cooked for 20 min. This work was financed by Polish National Science Center, project no. UMO-2011/03/D/NZ9/05560 (2012-2015).

Key words: iodine, antioxidant activity, carrots, biofortification.

PO2829

CHEMICAL COMPOSITION OF WHOLE, HUSKED GRAIN AND HUSK OF SELECTED VARIETIES OF BUCKWHEAT

A. Kopeć¹, E. Pisulewska², E. Piłtkowska¹, T. Leszczyńska¹

¹Department of Human Nutrition, Agricultural University in Krakow, Krakow, Poland

²Department of Crop Production Agricultural University of Krakow, Krakow, Poland

Background and objectives: Buckwheat is a gluten free grain and may be used in preparation of gluten free products. This grain is a good source of proteins, carbohydrates and fiber. The aim of this study was to determine the chemical composition of whole, husked grains and husk of selected varieties and lines of buckwheat.

Methods: Varieties of buckwheat were obtained from Breeding Station of Palikije, Lublin Poland. Following cultivars were used for study: Panda, Kora, 8/2008, 9/2006, 5/2006, 21/2002. Fractions of buckwheat, previously grounded, were used to measure the content of proteins, fat, ash, total dietary fiber using the AOAC methods.

Results: The results showed that the whole grain of buckwheat, husked grains and husk, differed in terms of the content of chemical components. These differences also occurred

between the particular variants and families of buckwheat varieties. In all fractions of buckwheat, carbohydrates accounted for the largest percentage of whole determined chemical components and the richest source of them was husked grains especially Kora varieties. The content of proteins in whole and husked buckwheat grains was comparable. The richest in minerals was a fraction of whole buckwheat grains, whereas the smallest amount in the studied fractions appeared fat. The highest content of dietary fiber was found in husk.

Conclusions: Buckwheat is a rich source of carbohydrates and dietary fiber especially not husked grains. This wheat should be more often used for preparation of food products.

Key words: buckwheat, proteins, carbohydrates, dietary fiber

PO2830

EFFECTS OF FERMENTED SOY FOOD CONTAINING S-EQUOL (SE5-OH) ON BONE LOSS, BLOOD FLOW, AND MAMMARY ESTRADIOL LEVELS IN OVARIECTOMIZED RATS

T. Ueno¹, Y. Tousei², S. Uchiyama¹, Y. Ishimi²

¹Otsuka Pharmaceutical Co., Ltd., Saga Nutraceu-
ticals Research Institute, Saga, Japan

²National Institute of Health and Nutrition, De-
partment of Food Function, Tokyo, Japan

Background and objectives: We have developed a fermented soygerm food containing S-equol (SE5-OH) using equol-producing lactic acid bacteria (*Lactococcus* strain 20-92). Since S-equol has estrogen-like effects, there has been focused on its health benefits for postmenopausal women. In this study, we examined the effects of SE5-OH on bone mineral density (BMD), vascular function, and estradiol (E2) level in breast tissue in ovariectomized (OVX) rats.

Methods: Eleven-week-old female SD rats underwent either a sham operation (sham group) or OVX. The OVX rats were divided into those groups: OVX+SE5-OH (SE) group, OVX+ S-equol (EQ) group, and OVX groups. The OVX+SE and the OVX+EQ groups were fed a same dose of 0.06% S-equol. Tail blood flow was measured weekly. At 6 week, 24-hour urine was collected for measurement of isoflavone and equol concentration and BMD of the lumbar spine and femur were measured by DXA. The breast fat tissue was collected and E2 level was measured.

Results: Tail blood flow was significantly decreased in the OVX group compared with the sham group at weeks 4, 5, and 6. Tail blood flows were higher in the OVX+SE and the OVX+EQ groups compared with the OVX group at weeks 5 and 6. The BMDs of lumbar spine and femur in the OVX + SE and the OVX + EQ groups were higher than those in the

OVX group. Consequently, SE5-OH and S-equol prevented the OVX-induced decline in BMD. The E2 levels in the breast fat tissue in the OVX+SE and the OVX+EQ groups were lower compared with the OVX group.

Conclusions: SE5-OH and S-equol improved BMD, vascular function, and E2 level in breast tissue, suggesting that these may have health benefits for postmenopausal women including low breast cancer risk.

Key words: equol, soy, bone mineral density, blood flow

PO2831

REDUCED LIPID PEROXIDATION IN THE HEART OF DATE SEED POWDER FED RATS

W. Ibrahim¹, H. Habib¹, C. Platat¹

¹Department of Nutrition and Health, College of
Food and Agriculture, UAE University, Al Ain, United
Arab Emirates

Background and objectives: Date seeds have been shown to contain high amounts of polyphenols and a high antioxidant capacity. In a previous study we showed that date seed powder reduced lipid peroxidation in rat liver and serum. The purpose of this study was to determine the effect of date seed powder on lipid peroxidation in rat heart.

Methods: Male Wistar rats (six weeks old) were fed a basal diet with 0%, 7% or 14 % date seed powder for 30 days. All three diets were isonitrogenous and isocaloric. At the end of the feeding period, rats were killed and heart homogenate was analyzed for the levels of the lipid peroxidation product malondialdehyde (MDA). Additionally, the levels of the antioxidants glutathione (GSH), ascorbic acid, and vitamin E were also determined.

Results: Compared with the control group, rats fed either 7% or 14% date seed powder had significantly ($p < 0.05$) lower levels of heart MDA, and rats fed the 14% date seed powder diet had significantly lower heart MDA than those fed the 7% date seed powder diet. Date seed powder increased the levels of heart GSH and vitamin E in a dose-dependent manner, however, this effect was only statistically significant ($p < 0.05$) for GSH. Ascorbic acid levels were not affected by any of the dietary treatments.

Conclusions: The results obtained clearly showed that date seed powder reduced heart lipid peroxidation most likely due to its high content of polyphenols. Date seeds are increasingly being demonstrated to exert ameliorative effects on oxidative damage, thus a potential for protection from diseases in which oxidative stress is involved.

Key words: Date seed, lipid peroxidation, antioxidant status, heart, rat

PO2832**EFFECTS OF ORIENTAL PLUM EXTRACT ON THE COGNITIVE FUNCTION AND NEURODEGENERATION-RELATED PROTEIN EXPRESSION IN DIET INDUCED TYPE 2 DIABETIC RTAS***H. Liao¹, Y.W. Chien¹, S.H. Lin¹*¹School of Nutrition and Health Sciences, Taipei Medical University, Taipei, Taiwan

Background and objectives: Recent studies have indicated that Type 2 diabetes mellitus (T2DM) is one of the risk factors of Alzheimer's disease (AD). An impaired insulin signaling caused by insulin resistance may result in abnormal protein expressions in the brain and neuron damages. The study aimed to investigate the prevention of AD-type neurodegeneration by consuming polyphenols-rich oriental plum (*Prunus salicina* Lindl) extract on T2DM rats.

Methods: A 20-week period of high-fructose-high-coconut oil diet was given to induce T2DM on male Wistar rats, followed by an 8-week oriental plum extract (OP) feeding intervention.

Results: The results showed that OP intervention significantly reduced insulin resistance by improving the Homeostasis model assessment-insulin resistance (HOMA-IR). The Morris water maze test results indicated the spatial learning function was improved after the OP consumption. The intervention also reduced amyloid- β (A β) and phosphorylated tau (p-tau) protein levels in the cerebral cortex and reduced A β deposition in the hippocampus of the T2DM rats.

Conclusions: The oriental plum extract decreased the cognitive decline and reduced the expressions of AD-type pathological proteins A β and p-tau in T2DM rats.

Key words: Alzheimer's disease, Diabetes, Polyphenols

PO2833**EXPERIMENTAL OBSERVATIONS OF ANTI-DIABETIC ACTIVITY OF ZINC COMPLEXES WITH THEANINE***N. Kajiwara¹, Y. Yoshikawa², H. Yasui², K. Matsumoto¹*¹Department of Health, Sports and Nutrition, Faculty of Health and Welfare, Kobe Women's University, Kobe, Japan²Department of Analytical and Bioinorganic Chemistry, Kyoto Pharmaceutical University, Kyoto, Japan

Background and objectives: The insulinomimetic activity of the Zn²⁺ ion has been reported, and the zinc complexes are

less toxic compared to free zinc-ion, and is known to have insulinomimetic activity at lower concentration than the simple Zn²⁺ ion. Theanine is one of the main components of Japanese green tea, has been suggested to reduce fat tissue in rodents. Therefore we expected the theanine may strengthen the anti-diabetic action of Zn(II) complex. Observations of anti-diabetic activity of the Zn(II) complexes with Theanine have done.

Methods: Zinc complexes with Theanine (L- α -glutamylethylamide = gln-e) and L- α -glutamylmethylamide (gln-m), Zn(gln-e)₂ and Zn(gln-m)₂ synthesized respectively, and insulinomimetic activity were compared to that of Zn(gln)₂ in an in vitro study using isolated rodent adipocytes treated with epinephrine in the presence of glucose, expressed as IC₅₀ value (50% inhibition concentration) of free fatty acids (FFA) released from fat cells. Then the anti-diabetic activity of Zn(gln-e)₂ was examined in an in vivo experiment on KK-Ay mice, the model animals of type 2 DM, by intra-peritoneal (i.p.) injection of 3-4 mg Zn/kg b.w./day for 13 days.

Results: Zn(gln-e)₂ were found to have higher insulinomimetic activity than that of Zn(gln-m)₂, the IC₅₀ values being 0.56 and 0.61, respectively. The blood glucose level of the group treated with a Zn complex, Zn(gln-e)₂, decreased significantly after 13 days compared to those of non-treated and gln-e treated groups. The serum concentrations of triglyceride (TG) and HbA_{1c} decreased significantly in the Zn(gln-e)₂ treated KK-Ay mice compared to those of the gln-e treated group, respectively. Furthermore, the improvement in glucose tolerance was confirmed by an oral glucose tolerance test.

Conclusions: Result of anti-diabetic activity of Zn(II) complexes with Theanine expresses the possibility of useful compound to prevent or improve the diabetic conditions.

Key words: anti-diabetic activity, zinc complexes, Japanese green tea, theanine,

PO2834**EFFECTS OF DIETARY LACTOBACILLUS GASSERI SBT2055 ON GLUCOSE METABOLISM IN RATS***M. Sato¹, Y. Morita¹, A. Ogawa², Y. Kadooka², B. Shirouchi¹*¹Department of Bioscience and Biotechnology, Faculty of Agriculture, Graduate School of Kyushu University, Fukuoka, Japan²Milk Science Research Institute, MEGMILK SNOW BRAND Co. Ltd., Saitama, Japan

Background and objectives: We have already published that *Lactobacillus gasseri* SBT2055 (LGSP) as a probiotic has the effects of anti-obesity in rats (*Br J Nutr.* 99, 1013-1017, 2008) and human subjects (*Eur J Clin Nutr.* 64, 636-643, 2010). In this study, we focused on glucose metabolism in rats fed

LGSP.Methods: We used two rat strains that were Sprague-Dawley (SD) rats as a non-diabetic model and Goto-Kakizaki (GK) rats as a diabetic model. The SD and GK rats were fed diets containing skim milk (control diet) or skim milk fermented by LGSP (LGSP diet) for 4 weeks. Oral glucose tolerance test (OGTT) was performed at 3 week. After feeding, serum basic biomarkers for diabetes and glycogen levels in muscle and liver were measured.

Results: In the SD and GK rats, fasting serum glucose and insulin concentrations were not different between the control and LGSP groups. The area under the curve (AUC) following the OGTT in the SD rats fed the LGSP diet was smaller than in the SD rats fed the control diet. There was no difference in the AUC of the GK rats, but, in detail, the AUC after the peaks of the glucose level in the OGTT tended to decrease ($P < 0.059$) in the LGSP group. As the fate of glucose incorporated into the cells, we measured glycogen levels in muscle and liver. The glycogen levels in muscle and liver of SD rats did not differ between the groups. In the GK rats, the glycogen levels in the both tissues of the LGSP group were higher than those of the control group.

Conclusions: LGSP have different effects in the glucose metabolism depending on developmental diabetic status. This probiotic may prevent diabetic development in the early stage, mainly via improvement of insulin resistance.

Key words: probiotics, diabetes

PO2835

SYNTHESIS OF FOLATE BY KEFIR STARTER CULTURE

E. Gujska¹, J. Michalak¹, M. Czarnowska¹

¹Department of Food Science, University of Warmia and Mazury, Olsztyn, Poland

Background and objectives: Folate is relative to the nutritional needs of human, frequently among the most limiting of all vitamins. Important sources of folate in diet can be dairy products. Although, milk is not a rich source of dietary folate, many dairy products are processed using microbial fermentations in which folate can be synthesized. The purpose was to evaluate the main folate forms present in kefir produced with kefir granules consist of different strains of lactic acid bacteria and yeast.

Methods: Foliates were extracted in the 0.1 M phosphate buffer (pH=7.0), followed by deconjugation with conjugase and destruction of matrix by protease. The folates were separated by HPLC.

Results: The folate forms found in analyzed milk and kefir were 5-methyltetrahydrofolate and tetrahydrofolate. The results indicated great differences in the content of that forms in

kefirs produced with kefir granules consist of different strains of lactic acid bacteria and yeast. The amount of 5CH₃FH₄ and THF forms in UHT milk (2% of fat) were 4.22 and 0.67 micg/100 g., respectively. Total folate content in analyzed samples of kefir varied between 6.15 and 9.51 micg/100 g of product. However, the distribution of the individual folate forms in kefir differed clearly: the 5-methyltetrahydrofolate form from 2.98 to 7.18 and tetrahydrofolate from 1.64 to 2.73 micg/100 g. The results indicated that not each kefir had significantly higher level of total folate compared to UHT milk. This may indicate the importance of using kefir granules with suitable yeast and bacteria strains.

Conclusions: Producers should pay more attention to choose appropriate starter culture to improve the stability of folates during fermentation and storage and thus to increase the folate content in fermented dairy products.

Key words: folate, kefir, starter culture, HPLC

PO2836

FOLATE CONTENT IN DIFFERENT BRANDS OF BEER

E. Gujska¹, M. Czarnowska¹, J. Michalak¹

¹Department of Food Science, University of Warmia and Mazury, Olsztyn, Poland

Background and objectives: Foliates have identified as one of the most important vitamins for normal human metabolic function. They are required for the DNA and RNA synthesis, which are primary events for cellular replication and growth. There have been several reports of beer as a source of B-vitamins. Thiamine is relatively deficient in beer, but the others may be present in significant quantities.

Methods: In this work folate levels in range of different brands of beer have been measured using HPLC with fluorescence detection. Foliates were extracted in a 0.1 M phosphate buffer (pH 6.1), followed by deconjugation with conjugase (rat serum) and destruction of matrix by amylase and protease.

Results: Only one form of folate - 5-methyltetrahydrofolate (5MTHF) was identified. 5MTHF content in nine examined beers ranged from 0.26 to 5.10 micg/100 g of beer. One imported beer contained trace of folate. Higher levels of 5MTHF in no pasteurized beers were found and also in wheat beers with secondary fermentation in the bottle. It is possible that folates can be released from the yeast into the beer during subsequent maturation.

Conclusions: It is believed that by selection of raw material (barley, wheat) and some changing in the brewing process, beer with enhanced folate content could be produced.

Key words: folate, beer, HPLC

PO2837**EFFECTS OF LUPINUS ALBUS PROTEIN HYDROLYZATE AND INSOLUBLE FIBER IN A DIET-INDUCED HYPERCHOLESTEROLEMIC MODEL LIVER AND COLON HISTOLOGICAL EXAMINATION**

G. Kapravelou¹, R. Martínez¹, A. Andrade¹, C. Sánchez¹, L. Bustos¹, M. Lopez-Jurado¹, P. Aranda¹, S. Cantarero², F. Arrebola³, E. Fernandez-Segura³, M. Galisteo⁴, J M. Porres¹

³Department of Histology, University of Granada, Granada, Spain

⁴Department of Pharmacology, University of Granada, Granada, Spain

Background and objectives: The high content of protein, dietary fiber and bioactive compounds of Lupin (*Lupinus spp*) makes it a high nutritional value legume with promising antioxidant and hypocholesterolemic effects. We aimed to study the possible beneficial effects of lupin protein hydrolyzate, combined or not with lupin insoluble fiber, on the hepatic lipid profile and histological changes of liver and colon in an experimental animal model of rats fed a diet rich in cholesterol and coconut oil.

Methods: Lupin protein hydrolyzate (LPH) was prepared by alkaline water extraction and protein hydrolysis using recombinant proteases. The final insoluble fiber residue (LIF) was collected after the extraction process and freeze-dried. Thirty Wistar rats were divided into 5 groups (n = 6 per group): Casein-Cellulose normolipidemic control group (CT), and four high-fat hypercholesterolemic experimental groups: Casein-Cellulose group (HC), Casein-LIF group (HCF), LPH/Cellulose group (HID), and LPH/LIF group (HIDF). Caecum content, liver and colon were extracted to analyze pH of caecum and hepatic cholesterol and triglycerides. A portion of liver and colon was fixed in 10% phosphate-buffered formalin (PBF), embedded in paraffin, and sectioned for microscopy histological examination.

Results: Hepatic cholesterol and triglycerides levels were higher in animals fed with casein-based diets (HC, HCF) compared to those fed with lupin protein hydrolyzate-based diets (HID, HIDF). Caecum hypertrophy was directly related to the inclusion of lupin protein hydrolyzate in diets. There was a decrease in caecum content pH values in animals fed with HCF and HIDF diets. Significant changes in liver and colon histology were apparent due to different diet administration.

Conclusions: Lupin protein hydrolyzates and insoluble fiber improved the hepatic lipid profile and significant morpho-

logical changes in liver and colon of rats fed a high fat diet, thus showing promising potential health benefits.

Key words: Lupin, high-fat diet, protein hydrolyzate, insoluble fiber, liver, colon

PO2838**ENZYMATIC ASSAY FOR THEANINE USING γ -GLUTAMYLTRANSPEPTIDASE AND AMINE DEHYDROGENASE**

M. Wakayama¹, Y. Shimizu¹, M. Imaoka¹, Y. Sawaragi¹, S. Yano², K. Takagi³

¹Department of Biotechnology, College of Life Sciences, Ritsumeikan University, Kusatsu, Shiga, Japan

²Department of Biochemical Engineering, Graduate School of Yamagata University, Yonezawa, Yamagata, Japan

³Department of Applied Chemistry, College of Life Sciences, Ritsumeikan University, Kusatsu, Shiga, Japan

Background and objectives: Theanine, γ -glutamylethylamide, is a non-protein derived amino acid that was first isolated from green tea leaves in 1940s. It is known as its distinctive umami taste, and furthermore there is a considerable demand for theanine as a supplement or food ingredient because of its beneficial effects such as relaxation effects, improvement in learning ability, cancer prevention, prevention of vascular diseases and improvement of immune system. For measurement of theanine in commercial tea beverage and biochemical samples, simple enzymatic determination is useful as an easier and environmentally friendly process with lower costs. Here we report an enzymatic assay for theanine using the coupled-reaction of γ -glutamyltranspeptidase and amine dehydrogenase.

Methods: γ -Glutamyltranspeptidase from *Pseudomonas nitroreducens* NBRC 12694 (PnGGT) and amine dehydrogenase from *Paracoccus denitrificans* NBRC 12442 (PdAmDH) was used for quantification of theanine in several commercial tea beverages. Phenazine ethosulfate and 2, 6-dichloroindophenol (DCIP) were used as electron acceptors. Theanine solutions (5, 10, 20, 40, 60, 80, 120, 160, and 200 μ M) were used as standards. The assay was performed by measuring absorbance change at 600 nm derived from DCIP with a simple spectrophotometer.

Results: The calibration curve was linear between 0 to 200 μ M of theanine with $R^2 = 0.998$. The use of ascorbate oxidase in addition to the combination of laccase and polyvinylpyrrolidone was very effective for removal of antioxidants

from tea sample as pretreatment. No effect of the pretreatment even for 5 min on theanine was observed. Consequently, the values of theanine in the samples of commercial tea beverage in pet bottle obtained by the current method were close to the values with the pre-column derivatization high performance liquid chromatography.

Conclusions: Combination of PnGGT and PdAmDH can be used for L-theanine determination in food control and biological research.

Key words: theanine, tea, assay, γ -glutamyltranspeptidase, amine dehydrogenase

PO2839

EFFECTS OF SOYBEAN SOLUBLE POLYSACCHARIDE DERIVED FROM "OKARA" ON JAPANESE WOMEN WITH CONSTIPATION

Y. Asano¹, M. Katayama²

¹Faculty of Health Science, KIO University, Japan

²Koryo Public Health Center, Japan

Background and objectives: The purpose of this study was to estimate effects of soybean soluble polysaccharide (SSPS) derived from "Okara" on women with constipation.

Methods: A double-blind crossover study was conducted on 42 students (mean age of 19.1 ± 0.6 years) and 33 adults (mean age of 58.7 ± 13.8 years) with weak constipation. Each subject was given SSPS beverage (contains 5.0mg /100ml drink) or placebo beverage, one time a day for 2 weeks. The effect of SSPS was assessed after and before the intake of it using the questionnaire, Japanese GSRS (gastrointestinal symptom rating scale) and eating habits. Dietary intake was estimated with three-day records method.

Results: The defecation frequency of subjects following the intake SSPS period was significantly increased as compared with the observation period ($p < 0.01$); however, significantly increase was not observed with the placebo period. According to the intake of dietary fiber, the two groups were classified; group A was low intake (< 11.7 g) and group B was high intake (≥ 11.7 g). In group A, it was showed the defecation frequency of subjects following the intake SSPS period was significantly increased ($p < 0.01$); however, the placebo period was not significantly increased. The constipation scores which calculated from the GSRS in the intake SSPS period significantly decreased from 9.77 ± 4.08 to 7.53 ± 3.54 ($p < 0.01$). Also, the rate of change of the overall scores in the intake SSPS period significantly decreased ($p < 0.01$).

Conclusions: Based on these results, it was suggested that the SSPS beverage was effective for inducing defecation by subjects with constipation. The intake of the SSPS was considered

as one of the effective methods to improve the QOL of the person who have a gastrointestinal symptom.

Key words: soybean soluble polysaccharide, constipation, GSRS

PO2841

IMPROVEMENT OF LIPID METABOLISM AND LIFE SPAN BY RESVERATROL VIA PPARALPHA ACTIVATION

R. Nakata¹, Y. Takizawa¹, K. Matsushita¹, S. Hongo¹, A. Matsumoto¹, A. Takai¹, H. Inoue¹

¹Department of Food Science and Nutrition, Nara Women's University, Nara, Japan

Background and objectives: Long-term moderate consumption of red wine is associated with a reduced risk for cardiovascular diseases. Resveratrol, a phytoalexin contained in grapes, red wine and various plants, has been shown to be an antioxidative polyphenol, thereby exerting beneficial effects upon cardiovascular and central nervous systems. PPARs, ligand-dependent transcription factor belonging to the nuclear receptor superfamily, are considered molecular target against lifestyle-related diseases by regulating lipid metabolism. We found that resveratrol activates PPARalpha, beta/delta and gamma in cell-based reporter assays, and that daily oral intake of resveratrol protects brain against ischemic stroke in mice through a PPARalpha-dependent mechanism, suggesting that PPARalpha will be a potential molecular target for resveratrol (Neurosci. Lett. 2003, Nutr. Metab. 2010, Biol. Pharm. Bull. 2012). Methods and

Results: We showed that four-weeks intake of resveratrol as well as fenofibrate, the synthetic PPARalpha agonist, with normal diet reduces plasma triglyceride, and upregulates hepatic expression of SIRT1 and PPARalpha-responsive genes such as acyl CoA oxidase, carnitine palmitoyltransferase 1, and fatty acid binding protein 1 in the wild-type but not PPARalpha knockout mice. Moreover, long-term intake of resveratrol with high-fat diet prevented body weight gain and accumulation of lipid in both white adipose tissue and liver, and improved the life span in the wild-type, but not in PPARalpha knockout mice.

Conclusions: These findings indicate that PPARalpha activation by resveratrol is one of the providing beneficial effects against lifestyle-related diseases and aging. Supported by Grants-in Aid for Scientific Research (Nos. 24300217 and 21700753) from the Ministry of Education, culture, Sports, Science, and Technology, Japan.

Key words: resveratrol, PPAR, lipid metabolism, life span

PO2842**REDUCTION IN MYELOPEROXIDASE LEVELS AFTER CONSUMPTION OF READY-TO-EAT MEALS SUPPLEMENTED WITH COCOA EXTRACT WITHIN A HYPOCALORIC DIET**

I. Ibero-Baraibar¹, A. Massis-Zaid¹, I. Abete^{2,3}, S. Navas-Carretero^{1,3}, J.A. Martinez^{1,3}, M.A. Zulet^{1,3}

³CIBER Fisiopatología Obesidad y Nutrición (CIBEROBn) Instituto de Salud Carlos III, Spain

Background and objectives: Myeloperoxidase (MPO) is a biomarker positively associated with oxidative stress, inflammation and hypertension. Cocoa polyphenols provide protection in blood pressure but the effect on MPO levels remains untested. Therefore, the aim of this study was to assess if the daily consumption of cocoa-extract, integrated into ready-to-eat meals, within a hypocaloric diet, could have specific benefits on MPO and blood pressure in overweight/obese elderly subjects.

Methods: Forty seven subjects (mean age 57.53±5.27 y) participated in a randomized, parallel, double-blind study. The trial consisted on the consumption of ready-to-eat dishes (10 varieties) and desserts (4 varieties) without (control group) or containing 1.4g of cocoa extract (cocoa group) integrated in a calorie-restricted diet (15% E) during 4 weeks. Food record questionnaires, blood samples, blood pressure and body composition data were collected.

Results: Both groups improved significantly ($p<0.05$) anthropometric variables without losing significantly lean mass. Also, subjects in both dietary interventions significantly lowered total cholesterol, LDL-c (low density lipoprotein-cholesterol), TG (triglycerides), insulin and HOMA (homeostasis model assessment) levels. Interestingly, MPO decreased significantly only in the cocoa group ($p=0.007$), however no differences were found between groups ($p=0.171$). Regarding blood pressure, it decreased significantly in both groups ($p=0.001$). All of the participants reported similar adherence to meal consumption.

Conclusions: Cocoa extracts could be a suitable bioactive compound to improve pathologies related to inflammation, oxidative stress and hypertension, since MPO levels were specifically reduced after cocoa consumption. ⁴Instituto de Investigación en Ciencias de la Alimentación (CIAL). CSIC-UAM, Madrid

Background and objectives: The association of conjugated linoleic acid and omega 3-polyunsaturated fatty acids present in milk fat may have a preventive role in the cardiovascular risk mainly through the reduction of total body fat. We evaluated the combined effects of those fatty acids in a naturally PUFA enriched cheese on body composition.

Methods: Prospective, randomized, double-blind, placebo-controlled clinical trial. A total of 62 adults, were randomized to receive during a 12 weeks period the functional enriched cheese (group B) vs. placebo cheese (group A) in the context of an individualized hypocaloric diet and a physical activity promotion programme. We analyze the results of body weight change and body composition measured by DXA.

Results: 53 participants were included in the intervention study (68% were female, aged 49.26±9.65 year-old). At the end of the study group B showed a significant decrease of android fat percentage (A: -1.67±3.66% vs. B: -3.68±3.3% $p<0.05$), gynoid fat percentage (A: -0.65±1.69% vs. B: -2.22±2.47% $p<0.01$), total body fat mass (A: -0.76±1.83% vs. B: -1.98±1.77% $p<0.01$), body weight (A: -1.01±2.51 kg vs. B: -3.10±2.44 kg $p<0.05$), waist circumference (A: -1.75 2,6 cm vs. B: -2.58±2.05 cm $p<0.05$) and body mass index (A: -0.40±0.92 kg/m² vs. B: -1.15±0.90 kg/m² $p<0.05$).

Conclusions: This functional cheese modified positively the body composition of the overweight and obese patients, being a useful food in Dieting Programs. This work has been supported by CENIT-PRONAOs Project (CEN-20081004).

Key words: functional cheese, PUFA-enriched cheese, Obesity.

PO2844**SEARCH FOR FOODS WITH DPP-4-INHIBITORY ACTIVITY**

M. Tashiro¹, E. Tone¹, Y. Suzuki¹, M. Kotaru²

¹School of Human Environmental Sciences, Mukogawa Women's University, Nishinomiya, Hyogo, Japan

²school of Human Health, Kyoto Koka Women's University, Ukyo-ku, Kyoto, Japan

Background and objectives: Dipeptidyl peptidase (DPP)-4 inhibitors are promising new therapies for type 2 diabetes, since DPP-4 is an enzyme that inactivates incretin with an insulinotropic action. Foods containing a substance with DPP-4-inhibitory activity are also believed to be useful to dietary cure for type 2 diabetes. Therefore, we determined the inhibitory activity of 70% ethanol extracts from foods.

Methods: DPP-4 enzyme assays were carried out using 96-well microplates. For screenings of DPP-4 inhibitory activity, a sample extract, buffer (0.1M Tris-HCl), and the enzyme (the extract from rat intestinal mucosa) were mixed, shaken, and incubated for 5 min at 37 (final volume 50 µl). Then, the enzyme reaction was started by the addition of 50 µl of the assay buffer containing a substrate (2.5 mM Gly-Pro-pNA). Absorbance at 405 nm of the reaction mixtures was continuously determined with a microplate reader at 3 min time intervals. The inhibition was estimated by subtracting the reaction velocity of DPP-4 with a sample from the velocity of the enzyme without a sample.

Results and Conclusions: The ethanol extracts from about 70 kinds of food were tested and 6 extracts were found to have a significant inhibitory activity. Among these extracts, the extracts from black tea, oolong tea, and green tea leaves showed higher inhibitions than the others. The tea extracts also showed strong inhibitions against porcine and human DPP-4s.

Key words: DPP-4, Inhibitory activity, Diabetes, Tea

PO2845**CYTOTOXIC EFFECT OF AQUEOUS EXTRACTS OF SAFFRON FLORAL BIO-RESIDUES**

J. Serrano-Díaz^{1,2}, C. Estevan³, M.A. Sogorb³, M. Carmo-na^{1,4}, G.L. Alonso¹, E. Vilanova³

¹Cátedra de Química Agrícola, ETSI Agrónomos, Universidad de Castilla-La Mancha, Campus Universitario, Albacete, Spain

²Department of Food Science, Regional Campus of International Excellence

³Instituto Bioingeniería, Universidad Miguel Hernández, Elche, Alicante, Spain

⁴Albacete Science and Technology Park, Campus Universitario, Albacete, Spain

Background and objectives: Saffron (*Crocus sativus* L.) production is aimed to obtain the saffron spice which is the dried stigma of its flowers. For every kg of spice produced, about 63 kg of floral bio-residues are usually thrown away [1]. Saffron floral bio-residues proved to have high antioxidant contents [2] and a suitable nutritional composition [1] for using them as food ingredients. However, toxicity studies to demonstrate the safety of consuming these products have not been performed. Therefore, as a first study of its overall toxicity, the aim of this work was to determine the cytotoxic effect of aqueous extracts of saffron floral bio-residues to contribute to their potential use as functional ingredients.

Methods: Two aqueous extracts of freeze-dried floral bio-residues harvested in Castilla-La Mancha, Spain in 2010-2011 were prepared: 5 g in 150 ml of water (E1) and in 150 ml of water:HCl (100:1, v/v) (E2). They were filtrated through a Buchner funnel, concentrated under vacuum and freeze-dried. Total polyphenols and anthocyanins were determined [3, 4]. Cell viability and cytotoxicity were assayed with the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazoliumbromide (MTT) test [5].

Results: Aqueous extracts showed very high polyphenol and anthocyanin contents, being greater in E1 than in E2. The cytotoxicity induced after 3 days exposure to E1 and E2 was very low. Only the E1 at the highest tested concentration (900 µg/ml) caused a decrease of 38% in the cell viability. E2 did not cause any decrease in any of concentrations tested, even increased the cell viability. This could be due to their high sugar content or bioactive compounds such as polyphenols.

Conclusions: Aqueous extracts of saffron floral bio-residues are not cytotoxic at concentrations lower than 900 µg/ml. Thanks to JCCM-FEDER (POIC10-0195-984).

Key words: *Crocus sativus* L.; Flower waste; Phenolic content; Cell viability assays.

A COMPARATIVE STUDY ON FUNCTIONAL FOOD REGULATION BETWEEN CHINA AND THE EUROPEAN UNION

Y. Yang¹, S. Rong¹, Z. wang¹, X. Xiang¹

¹Department of Food Nutrition Assessment, Institute of Nutrition and Food Safety, Chinese Center For Disease Control and Prevention, China

Background and objectives: With the rapid development of functional (health) food market in the world, the supervision and management of it is facing a tremendous challenge. Aims: The purpose of this paper is to promote the development of functional food by contrasting the approval and supervision of functional foods in China with that in Europe.

Methods: The main path of obtaining information in the study were from academic journals, books, magazine and newspaper articles, market reports, proceedings, and web pages of relevant regulatory authorities and regulatory consultants etc.

Results: Based on the six specific comparative analyses, include definition, laws and regulations, application and supervision, evaluation, claims and labels, and product management, there are similarities and differences on the regulation processes between two countries.

Conclusions: These results could offer reference for learning from each other and further boost international cooperation and exchanges

PO2847

NEW SPL ON PHYTONUTRIENTS AND FUNCTIONAL FOOD REGULATION IN CHINA

Y. Yang¹

¹Institute of Nutrition and Food Safety, Chinese CDC, China

Background and objectives: With the rapid development of functional (health) food market in the world, the Science and management of it is facing a tremendous challenge. The purpose of this paper is to describe the New SPL (specific proposed level) for some phytonutrients and approval process on food claims in China.

Methods: The main of relevant regulatory analysis, evidence on proposed level of some phytochemicals, function claim regulatory systems in China.

Results: Introduce the six specific comparative analyses, include definition, laws and regulations, application and evaluation, claims and labels, and product management. And introduce the new recommendation for 21 SPL of phytochemicals.

Conclusions: These results could offer reference and further boost international cooperation and exchanges.

Key words: Function claims, specific proposed level, phytochemicals

BIOACTIVE FATTY ACIDS ANALYSIS ON DAIRY PRODUCTS BY FAST-GAS CHROMATOGRAPHY: A COMPARATIVE APPROACH BETWEEN TWO HIGHLY POLAR CAPILLARY COLUMNS

A. Gori¹, E. Guerra¹, A.M. Gomez Caravaca², M.F. Caboni¹

¹Department of Agricultural and Food Sciences (DISTAL), University of Bologna, Italy

²Department of Analytical Chemistry, University of Granada, Spain

Background and objectives: Bovine milk fat contains a large number of fatty acids (FA) exhibiting positive and negative physiological effects to human health. Special attention is placed on FA having a potential anti-atherogenic/carcinogenic role such as butyric acid and conjugated linoleic acid (CLA), and those essentials for the human metabolism such as linoleic and α -linolenic acid (n-6 and n-3). Conversely, milk fat encompasses FA ascribed to be detrimental for human health because leading to a high risk of cardiovascular diseases, such as the medium chain saturated FA and trans-FA. The advent of fast gas-chromatography (GC) has led to a significant reduction in analysis time. Therefore, in this investigation two fast GC methods were developed for the analysis of FA methyl esters (FAME) in dairy fat.

Methods: The analyses were performed with a fast GC-FID using a SLB-IL111 15m x 0.10mm i.d. 0.08 μ m df (ionic liquid stationary phase), and a BPX70 10m x 0.1mm i.d., 0.2 μ m df (cyanopropyl stationary phase) column, respectively. Complex commercial mixtures of FA and butter fat, were used for FA identification, method optimization and validation.

Results: About 50 FA were separated in less than 8 minutes by both columns. The SLB-IL111 and BPX70 showed an R2 value for the accuracy and linearity of 0.95, 0.99 and 0.99, 1.00 respectively. The limit of quantitation and limit of detection were less than 0.63 and 0.19 ppm in both the columns, and the RSD% value for the inter/intra day precision were higher than 10% on SLB-IL111 while less than 10% on BPX70.

Conclusions: The BPX70 capillary column showed the best analytical performances during the method optimization and validation. Furthermore, the BPX70 was able to resolve more complex coelutions than SLB-IL111, such as those relatives to the trans FA.

Key words: bovine milk, fast gas chromatography

PO2849

PHLORETIN SUPPRESSES THROMBIN-MEDIATED INTERACTIONS AMONG ENDOTHELIAL CELLS, MONOCYTES AND PLATELETS

Y H. Kang¹, M S. Kim¹, S H. Park¹, M K. Kang¹, J H. Gong¹, S Y. Han¹

¹Department of Food and Nutrition, Hallym University, Chuncheon, Korea

Background and objectives: The rupture of atherosclerotic plaques can cause arterial thrombosis by releasing thrombin. There is an association between hypercoagulability and increased atherosclerosis. Thrombin may influence the onset and progression of atherosclerosis as a pro-inflammatory mediator. This study investigated whether phloretin, a dihydrochalcone found in apple tree leaves, severed a linkage between thrombosis and atherosclerosis through blocking protease activated receptor (PAR).

Methods: Endothelial cells were pretreated with 1-20 μ M phloretin and stimulated with 10 U/ml thrombin. Cellular expression of several target gene proteins including PAR-1 was determined by Western blot analysis. Interaction of THP-1 monocytes onto activated endothelial cells was elucidated by using in vitro cell adhesion assay.

Results: Non-cytotoxic phloretin at the doses of 1-20 μ M attenuated adhesion of monocytes and platelets to thrombin-inflamed human endothelial cells in a dose-dependent manner, dampening endothelial expression of CD40 and P-selectin up-regulated by thrombin. Additionally, the phloretin supplementation inhibited thrombin-enhanced secretion of monocyte chemotactic protein-1, interleukin-6 and interleukin-8 proteins in THP-1 monocytes by interfering with rapid cellular expression of PAR-1. Thrombin-promoted production of plasminogen activator inhibitor-1 and tissue factor in THP-1 cells was attenuated by phloretin through blocking PAR-1. When 1-20 μ M phloretin was supplemented to thrombin-exposed endothelial cells, the rapidly enhanced expression of endothelial COX-2 was reduced. Accordingly, increased thrombosis may entail early atherogenesis accompanying endothelial interaction with monocytes and platelets.

Conclusions: Phloretin prevented inflammatory atherosclerosis highly activated in the hypercoagulation state through blocking the thrombin receptor PAR-1. Phloretin would be a potential alternative treatment for prevention of atherothrombotic diseases. Supported by National Research Foundation of Korea through the Human Resource Training Project for Regional Innovation and by Core Project of National Research Foundation of Korea.

PO2850

OLEANOLIC ACID SUPPRESSES VISFATIN INDUCTION VIA DISTURBING TRAF6-NF- κ B SIGNALING OF ADIPOCYTES

Y H. Kang¹, H S. Kim¹, Y H. Kim¹, E J. Lee¹, E H. Moon¹, I H. Cho¹

¹Department of Food and Nutrition, Hallym University, Chuncheon, Korea

Background and objectives: Oleanolic acid is a pentacyclic triterpenoid naturally present in foods and medicinal plants with anti-cancer, anti-oxidant, and anti-aging properties. The current study elucidated that oleanolic acid inhibited the production of insulin-mimetic and inflammatory adipokine of visfatin during adipogenic differentiation of 3T3-L1 adipocytes.

Method: Adipocytes were cultured in an adipogenic media with and without 1-25 μ M oleanolic acid up to 8 d for differentiation. Cellular expression and secretion of visfatin and activation of nuclear factor (NF)- κ B were determined with Western blot analysis. Secretion of interleukin (IL)-6 and macrophage inflammatory protein (MIP)-2 was measured by using ELISA kits.

Results: The cellular expression and secretion of visfatin was markedly enhanced in differentiating adipocytes, which was dose-dependently attenuated by 1-25 μ M oleanolic acid. Secretion of IL-6 and MIP-2 was highly elevated during differentiation, which was much earlier than visfatin production of adipocytes. The visfatin production was secondary to inflammatory IL-6 and MIP-2. This study further elucidated that NF- κ B signaling was responsible for cellular production of visfatin. NF- κ B was activated by translocating into the nucleus with increased phosphorylation of I κ B, which was disturbed by oleanolic acid. Cellular expression of TNF receptor associated factor 6 (TRAF6) and receptor activator of NF- κ B, was upregulated in parallel with transactivation with NF- κ B, in which oleanolic acid inhibited such upregulation. These results demonstrate that oleanolic acid inhibited visfatin and its inflammatory response during adipocyte differentiation through blocking TRAF6-NF- κ B signaling.

Conclusions: Oleanolic acid may be a potent therapeutic agent targeting against adipogenesis and visfatin-linked inflammation.

Supported by National Research Foundation of Korea through the Human Resource Training Project for Regional Innovation and by Core Project of National Research Foundation of Korea.

Key words: Adipocyte differentiation, obesity, oleanolic acid, visfatin, NF- κ B

PO2851

EVALUATION OF ANTIOXIDANTS AND ANTIMICROBIAL ACTIVITIES OF A MIXTURE OF POLYPHENOLS EXTRACTED FROM TEA, MINT AND LEMON LEAVES IN VITRO

K. Marouani¹, K. Dhaouadi², H. Jlassi¹, S. Fattouch², M. H. Hamdaoui¹

¹High School of Health Sciences Tunis EL Manar University, Tunisia

²Department of Biological and Chemical Engineering, National Institute of Applied Sciences and Technology, University of Carthage, Tunis, Tunisia

Background and objectives: Our objective was to determine the natural polyphenol extracts from green or black tea decoction (GTD, BTD), mint (MI) and lemon leaves (LL) to prepare a mixture of bioactive substances giving an optimal antioxidant and antimicrobial activities.

Methods: The relative proportions of different polyphenolic mixture (DPM) were determined using a biostatistics experimental plan (BEP). The antioxidant and the antimicrobial activities were determined by the anti-radical "DPPH and ABTS" methods and range of microorganisms commercially available, respectively.

Results: Results showed the relative superiority of certain extracts and mixtures designed (0, 5 GTD + 0, 5 MI / 0, 5 BTD + 0, 5 MI). However, there is a considerable decrease in antioxidant activity in the case of mixtures (0, 5 GTD + 0, 5 LL / 0, 5 BTD + 0, 5 LL).

Conclusions: The approach adopted by the BEP was justified by the intermolecular synergistic or antagonistic effects of DPM which allowed us to check the best optimal activities to be taken in application scale.

Key words: Tea; mint; lemon leaves; antioxidant; biostatistics experimental plan

PO2852

CHANGE IN CARBOHYDRATE COMPOSITION OF FRESH YACON (SMALLANTHUS SONCHIFOLIUS) ROOTS DURING STORAGE

M. Scheid¹, G. Pastore¹, M. Maróstica²

¹Department of Food Science, School of Food Engineering, University of Campinas(UNICAMP), Campinas, São Paulo, Brazil

²Department of Food and Nutrition, School of Food Engineering, University of Campinas(UNICAMP), Campinas, São Paulo, Brazil

Background and objectives: Yacon (*Smallanthus sonchifolius*) is an Andean root, which is recognized for its prebiotics potential due to its high concentration of Fructooligosaccharides (FOS). Changes in the carbohydrates concentration, FOS, glucose, fructose and sucrose, occur during storage. The aim of this work was to evaluate the changes of carbohydrates content in fresh yacon roots stored at 25 °C and 4 °C, on 3, 17 and 31 days post-harvest.

Methods: Sugar and FOS in fresh yacon roots stored at 25 °C and 4 °C were extracted with water and analyzed in Ion Chromatograph on 3, 17 and 31 days post-harvest.

Results: Results indicate high variability in the carbohydrate content during 31 storage days. The content of FOS and sucrose decreases and fructose and glucose, increases at the tubers storage at 25 °C and 4 °C. At 25 °C, the FOS and sucrose content decrease from 74% to 26% and from 32% to 27% dry matter, respectively, whereas fructose and glucose increase from 12 to 60% and from 9 to 22% dry matter, respectively. At 4°C, the FOS and sucrose content decreases from 74 to 30% and from 32 to 14% DM, respectively, whereas the content of fructose and glucose increase from 12 to 55% and from 9 to 20% DM, respectively. At 4°C a reduction in FOS content was greater after 17 days of storage.

Conclusions: Fresh Yacon has a high content of FOS. The FOS and sucrose content of yacon roots decreases with storage days, whereas the content of fructose and glucose increases, consequently unsuitable for diabetics. The decrease of FOS content of yacon root storage at 4 °C was in less proportion than at 25 °C. To preserve the FOS content of fresh yacon roots appropriate handling methods post-harvest must be developed.

Key words: fresh roots yacon, carbohydrate composition, post-harvest, fructooligosaccharides, storage

PO2853**DOES THE LACTIC ACID BACTERIA FERMENTATION PLAYS A SIGNIFICANT ROLE ON TOFU PHENOLIC COMPOUNDS COMPOSITION?**

Y. Riciputi^{1,2}, V. Verardo^{1,2}, D.I. Serrazanetti^{1,2}, M.F. Caboni^{1,2}, M.E. Guerzoni², F. Gardini^{1,2}

²Department of Agri-Food Science and Technology, University of Bologna, Italy

Background and objectives: The high nutritional value and low cost of soybean products make them a suitable solution for malnutrition problems for poor people living on grain centred diets. Tofu, a fundamental part of Asian food culture, is a traditional oriental soybean food and it may be the most popular food made of soy worldwide. Thousands of studies (in vivo and in vitro, with animals and human subjects) have shown that soybeans and soy components have many health-promoting effects; some of them were attributed to the isoflavones. In particular, various forms of isoflavones have been shown to possess different antioxidant activities. The aim of the study was to investigate the effect of lactic acid bacteria (LAB) fermentation on the free and bound phenolic fraction of tofu.

Methods: The fermentation process was established using specific strains of lactic acid bacteria. Free and bound phenolic compounds from soybean, traditional tofu and tofu obtained by soymilk fermentation were studied by HPLC-DAD-ESI-MS.

Results: Important effects of fermentation were seen on isoflavone profile: in fact, isoflavones content of fermented tofu showed significant differences compared to soybean and to traditional tofu. In particular, fifteen isoflavones were identified as aglycones and glycosides: the aglycone forms were significantly higher in fermented tofu compared to the traditional one. The ratio of aglycones/glycosylated isoflavones was 0.34 and 2.55 for the traditional and fermented tofu, respectively. Soy and traditional tofu presented the same content of bound phenolic compounds (mainly phenolic acids), instead fermented tofu showed a bound phenolic content 34 % higher than traditional tofu.

Conclusions: These results suggest that fermentation by LAB plays an essential role in the increase of the content of aglycone isoflavones and bound phenolic compounds with important biologically implications on human health.

Key words: tofu, fermentation, isoflavones, soybean, LAB

PO2854**PERSIMMON JUICE AS A SOURCE OF BIOACTIVE COMPOUNDS**

C. Jiménez-Sánchez^{1,2}, J. Lozano-Sánchez^{1,2}, C. Roldán-Segura^{1,2}, A. Segura-Carretero^{1,2}, A. Fernández-Gutiérrez^{1,2}

¹Department of Analytical Chemistry, University of Granada, Granada, Spain

²Functional Food Research and Development Centre (CIDAF), Health Science Technological Park, Granada, Spain

Background and objectives: Plant based diets rich in phytochemicals have been correlated with the decreased diseases such as cancer, cardiovascular diseases and so on. In this regard, fruit juices and particularly persimmon juice are an easily available and affordable source of bioactive compounds and arise as an effective complement to the diet and nutrition. For this reason, a complete characterization and identification of phytochemicals have been performed on a pilot plant produced persimmon juice to substantiate its potential health benefits in human nutrition.

Methods: Persimmon juice was obtained at pilot plant scale and underwent clarification and centrifugation after juice pressing. Juice samples were extracted using a liquid-liquid extraction procedure with a mixture of methanol:water (80:20) and then was filtered. These extracts were characterized through High Pressure Liquid Chromatography (HPLC) coupled to Electrospay Time of Flight Mass Spectrometry (ESI-TOF-MS).

Results: A total of 51 compounds were detected, among these, 37 compounds belonging to different chemical classes such as sugars, organic acids, protein derivatives, vitamins, polyphenols (mainly flavonoids and hydroxybenzoic acids) and their derivatives were tentatively identified in the persimmon juice extracts.

Conclusions: A complete characterization of persimmon juice produced at pilot plant-scale was performed in order to elucidate its chemical composition. A wide variety of phytochemicals belonging to different chemical classes such as sugars, organic acids, protein derivatives, vitamins, polyphenols mainly flavonoids and hydroxybenzoic acids have been found in persimmon juice, emerging as a potential source of bioactive compounds.

Key words: Persimmon juice, bioactive, HPLC-MS

Background and objectives: Asparagus is a vegetable that has traditionally been appreciated for its organoleptic and nutritional characteristics. This product is also a good source of phytochemicals which have been suggested to exert a protective effect against chronic diseases. Because health-promoting characteristics are increasingly demanded by consumers more concerned with human health, the investigation of the bioactive compounds responsible of its beneficial effects is of great interest for its revalorization. For this reason, we have developed a powerful bucketing algorithm to perform a complete and thorough characterization of four asparagus varieties based on mass spectra data.

Methods: Freeze-dried asparagus samples of four varieties (Purple-green, hybrid-green, NJ-953 and HT-801) were extracted by maceration with ethanol for 30 minutes and then filtrated. These extracts were analysed by High Pressure Liquid Chromatography (HPLC) coupled to Electrospray Time of Flight Mass Spectrometry (ESI-TOF-MS). After that, an intelligent bucketing algorithm for identifying relevant elution time-m/z peaks in mass spectrometry data based on rectangular bucketing was developed. It included mass calibration in order to allow appropriate high resolution bucketing, noise reduction in order to discard no relevant data of mass spectra and automatic and intelligent bucketing.

Results: Sugars, organic acids, protein derivatives, vitamins, polyphenols, and their derivatives have been tentatively identified in the four asparagus varieties, being polyphenols predominant. Comparison among varieties has been made.

Conclusions: This innovative tool has demonstrated its potential to characterize vegetable samples at a deeper level, providing a detailed list of potential bioactive compounds and thus enhancing asparagus value as food itself and as a new platform to develop functional foods.

Key words: Asparagus, HPLC-ESI-MS, bioactive, bucketing

PO2856

IDENTIFICATION OF BIOACTIVE COMPOUNDS IN FOUR ASPARAGUS VARIETIES THROUGH AN INTELLIGENT BUCKETING ALGORITHM USING MASS SPECTRA DATA

PO2857**EFFECTS OF WALNUT CONSUMPTION ON SELECT VASCULAR BIOMARKERS IN HYPERCHOLESTEROLEMIC POSTMENOPAUSAL WOMEN**

R. Hackman¹, S. Yim¹, D. Djurica¹, A. Shindel², R. Holt¹, C. Keen¹

¹University of California, Davis, Department of Nutrition, USA

²University of California, Davis, Department of Urology, USA

Background and objectives:Walnuts contain a number of nutrients that may benefit vascular function.

Methods:We compared the effects of two levels of walnut consumption (5 g vs. 40 g) after a single intake and after daily intake for 4 wks.Assessment was conducted after an overnight fast without any dietary preloading. Thirty-six hypercholesterolemic postmenopausal women were randomly assigned in a parallel-arm design. Outcomes were measured at baseline and at 4 hr after walnut intake on the first day (D1) and after 4 wks (D2) and included microvascular function as assessed by peripheral arterial tonometry (PAT), platelet function as assessed by PFA-100, and serum lipids. Data are presented as mean \pm SD.

Results:No significant changes in microvascular function were noted in the 5 g/d group. A significant increase in PAT was observed 4hr after intake of 40 g of walnuts on D1 (2.32 ± 0.39 vs. 2.82 ± 0.39 ; $p=0.001$).Daily intake of 40 g of walnuts for 4 wks was associated with an increased baseline PAT response compared to the baseline level at the start of the study(D1: 2.32 ± 0.39 vs. D2: 2.70 ± 0.31 ; $p=0.008$). No change inPAT was observed on D2 between baseline and 4 hr. No changes were noted in platelet reactivity for either group.LDL concentrations decreased significantly 4 wks after 40 g/day of walnut intake (D1: 154.76 ± 16.79 mg/dL vs. D2: 146.06 ± 17.33 mg/dL; $p=0.046$).No other changes were observed in serum lipids in either group. Reported dietary intake of n-3 and n-6 lipids was significantly increased in the 40 g group after 4 wks.

Conclusions: The results suggest that a single intake of 40 g of walnuts, as well as daily intake of 40 g for 4 weeks,can result in favorable vascular effects.This work was supported by the California Walnut Commission.

Key words:walnuts, vascular, women, lipids

PO2858**ENZYMATIC TREATMENT IN FLOUR RYE AND THE COMPARATIVE STUDY OF ANTIOXIDANT CAPACITY ORAC, WITH AND WITHOUT EDTA**

F. Lima¹, J. Macedo¹, J.Pallone¹, G. Macedi¹

¹Department of Food Science, of Food Engineering, University of Campinas, Brazil

Background and objectives: Rye is a cereal rich in bioactive compounds, as the polyphenols, but contains anti-nutrients, such as tannins. The tannase hydrolyzes tannins and increases the release of phenolics compounds. In addition, there is an increase in the antioxidant activity of the cereal, resulting in a product with high nutritional value. The oxygen radical absorbance capacity (ORAC) is a method widely used in the scientific scope for determination of the antioxidant activity. The literature recommends, the use of a metal chelator, Ethylenediaminetetraacetic acid hydrate (EDTA),for avoid phenolics autoxidation by metal traces present in foods. The study evaluated the antioxidant capacity of rye hydrolyzed with tannase from *Paecilomyces variotti* obtained under solid state fermentation and the influence of EDTA in the ORAC method.

Methods: The rye grain was milled and the obtained flour was hydrolyzed with tannase at 40°C, 200 rpm for 2 hours. The ORAC assay was conducted for two tests: in the presence and absence of EDTA (80 μ M). The results were expressed in μ M Trolox equivalents per 100 g of rye.

Results: The tannase from *Paecilomyces variotti* was effective in increasing the antioxidant capacity of rye because the antioxidant activity of the sample treated doubled compared to control. Samples were compared by ORAC method, without and with EDTA. The increase in antioxidant activity was greater in all flour tested in the presence of EDTA. Increases in antioxidant activity of 45% and 10% were observed for the control and the treated flour, respectively, compared to the performed test without the chelating agent. This occurs because the EDTA is able to reduce metal and, therefore, to preserve the power of polyphenols and others antioxidants.

Conclusions: It is interesting adding EDTA as chelating of metals in rich in mineral sample to assess the true capacity of the antioxidant.

Key words: (3-5 key words): Antioxidant activity, ORAC, tannase, rye, EDTA

PO2859**SYNERGIC ANTIBACTERIAL BEHAVIOR OF THE MAJOR POLYPHENOLS DERIVED FROM SPANISH CISTUS SPECIES**

L. Tomás Menor¹, A. Morales Soto^{2,3}, E. Barrajón-Catalán^{1,4}, C. Roldán Segura^{3,5}, A. Segura-Carretero^{2,3}, V. Micol¹

⁴R&D Department of ENDEMIC BIOTECH - QUÍMICAS DEL VINALOPÓ, S.L. Monóvar, Monóvar, Alicante, Spain

⁵Signal Theory, Networkings and Communications Department, ETSSI, University of Granada, Granada, Spain

Background and objectives: Cistaceae is a large family of shrubs commonly distributed in the Mediterranean ecosystem. We have recently reported the antimicrobial capacity of extracts derived from several Spanish *Cistus* species. The aim of this study was to deepen on the antimicrobial properties against *E. coli* and *S. aureus* as models for Gram-negative and Gram-positive bacteria, respectively, of different *Cistus* extracts and their major polyphenolic compounds.

Methods: Fourteen extracts were obtained for maceration and then dried by lyophilization or spray-drying. The bacteriostatic capacity of these extracts and their composition was compared by Folin-Ciocalteu assay, determination of flavonoids, antioxidant capacity measurements and RRLC-ESI-TOF-MS analysis (rapid-resolution liquid chromatography coupled with electrospray ionization time-of-flight mass spectrometry). Furthermore, we studied in-depth the potential synergistic interaction of the main compounds.

Results: The aqueous extracts of *C. salviifolius* exhibited potent bacteriostatic effects against Gram-positive bacteria compared with the other *Cistus* species tested. The polar fraction of *C. salviifolius* showed bacteriostatic and bactericidal activity against both bacteria tested. Up to forty-eight compounds were found in the aqueous extract of *C. salviifolius*. Moreover, pair combinations of some major compounds selected from *C. salviifolius* showed a potential synergistic behaviour.

Conclusions: The analysis of the composition of the extracts revealed that the inhibitory activity against *E. coli* may be related to the presence of galloylated flavanols and specific flavonols, whereas the inhibitory capacity against *S. aureus*

may be related primarily to polar compounds and to other flavonols. The synergic antimicrobial properties observed for the compounds of *C. salviifolius* extract deserve further. These extracts may serve as an alternative source of antimicrobial ingredients focused on medical devices or cosmetics.

Key words: Antibacterial, *Cistus*, polyphenols, synergy, RRLC-ESI-TOF-MS.

PO2860**IODINE FORTIFICATION OF FARMED FISH FILLETS: A HEALTHY WAY TO PREVENT IODINE DEFICIENCY**

A. Ramalho¹, R. Colen¹, M L. Nunes², A. Gonçalves², Y. Madrid³, M T. Dinis¹, J. Dias⁴

¹CCMAR, Aquaculture Research Group, University of Algarve, Faro, Portugal

²IPMA, Innovation of Fish and Aquaculture Products, Lisbon, Portugal

³Analytical Chemistry Department, University Complutense de Madrid, Madrid, Spain

⁴SPAROS Lda., CRIA - Universidade do Algarve, Faro, Portugal

Background and objectives: Data from WHO estimate that iodine intake of 42.7% (22.2 million) of school-age children in Europe is insufficient and extrapolations to the general population announce 244 million European individuals with insufficient iodine intake. Marine fish are a rich source of iodine in the human diet. Farmed fish, relying on exogenous feeding open the possibility to tailor fish composition with health valuable nutrients, such as iodine, and establish it as a functional food.

Methods: A 16 weeks study was undertaken to test the efficacy of various dietary iodine forms on the growth performance of gilthead seabream, the resulting iodine deposition in fish muscle and overall sensory criteria. Besides a detailed characterization of iodine species on fresh fillets, the influence of a culinary treatment on iodine chemical forms was also assessed. Four experimental diets were formulated: the control; a diet supplied with an inorganic form – potassium iodide (KI); another diet containing an organic form – ethylenediamine dihydroiodide (EDDI); and a fourth diet (LAM) formulated with *Laminaria*, an iodine-rich macroalgae.

Results: At the end of the trial, the overall performance of fish was not affected by dietary iodine supplementation level or form. Iodine deposition in muscle was significantly higher with *Laminaria* diet (3-fold increase) while EDDI and KI diets showed no differences in comparison with the control. Iodine content of seabream fillets was affected by culinary treatment

(steam-cooking). Trained panelists were able to differentiate fish fed the EDDI diet, but not LAM or KI from those fed the CTRL diet. Sensorial attributes of fillets from Laminaria enriched diet were closer to the control ones.

Conclusions: The use of marine macroalgae, as a dietary constituent, enabled the natural biofortification of farmed fish with iodine and may be an effective way to ensure higher iodine intake of human population.

Key words: iodine, macroalgae, functional fish, biofortification

SELENIUM, GERMANIUM AND HEAVY METAL CONTENTS IN REPRESENTATIVE NORTH KOREAN CROP

H.S. Chung³, E.J. Lee¹, P.J. Kim²

¹School of Biological Sciences, Seoul National University, Seoul, Korea

²Agglobe Services International Inc., Minneapolis, USA

³Department of Food and Nutrition, Duksung Women's University, Seoul, Korea

Background and objectives: This study was conducted to investigate selenium, germanium and heavy metal contents in 27 North Korean crops and edible mushrooms. These kinds of nutrition information are hardly to find up to these days.

Methods: Therefore, to investigate safety and usefulness of these 27 crops as food resources, we measured selenium, germanium and four heavy metal (As, Cd, Cr, Pb) contents by ICP-MS after thorough homogenization.

Results: The mean selenium content was 25.1 µg/kg and rich sources of selenium were oak mushroom (130 µg/kg), Pimpinella brachycarpa, Aster scaber, Aralia elata, and mulberry mushroom. The mean germanium content was 13.5 µg/kg and rich sources of germanium were Aster scaber, fern, mulberry mushroom and Aralia elata. Especially Aralia elata (33 µg/kg), Aster scaber and mulberry mushroom showed rich sources in selenium and germanium and can be regarded as potential useful trace element nutrition crops in North Korea. The mean cadmium (Cd) content was 0.22 mg/kg and osmund fern and mulberry showed 5 times higher than the mean content and needs caution to consume them. Also the mean lead (Pb) content was 1.01 mg/kg and Chinese matrimony vine, Aralia elata and mulberry mushroom had higher content than the safety guideline standard (2.0 mg/kg).

Conclusions: As and Cr results showed that all tested crops were under the safety guideline standard.

Key words: North Korean food, selenium, germanium, heavy metal

³School of Life Sciences & Biotechnology, Korea University, Seoul, Korea

Background and objectives: Bibimbap, most interested Korean cuisine, literally means 'mixed rice'. Bibimbap is served as a bowl of warm white rice topped with seasoned vegetables, meat and chili pepper paste. This study was investigated the mechanisms underlying the cytotoxicity of the Bibimbap on human colon cancer cell line, HT-29 in vitro and in vivo experiments, for the development of high-valued Korean cuisine.

Methods: Bibimbap was prepared with rice and vegetables with biological activities on human colon cancer cells. The anti-proliferative activity of Bibimbap on HT-29 was identified through cell viability, MTT, western blot, RT-PCR and animal test.

Results: In our study, Bibimbap was inhibited the growth of HT-29 in a dose-dependent manner (IC₅₀: 13.0, 11.7, 9.7 mg/ml on 24, 48, 72 hours, respectively). Concomitant activation of the mitochondria-dependent apoptotic pathway of Bibimbap occurred via modulation of Bax and Bcl-2 expression, resulting in activation of cleaved caspase-3 and caspase-8. As a result of animal experiments, the size and weights of tumor of colon were decreased with 2.7%, 4.0% and 38.9% (p<0.001), and 3.8%, 6.1%, 37.4% (p<0.001), respectively, treatment with 0.5, 1.0 and 2.0 mg/kg Bibimbap groups, compared to control group.

Conclusions: This is the first report to demonstrate the cytotoxic effect of Bibimbap on human colon cancer cells and to provide a possible mechanism for this activity.

Key words: BIBIMBAP, Korean Cuisine, HT-29, Apoptosis, Animal test

Background and objectives: According to literature the whole cold-pressed lipid fraction extracted from pomegranate seeds, if assumed through diet, can improve immune function *in vivo*, reduce hepatic triacylglycerol accumulation and act as a chemopreventive agent against hormone-related human cancers. Pomegranate seed oil comprises 10–20% of total seed weight, with an ideal highly unsaturated fatty acid content, mainly constituted by the rare conjugate linolenic acid isomer punicic acid, which activities against inflammation and metabolic syndrome have been confirmed by various *in vivo* experiments. However, besides several very encouraging studies on the possible beneficial effects of this oil, little is known about the composition of its minor fraction. Therefore, in this work, the main lipidic classes of 17 pomegranate varieties were determined.

Methods: The pomegranate oil was extracted by Folch method and several chromatographic techniques were used to determine fatty acid, tocopherol, sterol and phospholipid composition.

Results: The total lipid content of pomegranate seeds varied between 7.9 and 16 %. Pomegranate seed oil contained higher amount of CLnA (punicic acid) in the range of 73.6–85.0 % of total fatty acid content. Other major fatty acids were oleic, linoleic and palmitic acid, respectively. Pomegranate seed had high contents of tocopherol (0.6–2.6 mg/g of fat). Delta-tocopherol was 91.2–96.7 % of total tocopherols. The major phytosterols analyzed were delta5-avenasterol, campesterol, stigmasterol, and β -sitosterol. Moreover some triterpene compounds as betulin, botulinol and cyclolanostanol were identified. Three different phospholipids were detected; phosphatidylethanolamine was the first compounds in the range of 44–91% of total phospholipids. Phosphatidylinositol and phosphatidylcholine were, also, quantified.

Conclusions: In summary, these data indicated that pomegranate seeds are rich sources of CLnAs, tocopherols, phospholipids and sterols with potential beneficial physiological activities. In addition, different pomegranate cultivars may differ in their seed components and health properties.

Key words: pomegranate seed, lipid composition, punicic acid

PO2864**ANTIOXIDANT PROPERTIES OF ILEX PARAGUARIENSIS**

¹Cátedra de Toxicología, Farmacología Y Bioquímica Legal, Facultad de Bioquímica Y Ciencias Biológicas, Universidad Nacional del Litoral, Santa Fe, Argentina

²Instituto de Tecnología de Alimentos, Facultad de Ingeniería Química, Universidad Nacional de Litoral, Santa Fe, Argentina

Background and objectives: Yerba mate (*Ilex paraguariensis*) beverages have been consumed as popular infusions in South America for years. This plant attracts the scientific community for its beneficial effects on health. The aim of this work was to evaluate Yerba mate antioxidant properties in human lymphocytes exposed *in vitro* to oxidative damage, using the Comet assay, a sensitive and rapid method for DNA strand break detection in individual cells.

Methods: Two commercial brands were analyzed using 5% infusions, filtered and stored at -20°C (infusion 1 and 2). Lymphocytes were exposed *in vitro* to 10 μ M H₂O₂ for 10 min and then allowed to repair with increasing concentrations of the infusion for 30 min at 37°C: repair I (RI: 10 l/ml), repair II (RII: 100 l/ml) and repair III (RIII: 1000 l/ml), and a control with no repair (CWR), without the addition of the infusions. As a positive control, cells were exposed to 50 μ M H₂O₂ while the negative control remained without H₂O₂. Comet assay was performed following standard protocols. Samples were stained with Ethidium Bromide, analyzed under a fluorescent microscope and Damage Index (DI) and the percentage of reduction (%R) were calculated.

Results: Both commercial brands showed similar protective effects ($p > 0.05$). Differences were found among treatments of yerba mate used in the DI. For the infusion 1, results revealed that RI, RII and RIII showed a lower DI related to CWR ($p < 0.05$). In the infusion 2, RII and RIII groups presented less DI than CWR, while RI showed more damage than RIII ($p < 0.05$). The %R indicated a decreased in oxidative damage as infusion concentration increases ($p < 0.05$).

Conclusions: This study demonstrated an important protective properties attributed to yerba infusions. Thus we conclude that theregular ingestion of *Ilex paraguariensis* infusions could contribute to antioxidant defense on humans.

Key words: *Ilex paraguariensis*, Antioxidant, Comet Assay.

⁵Dipartimento di Scienze Agrarie, University of Bologna, Bologna, Italy

Background and objectives: Traditionally, pomegranate (*Punica granatum* L.) has been consumed as fresh fruit or as pomegranate juice and it has been described as a rich source of phenolic compounds. Several recent studies have shown that drinking pomegranate juice contributes to significant potential health benefits, and, today, it is known, that the positive health properties of pomegranate are due to the presence of bioactive compounds like, flavonoids, phenolic acids and tannins contained in it. Therefore, in this work, the main phenolic compounds of 17 pomegranate varieties were determined by HPLC-DAD-ESI-qTOF-MS.

Methods: A new chromatographic HPLC-DAD-ESI-qTOF-MS method, using a C18 fused-core column, was established and the analyses were performed in less than 20 minutes.

Results: Eight anthocyanins and fourteen other phenolic compounds were tentatively identified and quantified in the pomegranate juices. As far we are concerned, a new flavonol-glycoside has been tentatively identified for the first time in pomegranate juices. Total phenolic content ranged from 573.6 to 2519.8 mg/mL. Anthocyanins varied between 110.9 to 1925.5 mg/mL and they represented the 17-86 % of total phenolic content. Flavonoids were the 1.6-24.4 % of total phenolic compounds. Phenolic acid and ellagitannins were in the range of 300.9-810.2 mg/mL.

Conclusions: The results confirmed, as reported in literature, that the pomegranate variety influences substantially the phenolic composition. It is important to highlight that, as far we are concerned, a new flavonol-glycoside has been tentatively identified for the first time in pomegranate juices thanks to this method.

DISTRIBUTION OF FENOLIC COMPOUNDS AND OTHER POLAR COMPOUNDS IN SOLANUM TUBEROSUM L AND STUDY OF THEIR ANTIOXIDANT ACTIVITY

A. López-Cobo^{1,2}, A. M. Gómez-Caravaca^{1,2}, A. Segura-Carretero^{1,2}, A. Fernández-Gutiérrez^{1,2}

¹Department of Analytical Chemistry, University of Granada, Granada, Spain

²Functional Food Research and Development Centre, CIDAf, Armilla, Granada, Spain

Background and objectives: Potato (*Solanum tuberosum* L.) is the most widely grown crop around the world and the fourth largest in terms of fresh produce after rice, wheat, and maize. It represents the staple source of nutrients and energy and it is an important source of carbohydrates, quality proteins, minerals, vitamins and, even some varieties of potato are a rich source of polyphenolic compounds. Thus, the aim of this work was to identify and characterize different polar compounds in three fractions of potato: pulp, skin and whole tuber of two varieties: Bluebell and Melody by using UPLC-DAD-ESI-QTOF-MS/MS. Furthermore, to quantify the majority phenolic compounds by UV and to measure the antioxidant activity of the three fractions in the two varieties of potato by FRAP, TEAC and ORAC.

Methods: Samples were freeze-dried and extracted in methanol/water before being analyzed by UPLC-DAD-ESI-QTOF-MS/MS in positive and negative ionization modes. Quantification was carried out by UV and three standard calibration curves were built with standards: caffeic acid, ferulic acid and chlorogenic acid. FRAP, TEAC and ORAC methods were carried out.

Results: 27 polar compounds were identified in potato. Three caffeoylquinic acid isomers, caffeic acid, a di-caffeoylquinic acid isomer and N-[2-hydroxy-2-(4-hydroxyphenyl)ethyl]ferulamide were the main phenolic compounds in the three fractions in the two varieties of potato. Peels were the part which presented the highest content of phenolic compounds and Bluebell potato was the variety which presented the largest content of phenolic compounds.

Conclusions: Potato concentrates the most of the phenolic compounds in the outside of the tuber, the peel. This fact makes potato peel an interesting by-product of the potato industry because it can be used as a source of recovery and reutilization of phenolic compounds for the production of functional food and/or nutraceuticals.

Key words: *Solanum tuberosum* L, UPLC-ESI-Q-TOF-MS/MS, phenolic compounds, antioxidant activity.

PRODUCTION OF SWEET LOW-LACTOSE YOGURT

*M. Blazic*¹, *C A.Zalazar*², *S. Bernal*², *C M. Perotti*², *C. Venica*²

¹Karlovac University of Applied Sciences, Croatia

²Instituto de Lactología Industrial (INLAIN) (UNL-CONICET), 3000 Santa Fe, Argentina

Background and objectives: Lactose intolerance is a metabolic disorder that affects a large portion of world population. The origin of this problem lies in partial absence or deficiency of the enzyme α -galactosidase (lactase) present in the intestine, which disables the body to absorb lactose properly. In order to meet the needs of the population suffering from lactose intolerance, products with reduced lactose content exist in the dairy market. The aim of this study was to investigate the application of α -galactosidase to produce sweet yogurt with reduced concentration of lactose in order to develop a new functional fermented milk product.

Methods: The influence of added amount of sucrose (1% and 8%) in the hydrolysis of lactose was monitored and limiting enzyme concentration (0,016%) was tested to that effect. Biotechnological process parameters for production of yogurt with reduced concentration of lactose have been determined. The concentration of lactose in the samples was assessed indirectly by determining the glucose level using the enzymatic-colorimetric method of Trinder, by analytical hydrolysis.

Results: The obtained results show that the addition of 1% sucrose in the production of sweet yogurt with reduced lactose concentration lowered hydrolysis of lactose by 10%, and the addition of 8% sucrose lowered it by 20%, compared to the hydrolyzed yogurt during the production of standard yogurt with reduced lactose concentration and the same concentration of 0.016% α -galactosidase (v/v).

Conclusions: The method used for this study is selective, simple and effective with additional advantage of having cheap reagents. In yoghurt produced by this method more than 80% lactose has been hydrolysed which makes it suitable for lactose intolerant people.

Key words: Lactose intolerance, α -galactosidase, sweet yogurt

INTERACTION BETWEEN PROBIOTIC AND STARTER STRAINS INVOLVED IN THE ELABORATION OF FERMENTED GOAT'S MILK

*T. Bergillos-Meca*¹, *M. Moreno-Montoro*¹, *E. Moreno*², *M. Jiménez-Valera*², *C. Cabrera*¹, *R. Artacho*¹, *M D. Ruiz-López*^{1,3}, *M. Navarro-Alarcón*¹, *R. Giménez*¹, *M. Olalla*¹, *A. Ruiz-Bravo*²

¹Department of Nutrition and Food Sciences, University of Granada, Spain

²Department of Microbiology, University of Granada, Spain

³Institute of Nutrition and Food Technology, University of Granada, Spain

Background and objectives: The manufacture of a fermented goat's milk with probiotic properties requires compatibility between different bacteria involved in the fermentation process. The aim of the present research has been to study the interactions between the probiotic strain *Lactobacillus plantarum* C4 and the starter strains *Lactobacillus delbrueckii* subsp. *bulgaricus* and *Streptococcus thermophilus*.

Methods: We elaborated a probiotic fermented goat's milk with the starter strains and probiotic strain *Lactobacillus plantarum* C4. Viable microorganisms at different times of the fermentation process were enumerated by preparing serial dilutions of the product and culturing them on TSA, MRS and LPSM (*Lactobacillus plantarum* selective medium) agar plates. Antibiosis between the three different bacteria was investigated using the spot test on TSA, MRS and LPSM agar plates.

Results: When antibiosis was investigated by the spot test, *L. plantarum* was able to exert inhibitory effect on the growth of *L. bulgaricus* and *S. thermophilus*. This inhibition was attributable to acid production from dextrose fermentation. However, when the three strains were co-cultured in goat's milk, *L. plantarum* C4 did not inhibit the growth of both starter strains. On the contrary, the pH drop due to fermenting action of the starter strains abolished the proliferation of *L. plantarum* C4, although the viability of this probiotic bacterium was not affected.

Conclusions: Taking into account the behaviour of probiotic and starter strains, the optimal conditions for the fermentation process were fixed.

Key words: Antibiosis, probiotic fermented goat's milk

PO2869**OLEUROPEIN IMPROVES GLUCOSE TOLERANCE OF HIGH-FAT INDUCED OBESE MICE**

Y. Fujiwara¹, N. Ikeda¹, M. Sonoda¹, I. Ichi¹, Y. Sone², T. Ishikawa²

¹Department of Nutrition and Food Science, Life Sciences, Graduate School of Humanities and Sciences, Ochanomizu University, Tokyo, Japan

²Institute of Environmental Science for Human Life, Ochanomizu University, Tokyo, Japan

Background and objectives: Oleuropein, one of the polyphenols contained in the olive leaves and oil, is known to have various physiological activities such as anti-oxidative, anti-bacterial and hypotensive effects. Oleuropein is also reported to decrease blood glucose levels in the alloxan-induced diabetic mice, however, the effect on type 2 diabetes and the detail mechanism have not been clarified yet. Therefore we investigated the effect of oleuropein on the glucose tolerance in obese mice and also evaluated these effects using cell culture system.

Methods: Oleuropein was added to the medium of C2C12 myotubes, and then glucose uptake in C2C12 cells was measured. Phosphorylation of Akt and AMP kinase and translocation of GLUT4 was evaluated by western blotting. 3T3-L1 pre-adipocytes were incubated in the presence of oleuropein and the effect on the adipocyte differentiation was assessed by Oil-Red stain. C57BL/6J male mice was divided into three groups and fed by the low-fat diet, high-fat diet, and high-fat including 0.038% of oleuropein for 12 weeks. Oral glucose tolerance test (OGTT) and insulin tolerance test (ITT) were carried out. mRNA levels of target genes were measured by a real time RT-PCR and the localization of GLUT4 in skeletal muscle was analyzed by immunohistochemistry.

Results: Oleuropein promoted the phosphorylation of Akt and AMPK in C2C12 cells. It also increased the plasma membrane expression of GLUT4, resulting in the up-regulation of glucose incorporation. Oleuropein inhibited 3T3-L1 adipocyte differentiation. In animal study, OLE suppressed the body weight gain and improved OGTT and ITT. Immunohistochemistry showed that oleuropein significantly promoted the translocation of GLUT4 to membrane.

Conclusions: Oleuropein improved glucose tolerance of high-fat diet induced obese mice by reduction of adipose tissue and induction of insulin sensitivity in skeletal muscle.

Key words: Oleuropein, Obesity, Glucose tolerance, Insulin sensitivity

PO2870**EFFECT OF SHIMOTSUTO (SI-WU-TANG; CHINESE HERBAL MEDICINE TRADITIONALLY USED IN JAPAN) WITH/ WITHOUT IRON ADMINISTRATION ON IRON DEFICIENT RATS.**

S. Shinoda¹, F. Chen¹

¹Graduate School of Human Health Sciences, Tokyo Metropolitan University, Japan

Background and objectives: Administration of iron is effective for improvement of iron deficiency, but it is concerned about the intake of the long-term supplement giving the risk of the life-style related diseases such as cancers. Iron supplement should be used with low concentration when we take a supplement for a long term, because it may be associated with development of the oxidative stress. Shimotsu-to (Si-Wu-Tang), a Chinese herbal medicine traditionally used in Japan, is used for anemia and a blood vessel symptom, and an anemia improvement effect promotes is expected that our hematopoietic efficacy are raised through up-regulated expression of erythropoietin. Therefore we examined that an anemia improvement effect is accelerated by giving iron and Shimotsu-to at the same time to anemia rats.

Methods: We used crude herbs with definite locality to obtain reproducibility about effect of the Shimotsu-to administration, and first examined the combination ratio and extract conditions of these crude herbs. Wistar male rats were fed iron-free diet based on AIN-93G for 3 weeks to make them anemia. Then anemia rats fed low iron concentrated diet with / without the Shimotsu-to extract, other anemia rats were fed iron-free or AIN-93G diets. For a certain period of time later, the bloods were obtained and we measured a red blood cell count, hematocrit, a serum iron and TIBC. We are measuring serum ferritin and erythropoietin (EPO) concentrations, and EPO mRNA expression in the kidney. Results and

Conclusions: In the anemia rats fed low iron concentrated diet, the red blood cell count, the hematocrit and the serum iron were improved, but lower than the rats fed AIN-93G diet. Shimotsu-to administration with low iron diet slightly improved these measurements.

Key words: Iron deficiency, Shimotsu-to (Si-Wu-Tang), rat, erythropoietin

PO2871**LEAF EXTRACT OF DIETARY BLUEBERRY (VACCINIUM ASHEI READ) PREVENTS FATTY LIVER IN OB/OB MICE**

S. Nishizono¹, K. Nagao², M. Koga², M. Yoshimura², T. Kai³, H. Kataoka⁴, N. Fukuda⁵

²Department of Applied Biochemistry and Food Science, Saga University, Saga, Japan

³Nanaha Co., Miyazaki, Japan

⁴Faculty of Medicine, University of Miyazaki, Miyazaki, Japan

⁵Miyazaki International College, Miyazaki, Japan

Background and objectives: Blueberry (*Vaccinium ashei*), a species of the Ericaceae plant family, has been used in folk medicine for treating lifestyle-related diseases in Asia and Europe. We previously reported that blueberry leaf extract (BLE) exhibits antihypertensive and antidiabetic activities in OLETF rats. Here we examined the preventive effect of BLE on fatty livers in ob/ob mice.

Methods: We cultivated Rabbiteye blueberry plants and harvested their leaves, which were cut into small pieces, freeze dried, and powdered, followed by hot-water treatment; after centrifugation, the supernatant was freeze dried, powdered, and used as BLE. We fed diets with or without BLE to 5-week-old male ob/ob mice. BLE was supplemented at dietary levels of 1% and 3%. The diets were prepared according to the recommendations of AIN-76. After a 4 week-feeding period, we determined the serum and liver lipid levels and the activities of enzymes involved in the synthesis and oxidation of fatty acids. Furthermore, a section of the liver tissues was fixed, embedded, and stained with Hematoxylin-Eosin, and the results were compared with those for the mice fed diets without BLE.

Results: Dietary BLE had no adverse effects on food intake or growth; however, it reduced liver weight in a dose-dependent manner. A dose-dependent liver triglyceride-lowering effect of BLE was found in the ob/ob mice. Histopathological analysis of the hepatic tissues confirmed these findings. BLE showed marginal effect on serum lipid levels. We observed a dose-dependent decrease in the activities of fatty acid synthase, glucose-6-phosphate dehydrogenase, and malic enzyme in the liver of mice fed diets with 1% and 3% BLE; however, carnitine palmitoyltransferase activity remained unchanged.

Conclusions: Dietary BLE exerts beneficial effects on fatty liver in ob/ob mice. Reduced fatty acid synthesis is partly responsible for the triglyceride-lowering activity of BLE in the liver.

Key words: Blueberry leaf, fatty liver, ob/ob mice

PO2872**PHYSICOCHEMICAL PROPERTIES OF PLUKENETIA VOLUBILIS L. SEEDS AND OXIDATIVE STABILITY OF COLD-PRESSED OIL (GREEN NUT OIL)**

T. Emiko¹, S. Shizu², F. Masako¹

¹Graduate School of Human Life Sciences, Showa Women's University, Tokyo, Japan

²Iida Women's Junior College, Nagano, Japan

Background and objectives: The cold-pressed oil from seeds of *P. volubilis* (GNO) has been shown to be rich in omega-3 fatty acid content as well as flaxseed oil and perilla oil. GNO has a high anti-oxidative capacity, suggesting its potential to reduce oxidative damage to DNA. These fatty acids are readily oxidized at high temperatures and UV irradiation, the ways in which they can be used are limited. We, therefore, set out to clarify the physicochemical properties of green nuts. In addition, in order to explore means of consumption, we investigated the oxidation characteristics of GNO and the effects of oxidation on fatty acids.

Methods: General food composition and dietary fiber contents of green nuts were analyzed. The UV-irradiated GNO, flax oil and perilla oil were prepared by pouring Petri dishes and exposing each of these to UV light on a clean bench for 5, 10, 20 or 25 h. Heat-treated oil was prepared Teflon-coated frying pans on electric hobs, followed by heating at 80~180°C for ten minutes. Oil temperature was measured using a digital thermometer. The peroxide value and carbonyl value were determined by chemical methods. Tocopherol content was analyzed by high-speed liquid chromatography. Fatty acid composition was analyzed by gas chromatography. Results and

Conclusions: Food composition of green nuts was similar to that of dried peanuts. However, the dietary fiber content of green nuts is higher than that of peanuts. GNO was stable up to 140°C and exhibited greater UV resistance than flaxseed and perilla oil. It may be related to the 10% lower α -linolenic acid content of GNO when compared with the other two oils, and the presence of α - and γ -tocopherol. GNO can apparently tolerate a certain degree of heat processing.

PO2873**TOTAL IRON AND HEME IRON CONTENT OF SOUTH AFRICAN LEAN MEAT (BEEF, LAMB, PORK AND CHICKEN)***B. Pretorius¹, H.C. Schönfeldt¹, N. Hall¹*¹Institute of Food Nutrition and Well-Being, University of Pretoria, South Africa

Background and objectives:In South Africa, as in most countries, no reference is made to the specific type of iron found in food sources. Animal foods are considered to be good sources of the more bio-available heme iron with less interference from absorption inhibitors. No data on the heme iron content of South African meat is currently available. This study has determined the total (TFe) and heme (HFe) iron content in South African meat. Evidence suggests that significant differences exist in heme content of meats from different species and even between cuts within the same species.

Methods:Triplicate samples of raw commonly consumed meat cuts (lamb, pork and chicken) were obtained from four retail outlets. Nine beef (Bonsmara) carcasses within each of three age groups were directly sourced for analyses. Duplicate analyses were done on muscle only. Total iron was determined by atomic absorption spectrophotometry. Heme iron was determined by an adapted Hornsey method.

Results:Beef (TFe=2.46±0.41; HFe=1.97±0.19) and lamb (TFe=1.65±0.12; HFe=1.26±0.39) meat have the highest total iron (TFe) and heme iron (HFe) content with chicken (TFe=0.75±0.11; HFe=0.57±0.13) and pork (TFe=0.76±0.09; HFe=0.64±0.08) meat having the lowest values. In this study the percentage heme iron (%HFe) for beef (81%) and lamb (75%) meat was within the reported range, but %HFe for chicken (76%) and pork (84%) was higher than reported.

Conclusions:The meats in this study contain higher percentage of heme iron (>75%) than was used in the Monsen model (40%) to estimate iron availability. This indicated that the heme iron value used in the Monsen-equation, and other calculations, should not be a constant value, but should be different for each particular meat type consumed in the diet. Species, cut, as well as, cooking are all factors that might have an influence on the %HFe.

Key words:total iron content, heme iron, non-heme iron

PO2874**FATTY ACID PROFILE OF SOUTH AFRICAN LAMB AND MUTTON***H.C. Schönfeldt¹, N. Hall¹, B. Pretorius¹, S.M. Van Heerden²*¹Institute of Food Nutrition and Well-Being, University of Pretoria, South Africa²Animal Production Institute, Agricultural Research Council, Irene, South Africa

Background and objectives:Essential fatty acids play a part in many metabolic processes, and suggest evidence that low levels of essential fatty acids, or the wrong balance of types of fatty acids, may be a precursor for a number of illnesses such as increased blood cholesterol, heart disease and cancer. A study was conducted to determine the fat and fatty acid composition of South African sheep meat.

Methods:Mutton (n=18) and lamb (n=18) carcasses were selected from two different abattoirs, represented from three different production regions in South Africa. The left side of each carcass was kept raw, while the right sides were cooked prior to analysis. Each cut was cooked whole according to standardised cooking methods to an internal temperature of 70°C. The cuts were dissected into meat (muscle, intermuscular and intramuscular fat), bone and subcutaneous fat (SCF). The fatty acid profile was analysed using a GC method.

Results:Raw lamb contained 6.79g fat, 3.62 SFA, 2.92 MUFA, 0.25 PUFA and 3.37 g omega fatty acids /100g edible portion respectively. Raw mutton contained 7.85g fat, 4.18 SFA, 3.35 MUFA, 0.31 PUFA and 3.78 g omega fatty acids /100g edible portion respectively. Nutrients showing the greatest differences between raw and cooked treatments, were total fat, C16:0 saturated fatty acid (SFA) and C18:1n-7c monounsaturated fatty acid (MUFA).

Conclusions:Sheep meat contributes consistently to the essential fatty acids, linoleic and α -linolenic acids, as well as C20 and C22 polyunsaturated fatty acids. Although humans have the metabolic capacity to synthesize the latter from the n-6 or n-3 precursors from linoleic and α -linolenic acid respectively, an increase in the consumption of C20 and C22 n-3 PUFA's has the potential to overcome the perceived imbalance in the ratio of n-6:n-3 PUFA's in modern diets.

Key words:Sheep meat, fatty acids

PO2875

SECONDARY METABOLITES FROM RUMEX BALCANICUS RECH. HERB AND ROOT EXTRACTS AS POTENTIAL ANTI-INFLAMMATORY AGENTS

E. Svircev¹, D. Orcic¹, K. Balog¹, N. Simin¹, M. Lesjak¹, M. Franciskovic¹, N. Mimica-Dukic¹

¹Department of chemistry, biochemistry and environmental protection, University of Novi Sad Faculty of Sciences, Novi Sad, Serbia

Background and objectives: Rumex species (Polygonaceae) have a great potential for use as a functional food due to their taste and a high content of secondary metabolites, mostly flavonoid C- and O-glycosides, anthraquinones, stilbenes, tannins and phenolic acids. Compared to other Rumex species, data on R. balcanicus chemical composition and bioactivity are scarce. Therefore, our goals were detailed chemical analysis of ethanol extracts from herb and root of R. balcanicus species, widely growing in Balkan region, and evaluation of their anti-inflammatory activities.

Methods: Phytochemical analysis of R. balcanicus extracts included assays for total phenolic, total flavonoid and total anthraquinone content, and LC-MS/MS quantification of 50 phenolic compounds. Anti-inflammatory activity was evaluated by LC-MS/MS monitoring of selected metabolites (12-(S)-HHT, 12(S)-HETE, PGE2, PGF2?, and TXB2) formed in cyclooxygenase and lipoxygenase pathways of arachidonic acid metabolism. Human platelets were used as a source of enzymes, while inflammation was induced by calcimycin.

Results: The obtained results showed that although total phenolic content was similar in herb and root extracts (301±35 vs 324±24mg gallic acid eq./1g d.w.), there is significant difference in total flavonoids (40.2±0.9 vs 1.9±0.6 mg quercetin eq./1g d.w.) and anthraquinones content (17.4 vs 28.9 mg/1g d.w.). Dominant phenolics in herb were quercetin glycosides (up to 3.6% w/w) - quercitrin, rutin and quercetin-3-O-glucoside. Among flavan-3-ols, catechin was dominant in herb, but epicatechin in root extract. The most abundant phenolic acid was gallic acid (1.4 vs 0.7mg/g d.w.). Both herb and root extracts showed dose-dependent inhibition of 12(S)-HETE production (IC₅₀=0.89 and 0.53mg/ml), as well as thromboxan synthase inhibition (IC₅₀(TXB2) = 3.73 vs 0.35 mg/ml).

Conclusions: Root extract, although significantly poor in flavonoids content exhibited higher inhibitory activity towards COX and LOX pathway enzymes than herb extract. Acknowledgements: Ministry of education, science and technological development, Serbia, grant No.172058.

Key words: Rumex balcanicus Rech., phenolics, anti-inflammatory, LC-MS/MS

PO2876

ANTI-INFLAMMATORY PROPERTY AND PHENOLIC PROFILE OF JUNIPERUS COMMUNIS L. 1753 VAR. COMMUNIS NEEDLES AND CONES EXTRACTS

M. Lesjak¹, E. Svircev¹, I. Beara¹, N. Simin¹, M. Franciskovic¹, D. Orcic¹, J. Ristic¹

¹Department of Chemistry, Biochemistry and Environmental Protection, Faculty of Sciences, University of Novi Sad, Serbia

Background and objectives: Juniperus species are well known in traditional medicine and in cooking and alcoholic beverage industries. The unique taste and aroma of cones of J. communis are an indispensable additive in the manufacture of gin, while needles are well known spice with uniquely 'sharp and clear flavour', mainly used for pickling game birds and meat. However, despite great use of Juniperus representatives, most of them have not been described thus far in terms of biological activity and composition. Thus, the aim of this study was to examine anti-inflammatory properties and phenolic profile of methanol extracts of needles and cones of the Juniperus communis L. 1753 var. communis.

Methods: Anti-inflammatory properties of methanol extracts were determined using assays which measure inhibitory potency toward COX-1 and 12-LOX enzymes in human platelets. In applied assay LC-MS/MS technique is used for the quantification of three products (12-HHT, TXB2 and PGE2) of COX-1 and one product (12-HETE) of 12-LOX metabolism. Furthermore, the presence of 44 phenolics in extracts was studied using LC-MS/MS.

Results: Needles have shown greater potency in inhibition of production of examined metabolites of COX-1 and 12-LOX enzymes, compared with cones. Namely, needles were the most potent towards inhibition of PGE2 production (IC₅₀=2.76 mg/mL). Additionally, the most dominant phenolics in needles were rutin and catechin (103.83 and 103.27 mg/g of dw, respectively). However, in cone extract very low content of examined phenolics was determined, with only catechin (4.13 mg/g dw) found in reasonable amount.

Conclusion: According to obtained results examined J. communis, especially its needles, could be regarded as a promising source of bioactive natural compounds, which can be used both as a food supplement and as a remedy. Acknowledgement: The Ministry of Education and Sciences of Republic of Serbia (Grant No.172058).

Key words: Juniperus, anti-inflammatory activity, phenolics

PO2877**PROANTHOCYANIDIN OLIGOMER CONTENT IN DIFFERENT BARLEY VARIETIES**

F. Pasini¹, V. Verardo^{1,2}, A. Garcia-Abelaira¹, A. Gomez-Caravaca^{3,4}, E. Marconi⁵, M.F. Caboni

¹Department of Agro-Food Sciences and Technologies, Alma Mater Studiorum, Università di Bologna, Italy

⁴Functional Food Research and Development Centre (CIDAF), Health Science Technological Park, Granada, Spain

⁵Dipartimento Agricoltura, Ambiente e Alimenti, University of Molise, Campobasso, Italy

Background and objectives: Proanthocyanidins are mixtures of flavan-3-ol units linked mainly via B-type bonds, i.e., C4-C8 or C4-C6 linkages. Occasionally an additional C2-O7 or C2-O5 linkage may exist, leading to doubly bonded A-type. These phenolic compounds are widely present in plants and have been suggested to demonstrate antioxidant, antibacterial, antiviral, anticarcinogenic, anti-inflammatory, and vasodilatory activities. Surprisingly, quantitative information on the proanthocyanidin profiles in plant products is quite lacking, largely due to the absence of appropriate analytical methodology and commercially available standards for oligomers. The study reported here was undertaken to detect and characterise the procyanidins in different type of barley.

Methods: Fourteen barley varieties, four waxy and ten no-waxy, were collected and characterised. Proanthocyanidin compounds were extracted and their separation was performed by normal phase HPLC-FLD-MS.

Results: Monomers, procyanidin and prodelphinidin dimers, trimers, tetramers, and procyanidin pentamers were identified by mass spectrometry and quantified by fluorimetric detection. The total content of proanthocyanidins in barley samples ranged between 29.3 to 65.3 mg/100g. In all samples, the principal components consisting of procyanidin and prodelphinidin trimers with structure (galocatechin-catechin-catechin), followed by the procyanidin dimer and representing on average 19, 17 and 16 % of the total content. With exception of some barleys, monomer content was low. Waxy barley varieties reported the higher content of phenolic compounds compared to no-waxy varieties.

Conclusions: These results established that the barley varieties analysed in this work contain proanthocyanidins from monomer to pentamers and how these oligomers are a mixture of procyanidins and prodelphinidins, consisting mainly of ca-

techin units. Moreover the waxy varieties showed the higher content of proanthocyanidins.

Key words: barley, procyanidins, HPLC, ESI-MS

PO2878**LS-MS DETERMINATION OF ALLIIN IN SELECTED ALLIUM SPECIES**

D. Orcic¹, B. Bozin², N. Simin¹, E. Svircev¹, M. Lesjak¹, I. Beara¹, N. Mimica-Dukic¹

¹Department of Chemistry, Biochemistry and Environmental Protection, Faculty of Sciences, University of Novi Sad, Serbia

²Department of Pharmacy, Medical Faculty, University of Novi Sad, Serbia

Background and objectives: Members of genus *Allium* have been used and cultured for thousands of years for their medicinal properties and characteristic flavor, both originating from the presence of organosulfur compounds. The dominant S-alk(en)yl-L- cysteine sulfoxide in garlic (*Allium sativum* L.) is alliin. To evaluate quality and pharmacological potential of garlic and other *Allium* species a selective and sensitive method for alliin determination is needed. In this study a rapid, and reliable method for alliin quantification was developed, with very simple sample preparation and requiring no derivatisation.

Methods: To avoid degradation of alliin, alliinase activity in *Allium* samples cloves was inhibited by microwave irradiation. The samples were homogenized under extraction solvent (80 % aqueous methanol with 0,05 % HCOOH), filtered, evaporated and redissolved. Extracts were analyzed using reversed-phase high performance liquid chromatography coupled with electrospray ionization triple-quad mass spectrometry. Sample components were separated in 10 min on Zorbax Eclipse Plus C8 rapid-resolution column using gradient elution (0.1 % aqueous formic acid and methanol) and constant flow of 0,4 mL/min. Data acquisition was performed in SIM mode using positive polarity. Alliin concentration was determined by external standard method.

Results: Alliin was detected in all investigated samples (21 hybrids of *A. sativum* L. and four wild-growing species: *A. rotundum* L., *A. vineale* L., *A. ampeloprasum* L., *A. flavum* L.). The content ranged from 8.23 mg per g of irradiated clove to 59,1 mg/g for *A. sativum*, and 0.36-8.61 mg/g for wild-growing species.

Conclusions: The developed LC-MS method was successfully applied for alliin determination. The obtained results indicate that, regarding the alliin content, *A. sativum* possess superior biological potential in comparison to other investigated species.

PO2879

PHYTOCHEMICAL PROFILE AND BIOLOGICAL POTENTIAL OF ALLIUM FUSCUM WALDST. ET KIT VAR. FUSCUM

N. Simin¹, I. Beara¹, K. Balog¹, D. Cetojevic-Simin², M. Lesjak¹, Anackov¹, M. Franciskovic¹

¹Department of Chemistry, Biochemistry and Environmental Protection, Faculty of Sciences, University of Novi Sad, Serbia

²Oncology Institute of Vojvodina, Medical Faculty, University of Novi Sad, Serbia

Background and objectives: Members of the genus *Allium* have been used and cultured for thousands of years as vegetables and herbal remedies. Only two species of genus *Allium* (*A. sativum* L. and *A. cepa* L.) are explored in detail, while data on chemical composition and biological potential of other species, including wild-growing *A. fuscum* Waldst. et Kit var. *fuscum* are very rare. Therefore, the objectives of the present study were to investigate chemical composition, antioxidant, anti-inflammatory and antiproliferative properties of methanolic extract of this species.

Methods: Phytochemical profile was determined by measuring total phenolic, total flavonoid and total anthocyanin contents and by LC-MS/MS analysis of the extracts and headspace GC/MS analysis of fresh bulbs volatiles. The antioxidant activity was evaluated by measuring the effect on lipid peroxidation and by DPPH and NO assays, and anti-inflammatory activity by measuring the inhibitory potential on production of arachidonic acid metabolites in COX-1 and 12-LOX pathways. Antiproliferative activity was tested by sulforhodamine B assay in three cancer cell lines (HT-29, MCF-7 and HeLa) and one healthy cell line (MRC-5).

Results: High contents of total phenolics (11.25 mg gallic acid equiv./g of d.e.), total flavonoids (4.42 mg quercetin equiv./g of d.e.) and total anthocyanins (86.8 µg cyanidine-3-glucoside equiv./g of d.e.) were found. The dominant phenolic compounds in the extract were rutin, quercetin-3-O-Glc, kaempferol-3-O-Glc, isorhamnetin and ferulic acid. Dimethyl-disulphide was detected as the main volatile compound. The extract inhibited both COX-1 and 12-LOX pathways in a dose-dependent manner. Antioxidant activity was weak compared with synthetic antioxidants. The extract expressed moderate, but not selective antiproliferative activity against HeLa and MCF-7 cells.

Conclusions: *A. fuscum* is powerful source of bioactive compounds and good anti-inflammatory agent. Acknowledgements: Ministry of education, science and technological development, Republic of Serbia, grant No. 172058.

Key words: *Allium fuscum*, antioxidant, anti-inflammatory, LC-MS/MS, GC-MS

PO2880

THE PROFILE OF POLYPHENOLS AND ANTIOXIDANT CAPACITY OF SELECTED MEDICINAL PLANTS OF BANGLADESH

N. Shaheen¹, M. Mohiduzzaman¹, C P. Banu¹, A. Basak-Tukun¹, S. Munmun¹, T. Longvah²

¹University of Dhaka, Bangladesh

²National Institute of Nutrition, Jamai Osmania Po Tarnaka, India

Background and objectives: WHO has estimated conservatively that 60 to 90 percent of the populations of the non-industrialized countries, either totally or partially, rely on medicinal plants to meet their health care needs. Over the last decade, the most interested bioactive compounds with health beneficial role has been polyphenols. The objective of this study was to screen total phenol content (TPC), to estimate polyphenol profile and antioxidant capacity (AC) of 15 medicinal plants of Bangladesh.

Methods: Folin-Ciocalteu method, DPPH Inhibition and Simultaneous determination method of all polyphenols had been used for TPC, AC and individual polyphenols respectively.

Results: TPC ranged from 276.85 (*Moringa oleifera*) to 15.45 (*Zanthoxylum rhetsa*) mg per 100g. The % DPPH inhibition in methanol and water extract are high in *Zanthoxylum rhetsa* (92.86) and *Moringa oleifera* (91.87) respectively and they also show the lowest IC₅₀ in corresponding solvent system. The lowest % DPPH inhibition is found in *Spilanthes calva* (24.49) and *Centella asiatica* (4.88) in methanol and water extract respectively. Ten individual polyphenols are screened (Chlorogenic acid, coumaric acid, caffeic acid, apigenin-7-o-neohesperidoside, apigenin, quercetin-3-beta D-glucoside, quercetin-3-o-glucopyranoside, kaempferol, isoramanetin, luteolin). *Amaranthus viridis*, *Spilanthes calva*, *Oxalis corniculata*, *Piper retrofractum*, *Moringa oleifera* contain highest amount of chlorogenic acid, coumaric acid, caffeic acid, apigenin-7-o-neohesperidoside, apigenin respectively. *Senna tora* contain highest amount of quercetin-3-beta D-glucoside, kaempferol and isoramanetin respectively whereas quercetin-3-o-glucopyranoside and luteolin are highest in *Alternanthera sessilis*.

Conclusions: *Moringa oleifera*, with lowest IC₅₀ and highest %DPPH inhibition and TPC, is the most potent antioxidant sample among analyzed samples. Acknowledgement: The authors wish to acknowledge the support received from the Center for Advance Research in Sciences, University of Dhaka, Bangladesh.

Key words: Polyphenol, antioxidant capacity, medicinal plant, DPPH, IC₅₀.

PO2881**PROTECTIVE ROLE OF WHEAT PEPTIDES IN A NON-STEROIDAL ANTI-INFLAMMATORY DRUGS INDUCED STOMACH DAMAGE MODEL RATS***H. Yin¹, F. Liu¹, S. Wang¹, L. Yang¹, G. Sun¹*

¹Key Laboratory of Environmental Medicine and Engineering of Ministry of Education, and Department of Nutrition and Food Hygiene, School of Public Health, Southeast University, Nanning, China

Background and objectives: Non-steroidal anti-inflammatory drugs (NSAIDs) are able to produce tissue damage and oxidative stress in animal models of stomach damage. In this study, the putative protective effect of wheat peptides was evaluated in a NSAID induced stomach damage model in rats.

Methods: Different dose wheat peptides or distilled water were administered daily by intragastric administration for 30 days. On the last day of experiment, NSAIDs (aspirin and indomethacin) or physiological saline were given by intragastric administration. Then the rats were sacrificed by cervical dislocation. The blood sample and stomach were collected. Histologic observation, the MDA, NO, NOS and antioxidase activity levels of stomach were detected. And the expression of mRNAs of mu-opioid receptor in stomach was examined using semi-quantitative reverse transcription polymerase chain reaction (RT-PCR).

Results: Wheat peptides administration decreased gastric epithelial cell degeneration. Oxidative stress and NO level were significantly increased after NSAID infusion and were reduced by wheat peptides. Wheat peptides significantly increased SOD & GSH-Px activity and decreased NOS activity in stomach. Mu-opioid receptor mRNA expression significantly decreased in wheat peptides treated rats than in the model control group.

Conclusions: Non-steroidal anti-inflammatory drugs induced stomach damage in rats and wheat peptides administration may be an effective tool for protecting stomach tissue against NSAID-induced stomach damage and oxidative stress.

PO2882**ANTITUMOR ROLRS OF ESSENTIAL OILS FROM CHRYSANTHEMUM MORIFOLIUM RAMAT***Z. Song¹, F. Zhag¹, L. Yang¹, S. Wang¹, G. Sun¹*

¹Key Laboratory of Environmental Medicine and Engineering of Ministry of Education, and Department of Nutrition and Food Hygiene, School of Public Health, Southeast University, China

Background and objectives: It is essential to screen new medicines that are less toxic, highly effective and provide better management of the cancer. Traditional Chinese medicines have attracted great interest to researchers recent years as alternative anti-cancer therapies. The aim of study is to explore the anti-cancer role of the essential oil from *Chrysanthemum morifolium* Ramat both in vitro and in vivo.

Methods: In vitro, cell proliferation inhibition action on human liver cancer HepG-2 of essential oils extracted from *Chrysanthemum* was examined by MTT method and cell apoptosis was observed using flow cytometry. In vivo, we used S-180 tumor-bearing mice to research antitumor effect of the oils.

Results: The oils showed significant antitumor activity towards HepG-2 cells, with IC₅₀ values 1.4232µl/ml, and increased the apoptotic rates in a dose dependent manner. In addition, the oils inhibited tumor growth of S-180 tumor-bearing mice and the tumor suppressor rate of high dose reached 54.94%. Giving the oils improved the thymus/weight index of tumor-bearing mice which means it increased immune function.

Conclusions: Our findings suggest that the essential oil from *Chrysanthemum morifolium* Ramat has antitumor activity. It is a candidate for exploring new antitumor agents.

PO2883**A STUDY ON TOTAL POLYPHENOLS CONTENT IN SPENT COFFEE EXTRACTS (BLACK, ESPRESSO AND FILTER COFFEE)***M. Ranic¹, M. Pavlovic², S. Siler-Marinkovic², S. Dimitrijevic Brankovic²*

¹Centre of Research Excellence In Nutrition and Metabolism, Institute For Medical Research, University of Belgrade, Serbia

²Faculty of Technology and Metallurgy, University of Belgrade, Serbia

Background and objectives: Evidence of polyphenols role in the prevention of degenerative diseases such as cancer and cardiovascular diseases is emerging. Coffee constitutes one of

the principal sources of polyphenols. As the one of the most popular beverages, coffee is consumed by millions of people all over the world, several times a day. Spent coffee (SC) that is produced in tons by restaurants and cafeterias, and domestic environment, could be a good opportunity to have an important source of polyphenols as a natural antioxidants, also from an economical point of view.

Methods: In this work, microwave-assisted extraction (MAE) has been used as a potential alternative to conventional solvent extraction for the isolation of phenolic compounds from plants, considering certain limitations in terms of extraction time, energy, solvent consumption and cost. Response Surface Methodology (RSM) has been used for monitor the extraction characteristics, as affected by various extraction conditions. 20% solution of ethanol in distilled water was used as solvent. For optimization and statistical analysis Design Expert 8 (Trial version, Stat-Ease, Inc.) was used. Three independent parameters in the extraction were considered: microwave power (240-550W), extraction time (11-209s) and liquid-to-solid ratio (4.76-13.24ml/g). Total phenols were determined by Folin-Ciocalteu reagent.

Results: The total phenolic content, expressed as mg of GAE per g of dry weight, was for black SC 101.450-572.82mg/g, espresso SC 188,270-798,270mg/g and for the filter SC 161,45-558,270mg/g. Corresponding phenolic content in coffee beverage (black, espresso and filter) was 126,455, 144,436 and 109,182mg/g.

Conclusions: This result strongly supports the possibility of exploiting the remaining solid residue of coffee preparation for turning a waste material into a valuable source of phenolic compounds as a natural antioxidants. **Acknowledgment:** This work is funding by the Ministry of Education, Science and Technological Development, Republic of Serbia, Project TR31035.

Key words: polyphenols, spent coffee, MAE, RSM

PO2884

IDENTIFICATION AND QUANTIFICATION OF PHENOLIC COMPOUNDS BY HPLC-DAD-ESI-TOF-MS IN DIFFERENT VARIETIES OF EGGPLANT GROWN AT DIFFERENT SEASONS

P. García Salas^{1,2}, A. Gómez Caravaca^{1,2}, V. Verardo^{3,4}, A. Segura Carretero^{1,2}, A. Fernández Gutierrez^{1,2}

¹Department of Analytical Chemistry, University of Granada, Granada, Spain

²Research and Development of Functional Food Centre (CIDAF), Health Science Technological Park, Granada, Spain

³Inter-Departmental Centre for Agri-Food Industrial Research (CIRI Agroalimentare), University of Bologna, Cesena, Italy

⁴Department of Agro-Food Sciences and Technologies, Alma Mater Studiorum, Università di Bologna, Cesena, Italy

Background and objectives: Eggplant (*Solanum melongena* L.) is an important vegetable for their richness in healthy components such as phenolic compounds. Previous studies have shown that environmental conditions and growing techniques may influence the content in phenolic compounds in plants. Therefore, the aim of this study was the characterization and quantification of phenolic compounds on three eggplant varieties grown at different seasons using HPLC-DAD-ESI-TOF-MS.

Methods: The eggplant samples were crushed and placed on a lyophilizer, which was pre-cooled to -50°C for 1 h at 1 mbar. The extracts were prepared and recovered using methanol: H₂O (80:20, v/v). The analyses of phenolic compounds were carried out by HPLC-DAD-ESI-TOF-MS. The separation was performed with a Poroshell 120 column (EC-C18) and, water with 0.5 % acetic acid and acetonitrile as mobile phases.

Results: Twenty five compounds were identified and quantified by the optimized methodology. Derivates of caffeic, coumaric and ferulic acids, together to delphinidin rutinoside were the major compounds in all varieties of eggplants studied. Chlorogenic acid was the polyphenol found in a highest concentration in all samples, changing in the range 48.16-250.20 µg/g of sample. Furthermore, most phenolic compounds showed significant differences depending on the growing season.

Conclusions: Results obtained have shown that there is a high variability among the content of phenolic compounds in eggplants from different varieties. Besides, samples grown in summer possessed a higher concentration of phenolic compounds than those grown during the cold season. These findings are due to high temperatures that cause stress to the plants and, thus, eggplants accumulate higher concentrations of secondary metabolites such as polyphenols. The control of

the growing season of eggplants will be of interest for food industry due to the benefits of polyphenols in health.

Key words: eggplant, phenolic compounds, HPLC, mass spectrometry, season.

PO2885

DATE FRUIT AND SEED: FIBER, SUGAR, TEXTURE, AND COLOR PROFILES OF EIGHTEEN VARIETIES

H. Habib¹, H. Kamal¹, C. Platat¹, A. Al-awad², I. Abd El Haliem³, W. Ibrahim¹

¹Department of Nutrition and Health, College of Food and Agriculture, United Arab Emirates University, Al Ain, UAE

²Department of Aridland Agriculture, College of Food and Agriculture, United Arab Emirates University, Al Ain, UAE

³Department of Food Science, College of Food and Agriculture, United Arab Emirates University, Al Ain, UAE

Background and objectives: Date is enjoyed as a fruit and is considered as a basic food commodity in many regions of the world. Date paste came into existence as a storage option for the surplus production of dates, this product is now being used as an ingredient in a few products, but the knowledge is still limited. Same is the case with date pits, which are treated as a by-product. The purpose of this study was to analyze the texture, fiber, color and sugar composition.

Methods: The eighteen date, date paste and date seed varieties were analyzed for their texture, fiber, color and sugar composition.

Results: hardness of the whole date (flesh) decreased considerably during conversion of date paste and the solid rubbery structure has been changed to leathery stage with lower hardness, but increased levels of gumminess and cohesiveness. In comparison to date paste, the insoluble fiber comprising of ADF, NDF, cellulose, hemicellulose and lignin were found in great magnitudes in all the date seed varieties. Date paste varieties had higher values of “L”, “a” and “b” Invert sugars, glucose (22.42±/−3.25) and fructose (28.98±/−2.84) were found dominant, however, sucrose content was found very low (1.37±/−0.39) in all the eighteen varieties of date paste. Our study, also focused on the sugar content of date seeds and results concluded presence of fructose (0.46±/−0.35), glucose (0.77±/−0.02), sucrose (0.47±/−0.16) and maltose (0.54±/−0.11).

Conclusions: Date pits had a higher content of ADF, NDF, cellulose, hemicellulose and lignin in comparison to date paste, so that the most interesting aspect of the study was the possibility of use the date pits as a proper functioning ingredient in the manufacturing of other products.

Key words: Date, Texture, Fiber, Sugar, Color

PO2886

THE ABSORPTION AND THE FATE OF METABOLISM OF BIOACTIVE DIETARY BENZOXAZINOID IN MAMMALS

K B. Adhikari¹, H N. Lærke², B M. Jensen³, H J. Schnoor³, L K. Poulsen³, I S. Fomsgaard¹

²Department of Animal Science, Aarhus University, Slagelse, Denmark

³Allergy Clinic, Copenhagen University Hospital - Gentofte, Denmark

Background and objectives: Benzoxazinoids are a group of bioactive phytochemicals mostly limited in cereals. In addition to allelopathic effects, benzoxazinoids contain a range of potential pharmacological properties and health-promoting effects including anticancer, immunoregulatory, antimicrobial, antinociceptive, aphrodisiac, appetite suppression, weight reduction, central nervous system stimulating, and reproductive system stimulating activities. These chemicals were recently found in mature cereal grains and bakery products making them interesting compounds from nutritional point of view. Relating the daily consumption of 50 g of rye bread (the major wholegrain product in Northern and Eastern European Countries), the daily total benzoxazinoids intake through a specific brand of wholegrain rye bread can be estimated to be higher than 5 mg/d. However, there is a paucity of information regarding the absorption, distribution, metabolism, and elimination of these bioactive dietary compounds in mammals.

Methods: We fed benzoxazinoids containing rye bread-based diet to pigs (n=6), rats (n=6), and humans (n=20) and analyzed the content of benzoxazinoids and their potential metabolites in plasma, urine, bile, and feces using LC-MS/MS.

Results: The most dominant dietary benzoxazinoid 2- α -D-glucopyranosyloxy-4-hydroxy-1,4-benzoxazin-3-one (DIBOA-glc) was apparently reduced to 2- α -D-glucopyranosyloxy-1,4-benzoxazin-3-one (HBOA-glc), the most dominant circulating benzoxazinoid in the plasma in all three experiments. HBOA-glc being the most dominant urinary benzoxazinoids, 8 different benzoxazinoids and their derivatives including some glucuronide and sulfate conjugates were excreted through the urine.

Conclusions: These studies revealed for the first time that bioactive benzoxazinoids in rye bread are highly bioavailable in mammals including humans. These unprecedented results indicated that benzoxazinoids could be one of the key ingredients contributing to the overall health effects of whole grain consumption.

Key words: Benzoxazinoids, bioactive, metabolism, rye

PO2887**EFFECT OF BIFIDOBACTERIUM ANIMALIS SSP. LACTIS BF-6 (LMG 24384) YOGURT ON COLONIC TRANSIT TIME IN HEALTHY ADULT FEMALES**

⁴DSM Food Specialties B.V., Heerlen, NL (Corporate Headquarters)

⁵Department of Food Science, The Pennsylvania State University, University Park, PA, US

Background and objectives: Probiotics have the potential for therapeutic effects on gastrointestinal health. Several strains of bifidobacteria have been investigated for their possible improvements on gastrointestinal function. This study investigated the effect of *Bifidobacterium animalis ssp. lactis* Bf-6 (LMG 24384) supplemented yogurt versus placebo yogurt on colonic transit time.

Methods: A triple-blinded, randomized, placebo-controlled, two-period crossover trial was conducted with 68 adult women with a self-reported history of straining during bowel movements or hard or lumpy stools in the past two years. Women were generally healthy and not actively constipated due to regulatory requirements for probiotic studies. After a two-week run-in period, both Bf-6 and placebo yogurts were given to all participants for fourteen days each in a randomized order, with a six-week washout period between treatments. The primary outcome, colonic transit time, was assessed using a simplified segmental colonic transit technique via Sitz marker X-rays.

Results: The average colonic transit times observed in this study was 42.1 hours for the active period and 43.1 hours for control period (mean difference of 1.2 hours, 95% confidence interval: -4.9, 7.4). Few adverse events were reported and there were no significant differences in adverse events for the active and control periods.

Conclusions: The analysis showed no significant differences between the active and control groups during the crossover trial. Bf-6 appears to be safe and further trials should be conducted in populations with underlying diseases, as there is a greater chance of probiotic impact in a diseased state.

Key words: probiotics; gastrointestinal function; gastrointestinal transit; crossover trials

PO2888**APPETITE AND FOOD INTAKE AFTER CONSUMPTION OF SAUSAGES WITH 10% FAT AND ADDED WHEAT OR RYE BRAN**

S. Vuholm¹, L.M. Jakobsen¹, K.V. Sørensen¹, U. Kehlet², A. Raben¹, M. Kristensen¹

¹Department of Nutrition, Exercise and Sports, Faculty of Science, University of Copenhagen, Frederiksberg, Denmark

²Danish Meat Research Institute, Danish Technological Institute, Roskilde, Denmark

Background and objectives: The use of dietary fibers in sausages gives less energy-dense and thereby healthier foods. Also, dietary fibers have been shown to induce satiety. The objective of this study was to investigate if addition of rye or wheat bran to sausages with 10% (w/w) fat induced satiety and if the effect was affected by the source of dietary fiber used or by food matrix in which the dietary fibers were incorporated.

Methods: This randomized cross-over study in 25 young men compared four test meals each consisting of three sausages and a bread. The test meals contained ~10g fiber per meal and differed in the source of dietary fiber and in the food matrix of the dietary fibers given the four test meals; wheat flour sausages (WFS), wheat bran sausages (WBS), rye bran sausages (RBS) and rye bran bread (RBB). The meals were served after an overnight fast and appetite ratings, evaluated by visual analogue scales (VAS), were assessed for 240 minutes followed by an ad libitum lunch meal where energy intake (EI) was assessed.

Results: Both RBS and WBS increased satiety ($p < 0.01$) and fullness ($p < 0.02$) and decreased hunger ($p < 0.001$) and prospective intake ($p < 0.001$) compared to WFS. The effect of RBS tended to be higher than the effect of WBS but did not differ significantly. RBS furthermore increased satiety ($p < 0.05$) and fullness ($p < 0.02$) and decreased prospective intake ($p < 0.01$) compared to RBB. No effect on EI was observed.

Conclusions: Addition of wheat or rye bran to sausages with 10% fat proofed decreased appetite sensations and has thereby potential added health benefits. Additionally the satiating effect of dietary fibers appears to be more pronounced when added to sausages than when added to bread, stressing the importance of food matrix and food processing.

Key words: Rye bran; Wheat bran; Sausages; Appetite; Energy intake

PO2889

DETERMINATION AND COMPARISON OF PHENOLIC COMPOUNDS IN LEAVES FROM SIX IMPORTANT VARIETIES OF OLEA EUROPAEA L TREES BY HPLC -DAD-TOF-MS.

N. Talhaoui^{1,2}, A. Gómez-Caravaca^{1,2}, L. León³, R. de la Rosa³, A. Segura-Carretero^{1,2}, A. Fernández-Gutiérrez^{1,2}

¹Department of Analytical Chemistry, University of Granada, Granada, Spain

²Functional Food Research and Development Centre (CIDAF), Health Science Technological Park, Granada, Spain

³IFAPA Centro Alameda del Obispo, Córdoba, Spain

Background and objectives: The therapeutic benefits of olive leaves (*Olea europaea* L.) have been claimed by Mediterranean's countries and explored for many centuries. These potential health benefits of olive leaves are mostly related to low molecular weight polyphenols. The characterization of their polyphenols is one of the first steps to evaluate the contribution of the olive to human health. Thus, differences between the phenolic compounds in olive leaves from different cultivars have been examined.

Methods: Leaves from six important olive cultivars: 'Arbequina', 'Arbosana', 'Changlot Real', 'Koroneiki', 'Picual' and 'Sikitita', grown under the same agronomic and ambiental conditions from the same olive orchards were used. Samples were collected in the middle of June, transferred to the laboratory, dried outdoors and processed. Analyses were carried out by HPLC-DAD-(microTOF) MS with a Poroshell 120 EC-C18 analytical column.

Results: Thirty phenolic compounds were identified and quantified being oleuropein and elenolic acid the most important. Significant differences between varieties were observed for all the compounds. 'Arbosana' leaves showed the highest concentration of phenolic compounds while no big differences were observed among the other varieties. 'Arbosana' leaves also presented the highest level of oleuropein and elenolic acid: 20.69 mg/g leaf and 14.19 mg/g leaf, respectively; whereas 'Arbequina' showed the lowest concentration of oleuropein, 17.08 mg/g leaf, and 'Sikitita' the lowest quantity of elenolic acid 3.53 mg/g leaf.

Conclusions: Cultivars showing the highest levels of phenolic compounds as 'Arbosana' could be used as a source of phenolic compounds in pharmaceutical and food industry. Further work will be carried out for monitoring the evolution of phenolic compounds across the growth period.

Key words: Olive leaves, phenolic compounds, HPLC-DAD-TOF-MS.

PO2890

OXIDATIVE STABILIZATION OF LINSEED OIL BY INDUSTRIAL GRAPE (VITIS VINIFERA, L.) BY-PRODUCTS

¹Research & Development Department, Dulcinea Nutricion SL, Puertollano, Spain

²Department of Novel Food Production and Characterization, Institute of Food Science Research (CIAL-CSIC-UAM), Madrid, Spain

Background and objectives: The omega-3 polyunsaturated essential fatty acids are a recognized supplement in biofunctional food formulations. Their main current natural source is fish oil, but its use presents some limitations: it is a potential allergen, contains cholesterol and frequently, traces of heavy metals and it has unpleasant odour. The objective of this work was to study some alternative natural sources and procedures for replacement of the fish oil omega-3 fatty acids and the synthetic antioxidants used in functional food formulations by other alternative sources, such as linseed oil and extracts from industrially available grape by-products.

Methods: The grape by-product was obtained at industrial scale by drying of grape pomace (*Vitis vinifera* L.) with hot air and separation of the seeds by sieving. The "seedless" fraction contained grape skins, stalks, leaves and seeds (63%, 26%, 9% and 2%, dry weight, respectively). Ultrasound-assisted extraction or maceration with shaking at 60 °C in ethyl butyrate, ethyl acetate, ethanol and ethanol:water 80:20 (v/v) were performed. Antioxidant capacity was determined by the 2,2-diphenyl-1-picrylhydrazyl (DPPH) and Rancimat assays, and polyphenols, by the Folin-Ciocalteu method. The qualitative composition on polyphenols, carotenoids and chlorophylls was studied by HPLC-Photodiode Array Detector.

Results: The highest Efficient Concentration (EC100) and polyphenol content values were found in the extract obtained at 60 °C with ethanol:water (576.4 micromol Trolox/g and 90.1 mg gallic acid/g, respectively) and ethanol (341.2 micromol Trolox/g and 58.2 mg gallic acid/g, respectively).

Conclusions: The ethanol grape extract obtained at 60 °C showed the highest stabilization effect of the linseed oil at a ratio of 15% (w/w), increasing 3-fold its induction period (from 4.16 to 12.6 h under Rancimat conditions: 100 °C and a flow rate of 20 L/h).

Key words: omega-3, grape antioxidants, linseed oil.

MICROBIOLOGICAL, CHEMICAL AND SENSORY CHARACTERISTICS OF NEWLY DESIGNED SYMBIOTIC FERMENTED BEVERAGES DURING STORAGE

G. Kunova¹, I. Lisova¹, I. Bohacenko², J. Pinkrova², M. Pechacova¹

¹Dairy Research Institute Prague, Czech Republic

²Food Research Institute Prague, Czech Republic

Background and objectives: The aim of this work was to design new symbiotic fermented beverages. According to the international standards at least one million viable cells of probiotic bacteria per gram of product until the end of the warranty is required. The recommended daily dose of fructans to ensure prebiotic properties is 4-6 g per product.

Methods: A storage test (30 days at 4-6 °C) was conducted while in 7-day intervals the following parameters were monitored: a) bacterial counts, b) pH, c) prebiotic content, d) sensory evaluation. Probiotic strains: *Bifidobacterium animalis* subsp. *lactis* CCDM 94, *Lactobacillus rhamnosus* CCDM 150, *Enterococcus durans* CCDM 922 Starter culture: CCDM 17 (containing strains *Lactococcus lactis* subsp. *cremoris*, *Lactococcus lactis* subsp. *lactis*, *Lactococcus lactis* subsp. *diacetylactis*). All strains originate from the Culture Collection of Dairy Microorganisms Laktoflora, Czech Republic. Commercially available prebiotic formula on the basis of fructooligosaccharides - Orafti P95 (oligofructose ≥ 93.2%, BENEEO, Belgium) was used. Fructan content was measured using HPLC method, bacterial counts were determined by plate method.

Results: In all samples the bacterial counts during storage test decreased, while a slight steadily decrease without significant fluctuations, both in the case of probiotics as well as for the basic culture was observed. Fructooligosaccharide content remained constant during storage. A slight decrease in pH of beverages during storage was detected, which significantly decreased in the first 14 days.

Conclusions: In all samples the viable counts of microorganisms in the end of the storage test was higher than 6,0 log cfu/ml, fructooligosaccharide content remained unchanged and all samples were evaluated very positively from a sensory point of view. The study was supported by the Ministry of Agriculture, Czech Republic (Grant No. QI91B274).

Key words: probiotic, fructans, fermented beverages, storage

PO2892

EFFECTS OF APLYSIN ON THE APOPTOSIS OF HUMAN BREAST CANCER FCM-7 CELL

H. Liang¹, Y. Liu¹, N. Ge¹, A. Ma¹

¹The Institution of Human Nutrition, Medical College, Qingdao University, Shandong, China

Background and objectives: To investigate the effects of Aplysin on the apoptosis of human breast cancer FCM-7 cell in vitro.

Methods: The apoptosis of FCM-7 cell lines were determined by MTT assay. Cell cycle and positive rate of proliferation cell nuclear antigen (PCNA) apoptosis associated protein Fas and Bcl-2 and intracellular calcium ions (IE Ca²⁺) levels were measured by flow cytometry.

Results: Aplysin could decrease the proliferation significantly in a dose-dependent manner in FCM-7 cell. The IC₂₅ and IC₅₀ of Aplysin on FCM-7 cell for 48h were 28.3 and 31.9mg/L. When treating FCM-7 with Aplysin in concentration of 10, 20, 40mg/L for 48h, the growth of the cell was obviously inhibited, typical apoptosis sub-diploid peak was found, and the apoptotic rates of FCM-7 were 10.8%, 23.9% and 33.6%, respectively, which was significantly higher than 1.83% that in control group (P<0.05). And cellular quantity increased from 59.3±2.27% to 79.5±2.37% at G₀/G₁ phase, respectively, which was significantly higher than 48.6±2.92% that in control group, meanwhile, cellular quantity decreased from 27.3±1.63% to 15.0±1.34% at S phase, respectively, which was significantly lower than 31.5±1.72% that in control group (P<0.05), cell cycle was arrested in G₀/G₁ phase. Compared with control group, Aplysin groups could effectively increase Fas expression and IE Ca²⁺ levels, and inhibited the expressions of PCNA and Bcl-2 significantly in FCM-7 cells (P <0.05).

Conclusions: Aplysin can inhibit the proliferation and induces apoptosis of FCM-7 cells.

Key words: Aplysin; FCM-7 Cell; Apoptosis

PO2893

EFFECTS OF APLYSIN ON THE TUMOR GROWTH AND EXPRESSION OF VEGF AND PCNA IN H22 MICE

H. Liang¹, Y. Liu¹, N. Ge¹, A. Ma¹

¹The Institution of Human Nutrition, Medical College, Qingdao University, Shandong, China

Background and objectives: To investigate the effects of Aplysin on the tumor growth and expression of VEGF and PCNA in H22 mice.

Methods: KM mice were randomly divided into five groups: the model group, the Aplysin groups (25, 50, 100 µg/kg/d), the cyclophosphamide control group and each group had ten mice. H22 Cells were inoculated subcutaneously into left anteromedial of KM mice. Animals of four groups (except the model group) were treated with ig Aplysin of different dosage and pi CTX on the second day and executed after 15 days. We weighed the tumor which was stripped completely and calculated the tumor inhibition rate. Simultaneously the expression of VEGF and PCNA in tumor tissue was determined by immunohistochemistry.

Results: In vivo, the increase of H22 tumor weight in the Aplysin groups was slower than that in model group ($P < 0.05$), and the tumor inhibition rate was 28.3%, 33.8%, 42.9% respectively. The treatment with mid and high-dose Aplysin inhibited the expression of VEGF ($P < 0.05$), while there is no significant changes in low-dose group. Different dose Aplysin inhibited the expression of PCNA within tumor ($P < 0.05$).

Conclusions: Aplysin inhibits tumor growth possessing higher tumor inhibition rate. The depressant effect may be related with inhibiting the expression of VEGF, PCNA in H22 tumor.

Key words: Aplysin; H22 cell; VEGF; PCNA; Mice

PO2894

UPLC-ESI-Q-TOF-MS FOR CHARACTERIZATION OF PHENOLIC AND OTHER POLAR COMPOUNDS IN LOQUAT (ERIOBOTRYA JAPONICA L.) FRUIT EXTRACT

A. Morales-Soto^{1,2}, A. Segura-Carretero^{1,2}, A. Fernández-Gutiérrez^{1,2}

¹Department of Analytical Chemistry, University of Granada, Granada, Spain

²Functional Food Research and Development Centre (CIDAF), Health Science Technological Park, Granada, Spain

Background and objectives: Loquat (*Eriobotrya japonica* L.) belongs to Rosaceae family and it probably had its origin in south-eastern China. Currently, it is also cultivated in the Mediterranean area, amongst other regions. Both loquat fruit and leaf are often included in Chinese herbal remedies for cough and asthma as the latter contains many phenolics and some triterpenes which exhibit anticancer, anti-inflammation and hypoglycemic effects. Therefore, due to the important role that these naturally occurring antioxidants play in human health, the aim of the present work was to reveal the phenolic profile of the loquat edible portion.

Methods: In order to characterize the polyphenolic compounds in an extract of *Eriobotrya japonica* L. cultivated in Andalucía, a simple and rapid method was developed. This method used Reversed-Phase Ultra-Performance Liquid Chromatography coupled to Electrospray Ionization Quadrupole Time-of-Flight Mass Spectrometry (RP-UPLC-ESI-Q-TOF-MS).

Results: The accuracy of mass data generated by Q-TOF-MS together with the fragmentation pattern of the full scan run of MS/MS analysis have been an useful tool to tentatively characterize many well-known phenolic compounds such as glycosylated species of flavonols (Kaempferol-3-O-rhamnoside) and phenolic acids such as p-hydroxybenzoic acid glucoside. Other polar compounds such as quinic acid, citramalic acid and pyridoxine were also identified.

Conclusions: In conclusion, data reveals that loquat is qualitatively an abundant source of phenolic compounds.

Key words: *Eriobotrya japonica* L.; loquat; phenolic compound; UPLC-ESI-Q-TOF-MS.

PO2895

COMPARATIVE STUDY OF ANTIOXIDANT ACTIVITY OF THIRTEEN VEGETABLE SAMPLES CULTIVATED IN ANDALUCÍA

A. Morales-Soto^{1,2}, C. Rodríguez-Pérez^{1,2}, P. García-Salas^{1,2}, C. Jiménez-Sánchez^{1,2}, M. Cádiz-Gurrea^{1,2}, A. Segura-Carretero^{1,2}, A. Fernández-Gutiérrez^{1,2}

¹Department of Analytical Chemistry, University of Granada, Granada, Spain

²Functional Food Research and Development Centre (CIDAF), Health Science Technological Park, Granada, Spain

Background and objectives: The Mediterranean diet is characterised for a high consumption of fruits and vegetables. Specifically, in the region of Andalucía vegetable cultivation is particularly important. The intake of these vegetables supposes an important health-protecting factor because of their antioxidant activity, amongst other biological effects. Since the antioxidant activity of phytochemicals present in the diet has been of increasing interest in recent years, the whole aim of this work is to give a better understanding about the antioxidant activity of some typical Mediterranean vegetables cultivated in Andalucía.

Methods: The antioxidant activity of thirteen vegetable samples has been studied. These included different varieties of asparagus, tomato, onion, garlic, artichoke, carrot, lettuce, green bean, fava bean, pepper, eggplant, zucchini and potato. Three different assays were employed: Trolox Equivalent An-

tioxidant Capacity (TEAC), Ferric Ion Reducing Antioxidant Power (FRAP) and Oxygen Radical Absorbance Capacity (ORAC).

Results: According to ORAC assay, samples that showed the highest antioxidant capacity were red onion, asparagus and red garlic, in this order. Red onion showed also the highest results for TEAC and FRAPS assays. However, according to TEAC and FRAP assays, the second and third-highest results were achieved with tender onion and asparagus, in this order.

Conclusions: The antioxidant capacity of different typical Mediterranean vegetables cultivated in Andalucía was determined and related to their antioxidant content to render their antioxidant potential more comprehensive.

Key words: Mediterranean vegetables; antioxidant activity; ORAC; TEAC; FRAP.

PO2896

BIOACTIVE COMPOUNDS IN DEFATTED DABAI PERICARP FOR INHIBITION OF OXIDATIVE STRESS BIOMARKERS IN HYPERCHOLESTEROLEMIC RABBITS

H.E. Khoo¹, A. Azlan^{1,2}, F.H. Shakirin³, A. Ismail^{1,2}

¹Department of Nutrition and Dietetics, Faculty of Medicine and Health Sciences, Universiti Putra Malaysia, UPM Serdang, Selangor, Malaysia

²Laboratory of Halal Science Research, Halal Products Research Institute, Universiti Putra Malaysia, UPM Serdang, Selangor, Malaysia

³Department of Biochemistry, Faculty of Biotechnology and Biomolecular Sciences, Universiti Putra Malaysia, UPM Serdang, Selangor, Malaysia

Background and objectives: Dabai fruit, scientifically known as *Canarium odontophyllum* is a potential source of nutraceutical. The antioxidant-rich purplish defatted dabai pericarp as waste of future dabai oil industry is potentially used as pharmaceutical ingredient for cardio-protection. This study aims to determine the effect of defatted dabai supplementation on oxidative stress biomarkers in high cholesterol-induced rabbits.

Methods: A total of 28 healthy rabbits were divided into four groups (n=7 in each group). A group of hypercholesterolemic rabbits were treated with 50 g defatted dabai pericarp per kg body weight daily for 8 weeks, while a statin group and two control groups (normal and hypercholesterolemic) were used for comparison. Plasma total antioxidant status (TAS), plasma malonaldehyde (MDA) and cellular antioxidant enzymes (SOD, GPx and catalase) of the rabbits were determined after 8 weeks of experiment.

Results: Results show that all groups showed significant reduction in plasma TAS and increment of plasma MDA except the group treated with defatted dabai pericarp that showed significant increment in plasma TAS and no significant increment in plasma MDA when compared to baseline. The normal rabbits had significant reduction in cellular SOD and GPx activities with no changes found for catalase activity. The group supplemented with defatted dabai pericarp showed significant up-regulations of SOD and catalase enzymes, but reduced GPx activity. Treatment with simvastatin was found to down-regulate the antioxidant enzymes except catalase, while treatment with defatted dabai pericarp (antioxidant-rich) showed further reduction in SOD activity in the group compared to non-treated hypercholesterolemic group.

Conclusions: Reduction in plasma MDA together with high increment in plasma TAS of the tested model indicates protective effect of the defatted dabai pericarp supplementation, thus offer beneficial cardio-protection.

Key words: antioxidant enzyme, dabai, hypercholesterolemic, malonaldehyde, oxidative stress

PO2897

ISOLATION AND CHARACTERIZATION OF EXOPOLYSACCHARIDE PRODUCED BY *LACTOBACILLUS REUTERI* FY-004

C.Y. Hu¹, H.H. Chuang¹, Y.C. Chen², H.L. Chan², C.H. Chien³, C.M. Shih³

¹Dept. of Nutrition and Health Science, Fooyin University, Kaohsiung City, Taiwan

²Dept. of Biological Science and Technology, National Pingtung University of Science and Technology, Kaohsiung City, Taiwan

³Dept. of Nutrition and Health Science, Fooyin University, Kaohsiung City, Taiwan

Background and objectives: Probiotics, food-grade organisms, are capable of producing extracellular polysaccharide (Exopolysaccharide, EPS), which contribute to functions such as preventing dyspepsia, antitumor, anti-allergy of human, and inhibition the growth of food-poisoning microbe.

Methods: We screened proper probiotics from infant's feces and fermented vegetable, and we used *Bifidobacterium longum* BCRC14634 from BCRC as a standard strain. After cell absorbing test, Gram stain, milk coagulating test, catalase test, acid and Bile salt tolerance test, we screened and purified effective organ. We also separated and purify EPS. As to EPS detection, we used phenol-sulfuric acid method to determine the quantity of EPS. We purified EPS by molecular sieving column and anion exchange chromatography, and determined its molecule weight by S-200 size-exclusion chromatography.

Results: The result of 16S rDNA sequence comparison results are showing with the same species, and the first one is *Pediococcus pentosaceus* FY-001, the second is *Enterococcus faecalis* Fy-002, the third is *Lactobacillus fermentum* Fy-003, the fourth is *Lactobacillus reuteri* Fy-004. We chose *Lactobacillus reuteri* Fy-004 to be our target species as to its high productivity and biological activity of EPS. The EPS fraction was composed of a single high-molecular-mass polymer of 4.6×10^5 Da containing glucose, fructose and rhamnose.

Conclusions: The results revealed beneficial physiological effects of exopolysaccharide from probiotics, such as antidiabetic, immunomodulative and anti-inflammatory properties.

Key words: Probiotics, Exopolysaccharide (EPS), Identification, Chromatography

PO2898

CLINICAL ANTI-OBESITY EFFECT BY ADMINISTRATION OF CARNITINE AND SYNEPHRINE CONTAINING DRINK

Y C. Shen¹, Y L. Wang¹, S Y. Jin¹, C H. Yen¹, J T. Chen¹, Y H. Yeha¹, C K. Wang¹

¹Chung Shan Medical University, Taichung, Taiwan

Background and objectives: Obesity is a serious health problem in developed countries and the prevalence of obesity has been increasing dramatically for several decades. The Carnitine and Synephrine, have been a variety of studies which are decreased body fat. This study was to investigate the Carnitine and Synephrine containing drink regulation of body fat in BMI > 27 or body fat > 30% subjects.

Methods: This was a randomized, placebo controlled, double blind design. 35 subjects (20 to 65 years) were enrolled and randomly divided into two groups. The trial total was 8 weeks. Anthropometric measurements and blood collection were given at initial, 3rd, 6th, and 8th week, including weight, body fat, and blood lipid profile.

Results: The results revealed that weight and BMI were significantly reduced ($p < 0.05$), and body fat was decreased 0.9% compared with placebo, and total cholesterol in plasma was greatly reduced 3.8% after administration of Carnitine and Synephrine containing drink.

Conclusions: These results suggested that the Carnitine and Synephrine containing drink could be down-regulation of weight and body fat.

Key words: Carnitine, Synephrine, body fat.

PO2899

COMPARATIVE STUDY OF RESVERATROL, POLYPHENOLIC CONTENT AND RELATIVE ANTIOXIDANT CAPACITY OF ROMANIAN RED WINES

L. Filip¹, R. Banc¹, D. Hanganu¹, D. Benedec¹, A. Cozma¹, D. Miere¹

¹University of Medicine and Pharmacy 'Iuliu Hatieganu' Cluj-Napoca, Romania

Background and objectives: Romanian viticulture is characterized by tradition, progress and quality. Romanian wines produced from foreign and domestic grapes were positively evaluated at various competitions in the field. Their quality is not only organoleptic but it also related to their composition giving the wines to potential to exert a human health benefits.

Methods: To prove this we have analyzed 65 samples of wine produced in different wine-growing regions of Romania, in which we determined the concentrations of trans- and cis-resveratrol, the total polyphenolic compounds and the antioxidant activity. We are using a sensitive, high throughput liquid chromatography coupled with mass spectrometry method (LC-MS/MS) for resveratrol determination. The total phenolic compounds (TPC) were determined using modified Folin-Ciocalteu method. The antioxidant capacity was tested by DPPH method, BHT was used as standard control and the capability of samples to scavenge DPPH was expressed as percentage values.

Results: The biggest average quantity of resveratrol was found in the wine obtained from the Pinot Noir variety: 0.893 micrograms/ml, followed by Cabernet Sauvignon, Merlot and Feteasca Neagra varieties. All antioxidant activity values obtained were highly correlated with total polyphenol and resveratrol content.

Conclusions: It turned out that local varieties such as Feteasca Neagra si Babeasca neagra have a high content of polyphenols and antioxidant shows comparable with the other red wine varieties known in Europe.

Key words: red wine, resveratrol, polyphenol, antioxidant capacity

PO2900**LPS-BINDING CAPACITY OF FRUIT PROANTHOCYANIDINS.**

K. Tralma¹, C. Arbulo², C. Carrasco¹, E. Pastene², M. Goteland¹

¹Department of Nutrition, Faculty of Medicine, University of Chile, Santiago, Chile

²Laboratory of Pharmacognosy, University of Concepción, Concepción, Chile

Background and objectives: The lipopolysaccharide (LPS) originated from gram-negative bacteria belonging to the intestinal microbiota has been recently proposed as a key factor in the development of metabolic endotoxemia and low grade inflammation, frequently associated with metabolic syndrome and its complication. Proanthocyanidins (PACs) are phenolic compounds abundant in fruits which display antioxidant activity and are involved in the protection against non-transmissible chronic diseases. In a first step to elucidate whether dietary PACs may interfere with intestinal absorption of LPS, the aim of the study was to determine the in vitro LPS-binding capacity of fractionated PACs obtained from cranberry and avocado (A-type PACs), and apple and grape (B-type PACs).

Methods: Fruit PACs were fractionated according to their molecular weight by adsorption chromatography on Sephadex LH-20 and semipreparative diol-phase HILIC-HPLC columns. Polymerization degrees and structure features were subsequently carried out by phloroglucinolysis and mass spectrometry, respectively. The LPS-binding capacity was evaluated by incubating LPS-FITC with polymyxin B conjugated to agarose beads, in the presence or absence of PACs fractions. Unbound LPS-FITC was removed and the remaining fluorescence determined in a Synergy HT Microplate Reader.

Results: The most efficient PAC fraction in inhibiting LPS binding to polymyxin-agarose beads was the Low Molecular Weight Fraction and the crude extract from avocado (IC₅₀=27.0µg/ml and 30.1µg/ml, respectively), followed by the High Molecular Weight Fractions from cranberry (IC₅₀=40,5µg/mL), apple (IC₅₀=86.1µg/ml) and avocado (IC₅₀=97.6µg/ml).

Conclusions: Dietary PACs from avocado and cranberry seems to be particularly interesting in their ability to bind LPS, suggesting that these bioactive compounds may interfere with endotoxin absorption in the intestinal lumen, contributing to the protective effect of PACs against non-transmissible chronic diseases. Supported by Fondecyt 1120290.

Key words: Proanthocyanidins; lipopolysaccharide; non transmissible chronic diseases; metabolic endotoxemia

PO2901**ANTIOXIDANT AND PROOXIDANT ACTIVITY OF ESSENTIAL OIL OF GARLIC BY ELECTRON SPIN RESONANCE IN PORK PATTIES**

G. Nieto Martínez^{1,2}, L.Skibsted², M. Andersen², G. Ros¹

¹Department of Food Science and Technology, Veterinary Faculty/ University of Murcia, Espinardo, Spain

²Department of Food Science/ University of Copenhagen, Copenhagen, Denmark

Background and objectives: The aim of this study was to study the antioxidant and prooxidant activity of the essential oil of garlic (AE) and the AE added at doses of 0.05 % (A1) and 0.4% (A2) in pork patties packaged in aerobic conditions and stored in refrigeration during 6 days.

Methods: For that, the antioxidant activity of the AE in a model system (Fenton reaction), and in burgers with ESR (electron spin resonance) by free radical formation during heating at 55 °C and its binding to PBN (p-fenil-N-tert-butilnitrona) on days 0, 3 and 6 of storage was studied.

Results: The results showed that AE showed prooxidant effect at phenol concentration ≥ 1.6 mg GAE/L. In patties A1, the radical formation after 3 hours of heating at 55° C was significantly lower (P <0.05%) than in control samples (C) and A2 throughout the storage. In contrast, burgers treated with 0.4% of AE showed that radical formation was higher (P <0.05%) than C and A1, therefore, the higher level of AE showed a prooxidant effect.

Conclusions: The results indicate that the use of 0.05% essential oil of garlic, as a natural antioxidant in pork burgers, being a good strategy of conservation.

Key words: Garlic; Essential oil; Patties; Antioxidant; Prooxidant.

PO2902**EFFECT OF THE ADMINISTRATION OF A MILK PRODUCT CONTAINING A HEAT-TREATED PROBIOTIC AND A PREBIOTIC IN PRESCHOOL CHILDREN**

M L. Mizgier¹, J. Brignardello¹, P. Morales¹, C. Carvallo¹, M J. Cires¹, S. Cruchet¹, G. Prioult², J. Benyacoub³, R. Mukherjee⁴, D. Henriquez¹, M. Gotteland¹, O. Brunser¹

¹Institute of Nutrition and Food Technology (INTA), University of Chile

²Nestlé Product Technology Center, Konolfingen, Switzerland

³Nestlé Research Center, Lausanne, Switzerland

⁴Clinical Development Unit-Nestlé, Lausanne, Switzerland

Background and objectives: Some heat-treated probiotics, such as *Lactobacillus johnsonii* La1, retain immunomodulating capacity in vitro and in in vivo preclinical models. However overall data in humans are scarce. The aim of this study was to investigate the effect of a non-fermented milk product containing a heat-treated La1 (HTLa1) and a fructooligosaccharides prebiotic (FOS:Inulin) on immune functions and fecal microbiota of preschool children.

Methods: randomized, double-blind, multicentric, placebo-controlled clinical trial carried out in 282 children from 5 day-care centers. The test group received for two months 2x200ml/d of a product containing HTLa1 and FOS-inulin; the control group received the same product without probiotics and HT probiotic. Acute respiratory infections and diarrhea were registered along the study. Salivary and stool samples were collected at baseline and at the end of treatment. Salivary SIgA and β -defensin-1, and fecal SIgA and β -defensin-2 were assessed by ELISA. Fecal concentrations of *Bifidobacterium*, *Bacteroides* and *Lactobacillus* were determined by qPCR.

Results: dropout rate was 25.9% (73/282). No significant adverse events were reported and no differences in the incidence of diarrhea were observed between the groups. The incidence of upper respiratory infections was slightly lower in the test group, 19.8% vs 26.2 % in the controls (not significant). Salivary and fecal concentrations of SIgA were not affected by HTLa1+FOS:inulin nor was that of β -defensin 2 in feces. Saliva β -defensin-1 concentrations decreased along time in both groups. However, this decrease was significantly less pronounced in the treated group. No differences in the fecal bacterial populations were observed.

Conclusions: These exploratory data suggest that the administration of a HTLa1+FOS:inulin does not significantly affect the salivary and fecal defense factors in children although a rather maintenance effect on salivary β -defensin-1 was observed. The clinical meaning of such effect deserves further investigation.

Key words: Heat-treated probiotic; children; β -defensins; secretory IgA; microbiota.

PO2903**WATERMELON LYCOPENE AGAINST DIET INDUCED HYPERCHOLESTEROLEMIA**

A. Naz¹, M. Butt¹, I. Pasha¹

¹National Institute of Food Science and Technology, University of Agriculture, Faisalabad, Pakistan

Background and objectives: Contemporary dietary patterns have strengthened the notion of functional/nutraceutical foods to ameliorate various lifestyle related disorders. In developing economies like Pakistan, use of phytonutrients based designer foods is a pragmatic approach to support nutrition and ultimately health. In this relation, watermelon (*Citrullus lanatus*) is considered as one of the promising source of nutraceuticals especially lycopene. The current study was tailored to assess the therapeutic worth of watermelon lycopene to cope with diet induced hypercholesterolemia.

Methods: For the purpose, cholesterol, low density lipoprotein (LDL), high density lipoprotein (HDL) and triglycerides (TG) were assessed in hypercholesterolemic and hyperglycemic states of body. Lycopene based functional/nutraceutical drinks T1 (whole watermelon juice), T2 (watermelon strawberry blend+lycopene), T3 (lycopene supplemented watermelon juice) & T0 (control) was given to experimental rats throughout the eight week study period. The efficacy assessment was conducted in Sprague Dawley rats as study I (normal rats), study II (hypercholesterolemic rats) and study III (hyperglycemic rats).

Results: The provision of lycopene based functional/nutraceutical drinks caused a significant reduction in serum cholesterol, LDL and triglycerides whilst, a noticeable rise was recorded for HDL. The highest decline in cholesterol was noticed as 5.99 to 6.74% (study I), 12.20 to 13.16% (study II) and 8.12 to 9.02% (study III) T3 followed by T2, T1 and T0. Likewise, a pronounced decrease in serum LDL and triglycerides was assessed in T3 groups. In contrary, the rise in HDL was observed in groups relied on therapeutic drinks.

Conclusions: In the nutshell, diet induced hypercholesterolemia and allied health claims can be prevented with oral provision of lycopene. Lycopene based watermelon juice proved effective to manage dyslipidemia. Further, lycopene based therapeutic food has ability to manage serum lipid within normal range by inhibiting the in vivo cholesterol synthesis.

Key words: Watermelon, Lycopene, Functional/Nutraceutical, Cholesterol, LDL

PO2904**CAROTENOID AND POLYPHENOL PROFILES OF CABBAGE AND PLUM VARIETIES AND THEIR CONTRIBUTION TO TOTAL ANTIOXIDANT CAPACITY***A. Kaulmann¹, Y.J. Schneider², L. Hoffmann¹, T. Bohn¹*

¹Centre de Recherche Public - Gabriel Lippmann, Environment and Agro-biotechnologies Department, Belvaux, Luxembourg

²Institut des Sciences de la Vie, Université catholique de Louvain, Louvain-la-Neuve, Belgium

Background and objectives: Diets rich in fruits and vegetables are recommended by health organizations such as the WHO. However, it is poorly understood which compounds in fruits/vegetables are the most bioactive with respect to beneficial health effects. Carotenoids and polyphenols constitute important classes of phytochemicals possessing both anti-oxidative properties and may further influence gene expression. A disturbance of the prooxidant-antioxidant-balance could lead to oxidative stress and inflammation, major factors associated with chronic diseases such as ulcerative colitis and diabetes.

Objectives and Methods: We investigated the contribution of two major groups of vegetables/fruits (cabbage, plums), to total dietary carotenoid and polyphenol intake. Plum (n=17) and 27 cabbage varieties from Luxembourg were investigated for their individual polyphenol and carotenoid profile (UPLC), vitamin C, micro-macronutrient content, and their association with markers of antioxidant capacity. Antioxidant capacity was determined via the FRAP and ABTS tests, vitamin C was measured via Tillmann's reaction.

Results: Total carotenoid and polyphenol content varied considerably between the different cabbage/plum varieties, with highest concentrations in Kale (13.3±0.58 mg/100g FW) and in Cherry plums (1.96±0.28 mg/100g) for carotenoids; and Kale (27.0±0.91 mg/100g) and Kirks plums (151±14 mg/100g) for polyphenols. In multiple linear regression models, flavonoids, neochlorogenic acid and vitamin C were the best predictors of antioxidant capacity as assessed by ABTS (beta = 0.582, 0.238 and 0.224, R² = 0.831) and flavonoids, anthocyanins, lutein and vitamin C as assessed by FRAP in cabbage (beta = 0.258, 0.580, 0.272 and 0.310, R² = 0.832), while for plums these were selenium, total sugars, chlorogenic acid and vitamin C for ABTS (beta = 0.535, 0.405, 0.254 and 0.276, R² = 0.853) and selenium, chlorogenic acid and flavonoids for FRAP (beta = 0.424, 0.384 and 0.386, R² = 0.711).

Conclusions: Cabbage and plum antioxidant activity was best explained by several, not a single class of constituents, and the type of test used influenced results. It is estimated that cabbage and plums contribute to an antioxidant intake equivalent to 26.3 and 6 mg/day of ascorbic acid equivalents, respectively.

Key words: antioxidant capacity, carotenoids, polyphenols

PO2905**SETTING UP MODELS FOR STUDYING THE EFFECT OF DIETARY MINERALS ON BIOAVAILABILITY ASPECTS OF CAROTENOIDS***J. Corte-Real¹, E. Richling², L. Hoffmann¹, T. Bohn¹*

¹Centre de Recherche Public Gabriel Lippmann, Belvaux, Luxembourg

²Department of Chemistry, Division of Food Chemistry and Toxicology, University of Kaiserslautern, Kaiserslautern, Germany

Background and objectives: While data on carotenoid intake is available, much less is known on factors impacting their bioavailability. Some dietary factors known to alter carotenoid uptake/absorption include dietary lipids and fibre. A factor that so far has received little attention is dietary minerals and trace elements. In our previous results, employing an in-vitro digestion system coupled with a Caco-2 cellular epithelial model, a negative impact of high concentrations of calcium, magnesium, iron and zinc on carotenoid micellization and cellular uptake was found, with reductions on cellular uptake as high as 90%.

Objectives and methods: In this study we further investigate: a) physico-chemical characteristics of the digesta, e.g. micelle formation, by simulated gastro-intestinal digestion, using various emulsifying vehicles; b) the interaction between carotenoids and minerals at various concentrations, employing a Caco-2/HT-29 co-culture cell model; c) human postprandial absorption of carotenoids from kale in the presence of a high calcium supplement.

Results: Following in-vitro digestions of 60mg isolated beta-carotene, digesta particle size distribution in the aqueous phase, analysed by Nanoparticle Tracking Analysis using a NanoSight NS500 (Amesbury, UK), in combination with filtration trials at various cut-off sizes (20, 200nm) revealed incomplete embedding of beta-carotene into mixed micelle formation, with rather large particles being formed (90% around 50-200nm). Canola-oil appeared to be the best vehicle for carotenoid micellization (51%), also showing the least losses of beta-carotene after filtration (micellization 26%) when compared to milk (micellization 4%), where losses after filtration reached >90%.

Conclusions: Optimization of digestion parameters to obtain physiological mixed micelles is paramount. As mixed micelles have a diameter of approximately 8nm, we suggest that in future digestion models, a 20nm filtration should be included after digestion, to prevent over-estimation of carotenoid micellization and to remove particles that might be toxic for cellular cultures.

Key words: carotenoids; in-vitro digestion model; human trial; Caco-2/HT29

PO2906**PREBIOTIC EFFECT OF A FORMULA SUPPLEMENTED WITH GALACTO-OLIGOSACCHARIDES IN TERM INFANTS: A RANDOMIZED MULTICENTER TRIAL.**

⁶Unit of Biostatistics, Epidemiology and Public Health, Department of Cardiac, Thoracic and Vascular Sciences, University of Padova, Italy

⁷AAT-Advanced Analytical Technologies S.r.l., Piacenza, Italy

Background and objectives: There is accumulating evidence that human milk oligosaccharides play a crucial role on the intestinal microbiota. The principal objective was to demonstrate in healthy term infants the effect of a Galacto-oligosaccharides (GOS) supplemented infant formula (0.4g/100mL) in stimulating prebiotic effect.

Methods: This was a randomized, double blind, controlled, clinical trial performed by 6 centers in Italy. Three groups were considered: breast milk, GOS supplemented infant formula (study formula) and standard infant formula (control formula). Study and control formula were supplied by Heinz Italia S.p.A. (Latina, Italy). Anthropometric parameters were recorded at: baseline visit (B) within 15 days after birth, visit V1 (30 ± 10 days of life), visit V2 (60 ± 10 days of life), visit V3 (90 ± 10 days of life), visit V4 (120 ± 10 days of life) and final visit (Vf), before the introduction of complementary feeding. A fecal sample was collected at B, V1, V2 and Vf. Bifidobacteria, Lactobacilli, Clostridium, Escherichia coli were evaluated. Total bacterial DNA was extracted from faecal samples and subsequent qPCR analysis was performed.

Results: A total of 199 breast fed infants and 163 formula fed (80 in the control group and 83 in the study group) were recruited. All three groups showed appropriate physical development throughout the period. Study formula presented normal and soft stools in the majority of episodes (89%). Ratio between

Clostridium count and Bifidobacteria and Lactobacilli count was significantly more favourable when considering the study formula group with respect to the control one during the entire follow up (P=0.02).

Conclusions: Our study showed that the GOS supplemented formula mimicked the effect of human milk in promoting Bifidobacteria and Lactobacilli growth as well as in inhibiting Clostridium. This trial is registered with ClinicalTrials.gov, number NCT00486148.

Key words: GOS, formula, prebiotic, Clostridium, bifidogenic activity.

PO2907**DETERMINATION OF ANTI OXIDATIVE OF INDO-NESESIAN FOOD (KEMOJO CAKE)**

I.Y. Puri¹

¹Department of community nutrition, public health faculty, Andalas University, Indonesia

Background and objectives: Kemojo cake could be additional food program for elementary school students. Unfortunately, kemojo cake have not analyzed of nutrient label yet. Pandan, corn and durian are good source of antioxidant. The content of antioxidant of pandan leaf powder is higher than fresh form. To inform nutrient of kemojo cake. It is a communication between producer and consumer. To analyze antioxidant of kemojo cake. To promote traditional food as additional food program for elementary school and at International.

Methods: The study analyze eight samples kemojo cake before and after cooking which was determined by H-ORAC acid B Method. The basic ingredients are egg, flour, sugar, and coconut milk. Samples are dried by freeze dry system. Scaling the samples are in order to compare the weight before and after freeze dry system. After that, samples should be milled and extracted.

Results : There were almost the same result between first and second extraction which spawned durian had the huge antioxidant (8.13 µmol TE/gr) and it was followed by pandan which had antioxidant 7.62 µmol TE/gr. The lowest of antioxidant was corn which had 4.14 µmol TE/gr in 1 gram.

Conclusions: antioxidant capacity of food increased after cooking process than before cooking. It is shown that thermal processing at high temperature for 25 min significantly elevated the total antioxidant activity

Acknowledgement: Special appreciation is extended to all instructors of Department food function and labeling of National Institute of Health and Nutrition, Toyama, Shinjuku, Tokyo, Japan especially Jun Takebayashi, Ph.D and Yoshiko Ishimi, Ph.D.

Key words: kemojo cake, antioxidant, H-ORAC Method

PO2909**THE POSSIBILITY OF USING BIOLOGICAL ACTIVITY SUBSTANCES AND SWEETENERS IN COOKIES***D. Górecka¹, P. Komolka¹, K. Dziedzic¹*¹Poznan University of Life Sciences, Poznań, Poland

Background and objectives: In recent years consumer interest in biologically active substances, including dietary fiber and inulin has increased. These substances play an important role in the prevention of diet-related diseases. Sweeteners are another kind of functional substances, allowing for production of foods with reduced sugar content. The aim of this study was to assess the use of buckwheat hulls and buckwheat flour, inulin and sugar substitutes in pastry goods.

Methods: Buckwheat flour was used as a partial replacement for wheat flour at the level of 25% (oat cookies - CO), 60% (muffins - M) and 40% (sunflower cookies - CS). Inulin was used as a fat substitute at the level of 50%; aspartame and acesulfame K were used as a sugar substitute in M and CS cookies, but in oat cookies 50% of sugar was replaced by brown sugar. Buckwheat hulls, chokeberry and mulberry extracts were also used. The content of protein, lipids, carbohydrates, ash and total dietary fiber (TDF), soluble dietary fiber and insoluble dietary fiber was determined.

Results: Cookies with buckwheat hulls and flour contained much more protein (16% - CO, 45% - CS and 50% - M), ash (20% - CO, 11.5% - CS and 33% - M) and TDF (22% - CO, 78% CS and 550% M), but much less lipids (18% - CO, 17% - CS and 39% - M) in comparison with the control samples. The dominant fraction of TDF in all cookies was the insoluble fraction.

Conclusions: Substitution of flour by buckwheat flour and sugar by sweeteners in cookies' recipe is one of the possibilities to increase biological activity substances content in our diet and reduce of the caloric value of products.

Key words: cookies, buckwheat flour, sweeteners, dietary fiber

PO2910**GLYCOMACROPEPTIDE: A NEW DIETARY OPTION FOR IMPROVING PHENYLKETONURIA(PKU) DIET COMPLIANCE***S. Edalati¹, F. bagherzadeh¹*¹Students' Research Committee, Faculty of Health & Nutrition, Tabriz University of Medical Sciences, Tabriz, Iran

Background and objectives: Phenylketonuria (PKU) is a genetic metabolic disorder in which a defective liver enzyme cannot metabolize phenylalanine (Phe), an amino acid found

in many foods. Elevated Phe levels affect the cognitive and psychological profiles of PKU patients. PKU can be treated with a life-long low-protein diet, but maintaining compliance to the diet is difficult. Several new options for the life-long nutritional management of PKU have been proposed in recent years. Glycomacropeptide (GMP) is a protein derived from cheese whey that is rich in specific essential amino acids, but in its purified form, is free of tyrosine, tryptophan and phenylalanine and could therefore provide an alternative protein source for PKU individuals. A variety of foods or beverages can be made with GMP. This review focus on recent advances and studies about GMP, its safety and its potential benefits to PKU patients.

Key words: Phenylketonuria, Glycomacropeptide, functional food

PO2911**GYNURA FORMOSANA EXTRACT DECREASES SERUM URIC ACID AND URINE ALBUMIN IN MICE FED WITH HIGH-FAT DIET***H.M. Shaw¹, M.S. Wang¹, M.H. Tsai¹, S.C. Hung¹*¹Department of Health and Nutrition, Chia-Nan University of Pharmacy and Science, Taiwan

Background and objectives: *Gynura formosana* is a folk medicine in Taiwan used as a hypoglycemic agent. Obesity is a risk factor for type 2 diabetes mellitus and also is linked with chronic kidney disease. This study is to examine whether *Gynura formosana* show protective effect on kidney in obese mice induced by high-fat diet.

Methods: Four groups of male C57BL/6j mice were fed for 10 weeks with a control diet (5% fat, C), a high fat diet (35% fat, HF), or a high fat diet with 0.1% (G1) or with 0.5% (G2) *Gynura formosana* extract. The body weight, adipose tissues mass, serum lipids, uric acid, adiponectin and urine albumin were measured.

Results: The body weight, adipose tissue mass and the levels of serum uric acid and urine albumin were significantly increased in HF compared to the control group. In G2 group, the body weight, the relative weight of epididymal fat (EP) and retroperitoneal fat (RE) were significantly reduced to be respectively 88%, 75% and 70% of HF group. However, the adiponectin levels in G2 group showed 1.2-fold higher than that in HF group. The plasma uric acid and urine albumin were significantly decreased by *Gynura formosana* extract both with 0.1% or 0.5% in diet.

Conclusions: We conclude that a high fat diet increased body weight, adipose tissue mass, and hyperuricemia in mice and these effects can be reduced by *Gynura formosana* extract. *Gynura formosana* extract might have the renal protective effect in obese mice induced by high fat diet.

Key words: *Gynura formosana*, adipose tissue, uric acid, albumin

PO2912**POLYPHENOLS PROFILE AND ANTIOXIDANT CAPACITY OF SELECTED MEDICINAL PLANTS OF BANGLADESH**

N. Shaheen¹, M. Mohiduzzaman¹, C P. Banu¹, A. Basak Tukun¹, S. Munmun¹, S. Islam¹, T. Longvah²

¹Institute of Nutrition and Food Science, University of Dhaka, Dhaka, Bangladesh

²National Institute of Nutrition, JamaiOsmania Po-Tarnaka, Hyderabad, India

Background and objectives: Over the last few decades, medicinal plants with varying bioactive compounds of diverse health beneficial roles have been of major interest in the field of functional food science. The mostly pronounced bioactive compound from these plants has been polyphenols. This study aimed at assessing total phenolic content (TPC), polyphenols profile and antioxidant capacity (AC) of 15 comparatively under-utilized medicinal plants in Bangladesh.

Methods: Folin-Ciocalteu method and DPPH Inhibition, respectively, were employed for TPC and AC together with simultaneous determination of individual polyphenols through HPLC.

Results: TPC ranged from 276.85 (*Moringa oleifera*) to 15.45 (*Zanthoxylum rhetsa*) mg per 100g. The highest % DPPH inhibition in methanol extract was found for *Zanthoxylum rhetsa* (92.86) and in water extract for *Moringa oleifera* (91.87) those also showed the lowest IC₅₀ in corresponding solvent systems. The lowest % DPPH inhibition in methanol extract was found for *Spilanthes calva* (24.49) and in water extract for *Centella asiatica* (4.88). Ten individual polyphenols including Chlorogenic acid, coumaric acid, caffeic acid, apigenin-7-*o*-neohesperidoside, apigenin, quercetin-3- β -D-glucoside, quercetin-3-*o*-glucopyranoside, kaempferol, isoramanetin and luteolin were assessed. *Amaranthus viridis*, *Spilanthes calva*, *Oxalis corniculata*, *Piper retrofractum*, *Moringa oleifera* contained highest amount of chlorogenic acid, coumaric acid, caffeic acid, apigenin-7-*o*-neohesperidoside, apigenin respectively. *Senna tora* contained highest amount of quercetin-3- β -D-glucoside, kaempferol and isoramanetin respectively whereas quercetin-3-*o*-glucopyranoside and luteolin were highest in *Alternanthera sessilis*.

Conclusions: *Moringa oleifera*, with the lowest IC₅₀ and highest %DPPH inhibition and TPC, was found to be the most potent source of antioxidants for free radical scavenging capacity. The authors acknowledge the support provided by the National Institute of Nutrition, Hyderabad, India and the Center for Advanced Research in Sciences (CARS), University of Dhaka, Bangladesh.

Key words: Polyphenols, antioxidant capacity, medicinal plants, DPPH, IC₅₀.

PO2913**MINERAL AVAILABILITY OF INFANT FORMULAS SUPPLEMENTED WITH LACTOFERRIN AND / OR GOS AFTER IN VITRO GASTROINTESTINAL DIGESTION**

E. Aly¹, C. Frontela¹, C. Martínez¹, G. Ros¹

¹Department of Food Science and Nutrition, Faculty of Veterinary Sciences, Regional Campus of International Excellence "Campus Mare Nostrum", University of Murcia, Spain

Background and objectives: Infant formulas play pivotal role in the nutrition, especially 4-6 months after birth when nutritional requirements can no longer be met by breast-milk alone. Although human milk is the first choice for the newborn infants, infant formulas have been designed to provide with the required nutrients for optimal growth and development. Recently, the infant formulas are designed to contain the bioactive components present in human milk such as lactoferrin (Lf) and galactooligosaccharides (GOS) because of its functional roles. Lf improves the absorption of important minerals such as iron and calcium. In this study we determine the functionality of Lf and GOS added to infant formulas on mineral absorption using in vitro simulation of gastrointestinal digestion.

Methods: An in vitro solubility method was applied to infant formulas supplemented with Lf (0.1%, 0.15% and 0.2 %) and / or GOS (3.3%, 5% and 10%). The content of Ca, Fe, Mg, Zn, K, P and Mn of samples and soluble fractions were analyzed by using the inductively coupled plasma.

Results: The addition of Lf and GOS to formulas led to an increase on the mineral content in the soluble fractions. The presence of Lf and GOS in the same formulas had the best effect on Ca, P and Fe solubility (%). Meanwhile, no significant effect of Lf and GOS was observed in Mn, Zn and K solubility (%). Results indicate an increase on the bioaccessibility of essential minerals when infant formulas are supplemented with Lf and GOS.

Conclusions: The addition of Lf and / or GOS has a beneficial effect on mineral bioaccessibility indicating a possible role of Lf and GOS in enhancing the mineral bioavailability. In vivo studies are needed to further evaluate Lf and GOS as supplementation of infant formulas.

Key words: Lactoferrin, GOS, formula, minerals, solubility.

PO2914**INULIN AND FOS INHIBIT E. COLI INVASION OF INTESTINAL EPITHELIAL CELLS VIA ACTIONS ON BOTH BACTERIA AND EUKARYOTIC CELLS**

C J. Aranda¹, B. Ocón², M D. Suárez³, A. Zarzuelo⁴, F. Sánchez de Medina⁴, O. Martínez-Augustin³

¹Department of Biochemistry and Molecular Biology II, School of Pharmacy, University of Granada, Granada, Spain

²Department of Pharmacology, School of Pharmacy, University of Granada, Granada, Spain

³Department of Biochemistry and Molecular Biology II, CIBERehd, School of Pharmacy, University of Granada, Granada, Spain⁴Department of Pharmacology, CIBERehd, School of Pharmacy, University of Granada, Granada, Spain

Background and objectives: The non absorbable glucids inulin (INU) and fructooligosaccharides (FOS) are well known for their prebiotic properties, i.e. the capacity to favor the selective growth of host-friendly bacteria. Both FOS and INU have been ascribed therapeutic activities, including protection against intestinal inflammation and metabolic syndrome. In fact, these products are currently added to infant formulas to emulate human milk composition. In addition to their prebiotic qualities, oligosaccharides have direct effects on the intestinal mucosa. Here we describe the protection of model intestinal epithelia against bacterial invasion by FOS and INU.

Methods: In vitro invasion assays were carried out in IEC18 cell monolayers exposed to GFP-transformed *Escherichia coli* on the apical side at a 1:100 ratio for 4 hours. Bacteria were measured by flow cytometry analysis as GFP-positive events in the cell homogenate. Both enteroinvasive (LF82) and nonenteroinvasive (K12) strains were used. Two concentrations of each oligosaccharide (5 g/l and 10 g/l) were studied. In addition, *E. coli* biofilm formation assays were adapted from a microtiter plate protocol (Appl. Environ. Microb. 2002;68:6).

Results: FOS shows a 70% and 45% inhibition of LF82 invasion at 10 and 5 g/l, respectively ($p < 0.001$) INU only achieved a 30% inhibition ($p < 0.001$). By changing the experimental conditions (timing of oligosaccharides exposure and co-exposure to bacteria and oligosaccharides) it was estimated that almost 75% of the inhibitory effect was attributable to actions on bacteria, and the other 25% to enhancement of epithelial defense. There was no effect on bacterial growth. However, LF82 biofilm formation was inhibited by both products by 36% at 5 g/l and 50% at 10 g/l ($p < 0.001$).

Conclusions: Both INU and especially FOS reduce epithelial invasion by enteroinvasive *E. coli* by actions that involve bacteria and epithelial cells.

Key words: AIEC, Prebiotic, epithelial invasion, IEC18 cells

PO2915**EFFECTS OF UNSAPONIFIABLE MATERIALS IN RICE BRAN OIL ON SERUM CHOLESTEROL LEVELS IN RATS**

E. Tsuji¹, M. Takahashi², M. Tsuji³, S. Kinoshita⁴, C. Yamanaoka¹, T. Ishikawa¹, K. Tsuji⁵

¹Department of Nutrition and Life Science, Kanagawa Institute of Technology, Atsugi-city, Kanagawa, Japan

³Department of Health and Nutrition, University of Human Arts and Sciences, Saitama-city, Saitama, Japan

⁴Department of Health System Management, Hyogo University, Kakogawa-city, Hyogo, Japan

⁵Department of Food and Health Science, Ibaraki Christian University, Hitachi-city, Ibaraki, Japan

Background and objectives: Rice bran oil (R) lowers plasma cholesterol levels more effectively than other commonly used vegetable oils. R is characterized by a relatively high content of unsaponifiable materials (USM) of non-fatty acid components such as sterols (S), β -Oryzanol (O) and tocopherol families. The cholesterol lowering ability of R seems to be due to the contents of USM especially O. In this study, the effects of different contents of O and more additive of S on serum cholesterol levels were studied.

Methods: Male Sprague-Dawley rats were fed a hypercholesterolemic diet containing cholesterol and sodium cholate in the plural experiments of 3 or 4 weeks period. Dietary lipid sources were lard or soybean oil in the control group, in the experimental groups normal R, low or high level of O in R and commercial S added (1.0%, 2.0%) to R were used.

Results: There were no differences in the body weight of the rats between the control and the experimental groups in each experiment. In all experimental groups, serum TC level of R and added S, low or high O level groups were markedly decreased compared to each control group. Serum HDL cholesterol level significantly increased in the R and all experimental S or O group than the control group. Then we investigated whether the amount of S or O in R caused these effects. No differences in serum TC level according to the amount of S or O were found. From these results the correlation of serum TC level with all kinds of USM were examined. It was shown the lowering effect of TC correlate with tocotrienol content.

Conclusions: R is preferable for regulating lipid metabolism and is beneficial for promoting our health.

Key words: Rice bran oil, Serum Cholesterol, Unsaponifiable materials, Tocotrienol

PO2916**HYDROPHILIC ANTIOXIDANT CAPACITIES OF VEGETABLES AND FRUITS COMMONLY CONSUMED IN JAPAN AND ESTIMATION OF DAILY INTAKE**

⁵Department of Nutritional Epidemiology, National Institute of Health and Nutrition, Toyama, Shinjuku-ku, Tokyo, Japan

⁶Fujioil Co., Ltd., Mita, Minato-ku, Tokyo, Japan

Background and objectives: Dietary antioxidants are considered important elements for human body to prevent free-radical-related diseases and aging, but sum of antioxidants enough to maintain health is still unclear. As a first step to address this issue, hydrophilic antioxidant capacities of vegetables and fruits commonly consumed in Japan were measured and daily intakes were estimated in this study.

Methods: The hydrophilic antioxidant capacities of 23 vegetables and 13 fruits commonly consumed in Japan were evaluated by a modified hydrophilic-oxygen radical absorbance capacity (H-ORAC) method. The average daily intake was estimated from these H-ORAC values and food intake data of the National Health and Nutrition Survey in Japan for 2005-2009.

Results: The H-ORAC values for vegetables ranged from 1.63 to 66.07 (average 6.95) micromol Trolox equivalent (TE)/g and the H-ORAC values for fruits ranged from 1.58 to 33.47 (average 12.23) micromol TE/g. The daily intake of hydrophilic antioxidants from vegetables and fruits was estimated to be 4423 micromol TE/d (2967 micromol TE from vegetables and 1456 micromol TE from fruits). In addition, the comparison of the results of the H-ORAC assay with those of polyphenol content and 1,1-diphenyl-2-picrylhydrazyl (DPPH) assay was also studied. The H-ORAC values had a strong positive correlation with polyphenol contents ($r = 0.956$), and were 1.0-18.2-times higher than the antioxidant capacities evaluated by the DPPH assay.

Conclusions: The daily intake of hydrophilic antioxidants from vegetables and fruits in Japanese was estimated to be 4423 micromol TE/d. However, the biological significance of this va-

lue has not yet been clarified. The H-ORAC values obtained here will provide a foundation for high-quality epidemiological studies aimed at elucidating the relationship between daily intake of antioxidants and health.

Key words: Antioxidant; Hydrophilic-oxygen radical absorbance capacity (H-ORAC) assay; Daily intake; Vegetables and fruits.

PO2917**INFLUENCE OF BIFIDOBACTERIUM LONGUM CECT 7347 IN LIVER IRON MOBILIZATION AND INFLAMMATORY BIOMARKERS PRODUCTION IN A GLUTEN-INDUCED ENTEROPATHY ANIMAL MODEL**

J. M. Laparra Llopis¹, M. Olivares Sevilla¹, Y. Sanz Herranz¹

¹Institute of Agrochemistry and Food Technology, Paterna, Spain

Objectives and study: To evaluate the influence of orally administered *Bifidobacterium longum* CECT 7347 on nutritional iron status of weanling animals with gliadin-induced enteropathy.

Methods: Weanling rats, sensitized with interferon (IFN)- γ , were fed gliadins alone or with *B. longum* CECT 7347. Hemoglobin (Hb) concentration (Drabkin's), liver transferrin receptor (TfR)-2, interleukin (IL)-6 and TNF- α expression (mRNA), active hepcidin peptide production (LC-Ms/Ms) and total liver iron content (Atomic Absorption Spectrometry) were determined.

Results: Gliadin feeding increased hepatic iron deposition and reduced serum Hb concentrations in comparison with control animals. These observations were accompanied by decreased TfR2 expression and increased IL-6 and TNF- α gene expression. However, *B. longum* CECT 7347 administration to this animal model increased circulating Hb concentration and reduced iron deposition in the liver. *B. longum* administration also increased TfR2, IL-6 and TNF- α gene expression in comparison with IFN- γ sensitized animals fed gliadins. A similar trend was observed in hepcidin peptide production.

Conclusions: Animal with gliadin-induced enteropathy had reduced serum Hb concentrations in comparison with controls, demonstrating the enteropathy-associated iron deficiency. However, administration of *B. longum* CECT 7347 increased the expression levels of TfR2, and contributing to restoring normal liver iron and serum Hb concentrations. Although both TfR2 and IL-6 are involved in hepcidin regulation, their action seems to be dependent on iron serum levels.

Key words: Celiac, bifidobacteria, gliadin, iron, enteropathy.

PO2918**DETERMINATION OF GLUTATHIONE AND ITS DERIVATIVES IN HUMAN BLOOD AFTER ORAL ADMINISTRATION**

E Y. Park¹, N. Shimura¹, T. Konishi², Y. Sauchi², S. Wada¹, W. Aoi¹, Y. Nakamura¹, K. Sato¹

¹Department of Food Sciences and Nutritional Health, Division of Applied Life Sciences, Graduate School of Life and Environmental Sciences, Kyoto Prefectural University, Japan

²KOHJIN Life Sciences Co., Ltd, Japan

Background and objectives: Glutathione (GSH) has long history as supplement and medicine to improve liver function and skin whitening. However, previous studies have not detected increase of GSH and its fragments in human blood after oral intake of GSH. The objective of the present study was to elucidate absorption and transportation of food-derived GSH.

Methods: Healthy human volunteers were ingested GSH prepared from torula yeast (KOHJIN, 50 mg/kg body weight). Blood was collected from vein into heparinized tube. Plasma was mixed with 3 volumes of ethanol. The supernatant and precipitate were extracted with 5% TCA-2% 2-mercaptoethanol to liberate GSH and fragment peptides from protein. For determination of GSH and fragment peptides, derivatization with 6-aminoquinolyl-N-hydroxy succinimidyl carbamate (AccQ) followed by LC-MS/MS was used.

Results: There was no significant increase GSH after ingestion of GSH in the deproteinized fraction. However, Cys-Gly significantly increased. Also, protein-bound forms of all compounds significantly increased after the ingestion. These facts indicate that GSH and its derivatives are absorbed into blood system and transported as conjugate of protein. Further studies on change of GSH after exercise in human blood, are now in progress.

Conclusions: Supplementation of GSH can impact on blood GSH and fragment peptides levels. Also, GSH and fragment peptides are transported as protein-bound form in human blood.

Key words: glutathione (GSH), fÁGlu-Cys, Cys-Gly, oxidative stress, redox regulation

PO2919**IDENTIFICATION OF EPICATECHIN AS THE BIOACTIVE CONSTITUENT IN POLYPHENOL ENRICHED EXTRACTS THAT DEMONSTRATE A BENEFICIAL EFFECT ON ALLERGIC SYMPTOMS**

S. Nutten¹, A. Singh¹, A. Demont¹, L. Actis Goretta¹, A. Léveques¹, S. Holvoet¹

¹Nestlé Research Center, Nestec Ltd., Lausanne, Switzerland

Background and objectives: Polyphenols are naturally derived bioactive compounds found in abundance in a number of plant and food sources and have been attributed numerous beneficial health effects. We have previously characterized the anti-allergic effect of a polyphenol enriched apple extract in an OVA-induced murine model of food allergy. The objective of the current study was to better understand which major class of bioactive polyphenols is responsible in mediating the anti-allergic effect of the polyphenol enriched extracts.

Methods: Female BALB/c mice were sensitized orally to the allergen (OVA) given together with an adjuvant (cholera toxin). Polyphenol enriched fruit extracts or purified epicatechin polyphenol were administered in the diet of sensitized animals for 8 days following the last sensitization. Sensitized mice were challenged orally with ovalbumin following treatment, and allergic symptoms were compared between control and treated mice. OVA-specific serum immunoglobulins (IgE) and gene expression profiles in the intestine were measured together with a matrix analysis of the different polyphenol extracts.

Results: Polyphenol enriched apple extracts demonstrated a differentiating ability *in vivo* to modulate allergic symptoms. This beneficial immune-modulatory effect can be attributed to the epicatechin polyphenol, as oral administration of purified epicatechin in the diet of OVA-sensitized mice modulated allergic symptoms in a dose dependant manner. Epicatechin was enriched within the matrix of extracts that demonstrated a superior *in vivo* efficacy, but was not present in extracts that had no effect in the OVA-model.

Conclusions: Epicatechin class of polyphenols demonstrates anti-allergy properties.

Key words: anti-allergy, bioactive, immunomodulation, epicatechin, polyphenol

PO2920**FERMENTATION SUPERNATANTS OF KONJAC GLUCOMANNAN, INULIN AND CELLULOSE INHIBIT GROWTH BY APOPTOSIS AND CELL CYCLE ARREST IN HUMAN COLON CELLS***W.T. Wu¹, H.L. Chen¹*¹School of Nutrition, Chung Shan Medical University, Taichung, Taiwan

Background and objectives: Dietary fibers are potentially protective against colon cancer by production of short chain fatty acids (SCFA) through fermentation by the microflora. This study investigated the effects of konjac glucomannan (KGM), inulin, and cellulose on cell growth and cell cycle using two different human colon cancer cell lines (WiDr and LS174T).

Methods: The fermentations of dietary fibers (10 g/L) were conducted in vitro for 48 h under anaerobic conditions with mice fecal slurries. A negative control containing only the fecal sample was prepared as a fecal blank. The resulting fermentation supernatants (FS) were analyzed for SCFA. WiDr and LS174T cells were treated for 24 h with the concentration range of 5-20% (v/v) FS and the effect on cell growth, apoptosis and cell cycle were determined.

Results: FS of KGM and inulin contained 3.4- and 1.8-fold higher concentration of butyrate than the fecal blank, respectively. The effects of FS on the growth inhibition were stronger and more sensitive to the apoptosis in the LS174T cells. However, a cell cycle arrest in G0/G1 phase was observed in the WiDr cells after incubation of FS of KGM for 24 h.

Conclusions: Fermentation of dietary fibers may affect colon cancer cell lines through different modulation, apoptosis and cell cycle arrest.

Key words: konjac glucomannan, inulin, cellulose, fermentation

PO2921**SATIETY CONTROL THROUGH FOOD STRUCTURES MADE BY NOVEL PROCESSING: THE SATIN - SATIETY INNOVATION PROJECT***J. Halford¹, J. Harrold¹, C. Devine¹*¹University of Liverpool, Liverpool, UK

Background and objectives: SATIN is a five-year €6 Million EU funded project designed to develop foods that regulate appetite by reducing hunger, accelerating within meal satiation and enhancing between meal satiation. The project involves seven SMEs, four industry and seven academic partners and is led by the University of Liverpool (UK).

Methods: The SATIN project employs novel food processing methods to modify food structure to produce functional foods for weight management. This multidisciplinary collaboration will develop food products that help regulate food intake by accelerating satiation during a meal, enhancing satiety and/or reducing appetite through novel processing methods.

Results: The likely impact of these products will be assessed using in vitro modelling of the gastrointestinal tract using dynamic gut models and automated screening assays comprising of GI chemosensory and hormone secretion pathways. This will then be validated in human trials by examining key biomarkers, nutrient availability and behaviour.

Conclusions: These studies will not only substantiate individual product health claims but also identify and characterise the consumer benefits of satiety beyond weight management. Using foods from these studies and other products taken from the market SATIN will examine if a large scale intervention using a satiety based approach is an effective weight management strategy. For further information: www.satin-satiety.eu.

Key words: Satiety, Satiation, Food Processing, Innovation, gut models

PO2922**DAIDZEIN ATTENUATES 17 β -ESTRADIOL-REPPRESSED MYOGENIC DIFFERENTIATION***M. Ogawa¹, N. Harada¹, Y. Nakano², H. Inui³, R. Yamaji¹*¹Division of Applied Life Sciences, Graduate School of Life and Environmental Sciences, Osaka Prefecture University, Osaka, Japan²Osaka Women's Junior College, Osaka, Japan³Department of Clinical Nutrition, Graduate School of Comprehensive Rehabilitation, Osaka Prefecture University, Osaka, Japan

Background and objectives: The biological functions of 17 β -estradiol (E2) are exerted through two isoforms of estrogen receptor (ER), ER α and ER β , which regulate the transcriptions of target genes by binding to the estrogen-response elements (EREs). The two ER isoforms are expressed in the skeletal muscle. ER α represses myogenic differentiation by increasing the expression of ubiquitin-specific peptidase 19 (USP19), and ER β inhibits ER β -activated USP19 expression. Here, we investigated whether daidzein has an inhibitory effect on E2-repressed myogenic differentiation because the soy isoflavone daidzein increases the transcriptional activity of ER α rather than that of ER β .

Methods: C2C12 myoblasts and mouse satellite cells were cultured in differentiation medium containing 1 μ M daidzein in the presence or absence of 10 nM E2 for 8 days. Ovariectomized female ddY mice (8 weeks old) were fed diet containing 0.1% daidzein with or without E2 replacement.

Results: In both C2C12 cells and satellite cells, daidzein attenuated E2-decreased levels of structural muscle proteins (myosin heavy chain and tropomyosin) and E2-increased level of USP19. The knockdown of ER α abolished the inhibitory effects of daidzein on E2-increased USP19 level in C2C12 cells. Daidzein inhibited E2-activated binding of ER α to ERE in the intron 1 of USP19 gene and enhanced the binding of ER α to the ERE. In ovariectomized mice, dietary daidzein inhibited E2-induced decrease of muscle masses and attenuated E2-increased USP19 expression in skeletal muscles. Furthermore, daidzein decreased the binding of ER α to ERE of USP19 gene, and increased the binding of ER α to ERE.

Conclusions: Daidzein attenuated the E2-induced decrease of skeletal muscle masses, and down-regulated USP19 expression through the activation of ER α in vitro and in vivo. These results indicate that daidzein suppresses USP19 expression by activating ER α and consequently has beneficial effects on skeletal muscle mass in female mice.

Key words: daidzein, estrogen, skeletal muscle

PO2923

IN VITRO MODULATION OF GLP-1 ACTIVITY BY DIFFERENT AQUEOUS AND ORGANIC EXTRACTS OF EDIBLE SEAWEEDS

A R. Schultz Moreira¹, E. Rafferty², B D. Green², A. Garcimartín^{1,3}, J. Benedi³, S. Bastida¹, F J. Sánchez-Muniz¹

¹Departamento de Nutrición y Bromatología I (Nutrición); Facultad de Farmacia, Universidad Complutense de Madrid, Madrid, Spain

²Institute for Global Food Security; Biological Sciences, Queen's University, Belfast, Northern Ireland, UK

³Departamento de Farmacología; Facultad de Farmacia, Universidad Complutense de Madrid, Madrid, Spain

Background and objectives: There have been some indications that seaweeds could be used anti-diabetic foods/ingredients but the mechanisms of action remain unclear. Glucagon-like-peptide (GLP-1) is an incretin hormone secreted by the small intestine in response to nutrient ingestion, regulates the insulin secretion by pancreatic β -cells. Long-term infusion of GLP-1 improves glucose tolerance and lowers fasting glucose and augments satiety. On the other hand administration of GLP-1 receptor antagonists impairs glucose tolerance in humans. Performing various chemical extractions on edible seaweeds will determine the types of seaweed components which stimulate GLP-1 secretion. Aims. To study the effects of water-, ethanol- and chloroform-extracts of Nori, Wakame and Sea spaghetti on the in vitro GLP-1 secretion.

Methods: STC-1 cells (2 x 10⁶) were seeded into 6-well tissue culture plates and incubated overnight to allow attachment. Media was discarded, cells were washed with HEPES buffer and test incubations (n=8) containing the seaweed extract (50mg/ml) or vehicle control were added. After a 3h period, incubations were removed and stored at -20°C prior to measurement by ELISA. GLP-1 was measured using a commercial kit obtained from Phoenix Pharmaceuticals (Arizona, USA).

Results: Clear differences between alga and extracts were observed on the GLP-1 activity. Among extracts, the highest secretagogue GLP-1 activity was observed for the three Nori extracts (4 to 8-times higher than control). Water-Nori and Ethanol-Nori extracts also increased GLP-1 secretion (2 and 4.5 times higher than control, respectively). In contrast water Sea spaghetti extracts decreased GLP-1 secretion (by about 70%). The type of compounds present in aqueous, chloroformic and ethanolic extracts, would suggest that pigments such as phycoerythrin and fucoxanthin, and the amount and type of fibre could be responsible for stimulation GLP-1 secretion.

Conclusions: The chloroformic extract of Nori induces the highest GLP-1 secretion but a number of other seaweed extracts are worthy of further study. Granted by AGL-2011-29644-C02-02, Consolider-Ingenio 2010 # CSD2007-00016 and predoctoral fellowship to Adriana Schultz-Moreira by Universidad Complutense, Madrid, Spain.

Key words: GLP-1, seaweeds, extracts, in vitro.

PO2924

NEUROPROTECTIVE EFFECTS FROM SALVIA MILTIORRHIZA BUNGE IN THE GERBIL HIPPOCAMPAL CA1 REGION AGAINST INDUCED TRANSIENT CEREBRAL ISCHEMIA DAMAGE

Y E. Jeon¹, X F. Yin¹, Y H. Huang¹, D W. Jung¹, G H. Jang¹, I J. Kang¹

¹Hallym University, Gangwon, Republic of Korea

Background and objectives: We observed neuroprotective effects of five major lipophilic diterpenes derived from *Salvia miltiorrhiza* Bunge extract, such as cryptotanshinone (CTs), dihydrotanshinone I (DTsI), tanshinone I (TsI), tanshinone IIA (TsIIA) and tanshinone IIB (TsIIB), in the gerbil hippocampal CA1 region (CA1) against transient ischemic damage.

Methods: These diterpenes were administered 30 min before ischemia-reperfusion and the animals were sacrificed 4 days after ischemia-reperfusion. The neuroprotective effects of from *Salvia miltiorrhiza* Bunge extract were examined using cresyl violet (CV) staining and neuronal nuclei (NeuN) immunohistochemistry.

Results: In the vehicle-treated-group, cresyl violet positive (CV+) cells and neuronal nuclei (NeuN)+ neurons were sig-

nificantly decreased in the CA1. CA1 pyramidal neurons were well protected from transient ischemic damage in the TsI-, and CTs-treated-ischemia groups compared with DTsI-, TsIIA- and TsIIB-treated ischemia-groups. In addition, the activations of astrocytes and microglia were examined by GFAP and IB4 immunohistochemistry. Reactive GFAP- and IB4-immunoreactive astrocytes were less observed in the TsI- and CTs-treated ischemia-groups than those in the other groups.

Conclusions: These results suggest that TsI and CTs among five major lipophilic diterpenes have strong potentials for neuroprotection against ischemic damage. Our present finding suggests that *Salvia miltiorrhiza*Bunge extract may be useful in protecting neurons from some ischemic insults.

Key words: *Salvia miltiorrhiza*Bunge, Transient cerebral ischemia, Hippocampal CA1 region, Neuroprotection

Background and objectives: We observed neuroprotective effects of five major lipophilic diterpenes derived from *Salvia miltiorrhiza*Bunge extract, such as cryptotanshinone (CTs), dihydrotanshinone I (DTsI), tanshinone I (TsI), tanshinone IIA (TsIIA) and tanshinone IIB (TsIIB), in the gerbil hippocampal CA1 region (CA1) against transient ischemic damage.

Methods: These diterpenes were administered 30 min before ischemia-reperfusion and the animals were sacrificed 4 days after ischemia-reperfusion. The neuroprotective effects of from *Salvia miltiorrhiza*Bunge extract were examined using cresyl violet (CV) staining and neuronal nuclei (NeuN) immunohistochemistry.

Results: In the vehicle-treated-group, cresyl violet positive (CV+) cells and neuronal nuclei (NeuN)+ neurons were significantly decreased in the CA1. CA1 pyramidal neurons were well protected from transient ischemic damage in the TsI-, and CTs-treated-ischemia groups compared with DTsI-, TsIIA- and TsIIB-treated ischemia-groups. In addition, the activations of astrocytes and microglia were examined by GFAP and IB4 immunohistochemistry. Reactive GFAP- and IB4-immunoreactive astrocytes were less observed in the TsI- and CTs-treated ischemia-groups than those in the other groups.

Conclusions: These results suggest that TsI and CTs among five major lipophilic diterpenes have strong potentials for neuroprotection against ischemic damage. Our present finding su-

ggests that *Salvia miltiorrhiza*Bunge extract may be useful in protecting neurons from some ischemic insults.

Key words: *Salvia miltiorrhiza*Bunge, Transient cerebral ischemia, Hippocampal CA1 region, Neuroprotection

PO2926

INHIBITORY EFFECTS OF LIGULARIA FISCHERI ON THE FORMATION OF ADVANCED GLYCATION END-PRODUCTS AND RAT LENS ALDOSE REDUCTASE

Y.E. Jeon¹, X.F. Yin¹, Y.H. Huang¹, D.W. Jung¹, G.H. Jang¹, I.J. Kang¹

¹Hallym University, Gangwon, Republic of Korea

Background and objectives: The aim of this study was to evaluate the preventive and/or therapeutic potency for diabetic complications.

Methods: *Ligularia fischeri*(LF) was tested inhibitory effects against advanced glycation endproducts (AGEs) formation, rat lens aldose reductase (RLAR) and scavenging effect on 1, 1-diphenyl-2-picryl-hydrazil (DPPH) radical.

Results: Among several fractions from 70% ethanol extract of LF, the ethyl acetate fraction showed the highest DPPH radical scavenging activity of 53.92% at concentration of 3.3g/mL. Moreover, the ethyl acetate fraction exhibited the most potent AGEs formation inhibitory effect of 73.57% at concentration of 1.1g/mL. Also the ethyl acetate fraction showed the most potent RLAR inhibitory effect of 88.97% at concentration of 0.12g/mL. Therefore, the ethyl acetate fraction exhibited the most potent antioxidant and anti-diabetic complications. NMR was used to identify the bioactive compound, which had been accomplished via bioactivity-guided fractionation from the ethyl acetate fraction of LF, as 3, 4-Dicaffeoylquinic acid.

Conclusions: These data suggest that this compound from LF might be effective as a potential source for prevention and treatment of diabetic complications.

Key words: *Ligularia fischeri*, 1, 1-diphenyl-2-picryl-hydrazil, advanced glycation endproducts, rat lens aldose reductase, diabetes complication.

PO2927

VISUALIZATION OF THE BIOLOGICAL EFFECTS OF FRUITFLOW® ON PLATELET ADHESION UNDER PHYSIOLOGICAL FLOW CONDITIONS

N. Richard¹, B. Mussler¹, D. Raederstorff¹, J. Schwager¹

¹DSM Nutritional Products, Departement of Human Nutrition & Health, Basel, Switzerland

Background and objectives: Epidemiological evidence indicates that the Mediterranean diet has cardio-protective effects. Thus, a high intake of e.g. tomato is purportedly linked with beneficial properties for the vascular system. Screening of libraries containing natural ingredients and nutrients led to the identification of tomato components that modified the function of blood platelets. A water soluble tomato extract (Fruitflow®) was found to inhibit platelet aggregation induced by ADP or collagen in human blood. Accordingly, Fruitflow® obtained a EFSA approved health claim for “maintaining normal platelet aggregation that contributes to healthy blood flow”. The aim of this study was to use a technological platform to (a) visualize the adhesion of platelets, (b) evaluate the effect of Fruitflow® on the extent and kinetics of platelet adhesion, (c) validate this method by comparing the observations with those made in platelet aggregation assays.

Methods: We implemented the BioFlux 1000Z system (FluXion, USA) to simulate physiological blood flow conditions at controlled shear flow in a microscopy system. Human whole blood was perfused at a shear rate of 1000/s in collagen I-coated channels of BioFlux plates for 10 min. The adhesion of platelets was observed in real-time, with images being taken every 15 sec with a CCD camera. The effect of Fruitflow® on platelet adhesion was then measured.

Results: The biological effect of Fruitflow® could be visualized using a microfluidic flow cells. FruitFlow® dose-dependently reduces the collagen I-induced adhesion of platelets. These data corroborate and extend previous observations described for Fruitflow® on platelet aggregation.

Conclusions: Platelet adhesion can be measured in real-time and under physiological condition using the BioFlux system. The effects of Fruitflow® on platelet adhesion indicate that Fruitflow® may help to maintain a healthy blood flow by preventing the adherence of platelets to blood vessel walls.

Key words: platelet, aggregation, shear flow, tomato

PO2928

INTERACTION BETWEEN PHENOLIC COMPOUNDS OF VIRGIN OLIVE OIL WITH A SALIVARY PROTEIN (MUCIN): AN APPROACH TO BIOAVAILABILITY.

A. Quintero-Flórez¹, A. Sánchez-Ortiz¹, G. Beltrán¹

¹Instituto de Investigación Y Formación Agraria Y Pesquera. Centro Venta del Llano, Mengíbar, Jaén, Spain

Background and objectives: Virgin olive oil (VOO) is appreciated for its nutritional benefits. Phenolic compounds are related with them by their antioxidant capacity. The interaction between proteins and phenolic compounds is of great interest in nutrition since the proteins would bind the polyphenols present in the diet, forming insoluble complex and reducing their bioavailability and antioxidant capacity. The objective of this work was to evaluate the interaction between phenolic acids (cinnamic, p-coumaric, caffeic, vanillic and protocatechuic acids), tyrosol (p-hydroxyphenylacetic) hydroxytyrosol (3,4-dihydroxyphenylacetic) and an extract phenolic from VOO with a salivary protein (mucin from porcine).

Methods: The interaction between polyphenol-protein was measured by the increasing turbidity of the reaction mixture and was expressed in nephelometric turbidity units (NTU). Polyphenols solutions (1% ethanol) at different concentration (80 to 1000 mg/L) were mixed with mucin solution (0,2% pH 3.5). Reaction mixtures were measured after 1, 30, 60, 90 and 180 min at 37°C.

Results: The results showed that the highest polyphenol-protein interaction were observed with VOO phenolic extract, cinnamic, p-coumaric and caffeic acids. The interaction polyphenol-protein increased with the concentrations of polyphenols. During the reactions, each compound had a different behavior but all produced turbidity immediately after 1min of the reaction. The maximum value of turbidity for the phenolic acids and hydroxytyrosol was obtained to concentration more than 400 mg/L at 30 min of reaction time, while the VOO phenolic extract increase the turbidity during the reaction.

Conclusions: These results suggest that the polyphenols from VOO react with the salivary proteins forming an insoluble complex immediately. This interaction is related with the phenolic chemical structure and their concentrations.

Key words: virgin olive oil, polyphenols, bioavailability.

PO2929**OIL BULKING AGENTS AS FAT REPLACERS TO DEVELOP HEALTHIER MEAT PRODUCTS: A RAMAN SPECTROSCOPIC STUDY**

F. Jiménez-Colmenero¹, C. Ruiz-Capillas¹, P. Carmona², AM. Herrero¹

¹Institute of Food Science Technology and Nutrition (ICTAN-CSIC), Madrid, Spain

²Institute of Structure of Matter (CSIC), Madrid, Spain

Background and objectives: In the development of healthier meat products, one of the most relevant aspects are related to reformulation processes based on replacement of the animal fat with another fat whose characteristics are more in line with health recommendations. Special interest should attach to the development strategies which not imply loss of quality in the new derivate. The aim of this work was to examine quality changes in terms of technological and structural properties (using Raman spectroscopy) in healthier meat batters formulated using olive oil bulking agents based on polysaccharide gels as animal fat replacers.

Methods: Meat batters were prepared with pork backfat (MB-PF) or with a combination of olive oil, sodium alginate and dextrin (MB-A/D) or inulin (MB-A/I) as fat replacer. Proximate composition, cooking loss and lipid structural changes were evaluated.

Results: Fat content ranged between 16.95% and 20.06%, with the highest ($P < 0.05$) value in the MB-PF sample (all pork fat). In reformulated meat batters (MB-A/D and MB-A/I) fat content involved around 13.5 g of olive oil per 100 g of product. Besides, these samples showed optimal technological properties. It was also found increased disorder in the oil acyl chains, which implicates lipid-protein interactions, in both MB-A/D and MB-A/I.

Conclusions: Reformulation process based on the use of olive oil bulking agents as fat replacer could be used to improve fat content of meat products. The understanding of the relationship between technological and structural characteristics could be helpful in optimizing the development of healthier meat products. **Acknowledgements:** AGL2010-19515, AGL2011-29644-C02-01, and CARNISENUSA (CSD2007-00016).

PO2930**BIFIDOBACTERIUM CECT 7765 AMELIORATES INTESTINAL AND PERIPHERAL TISSUE INFLAMMATION ASSOCIATED WITH OBESITY IN HIGH-FAT DIET FED MICE**

A. Moya¹, Y. Sanz¹

¹Microbial Ecology and Nutrition Research Group, National Research Council (IATA-CSIC), Valencia, Spain

Background and objectives: Obesity results from a long-term positive energy imbalance and is also associated with chronic, low-grade inflammation. Obesity has also been related to phylum and group-specific changes in the human intestinal microbiota in observational studies, suggesting a role for specific bacterial taxa in this disorder. However, direct evidence of the role specific bacteria play in this disorder is limited. Here, the objective is to evaluate the effects of administration of *Bifidobacterium pseudocatenulatum* CECT 7765 on metabolic and immune alterations in high-fat diet (HFD) induced obesity in mice.

Methods: Adult male wild-type C57BL-6 mice were fed a standard diet or HFD, supplemented or not with *B. pseudocatenulatum* CECT 7765 for fourteen weeks. Several parameters related to glucose and lipid metabolism and to immunity and microbiota-related features were analysed.

Results: *B. pseudocatenulatum* CECT 7765 reduced serum cholesterol, triglyceride, glucose and leptin levels, and decreased insulin resistance and improved glucose tolerance in obese mice. This bacterial strain also reduced the concentration of inflammatory cytokines in small intestine, pancreas and adipose tissues. The strain administration also modified the composition of the intestinal microbiota in HFD-fed mice, increasing the numbers of *Bifidobacterium* spp., and *Clostridium* coccioides and *Clostridium leptum* groups.

Conclusion: The study provides direct evidence of the ability of *B. pseudocatenulatum* CECT 7765 to ameliorate inflammation associated with obesity in a HFD-induced obesity mouse model.

Key words: *Bifidobacterium*, obesity, chronic inflammation, immunity, high-fat diet.

PO2931**INFLUENCE ON HEALTH MARKERS OF THE REGULAR CONSUMPTION OF ANEW MEAT PRODUCT DESIGNED WITH AN OPTIMIZED NUTRITIONAL PROFILE**

S. Navas-Carretero^{1,2}, M A. Zulet^{1,2}, I. Abete^{1,2}, J. Planes³, A. Avellaneda³, J.A. Martinez^{1,2}

¹Department of Nutrition, Food Science and Physiology, University of Navarra, Pamplona, Navarra, Spain

²CIBER Fisiopatología Obesidad y Nutrición (CIBEROBn), Instituto de Salud Carlos III, Spain

³Research & Development Department, EI Pozo Alimentación, S.A, Alhama de Murcia, Murcia, Spain

Background and objectives: Health and nutrition are in straight relationship, being diet the most common approach to prevent the incidence of overweight/obesity and associated comorbidities. Furthermore, cardiovascular disease prevalence together with overweight and obesity rates are increasing worldwide. The role of diet in these conditions is essential. Research and food industry are looking for healthier offerings to the consumer, to improve nutritional quality of highly demanded products. This work aimed at assessing the effects of regular consumption in healthy adults of optimized nutritional profile (ONP) meat products on health status and weight management compared to a reference product.

Methods: The study was designed as a randomized, placebo controlled, double-blind, nutritional intervention, with three arms, in which two optimized products were compared to a reference product when consumed within a balanced isocaloric diet. A total of 60 subjects were invited to participate and 47 finished the trial. Anthropometry was monitored fortnightly, while DXA analysis and biochemical parameters were assessed at the beginning and the end of the study. Weight, body composition, and fasting levels of glucose, insulin, total-cholesterol, HDL-cholesterol and some antiinflammatory biomarkers were also analyzed.

Results: Body weight and fat mass were reduced in the three dietary groups after the intervention, although the participants consuming the product with high omega-3 PUFA and reduced fat content experienced a higher fat mass loss than the other two groups. Concerning glucose and lipid metabolism markers, levels were maintained in all the dietary groups during the study, without differences among them. Similarly, this trend also occurred with C-Reactive Protein levels or ICAM and VCAM values.

Conclusions: The regular consumption of new ONP meat products designed with a nutritional profile reduced in fat and improved lipid profile seems to be a feasible strategy for weight control and healthy status maintenance.

Key words: functional foods, obesity, cardiovascular risk.

PO2932**EFFECT OF METHYLATED CATECHINS ON PHYSIOLOGICAL ACTIVITIES IN RATS FED A HIGH-FAT DIET**

M. Kondo¹, H. Tsuji², R. Morimoto³

¹Faculty of Human Life Science, Shikoku University, Japan

Background and objectives: “Yabukita” green tea, a popular tea cultivar in Japan lacks methylated catechins, but “benifuuki” green tea contains unique methylated catechins (MC) such as epigallocatechin-3-O-(3-O-methyl) gallate. It has already been reported that adipose tissue weight gain in high-fat diet-fed mice were suppressed by “benifuuki” green tea consumption. In the present study, we examined whether the anti-obese effects would be accepted by the obese rats who consumed “benifuuki” tea powder.

Methods: Male Wistar rats, 12 wk olds, were divided into four groups that were assigned to a control diet (C group, a commercial chow), a 30% high-fat diet (HF group), or a 30% high-fat diet +200mg MC/kg diet (LMC group), or a 30% high-fat diet +600mg MC/kg diet (HMC group). “Benifuuki” tea leaf powder were used for as MC. The rats had free access to tap water and experimental diets for 6 wk. Food intake and body weight were determined tri-weekly. Energy expenditure were measured for 1d the 6th week. At the end of the experimental period, the rats were sacrificed by drawing blood from the inferior vena cava under pentobarbital anesthesia. Liver, pancreas, and abdominal adipose tissues (epididymis, perirenal, and mesenteric adipose) were immediately excised and weighed.

Results: The HMC rats showed a slightly decreases in body weight, adipose tissue weights and significant decrease in serum leptin concentration, compared with those fed a high-fat diet. The pancreas amylase activities of HF group showed the low value about 30% compared with C group. When MC was added, pancreatic amylase activities were recovered to the same extent as C group. The rats fed a high-fat diet with MC showed a significant increase in energy expenditure, compared with C group and HF group.

Conclusions: The results indicated that MC had an anti-obese effects. Furthermore, MC had improvement effects of energy expenditure and digestive enzyme activities.

Key words: methylated catechins, energy expenditure, anti-obese effects

PO2933**PREBIOTIC EFFECT OF NEW TYPE RESISTANT STARCH ON SERUM LIPIDS IN HUMAN**

S. Kasaoka¹, A. Yamada¹, M. Machidera¹, Y. Nagahata², I. Kobayashi², M. Goto²

¹Bunkyo University, Kanagawa, Japan

²Starch Laboratory, J-OIL MILLS, Inc., Tokyo, Japan

Background and objectives: Resistant starch (RS) is defined as the sum of starch that is not absorbed in the small intestine as same with dietary fiber. A wide range of health benefits of RS have been suggested such as prebiotic effects. J-OIL MILLS Inc. develop new type of resistant starch, AmyloFiber, which is hydrolyzed of high-amylose cornstarch with 1.5% hydrochloric acid at 50°C for 16 h). RS content of AmyloFiber is about 70%, that is one of the highest RS in food materials. Our preliminary study might be suggested AmyloFiber is easily fermentable for bacteria in the intestine, and changes microflora, especially increases Bifidobacterium. These data make us expect AmyloFiber that would maintain proper level of serum lipid through the some mechanism of short-chain fatty acids by cecal fermentation. AmyloFiber is low peak molecular weight and high degree of crystallinity. Amylose of high-amylose cornstarch might be susceptible to acid hydrolysis, and form double helices may form crystals, which are resistant to enzymatic hydrolysis. AmyloFiber is heat stable, which means RS does not decrease after food processing. AmyloFiber could be added to foods such as pasta, cookie, bread without adversely affecting their organoleptic properties.

Methods: In this study, prebiotic effect of AmyloFiber on fecal characteristic and serum lipids were examined for healthy volunteers. They took a slice of AmyloFiber bread (6.9 g RS), two pieces of AmyloFiber cookie (6.0 g RS), and one dish of soup with AmyloFiber (3.1 g RS) at every breakfast for 30 days. Serum triglyceride, and total-, HDL-, and LDL-cholesterols were measured at day 1, and each 10 days during experimental period.

Results: Serum lipids were changed after experiment.

Conclusions: AmyloFiber is useful candidate for RS food source.1) Journal of Applied Glycoscience, 60(2), (2013)

PO2934**ENDOGENEOUS ANTIOXIDANT CAPACITY OF SCHIZANDRA CHINENSIS BAILLON AGAINST TERT-BUTYL HYDROPEROXIDE-INDUCED OXIDATIVE HEPATIC DAMAGE IN RATS**

G M. Do¹, H I. Jang¹, O. Kwon¹

¹Department of Nutritional Science and Food Management, Ewha Womans University, Seoul, Republic of Korea

Background and objectives: Antioxidants exert their protective effects not only by scavenging ROS, but also by inducing the expression of phase II detoxifying / antioxidant enzymes which are contribute to detoxification of xenobiotic and the inactivation of ROS. This study was carried out to evaluate endogenous antioxidant capacity and hepatoprotective potential of SchizandrachinensisBaillon extract (SCE) against tert-butyl hydroperoxide (t-BHP) induced oxidative liver damage rats.

Methods: Sixty male Sprague-Dawley rats were randomized into six groups as follows; NC, Normal control; TC, t-BHP control; PC, positive control, 100mg/kg BW of Silymarin; SCE-L, 300mg/kg BW of SCE; SCE-M, 600mg/kg BW of SCE; SCE-H, 1,200mg/kg BW of SCE. SCE pretreatments were administered orally for 14 days prior to t-BHP injection. After 16 hours, rats were sacrificed. We examined the abilities of each to regulate phase II antioxidant enzyme and hepatoprotective potential in liver.

Results: SCE prevented decrease of superoxide dismutase (SOD) activity that was induced by t-BHP. Especially, SCE were alleviated hepatic damage in a dose-dependent manner by induction of phase II antioxidant enzymes expression such as glutathione S-transferase (GST), glutamate-cysteine ligase catalytic subunit (GCLC) in mRNA. GST, GCLC and GCLM mRNA expressions also showed dose-dependent increase in SCE pretreated groups. Furthermore, serum alanine aminotransferase (ALT) and aspartate aminotransferase (AST) activities tended to decrease in SCE-H. Hepatic TNF-alpha level was significantly reduced in SCE-L, SCE-M and SCE-H compared to TC. In histopathological analysis, SCE pretreatment reduced the incidence of the lesions such as neutrophil infiltration, swelling of liver cells and necrosis compared with TC.

Conclusion: These results suggest that SCE is capable of alleviating t-BHP-induced hepatic damage by regulating endogenous antioxidant capacity by modulating phase II antioxidant enzymes expression in liver, thereby improving hepatic toxicity.

²Departamento de Farmacología, Facultad de Farmacia, Universidad Complutense de Madrid, Spain

³Institute for Global Food Security; Biological Sciences, Queen's University, Belfast BT9 5AG, Northern Ireland, UK

Background and objectives: Hypoglycemic properties of seaweeds have been related to modification on carbohydrate digestion and absorption and show interest as antidiabetic-food. Chloroform-, ethanol- and water-soluble extracts from, *Himantalia elongata* (HE), *Porphyra umbilicalis* (PU), *Undaria pinnatifida* (UP) were used to test the in vitro inhibitory activity on α -glucosidase model. Principal component analysis (PCA) was conducted on water- and ethanol- extracts to identify patterns in data and relation between the soluble bioactive constituents and α -glucosidase activity inhibition in the seaweeds tested.

Methods: Degree of inhibitions was assayed measuring the production of glucose from maltose solution at 15, 30, 45, 60 and 75 min. PBS buffer was used as a control and acarbose, an α -glucosidase inhibitor, was used as positive control. PCA was carried out by selecting those Principal Components (PCs) with eigenvalues larger than 1.0. Then, the factors were rotated, using Varimax method, to obtain the expected weight for each extraction factor. The higher eigenvalue, the higher percentage of the total variance explained. Differences were considered significant at $p < 0.05$.

Results: Water- extracts from HE followed by PU or UP showed the highest α -glucosidase inhibitory activities. In the case of ethanolic and chloroformic extracts non significant differences were found. Water extract of HE with respect to control and to the other water extracts, possessed significant in vitro inhibitory effects after 30 min (62.0% vs. control, at final incubation time of 75 min.). Moreover, PCA clearly distinguished HE effects from those of the other algae, supporting that soluble fibre and polyphenols were involved.

Conclusions: Present results suggest clear differences between the chloroformic, aqueous, and ethanolic extracts of the three algae. HE water extracts deserve future studies on humans and domestic animals in vivo experiments. Granted to project AGL2011-29644-C02-02.

Key words: Seaweeds, extracts, in vitro, carbohydrate digestion, α -glucosidase

PO2936**INFANT FORMULA WITH GALACTOOLIGOSACCHARIDES STIMULATES BIFIDOBACTERIUM POPULATION, WITHOUT REDUCTION OF INFECTIONS IN THE FIRST YEAR OF AGE ON HEALTHY INFANTS.**

⁷Hospital Clínico Universitario, Santiago de Compostela, Spain

⁸Hospital Virgen de las Nieves, Granada, Spain

⁹Hospital Doce de Octubre, Madrid, Spain

¹⁰Hospital Puerta de Hierro, Madrid, Spain

Background and objectives: Currently, there is not enough scientific evidence on clinical effects of infant formulas supplemented with prebiotics. The aim was examine the effects of an infant formula supplemented with 0.44 g/dl and later a follow-on formula with 0.50 g/dl of galactooligosaccharides (GOS) on the intestinal microbiota and incidence of infections in infants during the first year of age.

Methods: A multicentre, randomized, double-blind, placebo-controlled study was carried out on 365 healthy infants up to two months of age, randomly assigned to either formula, 177 infants to formula without GOS and 188 to formula with GOS. 132 infants in each group successfully completed the study until 12 months of age. The prebiotic effect of GOS formula was studied in a subgroup of 81 subjects. Incidence of infections was the main outcome. A secondary outcome was to determine *Bifidobacterium* genera and species (*B. longum*, *B. bifidum*, *B. adolescentis*, *B. breve*, *B. catenulatum* and *B. dentium*) in faeces measured by RT-PCR.

Results: The number of infections (diarrhoea and upper respiratory tract infections) of both interventions group during the first year of life was similar (no statistical differences). Despite the infections were not reduced, a bifidogenic effect was obtained on faecal analysis, with a higher *Bifidobacterium* count ($P=0.010$) in GOS group, different profile in *Bifidobacterium* species and higher percentage of infants colonized by *B. breve* in GOS group (57.50 %) than in control group (41.38 %).

Conclusions: The intake of infant formula supplemented with GOS produces changes in growth and species characterization of the *Bifidobacterium* population, being *B. breve* highly

abundant, as it is in breastfed infants, without relation with a reduction of infections in the first year of life.

CAROTENOID AND FLAVONOID COMPOSITION OF A LOW ALCOHOLIC NOVEL ORANGE DRINK OBTAINED BY FERMENTATION AND PASTEURIZATION OF ORANGE JUICE.

B. Escudero-López¹, D. Hornero-Méndez², A. Gil-Izquierdo³, S. Medina³, F. Ferreres³, I. Cerrillo¹, G. Berná¹, F. Martín¹, M S. Fernández-Pachón¹

¹Department of Molecular Biology and Biochemistry Engineering, University of Pablo de Olavi de Seville, Spain

²Department of Food Biotechnology, Instituto de la Grasa-CSIC, Sevilla, Spain

³Department of Food Science and Technology, CEBAS-CSIC, Murcia, Spain

Background and objectives: It is accepted that the intake of fruits and vegetables, which contains antioxidant compounds such as flavonoids and carotenoids, intensify the protection against many diseases related to oxidative stress. Moreover, moderate alcohol consumption confers cardiovascular protection. Both effects could join in a novel drink created by alcoholic fermentation of orange juice. The aim was to analyze the carotenoid and flavonoid composition of orange juice after fermentation and pasteurization processes.

Methods: The new orange drink was produced from commercial orange juice by a controlled alcoholic fermentation process (20 °C – 10 days) and subsequently pasteurization process (80 °C – 30 seconds). Collection of samples was made at the beginning (OJ) and at the end of fermentation (F-OJ) and pasteurization (FP-OJ) processes. The identification and quantification of carotenoid pigments and flavonoid compounds were performed using LC-MS techniques.

Results: Twenty-one carotenoid pigments were identified in OJ, F-OJ and FP-OJ samples. Isomers of auroxanthin, β -Cryptoxanthin and β -Carotene were the most relevant pigments, outstanding the second one with its provitamin A activity. Regarding flavanones, a total of 9 phenolic compounds were identified, of which narirutin, hesperidin and didymin were the most relevant. The fermentation process caused a significant increase ($p < 0.01$) in total flavanones (32.2 %) and carotenoids (28.9 %). Subsequently, pasteurization led to decrease these bioactive compounds, compared to F-OJ (about 6.7 % and 42.7 % for flavanones and carotenoids, respectively), being a significant decrease ($p < 0.01$) only for carotenoids.

Conclusions: Alcoholic fermentation and pasteurization produces a novel orange drink with low alcoholic content, which contains higher content of flavanones ($p < 0.05$) and lower content of carotenoids ($p < 0.01$) than the original orange juice.

Key words: Orange juice, Fermentation, Pasteurization, Carotenoids, Flavonoids

GLYCEMIC RESPONSE OF CEREAL PRODUCTS IS MAINLY EXPLAINED BY ITS SLOWLY DIGESTIBLE STARCH, FAT AND FIBRE CONTENT

A. Meynier¹, A. Goux¹, D. Ndao¹, S. Vinoy¹

¹Mondelez International R&D, Nutrition Research, Saclay, France

Background and objectives: Cereal products exhibit a wide range of glycemic and insulinemic responses. It is however still unclear which parameters among nutritional composition and starch digestibility influence the more glycemic and insulinemic responses. The aim of the present analysis was to determine which parameters within nutritional composition and starch digestibility can explain the most Glycemic Index (GI) of cereal food products.

Methods: An internal database including the nutritional composition, starch digestibility parameters and GI of 190 cereal products have been used for this analysis. Relationships between nutritional composition, starch digestibility of the products and GI and insulin index (II) were analysed by simple and multi regression models. Only models where K_{HI-2} , tolerance and inflation values indicated that there was no collinearity were selected.

Results: The GI and II values obtained with the present cereal products were well correlated with a r of 0,62. Simple regression analysis of GI as principal variable and using a model including both starch digestibility and nutritional composition displayed a R^2 of 45%. In this model, Slowly Digestible Starch (SDS), fat and fibres were significantly associated to GI ($p < 0,01$) as well as resistant starch ($p < 0,05$). No valid model was found to explain II based on macronutrient and starch digestibility.

Conclusions: These analyses confirm on a wider range of products previous data showing that GI of the cereal products is mainly explained by SDS, fat and fiber content of these latter. Therefore, SDS appears as highly relevant parameter for selecting cereal products inducing low glycemic products which should contribute to some health benefits.

Key words: Glycemic Index, Insulinemic index, cereal foods, starch digestibility, nutritional composition

PO2939**BIOACCESSIBILITY OF BIOACTIVE COMPOUNDS (ACE INHIBITORS AND ANTIOXIDANTS) FROM EXTRUDED MAIZE PRODUCTS ADDED WITH PORPHYRA COLUMBINA RED SEAWEED**

R.E. Cian^{1,2}, M.S. Caballero¹, N. Sabbag¹, R.J. González¹, S.R. Drago^{1,2}

¹Food Technology Institute, Faculty of Chemical Engineering, Universidad Nacional del Litoral

²Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), Ciudad Autónoma de Buenos Aires, Argentina

Background and objectives: Red seaweed belongs to the genus *Porphyra*, traditionally known as nori in Japan, is a popular food. Red seaweed *P. columbina* is found on hard substratum in Patagonia Argentina coasts. Among red algae proteins, phycobiliproteins have drawn attention because of their immunomodulatory, ACE inhibition and antioxidant properties. Also, many researchers have attributed the antioxidant capacity mainly to phenolic compounds. On the other hand, extrusion cooking is one of the most important food processing technologies which have been used for the production of different cereal based foods. Nowadays, there is not information about addition of red seaweed and even less about this particular alga into extruded foods. Moreover, there is no information about the bioaccessibility of bioactive compounds from this kind product. The aims of this work were to develop extruded maize products added with red seaweed *P. columbina* as functional food and to evaluate the bioaccessibility of bioactive compounds.

Methods: Three extruded maize product with different *P. columbina* replacement levels (1.7%, 3.5% and 5.2%; w/w) were obtained. Physical characteristic, sensory analysis, ACE inhibition, DPPH inhibition, TEAC, reducing power, and color were studied. From sensory analysis 3.5% replacement level was selected as the most appropriate and acceptable for human consumption. Then, bioaccessibility of mineral and bioactive compounds of extruded maize product (M) and extruded maize product with 3.5% *P. columbina* was evaluated (MP).

Results: MP showed: magnesium (59.3%), ACE inhibitor compounds (41.0% ACE inhibition), phenolic compounds (0.83 mg gallic acid/ g dialysate) bioaccessibility higher than M. Also, antioxidant capacity (36.6% DPPH inhibition, 2.4 mM TEAC, power reduction and 99.4% copper-chelating activity) were higher in MP than M dialyzates.

Conclusions: Results about bioaccessibility of bioactive compounds provided by *P. columbina* may help food technologists to tailor new bio-functional foods, such as functional snacks.

Key words: accessibility, bio-functional foods, seaweeds.

PO2940**PROTEOMIC IDENTIFICATION OF SMALL ANTIOXIDANT PEPTIDES IN DRY-CURED HAM**

F. Toldrá¹, L. Mora^{1,2}, E. Escudero¹, P.D. Fraser², M.C. Aristoy¹

¹Instituto de Agroquímica Y Tecnología de Alimentos (CSIC)

²Centre for Systems and Synthetic Biology, University of London, UK

Background and objectives: The antioxidant activity of peptide fractions extracted from dry-cured ham was recently assayed. It was observed that several collected fractions exhibited DPPH (2,2-diphenyl-1-picrylhydrazylradical) radical-scavenging activity as well as superoxide ion extinguishing ability. One group of fractions containing peptides of low molecular mass exerted a strong DPPH radical-scavenging activity thus suggesting the presence of peptides with antioxidant activity that should be identified which is the goal of this communication.

Methods: Water-soluble peptides were extracted from dry-cured ham and separated through size-exclusion chromatography. Fractions at elution volumes from 200 mL to 275 mL with strong antioxidant activity as determined through the DPPH radical-scavenging activity assay, were collected and subjected to proteomic tools. Identification of sequences was carried out by Matrix-assisted laser desorption/ionization time-of-flight (MALDI-ToF) and nESI-ion trap mass spectrometry.

Results: The assayed fractions showed strong antioxidant activity (from 39% to 92%). The molecular masses of peptides in such antioxidant fractions were found between 400 and 2000 Da. A total of 93 peptides were sequenced. From them, 27, 23, 19 and 17 peptides were identified from relevant pork muscle proteins like actin, α -enolase, myosin heavy chain, and creatine kinase proteins, respectively and the remaining 27 peptides were from other pork muscle proteins.

Conclusions: Results from this study show that Spanish dry-cured ham may represent a source of natural peptides exhibiting antioxidant activity and thus with potential benefit for human cardiovascular health. Acknowledgements: HEFCE infrastructure funding is acknowledged for MS equipment to PDF. LM and PDF are grateful to the EU-FP7 Marie Curie IEF scheme (FOOSAF project) for financial resources. FPI Scholarship from MINECO to E.E. and grants Prometeo/2012/001 from Conselleria d'Educació (Generalitat Valenciana) and AGL2010-16305 from MINECO and FEDER funds and are fully acknowledged.

PO2941**MODULATORY EFFECT OF FERULIC ACID ON LPS-INDUCED INDOLEAMINE 2, 3-DEOXYGENASE (IDO) EXPRESSION IN MICROGLIA**

M. Koshiguchi¹, H. Komazaki¹, M. Otsuka¹, S. Hirai¹, Y. Egashira¹

¹Laboratory of Food Nutrition, Graduate School of Horticulture, Chiba University, Japan

Background and objectives: Indoleamine 2,3-deoxygenase (IDO) act as rate-limiting enzyme in inflammation of the central nerve system(CNS). Ferulic acid (FA) is a kind of polyphenol contained in rice bran, and is reported to have anti-inflammatory effect. In this research, we investigated the effect of FA on lipopolysaccharide (LPS) induced IDO in microglia.

Method: Microglia cell line MG6 treated with various concentration of FA and E.coli derived LPS, and was measured of IDO mRNA expression by real-time PCR, TNF- α and IL-6 production was also measured by ELISA. Furthermore, to reveal the mechanism of inhibitory effect of FA, we performed western blotting to measure some kinds of proteins involved in MAPK and NF κ B signaling pathways using western blotting.

Result: FA suppressed LPS-induced IDO mRNA expression, but not TNF- α and IL-6. LPS induced I NF κ B degradation was suppressed by FA in a dose dependent manner. However, phosphorylation of proteins involved in MAPK pathway weren't suppressed by FA.

Conclusion: These results suggested that inhibition of NF κ B pathway involved in suppression of LPS induced IDO mRNA expression by FA.

Key words: tryptophan, IDO, ferulic acid, inflammation, microglia

PO2942**VITAMIN D STABILITY IN FORTIFIED FOOD EMULSIONS**

D. Leskauskaitė¹, I. Jasutiene¹, M. Kersiene¹, P. Matusevicius², E. Malinauskyte¹

¹Department of Food Technology, Kaunas University of Technology, Kaunas, Lithuania

²Department of Animal Nutrition, Lithuanian University of Health Sciences, Kaunas, Lithuania

Background and objectives: Designing food products to control stability of lipophilic food compounds includes developing emulsions with specific structural characteristics. We focus on building interfacial layers from proteins and polysaccharides that surround lipid droplets and are resistant to degra-

ation during technological process and digestion. The aim of this study was to analyse storage stability of vitamin D in fortified emulsions and find out whether it is possible to increase bioavailability of vitamin D from these emulsions.

Methods: Objectives of our study were emulsions stabilized by whey proteins (WP) alone and together with carboxymethylcellulose (CMC) with addition of 0.5% vitamin D3. Vitamin D content in emulsions was determined by RP-HPLC after cleaning by normal phase chromatography. Emulsions were fed to rats. Rats were divided into 3 groups: control (usual diet); usual diet + 2 g emulsion with WP (Diet 1); and usual diet + 2 g emulsion with WP and CMC (Diet 2). Rats were given free access to food and water, emulsions were given once a day for 2 weeks. Levels of serum 25-hydroxyvitamin D (25(OH)D) as an index of the nutritional vitamin D in the rats body were evaluated.

Results: Analysis of vitamin D3 retention in emulsions stabilised by WP alone and WP together with CMC showed no statistically significant differences in vitamin content. Quantitative analysis of vitamin D3 in all emulsions stored for 10 days in the dark at +40C showed that vitamin content was stable and varied within standard deviation limits. Supplementation of rats diet by vitamin D3 for 1 week increased serum 25(OH)D level up to 151+/-31,5 nmol/L for Diet-1 and 169,7+/-10,17nmol/L for Diet-2, whereas for control group serum 25(OH)D concentration was 71+/-24,97 nmol/L (SD).

Conclusions: After 2 weeks in both groups receiving emulsions with vitamin D a plateau of 175,17nmol/L serum 25(OH)D was reached.

Key words: food emulsions, vitamin D

PO2943**BIOACCESSIBILITY ASSESSMENT OF CAROTENOIDS FROM COMERCIAL NUTRACEUTICAL PRODUCTS**

F. Peixoto¹, J. Cavalcante², R. Borguini³, S. Pacheco³, A. Gouvêa¹, M. Santiago³, R. Godoy³, L. Nascimento³

¹Program of Post Graduate Food Science and Technology, Rural Federal University of Rio de Janeiro, Brazil

²Department of Chemistry Engineer, Rural Federal University of Rio de Janeiro, Brazil

³Embrapa Food Technology, Rio de Janeiro, Brazil

Background and objectives: Health-promoting products are getting popular among consumers and a large list of nutraceuticals containing phytochemicals from foods is available in the Brazilian market. Research on their bioavailability is essential to elucidate the potential health benefits of carotenoids formulations, since it depends on digestive stability, released

from the matrix (referred as bioaccessibility) and transepithelial passage efficiency. In vitro digestion models are being extensively used to predict carotenoids bioaccessibility in a rapid and cheaper way, besides not involve ethical aspects as in vivo assays. The aim of this study was to assess carotenoids bioaccessibility from five available capsule-formulations of nutraceuticals in the Brazilian market, claimed as carotenoid source and with several health benefits. The nutraceuticals products were purchased in local stores in Rio de Janeiro, Brazil.

Methods: An in vitro digestion model was applied by mimicking oral, gastric and intestinal physiological conditions. Five percent (w/w) of canola oil was added to the samples. Analyses involved enzymes as α -amylase, pepsin, bile, pancreatin, lipase and inorganic salts. Physiological variations were reproduced by the bath shaker with orbital gyros (37°C) and ultracentrifugation (5000g, 45 min). Identification and quantification of carotenoids were performed by HPLC, using a 33°C column oven, PDA detector, and a C30YCM Column. Carotenoids separation was obtained by a gradient elution of methanol and methyl tert-butyl ether, using a 0.8mL/min flow rate, injection volume of 15 μ L and run time of 28min.

Results: Bioaccessibility of carotenoids was decreased after pass through the gastro-intestinal model and varied among the five formulations. A lycopene formulation presented greater bioaccessibility in the small intestine (48,02%) than other ones rich in β -carotene (0.96%, 31.29%, 34.45% and 36.22%) or one rich in lutein (0.86%).

Conclusions: These results showed that the available carotenoids amounts for absorption in these products are much lower than declared in the label.

Key words: In vitro digestion, β -carotene, lycopene, lutein, bioavailability

ter fruit. In Brazil it is cultivated for a long time, but only in domestic orchards, known as caferana, cafezinho, ciruela, caramela, ameixa-do-pará or ameixabrava. Due to its orange to red color, typical of carotenoids, the aim of the present study was to quantify and determine the carotenoids profile in the edible parts of the fruits.

Methods: Peanut butter fruits were collected in January 2013 in the city of Rio de Janeiro, Brazil. Total carotenoid content were evaluated by spectrophotometric method at 450nm and the carotenoids profile by High Performance Liquid Chromatography.

Results: The fruit pulp presented high levels of total carotenoids (40 mg/100 g wet basis), in which 89% was lycopene (36 mg/100 g), followed β -carotene (2.5 mg/100 g) and lutein (0.3 mg/100 g). Lycopene is the carotenoid with the highest antioxidant activity and is present in high concentrations in the prostate tissue, which may explain its role in reducing the risk of prostate cancer. In Brazil, prostate cancer is the second most common among men, behind skin cancer. It is the sixth most common cancer type in the world and the more prevalent in men, accounting for about 10% of all cancers. The tomato and its products are considered the main sources of lycopene in the Western diet.

Conclusions: The peanut butter fruits are a rich source of lycopene presenting 10 times more than the tomato fruit (3.5 mg/100 g). This biodiversity fruit has a great potential of use, once it has a good taste to eat fresh and can also be used as an ingredient in preparations to increase the lycopene levels in food.

Key words: Bunchosia armeniaca, carotenoids, biodiversity fruits, bioactive compounds.

PO2945

EVALUATION OF ANTHOCYANIN PROFILE IN APPLE PEEL OF THREE CULTIVARS PRODUCED IN BRAZIL

A. Gouvêa¹, M. Santiago², R. Godoy², R. Borguini², S. Pacheco², L. Nascimento²

¹Program of Post Graduate Food Science and Technology, Rural Federal University of Rio de Janeiro, Rio de Janeiro, Brazil

²Embrapa Food Technology, Embrapa, Rio de Janeiro, Brazil

Background and objectives: The annual apple production in Brazil has remained around one million tonnes/year. In the processing industry of fruit juices, apple juice is considered one of the main products. This juice production generates 25 to 30% of waste (bagasse: peel, pulp and seed) which has aroused the interest of the scientific community, aiming its use for the

obtaining of new products from these residues. The peel is the part of the residue with the higher concentration of pectin and flavonoids, such as anthocyanin, being its antioxidant activity responsible for reducing the risk of cardiovascular diseases and chronic diseases such as cancer. The objective of this study was to compare the anthocyanin profile in apple peel of three cultivars produced in Brazil.

Methods: The cultivars Gala, Fuji and Red were obtained in local market in the municipality of Rio de Janeiro, Brazil. The apple peels anthocyanins were extracted with acidified methanol solution. Chromatography analysis was performed on a Waters® Alliance 2695 system, with a Waters® 2996 photodiode array detector, Thermo® Scientific C18 BDS (100mm x 4.6mm; 2.4µm) column and gradient elution method with acetonitrile and formic acid. It was observed the same anthocyanin profile among cultivars.

Results: The majoritary anthocyanin detect was cyanidin-3-galactoside (corresponding to 88% of total anthocyanin content in the evaluated matrix). This anthocyanin, compared to others present in food, has one of the highest antioxidant activity.

Conclusions: Therefore, the three apple cultivars can be considered a source of anthocyanin, being wasted each year by juice industry in large quantities, while could be used, for example, as a food ingredient with antioxidant properties. It could also allow the fruit sector to diversify its production and increase income.

Key words: antioxidant, flavonoids, residues

PO2946

EFFECT OF NON-ALCOHOLIC BEER IN THE SUBJECTIVE SLEEP QUALITY IN AN UNIVERSITY STUDENT POPULATION UNDER STRESS

L. Franco¹, R. Bravo¹, C. Galán¹, A B. Rodríguez¹, C. Barriga¹, J. Cubero¹

¹University of Extremadura, Spain

Background and objectives: Sleep deprivation affects the homeostasis of the physiological functions of organism. Beer is the only beverage that contains hops, a plant with sedative effect. Our objective is to determine the improvement of subjective sleep quality using the Quality Index Questionnaire Pittsburgh Sleep.

Methods: The assay was conducted in a population of 30 university student. The experimental period was 3 weeks, the first 7 days for the control, and following 14 days individuals ingested beer during dinner.

Results: The results revealed that one beer took during dinner improve the Subjective Quality of Sleep, because the Sleep Latency (time period measured from going to bed until the onset of sleep) decreases ($p < 0.05$) respecting to control.

Conclusions: The overall rating Subjective Quality of Sleep also improved significantly ($p < 0.05$). In conclusion, the consumption of non-alcoholic beer at dinner is recommended to improve the quality of sleep.

Key words: Sleep, Pittsburgh, hop, beer, stress.

PO2947

HYPOCHOLESTEROLEMIC EFFECT OF COWPEA VICILIN IN RATS FED A HIGH-CHOLESTEROL DIET

V. Neves¹, E. S. Ferreira¹, A. Demonte¹, A. L. Amaral¹, C. F. Zanelli²

¹Department of Food and Nutrition, School of Pharmaceutical Sciences, São Paulo State University, Brazil

²Department of Biological Sciences, School of Pharmaceutical Sciences, São Paulo State University, Brazil

Background and objectives: In this work was evaluated the hypolipidemic effects of cowpea vicilin (γ -vignin) and a statin in rats.

Methods: Rats male ($n=27$) were divided into three groups that received a hypercholesterolemic diet (20% palm oil, 1% cholesterol and 0.5% cholic acid). Hypercholesterolemic group (HC diet) was treated with saline solution, while that HC+7SC (HC diet, plus cowpea γ -vignin), and HC+SVT (HC diet, plus drug simvastatin) have received daily doses of 300 and 50 mg/kg/day of protein and drug, respectively, by gavage during 4 wk.

Results: The HC+7SC group showed a decrease in the total serum cholesterol, non-HDL-C and the atherogenic index (32.5, 54.3 and 70.7%, respectively), and these values were higher than those treated with simvastatin. Serum HDL-cholesterol levels were increased (57.1%) in the HC+7S-C group and hepatic cholesterol and triglyceride contents were significantly lower than in the HC (13.7 and 17.1%, respectively). The lipoprotein lipase activity was higher in the HC+7S-C group than the others; however, there were no differences in glutamic pyruvic transaminase activities. Furthermore, the expression of low density lipoprotein receptors (LDLr) in the liver has presented an upregulation (more 119%), while others were downregulated: the sterol regulatory element-binding protein 2 (SREBP-2) minus 34%; the 3-hydroxy-3-methylglutaryl Coenzyme A-reductase minus 52%; HMGCoA-synthetase minus 77%; and the fatty acid synthase minus 10%.

Conclusions: Based on these data, it can be suggested that the oral daily administration of isolated vicilin from cowpea can promote a hypolipidemic effects in rats fed hypercholesterolemic diets and these effects could involve the regulation of

the expression of some genes involved in lipid metabolism. Currently, others target genes are being studied in our lab to determine other possible elements involved. Acknowledgments: FAPESP, PADC/FCF/UNESP and FUNDUNESP.

Key words: cowpea vicilin; hypolipidemic; hypercholesterolemia.

PO2948

EFFECTS OF ADZUKI BEAN VICILIN IN RATS FED A HIGH-CHOLESTEROL DIET

V A. Neves¹, E S. Ferreira¹, A. Demonte¹, A L. Amaral¹, C F. Zanelli²

¹Department of Food and Nutrition, School of Pharmaceutical Sciences, Brazil

²Department of Biological Sciences, School of Pharmaceutical Sciences, São Paulo State University, Brazil

Background and objectives: The effect hypolipidemic, and body fat-lowering, of isolated vicilin (7S) from adzuki bean (AB) were studied.

Methods: Wistar rats were divided into four groups (n=9): standard diet (STD, casein), hypercholesterolemic (HC) diet (STD plus 20g/100g palm oil, 1g/100g cholesterol and 0.5g/100g cholic acid), HC diet+7S-A (HC plus 300mg of 7S/kg/body weight/day) and HC diet+SVT (HC plus 50mg of simvastatin/kg/body weight/day). The protein and the drug were administered by gavage for 28 days.

Results: Fecal excretion and feeding efficiency were similar among HC, HC+7S-A and HC+SVT. The HC+7S-A and HC+SVT groups have reduced body weight gain in 11.8 and 12%, respectively, compared to HC. Administration of vicilin (AB) caused significant decrease in serum levels cholesterol (-33.1%), triacylglycerides (-17.8%), and non-high-density lipoprotein (-53.4%), and increase of HDL-C (+52.9%), while those that received simvastatin had reduction of cholesterol in 20.4%, triacylglycerides in 6.9%, non-HDL-C in 30.7% and increase in HDL-C of 18.6%. The atherogenic indexes of HC+7S-A and HC+SVT groups were 67.1 and 31.7% lower than that of HC group, respectively. The liver of the animals of HC+7S-A group showed lower total lipids (-13.9%) and cholesterol (-9.2%) while HC+SVT a reduction of 8.8 and 11.3%, respectively, compared to animals fed HC diet. In liver tissue sections of animals that received HC diet were observed microvesicles fat accumulation within hepatocytes. This analysis characterizes hepatic steatosis and ballooning in liver tissue of animals fed HC diet. The lipoprotein lipase activity was significantly higher in all groups fed HC diet. The relative concentration of mRNA of the fatty acid synthase enzyme (FAS) and sterol

regulatory-element binding protein-2 (SREBP-2) had a strong decrease in groups that received adzuki vicilin. Others target genes are being studied to determine other variants involved.

Key words: adzuki vicilin; hypolipidemic; cholesterol-lowering.

PO2949

PLASMA PHARMACOKINETICS FOLLOWING INTRAVENOUS ADMINISTRATION OF MASLINIC ACID, A PENTACYCLIC TRITERPENE FROM OLIVES

M. Sánchez González¹, G. Lozano Mena¹, H. Colom¹, A. García Granados¹, M E. Juan¹, J M. Planas¹

¹Departament de Fisiologia and INSA-UB, Universitat de Barcelona, Barcelona, Spain

Background and objectives: Maslinic acid is the main pentacyclic triterpene found in fruits and leaves of *Olea europaea* L. This component presents beneficial effects on health, including antiinflammatory, hypoglycemic, antiviral, antimicrobial and antitumor activities. The aim of the present study is to determine the pharmacokinetics parameters of maslinic acid in rats.

Methods: Maslinic acid was dissolved in hydroxypropyl- α -cyclodextrin and administered by a single intravenous dose of 1 mg/kg to 6-hour fasted male Sprague-Dawley rats. Blood samples were withdrawn from the saphenous vein at different times (2, 5, 10, 15, 30, 40, 50, 60, 70, 100 and 130 min). Plasma samples were processed by liquid-liquid extraction with ethyl acetate before LC-APCI-MS analysis. The plasma concentration-time data was analyzed by WinNonlin software to calculate the pharmacokinetic parameters.

Results: Non-compartmental and compartmental analyses were performed and intravenous data were best described by a two compartment model. After intravenous administration, maslinic acid showed a rapid distribution to an extravascular compartment, with half-life ($t_{1/2}$) of 8.86 min, followed by an elimination phase with $t_{1/2}$ of 48.0 min. The apparent volume of distribution in the steady state (V_{ss}) was 0.135 L/kg. Maslinic acid showed a maximum plasma concentration (C_{max}) of 18.32 $\mu\text{mol/L}$, body clearance (CL) of 8.65 mL/min/kg and area under the plasma concentration time-course (AUC) of 244.3 $\mu\text{mol}\cdot\text{min/L}$.

Conclusions: The pharmacokinetic model adequately described the plasmatic concentration of maslinic acid, suggesting that this pentacyclic triterpene rapidly leaves the bloodstream, with a low distribution to the peripheral compartment and fast elimination from the organism. Supported by grants AGL2009-12866 from MCT Spain and 2009-SGR-00471 from the Generalitat de Catalunya.

Key words: Maslinic acid, Rat plasma, Olives, LC-MS

PO2950**METABOLITE PROFILE IN PLASMA OF MASLINIC ACID, A BIOACTIVE COMPOUND FROM OLEA EUROPAEA L.**

M. Sánchez González¹, G. Lozano Mena¹, O. Jáuregui¹, A. García Granados¹, M E. Juan¹, J M. Planas¹

¹Departament de Fisiologia and INSA-UB, Universitat de Barcelona (UB), Barcelona, Spain

Background and objectives: Maslinic acid, the main pentacyclic triterpene of olives, exerts antioxidant, cardioprotective and antitumor activities. Despite its beneficial effects on health, there is a lack of knowledge on the metabolism of this compound. Therefore, the present study aims to identify and quantify maslinic acid and its metabolites in plasma.

Methods: Sprague-Dawley rats were orally administered with 50 mg/kg of maslinic acid and blood was collected after 30 min. Plasma samples were treated by liquid-liquid extraction with ethyl acetate prior to analysis by LC-APCI-MS. The triterpene was separated on a C18 column using a gradient elution of water and acetonitrile at a flow rate of 0.8 mL/min. The metabolites of maslinic acid were identified by LC-APCI-LTQ-Orbitrap-MS with a mass accuracy < 1 mDA.

Results: Maslinic acid was found in plasma with m/z 471.3480 and retention time (t) of 11.1 min at a concentration of $5.47 \pm 0.70 \mu\text{M}$. The screening of plasma samples revealed the formation of derivatives with mass shifts of +14, +16 and +30 in comparison to maslinic acid. Two monohydroxylated and dehydrogenated metabolites (m/z 485.3272) were quantified at $16.0 \pm 3.5 \text{ nM}$ (t = 8.19 min) and $508.1 \pm 75.1 \text{ nM}$ (t = 9.63 min), respectively. Three monohydroxylated derivatives (m/z 487.3418) were found at concentrations of $155.2 \pm 23.0 \text{ nM}$ (t = 6.70 min), $56.5 \pm 10.5 \text{ nM}$ (t = 7.33 min) and $45.6 \pm 11.3 \text{ nM}$ (t = 9.03 min), respectively. Finally, a dihydroxylated and dehydrogenated metabolite (m/z 501.3211) was detected with values of $14.3 \pm 3.5 \text{ nM}$ (t = 6.16 min).

Conclusions: After oral administration, maslinic acid is the main compound in plasma, along with 6 metabolites resulting from hydroxylation and dehydrogenation reactions. Supported by grants AGL2009-12866 from MCT Spain and 2009-SGR-00471 from the Generalitat de Catalunya.

PO2951**DIETARY N-METHYLSEROTONIN REGULATES SKIN TEMPERATURE IN A FEMALE RAT MODEL OF MENOPAUSE-RELATED HOT FLASH.**

M. Weiser¹, A. Garrison¹, H. Mohajeri², C. Butt¹

¹DNP-Boulder Neuroscience, DSM Nutritional Products, Boulder, CO, USA

²DNP-Biological Models, DSM Nutritional Products, Kaiseraugst, Switzerland

Background and objectives: Clinical evidence suggests that supplementation with black cohosh (*Cimicifuga racemosa*) relieves symptoms of menopause, but the data are mixed. N-methylserotonin (NMS) is a minor component of black cohosh and is a selective agonist of a serotonin (5-HT) receptor subtype that is involved in thermoregulation (5-HT₇). NMS also has inhibitory activity at the serotonin reuptake transporter [Powell et al. (2008) *J Agric Food Chem* 56:11718-26]. These findings implicate NMS as an active component of black cohosh that may relieve hot flash and mood-related symptoms of menopause, but the in vivo effects and effective dose(s) of NMS are currently unknown. In this study we sought to determine the effects of dietary supplementation with NMS on induced hot flash and mood in female rats.

Methods: Ovariectomized (OVX) female rats were fed diets that contained different levels of NMS (0-18.5 ug/kg/d) or were given estradiol implants. The animals were then tested for locomotor activity in the open field, anxiety-like behaviors on the elevated plus maze, and depression-like behaviors with the forced swim test. Hot flashes were subsequently induced with intravenous calcitonin gene-related peptide, and skin temperature was monitored with thermocouple probes.

Results: Dietary NMS did not affect OVX-induced weight gain, uterine growth, or mood-related behaviors. However, one-way ANOVA detected that dietary NMS significantly lowered baseline skin temperature [F(3,12)= 13.422, p< 0.001, Power= 0.997] and blunted the hot flash response [F(3,10)= 5.268, p= 0.018, Power= 0.796] in a manner similar to that observed in animals with estradiol implants.

Conclusions: These in vivo findings support NMS as an active component of black cohosh that could decrease menopausal hot flashes without the potential risks associated with hormone replacement therapy or phytoestrogen use.

Key words: black cohosh, serotonin, thermoregulation, menopause

PO2952

THE EFFECT OF IN VITRO SIMULATED DIGESTION ON THE BIOACTIVITY OF FREE AND COMPLEXED RESVERATROL IN ORANGE JUICE AND MILK

C. Lucas-Abellán¹, M I. Fortea¹, M T. Mercader-Ros¹, A. Serrano-Martínez¹, J A. Gabaldón¹, E. Núñez-Delicado¹

¹Dto. Tecnología de la Alimentación y Nutrición, Universidad Católica San Antonio de Murcia, Spain

Background and objectives: Resveratrol, has been reported to exert many different health-promoting effects. The dietary intake can be increased through resveratrol-enriched functional foods. The high hydrophobicity of resveratrol and oxidative enzymes may constitute a serious problem for its bioavailability, formulation in the elaboration of functional foods. In order to avoid this limitation, inclusion of resveratrol in cyclodextrins (CDs). In this work, we investigated the effects of an in vitro gastric and pancreatic digestion on the stability, composition and absorption of the 0.8 mM resveratrol in orange juice and milk, in the absence and presence of 13 mM of α -CDs.

Methods: Digestion was carried out with a mixture of pepsin-HCl for 2 h, followed by 2 h incubation with pancreatin and bile salts at 37°C with shaking, in the absence of light. After digestion, the samples were acidified, filtered and analysed by HPLC-DAD to determine the content of total soluble recovered.

Results: When the dialyzed samples were analyzed by HPLC, it was found that resveratrol was not attacked by digestive enzymes. When the absorption values of resveratrol were compared both in the presence and absence of α -CDs in orange juice and milk, it was observed that resveratrol complexed in α -CDs in orange juice and milk was absorbed mainly (0.72 mM and 0.69 mM respectively) whereas the resveratrol in absence of α -CDs in juice and milk was absorbed only 0.1 mM in both case. This indicated that resveratrol absorption is highest when it was complexed, because it is totally dissolved and α -CDs acts as a reservoir, releasing resveratrol according to their solubility limit allowing greater absorption.

Conclusions: This complexation phenomenon increased the absorption of the resveratrol in orange juice and milk, so the CDs act as controlled release reservoir.

Key words: Resveratrol, cyclodextrins, absorption, in vitro digestion.

PO2953

ANTI-INFLAMMATORY EFFECTS OF LACTOBACILLUS ACIDOPHILUS AND BIFIDOBACTERIUM LACTIS IN AN INFLAMMATORY MODEL OF HT-29 CELLS

W.F. Hsu¹, S.C. Li¹, C.K. Shih¹

¹School of Nutrition and Health Sciences, Taipei Medical University, Taipei, Taiwan

Background and objectives: Recent evidences suggest that pathogenesis of inflammatory bowel disease (IBD) may be due to imbalance of the intestinal microflora. Probiotics such as Lactobacilli and Bifidobacteria have been shown to exhibit a beneficial effect on treatment of IBD. Previous studies have showed the treatment of Lactobacillus acidophilus and Bifidobacterium lactis can improve the inflammatory symptom of rat colitis model. The present study examined the anti-inflammatory effects of L. acidophilus and B. lactis in an inflammatory model of human colorectal cancer cells.

Methods: HT-29 human colorectal cancer cells were treated with tumor necrosis factor- α (TNF- α) and lipopolysaccharide (LPS) for 24 hours as an inflammatory group. L. acidophilus and B. lactis were added at designated multiplicity of infection (MOI, 0.1, 1 and 10) with TNF- α and LPS as treatment groups. Interleukin-8 (IL-8) concentration in cultured medium was analyzed by enzyme-linked immunosorbent assay (ELISA). Protein expressions of phosphorylated nuclear factor kappa B (p-NF κ B), vascular cell adhesion molecule-1 (VCAM-1) and intercellular adhesion molecule-1 (ICAM-1) were analyzed by Western blotting.

Results: L. acidophilus at MOIs of 1 and 10 showed low IL-8 secretion as compared with inflammatory group. L. acidophilus at MOIs of 0.1, 1 and 10 showed low expressions of p-NF κ B and VCAM-1 as compared with inflammatory group. The expression of ICAM-1 was not affected by L. acidophilus. B. lactis at MOI of 10 showed low IL-8 secretion as compared with inflammatory group. B. lactis at MOIs of 1 and 10 showed low expressions of p-NF κ B and VCAM-1 as compared with inflammatory group. In addition, B. lactis down-regulated ICAM-1 expression in a dose dependency.

Conclusions: The results suggest that L. acidophilus and B. lactis may inhibit inflammation through different pathways.

Key words: Inflammatory bowel disease, Lactobacillus acidophilus, Bifidobacterium lactis

PO2954**ISOTHIOCYANATES PROTECT AGAINST OXIDIZED LDL-INDUCED ENOS REDUCTION AND ANGIOGENESIS VIA FOXO1-DEPENDENT REGULATION**A. Lin¹, C. Li²¹School of Nutrition, Chung Shan Medical University, China²Department of Nutrition, China Medical University, China

Background and objectives: Oxidized low-density lipoprotein (oxLDL) is a key contributor of atherogenesis through multiple mechanisms. OxLDL inhibits endothelial nitric oxide synthase (eNOS) activity and nitric oxide (NO) production, leading to interruption of NO-mediated responses in endothelial cells has been demonstrated to be involved in the pathogenesis of several cardiovascular disorders.

Methods: In this study, we investigated the protection effects of three structurally related isothiocyanates (ITCs), i.e., sulforaphane (SFN), benzyl isothiocyanate (BITC), and phenethyl isothiocyanate (PEITC), against oxLDL-induced eNOS reduction, cell migration and tube formation and the mechanism involved.

Results: Western blot and EMSA analyses reveal that oxLDL increases reactive oxygen species (ROS) production through activating NADPH oxidase complex, results in Akt and FOXO1 dephosphorylation, FOXO1 nuclear location and bound to the eNOS promoter in human umbilical vein endothelial cells (HUVECs). The correlation between oxLDL-induced FOXO1 activity and the expression of angiogenesis-related molecules, including hypoxia inducible factor-1 α (HIF-1 α), vessel endothelial growth factor (VEGF) and Angiopoietin-2 (ANG-2) also increased. In the presence of oxLDL, SFN, BITC, and PEITC (0-10 μ M) pretreatment dose-dependently reversed membrane activation of NOX and ROS production. The ITCs also prevent oxLDL-induced FOXO1 activity and eNOS reduction, cell migration and tube formation.

Conclusions: In conclusion, our results provide a new protective mechanism involving FOXO1 as a critical role in regulating angiogenesis in HUVECs and suggest a novel capacity for SFN, BITC, and PEITC in protect against oxLDL-induced endothelial destruction which may be potential compounds for the prevent from oxidative stress-related cardiovascular diseases.

Key words: isothiocyanates, oxLDL, HUVECs, eNOS, FOXO1.

PO2955**EXTRACT OF A JAPANESE PICKLING MELON PREVENTS ETHANOL-INDUCED LIVER INJURY IN RATS**A. Kojima-Yuasa¹, E. Hirauchi¹, A. Tamura¹, I. Matsui-Yuasa¹¹Dept. of Food and Human Health Sciences, Graduate School of Human Life Science, Osaka City University, Japan

Background and objectives: The development of alcoholic liver disease is a complex process that involves both the parenchymal and non-parenchymal cells of the liver. Tamatsukurikuronon-sirouri (TS), a Japanese pickling melon (*Cucumis Melo* var. *Conomon*), is a special vegetable in Osaka, Japan and its extract has a strong antioxidant activity. Here we examined the effect of an extract of TS (ETS) on ethanol-induced liver injury.

Methods: 1) In vitro experiments: Isolated hepatocytes or hepatic stellate cells (HSCs) were cultured with or without 100 mM ethanol. ETS (0~100 μ g/ml) was added to culture medium with ethanol simultaneously. The cells were harvested after 0~24 hrs. 2) In vivo experiments: Male Wistar rats were fed a diet with or without 0.3 or 0.5% ETS. Animals were given drinking water containing ethanol 5% (v/v) together with two doses of CCl₄ (0.1 ml/kg BW, i.p.) weekly for 3 weeks.

Results: In cultured hepatocytes, the treatment of ETS suppressed ethanol-induced increase in cell death via inhibiting CYP2E1 activity. ETS treatment maintained intracellular ROS levels in 100 mM ethanol-treated cells to the levels of the control cells. In HSC which is a key player in hepatic fibrosis, the treatment with ETS also suppressed ethanol-induced increase in expression of type I collagen and α -SMA, makers of HSC activation. Furthermore, we examined the effect of ETS on AST and ALT activities and liver fibrosis in rats treated with ethanol plus CCl₄. The treatment of ETS suppressed the leakage of AST and ALT in the ethanol plus CCl₄ treated rats. Furthermore, ETS treatment totally protected against ethanol plus CCl₄ induced liver fibrosis and necrosis.

Conclusions: These results suggest that ETS may be a candidate for preventing ethanol-induced liver injury.

Key words: Ethanol-induced liver injury, Hepatocytes, Fibrosis, Japanese pickling melon

PO2956

INFLUENCE OF VITAMINS FOR DIFFERENTIATION OF MONOCYTE, THP-1, TO MACROPHAGE

M. Andoh¹, K. Minato¹, K. Watanabe¹, A. Ohara¹

¹Department of Applied Biological Chemistry, Meijo University, Nagoya, Japan

Background and objectives: THP-1, a human monocytic cell line could be polarized into M1 / M2 macrophages. It is suggested that M1 macrophages play a key role in the defense against bacterial and viral infection. In contrast M2 macrophages play a role in parasite infection, tissue modeling, and angiogenesis. M1 produce inflammatory cytokines, such as IL-1, IL-12, TNF- and nitric oxide (NO) and, M2 produce anti-inflammatory cytokine IL-10. In this study, it was investigated for influence of micronutrients such as vitamins in differentiation to M1 and M2 macrophages.

Methods: THP-1 was treated for 48h with phorbol 12-myristate 13-acetate. Then, differentiated adherent cells were stimulated LPS and IFN, and, the vitamin was added to the differentiate cells. And we investigated for polarization on THP-1 macrophages towards either the M1 or M2A volume of cytokines and NO from differentiated THP-1 were examined. The expression of cytokines mRNAs was determined by qPCR. NO was determined by using griess reagent, and an expression of iNOS mRNA, related to produce NO, was analyzed by qPCR.

Results: Inflammatory cytokine, and nitric oxide productions were activated by LPS and IFN. It was suggested that M1 marker genes was induced by LPS and IFN. IL-12 was down-regulated, but M2 marker gene, IL-10 was up-regulated by only PMA-stimulated THP-1 macrophages. Nitric oxide production induced by LPS and IFN stimulation was slightly inhibited by addition with vitamin D3. Therefore, vitamin D3 induces macrophages into M2. Also, vitamin D3 induces into more M2 macrophages than M1 in macrophages differentiation.

Conclusions: Our study was suggested that vitamin D3 induce to differentiate macrophages into M2 was dominant. Vitamin D3 increase to in expression IL-10 mRNA more than IL-12. Therefore, vitamin D3 is good for the health against in parasite infection.

Key words: macrophage, monocyte, M1/M2, vitamin

PO2957

INFLUENCE OF FOODS ON DIFFERENTIATION OF MONOCYTE, THP-1, TO OSTEOCLAST

K. Watanabe¹, K. Minato¹, M. Andoh¹, A. Ohara¹

¹Department of Applied Biological Chemistry, Meijo University, Nagoya, Japan

Background and objectives: Bone remodeling is maintained by the balance of osteoclasts which perform bone resorption and osteoblast which perform bone formation. But, when this balance breaks down, it has bad influence on normal bone turnover. An influence of micronutrient in foods, such as calcium and vitamin D, on the bone metabolism was been investigated well. It would be also important to investigate influence of actual food intake on the bone metabolism.

Methods: In the present study, using human monocytic cell THP-1 differentiated into osteoclasts by phorbol 12-myristate 13-acetate (PMA), macrophage colony stimulating factor (M-CSF), and receptor activator of NF- κ B ligand (RANKL), or influence of food extracts on differentiation to osteoclast was examined. Osteoclasts are large, multinucleated cells, which originate from the fusion of macrophages. Tartrate-resistant acid phosphatase (TRAP) is a well-known marker of osteoclasts differentiation. Differentiation of osteoclast was confirmed by morphological analysis using TRAP staining, determination of TRAP activity and detection of receptor activator of NF- κ B (RANK) protein.

Results: TRAP staining and activity in THP-1 stimulated with PMA for 24hr were increased by M-CSF and RANKL treatment, compared with control cells without M-CSF and RANKL. When the influence of some food extract stimulation on the osteoclast differentiation was investigated, it was shown that hot water extract of an edible mushroom increased significantly TRAP activity. In bone metabolism, it is also important that the osteoclast differentiation would be promoted, in order to transpose old bone to a new one.

Conclusions: In our work, it was suggested that an edible mushroom might influence osteoclast action.

Key words: osteoclast, THP-1, edible mushroom

PO2958

A CO-ADMINISTRATION OF FLAVONOIDS TO INCREASE THEIR BIOAVAILABILITY IN RAT

A. Doi¹, Y. Aihara¹, T. Momota¹, A. Yokoyama¹, T. Hashimoto¹, K. Kanazawa¹

¹Department of Agrobioscience, Graduate School of Agricultural Science, Kobe University, Japan

Background and objectives: Functional food factors such as flavonoids undergo conjugations with UDP-glucuronosyl-transferases and/or phenol sulfotransferases at the intestinal absorption process and excreted to lumen side. Therefore, the dietary functional factors are usually low in the bioavailability. However, the conjugation reaction may be confused when plural kinds of flavonoids are simultaneously absorbed in the intestinal epithelial cells, and hereby a flavonoid may escape from the conjugation and be incorporated into blood circulation in the free aglycone form.

Methods: In the present study, we administrated rat with plural flavonoids and compared the levels of aglycone and conjugated forms in blood. First, a combination of flavonoid, quercetin and luteolin or quercetin and galangin, were dosed orally to rats and determined in the levels of aglycone and conjugated forms in blood.

Results: The plasma aglycone level of luteolin significantly increased by the co-administration with equal amount of quercetin, but did not by the co-administration with galangin. Then, a combination of flavonoid and glycosides, quercetin and apigenin (apigenin 7-O-glucoside) or quercetin and vitexin (apigenin 8-C-glucoside), were dosed orally to rats. The plasma level of conjugated quercetin significantly increased by the co-administration with apigenin, but did not with vitexin.

Conclusions: As a result, an O-glycoside flavonoid can enhance the incorporation of co-administrated flavonoid, may be because the O-glycosides undergo hydrolysis during the absorption process and thus the overall concentration of flavonoid can be high in intestinal epithelial cells. The idea of co-administration of flavonoids will be a strategy to enhance the bioavailability of biofunctional flavonoids and prevent degenerative diseases.

Key words: quercetin, bioavailability,

PO2959

STRUCTURALLY DIFFERENT GALACTO-OLIGOSACCHARIDES HAVE DIFFERENT DIGESTIBILITY PATTERNS AND BIFIDOGENIC PROPERTIES IN RATS

M C. Marín-Manzano¹, O. Hernández-Hernández², L A. Rubio¹, F J. Moreno³, M L. Sanz², A. Clemente¹

¹Estacion Experimental del Zaidin, Consejo Superior de Investigaciones Científicas, Granada, Spain

²Instituto de Química General, Consejo Superior de Investigaciones Científicas, Madrid, Spain

³Instituto de Investigación en Ciencias de la Alimentación, Consejo Superior de Investigaciones Científicas-Universidad Autónoma de Madrid, Spain

Background and objectives: Galacto-oligosaccharides (GOS) have demonstrated to increase the bifidobacterial population of fecal microbiota in healthy human's volunteers; however, such effect was not observed in other related studies. These dissimilarities can be attributed to several factors including the type, purity and composition of the GOS used. The relationship between bifidogenic properties and structural features of GOS in vivo has been investigated.

Methods: A comparative study regarding the resistance to gut digestion, fermentability and selective growth of beneficial bacteria in the large intestine of rats fed novel GOS derived from lactulose (GOS-Lu) or commercially available derived from lactose (GOS-La) was carried out. Animals were fed either a control diet or diets containing 1% (w/w) of GOS-Lu or GOS-La for 14 d; Cr2O3 was included in diets as an indigestible marker.

Results: Quantitative analysis of carbohydrates from dietary and ileal samples demonstrated that the trisaccharide fraction of GOS-Lu was significantly more resistant to gut digestion than that from GOS-La, according to their ileal digestibility rates (12.5 and 52.9%, respectively), whilst the disaccharide fraction of GOS-Lu was fully resistant. The low ileal digestibility of GOS-Lu was attributed to the great resistance of galactosyl-fructoses to mammalian digestive enzymes, highlighting the key role played by monomer composition and linkage type involved in the oligosaccharide chain. The absence of GOS-La and GOS-Lu digestion-resistant oligosaccharides in fecal samples indicated that they were readily fermented within the large intestine, enabling both GOS to have a potential prebiotic function. The novel GOS-Lu exerted a stronger bifidogenic effect on gut microbiota than GOS-La, having the former a selective and significant increase of *Bifidobacterium animalis*.

Conclusions: A direct relationship between patterns of resistance to digestion and bifidogenic properties of galacto-oligosaccharides is revealed.

Key words: bifidobacteria, galacto-oligosaccharides, prebiotics

PO2960**NEW SPL OF PHYTONUTRIENTS FOR ESSENTIAL LIFESPAN**Y. Yuexin^{1,2}¹DRI Experts Committee, Chinese Nutrition Society, China²Institute of Nutrition An Food Safety, China CDC, China

Background and objectives: There is increasing knowledge concerning phyto-chemicals potential for health maintenance or disease risk reduction throughout adulthood and during aging. This means that they are essential individual lifespan. The purpose of this paper is to describe the specific proposed level (SPL) and the tolerable upper intake level levels (UL) established by Chinese Nutrition Society are based on evaluations of functionality and possible adverse health effects.

Methods: Identification of possible indicators by Systematic Evidence-Based Reviews; Evaluating approaches for integrating evidence into processes for deriving SPL and UL; SEBR is essentially an approach to identifying, tabulating and grading the quality of available data.

Results: Both positive or adverse effects detected and identified at the quality of available data were evaluated by DRI experts committee. 12 phyto-chemistry SPL and 10 UL are established in the general population, including Carotenoid, Quercetin, Lutein, Glucosamine Sulfate so on.

Conclusions: These results show first the recommendation SPL and UL on non-essential nutrients substance by Chinese Nutrition Society. As a starting point, the result provides a guidance for professionals and industries.

Key words: phytochemicals, Evaluating approaches, specific proposed level, UL

PO2961**TEXTURE AND COLOR OF BREAD: INFLUENCE OF β -GLUCANS ADDITION**A E. Gallardo^{1,2}, I. Barbosa³, M. Erben^{1,2}, I M P L V O. Ferreira³, O. Pinho²¹Baking Laboratory, ITA, FIQ, Universidad Nacional del Litoral, Argentina²Faculty of Nutrition and Food Science, University of Porto, Portugal³Faculty of Pharmacy, University of Porto, Portugal

Background and objectives: β -glucans are soluble and fermentable fibers that, once in the intestine can compose solutions presenting benefits for health. The amount of yeast

β -glucans in foods must range between 50 and 200 mg per serving (EFSA). However, the influence of β -glucans addition on bread sensory characteristics was not understood. Quality control of bread was based on texture and color, since both parameters affect consumer preference. The objective was study the effect of adding different levels of β -glucans extracted from yeast cell wall to improve the bread's characteristics.

Methods: Breads were made from 500 g of flour mixture for bread and variable amounts of β -glucans (0; 0.5; 1; 1.5 and 2 g). Volume was evaluated. For texture assay a TA-XT-2iHR Texture Analyser. Regarding color, lightness (L^*), redness (a^*) and yellowness (b^*) were determined using a Minolta CR-300 colorimeter.

Results: The bread displaying the largest volume was that with a dose of 1.5 g. For Hardness, the highest value corresponded to the 0 g dose and the lowest to the 1.5 g one; whereas for Elasticity, the highest was for 1.5 g and the lowest for 0g and 0.5 g; the highest value for Masticability corresponded to 0.5 g and the lowest one to 1.5 g. In respect to color, L^* was the highest for the 1.5 g; a^* was the highest for 0 g and the lowest for 1.5 g; b^* was the highest for 0 g and the lowest for 1.5 g.

Conclusions: More studies are needed to confirm the influence of β -glucans addition to bread using different baking conditions.

Key words: bread, β -glucans, texture, color.

PO2962**BIOACTIVE AND CLAIMS : REGULATORY SYSTEM IN CHINA**Y. Yuexin¹¹National Institute of Nutrition and Food Safety, China

Background and objectives: Chinese have a long tradition and strong passion for using herbs and specific foods to be as tonics and to regulate body functions. In the present, regulation system defines health foods as foods with specific health functions.

Methods: Regulation Overview and Comparative analysis.

Results: The paper introduces the regulation system on function claim and nutrition claim in China, and compares with EU and US to Ingredient and claim on science approach and management. There are a rule for function food and novel Ingredients; conventional food which makes nutrition and function claims of nutritional benefits on its label or packaging (nutrition Labeling, GB28050).

Conclusions: There are novel ingredient approval regulation, 27 claims that are allowed, more than 10 thousand products in the marketing. The approach procedure is different with other countries.

Key words: Novel ingredient, Function claims, label

PO2963**MICROENCAPSULATED GREEN TEA EXTRACT SUPPLEMENTATION AMELIORATED DYSLIPIDEMIA AND FAT ACCUMULATION IN A FRUCTOSE FED RAT MODEL**

M. Chang¹, Y. Jun¹, M. Kim², P. Seoung³

¹Department of Food and Nutrition, Kookmin University, Seoul, Republic of Korea

²Department of Food Engineering, Dankook University, Cheonan, Republic of Korea

³National Institute of Animal Science, RDA, Suwon, Republic of Korea

Background and objectives: The effectiveness of polyphenols depends on preserving the stability, bioactive and bioavailability of the active ingredients. To protect polyphenolic green tea extract from adverse environmental conditions, it was microencapsulated with mean diameters of 3.4 μ m using maltodextrin (1:4, v/v) as a carrier and coating agents by hydroshear homogenization at 8,000rpm for 30 min. This study was initiated to compare the effects of microencapsulated green tea extract (MGTE) and non capsulated green tea extract (GTE) on hypertriglyceridemia induced by feeding a high fructose diet in wistar rats.

Methods: 8 week old rats were fed either AIN 93 diet (normal control, NC, n=10), or modified AIN-93 diet in which cornstarch was substituted with 63% fructose to induce hypertriglyceridemia for 8 weeks. The hypertriglyceridemic rats were treated with daily oral doses of 0 mg (hypertriglyceridemic control, HC, n=10), GTE (n=10) or MGTE (n=10) with dose of 50mg•kg bw⁻¹d⁻¹ for 4 weeks. Serum lipid profiles, visceral fat accumulation and antioxidative enzymes were analyzed.

Results: The serum triglycerides (TG), total cholesterol, HDL-cholesterol and uric acid (UA) were significantly increased by feeding a fructose diet. The treatment of GTE decreased serum TG and FFA levels compared with those of HC group. The supplementation of MGTE caused more decrease in serum TG, FFA, and UA than GTE did. The supplementation of GTE or MGTE in hypertriglyceridemic rats decreased the amount of epididymal fat and visceral fat significantly compared to those in HC group.

Conclusions: Our results indicated that the utilization of microencapsulated green tea extract, instead of free compounds, can effectively alleviate the dyslipidemia and fat accumulation induced by high fructose diet. This research was supported by joint research project (#PJ9071222012) from Rural Development Administration, Republic of Korea.

Key words: Microencapsulation, green tea extract, hypertriglyceridemia.

PO2965**ANALYSES OF A POLYPHENOL AGLYCONE PROFILE IN FRUIT AND VEGETABLES BY LC-MS QTOF**

L. L. Hamill¹, W. C. McRoberts², S. D. Floyd², M. C. McKinley¹, I. S. Young¹, J. V. Woodside¹

¹Centre for Public Health, Queen's University Belfast, Institute of Clinical Science B, Grosvenor Road, Belfast, BT12 6BJ, Northern Ireland, UK

²Food Chemistry Division, Agri-Food and Biosciences Institute, Newforge Lane, Belfast BT9 5PX, Northern Ireland, UK

Background and objectives: Epidemiological data indicates that increased intake of fruit and vegetables (FV) is associated with decreased incidence of chronic diseases. FV contain potentially protective components which may account for health benefits associated with increased intakes, including polyphenols. However, to determine polyphenol intake from FV it is important to assess content.

Methods: Data, collected within our centre, identified commonly consumed FV in Northern Ireland. One aim of our work was to measure polyphenol content of these FV. Samples (n 2) of each were lyophilised, milled and 0.05g was hydrolysed with enzymes. A profile of 14 polyphenol aglycones (flavonoids and phenolic acids) were analysed by LC-MS QToF, within a single run.

Results: Data are presented as mg/100gfw \pm SD. Content for raw and cooked cauliflower, respectively, were: chlorogenic acid (chl), 0.06 \pm 0.00 v. 0.16 \pm 0.00; caffeic acid, 0.26 \pm 0.04 v. 0.11 \pm 0.01; para-coumaric acid (p-cou), 0.14 \pm 0.00 v. 0.03 \pm 0.01 and quercetin, 0.02 \pm 0.00 v. 0.00 \pm 0.00. Chl content for raw and cooked parsnip was 0.24 \pm 0.05 v. 0.18 \pm 0.02. Chl content for gem and ice-berg lettuce was 1.00 \pm 0.11 v. 0.57 \pm 0.06. p-cou content for raw and cooked cabbage was 0.07 \pm 0.01 v. 0.03 \pm 0.00. Although un-ripe, ripe and over-ripe bananas were analysed, and epicatechin was present, amounts were <LOD.

Conclusions: Our results indicate that polyphenols are present in FV and therefore may play a role in beneficial effects associated with increased consumption. However, before we can fully establish impact on human health, further research is required, measuring polyphenol content in other FV, and examining the effect of ripeness, cultivar and domestic cooking. This research is on-going within our centre. Acknowledgements: Work is funded by the MRC.

Key words: fruit, vegetables, polyphenols

PO2966**EFFECT OF DAIRY CALCIUM FROM CHEESE AND MILK ON BLOOD LIPIDS IN HEALTHY YOUNG MEN**

K V. Sørensen¹, T K. Thorning¹, A. Astrup¹, M. Kristensen¹, J K. Lorenzen¹

¹Department of Nutrition Exercise and Sports, University of Copenhagen, Frederiksberg C, Denmark

Background and objectives: Calcium from different dairy sources might affect blood lipids differently due to differences in food matrix and nutritional composition of the individual dairy products. The aim of this study was to investigate the effect of high dairy calcium intake in the matrix of cheese or milk on blood lipid profile.

Methods: Fifteen healthy young men participated in a randomized cross-over study with three isocaloric 14-days intervention diets: i) high intake of semi skimmed milk (1200 mg dairy calcium/day and ~500 mg non-dairy calcium/day); ii) high intake of semi hard cows cheese (1200 mg dairy calcium/day and ~500 mg calcium from non-dairy sources) or iii) non-dairy calcium control diet (~500 mg non-dairy calcium/day). All diets were similar in macro-nutrients, dietary fiber and fatty acid composition. Fasting blood samples were taken before and after each diet period.

Results: Compared to non-dairy calcium, cheese consumption attenuated the increase in both total and LDL cholesterol (-0.48 ± 0.14 and -0.37 ± 0.12 mmol/L, respectively; Pdiff. < 0.01). Likewise, milk consumption attenuated the increase in total and LDL cholesterol (-0.32 ± 0.14 and -0.31 ± 0.12 mmol/L; Pdiff. < 0.05); however the magnitude of effect was slightly smaller than for cheese and no difference was found between the cheese and the milk diet (Pdiff. > 0.24). There was no effect of diet on changes in HDL cholesterol, triglycerides or lipid ratios.

Conclusions: Dairy calcium from milk and cheese attenuated fat-induced increases in total and LDL cholesterol. No difference between dairy calcium sources were found, thus these results do not confirm the hypothesis that the blood lipid response by dairy calcium depends on the dairy product type.

Key words: Dairy, calcium, blood lipids, milk, cheese

PO2967**INTESTINAL INFLAMMATION IN CYSTIC FIBROSIS: LACK OF EFFECTIVENESS AFTER TREATMENT WITH MESALAMINE AND PROBIOTICS**

V M. Navas-López¹, J. Blasco-Alonso¹, F. Girón Fernández-Crehuet¹, M J. Serrano Nieto¹, M I. Vicioso Recio², C. Sierra Salinas¹

¹Pediatric Gastroenterology and Nutrition Unit, Hospital Materno Infantil, Málaga, Spain

²Laboratory Unit, Hospital Materno Infantil, Málaga, Spain

Background and objectives: There is some evidence of intestinal inflammation in patients with Cystic Fibrosis (CF) but little is known about the pathophysiology. The objective was to assess the incidence of intestinal inflammation measuring faecal calprotectin (FC) and intestinal permeability (IP) in children with CF and to investigate whether mesalamine or probiotics could modify the inflammation.

Methods: FC ($\mu\text{g/g}$) and IP were assessed in CF patients before and after one-month treatment with mesalamine and VSL#3. IP was measured by dual test with lactulose (L) and mannitol (M). Fecal nitrogen and fat were obtained by Fenir (g/day).

Results:

Mesalamine treated patients (n= 25)	Basal	After treatment
FC ($\mu\text{g/g}$)	275 \pm 233	218 \pm 218
Fat (g/24h)	6.7 \pm 5.9	6.28 \pm 5.9
Nitrogen (g/24h)	2.3 \pm 1.9	2.11 \pm 1.31
%Lactulose (L)	1.59 \pm 1.2	1.77 \pm 1.42
%Mannitol (M)	49.85 \pm 50.35	35.73 \pm 22.14
% L/M	0.047 \pm 0.042	0.059 \pm 0.044
L/M	0.238 \pm 0.212	0.29 \pm 0.22

VSL#3 treated patients (n=17)	Basal	After treatment
FC ($\mu\text{g/g}$)	221 \pm 273	256 \pm 298
Fat (g/24h)	6.09 \pm 5.69	5.56 \pm 4.11
Nitrogen (g/24h)	1.9 \pm 1.5	1.83 \pm 1.18
%Lactulose (L)	1.97 \pm 2.33	2.13 \pm 1.7
%Mannitol (M)	18.60 \pm 11.01	26.83 \pm 15.4
% L/M	0.12 \pm 0.13	0.079 \pm 0.04
L/M	0.6 \pm 0.67	0.39 \pm 0.20

No statistically significant difference was found after treatment in both groups of treatment

Conclusions: Children with CF have increase of intestinal inflammation. The treatment with mesalamine and VSL#3 did not reduce the intestinal inflammatory state. This lack of improvement expresses a complex mechanism, which should be investigated in further studies.

Key words: Cystic fibrosis, intestinal permeability, mesalamine, probiotics, fecal calprotectin

EFFECT OF PREBIOTIC SUPPLEMENT TO ENTERAL FEEDINGS IN PREMATURE INFANTS: A CASE CONTROL STUDY

S. Shaaban¹, A. Elbialy², G. Ismail³, S. Maher¹

¹Pediatrics Department, Faculty of Medicine, Ain Shams University, Cairo, Egypt

²Food and Technology Institute, Agricultural Research Center, Cairo, Egypt

³Clinical and Chemical Pathology Department, Faculty of Medicine, Ain Shams University, Cairo, Egypt

Background and objectives: Preterm infants are in critical need for a balanced intestinal microflora that may protect them against infection. The study of a potential role of prebiotic products in the care of premature infants remains in a very early stage. We aimed to assess the prebiotic effect of inulin supplement to NICU preterm infants.

Methods: An ongoing prospective, unblinded case control study in premature infants; GA < 34 weeks with a birth weight > 1000 gram. The study group receives inulin as a prebiotic mixed with the feeds twice daily, and control infants receive only the plain feeds (prebiotic and probiotic free formula) for a period of 42 days. Stools have been collected on the 7th, 21st and 42nd days of feed commencement and are subjected to Lactobacilli and Bifidobacteria enrichment cultures. Small part of the stools is stored at -70 degrees Centigrade for future assessment by real time qualitative PCR for Lactobacilli and Bifidobacteria presence. Weight, length and OFC measurements are assessed on weekly bases, Other investigated parameters are; gestational age at home discharge, antibiotics used and their duration during the NICU admission, routine labs, calcium and albumin.

Results: Thirty infants have been enrolled till now (15 inulin, 15 control). The supplement appeared to be safe and did not cause any adverse effects. Preliminary results showed that Premature infants on inulin had more Lactobacilli- and Bifidobacteria-positive stool cultures that appeared earlier with larger number of colonies. Furthermore they tended to have less intolerance to enteral feedings, to reach full oral feeds sooner, and to be discharged home earlier.

Conclusions: The preliminary results support the safety and benefit of supplementing preterm infants' feeds with inulin waiting for the final outcome and the qualitative PCR results for confirmation.

Key words: premature, prebiotic, lactobacilli, bifidobacteria, PCR

INHIBITORY EFFECTS OF SALVIA HISPANICA L. SEED EXTRACTS ON ANGIOTENSIN I-CONVERTING ENZYME IN VITRO

B. González-Martínez¹, V. González-Ramos¹, M. López-Cabanillas¹, J. Verde-Star²

¹Universidad Autónoma de Nuevo León. Facultad de Salud Pública y Nutrición, Mexico

²Universidad Autónoma de Nuevo León. Facultad de Ciencias Biológicas, Mexico

Background and objectives: Currently, foods with functional compounds, which have the capability to act in a manner similar to drugs in certain pathological conditions but do not possess their side effects, have stimulated interest. It has been reported that *Salvia hispanica* L. seeds exert a hypotensive effect; however, the mechanism by which this effect is generated and which compounds are responsible for this effect are unknown. The inhibitory effects of angiotensin I-converting enzyme (ACE I) has not been previously described for this seed; such a mechanism was proposed based on the presence of certain compounds found in the chia seed, which showed an ACE-inhibiting effect in other foods. The purpose of the current study was to evaluate the potential of chia seed extracts on the inhibitory activity of ACE I in vitro, as well as to analyze the bioactive components in the extracts generating this effect.

Methods: Various extracts were studied (e.g., aqueous, methanol, acetone, and hexane). A phytochemical study of compounds present in chia extracts was performed using standard methods.

Results: The compounds present in the aqueous extract were only sugars; in the case of hexane and acetone extracts, unsaturated fatty acids and terpenoids were found, whereas in the methanol extract, phenolic oxides, glycosides, steroids, coumarins, unsaturated lipids, and carbonyl groups were found. IC50 values of the extracts on ACE I were 318±4.2 µg/mL, 218±5.6 µg/mL, and 63±3.7 µg/mL for hexane, acetone, and methanol extracts, respectively.

Conclusions: Results of this study show that active compounds exist, primarily in the methanol extract, which possess an ACE I-inhibiting effect that, in turn, could be responsible for the hypotensive effect already reported. These compounds could have biotechnological potential for the treatment of this hypertension.

Key words: chia, ACE, hypertension

Background and objectives: Inulin type fructans (ITF) are non digestible carbohydrates that counteract the high-fat (HF) diet induced metabolic disorders in mice. Moreover it is well established that ITF promote the growth of Bifidobacterium genus. The aim of the work is to check the possible influence of ITF in the composition of Bifidobacterium species and related microbial metabolites in obese individuals.

Methods: For humans, samples were taken from a randomized, double blind study performed in overweight women treated with ITF prebiotics (Synergy 1) or placebo (maltodextrin) during 3 months (16 g/day) (Dewulf et al; 2012). For animals, male C57B16/J mice were divided into 3 groups treated for 4 weeks such as: CT group fed a control diet, HF group fed a HF diet, HF-ITF group fed a HF diet supplemented with ITF (0.2 g/day/mouse). The qualitative and quantitative analysis of the gut microbiota was analyzed by PCR-DGGE and q-PCR and SCFA by GC-MS. Correlation analysis between species of Bifidobacterium and some biological parameters were also performed in the human clinical trial.

Results: Bifidobacterium-DGGE profiles in the mice study showed different clustering groups and only 2 Bifidobacterium species were detected: *B. animalis* and *B. pseudolongum*. DGGE and q-PCR analysis of Bifidobacterium species in the clinical study have shown that *B. longum*, *B. pseudocatenuatum* and *B. adolescentis* were the predominant species and those that significantly increased at the end of the treatment in the group of women receiving ITF prebiotics. *B. longum* was also negatively correlated with metabolic endotoxaemia. After the treatment, caproate was significantly higher in feces of the placebo group.

Conclusions: ITF prebiotics selectively changed bifidobacterial population patterns in obese women and diet induced obese mice, opening the possibility to supplement diet with

ITF to improve the intestinal microbial profile of obese individuals.

³Animal Production Department, Ain Shams University Egypt

Background and objectives: Enrichment of ruminants' products with polyunsaturated fatty acids (PUFA) is one of the possibilities to introduce these fatty acids into the human diet. However, the rumen unsaturated fatty acids biohydrogenation limits their quantity and thus bioavailability in the rumen, as well as in animal products. The alginate/carrageenan calcium beads of linseed oil were evaluated in vitro to verify the ability of these products to protect PUFA from biohydrogenation by ruminal microbes.

Methods: The treatments were: control (C) without supplements, LB1 (control + 4% of linseed beads containing 15% oil), LB2 (control + 4% of linseed beads containing 20% oil), LO (control + 4% of linseed oil). Each product was supplemented (4% dry matter) to the substrate that comprises of a mixture of meadow hay and barley meal in the ratio of 60:40 and incubated using batch culture technique (BC) for 48 h. All samples (feeds and rumen fluid after incubation) were analyzed for fatty acids profile. Encapsulation efficiency was evaluated by measuring the changes in fatty acids profile in linseed oil before and in linseed beads after encapsulation process.

Results: The results indicated that the encapsulation process have no a significant effect on PUFA fraction ($P > 0.01$). After incubation in BC system, linseed beads decreased ($P < 0.01$) total rumen saturated and monounsaturated fatty acids content. Omega 3 and omega 6 fatty acids contents increased statistically ($P < 0.01$) by LB1 and LB2. The omega 3 values were 2.5, 17.9, 18.5 and 9.7 mg/100 mg FAME (fatty acid methyl esters), and omega 6 values were 8.7, 25.2, 26.9 and 17.6 mg/100 mg FAME, respectively for control, LB1, LB2 and LO treatments.

Conclusions: In conclusion, new encapsulation method has the potential to protect linseed oil from rumen biohydrogenation in vitro, however further in vivo experiments are required.

Key words: PUFA, rumen, biohydrogenation, encapsulation, in vitro

PO2972**PROTECTIVE EFFECT OF PROBIOTIC TREATMENT ON INTESTINAL MICROBIOTA AND POTENTIAL RISKS***S. Al-Okbi¹, M. Amin², O. Sharaf³, A. Ali², A. Ramadan¹*¹Department of Food Sciences and Nutrition, National Research Centre, Cairo, Egypt²Department of Microbiology and Immunology, Faculty of Pharmacy, Cairo University, Cairo, Egypt³Department of Dairy Sciences, National Research Centre, Cairo, Egypt

Background and objectives: Probiotics and phytochemicals are functional foods that possess health benefits. Probiotics have profound effects against pathogenic bacteria and are known to improve intestinal health. In this work, we studied the potential benefit of selected probiotics (*Lactobacillus acidophilus* and *Bifidobacterium bifidum*) and functional food ingredients (methanol extract of chamomile) in prevention of intestinal microbiota perturbation following antibiotic treatment, their role in improving colonic microbiota in healthy rats and the possible risk of translocation in immunosuppressed rat model.

Methods: The study was conducted on white male albino rats where different groups received either: ampicillin, probiotic mixture (1×10^8 *Lactobacillus acidophilus* and 1×10^9 *Bifidobacterium bifidum*), chamomile extract or combinations of the three categories. Indicator pathogenic and beneficial bacteria were enumerated in rat feces. The effect of probiotics and functional food ingredients on nutritional parameters and growth was assessed. The immunosuppressed model was constructed by induction of immunosuppression in female white albino rats using dexamethasone as 0.5 mg/kg IM injection for 1 week followed by probiotic mixture daily oral dose for another week. Blood samples were inoculated on MRS agar.

Results: Antibiotic treatment produced microbiota perturbation. Administration of probiotic mixture alone or mixed with chamomile extract simultaneously with ampicillin significantly restored the normal level of microbiota ($P < 0.05$). Ingestion of probiotic mixture alone or with chamomile extract in healthy rats produced significant increase in colon beneficial bacteria together with significant reduction of pathogenic bacteria compared to control rats. Blood infection with *Lactobacillus acidophilus* and *Bifidobacterium bifidum* was noticed in 5 out of 8 immunosuppressed rats.

Conclusions: Probiotics may prevent the imbalance in intestinal microbiota resulting from antibiotic treatment and may improve the intestinal ecology in favor of the beneficial bacteria. Probiotic treatment might have some risks in immunosuppressed cases; further investigation is needed in this respect.

PO2973**EFFECT OF TEMPERATURE AND DAY LENGTH ON OMEGA-3, 6 FATTY ACIDS AND OXALIC ACID LEVELS IN PORTULACA OLERACEA***H. Oduro-Obeng¹, T.A. Ndanu², N.Dudai³*¹Food, Nutrition and Socio-Economic Division, CSIR-Food Research Institute, Accra Ghana²University of Ghana Dental School, College of Health Sciences, Korle-bu, Accra Ghana³Agricultural Research Organization, Newe Ya'ar Research Center, Ramat Yishai, Israel

Background and objectives: *Portulaca oleracea* (PO) is known to be a nutritious plant with appreciable levels of plant omega (w-3) fatty acids. The purpose of this study was to access the effect of varying temperature and day length conditions on the levels of the fatty acids and oxalic acids in the leaves of three species of the PO.

Methods: Three *Portulaca oleracea* microspecies, *P. sativa*(POS) *P. nitida*(PON) and *P. papillato-stellulata*(POP) were analyzed for their fatty acid and oxalic acid profile under day and night temperatures of 34/28(A), 28/22(B), 22/16(C), 16/10(D) degree celcius and long(16hrs) and short(9hrs) day conditions. Leaves were harvest at 8-true-leave-stage for the chemical analysis. Gas chromatography (GC) was used to analyze the fatty acids while HPLC was used for the oxalic acid.

Results: Mean levels of w-6 was 11.0 ± 5.7 ug/100g, w-3 was 50.7 ± 23.7 ug/100g dry-weight and oxalic acid 147.6 ± 6.6 ug/g fresh-weight. There was significant difference in the microspecies levels of w-6 and oxalic acid only, $p < 0.05$. W-6 was higher in the POS(13.8 ± 6.10) and low in POP(8.6 ± 4.4). Oxalic acid was high in POP(149.2 ± 6.2) and low in PON(145.4 ± 7.1) Temperature significantly influenced the levels of the acids with higher temperature producing the highest acid contents ($p < 0.05$). The w-6 ranged from (C= 12.97 ± 4.3 to D= 7.90 ± 8.8). W-3 from (B= 62.03 ± 7.6 to D= 26.15 ± 29.17) and oxalic acid, (D= 152.27 ± 6.6 to A= 146.23 ± 7.3). W-6 to w-3 ratio ranged from (C= 0.22 ± 0.15 to D= 0.13 ± 1.67). Only oxalic acid content showed significant differences between long day and short day ($p < 0.05$). The values were LD(148.89 ± 7.5) and SD(146.29 ± 5.3).

Conclusions: The microspecies differed in their fatty acid (w-6) and oxalic acid contents. Temperature and day length had significant effect on these. There was significant interaction between day length, temperature and microspecies on the oxalic acid levels. The authors are grateful to Pears Foundation of England for financial support.

Key words: *Portulaca oleracea*; w-3, w-6 fatty acid, oxalic acid.

PO2974**ROLE OF BIO- ACTIVE YOGHURT AND FERMEN-
TED SOBYA ON THE RESTORATION OF THE GUT
BARRIER FUNCTION AND COLONIC METABOLIC
ACTIVITY**

M. Gouda¹, M. Mohamed¹, E. Labib¹, M. Tawfik¹, L. Hus-
sein¹

¹National Research Center, Egypt

Background and objectives: Traditional fermented food commodities exert beneficial effects on public nutrition. The present study examines the effectiveness of fermented sobya supplement on colonic metabolic activities.

Methods: A human trial consisting of 32 healthy male adolescents was designed. The subjects were divided into four groups of equal number; (1) served as control and received fermented rice milk porridge. (2), (3), (4) received daily 190 grams portion of a fermented supplement Soba, commercially available fermented rice based semi solid puree providing 5.9×10^9 and 1.8×10^8 ; conventional yoghurt providing Bifidobacteria and Lactobacillus at 3.8×10^9 and 6.46×10^9 cfu, respectively or bio-active yoghurt lactel to provide respective bacterial counts of 2.8×10^8 and 9.7×10^9 . Before the intervention and at the termination of the trial, the urinary lactulose and mannitol dual test was assessed as an indicator of the integrity of intestinal permeability. Bacterial counts, pH values, hydrolytic enzyme activities and short chain fatty acids were measured in the fecal samples.

Results: Fecal lactobacillus and Bifidobacterial counts increased significantly following the 3 week nutritional intervention with all fermented supplements. The mean fecal pH values decreased also significantly among subjects consuming the fermented products. The mean activities of fecal β -galactosidase, β -glucosidase and β -glucuronidase increased among the groups consuming sobya and bioactive yoghurt with variable degrees of magnitude. Fecal β -glucuronidase enzymes correlate directly with microbiome richness and the diet composition partially explains the induction of genes expressing these enzymes.

Conclusions: Traditional fermented sobya affects the intestinal microbiota, These shifts had been linked to improving the colonic barrier function. Development of traditional fermented products should be encouraged for promoting the public nutrition of vulnerable groups.

PO2976**CIRSIIUM SETIDENS EXTRACTS INDUCES FATTY
ACID OXIDATION AND DECREASES FAT ACCUMU-
LATION IN THE LIVER OF A HIGH-FAT DIET FED
MICE**

J. Chung¹, H. Noh¹, H. Lee¹, E. Kim¹

¹Department of Food and Nutrition, Kyung Hee University, Seoul, Rep. of Korea

Background and objectives: *Cirsium setidens* is a perennial medicinal herb that is rich in flavonoids, mostly pectolinarin. In this study, we investigated the effect of *C. setidens* ethanol extracts (CSE) against the development of non-alcoholic fatty liver in mice fed a high-fat diet.

Methods: C57BL/6J mice were fed either a control diet (CON) or a high-fat diet (HF) for 8 weeks, and then fed CON, HF, or HF with 100mg/kg BW CSE (HF+CSE) for additional 7 weeks.

Results: Body weight gain and adipose tissue weight of mice fed HF with CSE were significantly decreased compared to the HF group. Moreover, CSE administration markedly attenuated the lipid droplets in liver tissue and significantly decreased hepatic TG concentrations, indicating a protective effect against HF-induced fatty liver. CSE administration strongly induced the hepatic mRNA levels of carnitine palmitoyl transferase 1 and medium-chain acyl dehydrogenase (MCAD), fatty acid oxidation enzymes, compared to HF group. Similar induction of MCAD mRNA by CSE was also observed in epididymal adipose tissue. Hepatic protein levels of phosphorylated-AMPK were higher in the HF+CSE group than in the HF group.

Conclusions: These results suggest that CSE decreases body weight gain and hepatic fat accumulation by up-regulating the gene expression of fatty acid oxidation enzymes.

PO2977**ENHANCED WATER DISPERSIBILITY OF POORLY
WATER-SOLUBLE POLYPHENOLS BY COMPLEXA-
TION WITH CASEIN AND CASEIN HYDROLYSATE**

T. Oshima¹, R. Yamashita¹, Y. Masuda¹, H. Takahashi¹,
Y. Baba¹

¹Department of Applied Chemistry, University of Miyazaki, Japan

Background and objectives: The polyphenols curcumin and quercetin are potential chemotherapeutic agents. Curcumin and quercetin are practically insoluble in aqueous media

and poorly absorbed from the gastrointestinal tract, which results in insufficient bioavailability. The present study describes the complexation between poorly water-soluble polyphenols and casein as well as the mixture of peptides (Pep) prepared as casein hydrolysate, for enhancing the water dispersibility.

Methods: The complex was prepared by mixing an aqueous solution of containing casein or Pep with an organic solution of a polyphenol (curcumin and quercetin), followed by removal of organic solvent in vacuo and lyophilization to obtain the complex as a powder.
